Background: Approximately 14% of CRC patients harbor a germline pathogenic variant (gPV) in a cancer susceptibility gene. As gPV prevalence alone is insufficient evidence for cancer causation, we performed an integrated germline and somatic genomic analysis to discover the extent to which gPVs may be driving CRC carcinogenesis. **Methods:** Using the MSKCC IMPACT dataset, we identified all patients with CRC who had undergone targeted tumor-normal sequencing (NCT01775072) inclusive of up to 90-genes assessed for germline variants. gPV in tested genes were categorized according to known association with CRC susceptibility and penetrance level. For example, high/moderate penetrance CRC-risk genes included: *APC, MLH1, MSH2, MSH6, PMS2, EPCAM*, biallelic *MUTYH, SMAD4, STK11, BMPR1A, PTEN, POLD1, POLE, TP53*. Low-penetrance CRC-risk genes included: monoallelic *MUTYH, APC I1307K, CHEK2, BLM*. In patients with a gPV, biallelic inactivation at the implicated germline region was inferred based on loss of heterozygosity (LOH) or somatic pathogenic alteration in the tumor. **Results:** Of 3988 CRC patients, 16.3% (650/3988) harbored at least one gPV (65 patients: 2 gPVs; 3 patients: 3 gPVs). Among a total of 721 gPVs encompassing 55 genes (252 high-penetrance, 118 moderate-penetrance, 351 low/recessive/uncertain-penetrance), overall biallelic inactivation was observed in 41%. In patients with gPVs associated with high/moderate penetrance CRC-risk genes, biallelic inactivation in tumors was present in 70%, while in patients with gPVs in high/moderate penetrance non-CRC genes this was 24% ($p < 0.0001$). When assessed according to age at CRC diagnosis, biallelic inactivation in high/moderate penetrance CRC-risk genes was higher in patients diagnosed at age < 35 than in patients age > 50 ($p = 0.003$); no such difference was observed in high/moderate penetrance non-CRC-risk genes. Among non-CRC-risk genes, in the high/moderate penetrance HRD genes, biallelic loss in the tumor was seen in 29% gATM, 54% gBRCA1, 22% gBRCA2, 30% gBRIP1, and 40% of gRAD51C/D positive patients. There was no difference in the rate of biallelic loss by age in patients with gPVs in HRD genes. Biallelic inactivation in tumors in patients with low-penetrance CRC-risk gPVs was 40% versus 14% in patients with low-penetrance non-CRC gPVs ($p < 0.0001$). **Conclusions:** Germline-somatic integration implicated nearly half of all identified gPVs in CRC carcinogenesis. While the highest rate of biallelic inactivation was seen in high/moderate penetrance CRC-risk genes, biallelic inactivation in non-CRC genes, such as the HRD genes, warrants further assessment to discern the contribution of these gPVs to CRC carcinogenesis. Our findings may have implications for novel treatment strategies exploiting these pathways. A randomized controlled trial evaluating pretest cancer genetics educational video or in-person genetic counseling. *First Author: Yanin Chavarri Guerra, Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubirán, Mexico City, DF, Mexico*

Background: Cancer genetic testing indications are rapidly expanding to determine treatment eligibility for patients with cancer, to identify individual cancer risk as well as to select family members at higher cancer risk when a pathogenic variant (PV) has been identified in the family. Currently, international guidelines recommend that all candidates for genetic testing should have genetic counseling to make an informed decision for genetic testing. However, with the increased demand for genetic testing, innovative ways to deliver pretest information are needed, especially in limited resource settings, where genetic cancer professionals' availability is scarce. **Methods:** This is a non-inferiority trial comparing a pretest educational video to in-person genetic counseling. Participants referred for genetic cancer risk assessment at the *Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán* in Mexico City were enrolled if they met international cancer genetic testing criteria and did not previously have genetic testing and/or counseling. The primary outcome was the uptake of genetic testing. Secondary outcomes included changes in genetic cancer knowledge, anxiety, and satisfaction using validated tools. **Results:** A total of 250 participants were included: 124 were randomized to the in-person genetic counseling arm and 126 to the educational video arm. Mean age was 47.9 years (SD 12.7), 86.4% were women, 37.2% had high-school or less and 86.4% had personal history of cancer (70% breast cancer). Overall, test acceptance was 100% in both arms. Cancer genetics knowledge improved in both groups: in-person from .53 to .74 (diff .20; 95%CI .24-.26; $p < 0.05$) and video from .51 to .68 (diff .16; 95%CI .20-.12; $p < 0.05$). However, the in-person arm had a higher post counseling knowledge score ($p 0.001$). 43.5% and 42% of participants in the in-person and video arms had moderate-severe baseline anxiety. After intervention, both groups had a decrease in anxiety score: in-person from 5.2 to 4.7 (diff .58; 95%CI .09-1.08; $p 0.01$) and video from 4.9 to 4.1 (diff .75; 95%CI 0.42-1.08; $p < 0.05$). Both groups were satisfied with genetic services (97.5% and 92.5%, respectively; $p 0.34$). **Conclusions:** A pretest educational video was non-inferior regarding genetic testing acceptance. It was also associated with improved genetic cancer knowledge and decreased anxiety levels. These results support the use of educational videos before genetic testing where in-person genetic counseling availability is limited. Clinical trial information: pending. Research Sponsor: None.

Cost-effectiveness analyses of population-based multi-gene testing for the prevention of breast and ovarian cancer in the United States. *First Author: Fangjian Guo, University of Texas Medical Branch, Galveston, TX*

Background: The current method of testing for BRCA gene mutations, which is based on family history, often fails to identify many carriers. With the advancement of next-generation sequencing technologies, which have significantly lowered the cost of genetic testing and sequencing, population-based testing has been proposed. We evaluated the cost-effectiveness of population-based multi-gene testing as a means of preventing breast and ovarian cancer. **Methods:** We developed a microsimulation model to assess the cost-effectiveness of multi-gene testing (BRCA1/BRCA2/PALB2) for all women aged 30-35 years compared to the current standard of care that is family history-based. We selected these genes for analyses as they are most prevalent high penetrance genes. We assumed a test uptake rate of 70%. Carriers of pathogenic variants who were not affected by cancer were offered interventions, such as MRI/mammography, chemoprevention, or risk-reducing mastectomy and risk-reducing salpingo-oophorectomy (RRSO), to reduce the risk of breast and ovarian cancer. We incorporated excess coronary heart disease (CHD) deaths from premenopausal RRSO. Our main outcome measure was the incremental cost-effectiveness ratio (ICER)(i.e., cost per-quality-adjusted life year (QALY) gained), with the commonly used societal willingness to pay of \$100,000/QALY in the US as the C-E threshold. We ran 500 simulations on 1,000,000 women, employing a lifetime time horizon and payer perspective, and adjusted the cost to 2022 US dollar. We also used probabilistic sensitivity analyses to evaluate model uncertainty. **Results:** In the base case, population-based multi-gene testing is more cost-effective compared to family-history based testing, with an ICER of \$41,306/QALY (95%CI \$35,630-\$48,441/QALY). This new testing method is able to prevent an additional 1,369 cases of breast cancer and 807 cases of ovarian cancer, but it will also result in 8 excess heart-disease deaths per million women. The probabilistic sensitivity analyses show that the probability that population-based multi-gene testing is cost-effective is 100% for all the simulations. When the cost of the test exceeds \$1,100 population-based multi-gene testing becomes economically inefficient (ICER \$10,0886/QALY). **Conclusions:** Population-based multi-gene testing is a more cost-effective option for the prevention of breast cancer and ovarian cancer when compared to current family-history-based testing methods. Technology-enhanced acceleration of germline evaluation for therapy (TARGET): Results of a randomized controlled trial of a pretest patient-driven webtool vs. genetic counseling for prostate cancer germline testing. *First Author: Veda N. Giri, Yale Cancer Center, Yale School of Medicine, New Haven, CT*

Background: Germline genetic testing is important for prostate cancer management, clinical trial eligibility and hereditary cancer risk assessment. Despite this, genetic testing is underutilized and there is a shortage of genetic counselors. To address these gaps, we designed a webtool to provide patient-driven genetic education and conducted a randomized non-inferiority trial to compare it with traditional pre-test genetic counseling. **Methods:** TARGET is a multi-center randomized controlled trial comparing standard pre-test genetic counseling versus web-based genetic education (intervention) (NCT04447703). The study protocol was previously published (PMID 35710085). Briefly, patients with prostate cancer who met criteria for germline testing (based on tumor features, ancestry or family history) were randomized to pre-test genetic education through genetic counseling vs a 9-module webtool created by the study team and Prostate Cancer Foundation. The primary endpoint was non-inferiority in reducing decisional conflict between the webtool and genetic counseling by a margin of 4 (set in advance) on the validated Decision Conflict Scale. Analysis of covariance was used to compare decisional conflict between groups. All participants opting for testing received a 51-gene Invitae panel, with results delivered to the patient and their provider. **Results:** 346 patients with prostate cancer with a mean age of 63.7 years were randomized to genetic counseling (n=174) or web-based genetic education (n=172). Compared to baseline, there were reductions in decisional conflict in both arms following pre-test genetic education (Table). Adjusting for study site and baseline decisional conflict, the test of non-inferiority in reducing decisional conflict between arms was statistically significant (difference = -0.04, 95% CI: -∞ to 1.95, $p < 0.001$). Overall 265 (76.6%) participants underwent genetic testing, including 146 (83.9%) in the genetic counseling and 119 (69.2%) in webtool arm, with the following results: negative (49.4%), variant of uncertain significance (35.5%) and pathogenic variant (15.1%). **Conclusions:** Delivery of pre-test genetic education through a webtool was non-inferior to genetic counseling in reducing decisional conflict. These results support a new standard of care for the use of patient-driven digital webtools for expanding access to pretest genetic education and informed decision-making for prostate cancer genetic testing. Clinical trial information: NCT04447703. Research Sponsor: Prostate Cancer Foundation.

Decisional conflict (*higher score: greater decisional conflict).			
	Total Mean (sd)	Genetic Counseling Mean (sd)	Web Based Genetic Education Mean (sd)
Baseline	36.73 (12.99)	36.69 (12.84)	36.77 (13.19)
After Pre-Test Education	28 (10.78)	28.06 (11.17)	27.93 (10.37)
*Mean Difference	-8.16 (13.13)	-8.21 (13.34)	-8.11 (12.93)

Evaluating interventions to increase the uptake of NCCN genetic counseling recommendations. *First Author: Sophie Stempel, Rush University Medical Center, Chicago, IL*

Background: Genetic counseling for hereditary breast cancer remains underutilized despite increased access. The lack of identification and/or referral of high-risk women for genetic counseling is the major contributor to the poor uptake. A cancer risk assessment program (CRA) utilizing NCCN guidelines was implemented in our breast imaging department to identify women at increased risk for breast cancer. We analyzed the impact of informing all women who get a screening mammogram of their genetic mutation risk and the effect of nurse navigation on increasing the subsequent uptake of genetic counseling. **Methods:** To assess the effectiveness of these interventions, data from July 2021 to January 2022 was extracted from the EMR and grouped into cohorts based on nurse navigation contact and the completion of genetic counseling. A chi-squared analysis was performed to determine the significance of the results. **Results:** A total of 22,915 patients participated in the CRA program during the study period. 2,671 (11.7%) patients qualified for genetic counseling based on NCCN guidelines. 414 (15.5%) of these patients completed a genetic counseling appointment. 298 of these patients received genetic testing (72%) and 18 (4.3%) had a pathogenic mutation found. The nurse navigator was able to reach 1,288 (48%) of the 2,671 patients (Cohort A). Of these patients, 324 (25.2%) completed genetic counseling appointments compared to 90 of the 1,383 (6.5%) patients who were not contacted by the nurse navigator (Cohort B). Statistical analysis determined there was a significant difference in uptake of genetic counseling between Cohort A and Cohort B ($p < .0001$). **Conclusions:** The implementation of the CRA program at the breast imaging center uncovered many patients who qualified for genetic counseling and testing based on NCCN guidelines. Genetic counseling uptake is significantly increased in patients who are reached by a Nurse Navigator. These interventions allowed for the discovery of unsuspected deleterious genetic mutations which require more aggressive screening to allow for the early detection of breast cancer and better overall prognosis. Research Sponsor: This research was supported by a generous gift from a donor, Sheli Rosenberg.

Genetic counseling uptake between nurse navigation cohort and control.

	Total N=2,671	Percent of Population	Completed Genetic Counseling N=414	Percent of Com- pleted appt.
Patients who talked to the Nurse Navigator (Cohort A)	1,288	48.22%	324	25.16%
Patients who did not talk to Nurse Navigator (Cohort B)	1,383	51.78%	90	6.51%

Genetic testing outcomes and pathogenic germline mutation prevalence in renal cell carcinoma. *First Author: Charles B Nguyen, Rogel Comprehensive Cancer Center, University of Michigan, Ann Arbor, MI*

Background: Germline mutations have been observed in renal cell carcinoma (RCC) with varying frequencies reported from 5% to 18% of patients. Due to the prevalence of germline mutations, current guidelines by the National Comprehensive Cancer Network (NCCN) recommend genetic testing for patients with RCC and high-risk factors such as young age, bilateral or multifocal tumors, family history of RCC, as well as certain RCC histologies. However, the germline mutational landscape in RCC has not been fully characterized. Here, we report the genetic testing results and clinicopathologic factors of patients with RCC who were referred for germline testing. **Methods:** All patients with a diagnosis code of kidney cancer and referred to the Cancer Genetics clinic at the University of Michigan between 2004 and 2022 were identified. Patients were excluded if they had erroneous RCC diagnosis codes, no history of RCC diagnosis, known familial/hereditary mutation or syndrome, or did not undergo germline testing. Genetic testing outcomes, germline mutation frequency, and clinical factors were obtained through chart review and analyzed using descriptive statistics. **Results:** A total of 322 patients with a history of RCC and referred for genetic testing were identified. The median age at diagnosis in all patients was 47 (interquartile range: 38-58). Males accounted for 56.8% of the cohort. Most patients (62.4%) had clear cell histology at initial diagnosis, whereas 30.7% had non-clear cell histology. The majority of patients (61.5%) were diagnosed at stage 1. Bilateral and multifocal tumors at diagnosis accounted for 18.9% and 12.7%, respectively. Pathogenic or likely pathogenic variants (P/LP) were identified in 43 patients (13.4%); 225 patients had negative germline testing (69.9%); 54 patients (16.8%) had a variant of unknown significance (VUS). The most frequently mutated RCC-associated genes were *FLCN* (n=10, 3.1%), *SDHA/B/D* (n=7, 2.2%), *VHL* (n=4, 1.2%), *MLH1* (n=3, 0.9%), and *FH* (n=2, 0.6%). Common mutations in other cancer-related genes were *CHEK2* (n=4, 1.2%), *ATM* (n=2, 0.6%), and *RAD50* (n=2, 0.6%). Most patients (81.4%) with a P/LP test result had at least 1 of the following: diagnosis age $\leq$ 46 years, bilateral or multifocal tumors, or at least 1 first-degree relative with RCC. Out of the patients with a P/LP result, 18 patients (39.1%) had a potentially actionable mutation. **Conclusions:** Among patients with RCC who were unselected for a known familial/hereditary predisposition, P/LP variants were present in 13.4% which is consistent with previous studies. The prevalence of *FLCN* mutations was higher in our cohort (3.1%) compared to prior observations. Most patients with a P/LP variant met the NCCN criteria for genetic testing. Future studies should optimize the current genetic testing criteria to identify a broader group of patients who may have germline mutations given potential cascade testing and therapeutic implications. Scalable new model of genomic care delivery: Assessing psychological outcomes. *First Author: Stacy W. Gray, City of Hope, Duarte, CA*

Background: Germline testing (GT) use is on the rise given testing implications for identifying cancer susceptibility and therapeutically actionable alterations. Scalable models of care that emphasize post-test, as opposed to pre-test, genetic counseling are needed to meet demand. However, little is known about the psychological impact (PI) of test result disclosure in such models. **Methods:** The enterprise-wide City of Hope INSPIRE study offers all consented patients GT for cancer susceptibility (155 genes) and actionable disorders (59 genes). In 2022, we surveyed a sub-set of English-speaking participants ~1 month following test result disclosure. We evaluated PI using the Feelings about Genomic Testing Results (FACToR) measure (distress/ uncertainty subscales 0-12; positive subscale 0-16) and explored associations between patient characteristics, GT results and PI. **Results:** Of 1000 patients surveyed, 615 completed at least one of the FACToR questions. Participants were mostly white (n=463, 75%) or Asian (n=12, 2%) and female (n=419, 68%) with a mean age of 62 yrs. 357 (61%) had a cancer diagnosis and most opted for both GT panels (97%). Eighteen percent had a pathogenic/likely pathogenic variant (PV/LPV) in an autosomal dominant condition, 8% were carriers for an autosomal recessive condition, 53% had at least one variant of unknown significance (VUS) and 21% had negative results. Most patients (n=583, 95%) had low levels of distress with a mean score of 1.67 (SD 2.31). Out of the 30 (5%) patients with higher levels of distress (score >7), results were similar for patients with and without cancer (5% and 4% respectively). Of the 30 patients with higher distress, 67% had a P/LPV variant (13 with and 7 without cancer). Patients also had low levels of uncertainty with a mean score of 2.22 (SD 2.61) and 93% (n=569) scored <7 . For those who scored higher on uncertainty (n=44, 7%), most people had cancer and a VUS (n=16, 36%), followed by cancer and LPV/PV (n=10, 23%) followed by patient without cancer with a VUS (n=6, 14%). Finally, 56% (n=44) had high positivity scores (9-16); mean 9.18 (SD 4.31). Fifty-six percent of patients felt a "good/great deal" happy about their GT and 54% were a good/great deal relieved about their results. **Conclusions:** After implementing an enterprise-wide germline testing program with an emphasis on robust post-test genetic counseling, we found very little evidence of post-disclosure distress or uncertainty. Similar to prior studies, we found that a small proportion of patients may be more vulnerable to negative PI. More work is needed to prospectively identify at risk patients to provide support to this population as we continue to develop safe, effective, and scalable models of care. Research Sponsor: None.

Poster Session

Clinical utility of reporting research genetic predisposition testing results to Total Cancer Care participants. *First Author: Megan Leigh Hutchcraft, University of Kentucky Markey Cancer Center, Lexington, KY*

Background: The American College of Medical Genetics and Genomics (ACMG) has identified genes with highly penetrant phenotypes with treatment, prevention, or early disease identification strategies called secondary findings (SF) genes. ACMG recommends clinical laboratories report pathogenic/likely pathogenic (P/LP) SF variants identified during genomic testing. Cancer patients may undergo germline sequencing as part of research studies that can identify valuable SF variants. The objective of this institutional sub-study is to evaluate the feasibility of using ACMG SF genes to assess hereditary disease risk in a cancer population undergoing research sequencing. **Methods:** Between June 2017 and January 2021, patients unselected for family history, disease site, or stage enrolled in the prospective, observational Total Cancer Care study. Patients underwent research-grade germline whole exome sequencing, with bioinformatic analysis in a CLIA certified laboratory to identify P/LP variants in any ACMG SF v2.0 genes. P/LP variants were reported to treating oncologists with recommendations for genetic counseling referral. We assessed if patients with P/LP variants met NCCN guideline-directed germline testing criteria to quantify benefit from reporting research results. **Results:** We enrolled 786 patients, which included those with gynecologic (182, 23%), colorectal (124, 16%), lung/bronchus (83, 11%), and head/neck (82, 10%) cancers. The median age was 61 (IQR 52-68) years, 57% were female, 96% were non-Hispanic White, 51% had stage III/IV disease, and 64% resided in an Appalachian community. We identified 57 patients (7%) with cancer predisposition and 14 (2%) with other hereditary disease variants. 2021 NCCN guideline-directed testing would have missed 59% (42/71) of these patients. Incremental high penetrance cancer gene variants included: *BRCA1* – endometrial cancer (n = 1); *BRCA2* – cholangiocarcinoma (n = 1), colon neuroendocrine tumor (n = 1), and lung (n = 2), endometrial (n = 1), and non-epithelial ovarian (n = 1) cancers; *MSH6* – duodenal cancer (n = 1); *SDHAF2* – non-melanoma skin cancer (n = 1); *SDHB* – head/neck cancer (n = 1); and *TP53* – CNS tumor (n = 1) and head/neck cancer (n = 1). We identified patients at risk for other hereditary diseases including hypertrophic/dilated cardiomyopathy (n = 1), malignant hyperthermia (n = 3), arrhythmogenic right ventricular cardiomyopathy (n = 1), Romano-Ward long QT / Brugada syndromes (n = 4), familial hypercholesterolemia (n = 4), and ornithine transcarbamylase deficiency (n = 1). **Conclusions:** Reporting germline variants identified during research sequencing is feasible and can benefit cancer patients and their relatives. Though not traditionally assessed, non-cancer predisposition genetic variants may have important intervention opportunities and unexpected patterns may have oncologic implications that require further study. Healthcare utilization among individuals diagnosed with lynch syndrome through a universal germline genetic testing program. *First Author: Heather Hampel, City of Hope, Duarte, CA*

Background: Most individuals with Lynch syndrome (LS) are unaware of their risk. Criteria-based testing will not close this gap as it fails to identify ~50% of mutation carriers. Universal germline testing (GT) for in oncology stands to identify more mutation carriers and advance cancer control. However, the clinical utility of universal germline testing is unknown. **Methods:** The enterprise-wide City of Hope INSPIRE study offers all consented patients GT for cancer susceptibility (155 genes) and actionable disorders (59 genes). We used an informatics approach to evaluate healthcare utilization for patients found to have *MLH1*, *MSH2*, *MSH6*, *PMS2* or *EPCAM* mutations. We queried codified data elements in our electronic data warehouse before and after GT (post testing interval: 1-29 months). We binned care as possibly related/ not related to HBOC based on NCCN guidelines. **Results:** Of 10,814 patients who had GT, 80 (0.74%) had a pathogenic/ likely pathogenic mutation in either *MLH1*, *MSH2*, *MSH6*, *PMS2* or a 3' deletion of *EPCAM*. The demographic distribution of LS patients was: white (n = 51, 64%), Asian (n = 13, 16%), Hispanic (n = 19, 24%); female (n = 51, 64%); the mean age was 54 yrs. Eighty-six percent (n = 69) had cancer, including 45% with cancers associated with LS (colorectal 17%, endometrial 7%, ovarian 6%, esophageal/stomach 5%, bladder/urinary tract 5%, and prostate 5%) and 41% with cancers that are not associated with LS. Fifty-two percent of all LS patients had procedures, imaging, and/or therapy potentially related to their LS diagnosis. As expected, utilization of colonoscopy, EGD, MRCP/EUS, transvaginal ultrasound, and hysterectomy with bilateral salpingo-oophorectomy (HSO) occurred both before and after testing for the cancer cohort, with the majority of utilization occurring after testing likely related to their Lynch syndrome diagnosis. Twelve (17%) cancer patients with Lynch syndrome received Immune Checkpoint Inhibitor therapies. In the unaffected cohort, rates of utilization were higher prior to testing for transvaginal ultrasound possibly because 2% underwent a HSO after their diagnosis and no longer required endometrial surveillance. Rates of colonoscopy, EGD, and HSO were all higher after GT. **Conclusions:** We found high levels of relevant healthcare utilization for Lynch syndrome gene mutation carriers in the context of universal GT. However, this initial informatics approach is limited because key information on prior GT and motivations for surgery (e.g., therapeutic vs prophylactic HSO) are not adequately captured in codified data. Codified EHR queries will need to be augmented by text mining and/or manual chart review to fully capture care and assess the clinical utility of system-wide genetic care delivery interventions. Validation of a guidelines-based brief patient-administered digital tool to assess the need for germline genetic testing. *First Author: Callan Russell, Northside Hospital, Atlanta, GA*

Background: Scalable and reliable approaches are needed to assist non-genetics clinicians in assessing whether a patient meets criteria for germline genetic testing. Insurance coverage of genetic testing often depends on such assessments. RISE Risk Assessment Module: Hereditary Cancer is a brief patient-administered digital tool designed for this purpose. The tool's assessment is based on personal and family history and is informed by national guidelines. The aim of this study was to assess the clinical validity of this digital tool by evaluating its agreement with assessments made by genetic counselors. **Methods:** We performed a chart review of cases from a telehealth genetic counseling practice seen July to October 2020. Extracted history was entered into the tool by the research team to model how a patient would complete the digital tool. The tool's assessment of whether the patient met criteria for genetic testing was compared to the assessment of the genetic counselor who saw the patient. To further validate the tool, a subset of cases were analyzed for agreement between the tool and research team on which specific history-based rules in the tool's algorithm applied for a given case. **Results:** The majority (121/152; 80%) of cases were female and the mean age was 52.3 (SD 15.9). Just over half of cases (85/152; 56%) had a personal history of cancer, including breast (27/85; 32%), colon (15/85; 18%), prostate (10/85; 12%), endometrial (12/85; 14%), and ovarian (7/85; 8%). 100/152 (66%) of cases met criteria for genetic testing. In 146/152 (96%) cases there was agreement between the assessments made by the tool and the genetic counselor regarding whether the patient met criteria for germline genetic testing. Nearly all disagreement (4/6; 67%) resulted from history intentionally left out of the tool as patients can rarely report them (aspects of tumor pathology 3/4; risk of having a pathogenic variant based on predictive models 1/4). For a subset of cases (62/152) we compared the tool and research team's assessments of which aspects of the patient's personal and family history met criteria for genetic testing. This was done by looking at which rules in the tool's algorithm were triggered by the patient's history. There was complete agreement between the tool and research team on which rules should be triggered. Completion of the tool took a mean of 3.3 minutes. **Conclusions:** The high level of agreement between the digital tool and genetic counselors supports RISE Risk Assessment Module: Hereditary Cancer as a clinically valid method of identifying individuals in need of evaluation for hereditary cancer predisposition. Complete agreement on which history-based rules applied in these cases further supports the clinical validity of the tool. Our results also suggest that the tool's assessment can be delivered in under 5 minutes, which is critical to feasibility and scalability of the digital tool. Research Sponsor: Genome Medical.

Healthcare utilization among individuals diagnosed with hereditary breast-ovarian cancer syndrome through a universal germline genetic testing program. *First Author: Stacy W. Gray, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Most individuals with Hereditary Breast-Ovarian Cancer Syndrome (HBOC) are unaware of their risk. Criteria-based testing will not close this gap as it fails to identify ~50% of mutation carriers. Universal germline testing (GT) in oncology stands to identify more mutation carriers and advance cancer control. However, the clinical utility of universal germline testing is unknown. **Methods:** The City of Hope INSPIRE study offers all consented patients GT for cancer susceptibility (155 genes) and actionable disorders (59 genes). We used an informatics approach to evaluate healthcare utilization for patients found to have *BRCA1/BRCA2* mutations. We queried codified data in our electronic data warehouse before and after GT (post testing interval: 1-29 months). We binned care as possibly related/ not related to HBOC based on NCCN guidelines. **Results:** Of 10,814 patients who had GT, 217 (2%) had a pathogenic/ likely pathogenic mutation in either *BRCA1* or *BRCA2*. The demographic distribution of mutation carriers was: white (n = 162, 75%), Asian (n = 28, 13%), Hispanic (n = 65, 30%); female (n = 184, 85%); the mean age was 54 yrs. Eighty-four percent (n = 182) had cancer, including 64% with cancers associated with HBOC (breast 40%, ovarian 13%, pancreatic 3%, 5% prostate, and 0.5% melanoma) and 18% with cancers that are not associated with HBOC. Eighty-three percent of patients had procedures, imaging, and/or therapy potentially related to the *BRCA* mutation. Eighty-six percent of cancer patients had potentially related care. As expected, use of breast MRI, mammography, MRCP, mastectomy, and bilateral salpingo-oophorectomy (BSO) occurred both before and after testing, with most utilization occurring prior to GT and likely related to cancer staging and treatment. The exception was MRCP which occurred more often following GT (0.6% before vs 1.2% after). Fifty-one (28%) cancer patients received PARP inhibitors. In the unaffected cohort, 67% of patients received possibly related care. Use of mammography was higher prior to GT (7% vs 2%). Consistent with the fact that some unaffected patients were likely known mutation carriers prior to consent, mastectomy was higher prior to GT (5% vs 0%) and BSO was equivalent before and after GT (1.8%). Use of breast MRI (9% vs 15%), MRCP (1.8% vs 3%) and transvaginal US (5% vs 7%) were all higher after GT. **Conclusions:** We found high levels of relevant healthcare utilization for *BRCA* mutation carriers in the context of universal GT. However, this initial informatics approach is limited because key information on prior GT and motivations for surgery (e.g., therapeutic vs prophylactic mastectomy) are not adequately captured in codified data. Codified EHR queries will need to be augmented by text mining and/or manual chart review to fully capture care and assess the clinical utility of system-wide genetic care delivery interventions. A comprehensive analysis of clinical characterization in 149 Chinese patients with Lynch syndrome. *First Author: Junqiong Lin, Second Affiliated Hospital of Guangdong Medical University, Zhanjiang, China*

Background: Lynch syndrome (LS) caused by germline pathogenic variants (PVs) in mismatch repair (MMR) genes, which increased risk of malignancy in different organs. LS-related tumors included colorectal, endometrial, gastric, ovarian, pancreas, urinary system, biliary tract, central nervous system, skin and small intestinal carcinomas (CRC, EC, GC, OC, PC, UST, BTC, CNST, SC, SIC). As sequencing technology becomes more economical and widespread, more MMR PVs were detected in LS-unrelated tumors. The aim of this study was to explore the clinical characterization in Chinese real-world LS solid tumor. **Methods:** We applied next-generation sequencing (NGS) screening to detect the germline mutation in MMR (include *MLH1*, *MSH2*, *MSH6*, *PMS2*), tumor mutation burden (TMB) and microsatellite instability (MSI) in Chinese solid tumor patients (pts). In the cohort, lung cancer (LC) was the most common cancer type, followed by CNST, CRC, hepatic carcinoma (HC). **Results:** 149 LS pts were observed in our cohort, among which 81.2% (121/149) carried LS-related tumors (44 CRC, 47 CNST, 9 EC, 9 BTC, 4 UST, 3 OC, 2 GC, 2 SC, 1 SIC), 18.8% (28/149) carried with LS-unrelated tumors (18 LC, 5 HC, 3 sarcoma, 1 ampullary carcinoma, 1 peritoneal cancer), and the age showed no significant difference between LS-related tumors and LS-unrelated tumors (average age: 48 vs 53, $p=0.08$). The distribution of MMR PVs were as follows: *MLH1* (37, 24.8%), *MSH2* (46, 30.9%), *MSH6* (34, 22.8%), *PMS2* (32, 21.5%), and comparative analysis showed that LS-related tumors tended to carry *MLH1* and *MSH2* PVs (60.3%, 73/121), while LS-unrelated tumors tended to carry *MSH6* and *PMS2* PVs (67.9%, 19/28) ($p<0.05$). 46.3% LS pts had MSI-H, concentrated in *MLH1* or *MSH2* PVs carriers. MSI-H showed a higher detection rate in LS-related tumors other than LS-unrelated tumors (56.1% vs 3.6%, $p<0.005$). Among LS-related tumors, the top 3 prevalence of MSI-H were CRC (93.2%, 41/44), BTC (55.6%, 5/9) and EC (44.4%, 4/9), which were lower in CNST (31.9%, 15/47). In addition, we found that the rate of TMB-H in LS-related tumors was also higher than LS-unrelated tumors ($p<0.001$). **Conclusions:** In our dates, 18.8% (28/149) LS pts carried with LS-unrelated tumors, which emphasized the importance of germline genetic assessment for LS in pan-cancer. In addition, MSI-H, TMB-H and MMR PVs distributions were significantly different in LS-related tumors and LS-unrelated tumors. The differences about LS clinical characterization associated with MMR genes require further study. Research Sponsor: None.

Using patient-reported outcomes to assess the impact of germline genetic testing on prostate cancer patients. *First Author: Sarah M. Nielsen, Invitae, San Francisco, CA*

Background: Germline genetic testing (GGT) affords prostate cancer (PCa) patients (pts) opportunities for targeted therapies, prevention and cascade testing. Patient-reported outcomes (PRO) can evaluate physician effectiveness in promoting patient test comprehension and clinical decision making, which are critical to realize the benefits of GGT. PROs from a large PCa GGT study among urologists were analyzed. **Methods:** A prospective study enrolled unselected PCa pts from 15 primarily community urology practices. Pts underwent 84-gene GGT, with PROs collected via electronic or paper surveys >1-month post GGT. Differences in proportions were determined using two-tailed Fisher's exact test and significance was set at <0.05. **Results:** PROs were completed by 561/982 (57%) pts (85% white, 82% non-metastatic, median age at testing 70 years). 59 (11%) pts had positive results, 247 (44%) negative and 255 (46%) variants of uncertain significance (VUS). 72% accurately recalled their result (range, 50% [VUS]-93% [negative]). 66% of positive pts, 80% negative and 54% VUS correctly understood if their result was associated with cancer risk or not. 72% of positive pts had or planned to complete ≥1 physician recommendations, significantly more than negative or VUS pts (Table). Most pts reported that their test result reduced their concerns (40%) or did not impact their level of concern (52%) regarding their PCa diagnosis, treatment or followup. 19% of positive pts reported increased concern. **Conclusions:** GGT for PCa was deployed without causing undue concern and resulted in adherence to physician recommendations. Still, there is room for improvement in how test results (especially VUS) and recommendations are communicated to pts. Research Sponsor: Invitae Corp.

Uptake of physician recommendations among PCa position.

Recommendation	Total (n=561)	%*	Positive (n=59)	%*	Negative (n=247)	%*	VUS (n=255)	%*
No response	25	5	2	3	11	5	12	5

Prospective prevalence estimation of BRCA1, BRCA2, and other germline mutations associated with hereditary pancreatic cancer (HPC) using a comprehensive gene panel in an unselected cohort of Mexican patients with pancreatic ductal adenocarcinoma (PDAC). *First Author: Vanessa Rosas Camargo, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico*

Background: Prevalence of pathogenic or likely pathogenic germline variants (PGVs) in patients with PDAC varies across populations. There is limited information on the prevalence of PGVs among Mexican patients with PDAC. We prospectively tested an unselected cohort of newly diagnosed PDAC patients using a comprehensive gene panel in order to estimate the prevalence of BRCA1/2, and other germline mutations associated with HPC. **Methods:** The protocol was approved by the ethics committee at each institution: INCMNSZ, INCAN, and CM ABC Observatorio. Key inclusion criteria: age > 18 years and PDAC diagnosed within 6 months of inclusion. Patients were enrolled consecutively, regardless of age, personal or family history of cancer, known hereditary cancer syndrome, or stage of the disease. Written informed consent was obtained before any procedure. Clinical variables including family history of cancer were collected. We used the 84-gene Invitae Multi-Cancer Panel. Genetic testing had no cost for patients. Patient characteristics and family history were summarized using descriptive statistics (IBM SPSS Statistics Version 25). The trial was registered on Clinical Trials (NCT05305001). **Results:** From August 2020 to June 2022, 119 patients with newly diagnosed PDAC were identified. Of these, 107 patients were included: 58% women, median age was 63 y/o, clinical stages at diagnosis were: I (24%), II (22%), III (6%), and IV (48%). All patients had Hispanic ancestry except one (Ashkenazi Jewish). Only 7.5% (n = 8) had a personal history of other cancer, mainly breast cancer (N = 3); 62% had a family history of any cancer, while 47.6% had a first-degree relative (FDR) with any cancer. 11% (n = 12) had family history of pancreatic cancer (PC), and 9% (n = 10) had an FDR with PC. Five patients met clinical criteria for hereditary cancer syndrome: familial pancreatic cancer (4) and Lynch syndrome (1). PGVs were identified in 17.8% (n = 19) of patients. The prevalence of PGVs in genes associated with autosomal dominant risk of PC was 11.2%: *CDKN2A* (5.6%), *ATM* (3.7%), *BRCA2* (0.93%), and *MSH6* (0.93%). Two patients had a PGV associated with autosomal dominant predisposition to other cancers (*CHEK2* and *NF1*). Six patients (5.6%) had PGVs associated with autosomal recessive predisposition to rare syndromes with increased cancer risk other than PDAC (*MUTYH*, *RECQL4*, *FH* and *WRN*). Variants of uncertain significance were present in 42% of patients. **Conclusions:** In Mexican patients with PDAC, the prevalence of PGVs on BRCA1/2 is < 1%. The prevalence of PGVs in other susceptibility genes is 11%. Our results support the role of universal germline testing in Mexican patients with PDAC using a comprehensive gene panel. Selective testing for BRCA1/2 is discouraged. Research Sponsor: Externally Sponsored Scientific Research Program by AstraZeneca.

Somatic profiling guides germline genetic testing in patients with mutations in cancer predisposition genes. *First Author: Sourat Darabi, Hoag Family Cancer Institute, Newport Beach, CA*

Background: 15% of patients with advanced cancer have an inherited predisposition to cancer. Over a third of patients carrying a pathogenic germline variant would not qualify for genetic testing based on current National Comprehensive Cancer Network genetic testing guidelines. Supplementing the current practice of somatic sequencing with germline testing would improve treatment decisions and be informative of the risk of developing subsequent cancers in the individual. It may also extend the benefits of high-risk screening programs to family members. Offering genetic testing to patients with the highest likelihood of carrying a germline mutation is preferable to unselected sequencing given the current environment. **Methods:** We developed a list of genes to help identify patients whose somatic mutations were more likely to be found in the germline as well. We classified these genes into 3 tiers based on the likelihood of germline pathogenicity. All somatic sequencing panel results were reviewed based on the IRB-approved protocol for our designated Tier One genes (*ATM*, *BAP1*, *BMPR1A*, *BRCA1*, *BRCA2*, *BRIP1*, *MSH2*, *MSH6*, *MUTYH*, *MYH11*, *PALB2*, *RUNX1*, *SDHAF2*, *SDHB*, *SDHC*, and known founder mutations in additional genes). Treating physicians for patients whose tumors harbored a mutation in one of these genes were contacted and, if they agreed, patients were offered participation in this ongoing study. Enrolled patients had genetic counseling and testing for a multi-gene panel at no cost to them. **Results:** We reviewed 3621 somatic test results, and 339 (9.4%) patients were eligible for the study. 34 (10.03%) eligible patients were enrolled, and 33 (9.73%) completed testing. Of these, 16 had positive germline results (48.5%, though they may not all be in the originally identified genes), 8 had a variant of uncertain significance (24.2%), and 9 had negative testing (27.3%). Some patients were not referred by their treating physicians based on their own clinical assessment. Others were hesitant to enroll due to concerns about the privacy of genetic information. Other confounding factors may have affected our accrual, including the pandemic. **Conclusions:** Implementing a somatic profiling-based screening program to identify inherited cancer predisposition syndromes is feasible in patients who may not meet current germline genetic testing guidelines. Our study showed 9.73% of eligible patients underwent genetic counseling and testing, and an inherited predisposition to cancer was confirmed in almost 50% of these patients. In addition, family members were offered cascade testing. Germline genetic evaluation remains underutilized even when payor constraints are removed as a barrier. To increase the identification of patients with inherited predispositions to cancer other barriers such as a lack of referrals by treating oncologists need to be overcome. Research Sponsor: None.

Cancer risk and characteristics in older female BRCA1/2 mutation carriers. *First Author: Bipin Ghimire, Corewell Health William Beaumont University Hospital, Royal Oak, MI*

Background: Cancer risk and characteristics in older females with *BRCA1/2* mutations are less well studied, and the role of risk-reducing strategies in this population remains unclear. **Methods:** From a database of 1070 female carriers of *BRCA1/2* pathogenic (PV) or likely pathogenic variants (LPV) seen at Nancy and James Grosfeld Cancer Genetics Center in Beaumont Health from January 2006 to December 2021, we identified 283 females who lived to age 65 or older. We analyzed cancer risk and clinical characteristics, focusing on females with cancer diagnosed at age 65 or older. **Results:** Of the 283 *BRCA1/2* carriers, 229 (81%) had a cancer diagnosis, out of which 84 (37%) were diagnosed at age 65 or older. Of all the breast cancer diagnoses (n = 173), 45 (26%) were diagnosed at age 65 or older. Among these 45 patients, median age at diagnosis was 69 years (65-87); majority were *BRCA2* carriers (62%), with invasive ductal carcinoma (80%), ER-positive (58%), PR-negative (55%), HER2-negative (97%), high grade (55%) and had stage I or II disease (78%). Fifteen patients (38%) were triple-negative. A minority (32%) received adjuvant chemotherapy, 43% received adjuvant endocrine therapy, and 54% received adjuvant radiation. During a median follow-up of 205 months for all breast cancers (n = 173), there were 52 recurrences, 28 of these (54%) were diagnosed at age 65 or older, of which 13 were contralateral (median time to recurrence: 140 months); 5 were local/regional (median time: 186 months) and 10 were metastatic (median time: 76 months). Ten of the 13 contralateral recurrences (77%) were in *BRCA1* carriers. Of the ovarian cancer diagnoses (n = 69), 27 (39%) were diagnosed at age 65 or older. Among these 27 patients, median age at diagnosis was 71 years (65-87); majority were *BRCA2* carriers (74%), had serous carcinoma (84%), with stage III or IV disease (96%). Of all ovarian cancers (n = 69), there were 15 recurrences (22%), 9 of them (60%) were diagnosed at age 65 or older. Of the 8 pancreatic cancers, 6 were diagnosed at age 65 or older. Of the 283 *BRCA1/2* carriers, 249 still had at least one breast at the time of genetic testing, and 34% elected for risk-reducing mastectomy (RRM). Of the 177 patients with intact ovaries, 71% opted for risk-reducing salpingo-oophorectomy (RRSO). Compared to *BRCA* carriers with cancer diagnosed under age 65, a smaller proportion of those diagnosed at age 65 or older opted to undergo RRM (26% vs. 40%) or RRSO (67% vs. 78%). **Conclusions:** Our study reveals that female *BRCA1/2* mutation carriers over age 65 continue to retain a significant risk of cancer, including breast, contralateral breast, ovarian, and pancreatic cancer. This finding supports the importance of continued high-risk surveillance and risk-reducing interventions in this growing demographic. Further studies are needed to better define the cancer risks and optimal management of older females with *BRCA1/2* mutations. Research Sponsor: None.

Beyond the standards: The impact of provider collaboration on referrals to genetic counseling. *First Author: Eric S Fowler, City of Hope Atlanta, Chicago and Phoenix, Zion, IL*

Background: The Commission on Cancer standards require institutions to monitor genetic assessment for a selected cancer site, providing an opportunity to increase referrals to genetic counseling. Genetic counseling, risk assessment, and testing improve patient care, outcomes, and facilitate cascade testing in families. This study investigated how collaboration with referring providers through education, feedback, and ongoing communication impacted referrals to genetic counseling. **Methods:** Study participants included new patients with colorectal cancer (CRC) diagnosed under age 50 presenting to our institution from July 2021 to September 2022. Patients were excluded if they did not return after initial visits. Baseline and intervention time periods were compared. Interventions to increase referrals included communication with the medical staff through memoranda co-authored by genetic counselors and physician champions, presentations by genetic counselors at tumor board, medical oncology, cancer committee meetings, and emails providing quarterly and final outcomes. Descriptive statistics were utilized to review categorical data, with baseline and intervention referral rates compared with the Pearson Chi-Square Test. **Results:** 133 patients met referral criteria with ages at diagnosis ranging from 19-49 years old. Mean (and median) patient ages were comparable between baseline and intervention study periods: 42.5 (45) and 43.0 (45), respectively. In the baseline period, 10/32 (31.3%) patients were referred to genetic counseling. In the intervention period, 58/101 (57.4%) patients were referred to genetic counseling representing a 26.1% increase over baseline. The Pearson Chi-Square Test yielded a p-value of 0.01. Referral rates varied by quarter (collaboration/education began in mid-Q2): Q1 - 26.7%, Q2 - 45.8%, Q3 - 77.8%, Q4 - 60.0%, and Q5 - 34.4%. **Conclusions:** Collaboration and communication with referring providers resulted in statistically and clinically significant increases in referrals to genetic counseling. The increase in referrals was most pronounced immediately after collaboration began and declined by the last quarter. This study highlights the importance of genetics educational initiatives and ongoing communication in the oncology setting, and the need for alternative and more sustainable strategies to maintain and increase referrals to genetic counseling. Referrals to genetic counseling facilitate the provision of cancer screening guidelines for patients and their families, based on genetic test results and personal/family histories, and reinforce the importance of cascade testing where appropriate. Research Sponsor: None.

Genetics referrals: New patients with CRC < 50.				
		Baseline	Intervention	Total
n (%)	Not Referred	22 (68.7)	43 (42.6)	62 (46.6)
	Referred	10 (31.3)	58 (57.4)	71* (53.4)

Impact of early testing and analysis of germline genetic mutation patterns in patients with breast cancer: A single institution experience. *First Author: Aswanth Reddy, Mercy Clinic Oncology, Fort Smith, AR*

Background: Approximately 3% of patients with breast cancer have a pathogenic or likely pathogenic variant (mutation) in a high-risk breast cancer gene, such as BRCA1, BRCA2 and PALB2, which increases breast cancer risk more than fourfold. Approximately 3% have a germline mutation in a moderate-penetrance breast cancer gene, such as ATM or CHEK2, which confers a two- to threefold increased risk of breast cancer. **Methods:** In 2020 we started offering germline genetic testing to all newly diagnosed breast cancer patients at the time of diagnosis irrespective of their family history. Our objectives included the following: Prevalence of mutations in breast cancer patients treated at our institution. Germline mutations in patients with Ductal carcinoma in situ (DCIS). To identify if early universal germline testing affected the surgical modality. **Results:** A total of 525 patients were seen in the oncology clinic from January 2020 to December 2022 with a breast cancer diagnosis. The median age of diagnosis is 66 (32-91) years. Invasive ductal cancer (IDC 66 %) was the most common subtype, followed by DCIS (18%) (Table 1). Most patients had estrogen-positive cancer (82% vs. 18%), and approximately 13% had HER2-positive disease (61% HER2 low). Mutation in CHEK2 (9 patients) was our cohort's most common pathogenic mutation, followed by BRCA1 (6 patients) and MUYTH (6 patients) genes. Predominant germline mutations were identified in patients with IDC, followed by DCIS. One patient with a pure mucinous subtype had a germline pathogenic mutation (RECQL4 gene). We identified a higher percentage of pathogenic breast cancer-related mutations in patients above 60 years (63% vs. 37%) and all CHEK2 mutations were in patients above 60. Out of 41 patients with pathogenic mutations, 17 underwent a partial mastectomy, 12 had a bilateral mastectomy, and two had a unilateral mastectomy. All patients with BRCA1/2 mutation chose bilateral mastectomy, and all patients with a CHEK2 mutation underwent a partial mastectomy. Several variants of unknown significance (VUS) mutations were identified, and they followed a similar pattern, being more common in patients with IDC. VUS mutations in the ATM gene were the most reported abnormality. **Conclusions:** Pathogenic mutation in the CHEK2 gene is more prevalent, and we hypothesize that this finding could be related to the demographic population treated in our institution. Also, CHEK2 mutation was only identified in patients older than 60, which argues for more testing in patients in this age group. Approximately 9% of all IDC patients had a germline mutation compared to 4.2 % in patients with DCIS. Our review identifies that patients with BRCA1/2 mutations tend to undergo prophylactic mastectomy, and early testing likely impacted this decision. From our study, we believe that germline genetic testing should be offered to all breast cancer patients. Research Sponsor: None.

Digital cancer genetic risk assessment in a gynecologic oncology clinic. *First Author: Emily M Webster, Weill Cornell Medicine, New York, NY*

Background: Population-based screening for hereditary cancer syndromes and referral of those who screen positive for genetic testing is a cost effective, evidence-based national health priority. However, under-recognition of hereditary cancer syndromes remains a critical concern, with fewer than 20% of individuals with Hereditary Breast and Ovarian Cancer Syndrome and Lynch Syndrome identified. Here, we evaluate the Ambry Genetics Comprehensive, Assessment, Risk, and Education (CARE) Program, a risk-stratification tool to assess eligibility for National Comprehensive Cancer Network (NCCN) genetic testing criteria and lifetime risk for breast cancer based on the Tyrer-Cuzick (version 8.0) risk algorithm. **Methods:** Between November 2022 and February 2023, new patients in a gynecologic oncology clinic were prompted by text message to complete CARE prior to their appointment. Those using CARE then completed a System Usability Scale (SUS), a validated 10-item questionnaire for the assessment of perceived usability. **Results:** Sixty patients presented for a new patient gynecologic oncology appointment and were prompted to complete CARE. The median patient age was 55 years (interquartile range, 40-68). The patients self-identified as Non-Hispanic White (44, 73%), Non-Hispanic Black (5, 8%), Asian (5, 8%), Hispanic (3, 5%), other (2, 3%), and unknown (1, 2%). All identified as female. Forty-three patients (72%) completed CARE. Among CARE users, 11 (26%) were identified as meeting criteria for genetic testing; of these, 9 (82%) proceeded with point-of-care same day genetic testing. Nine (21%) patients were eligible for enhanced breast cancer screening based on an estimated lifetime breast cancer risk of 20% or greater; of these, 100% were referred for high-risk breast screening. There were no patient demographics associated with completion of CARE. Forty-one patients (72%) completed the SUS survey; the median SUS score was 80 (interquartile range, 60-92.5), which corresponded to 85-89th percentile and a letter grade of A-. **Conclusions:** Implementation of a digital tool for cancer genetic risk assessment identified a quarter of patients to be eligible for genetic testing, among whom 82% completed same-day genetic testing. Additionally, the tool was reviewed favorably by patient users. Large randomized controlled trials of health information technology tools are needed to move closer to the goal of population-based hereditary cancer risk assessment. Research Sponsor: None.

Therapeutic applications of germline testing for cancer predisposition genes in Asia in the real world. *First Author: Seng Wee Cheo, Department of Haematology-Oncology, National University Cancer Institute, Singapore, Singapore*

Background: Germline genetic testing is traditionally done in patients suspected with hereditary cancer syndrome for enhanced cancer surveillance and/or prevention. In recent years, germline genetic testing is increasingly performed for therapeutic indication, given the approval of PARP inhibitor in advanced cancer patients with germline BRCA1/2 or other homologous recombination repair (HRR) gene mutations, and immunotherapy for patients with mismatch repair gene mutations. We evaluated the clinical utility of actionable (treatable) pathogenic germline mutations (PGM) in a tertiary cancer center in Asia. **Methods:** We conducted a retrospective review of cancer patients who underwent germline genetic testing at the National University Cancer Institute, Singapore, Cancer Genetics Clinic. The primary objectives were to determine the prevalence of potentially actionable PGM in cancer predisposition genes and their therapeutic applications, with focus on BRCA, HRR and mismatch repair genes. **Results:** From 2000 till 2022, 1154 cancer patients underwent germline genetic testing, with the majority (81.9%) tested with multi-gene panels comprising 9-134 genes. 93% (n = 1069) fulfilled conventional criteria for genetic testing; 7% (n = 81) were tested specifically for treatment decisions. 411 (35.6%) patients tested positive for a PGM, of which 334 (81%) were potentially actionable. BRCA1/2 mutations accounted for 62.3% of actionable mutations, followed by mismatch repair (18%; MLH1 8.7%, MSH2 6%, MSH6 2.1%, PMS2 1.2%), and other HRR genes (19.7%: RAD51 6.3%, ATM 4.8%, PALB2 3%, BRIP1 2.4%, others 3.3%). Among patients with BRCA/HRR gene mutations, breast (60%) and ovarian cancer (26.7%) were the commonest primary cancer. 152 germline positive patients have advanced cancers, and 79 (52%) patients received germline directed therapies (PARP inhibitor: n = 75; immunotherapy: n = 4). Median duration of immunotherapy in the 4 mismatch repair gene carriers was 20.5 months (range 5-40). Among germline BRCA/HRR mutation carriers with advanced cancer who were treated with PARP inhibitor, ovarian cancer was the commonest (n = 49), followed by breast (n = 14) then prostate (n = 6). Median PARP inhibitor treatment duration was 8 months (range 1-76). Among germline BRCA/HRR mutation carriers who received platinum-based chemotherapy, pathological complete response rate in the neoadjuvant setting was 53% (n = 17 breast cancers; TNBC [n = 11], other subtypes [n = 6]) and objective response rate was > 80% in the advanced setting (n = 71; ovarian = 51, breast = 9, others = 11). **Conclusions:** About one-third of cancer patients tested in a high risk Cancer Genetics Clinic in a tertiary cancer centre in Asia carry PGM, of which ~80% are potentially actionable. > 50% advanced cancer patients with actionable PGM received germline directed therapies, confirming the clinical utility of germline testing in the real world. Utility of multi-gene panel-based germline analysis following genomic profiling and cascade testing in advanced solid tumors: An initial report of the BRANCH study. *First Author: Takeshi Kuwata, National Cancer Center Hospital East, Kashiwa-Shi, Japan*

Background: Genetic testing for pathogenic germline variants (PGVs) is performed to identify hereditary cancer syndromes (HCS) and to evaluate the application of targeted therapies in clinical oncology. Multi-gene panels (MGPs) have become popular for identifying HCS; however, their clinical utility in therapeutic applications and confirmatory germline testing for presumed PGVs and in cascade testing are not well established. **Methods:** BRANCH [UMIN000046085] is a multicenter clinical study to confirm PGVs in: i) patients with advanced solid tumors in whom a presumed PGV has been detected by comprehensive genomic profiling (CGP) (cohort A); ii) patients who received a germline BRCA (gBRCA) test (cohort D); and iii) first-degree relatives of patients with PGVs identified in this study (cohort C). PGVs were examined in 35 HCS genes using an MGP combined with digital multiple-ligation-dependent probe amplification. **Results:** MGP results were available for 75 patients in cohort A and 83 in cohort D (3 February 2023). The most common cancer in cohort A was colorectal cancer (13%) followed by ovarian (12%) and breast (11%) cancers. Of 103 tested presumed PGVs, 46 (45%) were confirmed as PGVs, with the highest germline conversion rates in *BRCA1* (8/8, 100%), followed by *PALB2* (5/6, 83%) and *BRCA2* (15/19, 79%) among the genes tested in ≥ 3 patients. In tissue-based CGP, true PGVs had a higher variant allelic frequency (median 55.7% [range, 31.9–96.8]) than non-PGVs (37.0% [9.3–86.9]). In cohort D, 61 (74%) patients had breast cancer, including one with both breast and ovarian cancers. All BRCA PGVs identified by gBRCA test were identified by MGP in 28 BRCA-positive patients. Intriguingly, among 55 patients (66%) in whom no BRCA PGV was detected by gBRCA test, non-BRCA PGVs were identified in 6 (11%) patients (2 *PALB2* and 1 each of *ATM*, *CHEK2*, *MSH2* [large deletion], and *TP53*). Thirty relatives in 18 pedigrees received MGP-based cascade testing in cohort C. The most frequent target genes were *BRCA2* followed by *BRCA1* and *PALB2*. The same PGVs as the probands were confirmed in 11 (37%) individuals and novel PGVs were identified in 2 (7%) relatives, leading to double PGVs in homologous recombination genes (*PALB2+BRCA2* and *BRCA2+ATM*), respectively. **Conclusions:** MGP successfully determined germline variants among presumed PGVs identified by CGP in patients with advanced solid tumors, and detected non-BRCA PGVs in 10% of gBRCA-negative patients. Furthermore, MGP-based cascade testing has the potential to identify other PGVs in addition to those detected in the probands. Clinical trial information: UMIN000046085. Eliminating barriers to uptake of germline genetic testing for patients with advanced cancer: The GTAC study. *First Author: Kara K. Landry, University of Vermont Larner College of Medicine, Burlington, VT*

Background: Identification of pathogenic germline variants (PGVs) is important in guiding treatment decisions, cancer screening and testing of family members. While genetic testing indications expand, barriers to testing still exist. Streamlined processes for genetic testing are needed. Our study assessed the feasibility of a novel approach in which patients with cancer underwent genetic testing first with genetic counseling after for only those with a PGV. **Methods:** This was an IRB approved study of patients with metastatic solid tumors within < 1 year of diagnosis. Participants were referred by their oncologist and underwent germline testing with an 84-cancer gene panel after signing informed consent. Results were called to patients by a research coordinator if testing was negative and by a genetic counselor if found to have a variant of uncertain significance. Patients with a pathogenic germline variant (PGV) were called by the genetic counselor and scheduled to meet with the genetics team for full counseling. All patients received a letter documenting results and implications. Patient and provider satisfaction surveys were administered in follow-up. **Results:** 125 patients were eligible and 91 enrolled. Reasons for lack of participation included: early death or decline in health (n = 11, 32.4%). The mean age of patients was 66 (SD 12.6). 60 (65.9%) were male and 43 (47.3%) resided in a rural area. Cancer types represented included: GI (n = 27, 16.5%), lung (n = 22, 13.4%), prostate (n = 19), and renal (n = 4). A PGV was identified in 13 (14.8%) participants. 10 (76.9%) had follow up with a genetic counselor, 2 (15.4%) declined and 1 (7.7%) died prior to being seen. PGVs identified include: *MUTYH* (n = 5), *MITF* (n = 2), *CHEK2* (n = 2), *WRN* (n = 1), *RAD51D* (n = 1), *CDH1* (n = 1), *NTHL1* (n = 1). 74 (81.3%) participants completed the survey. The vast majority appreciated having undergone testing (n = 70, 94.6%) and having testing incorporated into an existing appointment (n = 69, 93.2%). 61 (82.4%) participants felt confident in their understanding of the results. All providers (n = 16, 100%) were satisfied with this testing process and most (n = 15, 93.8%) felt that genetic test results were obtained in a timelier fashion and reported interest in continuing this testing process. 5 (38.5%) patients with PGVs had a first degree relative undergo cascade testing within 6 months of results. **Conclusions:** We show that this paradigm shifting process of testing first and counseling after is feasible and acceptable for cancer patients with high rates of cascade testing. Patients and providers report high satisfaction with this process. This process removes known barriers to testing, such as extra clinic visits and time delays to testing. Further use of this process will require delivering education to patients prior to testing and ensuring that providers are comfortable ordering testing. A population-based study of BRCA breast cancer incidence and prognosis in the Italian Emilia Romagna region: The MUTina study. *First Author: Laura Cortesi, Department of Oncology and Haematology, University Hospital Modena, Modena, Italy*

Background: In Italy, about 3% of all breast cancer (BC) are related to BRCA1 and BRCA2 gene mutations. In the Emilia Romagna Region, a unique hub and spoke model was adopted for select and follow people at risk, starting from the Regional Screening Programs, General Practitioners and specialists, covering all the area. This study was designed to uniformly identify and treat BRCA1/2 related BC. Characteristics and outcome of tumors detected by this protocol will be presented. **Methods:** In this multicenter-retrospective study, seven out of nine provinces collected data about BRCA-related BC identified in the Emilia-Romagna region. Patients and tumors characteristics, surgical information, treatment modalities for early (neoadjuvant or adjuvant therapies) and advanced disease, type of relapse (local/distant), second primary tumors occurrence, surgical preventive strategies (bilateral mastectomy, oophorectomy), gene testing data, disease free survival (DFS) and overall survival (OS) were registered. Comparisons between BRCA1 and BRCA2 tumors were performed. **Results:** Since 2000 to 2011, 284 BC were registered (171 BRCA1, 110 BRCA2 and 3 BRCA1 and BRCA2 mutated) with a median age at onset of 42 years. BRCA1-related tumors were mostly triple negative BC (TNBC) compared to BRCA2 ones. The diagnosis was at stage I in 52.3% of cases, being 59.7% BRCA1 and 39% BRCA2 (P = 0.0015). BRCA2 patients, compared to BRCA1, received more frequent up-front surgery (85% vs. 74.9%, P = 0.049) and less chemotherapy (34.1% vs 65.9%, P = 0.004). After a median 12-years follow-up period, 136 patients (47.9%) developed an ipsilateral/local or systemic recurrence or contralateral second BC. BRCA1 developed more local recurrences, compared to BRCA2 that had more distant relapses (P = 0.013). Median OS was not reached in the whole population, with 80.3% of patients alive at the analysis cut-off. Among the two populations, there was a benefit trend for BRCA1 patients (P = 0.071), mostly for those who received chemotherapy (P = 0.0036), contralateral mastectomy (P = 0.0001) and oophorectomy (P < 0.0001). Finally, 25.7% of patients developed a second tumor, excluding BC, mostly ovarian cancer. **Conclusions:** Although BRCA1-related BCs show more aggressive characteristics than BRCA2 BC, the early diagnosis due to our regional surveillance program, leads to a trend for better outcome, even if not statistically significant. The BRCA1 highest rate of recurrence reflects the tendency to local rather than distant relapse. Furthermore, the BRCA deficiency appears to be a predictor of chemosensitivity. Finally bilateral mastectomy and oophorectomy seem to be associated to better outcome. In conclusions, our data support the using of an intensive screening associated to maximal surgery and chemotherapy when BC arises in BRCA carriers, to overcome the unfavorable tumors characteristics of these patients. Geographical impact on prostate cancer genetic testing eligibility: A preliminary study from an academic cancer center. *First Author: Samantha Beck, University of Utah, Salt Lake City, UT*

Background: Germline testing (GT) for prostate cancer (PCa) helps to determine treatment selection and other cancer risk, which guides screening recommendations. Patients with PCa that is high risk group by NCCN and greater stage should receive genetic counseling (GC) referral. There is limited data on differences in genetic services given the rurality of PCa patients. This study aims to determine the geographical distribution of PCa patients meeting GC referral and GT criteria. **Methods:** A retrospective analysis evaluated data from electronic medical records of PCa patients at an NCI-designated cancer research facility. Data was abstracted from new PCa patients seen in 2019 and 2021, years before and after the COVID-19 pandemic. Data includes demographic information, cancer staging, and pathology results. Regions of urbanicity, urban and non-urban (rural/frontier), were categorized through zip codes and defined by Utah Department of Health and Human Services. Criteria for GT followed NCCN guidelines (v.1.2023). Statistical methods for descriptive and comparative analysis done using Chisquare, Fisher's exact, and Mann Whitney tests in R*Stats to compare 2019 and 2021 cohorts. **Results:** Out of 525 PCa patients' initial treatment at HCI in 2019 (n = 346) and 2021, (n = 179) 94% self-reported as White (p = 0.164) with a median age of 66 (p = 0.690) and 51% being employed (p = 0.396) at time of first treatment. Of these, 414 (79%) were from an urban area and 111 (21%) from a non-urban area (p = 0.883). The cohort was primarily from 2019 (66%), with 274 (79%) and 72 (21%) of the PCa patients living in urban and non-urban areas, respectively. In 2021 (34%), 140 (78%) and 39 (35%) patients were from urban and non-urban areas. Criteria for GT were met in 37% (n = 196) of PCa patients (p = 0.595). Regions were independently compared by race, age, employment, and year. No statistical difference across all variables was found (p > 0.05). Geographical regions did not impact GT eligibility. **Conclusions:** This preliminary study shows that geographical region does not impact GT eligibility in PCa patients seen at HCI during 2019 and 2021. The years analyzed is a proxy for differences in aggressiveness by rurality. The results show 37% of the PCa patients met criteria for GT. No significant differences were identified by geographical region, race, age, employment, or the year of initial treatment. Further research is being conducted to determine if access to PCa GC uptake is impacted by geography and differing service delivery models after criteria for GT has been met. Perceived mental and physical health in patients with common cancers: A study using the PROMIS framework in All of Us database. *First Author: Rajaa Mohamed Salih, Harlem Hospital Center, New York, NY*

Background: The self-perception of one's mental and physical health (MH and PH) is of utmost importance for individuals diagnosed with cancer. This study focuses on the assessment of self-perceived mental and physical health (MH and PH) in individuals diagnosed with cancer. The Patient-Reported Outcomes Measurement Information System (PROMIS) framework is used to measure health outcomes, with PROMIS-PH measuring physical well-being and PROMIS-MH measuring mental health status. The study aims to evaluate self-reported mental and physical health of individuals with common cancers in the All of Us database, which includes over 414,000 participants in the US who have completed PROMIS-PH and PROMIS-MH surveys. **Methods:** We included participants from All of Us dataset version 6, which includes survey data collected between May 6, 2018 and January 1, 2022 who had available electronic health records data (N = 258,188). From the survey data, we calculated PROMIS-PH and PROMIS-MH score in participants with diagnosis code (ICD9/ICD10) of any cancers (N = 36377), breast (N = 5172), prostate (N = 5234), colon (N = 2366), and lung cancer (N = 2338). The study compared scores each cancer groups using Wilcoxon rank sum test, with a significance level of $P < 0.05$. Analysis was performed in the web-based platform Jupyter Notebook using programming language R. **Results:** The study calculated PROMIS-MH and PROMIS-PH scores based on two questions, with response options valued from 1 to 5. The higher the score, the higher the level of perceived mental and physical health. Results showed that the mean PROMIS-MH score for all cancers was 7.38, with the highest score of 7.67 in prostate cancer and the lowest score of 7.10 in lung cancer. The mean PROMIS-PH score for all cancers was 7.31, with the highest score of 7.62 in prostate cancer and the lowest score of 6.71 in lung cancer. Prostate cancer group showed the highest PROMIS-PH and PROMIS-MH scores among the four cancer groups ($P < 0.05$), while participants with lung cancer reported the lowest PROMIS-PH and PROMIS-MH scores ($P < 0.05$). Additionally, breast cancer had higher PROMIS-MH and PROMIS-PH scores compared to all cancers ($P < 0.05$), while lung cancer had lower PROMIS-MH and PROMIS-PH scores ($P < 0.05$). There was no significant difference in PROMIS-MH score between all cancers and colon cancer. **Conclusions:** These results suggest that individuals with lung cancer may have a lower level of perceived mental and physical health compared to those with other cancers. Further research is needed to understand the underlying causes of these differences and to evaluate the effectiveness of interventions aimed at improving the well-being of individuals with cancer. Clinical and social importance of follow-up assessment of family members of patients with BRCA mutations. *First Author: Ivana Lucia de Oliveira Nascimento, Oncoclinicas - Grupo Oncoclinicas, Salvador, Brazil*

Background: The identification of *BRCA1* and *BRCA2* genes mutations are of paramount importance in the treatment and follow-up of hereditary cancer patients. When a pathogenic variant (PV) is identified in one of these genes, the surveillance for new primary tumors becomes individualized. When a pathogenic mutation is identified other family members may also be at high risk for developing tumors. Then the investigation should become familiar. **Methods:** This study reports the experience of a public oncogenetics service with the identification and follow-up of relatives of patients with *BRCA* mutations. Of the 1505 patients registered, 773 are probands, of which 71 had a mutation in one of the *BRCA* genes. A total of 503 family members were evaluated, with an average of 13 relatives per proband. **Results:** Of the 353 relatives with a *BRCA1* mutation, 132 had the familial mutation, and only 18 had cancer diagnosis. The mean age of the evaluated family members was 37 years, lower than the mean age at diagnosis of the probands, which was approximately 41 years, two founder mutations in *BRCA1* (NM_007300.4:c.3331_3334del and NM_007300.4:c.211A > G) were more recurrent among index cases, which is associated with the ancestral background of the local population. For the *BRCA2* gene, 148 family members were evaluated, of which 77 had a mutation and 23 had a previous cancer diagnosis. The mean age of family members evaluated for *BRCA2* mutation was 43 years, similar to the mean age at diagnosis of the proband: 41 years. The NM_000059.4:c.1389_1390del and NM_000059.4:c.7124T > G variants was the most frequent in *BRCA2*. **Conclusions:** This data reinforces the importance of genetic counseling and testing of family members when a pathogenic variant is identified in a cancer patient. It is clear that early initiation of surveillance protocols, with screening and prophylactic surgeries are very effective tools for those high risk patients, they just have to be early diagnosed with the PV to benefit from this strategies. In addition, this assessment helps in understanding the mutational profile of the population in order to improve the planning of services in oncogenetics. Spectrum of germline pathogenic variants among patients with cancer in Mexico. *First Author: Jose Luis Rodriguez Olivares, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, México, Mexico*

Background: Up to 10% of patients with cancer harbor pathogenic germline variants (PVs) in one or more cancer susceptibility genes. Genetic cancer risk assessment (GCRA) is an important tool for the management of patients with cancer. It allows the identification of candidates for structured screening protocols, risk reduction strategies, targeted therapies and cascade testing. Knowledge about the prevalence and spectrum of PVs is limited among underrepresented populations. We studied the prevalence of germline PVs in a cohort of Mexican patients with cancer. **Methods:** Between April 2017 and September 2022, patients with diagnosis of cancer who met clinical criteria for GCRA according to international guidelines (NCCN) and were enrolled in the international Clinical Cancer Genomics Community Research Network (CCGCRN) registry at Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán were included. Cancer risk counseling and germline multi-gene panel testing were performed. Post-test counseling and cascade testing with known PV analysis was offered. **Results:** 1322 patients met inclusion criteria (probands n = 1027, relatives n = 295). Among the probands, 72.4% (744/1027) were women, median age at cancer diagnosis was 48.2 years (range 1-88) and 9.8% (n = 101) had more than one primary tumor. 14.5% (149/1027) of probands had a positive result in which 152 PV were identified (*BRCA1* n = 39, *BRCA2* n = 33, *ATM* n = 11, *CHEK2* n = 11, *MLH1* n = 11, *TP53* n = 7, *PALB2* n = 7, *NF1* n = 6, *MSH2* n = 5, *MSH6* n = 3, *PTEN* n = 3, *APC* n = 2, *BRIP1* n = 2, *CDH1* n = 2, *RB1* n = 2 and 1 PV in the genes: *CDKN2A*, *MAX*, *MUTYH*, *NBN*, *PTCH1*, *RAD50*, *SDHA* and *SDHB*). The frequency of PV according to cancer diagnosis was: breast 15.5% (82/527), prostate 2% (4/198), ovarian 15.6% (12/77), colorectal 26.6% (16/60) and pancreatic 11.9% (5/42). The frequency of recurrent, potentially founder PVs in their respective genes was as follows: *BRCA1* del(exons9-12) 30.7% (12/39) and *CHEK2* c.707T > C 81.8% (9/11). Among the relatives referred for cascade testing the frequency of PV was 40% (118/295), 18.6% (55/295) had personal history of cancer with a median age at diagnosis of 47 years. **Conclusions:** Our results show a wide spectrum and a variable frequency of PVs among one of the largest examined cohorts of Mexican patients with cancer, with a high frequency of PVs among cases of breast, ovarian, and colorectal cancer. In contrast to reports from other populations, there was very low frequency of PVs among patients with prostate cancer. The outcomes of this study add to our understanding of the genetic epidemiology of cancer in the Mexican population, and support creating GCRA programs to improve access to multi-gene panel testing among underrepresented patients in limited resource settings. A scalable approach to democratizing cancer risk stratification: One health-care system's approach using a patient-facing digital platform. *First Author: Heather Fecteau, Ambry Genetics Corporation, Aliso Viejo, CA*

Background: Access to genetic testing and risk stratification is primarily gated by referrals from non-genetics providers for patients who meet testing criteria. The majority of Americans seek care at community hospitals that are closer to home; community hospitals are faced with the challenge of how to democratize access to precision oncology and cancer prevention. Research has shown that the establishment of such protocols is challenging, requiring organizational buy-in, capital, resources, and the involvement of multiple levels of clinical and nonclinical stakeholders. Here we highlight Sarah Cannon, the Cancer Institute of HCA Healthcare, and their programmatic approach to risk stratification using a digital platform offered universally to all patients undergoing screening mammography. **Methods:** From February to November in 2022, fourteen sites were assessed to have appropriate provider and facility capabilities to support the implement the CARE program. The web-based risk-stratification tool is sent to individuals before standard ambulatory appointments to assess their lifetime risk for breast cancer based on the Tyrer-Cuzick (version 8.0) risk algorithm and National Comprehensive Cancer Network (NCCN) genetic testing criteria. Testing criteria included hereditary breast, ovarian, pancreatic, and prostate cancers, Lynch syndrome, and familial adenomatous polyposis (FAP). Retrospective data was pulled from patients seen between February 2022 through January 2023. The outcome measures included percentage of individuals who completed the risk-assessment, met genetic testing criteria, pursued germline genetic testing, received a positive germline result, and/or had a breast cancer risk $\geq 20\%$. **Results:** During the 10 months at the 14 community hospitals a total of 25,671 individuals were invited for risk assessment through the CARE program; 19,277 (75.1%) individuals completed assessment. Overall, 5,070 (26.3%) met genetic testing criteria and 1,536 individuals had a $\geq 20\%$ lifetime risk of breast cancer, for a total of 34% of patients identified as elevated risk. 23.4% (1,187) of those meeting criteria opted to proceed with germline genetic testing. An additional 126 individuals who did not meet criteria pursued genetic testing. Of the 1,313 completed genetic tests, 96 (7%) had positive genetic test results. Fifty-four of 96 (56%) positive results had an impact on medical management and cancer prevention. **Conclusions:** Sarah Cannon and HCA Healthcare have successfully begun implementing a comprehensive, digital risk stratification program in the community hospital setting to provide standardized access to genomic testing and risk stratification. By identifying patients with an elevated risk for cancer, the potential for increased early cancer detection and precision oncology can be observed in a scalable and sustainable program. Impact of risk-reducing mastectomy on quality of life of women with Li-Fraumeni syndrome. *First Author: Natalia Polidoro, Sirio Libanês Hospital, Sao Paulo, Brazil*

Background: Risk-reducing mastectomy (RRM) is a common strategy for managing breast cancer (BC) risk in women with Li-Fraumeni syndrome (LFS). Data on uptake and health-related quality of life (HRQoL) in LFS are limited and often extrapolated from *BRCA* scenario, despite the lack of evidence on survival benefits in LFS. This study evaluated RRM uptake and its impact on HRQoL in women with LFS. **Methods:** TP53 PV female carriers from a Brazilian LFS cohort from January 2012 to December 2022 were eligible. After informed consent, 90 women reported oncological status, uptake of RRM, and completed BREAST-Q questionnaire. Scores were compared among different BC risk management strategies and minimal important difference (MID) of ≥ 4 was described. Multivariable analyses were performed to identify surgical factors related to HRQoL outcomes. **Results:** 71.7% (n=33) of women diagnosed with unilateral BC (n=46) underwent contralateral risk-reducing mastectomy (CRRM) at a median age of 39 years. Among unaffected BC women (n=44), 36.3% underwent bilateral risk-reducing mastectomy (BRRM) at a median age of 36 years. CRRM was associated with lower scores for psychosocial (64[±19] vs 93[±21], $p=.05$) and physical well-being (72[±16] vs 92[±18], $p=.001$). BRRM women had lower physical well-being scores (72[±19] vs 92[±13], $p=.003$). MID associated with worst HRQoL outcomes were seen in all four domains on CRRM women and on satisfaction with breasts and physical well-being of BRRM patients (table). Nipple-sparing mastectomy (NSM) presented better psychosocial (74[±20] vs 52[±19], $p=.04$) and sexual well-being (60[±20] vs 46[±20], $p=.05$) when compared to skin-sparing mastectomy (SSM) on CRRM patients and with higher sexual well-being (60[±20] vs 46[±20], $p=.05$) on BRRM patients. Women with BRRM > 2 years had better physical well-being (83[±14] vs 56 [±12], $p<.001$). There were no significant differences in scores of women with age ≥ 35 years at the time of BRRM, although MID ≥ 4 was observed on psychosocial and sexual well-being and satisfaction with breasts: -23.0, -14.4, and -20.0, respectively. **Conclusions:** We observed high rates of RRM in LFS women and those were associated with worse outcomes on breast HRQoL in comparison to surveillance. The potential benefits and harms of RRM should be carefully discussed with patients before performing it, especially in LFS women where the survival benefits of these interventions remain uncertain. Research Sponsor: None.

Risk of death among lung cancer patients before and during the COVID-19 pandemic. *First Author: Teddy Tai Loy Lee, The University of Hong Kong, Hong Kong, Hong Kong*

Background: The survival of lung cancer patients in Hong Kong before and during the COVID-19 pandemic is poorly understood. **Methods:** Patients diagnosed with lung cancer from January 1 2010 to October 31 2022 were recruited from all 43 public hospitals in Hong Kong. Patients who died on the day of cancer diagnosis were excluded. Patients between 2020-2022 (pandemic) were matched with patients diagnosed between 2010-2019 (pre-pandemic) using 1:1 propensity score matching, based on demographics and comorbidities such as age, sex, and Charlson Comorbidity Index (CCI), to study survival before and during the pandemic. The outcomes were 1-year and 6-month all-cause mortality. In subgroup analysis, patients were categorized into 12 groups, from 2010 to 2022, based on the year of first diagnosis of lung cancer to investigate yearly changes in mortality. Patients with confirmed diagnosis of COVID-19 infection were also analyzed. **Results:** A total of 42102 lung cancer patients (66.0% male, age 72±12 years (median±SD), CCI 7.00±2.42) were recruited from 2010 to 2021 with 1-year follow up. Only 36 patients were confirmed COVID-19 positive. The matched cohort consisted of 4958 pandemic patients (68.6% male, age 72±12 years, CCI 8.00±2.43) and 4958 pre-pandemic patients (67.7% male, age 73±12 years, CCI 7.53±2.48). 2782 (56.1%) and 3846 (77.6%) pandemic patients died within 6 months and 1 year respectively, compared to 2338 (47.2%) and 3194 (64.4%) pre-pandemic patients. In subgroup analysis by year of lung cancer diagnosis, patients diagnosed in 2021 had highest risk of 1-year mortality (85.1%). There was no significant difference in mortality between patients with and without confirmed COVID-19 positivity. The cohort of 2022 lung cancer patients, with higher COVID-19 positivity, was still undergoing follow-up and will be included in the analysis at the time of presentation. **Conclusions:** Lung patients diagnosed during the COVID-19 pandemic are associated with higher risk of death within the first year compared to that of pre-pandemic patients, and is likely not associated with COVID-19 positivity. Research Sponsor: None.

Newly diagnosed lung cancer in hospitalized patients during the COVID-19 pandemic: How well are LDCTs utilized? *First Author: Jonathan Assis, HCA Florida Brandon Hospital, Brandon, FL*

Background: Medicare covers the cost of lung cancer screening in individuals aged 50-77 years with a high-risk smoking history. The COVID-19 pandemic caused a decrease in outpatient visits and cancer screenings. The objective of this study was to provide a comparison between the multitude of lung cancer diagnoses upon presentation to the hospital predating and during the COVID-19 pandemic in patients with varying insurance types. **Methods:** We retrospectively reviewed fifteen hospitals in West Florida with newly diagnosed lung cancer during the pre-pandemic period from March 2019-August 2020 and the pandemic period from March 2020- August 2021. These patients were split into subcategories based on insurance type: private medical insurance; Medicare; Medicaid; no insurance; and other. The chi-square test was used for statistical analysis. **Results:** A total of 1409 inpatients, 676 during the pre-pandemic and 733 during the pandemic, were identified with a new diagnosis of lung cancer upon presentation to the hospital. 74% of the pandemic population and 77% of the pre-pandemic population were patients insured with Medicare. Hospitals without LDCT screening programs were found to have 317 lung cancer diagnoses during the pre-pandemic period and 292 during the pandemic period. Hospitals with LDCT screening programs were found to have 359 lung cancer diagnoses during the pre-pandemic period and 441 during the pandemic period. Chi-square tests comparing pre-pandemic to pandemic did not show a p-value of statistical significance. **Conclusions:** A substantial number of patients with Medicare were newly diagnosed with lung cancer during the pre-pandemic and pandemic periods compared to patients with other insurance types. Although Medicare provides LDCT screening for lung cancer in high-risk populations at no out-of-pocket cost, about 75% of West Florida's patients were diagnosed with lung-cancer upon presentation to the hospital. Hospitals with LDCT screening programs had an increase in cancer diagnoses during the pandemic, consistent with prior research data. Instead, the pandemic did not seem to affect hospitals without LDCT screening programs. We need to address the barriers in implementation of LDCT hospital-based screening programs to increase early diagnoses and decrease hospitalization diagnoses, leading to improved lung cancer mortality. Research Sponsor: None.

Frequency of patients with newly diagnosed lung cancer based on insurance type.

Immunogenicity after COVID-19 vaccination in patients with solid tumor and hospital staff: A prospective single-center observational study. *First Author: Yuki Katsuya, Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan*

Background: Patients with tumor are at high risk of severe COVID-19, and vaccination against SARS-CoV-2 is recommended. Impact of cancer treatment on immunogenicity has not been evaluated well. **Methods:** This prospective study was conducted to assess the seroconversion rate of SARS-CoV-2 vaccines among patients with cancer and hospital staff. Further, we focused on the difference among cancer treatment regimens. SARS-CoV-2 spike protein-specific IgG (S-IgG) were evaluated before the first vaccination, 1-3 months, 4-6 months, and 7-12 months after the second vaccination, and 1-3 months after the third vaccination. The primary endpoint was seroconversion rate measured 1-3 months after the second vaccination. **Results:** From April 2021 to November 2021, consent was obtained from 629 cancer patients and 210 hospital staff. Excluding missing data and withdrawal of consent, 590 cancer patients and 183 hospital staff without complications was analyzed. At 1-3 months after the second vaccination, S-IgG antibody concentration higher than the cut-off value (20 BAU/mL) was found in 96.1% (567/590) patients with cancer and 100% (183/183) of the healthy controls (p = 0.0024). At 4-6 months after second vaccination, S-IgG antibody concentration higher than the cut-off value was found in 93.1% (461/495) patients with cancer and 100% (170/170) of the healthy controls (p < 0.0001). The significant difference in seroconversion rate between the two groups persisted even after 7-12 months. Patients undergoing treatment regimens such as platinum combination therapy (median: 423.7, 95% CI: 264.2-767.0, p = 0.003) and alkylating agent (median: 57.5, 95% CI: 5.4-748, p < 0.0001) among cytotoxic drugs, and PARP inhibitor (median: 264, 95% CI: 43-690.4, p = 0.0004), mTOR inhibitor (median: 227.4, 95% CI: 5.7-323.4, p = 0.0036), BCR-ABL inhibitor among drugs (median: 124.4, 95% CI: 0.0-288.9, p = 0.005) among target molecule drugs showed lower antibody titer compared to the no-treatment patients with cancer group. **Conclusions:** SARS-CoV-2 vaccine immunogenicity was low among patients with cancer compared to healthy control. Also, several treatment regimens were found to negatively impact immune response. Clinical trial information: UMIN000049403, UMIN000049430. Research Sponsor: Sysmex.

AI to characterize patients with lung or ovarian cancer and those with cachexia for discovery of undiagnosed, misdiagnosed, and miscoded patients at scale in a privacy-preserving manner. *First Author: Yike Guo, Imperial College London, London, United Kingdom*

Background: Discovering undiagnosed, misdiagnosed or miscoded patients is critical to ensure suitability for clinical care pathways and for maximizing clinical trial recruitment. Meta-data (e.g. ICD) and generic NLP based approaches fall short due to: lack of scalability, significant miscoding of patient records and searching a pre-empted list of features without understanding their context or relationships between them. This study addresses these limitations through the application of Pangaea's novel AI product (PIES) to characterize patients, which has discovered 4x more undiagnosed, misdiagnosed and miscoded patients in a scalable and privacy-preserving manner. **Methods:** PIES was configured on 235 clinically validated lung, ovarian and cachectic cancer patient records from secondary care. First, PIES determines all concepts which are reflected in a patient's record based on a medical knowledge base. Second, PIES determines key clinical features and actionable relationships between them which help stratify the target patient population. Third, the findings from steps 1 and 2, are validated by clinicians and all feedback is used to refine these steps and evolve the results through a continuous loop. Following these, PIES's characterization of the target patient population is applied across clinically validated datasets for evaluation and then across multiple healthcare systems behind their firewalls to ensure scalability and privacy compliance. **Results:** Applied to a dataset of 100 clinically validated patients, ICD codes correctly discovers 48 lung cancer patients and misses 18 patients (i.e. who had a diagnosis of lung cancer but were miscoded). By contrast, PIES discovers 63 lung cancer patients and misses only 3 patients. Similarly, ICD codes correctly discovers 36 ovarian cancer patients and misses 16 patients in a dataset of 100 clinically validated patients. PIES correctly discovers all 52 ovarian cancer patients. Separately, in a dataset of 235 clinically validated patients, ICD codes correctly discovers 39 cachectic cancer patients and misses 122 patients. By contrast, PIES discovers 146 cachectic cancer patients and misses only 15 patients. **Conclusions:** Pangaea's AI-driven product for characterizing patients discovered 48% more lung cancer patients, 62% more ovarian cancer patients and 276% more cachectic cancer patients for screening, compared to ICD codes. This includes undiagnosed and misdiagnosed patients. Pangaea's product platform permits the evolution of knowledge for characterizing different target patient populations through its application across multiple healthcare systems, without the need to move or touch the data, thereby ensuring scalability in a privacy compliant manner. Inverse association of post-transplant malignancy and graft failure on survival outcome following double lung transplantation. *First Author: Jeeyeon Lee, Northwestern Memorial Hospital, Chicago*

Background: Graft failure (GF) and post-transplant malignancy (PTM) are common causes of death in lung transplantation. Immunosuppression to prevent graft failure is known to lead to de novo malignancies after solid organ transplantation. Here, we assess the relationship between graft failure and de novo malignancies after double lung transplantation (DLT). **Methods:** Data extracted from the Organ Procurement Transplantation Network (OPTN) registry were analyzed. DLT cases for non-cancerous diseases were selected. We evaluated the overall survival (OS) of recipients with or without PTM (PTM+ or PTM-), and that of recipients with or without GF (GF+ or GF-) after DLT. The association between GF and PTM was investigated. **Results:** Among 23,935 DLT recipients, there were 5,629 cases (23.5%) of PTM+ and 18,306 cases (76.5%) of PTM -, and 2,316 cases (9.7%) of GF+ and 21,619 cases (90.3%) of GF- following DLT. Among GF+ cases, the prevalence of acute, hyperacute, and chronic rejection after DLT was 1,962 cases (84.7%). The OS in recipients with GF+ was worse than that in recipients with GF- (p < 0.001). However, inversely, the OS in recipients with PTM+ was better than that of recipients with PTM- (p < 0.001). When patients were categorized into four categories by each factor (GF-, GF+, PTM+, PTM-), the GF rate was lower in recipients with PTM+ than in those with PTM- [GF+/PTM+ (n = 368, 1.5%) versus GF+/PTM- (n = 1,948, 8.1%)] (p < 0.001), and the PTM+ rate was higher in recipients with GF- than in those with GF+ [GF-/PTM+ (n = 5,261, 22.0%) versus GF+/PTM+ (n = 368, 1.5%)] (p < 0.001). And the GF-/PTM+ group showed the best prognosis with 97.3 months of median OS, and the GF+/PTM- group showed the worst prognosis with 36.8 months of median OS (p < 0.001). **Conclusions:** Recipients who developed PTM following DLT had longer OS compared with those who did not. And the GF rate was significantly lower in recipients with PTM compared to those without PTM. Further research is needed to investigate the underlying mechanism of the inverse association between PTM and GF in DLT recipients. Research Sponsor: None.

Learned lessons from a US-wide outreach program to broaden enrollment to the PROMISE Registry, a prostate cancer genetic registry. *First Author: Channing Judith Paller, The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Updates to NCCN genetic testing recommendations and approved PARPI treatments for prostate cancer (PCa) patients (pts) have clarified the need for genetic registries to identify pts for novel treatments and understand real-world effects of targeted therapies. PROMISE (NCT04995198) is a US prospective genetic registry that has deployed an outreach program to broaden enrollment beyond the usual approach of academic medical centers as recruitment sites. PROMISE aims to create a PCa genetic registry by enrolling and screening 5,000 PCa pts via germline testing to identify 500 for long-term follow-up with germline mutations in genes of interest. **Methods:** The outreach program was initiated in May 2021 alongside enrollment. The program aims to supplement ongoing recruitment at 23 institutions by broadening enrollment to include populations and areas not served by academic medical centers. Direct-to-pt outreach was prioritized via partnerships with PCa advocacy organizations with groups and geographic areas with high prevalence of PCa. Online activities include webinars, interviews, podcasts, articles, partner email blasts, and newsletters. In-person activities include tabling and presentation at patient- and provider-facing conferences, and tabling at pt walks. Letters were sent introducing PROMISE through the Maryland Cancer Registry to individuals with PCa. A dedicated team including marketing, partnerships and engagement, and website SEO specialists support the program. Funding for the outreach program is provided by the study funder, Advancing Clinical Trials (ACT). **Results:** As of January 2023, study accrual is 54% ahead of initial projections. 2,178 have been enrolled and 219 are eligible for long-term follow-up across 48 states, with most enrollment occurring on the east and west coasts. Race/ethnicity distribution is as follows: American Indian or Alaska Native 0.4%, Asian 2.0%, Black 3.9%, Hispanic 1.8%, Native Hawaiian or Pacific Islander 0.1%, White 76.4%, unknown 0.4%, and no response provided 16.3%. **Conclusions:** Traditional recruitment efforts by academic medical centers, when supplemented with direct-to-pt outreach yields increased enrollment. Effective components include 1) partnerships with PCa advocacy organizations, 2) communication from PIs, Investigators, and other medical professionals via webinars and interviews with clinically relevant topics and Q&A, and 3) varied methods of outreach. While the program has led to high accrual, distribution of enrolled participants supports findings from other genetic and genomic registries indicating that increasing diversity continues to be a challenge. Moving forward, we will continue to work with outreach partners to find well-targeted, efficient ways to reach PCa patients with attention to increasing participant diversity. Clinical trial information: NCT04995198. Research Sponsor: Advancing Cancer Treatment, Inc.; Partial support by a grant (W81XWH-18-2-0060, W81XWH-17-2-0043) from the Department of Defense.

Prevalence of pathogenic germline variants in a cohort of patients with early onset non-small cell lung cancer (EOLUNG). *First Author: Maria Jove, Catalan Institute of Oncology, Hospital Duran i Reynals, IDIBELL. Medical Oncology, Hospitalet, Spain*

Background: Patients with early onset lung cancer might be more likely to carry pathogenic (or likely-pathogenic) germline variants (PGV) in genes associated with cancer predisposition. However, germline testing is not recommended in this population. We designed this study to determine the prevalence of PGVs in patients with early onset lung cancer. **Methods:** This prospective, multicenter cohort study assessed PGV in patients younger than 51 years diagnosed with non-small cell lung cancer (NSCLC) in 3 sites at the Catalan Institute of Oncology between June 2018 to May 2022. Genomic DNA was sequenced using a custom-designed NGS panel covering 164 cancer-predisposing genes and results were discussed in a multidisciplinary tumor board. **Results:** 138 patients were included. Median age was 45.5 (28-50) years; 49% were females; 79% were ever-smokers with a median packs-year of 24 and median age of tobacco initiation of 16 years old. Most patients had non-squamous histology (88%) and had stage IV (62%) at diagnosis. Somatic oncogenic drivers were found in 74 patients (54%): *EGFR* 27 (20%), *ALK* 22 (16%); *KRAS* 20 (14%); *RET* 3 (2%); *ROS1* 1 (1%); *BRAF* *V600E* 1 (1%). Only 4% had past personal history of cancer and 50% had family history of cancer in a first-degree relative, being lung and breast cancer the most common tumors. Overall, 20 patients (14%) carried PGVs involving 12 genes associated with cancer predisposition: *PARK2* (n=4); *SBDS* (n=3); *NBN* (n=2); *ATM* (n=2); *TSC1* (n=2) and *BLM*, *FANCA*, *MCPH1*, *PMS2*, *POLH*, *SDHA*, *RECQL4* (n=1, each). Four patients (3%) fulfilled criteria to be referred to genetic counseling clinic. There were no significant differences in clinical and molecular characteristics among patients with PGVs compared to their counterparts (Table). **Conclusions:** In this prospective cohort, 14% of patients with early onset NSCLC harbored germline PGVs. As clinicopathological and genomic features were not associated with PGVs, germline testing might be considered in addition to comprehensive genomic characterization of tumor tissue in young patients with NSCLC. However, only a minority of PGVs were deemed clinically actionable. Research Sponsor: Spanish Lung Cancer Group, Spanish Society of Medical Oncology.

Summary of epidemiological, clinicopathological and molecular features by PGV status.			
	No PGV (n = 118)	PGV (n = 20)	p-value

Validation of a breast cancer polygenic risk score in 15,490 Brazilians using exome sequencing. *First Author: Flavia Eichemberger Rius, Mendelics, São Paulo, Brazil*

Background: Brazil has a highly admixed population with significant Southern European, African and Native American genetic ancestries. Approximately 75% of the population has two or more continental ancestries. Therefore, breast cancer polygenic risk scores (PRS) developed in predominantly European populations requires validation in the Brazilian population. Compared with genotyping arrays and whole genome sequencing, affordable and scalable whole exome sequencing (WES) allows genotyping of both rare and common variants in the targeted regions and imputation of common variants not directly captured. In this study we validate a previously developed 3820-variant PRS using WES in 15,490 Brazilians. **Methods:** The cohort consisted of 6,362 women with a history of breast cancer (mean age 49.6, stdev 11.6) and 9,128 unphenotyped adults as controls (mean age 41.6, stdev 13.3). WES were performed on germline DNA and variants were called and curated. Imputation was done using the 1000 Genomes Phase 3 reference panel for variants falling outside the WES captured regions. After excluding subjects with known pathogenic or likely pathogenic variants in *BRCA1*, *BRCA2*, *PALB2*, *PTEN*, or *TP53*, and first or second-degree relatives of the probands, 14,577 individuals remained in the final analysis (5,730 cases and 8,847 controls). We restricted PRS calculation to 2,893 of the original 3,820 variants with an estimated global imputation accuracy of 96%. Odds ratios (OR) were adjusted using the top 10 principal components. **Results:** The breast cancer PRS showed a highly significant correlation with cancer risk (p-value = 7.1e-81, OR = 1.43, 95% confidence interval (CI) = 1.38-1.48 per PRS standard deviation). Compared with women in the middle deciles, those in the highest 10% had an OR of 1.93, while those in the lowest 10% had an OR of 0.52 (Table). **Conclusions:** In this study we show that WES can capture 76% of the variants included in a previously developed and validated breast cancer PRS, and the calculated PRS is correlated with breast cancer risk in the admixed Brazilian population. This opens the door for clinical studies into the application of PRS in Brazil, particularly in women without mutations in breast cancer high-penetrance genes. In addition, our WES-based PRS strategy can be quickly, affordably, and seamlessly adopted by labs that already offer Hereditary Breast Cancer panels that use WES as a backbone. Research Sponsor: Mendelics.

Breast cancer odds ratio per PRS decile.

Decile (%)	OR (95% CI)	p-value
0-10	0.52 (0.44 - 0.60)	3.4e-18
11-20	0.72 (0.62 - 0.83)	6.7e-06
21-30	0.76 (0.66 - 0.88)	1.4e-04
31-40	0.91 (0.79 - 1.05)	0.19
41-50	1.18 (1.03 - 1.35)	0.018

Overall and non-lung cancer incidence in the national lung screening trial (NLST) as indicators of potential for multi-cancer screening. *First Author: Ellen T. Chang, GRAIL, LLC, a subsidiary of Illumina, Inc., currently held separate from Illumina, Inc., under the terms of the Interim Measures Order of the European Commission dated 29 October 2021, Menlo Park, CA*

Background: Single-cancer screening strategies address only one component of the overall population cancer burden. Even high-risk populations in single-cancer screening trials experience a considerable burden of other cancer incidence; therefore, we assessed non-lung cancer incidence in the NLST to evaluate the proportion of un-screened cancers. **Methods:** The NLST was a randomized controlled trial of screening for lung cancer in adults aged 55–74 years with ≥30 pack-years of smoking history, enrolled in 2002–2004 and actively followed through 2009. Incident cancers were identified via participant questionnaires, death certificates, and direct notifications, and confirmed by medical record abstraction. The present analysis includes first invasive primary cancers diagnosed after study randomization. Non-lung cancer incidence was similar between the two trial arms, which were therefore combined for analysis. **Results:** Among 53 229 subjects (median follow-up 6.5 years), the incidence of any first primary cancer was 1941 per 100 000 person-years, of which 1327 per 100 000 (68%) was non-lung cancer. Non-lung cancer incidence rates exceeded that for lung cancer in all 5-year age categories (especially at younger ages) and all quintiles of smoking pack-years (especially with fewer pack-years). After lung cancer, the most common cancers were other leading cancer types in the general US population, as well as other smoking-related cancers (Table). No recommended population-based screens exist for 54% of observed cancer cases (3332 of 6142, excluding lung, colon/rectum, female breast, and cervix). **Conclusions:** In the NLST, only 32% of first primary cancer incidence was lung; non-lung cancer comprised 68%, and most cases were cancer types with no generally recommended screening strategy. Even in a high-risk population, a single-cancer screening test misses most cancers, illustrating the value of multi-cancer screening tests that can detect a broad spectrum of cancers and, therefore, have the potential to address a currently inaccessible portion of cancer morbidity and mortality. Research Sponsor: GRAIL, LLC, a subsidiary of Illumina, Inc., currently held separate from Illumina, Inc., under the terms of the Interim Measures Order of the European Commission dated 29 October 2021.

Cases and crude incidence rates (per 100 000) of first primary invasive cancers after randomization in the NLST.

Implementing a germline testing program using fingernail specimens for patients with hematologic malignancies and initial clinical findings. *First Author: Michael Francis Walsh, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: About 5-20% of hematologic malignancies (HM) occur in the setting of a genetic cancer predisposition syndrome. Additionally, overt constitutional syndromes involving multiple systems may also predispose to HM. The spectrum of cancer predisposition in patients with HM has been limited partially due to the difficulty of germline sample ascertainment from patients with liquid tumors as skin biopsies and fibroblast cultures are often required for testing. **Methods:** Hematologic malignancy patients enrolled in Memorial Sloan Kettering Cancer Center's institutional 12-245 study who were having somatic testing performed on their tumor were given the option to consent to germline testing using fingernail specimens. The validated germline assay using nails as a sample type was approved as a clinical test by the New York State Department of Health. Samples were analyzed using a custom panel consisting of 82 cancer predisposition genes. Single nucleotides, insertions/deletions, and copy number variants were detected using our analytic pipeline and analyzed according to ACMG criteria for pathogenicity. Only pathogenic and likely pathogenic germline variants (gPV) were returned. **Results:** Among 86 HM patients (acute myeloid leukemia, n = 19; myelodysplastic syndrome, n = 16; acute B lymphoblastic leukemia, n = 9; acute T-cell leukemia, n = 4; mixed phenotypic acute leukemia, n = 1; chronic lymphocytic leukemia, n = 7; hairy cell leukemia, n = 1; chronic myeloid leukemia, n = 4; chronic myelomonocytic leukemia, n = 1, non-Hodgkin lymphoma, n = 12; Hodgkin lymphoma, n = 8; and multiple myeloma, n = 4), gPV were detected in 16% (14/86). Heterozygous gPV identified in high/moderate penetrant genes included 2 *BRCA1*, 2 *ATM*, 1 *PALB2*, and 3 *CHEK2*. Monoallelic carriers for homozygous disease included 2 *MUTYH* and 1 *MSH3*. Biallelic gPV were identified in 3 patients (1 *FANCA*, 1 *ATM*, 1 *MSH6*); the patients with Fanconi anemia (age 25) manifesting with MDS and constitutional mismatch repair deficiency (age 13) presenting with T-cell lymphoblastic lymphoma had not been previously diagnosed with these conditions and did not have obvious clinical features outside of their cancer diagnosis. In all 3 patients, identification of an autosomal recessive syndrome impacted therapeutic planning. **Conclusions:** Our study demonstrates the feasibility of utilizing nails, a non-contaminated germline sample source, for HM predisposition with a significant proportion of pediatric and adult HM patients identified to harbor gPV in a cancer predisposition gene. Autosomal recessive diseases should be considered not only in pediatrics but also adult patients and requires confirmation of allele segregation in parents. Our data also demonstrate the importance of gPV in HM for therapeutic planning. Research Sponsor: Niehaus Center for Inherited Cancer Genomics; V Foundation.

Correlation of unobserved incidence of cancer in earlier stages with the observed incidence. *First Author: Jagpreet Chhatwal, Massachusetts General Hospital, Harvard Medical School, Boston, MA*

Background: Population-level cancer registries report observed (screening or clinically detected) incident cancer cases. However, the underlying true cancer incidence may be higher than observed. We estimate the unobserved cancer incidence by stage for eight different cancers. **Methods:** Using the CDC's National Program of Cancer Registries (NPCR) and the National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) combined incidence databases, we first estimated observed incidence rates by cancer type and stage. Newly observed cancers in later stages must have existed at a previous point in time at an earlier stage (and age). Considering that, we used backward induction approach to estimate the unobserved incidence rate of cancer. We also accounted for mortality from competing factors before cancer was detected. Cancer progression between stages was defined by dwell times, which were synthesized in an ensemble approach from published literature and empirical estimates. We estimated unobserved annual incidence cases in early-stage (stages I and II) for the age 50+ population and compared them with observed incidence cases for each cancer type between 2015-2019. **Results:** The below table shows the annual unobserved and total (unobserved plus observed) cancer incidence by stage for the eight most prevalent cancers. We estimated that the top three cancers with the highest proportion of unobserved early-stage annual incident cases were lung (157,400 cancers unobserved out of 226,400 total), with 70% unobserved; pancreatic (34,700 annual unobserved out of 52,500 total), with 66% unobserved, and non-Hodgkin's lymphoma (46,400 unobserved out of 73,600 total), with 78% unobserved. In contrast, the cancers with the lowest proportion of unobserved early-stage incident cases were breast (29,100/203,400 [14%]), urinary bladder (27,000/81,800 [33%]), and prostate (110,600/258,900 [43%]). Cancers with a high screening rate have lower unobserved early stage incidence than cancers with a low screening rate or without a screening test. **Conclusions:** We estimated a large undiagnosed incidence of cancer in early stages. This represents an opportunity for novel early detection technologies to detect cancer in earlier stages. Research Sponsor: Exact Sciences Corporation.

Cancer	Stage I-II Unobserved/Total (%)	Screening Test Available	National Annual Screening Rate in Eligible Population
Lung	157,400/226,400 (70%)	For high-risk smokers only	0.2% ¹
Pancreatic	34,700/52,500 (66%)	No	-
Non-Hodgkin's Lymphoma	46,400/73,600 (63%)	No	-
Head and Neck	27,400/47,200 (58%)	No	-
Colorectal (colonoscopy)	71,300/136,900 (52%)	Yes	8.8% ¹
Prostate	110,600/258,900 (43%)	Yes	39% ²
Urinary Bladder	27,000/81,800 (33%)	Yes	-
Breast	29,100/203,400 (14%)	No	48.1% ¹

Pre-diagnosis dietary patterns and risk of multiple myeloma in the NIH-AARP cohort. *First Author: Richa Parikh, Department of Hematology/Oncology, Karmanos Cancer Institute, Wayne State University, Detroit, MI*

Background: Despite patient interest in knowing whether diet is linked to multiple myeloma (MM), there is limited research on dietary patterns and MM risk (Malik et al. BCJ 2022). Two studies have assessed this risk, albeit with a small number of MM cases. The EPIC-Oxford cohort and Oxford Vegetarian study (65 MM cases) showed that fish eaters, vegetarians and vegans had significantly reduced MM risk compared to meat eaters (Key et al. AJCN 2014). The Nurses' Health Study and Health Professionals Follow-up Study (478 MM cases) showed a significantly increased MM risk in men with Empirical Dietary Inflammatory Pattern (Lee et al. JNCI Can Spectr 2019). To our knowledge, this is the largest epidemiologic study to date assessing pre-diagnosis dietary patterns and MM risk. **Methods:** The NIH-AARP Diet and Health study is a prospective cohort of 567,169 persons who completed a food frequency questionnaire in 1995-1996 and were followed until December 2011. Healthy Eating Index-2015 (HEI-2015), Healthy Diet Score (HDS), alternate Mediterranean Diet (aMED) and healthful Plant-based Diet Index (hPDI) scores were calculated using *a priori* defined methods and grouped into quartiles, with higher scores reflecting healthier eating patterns. We prospectively evaluated the association between pre-diagnosis dietary patterns and MM incidence in this cohort. Hazard ratios (HR) and 95% confidence intervals (95%CI) were estimated using multivariate Cox proportional hazards models adjusted for age at study entry, sex, race, body mass index, education, and total energy intake (by residual method). Sensitivity analysis was conducted to assess reverse causality by excluding MM cases diagnosed within one year of follow-up. **Results:** Among 392,589 participants (after exclusions), a total of 1,366 MM cases (59% males; 92% non-Hispanic whites) were identified during the follow-up period. Analysis revealed a significant association between hPDI scores and reduced MM risk (highest vs lowest quartile, HR 0.85; 95%CI 0.73-1.0; p=0.043) (Table). In sensitivity analysis (1,302 MM cases), the association was no longer significant (HR 0.87; 95%CI 0.74-1.03; p 0.09) but trended in the same direction. This may be due to small sample size, given MM is a rare disease. HEI-2015, HDS and aMED scores were not associated with MM risk. **Conclusions:** A healthful plant-based diet was associated with reduced MM risk in the NIH-AARP cohort. These results will help oncologists and patients make informed choices about their diet. Characterization of pre-malignant lesions in patients with pediatric neurofibromatosis type 1 using a novel whole-body magnetic resonance imaging technique. *First Author: Nicole M. Baca, Cedars-Sinai Medical Center Medical Pediatric Hematology/Oncology, West Hollywood, CA*

Background: Neurofibromatosis Type 1 (NF-1) patients can develop benign tumors, plexiform neuromas (PN), that may transform into malignant peripheral nerve sheath tumors (MPNST)(Tucker, et al. 2009). MPNST are rare, but in NF1, the lifetime incidence is 8-13% and MPSTs present at younger ages(Miettinen, et al. 2017). MPNST are aggressive tumors requiring full resection for best outcomes (Mautner, et al. 2008). Emerging data suggests whole-body MRI (WB-MRI) can identify NF patients with higher PN tumor burden and maybe at risk of developing MPNST. We have created a rapid, motion-robust quantitative WB-MRI technique that is likely suitable for pediatric patients. High-resolution multiparametric tissue mapping, including T1, T2, and ADC (apparent diffusion coefficient), are acquired concurrently in a single scan, as shown in prior studies (Christodoulou, et al. 2018, Ma, et al. 2020, Nguyen, et al. 2016, Wang, et al. 2020). This project will evaluate the feasibility and reproducibility of novel WB-MRI for the characterization of pre-malignant lesions in NF-1 patients. **Methods:** Trial Design: Pilot study of novel WB-MRI technique in pediatric NF-1 patients with a goal of 15 patients between the ages of 5-17 years. Trial MRI scans are performed at baseline, 1 month, and then 12 months (+/-3 months). A clinical 3T MR scanner (Siemens MAGNETOM Vida) performs a head-to-knee WB-MRI in 70 minutes. Signal-to-noise ratio (SNR) and imaging quality scores will be evaluated. The lesion volume and mean T1/T2/ADC are measured for each lesion on the corresponding quantitative maps based on manual ROI's (regions of interest). To assess scan-rescan reproducibility, image quality metrics (SNR and quality score), lesion identification, and lesion characteristics (T1, T2, and ADC) will be compared between the baseline and the 1-month scan using a Bland-Altman analysis and Schuirman's equivalence. The coefficient of variation (CV = 100 [SD/mean] %) values for each of the quantitative values will be calculated. To evaluate for lesion characterization, changes in the mean in each MRI quantitative metrics (T1, T2, and ADC) will be measured for each lesion on the baseline and 12-month visit. Spaghetti plots will be used to visualize the change over time, and the difference in mean will be tested using an appropriate parametric or nonparametric test depending on the results of tests on normality and homoscedasticity. Intervention: WB-MRI at baseline, 1 month, and 12 months (+/-3 months) Eligibility: 5 to 17 years old not requiring sedation; Clinically or molecularly diagnosed NF-1 including mosaic/segmental subjects; Not Eligible: allergy to animal dander, animal-instigated asthma, pregnant, breastfeeding, or have intrauterine device; Current Enrollment (February 2023): 5 subjects (One unable to finish a non-sedated MRI). Clinical trial information: NCT04763109. Research Sponsor: Cedars-Sinai Cancer Pilot Project Committee 2020 Developmental Funds for Investigator Initiated Trials (IIT) Award.

Metformin for chemoprevention of lung cancer in high-risk overweight or obese individuals. *First Author: Isra Nour, Northwestern University, Chicago, IL*

Background: Lung cancer is the most common cause of cancer-related deaths in the United States, with tobacco smoking being the most important risk factor. However, ~60% of individuals at a high risk for lung cancer or with early-stage lung cancer are either overweight or obese. Preliminary studies suggest that the diabetes drug metformin improves survival in high BMI lung cancer patients and inhibits lung cancer progression in preclinical models, likely through its effects on the obesity-triggered changes to the immune microenvironment of the lung, particularly, the regulatory T cells (Tregs) in the airway. Given the known dysregulation of Tregs in obesity and the importance of Tregs in lung carcinogenesis, we hypothesize that metformin therapy will reprogram the immune defense of obesity in directions that are consistent with the control of nascent lung tumor development. While more generalized lung cancer prevention approaches have to date shown limited effectiveness, the targeting of a specific subset of individuals at high risk for lung cancer provides a precision prevention approach, which is likely to be more effective. **Methods:** This is an open-label, randomized, wait-list control trial, where 50 non-diabetic obese/overweight former smokers with over 20 pack year smoking history and PLCOm2012 Lung Cancer Risk Prediction score above 1.34% will be enrolled. They will be equally randomized to either oral metformin or no treatment for 26 weeks followed by partial crossover, whereby no-treatment subjects will receive metformin for 26 weeks. The open-label, wait-list control design allows inclusion of a control group to assess stability of the primary biomarker in an untreated population while retaining the statistical power of 40 metformin-treated subjects (assuming 20% subject attrition) and will aid accrual since all trial participants will be treated. Treatment regimen is one daily dose of metformin at 500 mg for 1 week followed by 1000 mg for the second week and 2000 mg thereafter for a total of 24 weeks. Sampling for endpoint assessment include bronchoscopy with biopsy and bronchoalveolar lavage (BAL) and blood collection before and after completion of metformin treatment. The primary endpoint is to evaluate the effect of metformin treatment on the expression of PD-1, an immune checkpoint factor, on BAL Tregs. The secondary endpoints include stability of BAL Treg PD-1 expression over time and the impact of metformin on circulating immune cells. Trial sites include Roswell Park Comprehensive Cancer Center, the Rocky Mountain Regional Veterans Affairs Medical Center, and University of British Columbia, Vancouver. Since the trial opened to accrual in March 2022, 77 patients have been pre-screened and 19 were consented. Among them, 10 participants have been enrolled and randomized, 5 in each arm. We expect to complete accrual by April 2024. Clinical trial information: NCT04931017. Research Sponsor: U.S. National Institutes of Health.

Connecting Black families in Houston, Texas, to hereditary cancer genetic counseling, genetic testing, and cascade testing by using a simple cancer genetic risk assessment and telegenetics. *First Author: Darya Aleksandrova Kizub, Division of Cancer Medicine, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Hereditary breast and colorectal cancers accounts for 5-10% of all cases, but less than half of all eligible patients undergo NCCN guideline-concordant screening. This proportion is even lower among Black patients, who have a higher breast cancer and colorectal incidence and mortality. Recruitment through community organizations has been shown to identify patients who are eligible for genetic testing but have not been offered it by their doctor. Our one-page cancer genetic risk assessment (CGRA) and telegenetics were previously shown to improve adherence to genetic testing guidelines for hereditary breast and ovarian cancer. Our objective is to identify adults eligible for hereditary breast and colorectal cancer syndromes genetic testing using trusted community organizations that serve the Black community as entry points, reach them with our tailored program, and measure impact. **Methods:** In this prospective single-arm trial, adults of > 18 years old who self-identify as Black or African American are recruited during events put together by community organizations in Houston, Texas. The CGRA was modified to encompass hereditary breast and colorectal cancer syndromes based on NCCN guidelines. To improve convenience, eligible participants can be consented and fill out the CGRA in-person or via QR code link using a smart phone. Study team members attend community events and are also available via phone to help with informed consent, CGRA, etc. Those at high risk for hereditary breast and colorectal cancer syndromes are provided with educational materials and can be sent the saliva-based kit or complete it on-site. When results of genetic testing include a pathogenic mutation (PV) or variant of uncertain significance, individuals receive telegenetic counseling and risk reduction resources, including about cascade genetic testing. Others are notified of negative results. The program includes education for interested community organization members about importance of genetic testing. The program is projected to reach 1,000 participants with 300 completing genetic testing and identification of 11 PV. The study is overseen by a Community Advisory Board. Impact will be evaluated via a multiple methods design using the Reach, Effectiveness, Adoption, Implementation, Maintenance (RE-AIM) Qualitative Evaluation for Systematic Translation (QuEST) framework six months after program start. Quantitative data will be analyzed using descriptive statistics and standard tests of association. Data collected via semi-structured interviews with participants and program implementers will be audio-recorded, transcribed, double-coded, and analyzed via thematic analysis. Enrollment started December of 2022. 15 participants patients enrolled during two community events. Clinical trial information: NCT05694559. Research Sponsor: Susan G. Komen.

Differential burnout by race, sex, and sexual orientation in academic oncology. *First Author: Bismarck Odei, University of Utah, Salt Lake City, UT*

Background: Burnout is a concern in medicine with negative effects on physician wellbeing, workforce retention, and patient outcomes. Research has shown that rising burnout can lead to medical errors, lower patient satisfaction, and decreased professional work effort. The presence of burnout in oncology is well documented, however it is unclear if burnout affects all groups equally in academic oncology. **Methods:** We obtained national faculty data from the Association of American Medical Colleges StandPoint Faculty Engagement Survey, conducted 2017-2020 (overall response rate 64%). Burnout was considered any response endorsing at least "one or more symptoms of burnout". Self-reported workplace culture was assessed for key factors: collegiality, diversity, faculty wellness, and recruitment/retention of underrepresented in medicine (UiM) faculty. Faculty demographics included age, sex, race/ethnicity, sexual orientation (heterosexual, bisexual, lesbian/gay), rank, degree, and any department or institutional leadership role. Multivariate analysis (MVA) identified factors associated with faculty burnout. **Results:** A total of 724 academic oncologists were identified. Most were male (58%) and identified as heterosexual (95%). Race/ethnicity were mostly White (65%), with 29% Asian, 2% Black, and 3% Hispanic/Latino; 7% were considered UiM. Most (53%) were senior faculty; 37% had a leadership role. Overall, 22% reported burnout. Self-identified lesbian/gay/bisexual faculty had the highest rate of burnout (43% vs 21%, $p = 0.0005$) followed by female faculty (31% vs 16% men, $p = < 0.0001$). Asian faculty had the lowest burnout rates (12%) followed by White and Hispanic (both 26%), Black (33%), and multi-racial physicians (50%, $p = 0.003$ for comparisons). Pooled UiM had numerically higher burnout but this was not statistically significant (30% vs 22%, $p = NS$). On MVA, lesbian/gay/bisexual (OR = 3.56, 95%CI 1.55-8.18, $p = 0.003$) and female (OR = 2.32, 95%CI 1.51-3.56, $p < 0.0001$) faculty had increased odds of burnout. Most agreed that their institution cultivates collegiality (80%), diversity (73%), and faculty wellness (53%); men were more likely to endorse positive diversity (77% vs 68% women, $p = 0.004$). Most agreed their institution was successful in recruiting (63%) and retaining (58%) UiM faculty, however non-UiM were more likely to agree with this for recruitment (64% vs 46% UiM, $p = 0.01$) and retention (50% vs 42% UiM, $p = 0.01$). **Conclusions:** Nearly 1 in 4 oncologists report burnout with self-identified female and lesbian/gay/bisexual faculty at the highest risk. Additionally, in general, men and non-UiM faculty were more likely to feel their workplace culture was favorable. Urgent and tailored interventions at the institutional and departmental level will be critical to address both drivers of faculty burnout and the impact of burnout on attrition and career trajectory for marginalized and minoritized groups. Research Sponsor: None.

11002Clinical Science Symposium

Diversity, equity, and inclusion (DEI) and health equity (HE) education in hematology/oncology (HO) fellowship: A longitudinal curriculum. *First Author: Norin Ansari, Yale Cancer Center, Yale School of Medicine, New Haven, CT*

Background: The medical workforce remains markedly less diverse than the patients we care for, and outcomes disparities persist. This highlights the need for DEI efforts and HE education. In 2021, we implemented a DEI curriculum in the HO fellowship at Yale Cancer Center (YCC) and found improvements in our fellows' upstander responses. We present an assessment 1 year after initiation of this series and we share our longitudinal 3-year DEI/HE curriculum and other institutional steps taken to improve equity. **Methods:** An anonymous survey assessing DEI/HE needs, experiences with and comfort level addressing discrimination, and preferences for curriculum was emailed to all YCC HO fellows. 1st year fellows had no formal DEI education prior to the survey. Senior fellows had completed 1 year of the fellowship's DEI series. **Results:** 23 fellows (79%) responded, including 8 1st year and 13 senior fellows (2 unknown). Most fellows had experienced (78%) or witnessed (87%) some form of discrimination. Notably, 1st year fellows felt under-equipped to navigate bias and microaggressions compared to senior fellows. 1st year fellows reported a mean confidence score of 2.5/5 navigating these events when experienced personally and 2.9/5 when directed at others, compared to senior fellows (mean confidence scores 3 and 3.2 respectively). Fellowship DEI education was perceived as important (mean 8.6/10). When asked which DEI/HE topics they would be interested in learning about, the most popular choices among the 23 fellows were cancer treatment and outcomes disparities (78%) and bystander training (70%). They indicated lectures from field experts (65%), affinity groups (57%), small group discussions (52%), and advocacy education (52%) would be useful to them. The chief fellows convened a series of discussions with faculty and field experts, which led to creation of a 3-year longitudinal DEI/HE curriculum. This includes an annual cancer disparities lecture and bystander training session, and 2-4 rotating lectures per year covering implicit bias training, issues of race, gender, LGBTQIA+, disability, and religion in the workforce and in patients' experiences, pay and promotion disparities, and financial toxicity for patients. YCC and fellowship leadership have also implemented a DEI lecture series, increased recruitment of under-represented in medicine (URiM) physicians, established an URiM mentorship group and a diversity enhancement program for rotations for URiM medical students, and encouraged community engagement. **Conclusions:** DEI/HE education at all levels is essential for fostering equity in the workplace and patient care. Implementation of a longitudinal curriculum in parallel with other YCC initiatives has improved fellows' confidence in navigating bias and microaggressions. This curriculum can serve as a guide for other programs developing DEI/HE education. Research Sponsor: None.

11001Clinical Science Symposium

The ticking "biological clock": Reproductive assistance, costs, and elective fertility preservation in female oncologists and trainees. *First Author: Emily MacDuffie, University of Pennsylvania, Philadelphia, PA*

Background: Women in medicine are often in training during their peak fertility years. Many women defer childbearing until after training due to career concerns; in consequence, female physicians experience a higher rate of infertility than the general population. Experiences of infertility among female physicians and attitudes towards fertility preservation have not been well described. **Methods:** A novel 39 question survey was designed after comprehensive literature review to collect cross-sectional data on attitudes toward family planning and utilization of assisted reproductive technology (ART) among self-identified US female oncologists of all career levels. Descriptive statistics summarized frequencies of responses. **Results:** A total of 1005 responses were collected from female oncologists, of which 811 (81%) were attending/practicing physicians and 194 (19%) were trainees (192 residents/fellows and 2 medical students). 32% reported experiencing infertility. Of these 318 women, 9% reported no out-of-pocket expenses for ART while 39% spent more than \$10,000 and 20% spent $\geq$ \$30,000. Side effects from infertility treatment required missing work for 22% and another 25% suffered mental health concerns related to infertility. Elective cryopreservation of eggs or embryos was reported by 6% of attendings and 4% of trainees. Among the 25 attendings who reported plans/desire to undergo fertility preservation in the future, most (76%) were unsure of feasibility. This was similarly reported in 72% of the 32 trainees with plans/desire to pursue fertility preservation. More trainees than practicing physicians (73% vs 65%) felt that fertility preservation should be discussed during medical training. Similarly, more trainees than attendings (58% vs 47%) felt that fertility concerns have a negative influence of their decision on when to start a family. While only 5% of all respondents reported using fertility preservation, an additional 6% were planning/considering using it and 21% felt that it would have benefitted them had it been available and affordable during training. Of the group that felt it would have been beneficial, 52% had experienced infertility. **Conclusions:** A third of surveyed female oncologists report experiencing infertility. Those that seek reproductive assistance can incur significant out of pocket costs with treatment related effects that can disrupt work or cause mental health concerns. Although fertility preservation was used by very few, one in five felt it could have been helpful to them if it was available and affordable. These results underscore the need to better support women in medicine to reduce the impact of infertility for female oncologists. Research Sponsor: None.

11003Poster Discussion Session

Workplace sexual harassment in academic oncology. *First Author: Divya Yerramilli, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Research has shown workplace sexual harassment (WSH) is a pervasive problem in academia, affecting recruitment, retention & career advancement of women faculty. This study examines WSH in academic oncology faculty in a national survey. **Methods:** We obtained data from the Association of American Medical Colleges StandPoint Faculty Engagement Survey between 2020-22 representing a national sample of academic faculty from 25 medical schools (overall response rate (RR) 58%). WSH was considered specific "unwanted behavior" by coworkers that occurred at least once in the past year. Reporting questions were asked on a 5-point Likert Scale from Strongly Disagree to Strongly Agree, with 6th option "I Don't Know." Responses were grouped as Agree/Strongly Agree vs all others. Chi-square tested for differences by gender and race/ethnicity. **Results:** 807/1,287 oncologists participated in the survey (RR 63%), and 91% (731) answered the WSH questions. Most self-identified as men (58%) and only 8% identified as underrepresented race/ethnicity (URiM). See Table for findings. In oncology, women experienced any WSH at higher rates than men (33.1% vs 10.3%, $p=0.001$). The most common was derogatory comments due to gender. Regardless of gender, most knew how to report WSH incidents, but men were more likely to feel safe reporting. While 64.9% of men felt confident that their medical school would resolve WSH incident(s) effectively, only 48.7% of women did. Positive perceptions of reporting decrease among those who reported harassment. URiM faculty (35.6% vs.18.5%, $p=0.001$) were more likely than non-URiM faculty to experience at least one of the five harassment behaviors, although this was limited by small sample. **Conclusions:** In academic oncology, women and URiM experience workplace sexual harassment more often than men and non-URiM. Less than half of women felt confident that reporting an incident would lead to effective resolution. Urgent intervention is needed to combat the negative force of sexual harassment on workforce equity. Research Sponsor: Cancer Center Support Grant from the National Cancer Institute (P30 CA008748).

	Men	Women	
In thinking about unwanted behaviors over the past 12 months, how often did a school of medicine faculty member or staff member (including supervisors)...			
Tell sexist stories/jokes	8.1% (34/422)	17.3% (53/306)	$p<0.001$
Make offensive remarks about appearance, body, sexual activities	2.4% (10/421)	7.8% (24/306)	$p=0.001$
Refer to your gender in offensive, insulting, or vulgar terms	2.6% (11/421)	11.9% (36/303)	$p<0.001$
Put you down or acted in a condescending way due to gender	2.4% (10/419)	25.2% (77/305)	$p<0.001$
Overall Rate of Harassment	10.3%	33.1%	$p=.001$
If I experienced sexual harassment... Agree/Strongly Agree			
I would feel safe reporting the incident(s)	81.3% (343/422)	68.7% (211/307)	$p<0.001$
I know to whom I can report the incident(s)	77.7% (328/422)	71.7% (218/304)	$p=.121$
I feel confident the incident(s) would be resolved effectively	64.9% (271/417)	48.7% (149/306)	$p<0.001$

Poster Discussion Session

Should I stay, or should I go? Factors associated with intent to leave academic oncology. *First Author: Ana I. Velazquez Manana, University of California San Francisco, San Francisco, CA*

Background: Physicians who are female and/or belong to racial/ethnic groups underrepresented in medicine (UIM) face disparities in salary, promotion, and leadership opportunities in academic oncology. Also, growing rates of burnout, increasing burden of documentation/administrative tasks, and lack of adequate supportive staff represent threats to workforce retention, particularly for female and racial minority subgroups. We evaluated the prevalence and factors associated with likelihood of leaving their specific academic institution in a national sample. **Methods:** We obtained national faculty data from the AAMC's StandPoint Faculty Engagement Survey, conducted between 2017-2020 with 25 U.S. medical schools. Chi-squared and Fisher's exact tests were used to determine differences in likelihood of leaving their institution within 1-2 years by sex and UIM status. Multivariate analyses (MVA) examined the associations between likelihood of leaving their institution and self-reported sex, year born, sexual orientation, UIM race/ethnicity, degree, academic rank, and administrative role. **Results:** We identified 724 oncology faculty at academic institutions (overall response rate 64%). Slightly less than half of oncologists self-identified as female (42%, n = 303) and only 7% (n = 47) as UIM. When asked about the likelihood of leaving their current institution, 22% (n = 152/687) of oncologists reported being at least somewhat likely to leave within the next 1-2 years. Notably, 26% of female oncologists reported they were likely to leave, compared to 19% of males (p = 0.022); no differences were observed by UIM status (p = 0.714). MVA identified sex as associated with likelihood of leaving; females had 78% higher odds of leaving their institution within 1-2 years (aOR 1.78; 95% CI, 1.13-2.79). Among those likely to leave, 46% (n = 72/157) reported intent to leave academic medicine completely; rates were similar across sex and UIM groups (p = 0.746). When evaluating workplace experience, most oncologists (86%, n = 621) felt respected in their workplace. Among those reporting feelings of disrespect in the workplace, 16% of female oncology faculty felt disrespected due to their gender (n = 47), compared to 0% of male oncologists. A small number of faculty reported disrespect due to age (n = 26), race/ethnicity (n = 11), sexual orientation (n = 2), marital status (n = 10), or religion (n = 7). Females endorsed greater feelings of disrespect in all categories other than religion. **Conclusions:** Female oncologists are almost twice as likely to state they are likely to leave their academic institutions within 1-2 years; this aligns with published data on attrition of female faculty in academic medicine. Our findings confirm the persistence of these trends in the modern era and stress the urgency of improving workplace experience, culture, and supports in order to preserve and enhance the diversity of faculty in academic oncology. Poster Discussion Session

A multifaceted approach to wellness in a hematology/oncology fellowship program. *First Author: Thejal Srikumar, Yale New Haven Hospital, New Haven, CT*

Background: Burnout is widespread among physician trainees and is a growing problem despite increasing awareness. We describe multiple efforts in a single institution's Hematology/Oncology (HO) fellowship program to help support trainees' wellness. **Methods:** A needs assessment was conducted to identify wellness topics and programming important to fellows. Anonymous surveys were distributed to all fellows in Yale's HO fellowship program at the start of the academic year. Three senior fellows reviewed the results and, with the support of core faculty, designed initiatives to address top priorities. The interventions included off-campus debrief sessions for fellows only, Schwartz Rounds-style discussions during weekday didactic slots, faculty-led didactics on Imposter Syndrome and Perfectionism, and several off-campus, after-hours social activities. A follow-up survey was conducted six months after the initial survey (mid-academic year) to garner feedback. **Results:** Of the 23 fellows who were sent the initial survey, 17 responded (73.9%). The most requested discussion topics were Perfectionism Traps, Imposter Syndrome, Achieving Happiness/Defining Success at Work, and Myths About Work/Life Balance. Most fellows (76.5%) responded that they would attend off-site debrief sessions if offered. In response to the initial survey, several initiatives were undertaken as described in Methods. The mid-year survey was completed by 16 of 23 fellows (69.6%). Of these 16 respondents, attendance was as follows: 31.3% for after-hours debrief sessions, 75% for Schwartz Rounds-style discussion, 75% for Imposter Syndrome and Perfectionism lecture, and 75% for at least one social activity. The majority of fellows who attended these events reported them to be helpful (range 75-100%). Themes identified from written comments included universal appreciation for wellness programming efforts and a desire for more sessions for group reflection. One fellow noted these activities were "helpful for wellness and fostering a pleasant work environment." Other fellows noted the Imposter Syndrome discussion "should be mandatory" and "would be helpful earlier in the year." Several fellows expressed their wellness was linked to clinical workload, and one fellow noted sessions outside of regular work hours are difficult to attend. **Conclusions:** Structured needs assessment and implementation of wellness programming in a HO training program appeared to be beneficial to the majority of fellows. To our knowledge, this is the first description of comprehensive fellow-directed wellness initiatives in HO training. Continued efforts must be made to better support fellows, including options in location, timing, faculty presence, and optimizing work responsibilities and expectations. Further study is necessary to quantify the impact of these initiatives and to tailor the most effective approach to fellows' wellness. Research Sponsor: None.

Hematology/oncology program director perspectives on recruitment and inclusion of a diverse workforce. *First Author: Ana I. Velazquez Manana, University of California San Francisco, San Francisco, CA*

Background: Despite progress in the enrollment of underrepresented in medicine (UIM) individuals in medical schools, hematology/oncology (HO) remains one of the least diverse medical subspecialties. We evaluated current recruitment efforts and barriers to the inclusion of UIM individuals in HO fellowship programs. **Methods:** We conducted a national online survey of program directors (PDs) and associate PDs (reported in aggregate as PDs) of adult and pediatric HO fellowships. Each PD received a unique survey link via email and 4 email reminders over the 8-week study period. Interim results at 4-weeks are presented and summarized with descriptive statistics. **Results:** At a pre-defined interim time point of 4 weeks, 78 HO PDs participated (18% response rate) and 69 completed the survey (88% completion rate). Most self-identified as women (57%, n = 38) and White (55%, n = 37), were affiliated with an academic program (79%, n = 53), and led an adult HO fellowship (73%, n = 49). Most PDs reported under or no representation of UIM faculty in their divisions; 9% (n = 6) self-identified as UIM. PDs reported their HO fellowships matched a median of 3 UIM fellows over the last 5 years (IQR 2-5 over 5 years); 46% (n = 32) reported UIM recruitment was unchanged and 4% (n = 3) decreased during this period. About half of PDs (51%, n = 35), matched a UIM candidate in the 2023 match. Of the 21% (n = 14) of PDs whose programs had no UIM fellows, 0% matched a UIM applicant in the 2023 match. 52% (n = 36) of PDs endorsed an inability to match UIM applicants despite consistently ranking them highly. PDs perceive the top 3 barriers to UIM recruitment as: low number of UIM applicants (53%, n = 41), geographic program location (50%, n = 39), and lack of diverse faculty/fellows in their program (42%, n = 31). 10% (n = 7) also reported meeting resistance about DEI initiatives. While 53% (n = 41) of PDs believe fellow demographics should reflect the local population, 23% (n = 16) don't know how to increase diversity and 11% (n = 8) do not believe their program's diversity needs to increase. In answers to open ended questions, some PDs expressed disagreement with the definition of UIM and reported a perceived limited number of qualified UIM applicants. Almost all institutions provide DEI training (96%, n = 72) for faculty and most PDs believe it has improved recruitment and inclusion of diverse individuals (52% and 65%, respectively). Yet, 34% (n = 23) agree that UIM fellows in their program are treated differently because of their race/ethnicity and 22% (n = 15) agree that UIM fellows reported their identity or background to be respected by faculty, peers, and staff. **Conclusions:** Historically and currently excluded populations remain underrepresented in the HO workforce. PDs face multiple barriers to the recruitment of diverse fellows, including differing views on the definition of UIM and perception of the value of diversity in the physician workforce. Poster Discussion Session

Remote delivery of a mindfulness-based intervention to decrease stress levels and promote coping among health-care workers during the COVID-19 pandemic. *First Author: Joelle Antoine Helou, Department of Oncology, Western University, London, ON, Canada*

Background: The COVID-19 pandemic has caused significant stress amongst everyone around the world. Healthcare workers (HCW) in particular, experience substantial stress in these challenging environments. In an effort to find supportive interventions for radiation oncology providers, while respecting the requirements of physical distancing, we proposed the remote delivery of a mindfulness-based intervention (MBI). The primary aim of this study is to determine the association of this intervention with a reduction of perceived stress. Secondary aims are to evaluate the impact on coping and burnout amongst HCW in the Radiation Program (RP). **Methods:** This is a single-centre, single-arm, pilot study. All HCW associated with the RP were eligible. This was a voluntary effort. The intervention - manualized, mindfulness-based group for HCW, entitled Mindfulness-Based Resilience and Well-Being Training, consisted of four 1-hour sessions per week for 4 weeks. From Nov 2020 to Dec 2021, 6 consecutive closed groups MBI were delivered remotely using Zoom. Each group consisted of 5-12 participants and one professional with a background in mindfulness facilitation. The Perceived Stress Scale (PSS), The Maslach Burnout Inventory and the BriefCOPE questionnaire were collected pre-intervention, and at 1, 4 and 12 weeks post-intervention. Linear mixed effect models with a random intercept to account for the repeated measures were used to assess the change of outcomes over time. **Results:** Amongst 43 HCWs who expressed initial interest, 33 completed the study. At 1-, 4- and 12-weeks post-intervention 25, 24 and 21 participants provided completed questionnaires respectively. Time constraint was the main reason for withdrawal and missing data. There was a significant decrease in perceived stress at week 1, 4 and 12 when compared to baseline [mean baseline PSS score: 22.5 (SD = 4.6), week 1: 18.4 (4.9), p = 0.002, week 4: 16.8 (6.5), p < 0.001, week 12: 16.3 (6.8), p < 0.001]. Overall, 7 (21%) participants reported high PSS (27-40) at baseline while none reported high levels at 1 and 12 weeks. Problem focused coping (p = 0.02), and active coping (p = 0.009) were significantly higher at 1 week but not at 4 and 12 weeks. **Conclusions:** The remote delivery of a MBI is feasible and effective to reduce perceived stress levels and to promote coping across HCWs. These findings need to be validated in a larger cohort. Time was a major constraint preventing the participation of interested HCWs. It would be extremely valuable for departments to support such interventions and programs to help HCWs cultivate skills to meet the demands related to working in healthcare environments throughout and beyond this crisis. Tumor board tuesday and awareness of novel therapies and toxicities in solid tumor oncology. *First Author: Johnathan Ebben, University of Wisconsin Hospitals and Clinics, Madison, WI*

Background: Social media platforms, including Twitter, offer novel tools to accelerate discussion and learning that crosses national borders, flattens hierarchies, and enables collaborations not previously possible. Here, we report on a new initiative, Tumor Board Tuesday (TBT), which facilitates the presentation of cases with active discussion from thousands of stakeholders across the oncology community, highlighting new practice changes and precision oncology strategies. Herein, we sought to evaluate 1) the nature of participation by individuals and groups, as well as their scope of participation in TBT; 2) the impact of participation in TBT, including new collaborations forged, practice changes, increased knowledge of the use of novel agents, and their associate toxicities, as well as emerging clinical trials available to patients. **Methods:** TBT performed a survey designed to assess the demographics, experience, and opinions of platform users. This survey was collated with voluntary pre/post TBT presentation knowledge checks to assess knowledge acquisition. **Results:** Based on the survey of TBT participants (n = 38), participant gender is roughly balanced (48.4% women, 48.4% men; 3.2% prefer not to answer). 83.6% of respondents reside in the United States, 8% in Brazil, 5.4% in India, and 3% in Ireland. Interestingly, the majority of respondents identified Twitter as their primary source for oncologic and practice changing updates. Among self-identified oncologists, 12.9% identified as senior members of the field, 51.6% as mid-career, 16.1% as early career, and 12.9% as fellows/trainees. Despite the wide variation in career stage, 81.1% of respondents noted that they had become aware of a new treatment option or modality through TBT participation, which caused 78.4% to change or re-think their treatment approach. In addition, 75.7% of respondents noted that TBT had helped them to become more aware of novel agent toxicities, and 78.4% became aware of a clinical trial option because of TBT participation. Finally, 78.4% of respondents identified TBT as a tool that had helped grow professional connections and networks. On average, there were 56 respondents to knowledge-based questions within each TBT presentation. Analysis of responses to pre and post TBT questions focused on breast, GU, and pulmonary malignancies revealed a 12%, 13%, and 6% respective increase in correct answer choices. **Conclusions:** Social media, specifically, the use of the TBT platform engages oncology professionals across the career spectrum, enhances learning about novel therapies and corresponding toxicities, and broadens professional connections. Quality and accessibility of liquid biopsy information: An analysis of online content. *First Author: Henry Kazunaru Litt, University of California, San Francisco, San Francisco, CA*

Background: Circulating tumor DNA assays, also known as liquid biopsies, are increasingly used by oncologists to evaluate residual disease, cancer genomic composition, resistance mechanisms, and guide therapy selection. Since patients often use the internet as a source of medical information, we evaluated the quality, accessibility, and understandability of publicly available online information on liquid biopsies. **Methods:** We performed a cross-sectional study of 100 videos and 100 webpages that resulted from the search of "liquid biopsy" on a commonly used search engine (Google) and social network (YouTube). Videos over 5 min, scientific articles, and non-English content were excluded. Videos were evaluated for content, intended audience, and perceived sex and race/ethnicity of speakers. Two independent reviewers evaluated understandability and quality of health information using two validated tools for consumer health information (PEMAT, DISCERN). Any disagreements were resolved by a 3rd independent reviewer. Webpages were evaluated for accessibility (use of visual aids, other languages), quality of information (authors, citations, indications, limitations, cost), reading level, and presence of commercial bias. Reading level was evaluated using the validated Flesch-Kincaid (FK), Gunning Fog (GF), and SMOG indices. Data was summarized with descriptive statistics. **Results:** We reviewed 100 videos, with 190 median views per video (IQR: 75-719). Most videos were intended for a scientific audience (72%) and lacked diversity of speakers. The majority of featured speakers were perceived as male (65%) and non-Hispanic white (72%). Overall, liquid biopsy videos were complex and low quality. Only 9% of videos were understandable and 8% presented moderate to high quality health information. Furthermore, we reviewed 100 webpages about liquid biopsies; key characteristics are summarized in the table. About a third of webpages included indications (36%) and limitations (35%) of liquid biopsies. Webpages had a median text reading level of 14.1 (IQR: 12.1-15.8), 16.4 (IQR: 14.4-18.6), and 15.9 (IQR: 13.9-16.9) based on FK, GF, and SMOG indices, respectively. Only 2 websites had one index reading level of 8th grade or lower as recommended by the NIH and CDC. **Conclusions:** Online content about liquid biopsies is complex and requires education levels exceeding the reading level of the general US population. Extensive shortcomings in sources of unbiased and understandable information for patients with cancer exist. As novel diagnostic technologies and treatments emerge, efforts should be made to develop understandable, unbiased, and high-quality information resources for patients with cancer. Assessment of YouTube as an information source for immune checkpoint inhibitors (ICIs). *First Author: Tulika Garg, Government Medical College and Hospital, Chandigarh, India*

Background: YouTube is an open-access source of information. With more than 2.5 billion users, it can play a pivotal role in educating or misinforming cancer patients. ICI has changed the treatment paradigm for cancer over the past decade. There is scarce data to evaluate the quality of information on ICI uploaded on YouTube. We aim to assess the quality and engagement parameters of the 100 most viewed videos on YouTube focusing on ICI. **Methods:** A systematic search was conducted on YouTube using the search terms ("Immunotherapy AND Cancer"; "Immune Checkpoint Inhibitors AND Cancer"). The 100 most viewed English videos were selected. We utilized the already validated PEMAT¹ and DISCERN² tools to assess the quality of these videos on ICI. Additionally, we looked at the number of views, comments, and likes. Descriptive statistics and Pearson correlation tests were performed using R studio v2022.12.0-353. **Results:** The videos in our study had up to 42 million views (median views: 17,617). These videos were categorized by sources; academic (54%), media (31%), and industry (15%). The mean DISCERN score for the videos was 43.4. Only 22% videos were in the good or excellent category. Most videos (53%) discussed the benefits of ICI, whereas only 29% discussed the adverse effects of ICI. Shared decision-making was promoted by 34% of videos, and only 6.7% of videos summarized the information at the end, based on the DISCERN criteria. The medical terminologies were defined by 48.5% of videos, and 31% were broken into short sections with informative headers per PEMAT understandability criteria. There was no significant association between the video source and video engagement parameters, including likes, views, and comments. However, a trend towards an increased number of likes (r=-0.195, p=0.04) and comments (r=-0.213, p=0.03) was noticed with lower DISCERN scores (poor quality videos). **Conclusions:** The majority of YouTube videos are focused on the benefits of ICI. They are less likely to discuss the adverse effects or shared decision-making. In summary, YouTube videos contain biased information on ICI. Further efforts from academic institutions are needed to improve the quality and engagement of these videos. 1. Shoemaker SJ et al. The Patient Education Materials Assessment Tool (PEMAT) and User's Guide; 2. Charnock D et al. DISCERN: an instrument for judging the quality of written consumer health information on treatment choices. J Epidemiol Community Health. 1999. Pearson correlation coefficient (r) between quality assessment scores and video variables. Research Sponsor: None.

Video variables	DISCERN
Likes	r=-0.195, p=0.04
Video length	r=0.104, p=0.29
Comments	r=-0.213, p=0.030
Views	r=-0.101, p=0.30

Defining the educational needs for a community-based hematology/oncology career: A national needs assessment. *First Author: Shubham Agrawal, Mercy Catholic Medical Center, Darby*

Background: Fellowship training is largely rooted in academic medical centers, though many graduates will ultimately pursue careers in community-based settings. We initiated a national survey of hematologists/oncologists practicing in community or academic-community hybrid settings to understand providers' educational needs. We hypothesized that the current model of fellowship training is not optimized for those pursuing community-based hematology/oncology careers. **Methods:** An electronic questionnaire was developed surveying current attitudes and practices of community-based hematologists/oncologists. Survey participants from across the United States were contacted via professional organizations. We primarily assessed whether survey participants received any specific training during fellowship for community-based practice. Participants were also surveyed regarding whether such training may have affected their preparation. Relative risk (RR) and 95% confidence intervals (CI) were calculated using modified Poisson regression with robust error variance adjusted for: time in clinical practice (< 10 years), size of graduating fellowship training program (> 5), board certification (hematology and oncology vs. either), and training program geographic location (by region) to identify factors associated with receiving community oncology-specific training. **Results:** Of the preliminary cohort of 120 participants from across 25 states, 66% were male, 69% identified as White, and 69% had been in practice for > 10 years. Less than half (43.2%, binomial 95% CI 34.6%-52.2%) received any training for a career in a community-based setting. Participants identified rotations in community settings (48%), direct mentorship from community-based physicians (41%), and longitudinal clinic in a community setting (39%) as experiences that would have been valuable. Specific curricula of interest included: medical operations and administration (67%), health policy (38%), and quality improvement (30%). Respondents in clinical practice for < 10 years were more likely to have received any community oncology-specific training (RR 2.02, 95% CI 1.10-3.72); other factors were not significantly associated with the primary outcome (P > 0.05). **Conclusions:** National trends indicate a growing need for hematology/oncology graduates in community-based settings. Our study demonstrates substantial unmet needs as they relate to training fellows destined for careers in community-based practice. Prospective design of clinical training and curricula emphasizing longitudinal exposures to and key aspects of health care delivery in the community setting are paramount to achieving optimal, goal-concordant hematology and oncology training. Integration of clinical trial development in hematology and oncology fellowship training: Washington university school of medicine experience. *First Author: Christine Auberle, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Education in clinical trial design and development is highly variable among Hematology and Medical oncology fellowship programs. The Clinical Trial Development (CTD) program at Washington University in St. Louis (WUSM) is an experiential learning curriculum designed to provide a structured and personalized education to fellows about clinical investigation in Hematology and Oncology. We describe the results of the CTD program and its impact on subsequent academic faculty appointments. **Methods:** The CTD program was initiated at WUSM in 2002 as a hands-on learning experience for Hematology and Oncology fellows in the design, implementation, evaluation, and publication of clinical trials. Each fellow was required to identify a mentor in their first year of training and propose at least one CTD project, determined as a prospective investigator-initiated clinical trial involving human subjects or materials. Outcome data were collected from an internal registry of fellow CTD projects, Clinical Trials Management System (OnCore), PubMed, ClinicalTrials.gov and e-mail inquiries to fellows and mentors. Descriptive statistics were collected for the characteristics of CTD projects, including the phase of study, site (single center or multicenter), disease subtype, projects that received IRB approval, and projects that resulted in publication. Logistic regression and odds ratios (OR) were also used to assess the association between these characteristics and academic faculty appointments. **Results:** We included 118 fellows who began fellowship from 2002 to 2021 for this analysis with 16 still in training. Many trials were phase I/II (n = 53; 45%), phase I (n = 34; 29%) and phase II trials (n = 17; 14%) and most trials were single center studies (n = 93; 79%). Disease types of the investigations were evenly distributed between Oncology (n = 60, 51%) or Hematology (n = 58, 49%). Most fellows were successful in obtaining IRB approval for their CTD project (n = 93, 79%) and approximately two thirds of those with IRB approval went on to publish their results in peer-reviewed journals (n = 60, 65%). Forty-five percent of fellows who published their CTD projects were first authors (n = 27) and 38% published in journals with an impact factor of greater than 10. Among the graduating fellows, two-thirds (n = 67, 66%) secured an academic faculty appointment. Fellows with IRB approved CTD projects had significantly higher odds of obtaining an academic faculty appointment (OR 4.96, 95% CI 1.54-15.98, p < 0.05). **Conclusions:** The CTD program is a well-established clinical investigation program for fellows with a track record of success and impact on subsequent academic faculty appointments. The CTD program is a model that other fellowship programs can emulate for education related to clinical trials. Research Sponsor: Washington University in St. Louis.

Innovating the hematology/oncology (H/O) curriculum for internal medicine (IM) residents: A modified flipped classroom (FC) approach. *First Author: Parva Kiran Bhatt, Tufts Medical Center Hematology-Oncology Fellowship, Boston, MA*

Background: Nationally, a framework for H/O education for IM residents that is simultaneously clinically relevant, concordant with the ABIM Blueprint, and efficient in delivery is lacking at the graduate medical education (GME) level. At our institution, based on feedback from our residents we recognized an opportunity to innovate the H/O curriculum through active learning approaches to better meet the needs of our residents. **Methods:** Adopting the Kern Model of curriculum development, a needs assessment was performed to gauge resident opinions on the current H/O didactics and towards active learning approaches. Survey results informed the development of 4 FC modules, meant to seamlessly integrate into the existing didactics of morning report (MR) and noon conference (NC). Each module consisted of a video on a cancer type viewed during MR, case-based activity during NC, and an instructor's guide. Following the Kirkpatrick model, resident opinions were assessed via surveys and feedback sessions. Pre/post-tests at 3 time points were used to assess learning. Standardized patient encounters (SPEs) with clinical competency scoring scales were developed to assess clinical reasoning skills. **Results:** 43% of residents (33/76) completed the needs assessment. A majority of respondents (82%) indicated the existing H/O didactics did not provide enough foundational knowledge. 87% of residents indicated a need for more active learning and 72% expressed interest in a FC approach. 43% (33/76) of residents attended ≥1 session (NC or MR). Post-intervention, 81% of residents strongly agreed the FC modules were relevant to clinical practice and board exams. 93% of residents strongly or somewhat agreed it was feasible and manageable to incorporate the FC format. Pre/post-test results showed statistically significant improvement in scores from before to after viewing the MR video (1-way ANOVA, p<0.011) with a medium effect size of 0.11. Significant change was not seen when the same test was taken after the case-based NC activity (p=1). Clinical competency scores from SPEs of full-participant residents were significantly higher compared to residents who did not participate in a FC module (t-test, mean 8.4 vs. 6.2/10, p<0.001). **Conclusions:** Our pilot H/O FC curriculum was overwhelmingly viewed as favorable and reported as clinically relevant, feasible, and manageable by our residents. Pre/post test results suggest that viewing the pre-session video during MR resulted in significant learning as compared to attending the case-based session during NC. Superior performance on SPEs by residents attending in full as compared to non-participants provides strong evidence supporting our modified FC approach in improving clinical reasoning skills. Overall, our study supports a broader application of our innovative FC model into existing traditional lecture-based resident H/O curricula. Research Sponsor: None.

Novel curriculum for training in medical cannabis in oncologic populations for oncology trainees. *First Author: Rushad Patell, Beth Israel Deaconess Medical Center, Boston, MA*

Background: There is continued uptake in the use of medical cannabis (MC) among patients with cancer. Our group previously conducted a national study that showed that while a majority of oncology fellows discussed MC with patients, very few feel well informed in doing so. We hypothesized that an evidence-based curriculum on the use of MC for oncology trainees is feasible to develop and would be effective in improving confidence to discuss MC with patients. **Methods:** A multidisciplinary expert team designed an evidence-based educational curriculum in 5 modules specifically for MC in oncology populations that included pharmacology/history, symptom management, cancer-directed effects, toxicities and practical/logistic concerns. The curriculum was piloted as a one-hour webinar at three US hematology oncology fellowship training programs in 2022-2023. Anonymous incentivized survey instruments that were designed to assess self-perceived knowledge, attitudes and behaviors pertaining to MC (on a 5-point Likert scale; strongly agree to strongly disagree) were distributed anonymously via email at the pilot (t = 0) and immediately after (t + 7 days); additional delayed surveys (t+90 days) are in progress. **Results:** Of 35 eligible trainees, 31 completed the pre-training surveys (88.6%), and 26 (74.3%) completed the post-training surveys. Most trainees indicated that the curriculum is helpful (88.5%, 95% CI: 69.8-97.6) and that they would recommend it to their colleagues (80.8%, 95% CI: 60.6-93.4). Following the webinar, there was significant improvement in self-reported comfort with discussing MC for symptom management (3.2% vs. 92.3%, P < 0.001), risks of MC (9.7% vs. 76.9%, P < 0.001) and modes of MC use (16.1 vs. 80.8%, P < 0.001). The majority of participants (80.0%, 95% CI: 59.3-93.2) reported that they were more likely to initiate conversations about MC with their patients after attending the webinar. **Conclusions:** In this multi-center study, we demonstrate that it is feasible to develop and deliver a fellow-focused, evidence-based curriculum for MC use in patients with cancer. The webinar was well received and demonstrated significant improvement in fellow-reported attitudes surrounding MC efficacy, risks, and modes of use. Further work to assess durability of the curriculum on knowledge, attitudes, and behaviors is ongoing. Research Sponsor: None.

Poster Session

Creating an infrastructure to address physician and advanced practice provider burnout at a complex community cancer care delivery system. *First Author: Alison Tray, Hartford HealthCare, Hartford, CT*

Background: Oncology clinicians are at risk for developing burnout due to work-related factors such as high acuity patients, long work hours, limited autonomy, administrative and documentation demands (Copur, 2019; Eelen et al, 2014). The COVID-19 Pandemic has intensified burnout due to rapid and multiple changes in clinical practice, lack of fulfillment, and heightened moral distress and personal challenges (Hlubocky et al 2021). As a multi-center community cancer care system, an infrastructure was created and operationalized to address the work-related factors contributing to burnout. The purpose of the project was improved identification and prioritization of clinician (physician and APP) needs with subsequent targeted intervention. **Methods:** To measure success, a partnership with the American Medical Association (AMA) was formed to deploy the Mini-Z burnout survey. The survey was administered on July 2-August 20, 2021 to all Medical Oncology physicians and Advanced Practice Providers (APPs), n = 60. The survey was re-deployed from July 13-September 2nd, 2022. Data was collated by the AMA and presented back to executive leadership. Through this survey and follow up focus groups, it was identified that physicians tended to struggle more with the EHR and inability to disconnect from work compared to APPs. Our APPs identified several areas of opportunity including onboarding/orientation, mentorship/professional development, pay and scope of practice. An EHR Well-being Committee was established to evaluate EPIC signal reports to address both system and individual clinician needs. To address APP needs, key factors were addressed in the realm of professional development/orientation, compensation and scope of practice. This was approached with the goal of short-term gains and long-term sustainability. **Results:** The results indicated a 23.8% improvement in job satisfaction, 4.9% improvement in job stress, and 26.3% improvement in employment outlook. A decrease was also noted in EHR time outside of work (4.5%) and burnout (16.1%). All areas of improvement met or exceeded national benchmarks. Analysis of these results indicate statistical significance for job satisfaction (p = 0.028, CI 2.8-40.4%) and employment outlook (p = 0.033, CI 2.4-45.8%). Results that indicated improvement but were not statistically significant were job stress (p = 0.688, CI 17.6-27.4%), burnout (p = 0.191, CI 7.4-37.5%) and EHR time outside of work (p = 0.806). **Conclusions:** While the survey data does not account for clinician turnover between 2021 and 2022, initial review indicates a positive impact on job satisfaction and employment outlook which may be an early indication of improved colleague appreciation. Further study, post-pandemic is needed to evaluate effectiveness of care team efficiency and ongoing work to streamline EHR usage. Research Sponsor: None.

Addressing resiliency and burnout: A quantitative needs assessment of oncology physician assistants (PAs). *First Author: Eric Daniel Tetzlaff, Fox Chase Cancer Center, Philadelphia, PA*

Background: Significant progress has been made in understanding the factors associated with oncology (onc) PA burnout. However, little is known about what PAs need to mitigate burnout, the availability of resources, and barriers to interventions. **Methods:** A national survey of onc PAs was conducted in 2022. PAs completed a quantitative needs assessment to determine the importance of and their perceived skills in topics of self-care, clinical care, and professional development. For importance, “high importance” included ratings of ‘Essential’ or ‘Very Important’; for perceived skill, “high skill” included ratings of ‘Excellent’ or ‘Good’. Engagement with employee assistance programs (EAPs) was examined. Resiliency & Burnout were assessed using the Connor-Davidson Resilience Scale & the Maslach Burnout Inventory. **Results:** PAs (n = 171) were mostly practicing in medical oncology (66%) and outpatient (66%). The high importance topics most often identified were dealing with difficult patients (93%), dealing with difficult providers (89%), delivering bad news (88%) and coping with death / patient suffering and personal grief (86%). Topics less often reported as high importance included opportunities to be a mentor (61%), professional coaching (59%) and mindfulness skills (53%). PAs frequently reported high skills in dealing with difficult patients (75%), delivering bad news (72%), and resiliency skills (59%). Fewer PAs reported high skills for debriefing following significant events (49%) and mindfulness skills (42%). Burnout (BO) rates were higher for those with lower perceived skills in resiliency (p = 0.03) and dealing with difficult providers and staff (p = 0.03) but did not differ based on importance of any topics. Resiliency significantly increased with increasing levels of reported importance for the mindfulness skills training, cognitive skills training, and debriefing after significant events topics. Resiliency significantly increased with increased levels of perceived skill for all topics explored. Common barriers to well-being EAP participation were lack of time (58%) and concerns about confidentiality and stigma (26%). For PAs with concerns about stigma, resiliency scores were lower (6.4 vs 7.0; p < 0.001) and BO rates were higher (73% vs 47%; p = 0.005). **Conclusions:** Perceived deficiencies in resiliency training and managing difficult work relationships correlate with higher rates of burnout in onc PAs. Barriers to participation in EAPs, which may help address these deficits, are common and when present are associated with an alarming rate of burnout and lower resiliency. Cultural change in medicine is needed to reduce perceived and experienced stigmatizing experiences to address burnout. These findings suggest that burnout interventions which focus on building resiliency and managing work relationships are crucial and may be best implemented outside of the workplace. Characterizing imposter syndrome among oncologists on social media. *First Author: Eleonora Teplinsky, Valley Health System, Paramus, NJ*

Background: Imposter syndrome (IS) is defined as an inability to believe that one's success is deserved. It is commonly encountered by physicians, with cited statistics ranging from 22% to 98%, is associated with negative mental health impacts and can be harmful to one's wellbeing. Given increasing SM use in hematology/oncology (H/O), we aimed to evaluate the effect of SM on IS among oncology trainees and oncologists. **Methods:** An anonymous online survey was distributed to oncology trainees and oncologists through SM platforms (Twitter, Facebook (FB), Instagram (IG)) and e-mail. Questions included demographics, current SM use, a novel scale for IS on SM (Table), Young Imposter Syndrome (YIS) Scale (a validated IS instrument) & assessment of mental health impacts of SM. **Results:** Out of 195 respondents, 103 answered all questions; median age 40y (27-65), 81% female. 21% were trainees and 36%, 30%, and 12% were early, mid and late-career faculty, respectively. Specialties included: adult H/O (72%), gynecologic oncology (11.3%), radiation oncology (10.5%), surgical oncology (4.1%), and pediatric H/O (1.5%). Twitter was the most commonly used SM platform (68%) followed by FB (36%) & IG (20%). 26% utilized professional SM 0-1 times/week while 28% did so daily. 97/157 (62%) noted positive mental health impacts from SM. 41% felt anxious, lonely or depressed due to SM. 19.7% have experienced SM harassment or cyberbullying. More than 50% of respondents met criteria on the YIS and IS scale; indeed, the YIS and IS on SM Scales were significantly correlated with each other (r = 0.57, p < 0.001, N = 103). The presence of IS on SM was associated with gender but not race/ethnicity or career stage. 59% of females versus 28% of males met criteria for IS (p = 0.02). The presence of IS on SM was significantly associated with self-perceived IS in professional settings (p < 0.001), but not in personal settings (p = 0.21). **Conclusions:** Many oncology professionals experienced IS while interacting on SM, but also note a positive mental health impact with SM use. The presence of IS on SM correlated with results on the YIS Scale, suggesting a novel assessment method, but further validation is needed. Future efforts to combat IS on SM while enhancing positive aspects of medical SM are warranted. Research Sponsor: None.

IS on SM for medical professionals scale (Thermometer 1-10); 10=always/significant impact; 0=never/no impact.
How often do you feel insecure posting about a medical topic on SM?
How often do you feel like you aren't qualified to comment on medical topics on SM despite having appropriate training?
How often are you fearful of joining in medical conversations on SM due to concerns about misspeaking?
How often do you feel insecure on SM due to comparing yourself with topic/disease experts in your field?
Do you feel better or worse after logging off of SM?
How does the number of followers you have on SM impact your mental health?
How does the number of likes or shares on your SM posts impact your mental health?

The implementation of a self-care tool for patients that may reduce clinician burden. *First Author: Jenny Wei, Department of Medicine, The Permanente Medical Group, San Francisco, CA*

Background: Addressing the side effects and concerns of patients is paramount during cancer treatment. At this time, this significant workload often involves active management by oncology clinicians which may exacerbate clinician burnout. However, minor side effects and routine concerns may be managed by patients themselves. While there are valuable resources available online including Cancer.net by the American Society of Clinical Oncology (ASCO), patients may benefit from a targeted and personalized approach. Herein, we developed a novel online patient self-assessment and self-care tool within Kaiser Permanente Northern California (KPNC), an integrated healthcare system caring for about 4.5 million patients, that aims to help patients with cancer address routine concerns, enabling them to participate in targeted self-management. **Methods:** Under the novel 4R Oncology model (Right Info / Right Care / Right Patient / Right Time), the self-care tool was implemented to promote patient self-management and improve team-based care and was further developed into a web-based intervention by KPNC. Patients with specific minor concerns were directed to Cancer.net webpages that described how these concerns could be self-addressed. We assessed pageview (a page loaded within a browser) data from May 2021 to December 2022. Main topics were Managing Side Effects and Concerns Related to Your Cancer Treatment, Nutrition Concerns, Emotional or Practical Concerns, Additional Resources and COVID-19 information. If patients were unable to address their concerns with the self-care tool, they were instructed to contact their care team for follow-up. **Results:** Within the 20-month study period, there were 4,991 total pageviews of the self-care tool. The most pageviews in one month were 501 in November 2022 and the least were 93 in December 2021. Pageviews increased over time with most months in 2022 reaching over 200 pageviews compared to only half of months in 2021 surpassing 200 pageviews. The most frequent pageviews were diarrhea (124), nutrition (124), sleep (101), use of herbs or supplements (100) and nausea or vomiting (98). While there were many topics available on the website, the most viewed pages involved gastrointestinal concerns. The least viewed included Life Care Planning/Advance Health Care Directive (6) and Chemobrain (8). **Conclusions:** Examination of pageview data from a self-assessment and self-care tool targeting patients with cancer within an integrated healthcare system reveals substantial interest in self-management. While it is unclear whether patients find the self-care tool's information useful currently, further research is underway using patient surveys to evaluate its utility. Implementation of helpful information can empower visitors to be aware of their options and engage in self-management of routine conditions, which in turn can optimize their health while decreasing oncology clinician burnout. Research Sponsor: None.

Impact and engagement of a virtual platform to provide equitable oncology education globally. *First Author: Yan Leyfman, Icahn School of Medicine at Mount Sinai South Nassau, Oceanside, NY*

Background: Social media has emerged as a powerful outlet for the dissemination of medical information, especially in resource-limited regions, due to its mass global reach. However, misinformation has presented an unexpected detriment to public health on a global scale. To address this, *MedNews Week (MNW)*, a free, virtual educational platform streamed on most social media platforms was developed to provide global oncology education through biweekly programming. Its leading show, *Keynote Conference*, features live virtual presentations from oncology's premier global leaders discussing the latest developments in the field before a mainstream global audience. The aim of this study was to assess the worldwide reach and impact of this cost-free, virtual oncology education platform. **Methods:** From January 2022 to February 2023, *MNW* hosted 33 global leaders as Keynote Speakers discussing the latest developments in oncology. Viewership, impressions, and outreach data were collected from *MNW's* social media accounts and Tweepmaps. Data was analyzed to assess *MNW's* global reach and engagement and stratified based on engagement sentiment, gender, age group, and occupation. **Results:** During this period, *MNW* produced a healthcare social grasp score of 64% and generated over 64,000 Twitter impressions engaging 1.9 million viewers over 13 months in the US, UK, Ireland, India, France, and 16 lower socioeconomic (SE) countries and 99 cities. Most of the followers were from non-healthcare fields with more males than females (Table). Those who engaged conveyed positive sentiments (64%) contributing to a viewership increase from 47,589 (6 months) to 61,539 (1 year), where 60% of the audience was found to originate from lower SE regions globally. **Conclusions:** *MNW* has demonstrated an ability to attract and sustain a diverse, global, growing mainstream audience. Given *MNW's* continued growth, it provides a proof-of-concept model to engage and disseminate medical information to mainstream audiences. The platform's ability to showcase global leaders to mainstream audiences gratuitously, especially in lower SE regions that have been historically underserved, offers a practical approach to combat educational inequity. Consequently, such a platform has demonstrated great potential to positively impact global oncology education. Demographics of *MedNews Week's* audience. Research Sponsor: None.

Reliability of audiovisual information on lung cancer from cancer organizations. First Author: Hardik Dand, Swedish Hospital, Chicago, IL

Background: In the US, lung cancer is the leading cause of cancer death and second most common cancer. YouTube (YT), a social media platform with billions of users, can improve knowledge but also disseminate inaccurate information. Research has shown YT plays a key role in public health. This study assesses the reliability of YT videos about lung cancer using its own algorithm compared to videos from three cancer organizations. **Methods:** We searched “lung cancer” on YT and selected 8 videos with the most views. Then, “lung” was searched from YT profiles of American Cancer Society (ACS), National Cancer Institute (NCI), and National Comprehensive Cancer Network (NCCN). Criteria required videos to be less than 10 minutes and have “lung” in the description. Videos were excluded if not in English, older than 15 years, patient stories, or sponsored by pharmaceutical entities. The videos were graded by 3 independent medicine residents using the validated methods of Patient Education Materials Assessment Tool Understandability and Actionability (PU and PA) and Journal of the American Medical Association (JAMA) scoring. Higher percentages of PU and PA represented more understandable and actionable material. Higher JAMA score (up to 4) indicated better quality of information. Descriptive statistics and non-parametric Kruskal-Wallis tests were done. **Results:** A total of 36 videos were identified. PU mean was 74.2% (SD 21.4) in YT compared to 62.4% (SD 15.2), 53.1% (SD 28), and 58.8% (SD 13.9) for ACS, NCI, and NCCN respectively. PA mean was 46.6% (SD 46.8) for YT compared to 12.9% (SD 31.7), 38.9% (SD 53.6), and 8.2% (SD 21.2) for ACS, NCI, and NCCN respectively. A statistically significant higher median actionability score can be seen in YT. The JAMA average was 1.9 (SD 0.2) for YT compared to 2.1 (SD 0.1), 2.3 (SD 0.6), and 2.0 (SD 0) for ACS, NCI, and NCCN respectively. While a statistically significantly higher median JAMA score is seen in NCI videos, no meaningful difference can be extrapolated given all average scores of roughly 2. **Conclusions:** YT produced videos of higher understandability and actionability compared to videos from cancer organizations. As patients continue to rely on social media for information, trusted cancer sources should develop more reliable material for improved patient education. Comparison of scores from averages of 3 reviewers. Research Sponsor: None.

The impact of physician gender on patient satisfaction in an academic hematology/oncology practice. First Author: Alaina Marie Turchi, Indiana University, Indianapolis, IN

Background: Gender disparities continue to remain under addressed in medicine. While prevalent in many forms, patient bias and perceptions toward their healthcare team can impact patient compliance and care. Health systems often gauge patient satisfaction with physicians and post these ratings online. It is possible that gender biases affect patient satisfaction scores and evaluations. Here, we assess the impact of physician gender on patient satisfaction scores and comments in an academic hematology/oncology practice. **Methods:** A retrospective mixed-method analysis was conducted from patient satisfaction scores and comments obtained between January and June of 2021. Patients were asked a series of three questions about their care. Patients' response to the question, “How likely would you be to recommend this providers office to friends and family?”, was analyzed on a score of 0-10, with 10 being extremely likely and 0 being not at all likely. Patients were then asked for the primary reason for their scoring, in an open-ended format. Mixed-gender codified data was quantified from de-identified, de-gendered patient comments. To identify the differences in patient perception between male and female physicians, we specifically examined the data of positive and negative impressions of variables including professional behaviors, expertise, kindness, compassion, and interactions with ancillary staff amongst providers. **Results:** Patient satisfaction scores from 199 unique patients were reviewed; 140 (70.4%) were about male-identifying physicians while 59 (29.6%) were related to female-identifying physicians. The mean satisfaction score was 9.95 ± 0.29 for female physicians and 9.64 ± 1.38 for male physicians ($p = 0.011$). Of patients responding, 76 (38%) were male and 123 (63%) were female. Female physicians scored higher than male physicians for both male and female patients (10.0 ± 0 versus 9.65 ± 1.37 ($p = 0.011$) and 9.77 ± 0.60 versus 9.62 ± 1.40 ($p = 0.011$), respectively). Kindness and compassion were mentioned in 36% and 42% of all female physician scores, respectively, and in 29% and 33% of all male physician scores; these did not reach statistical significance ($p = 0.587$ and $p = 0.257$). 21% of all male physician scores positively mentioned physician expertise, compared to 15% of female physician scores; this also did not reach statistical significance ($p = 0.434$). **Conclusions:** Female physicians had a higher mean satisfaction score in patient evaluations than their male counterparts by both male and female patients. Numerically, more patient comments about female physicians mentioned kindness or compassion, while fewer mentioned expertise. This early work will be expanded to a larger dataset of evaluations in addition to further exploration of how female and male oncology providers are perceived by patients in multiple other categories. How reliable are post-mastectomy breast reconstruction videos on YouTube? First Author: Nina Morena, McGill University, Montreal, QC, Canada

Background: Social media are a significant source of information for young women with breast cancer (YWBC) undergoing post-mastectomy breast reconstruction (PMBR). The emphasis on visual storytelling and building community in online spaces renders YouTube (YT) to be a common platform for discussions of BR. This study aims to assess the quality of YT videos about PMBR, identify themes related to the PMBR experience, and quantify perceptions of BR as an option PM. **Methods:** YT was searched incognito with terms “young women breast cancer reconstruction” in 08/2022, in order from most to least viewed. Title, upload date, length, poster identity, number of likes and comments were collected. The Patient Education Materials Assessment Tool for audiovisual materials (PEMAT A/V) evaluated understandability and actionability. DISCERN assessed quality and reliability. Presence of sponsorship, intended audience, patient and healthcare professional narratives, and perceptions of PMBR were collected. Reviewers noted whether PMBR was shown and how. Themes were collected inductively and deductively for thematic analysis. **Results:** 193 videos were identified. Mean video length was 14.6 minutes (SD 20.0 min). 87.1% included sponsorships. 95.9% of videos were posted by an organization. 60.6% were information-based; 45.6% experience-based. Mean PEMAT scores for understandability and actionability were 71.3% (SD 13.4) and 35.7% (SD 41.8), respectively. Mean DISCERN was 2.6/5 (SD 1.2). Patient narrative was present in 52.6% and healthcare professionals' in 68.4%. PMBR was visually presented 22.8% of the time. 13.5% of videos explicitly recommended PMBR. 2.6% explicitly discouraged it. Patients (77.7%) represent the majority of the intended audience. Most common deductively identified themes included treatment (87.1%), family relationship (17.1%), motherhood (15.5%), fertility (11.9%). Inductively identified subthemes included differentiating between various options for PMBR surgery, BRCA genetic testing, psychosocial effects of breast cancer and PMBR, and recovery from surgery. **Conclusions:** YT is a platform wherein various PMBR options are widely discussed and explained. PMBR videos are highly understandable but have moderate levels of actionability, quality, and reliability. Videos are highly sponsored, demonstrating significant institutional bias. Themes are overwhelmingly treatment and surgery-based. Personal themes were present but not dominant. Distribution of PEMAT and DISCERN scores. Research Sponsor: Nina Morena is supported by funding from the Social Sciences and Humanities Research Council and the Fonds de Recherche du Québec – Société et Culture.

A review of diversity, equity, and inclusion (DEI) efforts by medical oncology journals. First Author: Inas Abuali, Massachusetts General Hospital, Boston, MA

Background: In recent years, there has been a growing awareness of the ongoing structural inequities impacting all facets of academic medicine. Efforts are underway to adopt an intentional and systemic approach to meaningful incorporation of DEI in academia. Here, we review the ongoing efforts by scientific peer-reviewed journals to ensure an equitable publication process, and an inclusive and diverse participation and distribution of oncological research. **Methods:** Medical oncology journals with the highest impact factor were identified using the SCImago Journal Rank (SJR), a publicly available portal that includes the journals and country scientific indicators developed from the information contained in the Scopus database. 39 Journals in the first ranking quartile (Q1) with the highest impact were identified to have an SJR >2. An online review of journal websites' content was performed between Jan 8th – Feb 8th, 2023, to extract the data available in the accompanying table. **Results:** 38.5% of journals include a DEI statement on their website. One journal has a dedicated editorial director of equity. Three journals (8%) have a specific online DEI corner highlighting related articles and initiatives. 20% of the journals publicly outlined specific DEI policies, such as formalizing the process for assessment and reporting, and identifying and inviting peer reviewers with DEI expertise. Finally, 20% of journals published limited specific metrics assessing the impact of their DEI efforts, such as data regarding the primary corresponding authors at country and region level in the last five years, and the gender diversity of their editorial boards. **Conclusions:** Our study highlights the limited publicly available data online regarding ongoing DEI initiatives and dedicated editorial positions in high impact medical oncology journals. It is imperative that we aim for greater intentionality and transparency about such efforts, with reporting of clear and specific impact metrics. In addition, these efforts cannot be performative and must foster a more equitable scholarly publication process, promote accountability, and assist in formulating best practices. Our analysis suggests a clear unmet need and represents a call to action. High impact oncology journals have an opportunity to set the tone for the entire oncology medical community. Research Sponsor: None.

	Number of Journals
DEI statement available online	15/39 (38.5%)
Has a dedicated DEI editor/ associate editor	1/39 (2.5%)
Dedicated online DEI corner	3/39 (8%)
Specific DEI policies outlined	8/39 (20%)
Specific metrics and impact of DEI initiatives	8/39 (20%)

Bringing the teaching close to home: Implementation of a near-peer model for an introductory hematology-oncology fellowship lecture series. *First Author: Jonathan L Berry, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Hematology/oncology fellowship has a steep learning curve. Foundational knowledge at the start of fellowship is essential, given limited exposure to key disease-specific concepts in prior training. We have previously employed an expert faculty-led "introductory boot camp" during the first 2 months of fellowship training. Trainees provided feedback that this was not best meeting fellows' needs. We hypothesized that a near-peer teaching model, led by senior fellows, would better align lecture content and scope with the needs of new fellows and improve senior fellows' mastery of clinical knowledge and comfort with teaching skills. **Methods:** Using a constructivist theory of learning, we selected the most relevant topics from the curriculum and assigned each senior fellow 1-2 hour-long sessions on clinical areas of interest, paired with expert faculty. A one-hour workshop on lecturing techniques and instructional design was held for all senior fellows. Educational sessions led by senior fellows and expert faculty occurred July-September 2022 in a hybrid format. An IRB-exempt anonymous survey was sent to participating fellows and faculty regarding effectiveness of the educational sessions and the process of preparing to lead sessions. **Results:** 15 of 17 fellows (88%) and 12 of 15 faculty (80%) completed the survey. Overall, 71% (95% CI 33-82) of fellows and 75% (95% CI 43-95%) of faculty felt the new series was taught at an appropriate level for new fellows. All fellow respondents felt the approach was helpful for clinical practice and board preparation. All participating senior fellows felt equipped to teach and that the exercise improved confidence in the content and their teaching skills. No fellows proposed a return to the prior model, and 80% of faculty felt the near-peer approach should be continued in future years. Qualitative analysis of narrative responses identified several strengths, including emphasis on focused, introductory frameworks and the generation of living resources for future reference. Areas identified for future improvement include providing more guidance and structure for pre-lecture faculty-fellow preparations. **Conclusions:** A near-peer model of introductory lectures is feasible to implement, produces improved satisfaction with the curriculum, and can be a means of presenting foundational content in hematology and oncology concordant with the learners' needs. This method has important implications for developing learner-concordant, expert-driven curricula in large and rapidly changing content areas within hematology/oncology. Research Sponsor: None.

Utility of a novel trainee-level hematology/oncology podcast in graduate medical education. *First Author: Ronak Mistry, Vanderbilt University Medical Center, Nashville, TN*

Background: Despite the popularity of podcasts in medical education, there are a limited number of trainee-level hematology/oncology (H/O) podcasts. We created & implemented a novel H/O podcast curriculum to address this barrier. Here, we evaluated the utility of this podcast for H/O fellows & internal medicine (IM) residents on H/O rotations. **Methods:** We included IM residents & H/O fellows at Vanderbilt University Medical Center in the 2022-2023 academic year. Each IM resident starting on a H/O inpatient rotation received an email prior to their rotation with list of recommended episodes. H/O fellows were encouraged to listen to episodes at their discretion. We developed anonymous surveys using a 5-point Likert scale (1, "strongly disagree" to 5, "strongly agree") to understand how the podcast helped prepare them clinically & if H/O podcasts were effective educational tools. **Results:** A total of 20 trainees completed the survey including 7 residents (35%) & 13 fellows (65%). All post-graduate years were represented. Results of the survey are presented in the table. Most felt the podcast material helped with inpatient rotations & consults, was clinically relevant, & helped with clinical decision-making with a mean score of 4.76, 4.79, and 4.50, respectively. Respondents agreed the fundamentals of H/O are amenable to a podcast platform & are likely to continue to use podcasts as learning tools in H/O with a mean score of 4.68 and 4.40, respectively. When restricting to the fellow cohort, the majority felt that the podcast material helped them prepare for their clinic patients with a mean score of 4.62. Most found the podcast convenient & the most common activities while listening to our podcast were driving (70%), doing chores (35%), exercising (25%), and eating (25%). **Conclusions:** H/O fellows & IM residents found the trainee-level podcast curriculum clinically relevant and helped with clinical decision making. The respondents also all agreed or strongly agreed that podcasts are an effective medium to teach hematology/oncology. Our successfully piloted podcast curriculum can be adapted to other training programs to improve foundational knowledge in oncology. Research Sponsor: None.

Responses to survey.

Fellow-led didactics in a hematology/oncology fellowship program. *First Author: Rajat Thawani, Medical Oncology, Oregon Health & Science University, Portland, OR*

Background: The pandemic in 2020 made us used to virtual learning, but as we recover from the pandemic, we are forced to rethink how we deliver education to trainees in medicine. The pandemic has led to a significantly decreased attention span and face to face interactions, in addition to an increased screen time. In our program, this led to us noting a lower engagement in the fellowship didactics as we recovered from the pandemic. This forced us to rethink how the Oregon Health & Science University (OHSU) hematology and oncology fellowship delivers educational content. After interviewing all stakeholders, we moved to an in-person fellow led didactic approach, under the mentorship of a faculty expert who helps trainees design content and is present for discussion. The rationale behind this approach was to boost peer-to-peer learning, supply relevant content and increase engagement. The fellows and faculty were provided guidelines about length of talk, presentation of data and use of interactive tools. **Methods:** After 6 months of introducing fellow led didactics, we surveyed all fellows and select faculty who were mentors on more than one occasion about their opinion. A survey link was sent to all 12 fellows and 18 faculty members who regularly took part in fellowship didactics. **Results:** All 12 fellows responded to the survey. On a Likert scale of 1-5, they scored improvement in knowledge at 4.58 (0.64) and rated both the content and presenter at 4.25 (0.43). A third felt that this way of delivering didactics was a lot better and the rest felt it was a little better. On the negative side, they felt that they were spending more time preparing content (40% spent 7-9 hours a month) but were optimistic about lesser commitment next year as we bank the PowerPoint presentations. Nine of the 18 (50%) invited faculty responded to the survey, and on a scale of 1-5, they rated their improvement of knowledge as 4.44 (0.68). They scored the content and presenter at 4.44 (0.5) and 4.56 (0.68) respectively. 88.9% felt that the didactics were either a little or a lot better, and 11.1% felt them to be the same. On average, they spent less time on the content than they did if they were presenting. **Conclusions:** Overall, both faculty and fellows felt that this method of delivering didactics in a hematology oncology fellowship program was more effective. The fellows felt that they needed to put in extra hours for preparation, but this will probably go down as they build on earlier presentations. Research Sponsor: None.

Teaching how to navigate difficult conversations: A combined palliative care-oncology didactic simulation intervention for hematology/oncology fellows. *First Author: Megan Dupuis, Vanderbilt University Medical Center, Nashville, TN*

Background: ASCO strongly endorses the integration of palliative care to improve patient outcomes and support patients in their cancer trajectories. Developing core palliative care skills for trainees is therefore essential, with few ACGME approved pilot programs offering combined fellowship training. Our institution's Heme/Onc fellows reported a need for additional education in leading difficult conversations. **Methods:** We piloted a didactic simulation (sim) session for each fellowship class, led by a faculty member who is dual board-certified in Medical Oncology and Hospice/Palliative Medicine. Trainees received a lecture on validated communication tools and oncology-specific language to help navigate difficult conversations. Trainees then role-played in small groups using sample cases, with Heme/Onc faculty supervision and real-time feedback, followed by class reflection. Pre- and post-sim surveys were electronically administered to assess knowledge of communication tools and comfort in discussing difficult topics. Comfort questions were scored on a 5-point Likert Scale, using student t-tests to detect differences pre- and post-sim, and ANOVA to compare responses among classes. **Results:** A total of 16/21 (76.2%) fellows completed both pre- and post-sim surveys. Knowledge of communication tools increased from 21.9% pre-sim to 79.7% post-sim. Comfort significantly increased for explaining palliative-intent chemotherapy, hospice, and discussing an uncertain prognosis (Table). There was a significant difference among classes pre-sim for addressing negative emotions (mean comfort level: 1st years 2.8, 2nd years 3.4, 3rd years 3.83; p=0.046) and for discussing an uncertain prognosis (mean comfort level: 1st years 2.6, 2nd years 3.6, 3rd years 3.83; p=0.043); however, these interclass discrepancies were eliminated post-sim. Overall, fellows reported that the sim sessions were effective for developing their knowledge and comfort in having difficult conversations. **Conclusions:** A novel sim intervention led by a physician who is dual board-certified in palliative care and medical oncology improves trainee competency with navigating difficult conversations. Analysis of the intervention's durability of response and iterative refinement of its curriculum are ongoing. Research Sponsor: None.

Comfort with cancer communication topics.

	Pre-sim Mean	Post-sim Mean	P-value
I am comfortable...			
telling a patient bad news, such as having progression on a scan.	3.92	4.18	0.216
explaining palliative-intent chemotherapy.	4.13	4.63	0.003
explaining the role of hospice.	3.94	4.31	0.029
asking a patient about code status.	4.13	4.25	0.592
responding to negative patient emotions such as sadness or anger.	3.34	3.81	0.082
discussing prognosis when the outcome is predictable.	3.87	4.31	0.052
discussing prognosis when the outcome is uncertain.	3.34	4.06	0.020

Hematology and oncology fellow education about sexual and reproductive health: A survey of program directors in the United States. *First Author: Jennifer B. Reese, Fox Chase Cancer Center, Philadelphia, PA*

Background: Sexual and reproductive health (SRH) concerns are important areas of health and quality of life for patients with cancer that should be included in routine cancer care, according to clinical guidelines. Yet, oncologists often hesitate to raise SRH with their patients due to lack of training. We conducted a national survey of hematology/oncology fellowship program directors (PDs) in the U.S. to understand the state of current fellowship education on three key SRH subjects: fertility, sexual health, and safe sex practices. We assessed rates of provision of formal/informal instruction and endorsement of barriers to formal instruction. **Methods:** A 13-item survey of education on fertility, sexual health, and safe sex practices in adult hematology/oncology programs was sent to all PDs in the U.S. via an online link or paper survey. PD's received a \$5 gift card for participating. Descriptive statistics and McNemar tests were used. **Results:** One hundred-twelve PDs responded to the survey (63% response rate). Of these, 75% of PDs reported their programs offered >1 hour of formal instruction on fertility, 42% on sexual health, and 31% on safe sex practices; formal instruction was more common for fertility than either other subject (p 's < .001). Male and female fertility preservation was addressed in 62% and 59% of programs, respectively. Cancer-related sexual side effects for women and men were covered in less than one-quarter of programs (23% and 20%, respectively). Regarding informal instruction, > 73% of programs reported using clinical experience to train fellows in SRH; other informal instruction methods (i.e., case-based methods, webinars, journal clubs, grand rounds) were less common. Lack of experts/resources was the most widely endorsed barrier to providing education about fertility (55%), sexual health (75%), and safe sex practices (69%) and was more widely endorsed for sexual health and safe sex practices compared to fertility (p 's < .01). Lack of space in the curriculum and the topic not being required were also commonly endorsed barriers. **Conclusions:** Data from this national survey of fellowship program directors show that training in SRH is rare, particularly for sexual health. Barriers to training, especially difficulties in finding content experts, may be leading to a heavy reliance on informal methods of instruction, which are both variable and incomplete. Concerted efforts to integrate SRH into fellowship training, including novel educational curricula, are needed if SRH is to be addressed in routine cancer care. The brown university cancer prevention and survivorship curriculum: A case study on program development in an internal medicine residency. *First Author: Elizabeth Francis, Brown University/Lifespan Hospitals, Providence, RI*

Background: Advances in screening, early detection, and treatment have increased the number of cancer survivors. Cancer survivors have a unique set of medical, psychosocial, physical, and financial challenges. Though it is critical for provider teams to be attuned and equipped to address these issues, we identified two training programs in this discipline. Medical residency clinical education does not fully explore the role of cancer preventative services and survivorship experiences available to patients and their families. We developed an elective at Alpert Medical School at Brown University/Lifespan Internal Medicine Residency Program (Brown) to improve medicine residents' knowledge and clinical skills on different aspects of the cancer control continuum, with a focus on prevention, early detection, survivorship and surveillance. **Methods:** In 2020, a team of Brown internal medicine (IM) residents, faculty and one hematology oncology (heme/onc) fellow examined the existing cancer prevention and survivorship infrastructure, identified key faculty and clinics, and examined existing programs at peer institutions. A needs assessment was completed by Brown IM residents and heme/onc fellows. We then designed the Cancer Prevention & Survivorship Elective, an innovative and novel educational elective for medical residents to promote interest, awareness, and understanding of cancer prevention and survivorship. The 6 module one month elective features didactics and clinical experiences offered via a live and independent study fashion. The elective brought together 27 disciplines, 64 faculty lecturers from 10 peer institutions across the United States and included 20 unique clinics. Residents completed anonymous pre- and post-course surveys to measure their understanding and degree of confidence in different aspects of cancer prevention and survivorship, not limited to surveillance, health disparities and global perspective, primary and secondary prevention, late and long-term effects, and quality of life. **Results:** In January 2023, ten residents, ranging from first- to third-year IM and medicine-pediatrics, participated in the live elective. Two IM residents have registered to complete the elective via independent study in 2023. To date, the Cancer Prevention and Survivorship Elective has improved IM residents' confidence, comfort and clinical skills in treating patients along the cancer care continuum. **Conclusions:** This curricula serves as an example for inter-institutional collaboration, and highlights the need for a multidisciplinary approach when caring for patients at high-risk of developing cancer and surviving cancer. Recommendations for medical cannabis use in cancer patients by US oncology fellows and the impact of receiving prior training. *First Author: Kian Tehranchi, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Despite the rising use of medical cannabis, limited evidence informs the safety and efficacy of cannabis use in cancer patients. A national survey of oncology fellows found that fellows felt insufficiently informed to make clinical recommendations about cannabis. In this secondary analysis of that survey, we aimed to measure how frequently trainees recommend cannabis and determine factors that influence this practice. Given the lack of evidence, we hypothesized that fellows who had been trained in medical cannabis use would be less likely to recommend cannabis to their patients. **Methods:** An online survey assessing trainee practices on medical cannabis was sent to 155 oncology fellowship program directors between January - March 2021 and directors were asked to distribute it to their fellows. The primary outcome was the number of times oncology fellows recommended cannabis in the prior year. Log-binomial regression was used to calculate risk ratios (RR) and 95% confidence intervals (CI) to evaluate whether the number of cannabis recommendations varied by participant age, gender, legality of cannabis in the state of practice, and prior training in medical cannabis. **Results:** Nationally, 40 programs from 25 states participated, with 189 of 462 trainees across these programs responding (40% response rate). Twenty-two percent (95% binomial CI: 16.3-29.0%) of participants reported recommending medical cannabis to >5 patients in the past year. Twenty-four percent (95% binomial CI: 18.4-30.5%) of participants had prior training in medical cannabis. Among participant characteristics, only prior training in medical cannabis was associated with recommending cannabis to >5 patients (RR: 2.42; 95% CI: 1.39-4.20). **Conclusions:** Despite limited evidence to support medical cannabis use among cancer patients, one in five oncology fellows participating in our study recommended it to >5 patients in the past year. Prior training was associated with doubling of rates of recommending medical cannabis in this group. It is thus of critical importance that fellowship training on this subject reflects best available evidence to guide trainees in well-informed decision-making. Factors associated with trainees recommending medical cannabis to >5 patients. Research Sponsor: None.

Predictor	Unadjusted RR (95% CI)	Adjusted* RR (95% CI)
Birth year		
1975-1984	1.84 (0.67-5.10)	-
1985-1989	1.66 (0.78-3.55)	-
1990-1994	1.00	-
Legal status in state of practice		
Comprehensive medicinal and recreational	1.00	1.00
Comprehensive medicinal only	1.08 (0.59-1.96)	1.05 (0.60-1.85)
Allows products with low THC/high CBD	0.64 (0.25-1.62)	0.89 (0.34-2.32)
Prior training in medical cannabis	2.60 (1.54-4.40)	2.42 (1.39-4.20)

Mapping objectives of a new interprofessional morbidity and mortality conference to ACGME core competencies in hematology/oncology. *First Author: Aditya Sharma, Dartmouth-Hitchcock Medical Center, Lebanon, NH*

Background: Safety and quality improvement requirements are a part of the core competencies for ACGME-accredited hematology/oncology fellowships. The morbidity and mortality conference (MM) is a tool that has been used to identify safety issues and areas for improvement. The traditional format primarily includes an audience of clinicians. We sought to develop an interactive, interprofessional MM (i-MM), including institutional leadership, physicians, fellows, residents, advanced practice providers, nursing, and pharmacy, while meeting the ACGME Core competencies for Patient Safety and Quality Improvement in Hematology and Medical Oncology. **Methods:** A pilot i-MM was designed to create an enriching, interprofessional discussion regarding patient safety and quality improvement. We implemented a Plan-Do-Study-Act (PDSA) design to create the i-MM model that map to the core competencies. The first session was focused on two mortality events in immunocompromised hosts that triggered the sepsis bundle, one of which was due to toxic megacolon. The i-MM objectives were aligned with ACGME hematology/oncology fellowship requirements of quality and safety. The effectiveness of the pilot session was gauged via an anonymous post-session survey using a 4-point Likert scale. **Results:** A total of 32 people attended the pilot i-MM, including quality and safety leaders, faculty, fellows, medical residents, pharmacy, and nursing. A total of 10 participants across professions completed the post-i-MM survey. The survey demonstrated an average of 3.8/4 for all interprofessional educational goals, which included demonstration of mutual respect between healthcare professionals, engaging in effective interprofessional communication, and working within an interprofessional team. Content-specific aspects of the survey were rated with an average effectiveness of 3.60/4. Feedback on the survey recommended limiting i-MM to one case presentation instead of multiple. During the debrief session, it was reported that several nurses felt the moderated session was "inclusive and empowering". **Conclusions:** The i-MM was an effective approach to meeting ACGME requirements for safety and quality learning objectives while creating an inclusive environment for all team members. Future PDSA cycles will continue to map i-MM learning objectives to ACGME hematology/oncology fellowship program core competencies in Section VI.A.1 and the section on Professionalism. Core competency mapping will guide future presentations that address issues on quality, safety, and health care disparities. Specific presenters and moderators from different professions will be chosen to lead each i-MM, with the goal of examining each case from different perspectives to provide a holistic interprofessional view of delivering quality medical care to patients. Research Sponsor: None.

The cognitive load of inpatient consults involving immune-related adverse events. *First Author: Sam Brondfield, University of California, San Francisco, San Francisco, CA*

Background: Immune-related adverse events (irAE) requiring hospitalization involve complex, multidisciplinary management. Expertise in oncology and/or the affected organ(s) may be required in the form of inpatient consults. Trainees (fellows and residents) often provide such consults. irAE consults may be rich learning opportunities, but it is unclear whether the cognitive load, or mental effort, required for these complex cases may overwhelm trainees and impair learning. To investigate the cognitive load of irAE consults, we surveyed trainees who had recently completed an irAE consult and compared the results to a control dataset. **Methods:** Between October 2021 and January 2023, we identified patients hospitalized due to irAEs at the University of California, San Francisco by reviewing patient lists (oncology consults and hospital medicine admissions) daily. We emailed the published Consult Cognitive Load (CCL) survey to any residents or fellows who had signed initial consult notes in the charts of identified patients. The CCL uses 4-point scales to measure three types of cognitive load related to one consult: intrinsic load (IL) related to the consult task itself, extraneous load (EL) related to distractions during the consult, and germane load (GL), the mental effort left over for learning after IL and EL are accounted for. IL, EL, and GL scores range from 4 to 16. Using two-tailed t tests, we compared mean IL, EL, GL, and total cognitive load (the sum of IL, EL, and GL) between the irAE group and a control group of fellows and residents who performed a variety of consults at five University of California hospitals during a 2018-2019 study (n = 142). Detecting a difference of 0.5 with a variance of 0.5 (calculated for the control group), 80% power, and 95% confidence required an irAE group sample size of 18. **Results:** Of 36 trainees contacted for the irAE group, 18 completed the CCL (50% response rate, 61% fellows, 39% residents). The irAE group and the control group (80% fellows, 17% residents, 3% not reported) spanned multiple specialties. Total cognitive load (p = 0.49) and IL (p = 0.95) did not differ. EL was significantly lower (8.4 vs 10.3, p = 0.002) and GL higher (11.9 vs 10.8, p = 0.04) in the irAE group. **Conclusions:** Trainees experienced similar cognitive load when performing irAE consults as compared to other consults, but the sources of cognitive load differed. Trainees performing irAE consults expended less mental effort on distractions (EL) and more on learning (GL) as compared to other consults. The consult task itself (IL) imposed a similar amount of cognitive load whether or not it was an irAE consult. Complex irAE cases did not overwhelm trainees or preclude learning; rather, trainees performing irAE consults exhibited a sharpened focus on the task at hand and extracted more learning than trainees performing other consults. Educators should foster trainee exposure to inpatient irAE consults to promote worthwhile learning. Research Sponsor: UCSF RAP Grant.

Multimodality, online oncology learning resources: Meeting residents where they are—A pilot to create a new oncology curriculum. *First Author: Jennifer King, Indiana University Simon Comprehensive Cancer Center, Indianapolis, IN*

Background: The Accreditation Council for Graduate Medical Education (ACGME) requires internal medicine residents to have access to different medical subspecialties, including hematology/oncology. While inpatient rotations in hematology/oncology have been associated with a decreased interest in a career in oncology, dedicated educational sessions have been shown to improve residents' interest in the field. In recognition of different learning styles and modalities and the need for asynchronous delivery, we aimed to build an effective curriculum for oncology learners using interactive, multimodality, online learning tools and resources. **Methods:** Using the Canvas online learning management system, individual learning modules covering major cancer types were created. Each learning module consisted of a pre-survey assessing the learners' evaluation of their own knowledge and comfort with the topic, a brief audio or video file covering high-yield information about the cancer type, interactive case-based questions reviewing and reinforcing the information, and a post-survey assessing the change in the learners' evaluation of their knowledge and comfort in clinical application of the information. The pre- and post-surveys were rated on a 5-point Likert scale. Median values and interquartile ranges are reported. A one-sided t-test was used to compare responses. **Results:** Two fully completed learning modules have been created. The lung cancer module included a high-yield, 10-minute voice-over PowerPoint presentation followed by interactive, case-based questions. The breast cancer module used a high-yield, 10-minute podcast with an accompanying handout for notes followed by case-based interactive questions. Seven learners have completed both pre- and post-survey responses for comparison. Two were completed by PGY1, 4 by PGY2, and 1 by a PGY3 resident. Median rating of the learners' knowledge of the specific cancer type increased from 2- Fair (1.5) on the pre-survey to 3- Neutral (1) after completing the learning module (p = 0.001). 100% of learners agreed or strongly agreed that their knowledge increased after completing the module. All 7 residents felt more comfortable with their clinical application of the cancer topic material after completing the module, median 2(1) on pre-survey vs. 3(0.5) on post-survey; p = 0.0004. **Conclusions:** The creation of online, multimodality learning resources has resulted in improvements in learners' perceived knowledge and comfort with clinical application of oncology topics. Using learning science principles, this pilot project serves as the foundation for further innovative and interactive educational resources and modules created for oncology learners. Research Sponsor: None.

The impact of oncology hospitalist utilization on resident education. *First Author: Sunil Mahesh Bhatt, Yale University, New Haven, CT*

Background: In multiple U.S. cancer centers, dedicated hospitalists provide inpatient care to admitted patients as medical oncologists focus increasingly on outpatient care. Hospitalist integration is most common in medical oncology. Despite increasing prevalence of this model, little is known about the impact of oncology hospitalists on medical education. **Methods:** Beginning 6/26/21, an oncology hospitalist service was established at Yale-New Haven Hospital's Smilow Cancer Center. In the first year of the program, the Hospitalist Service (HS) provided a dedicated oncology hospitalist as the attending of record on one of two inpatient teaching services. The hospitalist was supported by a consulting medical oncologist. The traditional service (TS), led by a rotating board-certified medical oncologist, remained unchanged. The study interval was the first 11 months of the program, 6/26/21-5/28/22. Residents were randomly assigned to either the HS or TS. A two-week period in January was excluded due to hospitalist redeployment during the COVID-19 Omicron surge. At the conclusion of the study, a survey was distributed to residents to evaluate the educational experience on TS and HS. Questions using five-point Likert scales were used to elicit information on the quality and content of formal teaching, goals of care discussions and mentorship. The Yale University IRB considered this study to be Quality Improvement and required no further action. The Mann-Whitney U test was used to assess for differences between the two groups with a p-value of < 0.05 indicating statistical significance. **Results:** Out of 84 eligible residents, 36 (43%) responded including 19 interns (53%), 11 second years (31%) and 6 third years (17%). There were 15 responses (42%) following an HS rotation and 18 following a TS rotation (50%). Three individuals (8%) did not complete the entire survey and were excluded. All residents rotating on HS reported that their attending was easily accessible by phone compared with only 69% of those on TS (p = 0.11). Sixty-nine percent of residents on HS compared to 73% on TS noted having adequate opportunities to lead GOC discussions (p = 0.87). Fifty-four percent of residents on HS felt they had sufficient support during family meetings compared to 69% on TS (p = 0.98). Compared with only 8% on HS, 22% of residents on TS felt there were sufficient opportunities for oncology-specific professional mentorship (p = 0.64). Satisfaction with the amount of informal teaching did not differ significantly between the teams (p = 0.62). Altogether, 87% of residents reported that the total amount of teaching led to insufficient time for patient care. **Conclusions:** This survey suggests hospitalists provide greater accessibility at the cost of decreased specialty-specific mentorship in oncology. Further work is needed to better understand challenges and opportunities surrounding oncology hospitalist integration in academic medicine. Research Sponsor: None.

Efficacy of a hematology/oncology podcast curriculum at a community-based internal medicine program. *First Author: Madeline Campbell Fitzpatrick, University of Tennessee, Nashville, TN*

Background: Medical podcasts have gained increasing popularity; however, there is limited evidence regarding their utility as an effective learning resource in Graduate Medical Education. Community-based internal medicine (IM) residents often have less exposure and education in hematology and oncology. To address this barrier, we developed a novel trainee-level hematology/oncology podcast curriculum to improve foundational knowledge for IM residents. **Methods:** A hematology/oncology podcast curriculum was implemented for IM residents at a community-based residency program in the 2022-2023 academic year. We developed ten episodes regarding workup and management of cytopenias, oncologic emergencies, and hematologic emergencies. We distributed anonymous pre- and post-intervention surveys to understand the impact of the podcast curriculum on a 5-point Likert scale on residents' self-perception of their knowledge. Two sample paired t-test was used to compare mean differences in surveys. **Results:** A total of 17/27 residents (63%) completed the pre-intervention survey, and 9/27 residents (33%) completed the post survey. The pre-survey was more heavily weighted towards residents earlier in their training with 53% PGY1s, 29% PGY2s, and 18% PGY3s. With 5 being entirely comfortable, there was a statistically significant increase in mean comfort level in the workup and management of various cytopenias (2.65 to 4.0, p < 0.01) and the management of oncologic emergencies (2.29 to 4.2, p < 0.01). Comfort level in the management of hematologic emergencies numerically improved from 3.35 to 3.57 but was not statistically significant. Most residents (90%) agreed or strongly agreed that the fundamentals of hematology/oncology were amenable to a podcast platform. Many residents found this modality convenient and performed other activities while listening to the podcast including driving (82%) and exercising (55%). The majority of residents who completed the post-survey (64%) reported that they will continue to use podcasts to supplement their medical education. **Conclusions:** Community-based IM residents' comfort with the field of hematology/oncology improved following the medical podcast educational intervention. Residents found the learning platform amenable to the fundamentals of hematology/oncology and will continue to utilize medical podcasts to supplement their education. Our successfully piloted podcast curriculum can be adapted to other IM programs to improve foundational knowledge in hematology/oncology. Research Sponsor: None.

Effects of a focused one-day interactive session on oncology research on medical students' interest in and understanding of oncology research. *First Author: Jawad Alrawabdeh, University of Jordan, Amman, Jordan*

Background: Literacy and proficiency in medical research are crucial for the development of modern-day physicians. The need to equip future doctors with sufficient research skills is particularly important in oncology research, as cancer is the second leading cause of death in Jordan and the first worldwide. With the support of the University of Jordan ASCO-OSIG, we explored the efficacy of an interactive research intervention in highlighting the foundations of cancer clinical, basic, and translational research among undergraduate medical students. **Methods:** We designed and implemented a one-day educational program about all types of cancer research: clinical, basic, and translational. To evaluate the impact of this ASCO-OSIG initiative, students were asked to voluntarily fill surveys before and after the event. Medical students in both their pre-clinical and clinical training were invited to attend the event. Prominent researchers and experts from multiple tertiary cancer centers in Jordan presented 50min lectures on the foundations of clinical, basic, and translational oncology research. **Results:** A total of 111 participants filled the pre and post surveys, of which ASCO-OSIG members comprised 28.8% of the sample. Approximately 51.4% of participants were pre-clinical students and 48.2% were in their clinical years. About half of our cohort (50.2%) have previously engaged in research projects with only 10.2% of participants have been involved in oncology research. The event was effective in promoting participants' understanding and familiarity of the fundamentals of clinical (p-value < 0.001), translational (p-value < 0.001), and basic oncology research (p-value < 0.001). Most students were satisfied with the event; with 55% and 32.4% of students reporting being very satisfied and extremely satisfied with the event, respectively. Moreover, 83.8% of participants felt that oncology research was easier to get into after the event. About 96% of students reported that they would recommend this event to a colleague. **Conclusions:** We demonstrated that a focused one-day cancer research conference had improved medical students' understanding towards oncology research. Due to its design simplicity, other global ASCO-OSIG coordinators could implement the model within their respective institutions. Future efforts should expand on the available research initiatives and include other medical schools worldwide. Research Sponsor: None.

A pilot curriculum to transition from 2D to 3D image-guided brachytherapy: A preliminary needs assessment. *First Author: Joy Ogunmuyiwa, New York Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY*

Background: Gynecologic cancers are one of the leading causes of death globally with a disproportionate burden of disease found in low to middle income countries (LMIC). Brachytherapy is often a necessary component in treatment management as it can deliver a high dose of radiation to the tumor while employing a steep dose fall off that spares the adjacent organs at risk. With 3D image guided brachytherapy (3D-IGBT), treatment planning utilizes volumetric images with the target volume and organs at risk contoured, reducing toxicity and improving outcomes when compared to 2D planar imaging. Despite this advantage, only a limited number of LMIC centers perform 3D-IGBT. Transitioning to 3D-IGBT requires considerable planning, resources, and training. The development of a multidisciplinary, computer-based training program to facilitate the transition to 3D-IGBT was identified as a priority of multiple Radiation Oncology departments in Nigeria. The aim of this preliminary needs assessment was to identify the necessary resources and anticipated barriers to development of a pilot training curriculum for the transition to 3D-IGBT. **Methods:** An anonymous, 16-question online survey was distributed to clinicians, physicists, radiation therapists, and staff within a Radiation Oncology department of a teaching hospital in Lagos, Nigeria. **Results:** In January 2023, 53 respondents completed the survey. Of the respondents, 36.5% were female and 63.5% were male. The average age was 37.5 (SD = 7.8). Clinical experience ranged from < 5 years (52.6%), 6-10 years (9.4%), to > 10 years (30.2%). Respondents included radiation therapists (28.8%), clinicians (27%), nurses (23.1%), and physicists (15.4%). Multiple barriers to implementation of 3D-IGBT were identified including lack of training (79.2%) or experience (58.5%), lack of financial investment (50.9%), and anticipated repair/replacement of equipment (41.5%). A majority of respondents identified staff training/education (66%) as critical to delivering 3D-IGBT. When asked about the curriculum components needed, most respondents believed that it should include plan review (96.2%), contour review (94.3%), and peer review of clinical cases (92.5%). **Conclusions:** Various areas of potential need were identified through this preliminary needs assessment, most notably, staff training. These findings suggest that there is an unmet need to further develop and implement a structured didactic and skills-based curriculum to transition from 2D to 3D-IGBT at these institutions. Identified focus areas including contour, peer, and plan review will help guide the refinement of this curriculum. These findings are an important first step in delivery of safe and efficacious 3D-IGBT in an LMIC. Research Sponsor: None.

Early introduction to clinical radiation oncology through a self-directed competency-based medical student curriculum. *First Author: Cheryl Claunch, Baylor College of Medicine, Houston, TX*

Background: Specialty training is not traditionally incorporated into standard medical education and there is a deficiency in exposure to Radiation Oncology for "last minute" interested candidates, particularly from underrepresented backgrounds. Therefore, we implemented MERA0-200, an introductory 2-week in-person and virtual medical education curriculum without clinical prerequisites to facilitate early introduction to the field of Radiation Oncology and report its effect on student comfort and familiarity with radiation planning and contouring. **Methods:** Clinical students were enrolled in a 2-week elective without clinical prerequisites that integrated both clinical activities and self-directed learning through virtual contouring modules. The virtual curriculum was designed around three modules available on EduCase. A survey was conducted after completion of the modules that solicited self-identifying information and to assess their efficacy in increasing understanding of basic contouring skills. Paired t-tests were used to compare pre- and post-elective assessment results. **Results:** Twenty-three total students have completed MERA0-200 from Fall 2020 to Spring 2023. Of those, 15 submitted the survey. Eight (53%) students did not answer self-identifying information such as gender, race, ethnicity, or country of origin. Four (27%) students identified as Asian and 3 (20%) as white. No students identified as Hispanic, Latino or Spanish origin. Seven (46%) students identified as having USA as country of origin. Seven (47%) students reported interest in radiation oncology, medical oncology or surgical oncology. Three (20%) students were MS2, 7 (47%) were MS3, and 5 (33%) were MS4. Overall, there was a significant increase in comfort level using radiation planning software (p = 1.1e-4) as well as ability to find relevant contouring references (p = 4.2e-5). Knowledge of the anatomy and contouring principles also improved for the three modules: eye and brain (p = 2.8e-7), high grade glioma (3.2e-6), and head and neck nodal stations (4.5e-6). CNS module difficulty on a scale of 1-10 had a median difficulty score of 7 (range 3-8) and head and neck module difficulty was a median of 7 (range 3-10). **Conclusions:** Implementation of MERA0-200 improved medical student exposure to the field of Radiation Oncology and improved medical student comfort and familiarity with radiation planning and across all disease sites covered. More outreach work needs to be done to facilitate inclusion of minority student populations and students from underrepresented backgrounds. Early introduction at the medical student level could be a pathway to improve disparity in the field of Radiation Oncology. Research Sponsor: None.

Web-based patient educational material on chimeric antigen receptor T-cell therapy: Quantitative assessment of readability. *First Author: Rahul Kumar Thakur, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY*

Background: Chimeric antigen receptor (CAR) T-cell therapy is another paradigm-shifting advancement for hematologic malignancies, creating unprecedented treatment options. However, there is still a lack of knowledge and understanding among patients regarding this novel therapy. Most patients turn to online resources, ranging from social media to federal websites, to gather health information to supplement decision-making. Given that the average American adult reads between the sixth- and eighth-grade levels, national organizations recommend that patient resources be written at the sixth-grade level or below. The purpose of this study was to evaluate web-based patient educational material on CAR-T cell therapy resources using measures of readability and compare it to national guidelines. **Methods:** Online patient information on CAR-T cell therapy from the top 20 U.S. Cancer center as per US news ranking was collected. We analyzed the content by six of the most common readability tests- Flesch Reading Ease score (FRE), Gunning Fog (GF), Flesch-Kincaid Grade Level (FKGL), Coleman-Liau Index (CLI), Simple Measure of Gobbledygook (SMOG) Index, and the Automated Readability Index (ARI). The text from each article was carefully reviewed and analyzed using the software Readable, and the readability scores with standard deviation (SD) were obtained. **Results:** The mean score FRE score was 48.5 (SD: 6.7), which corresponds to college level and is difficult to read. The mean GF score was 8.7(SD: 1.5), which represents the writing of an 8th grader. The FKGL score was 8.6 (SD: 1.1), which represents a level of 8th grade or above. The mean CLI score was 11.5(SD: 1.3), which is the text level for high school juniors. The mean SMOG index was 10.9 (SD: 1), which is the level of a 12th grader. The ARI score was 7.8 (SD: 1.3), indicating a 7th-grade level. **Conclusions:** Overall, web-based CAR-T cell therapy patient educational materials scored poorly and does not meet the national recommendations. Authors of patient resources should incorporate readability criteria and prompt a revision or creation of new educational materials including videos and audio to support general patient understanding. By making CAR-T therapy information easily understandable, internet users can be better informed about their treatment decisions. Research Sponsor: None.

Empowering self-advocacy for breast health: A successful educational campaign on breast cancer risk and screening recommendations. *First Author: Matthew Culbert, Department of Radiation Oncology, University of Florida College of Medicine, Gainesville, FL*

Background: The purpose was to develop and distribute an educational campaign on breast cancer risk and screening recommendations to empower women, men, and transgender individuals to take charge of their breast health. Identifying individuals at high risk for developing breast cancer through educational campaigns can lead to earlier detection and improved health outcomes. It was hypothesized that the development of a multi-platform educational campaign including televised ads, website, and mobile applications (apps), would result in a broad reach and accessibility of breast cancer risk and screening recommendations. **Methods:** The campaign ran from 10/1/22 – 12/2/22 and included a variety of mediums, such as televised ads, website, and mobile apps for iOS and Android devices, all of which were available in English and Spanish. An educational video series was developed to raise awareness about the updated guidelines for breast cancer screening from the American College of Radiology (ACR). Videos focused on the importance of screening for women with a high risk of breast cancer and transgender individuals taking hormone therapy. To complement the televised video, case-based teaching illustrations were created for the website and apps. Resources included screening recommendations, local resources for breast cancer screening and foundations for financial assistance. These materials could be accessed at the website <https://myriskbreastcancer.com>. The website and mobile apps featured a risk calculator developed using the GAIL model from SAS, coded in the Dart programming language to ensure compatibility and all user inputs were stored in a secure Firebase database. To reach a wider audience, responsive social media ads were developed and distributed through targeted Google Ads campaign. Analytics were collected and analyzed using Google Analytics and user inputs from the mobile application to assess the campaign's effectiveness. **Results:** Televised ads reached a total of 673,920 impressions over 142 educational video sessions. Google display ads had 152,672 impressions and 462 click-throughs with an audience of 49.2% female and 50.8% male. The mobile application was downloaded 2,030 times on iOS and 722 times on Android, and installed in 131 countries. The website saw 930 impressions and 637 users completed the online calculator, with 72 identified as high risk at time of initial data collection on 12/1/22. **Conclusions:** The educational campaign was successful in reaching > 500,000 impressions within two months of release, sharing knowledge about breast cancer risk and screening recommendations across all gender types. Use of multiple platforms, including television, social media, and mobile apps, allowed for broad reach and accessibility nationally and internationally, including the identification of 72 individuals at high risk for developing breast cancer. Clinicians' experiences with patients with cancer or their families who endorse medical misinformation. *First Author: Amitabha Palmer, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Medical misinformation causes delays in cancer care, forgoing of treatment, economic harms, potentially toxic effects, and harmful medical interactions with standard curative treatments. Previous literature has examined patients' traits and beliefs. However, effectively caring for patients with cancer who endorse medical misinformation also requires better understanding the experiences, competencies, and concerns of the clinicians who treat them. We conducted an IRB approved study of physicians and advanced practice providers at a large cancer center. **Methods:** We surveyed clinicians about following themes: i) prevalence of misinformation, ii) attitudes towards patients endorsing misinformation, iii) strategies and competence, iv) resources to help them successfully address patients. **Results:** 87 clinicians responded to the survey. The median response was 15% of patients endorse claims that are false or misleading about standard-of-care cancer treatments and 20% endorse claims that overstate the benefits or understate the risks of unconventional treatments. The most common misinformation concerned herbs and supplements. Clinicians ranked provides hope and poor medical literacy as the top reasons for why their patients endorse medical misinformation followed by distrust in conventional medicine, cultural factors, and religiosity. The primary attitude clinicians project to patients when they request unconventional treatments was Openness/Equanimity (75.6%), Curiosity (43.9%), Skepticism (18.3%), Disdain/Disappointment (0, 0.0%), Other (6.1%). The primary internal attitude clinicians experienced in these situations was Openness/Equanimity (25.6%), Skepticism (57.3%), Curiosity (40.2%), Disdain/Disappointment (22.0%), Other (6, 7.3%). When asked if they'd be open to a patient using a harmless unconventional treatment that had no evidence of therapeutic benefit, 17.1% said yes, 17.1% said no, and 65.9% said it depends. Correcting misinformation is difficult: 38.2% report success rates below 60% for correcting misinformation and 68.5% report success rates below 80%. Several factors contributed to low success: Only 26% said that they have enough time to adequately address patients who endorse misinformation. Moreover, 46.9% report insufficient resources, 65% claim insufficient training, and 51.3% claim insufficient institutional support. **Conclusions:** Many cancer care providers feel insufficiently trained and supported to address patients who endorse medical misinformation. Cancer care institutions must develop training and resources to help clinicians effectively address patients who endorse misinformation about their care. Research Sponsor: None.

Oral Abstract Session

Efficacy and safety of nivolumab and trabectedin in pretreated patients with advanced soft tissue sarcomas (STS): Results of a phase II trial of the German Interdisciplinary Sarcoma Group (GISG-15, NitraSarc). *First Author: Peter Reichardt, HELIOS Klinikum Berlin-Buch, Klinik für Interdisziplinäre Onkologie, Sarkomzentrum Berlin-Brandenburg, Berlin, Germany*

Background: Programmed death-1 (PD-1) inhibitors alone have modest activity in the treatment of most STS. A possible synergistic effect of combined trabectedin with PD-1 inhibitor nivolumab has been previously reported. Herein we evaluated the efficacy and safety of trabectedin plus nivolumab as a second-line treatment of patients with anthracycline-pretreated metastatic or inoperable STS. **Methods:** The prospective, explorative, two-group, non-randomized phase II NITraSarc trial enrolled patients with advanced lipo- or leiomyosarcomas (Group A; GA) or with non-L-sarcomas (Group B; GB). Patients were initially treated with 3 cycles of trabectedin 1.5 mg/m², followed by the combination of trabectedin 1.5 mg/m² plus nivolumab 240 mg in a so-called "late combination cohort" (LCC) for up to 16 cycles. After positive results of a preplanned interim analysis, patients received the combination therapy already starting from Cycle 2 in an "early combination cohort" (ECC). Primary efficacy endpoint was progression-free survival rate after 6 months (PFSR6) according to RECIST v.1.1. A central pathological assessment (CPA) was done from tumor specimen from all patients. Updated results according to cpa are presented. **Results:** A total of 92 patients were recruited in the trial: 43 patients in GA and 49 in GB. In GA, 28 patients (63%) had leiomyosarcoma and 15 (37%) had liposarcoma. Most common sarcoma types in GB were pleomorphic (n = 12), spindle cell (n = 11), fibromyxoid (n = 6), synovial (n = 5) and epithelial (n = 4) sarcoma. After median follow up of 16.6 months, overall PFSR6 as per CPA in GA was 47.6% (60% in LCC vs 36.4% in ECC) and 14.6% in GB. Median PFS was numerically higher in GA compared to GB (5.5 vs 2.3 months) and even longer in LCC vs ECC (9.8 vs 4.4 months). Median overall survival was more than three times longer in GA vs GB (18.7 vs 5.6 months) and, again, longer in LCC vs ECC (24.6 vs 13.9 months). Safety of trabectedin and nivolumab was consistent with the safety profiles of each drug alone with no relevant new findings for the combination or between LCC and ECC. **Conclusions:** Our study confirms the activity of trabectedin plus nivolumab, particularly in patients with lipo- or leiomyosarcomas. There is a significant difference between ECC and LCC in terms of PFSR6, PFS and OS. The results in patients with non-L-sarcomas do not justify further investigation of this combination. Clinical trial information: NCT03590210. Research Sponsor: University Medicine Greifswald, Germany; PharmaMar, Bristol-Myers Squibb.

Oral Abstract Session

ImmunoSarc2: A Spanish Sarcoma Group (GEIS) phase Ib trial of doxorubicin and dacarbazine plus nivolumab in first line treatment of advanced leiomyosarcoma. *First Author: Javier Martin Broto, Medical Oncology Department, Fundacion Jimenez Diaz University Hospital, Madrid, Spain, Institute of Biomedicine of Seville, University of Seville, Seville, Spain*

Background: The immunogenic death caused by certain chemotherapy agents consists of molecular changes in tumor dying cells that stimulate immunogenicity and enhance antitumor effects. Doxorubicin is one validated drug related to immunogenic death, mainly through calreticulin membrane translocation that elicits immunogenic signals as phagocytosis by dendritic cells. Doxorubicin plus pembrolizumab was explored in a phase I/II trial treating patients with metastatic/unresectable sarcomas, achieving 22% PR, 59% SD, and 19% PD, with mPFS of 8.1 months superior to historical controls. We hypothesized that the addition of an anti-PD1 (nivolumab) would increase the antitumor activity of commonly used upfront polychemotherapy in leiomyosarcoma (LMS) of doxorubicin plus dacarbazine. We present here the phase Ib, cohort 7b of ImmunoSarc2 trial. **Methods:** Adult patients (pts), with ECOG 0-1, naïve of previous anthracycline-containing treatments and with centrally confirmed diagnosis of advanced/metastatic leiomyosarcoma (LMS) were eligible. Initial dose level 0 (LO) was defined as doxorubicin (DOX) 75 mg/m²/d 20 min on D1 followed by dacarbazine (DAC) 400 mg/m²/d 60 min on D1 and 2, plus nivolumab (NIV) 360 mg on D2 after DAC Q3W with GCSF support. This combo would be given up to 6 courses of 21-day cycles, followed by 1-year NIV maintenance. A -1 dose level (L-1) was defined with the same regimen but with NIV 240 mg. A classic 3+3 phase 1 design was used to determine the MTD based on DLTs (main endpoint) observed during the first 21-day cycle. The cohort was foreseen to be extended with the RP2D up to 20 evaluable patients. Secondary endpoints included ORR and safety profile among others. **Results:** Between January 2022 and February 2023, 20 pts (M/F 6/14), ECOG 0/1 (15/5), with median age 54 years (31-72) were enrolled. All patients were treated with the initial LO scheme and no DLTs were observed being LO the RP2D. Grade 3-4 toxicities were neutropenia (20%), anemia (10%), febrile neutropenia, asthenia, and GGT increased (5% each). Four pts are not evaluable for efficacy (1 due to uncompliant dosing and 3 for not reaching the first tumor assessment yet). Of 16 efficacy-evaluable pts, RECIST ORR according to local clinical site assessment was 9 PR (56.2%), 6 SD (37.5%), and 1 PD (6.3%) (2 SD cases had tumor size reductions > 20%). Five pts ended treatment due to progression (4 radiological, 1 clinical) and 15 pts remain under the trial therapy. mPFS for evaluable patients was 8.67 months (95% CI: 7.96-9.37) with a median follow-up of 8 months (2-12). **Conclusions:** DOX 75 mg/m²/d on D1 followed by DAC 400 mg/m²/d on D1 and 2, plus NIV 360 mg on D2 after DAC Q3W, followed by 1-year NIV maintenance is a feasible and well-tolerated scheme. Clinical activity is encouraging improving historical efficacy outcomes in first line of advanced LMS, which deserves further testing in phase II trials. Clinical trial information: NCT03277924. Research Sponsor: Drug supply, shipping and insurances were provided by BMS and Pfizer. Operational expenses were in charge of GEIS group.

Oral Abstract Session

A single-arm, open-label phase 2 trial of doxorubicin plus zalifrelimab, a CTLA-4 inhibitor, with balstilimab, a PD-1 inhibitor, in patients with advanced/metastatic soft tissue sarcomas. *First Author: Breelyn A. Wilky, University of Colorado Anschutz Medical Campus, Aurora, CO*

Background: Doxorubicin (DOX) is the standard of care for unresectable soft tissue sarcomas (STS). DOX induces immunogenic cell death in numerous preclinical models. Immune checkpoint inhibitors (ICIs) including antibodies (ab) to PD-1 and CTLA-4 have shown modest activity, but most STS are immune "cold" tumors and do not respond. We hypothesized that concurrent DOX would improve immunogenicity of STS and boost efficacy of ICIs, including anti-CTLA-4 ab zalifrelimab (ZAL) and anti-PD-1 ab balstilimab (BAL). **Methods:** We conducted a single arm Phase 2 trial of combination DOX/ZAL/BAL for patients (pts) with advanced/metastatic STS in the 1st/2nd treatment lines without prior DOX or ICI (NCT04028063). The study was a Simon minimax 2-stage design to accrue 28 pts evaluable for primary endpoint of progression-free survival rate at 6 months (PFS_{6mo}) by RECIST 1.1. We aimed to improve PFS_{6mo} by 20% with DOX/ZAL/BAL over null rate of 43.4% based on average PFS of 2 prior DOX monotherapy trials. Secondary endpoints were objective response rate (ORR), disease control rate (DCR), overall survival (OS), duration of response (DOR), and adverse events (AEs). All pts received up to 6 DOX cycles with concurrent ZAL/BAL; pts on stage 1 began DOX at cycle 2 with ZAL/BAL at cycle 1, pts on stage 2 began DOX/ZAL/BAL at cycle 1. Imaging was obtained prior to the first dose of DOX (baseline), and then every 6 weeks (wks) to 6 mo, and thereafter every 9 wks. Tumor biopsies/peripheral blood were obtained at baseline, on-treatment, and progression for immune profiling. **Results:** 35 patients were accrued as of 1/25/23. 25 pts are currently evaluable for primary endpoint of PFS_{6mo} and 28 for efficacy (at least one post-treatment scan). PFS_{6mo} is estimated at 52% (95%CI 31-72), with mPFS of 25.6 wks (24.0-44.9). ORR was 36% (19-56), and DCR was 86% (67-96). Median DOR was 12.8 wks (range 6-105). Most pts with PR who progressed did so on BAL after DOX completion. Responses were observed in pts with intimal sarcoma, angiosarcoma, MPNST, LPS, LMS, endometrial stromal sarcoma, UPS, and sclerosing epithelioid fibrosarcoma. Improved outcomes were observed in stage 1 pts compared to stage 2 pts, including PFS_{6mo} (56.3% v. 25.0%), mPFS (31.7 v. 25.3 wks), ORR (56% v. 8.3%), and DCR (94% v. 75%). Toxicity was as expected with grade 3/4 TRAEs in 48% of 31 evaluable pts, primarily DOX-related hematologic AEs, and immune-related AEs requiring steroids in 19% of pts. **Conclusions:** Combination DOX/BAL/ZAL led to meaningful efficacy, including favorable PFS_{6mo} and responses in several STS subtypes unlikely to respond to DOX or ICI monotherapy. Further investigation is required to determine if the stage 1 priming dose of ZAL/BAL prior to DOX improved clinical outcomes. An ongoing cohort is exploring a next-generation CTLA-4 inhibitor, botensilimab in combination with DOX +/- BAL. Clinical trial information: NCT04028063. Research Sponsor: Agenus Bio; Cancer League of Colorado; University of Colorado Cancer Center.

Oral Abstract Session

A multicenter phase II study of cabozantinib + nivolumab for patients (pts) with advanced angiosarcoma (AS) previously treated with a taxane (Alliance A091902). *First Author: Juneko E. Grilley-Olson, Duke Cancer Institute, Duke University, Durham, NC*

Background: Collectively, sarcomas have demonstrated less benefit from immunotherapy than many other cancers. Pts with AS have limited options, particularly after taxane chemotherapy. Although AS is a vascular malignancy, anti-VEGF therapies have minimal monotherapy clinical activity. Some cutaneous AS have a high UV damage signature, but other AS often do not. Cabozantinib (C) is a multitargeted inhibitor that may alter PD-1 expression in regulatory T cells, promoting an immune permissive environment when combined with nivolumab (N), a fully human anti PD-1 MAB. We hypothesize that the combination of C+N will be an effective therapy in AS, across AS subtypes. **Methods:** This open-label multi-arm study enrolled pts with locally advanced/metastatic AS. Arm 3, reported here, enrolled pts who had received a taxane for AS (including adjuvant) prior to study enrollment. Pts were not restricted on number of prior lines, but prior anti-VEGF and immunotherapies were not allowed. Eligible pts received C (40 mg po daily) with N (480 mg IV every 4 wks). Treatment was permitted beyond progressive disease (PD) in the 1st 12 wks (4 wk confirmatory scan), but PD response was censored at 12 wks. The Simon 2-stage design (null and alternative overall response rate (ORR) were 10% and 35%, respectively) required ≥1 confirmed response in 9 pts in the 1st stage, and >4 of 18 pts (91.4% power, alpha 0.095) for the primary endpoint. Secondary endpoints were adverse events (AEs), progression free, overall survival (PFS, OS), and pt-reported outcomes (PRO). **Results:** 21 eligible pts [median age 66 yrs (32-92), 10 female] received ≥1 dose of C+N. Primary disease sites: 12 cutaneous (scalp/face), 1 liver, 2 breast, 6 other. All pts received prior taxanes (11/21 = 52% as adjuvant therapy) and 5/21 (24%) had also received prior anthracycline (all relapsed AS). Primary endpoint: 13 of the first 18 evaluable patients (72%) experienced objective response (OR, 95%CI: 47%-90%). After a median follow-up of 11.2 mo, 13 of 21 pts achieved OR (11 partial response, 2 complete), for ORR 62% (95%CI: 38-82%). Responses were seen in pts with primary cutaneous disease 7/12 (58%) and noncutaneous disease 6/9 (67%). Median PFS was 9.6 mo (5.3-NR), and OS 20.5 mo (14.4-NR). Off treatment reasons include: progressive disease (14), comorbid condition unrelated to AS or study (1); 6 pts remain on study. Grade (G) 3 hypertension was the only possibly treatment related AE (TRAE) occurring in 310%. No G 4/5 TRAE were reported. **Conclusions:** C + N demonstrated significant antitumor activity in taxane-pretreated AS and was well tolerated without new safety concerns. Activity of the combination was seen across AS subtypes. PRO and exploratory analyses are ongoing. Support: U10CA180821, U10CA180882, U24 CA196171, U10CA180820; <https://acknowledgments.alliancefound.org>. U10CA180868; U10CA180888. NCT04339738. Clinical trial information: NCT04339738. Research Sponsor: U.S. National Institutes of Health.

Oral Abstract Session

Randomized phase II trial of cabozantinib combined with PD-1 and CTLA-4 inhibition versus cabozantinib in metastatic soft tissue sarcoma. *First Author: Brian Andrew Van Tine, Washington University Siteman Cancer Center, St. Louis, MO*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2023, issue of the *Journal of Clinical Oncology*.

11505

Oral Abstract Session

A phase II study of cabozantinib and temozolomide in patients with unresectable or metastatic leiomyosarcoma and other soft tissue sarcomas. *First Author: Mark Agulnik, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Potentiation of chemotherapy, without increased toxicity, to improve outcome is an area of interest. Preclinical and clinical evidence shows simultaneous utilization of antiangiogenic agents and chemotherapy have a synergistic effect. We hypothesized that the dual targeting of VEGF and c-MET pathways with cabozantinib (CAB) would result in clinical benefit for patients with soft tissue sarcoma (STS) when combined with temozolomide (TMZ), an alkylating agent. Utilization of CAB/TMZ is anticipated to produce a synergistic antitumor effect worthwhile to explore in STS. **Methods:** A multicenter phase II study of CAB/TMZ in patients with unresectable/metastatic leiomyosarcoma (LMS) and other STS was conducted by the Midwest Sarcoma Trials Partnership. Age ≥ 18 , adequate performance status, organ function, measurable disease (RECIST 1.1), and 0-5 prior chemotherapy regimens were required. CAB 40 mg PO daily plus TMZ 150-200 mg/m² PO 1-5 days were given in 28-day cycles until disease progression or unacceptable toxicity. Patients enrolled in 2 cohorts: 1. Uterine and non-uterine LMS 2. Other STS. The first 14 subjects to be enrolled in the study in either cohort served as a safety lead in. The primary endpoint was progression-free rate (PFR) at 12 weeks for cohort 1. Secondary endpoints include overall response rate (ORR), clinical benefit rate, median progression-free survival (PFS), overall survival, and safety and tolerability. The exploratory endpoint was to estimate the correlation of PFR and OS to expression levels of VEGF, amongst others. A Simon 2-stage design was used. **Results:** A total of 42 patients were enrolled in Cohort 1, and 30 in Cohort 2, across 5 sites. For Cohort 1, median age was 59 years (range 35-86), 85.7% were non-Hispanic, 73.8% were female, 61.9% had ECOG of 0. The PFR at 12 weeks was 45.9% (for 37 evaluable patient) with a median PFS of 6.4 months (95% CI 4.6-6.7). Five PR were observed for an ORR of 13.5%. For Cohort 2, median age was 63 (20-86), 83.3% were non-Hispanic, 36.7% were female, 53.3% had ECOG of 0. The PFR at 12 weeks was 50% (for 28 evaluable patients) with a median PFS of 3.2 months (95% CI 1.4-4.6). One PR was observed. Reported grade 3-4 adverse events attributed to one or both intervention drugs affecting $\geq 10\%$ of patients (n = 70) included hypertension (10%), decreased neutrophils (18.7%), decreased platelets (31%). **Conclusions:** The combination therapy of CAB/TMZ in patients with unresectable or metastatic LMS exceeded its primary endpoint with a PFR at 12 weeks $> 39\%$. The PFS of 6.4 months in Cohort 1 exceeds rates achieved with second line tyrosine kinase inhibitors (TKIs) and alkylators in LMS patients. Treatment was feasible and did not reveal any previously unreported toxicities. The combination with CAB with TMZ demonstrated meaningful clinical benefit and is worth further exploration in LMS. Clinical trial information: NCT04200443. Research Sponsor: Exelixis.

Oral Abstract Session

A phase III randomized trial of neo-adjuvant chemotherapy in high-risk soft tissue sarcoma (ISG-STIS 1001): Feasibility and activity of concurrent chemotherapy and radiation therapy. *First Author: Elena Palassini, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: The ISG-STIS 1001 was an international, randomized, phase III, clinical trial for localized, high-risk, soft tissue sarcoma comparing neoadjuvant chemotherapy (ChT) with a standard regimen of epirubicin plus ifosfamide (EI) versus an histology-tailored regimen (HT) in five histologic types, within the context of an integrated multimodality strategy. In addition, in this study, a parallel group of patients (pts) was not randomized but just registered and treated with EI. Radiation-therapy (RT) could be delivered either pre-operatively (concurrent to ChT) or post-operatively, according to clinical judgement. Final results of ISG-STIS 1001, published in 2020, showed a benefit in favor of EI, in terms of overall survival, in comparison to HT. Herein, we analyzed tolerability and activity of ChT with EI either in the standard arm of the trial or in the parallel group, whether alone and concurrent to RT. **Methods:** The EI regimen was made up of epirubicin 120 mg/m² plus ifosfamide 9 g/m². RT was delivered at a dose of 44-50 Gy pre-operatively or 60-66 Gy post-operatively. In the current analysis, toxicities related to EI were analyzed separately in the group receiving concurrent pre-operative ChT and RT and in the group treated with pre-operative ChT alone and receiving RT post-operatively. Surgical complications and radiological response according to RECIST were analyzed in the above mentioned two groups. Data on ChT dose-intensity will be provided. **Results:** Among the 548 pts (287 randomized and 261 registered) included in the ISG-STIS 1001, 289 pts were considered for the current analyses (111 pts randomized in the EI arm and 178 pts just registered). 146 pts were treated with pre-operative RT and 143 with post-operative RT. In regard to toxicities, no statistically significant differences were found between pts treated with pre-operative concurrent ChT and RT and pts treated with pre-operative ChT alone. When surgical post-operative complications were considered, a higher number of wound dehiscence (9% vs 3.5%, respectively, p = 0.053) and seroma (10.5% vs 3%, respectively, p = 0.009) were observed in pts treated with pre-operative concurrent ChT and RT compared to pts treated with pre-operative ChT alone. Finally, a statistically significant association between RECIST response and pre-operative RT was found (p = 0.041), RECIST partial responses (PR) being 19% and 10% in pts receiving concurrent pre-operative ChT plus RT and in pts treated with pre-operative ChT alone, respectively. **Conclusions:** The concurrent administration of EI and RT was confirmed to be feasible and safe, resulting in an increased number of PR. Also given the final results of this randomized trial, favoring the EI arm, this combination may help when tumors are of borderline resectability or function preservation is a goal. Research Sponsor: None.

Oral Abstract Session

Efficacy of combination lurbinectedin (LURBI) + doxorubicin (DOX) from the phase 1B soft-tissue sarcoma (STS) lead-in to a randomized phase 2 trial in leiomyosarcoma (LMS). *First Author: Gregory Michael Cote, MGH Cancer Center, Boston, MA*

Background: Single agent or combination chemotherapy, typically Dox- or gemcitabine-based, are standard 1st- and 2nd-line therapies in patients (pts) with metastatic LMS; however, objective response rates (ORR), progression-free, and overall survival (PFS/OS) remain inadequate. Lurbi (PharmaMar S.A. / Jazz Pharmaceuticals) binds to DNA inhibiting transcription and inducing double strand breaks leading to apoptosis and delaying S/G2 progression. In a prior pilot study, we showed Lurbi+Dox is well-tolerated, with signs of activity, particularly in LMS. We designed this phase 1b to optimize dosing to lead into a randomized (1:1) phase 2 trial of Dox+Lurbi in anthracycline-naïve LMS. Herein we provide updated efficacy and tolerability data for this Phase 1b cohort. **Methods:** Pts > 18 yrs with locally advanced/metastatic, unresectable non-GIST STS (Phase 1b only) w/o prior anthracycline or Lurbi/trabectedin, ECOG PS < 3 , RECIST 1.1 measurable, and normal organ function were eligible. The phase 1b followed a 3+3 design. Dosing included fixed Lurbi (3.2 mg/m² d1) with two Dox dose levels (DL; DL1: 25 mg/m² d1; DL2 25 mg/m² d1+8). All pts received GCSF prophylaxis. Tumor assessments were every 2 cycles. DL1 was chosen as RP2D and the phase 2 trial began accrual in Aug 2022 aiming to enroll 50 LMS pts randomized 1:1 (stratified by uterine LMS [uLMS]) v. other LMS) with PFS as primary endpoint. Pts progressing on Dox are allowed to cross to Lurbi monotherapy. **Results:** 10 patients were enrolled in Phase 1b. Histologies included 5 LMS (4 uLMS) and 1 each of myxofibrosarcoma (myxFS), undifferentiated pleomorphic sarcoma (UPS), dedifferentiated liposarcoma (DDLPS), endometrial stromal sarcoma (ESS), and solitary fibrous tumor (SFT). With a median follow-up of 344 days, 5/10 pts remain on treatment with median PFS of 357 days (95%CI 175-ND). 6 pts demonstrated partial response (PR; 5 confirmed), 3 with stable disease (SD), and 1 with progressive disease (PD, Table). Median time to PR was 81 days (range 46-207). Duration of response was over 132 days in all responders with 3 still on treatment. Treatment-related AEs were typical for Dox/Lurbi, including nausea, fatigue, and reversible LFT elevations/cytopenias. Updated safety and response data will be provided at the time of the meeting. **Conclusions:** Lurbi+Dox is well-tolerated with efficacy in STS including 6/10 pts achieving PR, 9/10 pts staying on treatment for > 120 d, and 6/10 pts > 200 d. The randomized phase 2 study is currently enrolling. Clinical trial information: NCT05099666. Research Sponsor: Jazz Pharmaceuticals.

Oral Abstract Session

Safety and clinical activity of TTI-621 in combination with doxorubicin in patients with unresectable or metastatic high-grade leiomyosarcoma: Results from the low-dose expansion cohort. *First Author: Sujana Movva, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: TTI-621 is a recombinant fusion protein combining the Fc region of human IgG1 with a fragment of human SIRP α , designed as a decoy receptor for CD47 on tumor cells to interrupt CD47-SIRP α signaling and promote macrophage-mediated phagocytosis of tumor cells as well as activation of NK cells. Preclinical studies suggest TTI-621 may enhance the response to doxorubicin in macrophage-rich tumors that express CD47, such as leiomyosarcoma (LMS). A phase 1/2 dose escalation study with high- and low-dose expansion cohorts evaluating TTI-621 + doxorubicin in patients (pts) with advanced LMS is ongoing (NCT04996004); results from the low-dose expansion cohort are presented. **Methods:** This open-label study enrolled anthracycline-naïve pts aged ≥ 18 y with evaluable unresectable or metastatic high-grade LMS and ≤ 1 prior line of therapy for advanced disease. Pts in the low-dose expansion cohort received TTI-621 0.2 mg/kg on Days 1 and 8 in combination with doxorubicin 75 mg/m² on Day 1 of 21-day cycles for a maximum 6 cycles, followed by TTI-621 monotherapy on Days 1 and 15 of 28-day cycles until objective disease progression. Primary objectives for the expansion phase were evaluation of safety and investigation of clinical activity via assessment of overall response and clinical benefit rates as defined by RECIST v1.1 criteria. **Results:** At data cut-off (Oct 3, 2022), 23 pts were evaluable for safety and 20 for clinical response. In the safety population, 39% had received prior treatment for advanced disease. Two pts (9%) experienced Grade ≥ 3 AE assessed as related to TTI-621 treatment: pancreatitis (n = 1, 4%) and platelet count decreased (n = 1, 4%). Seven pts (30%) experienced Grade ≥ 3 AE related to the combination of TTI-621 and doxorubicin, including two pts (9%) each with platelet count decreased and white blood cell count decreased and three pts (13%) with neutrophil count decreased. Grade ≥ 3 doxorubicin-related AEs were more common (n = 17, 74%); most frequent were neutrophil count decreased (n = 8; 35%), white blood cell count decreased (n = 7; 30%), and neutropenia (n = 6; 26%). One pt experienced an infusion-related reaction (Grade 1 chills) assessed as related to TTI-621. No pts attained complete response, but one pt had a complete resolution of all target lesions. Five pts (25%) attained partial response for an overall response rate of 25%; 11 pts (55%) attained stable disease for a disease control rate of 80%. **Conclusions:** Addition of TTI-621 to doxorubicin showed promising clinical activity and a favorable safety profile among pts with advanced LMS, including those with prolonged exposure to TTI-621 (> 360 d). Clinical trial information: NCT04996004. Research Sponsor: Pfizer.

Clinical Science Symposium

The clinical value of tumor-informed minimal residual disease detection in sarcoma. *First Author: Yiwei Fu, Department of Musculoskeletal Oncology, the First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: The high recurrence and metastasis rates lead to poor survival of patients with sarcoma. At present, circulating tumor DNA-based minimal residual disease (MRD) has been studied in various solid tumors and proved to be valuable in guiding treatment and predicting recurrence, but its application in sarcomas is rarely reported. **Methods:** Tumor tissue samples were used for whole exome sequencing (WES) and clonal mutations were selected for the customized MRD panel. Blood samples were collected for MRD detection. Experiments were conducted at Origimed, a College of American Pathologists accredited and Clinical Laboratory Improvement Amendments certified laboratory. **Results:** A total of 84 sarcoma patients including 47 bone tumor (BT), 32 soft-tissue sarcoma (STS), and 5 undifferentiated small round cell sarcoma (USRCS) patients were enrolled. Patients consisted of 49 (58.3%) males and 35 (41.7%) females, with a median age of 23 years old (1-85 years old). Based on WES, we found that 64% (49/36/77/15) of the mutated genes were unique to each patient, and 70.4% (859/1220) of selected tumor-informed single nucleotide variants (SNV) were variants with unknown significance, suggesting that tumor-informed MRD is superior to panel-based MRD in sarcomas. In this cohort, 78.6% (66/84) of patients successfully constructed MRD panels, including 85.1% (40/47) of BT patients, 75% (24/32) of STS patients, and 40% (2/5) of USRCS patients. The main reason for failure was the scarcity of SNVs detected. Preoperative MRD detection was performed on 6 cases and revealed a positive rate of 100%. MRD detection was performed twice on 2 patients during preoperative neoadjuvant therapy. For the patient with constant allele frequencies detected throughout the treatment course, imaging showed tumor enlargement; While for another patient with a trend of reduction in allelic frequency, imaging showed tumor shrinkage and necrotic tumor tissue was observed in surgery one month later. These two patients had not recurred after surgery at the time of analysis. Post-surgery MRD detection was performed on 27 patients, of which 1 STS and 7 BTs were positive (30%, 8/27). Three of them confirmed recurrence by imaging at 12, 30, and 101 days after detection of positive MRD, respectively. However, there were still no imaging recurrence in the other patients so far, including the 5 remaining patients with positive MRD and 19 patients with negative MRD. Follow-up is still ongoing. **Conclusions:** MRD tests had been successfully performed in most of the sarcoma patients. Due to the heterogeneity of sarcomas, about 64% of mutated genes of sarcomas are unique individually, which may be more suitable for monitoring with tumor-informed MRD panel. Tumor-informed MRD could be used to predict the efficacy of preoperative neoadjuvant therapy and discover recurrence earlier than imaging in sarcoma. Research Sponsor: None.

Clinical Science Symposium

Molecular residual disease (MRD) detection using bespoke circulating tumor DNA (ctDNA) assays in localized soft tissue sarcoma (STS). *First Author: Abdulazeez Salawu, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Surgery and (neo)adjuvant radiotherapy (RT) are the mainstay curative treatments for localized STS. Despite treatment, up to 50% of STS patients experience metastatic relapse, and routine use of adjuvant systemic therapy (AST) remains controversial. The presence of ctDNA following curative-intent treatment of STS is a potential biomarker for MRD and may identify patients who are likely to benefit from AST. Given the genomic heterogeneity of STS, a histology-agnostic approach to ctDNA detection in this population is desirable. **Methods:** Patients (pts) with localized, high risk (size ≥ 5 cm, grade ≥ 2) STS were enrolled prior to (neo) adjuvant RT and surgery. Pts who received (neo)adjuvant systemic treatment were excluded. Blood samples for ctDNA analysis were collected at diagnosis, post-RT, post-surgery and every 3 months for up to 2 years. Whole exome sequencing (WES) of archival tumor and matched normal were carried out to identify patient-specific, somatic, single nucleotide variants. Personalized and tumor-informed, multiplex PCR next generation sequencing-based ctDNA (Signatera) assays were then developed to track ctDNA in serially collected plasma samples. ctDNA levels were expressed as mean tumor molecules per milliliter (MTM/ml) of plasma. Radiologic surveillance was performed every 3 months following surgery. The primary endpoint was a ctDNA detection rate of >70% at diagnosis. Secondary endpoints included MRD detection after local therapy and correlation of ctDNA levels with disease relapse. **Results:** A total of 140 plasma samples from 22 pts [18 male and 4 female; median age: 65 years, range: 30 – 84] were obtained. RT was preoperative in 19/22 pts. Of the 22 tumor samples, 20 had adequate tissue quality for WES to enable ctDNA assay design. Tumor histologic subtypes included undifferentiated pleomorphic sarcoma (n = 6), myxofibrosarcoma (n = 5), and liposarcoma (n = 9). A median of 7 plasma samples per patient (range: 2 – 10) were analyzed. ctDNA was detected in 80% of pts (16/20) at diagnosis, with median ctDNA level of 3.4 MTM/mL (range: 0.2 – 1393.9). Of these 16 pts, 15 (94%) became ctDNA negative at the immediate post-surgical timepoint. In addition, ctDNA was detected in 4 pts (80%) prior to or around radiologic relapse with a median lead time of 92 days. **Conclusions:** Personalized, tumor-informed ctDNA assays can detect MRD after definitive local therapy and/or prior to radiologic recurrence in patients with localized high-risk STS. As such, serial ctDNA monitoring provides prognostic value and may further identify patients that will benefit from AST treatment. Additional studies evaluating ctDNA as a predictive biomarker for AST benefit are ongoing. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology; Natera.

Histopathological response (HR) after neoadjuvant chemotherapy (ChT) for high-risk soft tissue sarcomas (STS): A planned analysis of the ISG-STIS-1001 trial. *First Author: Sandro Pasquali, Molecular Pharmacology, Department of Experimental Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Milano, Italy*

Background: HR after neoadjuvant ChT for high-risk STS has not been prospectively characterized and the prognostic implications remain unclear. This planned analysis of the ISG-STIS-1001 trial, which compared neoadjuvant anthracycline plus ifosfamide (AI) and a histology-tailored (HT) ChT, was aimed at characterizing HR after neoadjuvant ChT and investigating association with the risk of recurrence. **Methods:** Patients registered in the ISG-STIS-1001 study (ID: NCT01710176) were included if they had the per-protocol assessment of HR in surgical specimens. The following morphological post-treatment changes were considered: residual stainable tumor cells, necrosis, hemorrhage, sclerosis, sclerothyalinosis, and fibrohistiocytic reaction with haemosiderin. Pathologists at each study site analyzed and expressed each of these changes as a rate within each tumor. Disease-free survival (DFS), which was the trial primary end-point, was the outcome variable. **Results:** HR was assessed in 201 of 287 randomized patients (47 had re-excision, 7 did not have surgery, and 32 were not evaluable after wide excision), who were followed up for a median of 89 months (IQR 75-102 months). Presence (>1%) of stainable tumor cells (N=194, 96%) was not associated with DFS (HR=1.47, 95%CI 0.36-5.98, P= 0.591). Conversely, presence (≥ 1) of necrosis (N=169, 84%) was associated with shorter DFS (HR=3.11, 95%CI 1.36-7.14, P=0.007) and sclerothyalinosis >20% (N=42, 21%) was associated with a lower risk of recurrence (HR=0.51, 95%CI 0.28-0.94, P=0.031). These findings were confirmed when patients who had preoperative radiotherapy (N=32) were excluded. In patients randomized to AI with tumors evaluable for HR (N=98), sclerothyalinosis >20% (N=24, 24.5%) maintained the association with a lower risk of recurrence (HR=0.24, 95%CI 0.09 – 0.67, P=0.007). Finally, the prognostic value of necrosis and sclerothyalinosis for DFS held also when patients registered in the study (187/361 evaluable for HR) were selected in addition to randomized patients. **Conclusions:** This is the first study that prospectively evaluated HR after neoadjuvant ChT in high-risk STS. Previous classifications of HR were based on expert consensus and had limited prognostic relevance. In this study residual stainable tumor cells, which is often considered the most relevant post-treatment change, did not stratify patient risk, while sclerothyalinosis (>20%) singled out patients with the best outcome after neoadjuvant ChT. Clinical trial information: NCT01710176. Research Sponsor: Partially funded through a European Union grant (EUROSARC FP7 278472; A.G.) and PharmaMar (A.G.). Deep learning with whole slides images to predict histological response to neoadjuvant chemotherapy in patients with resectable high grade soft-tissue sarcomas: A multicenter study. *First Author: Benjamin Adjadj, OWKIN, Paris, France*

Background: Two recent randomized trials have confirmed the potential benefit of neoadjuvant anthracycline-based chemotherapy in patients with high-grade soft-tissue sarcomas (STS) (Issels et al 2018, Gronchi et al 2017). However, as for adjuvant chemotherapy, the main issue with neoadjuvant treatment of STS patients is the identification of predictive factors of response to chemotherapy that could avoid for a majority of patients ineffective and potentially toxic treatment with impaired quality of life. Histological response, defined as the percentage of stainable tumor cells on the surgical specimen, has been shown to be a reliable surrogate for metastasis-free survival and overall survival in bone but also in soft-tissue sarcomas (Crombe et al JCO Clin Inf 2021). Developing a tool to help medical oncologists predict the potential benefit of neoadjuvant chemotherapy prior to starting the treatment would be of great value for precision medicine in sarcomas. To address this need, we propose a deep learning-based approach to predict histological response to neoadjuvant chemotherapy patients from routine histological whole slide images sampled at diagnosis. **Methods:** A cohort of 220 patients with high grade limb and trunk wall STS enrolled in the NEOSARCOMICS study (NCT02789384, sponsor: Institut Bergonié, Bordeaux, France) was used to train a model to predict the binarized histological response from diagnostic biopsies. Responders are defined by a histological response inferior or equal to 10%. Digitized hematoxylin/eosin slides were preprocessed to segment the tissue and decompose the image into patches of smaller resolution. Features were extracted from each patch using a Vision Transformer pretrained in a self-supervised fashion on histology slides. A Multiple Instance Learning model was trained on the resulting features to compute a prediction at the patient level. The algorithm was trained and validated through a 5-fold, 5-repeat cross-validation scheme. Finally, external validation is performed on an unseen cohort from Centre Léon Bérard to assess the robustness of the model. **Results:** To predict histological response to neoadjuvant chemotherapy, a model using only diagnostic biopsies achieved an AUC of 0.69 (95% confidence interval, 0.60-0.76). External validation is ongoing and shows promising preliminary results with an AUC of 0.67 (95% confidence interval with bootstrapping, 0.45-0.89). **Conclusions:** This multi-center study demonstrates that deep-learning models can accurately predict the histological response to neoadjuvant chemotherapy from routine histological whole slide images sampled at diagnosis. This model could be used as a pre-screening tool to improve patient selection for neoadjuvant chemotherapy in STS. Research Sponsor: OWKIN.

Poster Discussion Session

Tumor volume and T2 hyperintensity changes from DeFi: A phase 3, randomized, controlled trial of niraparic acid in patients with desmoid tumors. *First Author: Thierry Alcindor, McGill University Health Center, Montréal, QC, Canada*

Background: MRI tumor volume or T2 signal intensity changes may represent novel imaging techniques that could have a prognostic or predictive value for assessing response in desmoid tumors (DT). For example, hyperintense areas on T2-weighted images have been associated with active fibroblastic proliferation and ≥90% hyperintensity is associated with DT disease progression, whereas iso- or hypo-intense areas are associated with inactive sites of disease. In DeFi (NCT03785964), the novel gamma secretase inhibitor niraparic acid (n=70 patients) significantly improved the primary endpoint of PFS compared with placebo (n=72 patients; hazard ratio, 0.29 [95% CI, 0.15, 0.55; $P < 0.001$]) and significantly improved the secondary endpoint of ORR per blinded, independent central review (41% vs 8%; $P < 0.001$). Complete responses were achieved in 7% with niraparic acid and 0% with placebo. Here, we present an exploratory analysis of MRI tumor volume and T2 signal intensity changes in DeFi. **Methods:** Eligible adults had histologically confirmed DT that had progressed ≥20% per RECIST v1.1 within 12 months of screening. Patients were randomized 1:1 to receive niraparic acid 150 mg or placebo twice daily taken continuously in 28-day cycles. Volumetric MRI and T2 hyperintensity of the largest target tumor were evaluated at screening and every 6 cycles during the double-blind phase. MRI T2 signal intensity is represented as the ratio of hyperintensity in total tumor volume to muscle background. A blinded, independent, central radiologist reviewed all MRI scans. **Results:** Niraparic acid treatment led to more substantial reductions versus placebo in tumor volume and T2 hyperintensity ratio (Table). At baseline, similar proportions of patients in each arm had a T2 hyperintensity ratio ≥90% (95% vs 97%). This ratio changed from ≥90% at baseline to <90% at any time after baseline in 34% of patients in the niraparic acid arm and 15% of those on placebo. **Conclusions:** In DeFi, niraparic acid demonstrated substantial reduction of tumor volume and T2 hyperintensity of the largest target tumors by MRI compared with placebo in adults with DT. These results are consistent with the significant improvement in ORR achieved with niraparic acid. These data suggest that volumetric MRI and T2 hyperintensity might provide additional information in the evaluation of treatment response in DT. The prognostic or predictive value of these imaging techniques in DT should be further studied. Clinical trial information: NCT03785964. Research Sponsor: SpringWorks Therapeutics.

MRI tumor volume and T2 hyperintensity of the largest tumor.

Best % change from baseline at any time post-treatment	Median	Interquartile range (Q1, Q3)	Range (min, max)	P value
Tumor volume				
Niraparic acid (n=61)	-58.9	-84.7, -8.9	-100.0, 172.5	$P < 0.0001$
Placebo (n=61)	13.8	-26.1, 58.6	-97.8, 339.0	
T2 hyperintensity ratio				
Niraparic acid (n=53)	-55.1	-73.5, -20.8	-100.0, 517.2	$P = 0.0001$

Poster Discussion Session

Impact of pregnancy in women with desmoid fibromatosis: An international retrospective observational study. *First Author: Marco Fiore, Sarcoma Service, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Desmoid fibromatosis (DF) often occurs during pregnancy/peripartum. Guidance for planning new pregnancies during active surveillance or following DF resection has been limited. Thus, we sought to evaluate outcomes and decision making in the peripartum. **Methods:** Women of child-bearing age with DF diagnosed between 2000 and 2020 were interviewed about procreation decisions, in a multicenter retrospective observational study (NCT05284305). Pregnancies simultaneous or after diagnosis were analyzed. Primary outcome was DF progression/recurrence within 1 yr postpartum. Secondary outcomes were spontaneous regression, switch to active treatment, and obstetric risks. To estimate probability of progression, a random intercept logistic model was fit to account for correlation of progression in multiple pregnancies in the same patient. **Results:** Of 483 pts interviewed, 120 (24.8%) postponed, 32 (6.6%) interrupted, and/or 232 (48%) avoided pregnancy (in 93.3%, 50%, and 72.9% of cases because of DF), respectively. 147 pregnancies in 131 pts were concurrent with or after diagnosis: 26 (17.7%, Group A) concurrent with diagnosis, 48 (32.7%, B) after DF resection, and 73 (49.7%, C) with DF on surveillance. Estimated probability of progression was 12.0% (CI 2.0 – 48.4) during pregnancy and 15.8% (5.6 – 37.5) postpartum; for pregnancies after diagnosis (Groups B and C), these rates were 5.1% (0.4 – 40.0) and 9.0% (1.8 – 35.0). On multivariate analysis, age at pregnancy and size of primary DF were significant risk factors for progression (Table). Estimated probability of spontaneous regression was 3.6% (CI 0.2–40.7) during pregnancy and 7.1% (CI 0.3 – 67.2) postpartum. 7/38 (18.4%) spontaneously regressed after pregnancy-related PD, 4/23 (17.4%) in Groups B and C. Treatment for progression was needed in 9/79 (11.4%) postpartum, in 4/63 (6.3%) in Groups B and C. Obstetric complications were comparable to population data in developed countries. **Conclusions:** After DF diagnosis, pregnancy is safe with a risk of progression of 5% during pregnancy and 9% postpartum. Treatment is needed in only 6%. Spontaneous regression is less common but occurs even after initial progression. Patients decision making about procreation appeared to be influenced by their DF diagnosis. This study supports counseling that fertility options should be fully explored with expert guidance as intervention rates are low. Research Sponsor: None.

RINGSIDE phase 2/3 trial of AL102 for treatment of desmoid tumors (DT): Phase 2 results. *First Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: For patients with desmoid tumors (DT, aggressive fibromatosis), systemic therapy that results in tumor regression, symptom improvement and durable tolerability is needed. Gamma secretase inhibitors (GSIs) have demonstrated antitumor activity against DT. AL102 is a potent, orally available, selective GSI under investigation for treatment of DT. **Methods:** RINGSIDE (AL-DES-01) is a Phase 2/3 study for patients with progressing DT. In the open-label Phase 2 study (Part A), adults with progressing DT (≥10% unidimensional growth within 18 months or DT-related pain requiring non-opioid medication) were randomized to three dosing regimens: 1.2 mg QD, 2 mg intermittent BIW (2 days on 5 days off), or 4 mg intermittent BIW. Patients who complete Phase 2 roll over into an open-label extension (OLE). RINGSIDE Phase 3 (Part B) is a double-blind, placebo-controlled study evaluating the chosen dose regimen from Phase 2 (1.2 mg once daily) utilizing PFS as the primary endpoint. We report updated efficacy and safety results from RINGSIDE Phase 2. **Results:** Enrollment of all 42 patients into Phase 2 was completed as of March 2022. As of January 3, 2023, median time on study was 10.5 months (range 0.8 – 14.7) and 30 patients (71.4%) were still on study, 10 (23.8%) of whom rolled over to the OLE. Mean age was 39.9 years, 73.8% were women and 69% had received prior desmoid cancer therapy. The best response in the evaluable population as assessed by blinded independent central review (BICR) was partial response (PR) in 6/12 patients (50%) for 1.2 mg QD, 3/13 patients (23.1%) for 4 mg BIW, and 5/11 patients (45.5%) for 2 mg BIW. Disease control rate was 100%, 91%, and 97% in these groups, respectively. A consistent pattern of deeper, more rapid and maintained response was observed with 1.2 mg QD. Median volume change (BICR) from baseline was -51.9% for 1.2 mg QD, -9.5% for 4 mg BIW, and -15.2% for 2 mg BIW at Week 16 and -76.4%, -35.5%, and -51.2%, respectively, at Week 28. Similar patterns were observed for % changes from baseline in T2 signal intensity, suggesting reduction of tumor cellularity. Consistent with the mechanism of action of GSIs, the five most common Grade 1-2 treatment-emergent adverse events (TEAEs) were diarrhea, nausea, fatigue, alopecia, and dry skin. Grade 3 drug-related TEAEs were reported in 26.2% of patients across all tested doses. There were no Grade 4, Grade 5, or serious TEAEs related to AL102 per investigator assessment. There were no new safety signals. **Conclusions:** In this Phase 2 study, AL102 was safe and generally well tolerated across all tested doses. The safety profile was consistent with the GSI class of drugs. Tumor response, volume reduction and T2 signal reduction were observed earlier in the 1.2 mg QD group, with deeper and maintained treatment responses. This dose was selected for study in RINGSIDE Phase 3, which is currently enrolling in multiple countries. Clinical trial information: NCT04871282. Research Sponsor: Ayala Pharmaceuticals.

Poster Discussion Session

A phase II basket trial of dual anti-CTLA-4 and anti-PD-1 blockade in rare tumors (DART) SWOG S1609: The desmoid tumors (cohort 27). *First Author: Young Kwang Chae, Northwestern University, Chicago, IL*

Background: Dual inhibition with Anti-PD-1 and anti-CTLA4 checkpoint inhibitors is efficacious in many malignancies, but their potential role in numerous rare solid cancers is yet to be established. Desmoid tumors (DT; fibromatosis) are rare tumors of the soft tissue, and the mainstay of treatment is surgery (Richard Riedel, 2022). The utility of immunotherapy in this group of patients has not been explored. This study presents the first results of ipilimumab and nivolumab used in the DT cohort (#27) of the SWOG S1609 Dual Anti-CTLA-4 & Anti-PD-1 blockade in Rare Tumors (DART) trial. **Methods:** DART is a prospective, open-label, multicenter/multi-cohort phase 2 clinical trial of ipilimumab (1mg/kg intravenously every 6 weeks) plus nivolumab (240mg intravenously every 2 weeks). The primary endpoint includes objective response rate (ORR) (RECIST v1.1) (confirmed complete (CR) and partial responses (PR)). Secondary endpoints include progression-free survival (PFS), overall survival (OS), stable disease (SD) > 6 months, and toxicity. **Results:** Sixteen evaluable patients (median age 37) with desmoid tumors were analyzed. Location of the tumors are: 8, abdomen; 3, lower limb; 2, upper limb; 2, pelvis; and 1, neck. ORR was 18.8% with 3 patients attaining PR: 40% regression with ongoing duration of response (DoR) at over 30+ months; 83% regression (PFS 16 months); and 71% regression (PFS of 8.4 months). Of note, 3 patients had SD (3/16, 18.8%) with some shrinkage of the tumors and a durable response; 23% regression with PFS of 1820+ days; 6% regression with PFS of 902 days; 1% regression with PFS of 1147+ days. Overall clinical benefit rate (CBR; no progression > 6 months) was 62.5%. The median PFS was 17.9 months, 6-month PFS 69%, 1-year PFS 62%. All patients were alive at 1 years; median OS was not assessable as 14 patients are showing ongoing survival. The most common adverse events were fatigue (43.8%, n = 7), nausea (37.5%, n = 6), hypothyroidism (31.3%, n = 5), diarrhea, hyperthyroidism, headache, and adrenal insufficiency (25%, n = 4 each). There were 8 incidents (50%) of grade 3-4 adverse events. 7 adverse events led to discontinuation. There were no grade 5 adverse events. **Conclusions:** Ipilimumab plus nivolumab in treatment of desmoid tumors resulted in an ORR of 18.8% and CBR of 62.5% with durable responses seen. This is the first prospective study demonstrating efficacy of the combination in this rare disease. Correlative studies to determine response and resistance markers are ongoing. Expanded prospective studies in desmoid tumors are needed. Clinical trial information: NCT02834013. Research Sponsor: U.S. National Institutes of Health; Bristol-Myers Squibb.

Poster Discussion Session

Interim results of a phase II trial of first line retifanlimab (R) plus gemcitabine and docetaxel (GD) in patients (pts) with advanced soft tissue sarcoma (STS). *First Author: Evan Rosenbaum, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: GD is an alternative to doxorubicin in the front line setting in advanced STS. In the Phase I portion of this study, the PD-1 antibody R, plus GD, was generally well tolerated. We hypothesized that R+GD would be more effective than historical controls treated with GD alone. **Methods:** This is an ongoing open-label single-center study of R+GD in pts with treatment-naïve unresectable or metastatic high-grade STS. G (900 mg/m²) is administered on days 1 and 8 and D (75 mg/m²) on day 8, in 21-day cycles. R (375 mg flat dose) is administered on day 1 starting in cycle 2 and continued as monotherapy 'maintenance' after completion of 6 cycles of GD. Up to fifty pts can accrue into five histology-specific cohorts of 10 pts each. The primary endpoint is to estimate the progression-free survival (PFS) rate at 24 weeks. Secondary endpoints included safety, best overall response rate (RR) by RECIST 1.1, disease control rate (DCR), and duration of response (DOR). Subgroup analyses to evaluate all endpoints within each histology-specific cohort are preplanned. An early stopping rule for excessive toxicity will halt accrual if a prespecified severe adverse event rate is surpassed. **Results:** As of January 11, 2023, 43 pts were enrolled and treated with R+GD. The leiomyosarcoma (LMS), undifferentiated pleomorphic sarcoma (UPS)/myxofibrosarcoma (MFS), dedifferentiated liposarcoma (DDLPS), and other STS cohorts (n = 10 pts each) were fully accrued. Three of 10 angiosarcoma (AS) pts were enrolled. Median age was 59.5 (range 21 – 81) and 27 (63%) were male. Two DDLPS patients were not yet evaluable for response. Of 41 evaluable pts, the best overall RR was 22% (95% confidence interval [CI]) 11 – 38). Confirmed responses were seen in UPS/MFS (n = 4), LMS (2), AS (2), and follicular dendritic cell sarcoma (1). Three pts (LMS, ossifying fibromyxoid tumor, AS) had an unconfirmed PR, for a best RR of 29% (95% CI 16 – 46). Median PFS was 32.7 weeks (95% CI 26.4 – not estimable [NE]) and median DOR was 24 weeks (95% CI 15 – NE). Safety was evaluated in all 43 pts and the early stopping rule was not triggered. Eighteen (42%) pts had at least one Grade (Gr) 3 or 4 treatment-related adverse event (TRAE). The most common (> 5%) were anemia (16%), neutropenia (9%), febrile neutropenia (7%), lung infection (7%), and leukopenia (7%). Seven pts (16%) had pneumonitis: one Gr 1, four Gr 2, and two Gr 3. Six pts (14%) stopped treatment due to toxicity, including five with pneumonitis. **Conclusions:** The median PFS of R+GD appears promising compared to historical controls, although the primary endpoint analysis is pending completion of accrual. There was a higher incidence of pneumonitis with the combination compared to GD alone. Future studies of this combination will need to carefully consider the benefits and risks after the final efficacy and safety analyses are performed. Clinical trial information: NCT04577014. Research Sponsor: Incyte Corporation.

Poster Discussion Session

A pilot study of lenvatinib plus pembrolizumab in patients with advanced sarcoma. *First Author: Sujana Movva, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: New treatment options are needed for sarcomas. Lenvatinib (L) is an oral, multi-tyrosine kinase inhibitor with significant inhibitory activity against VEGF receptor (VEGFR) 1-3, FGF receptor (FGFR) 1-3, KIT, platelet-derived growth factor receptor (PDGFR) alpha/beta, and RET. Experimental models suggest that L can favorably alter the tumor immune environment, and the combination of L and pembrolizumab (P) has proven to be synergistic and effective across multiple solid tumor types, providing rationale for this study. **Methods:** This is a pilot study evaluating the efficacy of L and P in select sarcomas. Patients who had at least 1 prior regimen but ≤ 3 were enrolled into one of five cohorts (n = 10 each): A: leiomyosarcoma (LMS); B: undifferentiated pleomorphic sarcoma (UPS); C: angiosarcoma and epithelioid hemangioendothelioma (EHE); D: synovial sarcoma (SS) and malignant peripheral nerve sheath tumor (MPNST); and E: osteosarcoma (OS) and chondrosarcoma (CS). Patients were treated with an initial 2-week run-in of L 20 mg orally daily. Subsequently, P was administered at 200 mg IV every 21 days. The primary endpoint for each cohort was the best objective response rate (ORR) documented by RECIST v1.1 by 27 weeks. The combination was considered worthy of further study if 2 or more responses were observed in a cohort. Secondary endpoints included progression-free survival (PFS), overall survival, duration of response, and safety of the combination. Archival tissue and on-treatment biopsies were collected. **Results:** As of January 31st, 2023, cohorts A, D and E have completed accrual. The best response in the LMS cohort was stable disease (SD). In cohort D there were 3 partial responses (PR): 2 SS; 1 radiation associated high grade MPNST. In cohort E one of 6 patients with OS had a PR. To date, of the 6 patients with angiosarcoma, there was 1 PR in a patient with adrenal primary that occurred after the prespecified 27-week timepoint. One of 5 evaluable patients in Cohort B had a PR. Among the 44 patients evaluable for safety, most common AEs were hypertension (56.8%), diarrhea (45.5%), proteinuria (45.5%), fatigue (40.9%), headache (36.4%) and nausea (36.4%). Most common ≥ grade 3 AEs were hypertension (13.6%), dyspnea (6.8%), non-cardiac chest pain (6.8%), syncope (6.8%). **Conclusions:** A signal of activity was noted in this pilot study for patients with OS, MPNST, angiosarcoma and SS. In the LMS cohort, there were no responses, and PFS was poor. Enrollment to cohorts B and C is ongoing. Clinical trial information: NCT04784247. Research Sponsor: Parker Institute for Cancer Immunotherapy, Sarcoma Foundation of America, Witherwax Fund, Linn Fund, EHE Foundation.

Cohort	Subtype	Evaluable Disease (N)	Median Age, range	% Female	Best ORR at 27 weeks, % (N)	Median PFS (weeks), (95% CI)
A	LMS	10	50 (34-70)	90	SD: 60% (6)	17.9 (6.6-23)
B	UPS	5	55 (29-72)	40	PR: 20% (1)	25.3(8.3-38)
C	Angiosarcoma	6	64 (30-74)	62.5	SD: 60% (3)	40.9 (7.1-61.3)
D	EHE SS MPNST	2 6 3	36(25-71)	44.4	PR: 33.3% (3, SSx 1, MPNST x 1)	32 (4.3-51.1)

Poster Discussion Session

SARC037: Results of phase I study of trabectedin given as a 1-hour (h) infusion in combination with low dose irinotecan in relapsed/refractory Ewing sarcoma (ES). *First Author: Patrick Grohar, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Recurrent ES carries a poor prognosis, and systemic therapies have limited efficacy. Preclinical models suggested that trabectedin (T) could achieve serum concentrations high enough to suppress the dominant oncogene of ES (i.e. EWS::FLI1 transcription factor), and that this effect is sustained by subsequent administration of low dose irinotecan (I). We conducted a phase I study of T+I in patients (pts) with ES. **Methods:** This multicenter dose escalation study employed a standard 3+3 design. T was given as a 1-h infusion on day (D)1 with low dose I intravenously on D2 and 4 of a 21D cycle. Dose limiting toxicities (DLTs) were evaluated in cycle one. Eligibility required confirmed EWS::FLI1 fusion transcript, age ≥10 years, ECOG performance status ≤2, adequate organ function and willing to have a research biopsy if safely accessible. Primary objectives were to determine the recommended dose (RD) and safety of T+I. Secondary objectives comprised efficacy of T+I and avidity of ES for 3'-Deoxy-3'-¹⁸F Fluorothymidine (¹⁸F-FLT) PET. **Results:** 20 pts enrolled from 1/2021-12/2022 across 5 sites, 5F/15M, median age 18 years (range 10-59). Pts had received a median of 4 (range 2-9) prior therapy lines including irinotecan in 60% of pts. Grade (G) 3/4 treatment-emergent adverse events (TEAEs) occurring in ≥10% of pts were: elevated ALT/AST, elevated creatinine phosphokinase, febrile neutropenia, anemia, lymphopenia, neutropenia, and thrombocytopenia. There were 2 G5 respiratory TEAEs. ¹⁸F-FLT PET scans were obtained in 5 pts. ES tumors were ¹⁸F-FLT PET avid. Dose level (DL)2 was the RD. At DL 2 and above, there were 4 PRs, 6 SD in 14 evaluable pts (Table). **Conclusions:** T+I can be safely administered to heavily pretreated pts with ES, demonstrating activity at the RD with 3 PRs (n=5 evaluable). The ¹⁸F-FLT PET may be useful to understand patterns of disease progression in ES. Correlative studies will be critical to understanding the mechanism of drug activity. Given the clinical benefit seen with T+I at RD, a phase II portion in pts with ES ≥6 years old is actively accruing. Clinical trial information: NCT04067115. Research Sponsor: U.S. National Institutes of Health; 1 Million 4 Anna; Janssen Pharmaceuticals.

Dose Level	No. Pts treated	DLTs observed	Best Response (No. of evaluable pts)

Poster Discussion Session

SELISARC: A Spanish Sarcoma Group (GEIS) phase I/II trial of selinexor plus gemcitabine in selected sarcoma subtypes—Results of the phase I part. *First Author: Javier Martin Broto, Fundacion Jimenez Diaz University Hospital and Health Research Institute-Fundación Jiménez Díaz University Hospital, Autonomous University of Madrid (IIS-FJD, UAM), Madrid, Spain*

Background: Selinexor (KPT-330) (S), a small-molecule inhibitor of the nuclear export mediator exportin-1 (XPO-1), is able to reduce mRNA and protein expression of DNA damage repair (DDR) gene products, being synergistic with DNA damage agents as gemcitabine (G) in preclinical experiments. We hypothesized that selinexor would have a synergistic effect with gemcitabine in selected sarcoma patients (pts). **Methods:** Adult progressing pts, ECOG 0-1, with up to 2 previous systemic therapies for advanced disease (localized unresectable/metastatic) with centrally confirmed diagnosis of undifferentiated pleomorphic sarcoma (UPS), leiomyosarcoma (LMS), alveolar soft part sarcoma (ASPS), or osteosarcoma (OS) were eligible. S (days 1, 8, 15) and G (days 1, 8) were given in four dose levels, L1: S 60 mg + G 1,000 mg/m² 30 min, L2: S 60 mg + G 1,000 mg/m² (10 mg/m²/min), L3: S 60 mg + G 1,200 mg/m² (10 mg/m²/min), and L4: S 80 mg + G 1,200 mg/m² (10 mg/m²/min). A L1 level was defined with S 60 mg + G 800 mg/m² (30 min). A classic 3+3 design was used to determine the RP2D based on DLTs observed during the first 21-day cycle. *In vitro* research was performed in LMS and OS cell lines to test the synergy of the combination (MTS and flow cytometry assays). **Results:** Between November 2020 and June 2022, 17 pts (M/F 9/8), ECOG 0/1 (14/3), median age 50 years (22-71) were recruited. The median of previous lines was 1 (1-2). Diagnosis was: 9 LMS (52.9%), 6 OS (35.3%), 1 ASPS and 1 synovial sarcoma (SS) (5.9%). Three pts were treated in each of the first 3 levels and 8 pts in L4 (2 pts were not evaluable for DLT due to improper dosing). Only one DLT was observed in L4 (G4 thrombocytopenia) and this level was selected as RP2D. G3/4 toxicity: Neutropenia (52.9%), thrombocytopenia (41.2%), febrile neutropenia (11.8%), anemia, nausea, asthenia, vomiting, alopecia, and lipase increased (5.9% each). There were 3 RECIST PR, 7 SD, and 7 PD. Median PFS for LMS was 7 months (95% CI: 3-11). No relevant clinical activity was observed in OS. *In vitro* cell viability studies shown that S+G was synergistic in the majority of LMS cell lines tested (combination index of 0.789 for CP0024, 0.791 for SK-UT-1, 0.604 for AA and 1.186 for IEC005). However, our results indicated antagonism of S+G in OS cell lines, with values for the combination index of 1.67 for MG63, 1.54 for SAOS2 and 1.23 for U2OS. Apoptosis assays by flow cytometry confirmed these observations in LMS and OS cells. **Conclusions:** At the RP2D, S 80 mg + G 1,200 mg/m² (10 mg/m²/min) is a feasible scheme with manageable toxicity. S+G has shown promising clinical activity for LMS, which warrants further investigation in a phase II. Preclinical studies shown the synergy and the antagonism of S+G in LMS and OS, respectively. Clinical trial information: NCT04595994. Research Sponsor: Spanish Group for Research in Sarcoma; Karyopharm.

Poster Discussion Session

Multi-omic characterization of gastrointestinal stromal tumor (GIST) in a large real-world patient cohort. *First Author: Jonathan C. Trent, Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL*

Background: Molecular knowledge of GIST is limited due to its rarity, few genes have been identified as relevant determinants of outcomes, tumor evolution and therapeutic targets. Therefore, we aimed to dissect the GIST molecular landscape in the largest series of real-world patients reported to date. **Methods:** 946 GIST patient samples (536 localized, 369 metastatic, 41 unknown) underwent next-gen sequencing of DNA (592-gene, N = 495; whole exome, N = 451) and RNA (whole transcriptome, N = 592) at Caris Life Sciences (Phoenix, AZ). Gene expression signatures of proliferation (Cristescu, 2021), cell cycle activation (CINSARC; Chibon, 2010), inflammation (T-cell inflamed; Ayers, 2017) and tumor microenvironments (MCP-counter; Becht, 2016) were examined. Statistical significance tested by χ^2 , Fisher's exact, or Mann-Whitney U as appropriate. **Results:** GIST samples were comprised of 80% (N = 758) *KIT*mut, 8.1% (N = 77) *PDGFR*mut, and 11.7% (N = 111) *KIT*/*PDGFR* wild-type (WT), with 14.8% (N = 140) samples harboring a secondary *KIT* variant suggestive of TKI resistance. Overall median TMB was 2 mutations/MB (range 0-13). WT GIST were identified with mutations in *NF1* (33.7%), DNA repair genes (16.7%), *SDHX* (8.2%), *BRAF* (6.3%), and *PTEN* (1.9%), along with *NTRK3* fusions (3.1%). Primary *KIT* variants occurred in exons 11 (83.5%), 9 (13.9%), and 13 (2.6%), and secondary *KIT* variants (14.6% of total *KIT* mutations) were distributed across the ATP binding pocket (36.8%) and activation loop (63.2%). Primary *PDGFR* mutations were in exons 18 (62.4%), 12 (11.0%), 14 (4.6%) and other (16.5%). *KIT*/*PDGFR*mut GIST infrequently harbored *RB1*, *TP53*, *SETD2*, *ARID1A*, *PIK3CA*, *PTEN*, *TSC1*, *BRCA1*, or *CHEK2* co-mutations (1-5% each). Copy number amplification (≥ 6 copies) was overall uncommon ($\leq 2\%$ for all genes). Proliferation and cell cycle activation signatures were higher in *KIT* exon 11 indels v. missense mut (1.2-fold, $p < 0.05$) and *KIT* resistant v. *KIT* primary (1.2-fold, $p < 0.05$), but not in *KIT* exon 11 557/558 v. others, nor between *KIT* v. *PDGFR* v. WT subgroups. Deletion of tumor progression genes *MAX* (40.0%), *CDKN2A* (32.3%), and *DEPDC5* (33.9%) was associated with increased proliferative gene expression (1.2-, 1.3-, and 1.2-fold, $p < 0.05$ each), while *MDM2* deletion (52.5%) was not (1.1-fold, $p = 0.37$). Compared to *KIT*mut and WT GIST, *PDGFR*mut had increased abundance of several immune cell populations (range 1.2-3.7-fold, $p < 0.05$), along with enhanced inflammation signatures (1.1- and 1.2-fold, $p < 0.05$). **Conclusions:** This series provides unprecedented resolution of *KIT*/*PDGFR*mut GIST with features of clinical aggressiveness associated with *KIT* exon 11 indels and resistance mutations, illustrating a specific cytogenetic genotype with more aggressive growth and malignant behavior. Identification of less common molecular alterations that drive kinase activation and impaired DNA damage repair warrant further investigation. Research Sponsor: Caris Lifesciences.

Poster Discussion Session

A phase I study of nanoparticle albumin-bound sirolimus (NAB-S) combined with pazopanib (PAZO) in patients with advanced soft tissue sarcoma (STS). *First Author: Lee D. Cranmer, University of Washington, Fred Hutchinson Cancer Center, Seattle, WA*

Background: NAB-S (ABI-009, nab-rapamycin) is approved for treatment of adults with unresectable or metastatic perivascular epithelioid cell tumors. Albumin binding improves sirolimus solubility and may target it to tumoral cells. mTOR inhibition may enhance PAZO activity directly and by overcoming resistance. We assess feasibility and safety of the combination. **Methods:** Eligible patients (≥ 18 y) had: advanced, unresectable, non-adipocytic STS progressing after 1-5 prior therapies; adequate end-organ function; ECOG performance status 0-1; measurable target lesions (RECIST v1.1); and no prior mTOR or angiogenesis inhibitor treatment. The study was conducted according to a 3+3 design. Initial cohorts received 800 or 400 mg PAZO daily and 60, 45 or 30 mg/m² of NAB-S on days 1 and 8 on a 21-day cycle. Subsequently, NAB-S was administered only on day 1 based on preliminary analysis of adverse events (AEs) and pharmacokinetics (PK). Primary endpoint was determination of maximally tolerated dose (MTD). Dose-limiting toxicities (DLT) were grade 3-5 adverse events (AE) during the first cycle not due to PAZO. Secondary endpoints included AE characterization (CTCAE v5.0), descriptive evaluation of responses and their duration, and correlative/PK studies. **Results:** 19 patients were treated; initially, 13 received NAB-S on days 1 and 8. DLT included thrombocytopenia (TCP, n = 7), decreased WBC/neutrophils (n = 2), increased lipase (n = 1), and proteinuria (n = 1). Due to overlapping AEs or possible NAB-S/PAZO interaction, further cohorts received 400 mg PAZO daily and either 30 or 45 mg/m² NAB-S (n = 6). There were no DLTs in the 30 mg/m² cohort (n = 3). In the 45 mg/m² cohort, 2 out of 3 patients had TCP meeting DLT definition. Grade 3-4 AEs in more than 10% included: TCP (58%), neutropenia (11%), leukopenia (11%), lymphopenia (11%), and diarrhea (11%). Any grade AEs in $> 50\%$ included: TCP (74%), mucositis (63%), fatigue (58%), and acneiform rash (53%). There was no grade 5 AEs. Of 19 treated, 11 (58%) discontinued due to disease progression, 3 (16%) due to AE (TCP-2, transaminitis-1), and 1 (5%) due to death from disease. Four (21%) remain on study as of 2/2023. 18 were evaluable for best response: 3 partial responses (PR; leiomyosarcoma, solitary fibrous tumor, spindle cell sarcoma), 13 stable disease (SD), 2 progressive disease. Clinical Benefit Rates (CBR = PR+SD) at 3 and 6 months were 72% (13/18) and 59% (10/17). Among the leiomyosarcoma subset, CBR at 3 and 6 months were 90% (9/10) and 80% (8/10). Correlative and pharmacokinetic results will be presented. **Conclusions:** Thrombocytopenia was the most prominent DLT when studying the NAB-S/PAZO combination. 3 patients out of 19 discontinued therapy due to AEs; the remainder continued therapy after adjustment. MTD and RP2D is NAB-S 30 mg/m² day 1 and PAZO 400 mg days 1-21. Preliminary evidence of activity of the combination was observed. Clinical trial information: NCT03660930. Research Sponsor: Aadi Bioscience.

Poster Discussion Session

Clinical efficacy of avapritinib in gastrointestinal stromal tumors (GIST) with different *KIT* genotypes: Post hoc analysis of the phase 1 NAVIGATOR and phase 1/2 CS3007-101 trials. *First Author: Michael C. Heinrich, Portland VA Health Care System and OHSU Knight Cancer Institute, Portland, OR*

Background: Avapritinib, a novel *KIT*/platelet-derived growth factor receptor α (*PDGFR*) kinase inhibitor, is approved in patients (pts) with GIST harboring *PDGFR* activation loop (AL) exon 18 mutations, based on unprecedented clinical antitumor activity. Despite available treatments, there remains a great unmet medical need for pts with *KIT*-AL-mutant GIST receiving 2nd-line (2L) standard of care (SOC) sunitinib, and pts with primary *KIT* exon 9 (*KIT* 9)-mutant GIST receiving 4th-line (4L) SOC ripretinib. This post hoc analysis assessed the clinical benefit of avapritinib in pts with *KIT* mutations, especially with AL exons 17 and 18, or primary *KIT* 9 mutations. **Methods:** Tumor tissue and liquid biopsy samples were collected and analyzed to determine baseline mutational status. *KIT* molecular subgroups and outcomes were determined in pts with primary *KIT* mutations treated with oral avapritinib 300 mg once daily (starting dose) enrolled in the phase 1 NAVIGATOR (NCT02508532) and phase 1/2 (China bridging) trials (NCT04254939, CS3007-101). Pts with *PDGFR* mutations and *PDGFR*-*KIT* co-mutations were excluded. Progression-free survival (PFS) and objective response rate (ORR) were compared using Cox and logistic regression, respectively. **Results:** A total of 160 pts with *KIT*-mutant GIST were evaluated (NAVIGATOR, n = 131; CS3007-101, n = 29). At data cutoff (NAVIGATOR: March 31, 2021; CS3007-101: June 30, 2021), median follow-up duration was 22.0 months (95% CI 18.3-27.4). *KIT*-AL mutations were more frequently detected (n = 74, 46.3%) than *KIT*ATP-binding pocket (ABP) mutations (n = 34, 21.3%). Sixty pts (37.5%) had *KIT*-AL mutations without *KIT*-ABP mutations (AL^{pos}ABP^{neg} group); the remaining 100 pts were designated as *KIT* OTHERS. Across all lines of therapy, the adjusted (inverse probability weighting of baseline characteristics) median PFS (mPFS) was longer for the AL^{pos}ABP^{neg} group than for the *KIT* OTHERS group (9.1 vs 3.4 months; HR 0.47, 95% CI 0.32-0.68; $P < 0.0001$), and the ORR was higher (31.4% vs 12.1%; odds ratio 3.31, 95% CI 1.44-7.58; $P = 0.0047$). mPFS and ORR in the *KIT*AL^{pos}ABP^{neg} group were 19.3 months and 38.5%, respectively, in the 2L setting (n = 13) and 11.0 months and 36.4%, respectively, in Chinese pts (3-9 lines, n = 11). In pts with *KIT* 9 mutations in the 4L (n = 14) and > 4 L settings (n = 19), mPFS was 5.6 and 3.7 months, respectively. **Conclusions:** This post hoc analysis demonstrated significantly more robust avapritinib antitumor activity in pts with *KIT* AL^{pos}ABP^{neg} GIST versus pts with other *KIT* mutation profiles. The results suggest that avapritinib could confer meaningful clinical benefit in pts with GIST and specific *KIT* mutation types, especially *KIT*-AL or *KIT* 9 mutations. Avapritinib might be a potential 2L option for pts with *KIT*AL^{pos}ABP^{neg} GIST, and in later lines of therapy for pts with AL^{pos}ABP^{neg} or *KIT* 9 mutation profiles. Clinical trial information: NCT02508532, NCT04254939. Research Sponsor: CStone Pharmaceuticals.

Poster Discussion Session

Overall survival and long-term safety in patients with advanced gastrointestinal stromal tumor previously treated with imatinib: Updated analyses from INTRIGUE. *First Author: Robin Lewis Jones, Sarcoma Unit, The Royal Marsden NHS Foundation Trust and Institute of Cancer Research, London, United Kingdom*

Background: Ripretinib is a switch-control tyrosine kinase inhibitor approved for patients (pts) with gastrointestinal stromal tumor (GIST) who received prior treatment with ≥ 3 kinase inhibitors, including imatinib. Sunitinib is approved for advanced GIST after imatinib failure. In the first interim analysis (IA) for overall survival (OS) in the INTRIGUE trial, data were immature (OS event rate, 22.3%), and median OS was not reached in either arm for the *KIT* exon 11 intent-to-treat (ITT) and all-patient (AP) ITT populations (S Bauer, et al. *J Clin Oncol*. 2022). Additionally, ripretinib had a more favorable safety profile with fewer grade 3/4 treatment-emergent adverse events (TEAEs) than sunitinib. Here, we present the second IA of OS and updated safety from INTRIGUE. **Methods:** INTRIGUE is a global, open-label, phase 3 study that enrolled adult pts with advanced GIST who had disease progression on or intolerance to imatinib (NCT03673501). Randomization was 1:1 to ripretinib 150 mg once daily (QD) or sunitinib 50 mg QD (4 wks on/2 wks off) and was stratified by *KIT* mutational status and imatinib intolerance. OS was a key secondary endpoint; data cutoff for the second IA was Sept 1, 2022. **Results:** Of 453 pts in the AP ITT population, 444 received treatment; 51 remain on treatment (33/223 [14.8%] with ripretinib and 18/221 [8.1%] with sunitinib). Common reasons for treatment discontinuation were progressive disease (PD) assessed by independent radiologic review (55.4%), PD assessed by investigator (10.6%), clinical PD (5.9%), withdrawal of consent (5.4%), and adverse event (AE; 4.5%); fewer pts discontinued due to an AE for ripretinib vs sunitinib (2.7% vs 6.3%). Following study treatment discontinuation, 58 pts (25.6%) from the sunitinib arm received ripretinib; 139 pts (61.5%) from the ripretinib arm later received sunitinib. There were 185 OS events (40.8%) in the AP ITT population; median duration of follow-up was 28.7 and 28.5 months for ripretinib and sunitinib, respectively. OS was similar with ripretinib vs sunitinib in the AP ITT (median 35.5 vs 30.9 months; HR 0.88, 95% CI 0.66 to 1.18; nominal $P=0.39$) and *KIT* exon 11 ITT populations (median 34.0 vs 31.5 months; HR 1.05, 95% CI 0.75 to 1.48; nominal $P=0.77$). The updated safety profile was consistent with the primary analysis; fewer pts had grade 3/4 TEAEs with ripretinib vs sunitinib (95 [42.6%] vs 149 [67.4%]). Dose interruptions and reductions were lower with ripretinib vs sunitinib. The median (range) treatment duration was 7.9 (0.2–38.2) months for ripretinib and 6.5 (0.2–38.3) months for sunitinib. **Conclusions:** In the second IA from INTRIGUE, OS was similar between treatment arms. The safety profile remained consistent with additional data, and results demonstrate favorable safety with ripretinib in pts with advanced GIST previously treated with imatinib. Clinical trial information: NCT03673501. Research Sponsor: Deciphera Pharmaceuticals, LLC.

Camrelizumab in combination with doxorubicin, cisplatin, ifosfamide, and methotrexate as neoadjuvant therapy for osteosarcoma: A single-arm, exploratory phase II trial. *First Author: Qinglian Tang, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Tumor necrosis rate after neoadjuvant therapy is one of the strongest predictors of long-term outcome for patients with osteosarcoma. Patients with good response (tumor necrosis rate $\geq 90\%$) have a substantially better survival than those with poor response (tumor necrosis rate $< 90\%$), with 5-year overall survival of 75–80% and 55–65%, respectively. However, treatments for osteosarcoma have not yet shown much progress since the introduction of perioperative chemotherapy in 1970s. New neoadjuvant combinations are required to explore for osteosarcoma. **Methods:** In this phase II trial (NCT04294511), patients aged 14–65 years with histopathologically confirmed osteosarcoma and Eastern Cooperative Oncology Group performance status of 0–1 received three 21-day cycles of neoadjuvant regimen (camrelizumab 200 mg on day 1 of each cycle; doxorubicin 37.5 mg/m² or liposomal doxorubicin 25 mg/m² on days 1–2 of cycles 1 and 3; cisplatin 100 mg/m² on day 2 of cycles 1 and 3; methotrexate 8–12 g/m² on day 12 of cycle 1; and ifosfamide 3 g/m² on days 1–4 of cycle 2). Surgery was scheduled 12–14 days after neoadjuvant therapy. Two weeks after surgery, patients received 6 cycles of adjuvant therapy (camrelizumab 200 mg on day 1 of each cycle; doxorubicin 37.5 mg/m² or liposomal doxorubicin 25 mg/m² on days 9–10 of cycles 1, 3, and 5; cisplatin 100 mg/m² on day 10 of cycles 1, 3, and 5; methotrexate 8–12 g/m² on day 2 of cycles 1, 3, and 5; and ifosfamide 3 g/m² on days 1–4 of cycles 2, 4, and 6). The primary endpoint was good response (tumor necrosis rate $\geq 90\%$) rate after neoadjuvant therapy. **Results:** A total of 86 patients were screened and 75 patients signed informed consent from December 2019 to June 2022. By the data cutoff date on December, 2022, 8 patients did not complete neoadjuvant therapy and 2 patients refused surgery. 65 patients completed neoadjuvant therapy, one patient had disease progression before surgery, 64 received surgical resection and adjuvant therapy, and 44 completed adjuvant therapy. Thirty-one (48.4%, 95%CI: 36.6%–60.4%) of 64 patients showed good response. The most common grade 3–4 adverse events were decreased platelet count (44.0%), decreased white blood cell (37.3%), decreased neutrophil count (29.3%), oral mucositis (14.7%), increased alanine aminotransferase (12.0%), and increased aspartate aminotransferase (10.7%). **Conclusions:** Camrelizumab combined with doxorubicin, cisplatin, methotrexate and ifosfamide in the perioperative treatment of osteosarcoma patients were safe and tolerable. Postoperative good response rate was similar to previously reported results. Survival follow-up is still ongoing to analyze the effect of perioperative immunotherapy combined with chemotherapy on long-term outcomes of patients with osteosarcoma. Clinical trial information: NCT04294511. Research Sponsor: None.

Two schedules of vincristine, irinotecan and temozolomide (VIT) for patients with relapsed or refractory Ewing sarcoma: A randomized controlled phase 2 trial. *First Author: Jie Xu, Peking University People's Hospital, Beijing, China*

Background: Vincristine, irinotecan and temozolomide (VIT) has provided an effective regimen in relapsed or refractory Ewing sarcoma patients. Optimal dose schedule of VIT is still undefined. **Methods:** We did this phase 2 randomized controlled trial and included patients with relapsed or refractory Ewing sarcoma. They were randomly assigned (1:1) by random number table method to either shorter dx5 schedule (Irinotecan 50mg/m²/d D₁₋₅, Vincristine 1.4mg/m² D₁) or protracted dx5x2 schedule (Irinotecan 20mg/m²/d D_{1-5,8-12}, Vincristine 1.4mg/m² D_{1,8}) together with a fixed dose of temozolomide (100mg/m²/d D₁₋₅) in both groups. Patients were treated every 3 weeks till progression or unacceptable toxic effects for up to eight cycles. The primary endpoint was objective response rate at 12 weeks (ORR_{12w}). The secondary endpoint was progression-free survival (PFS), overall survival (OS) and safety. The study was powered to detect a 30% improvement in the response rate from 20% of dx5 schedule to 50% of dx5x2 schedule ($\alpha=0.1$, $1-\beta=0.9$, one-sided test favoring dx5x2 schedule since the only difference of clinical importance was an improved response with the inconvenient schedule of dx5x2). A sample size of 30 patients per group (60 randomly assigned patients) was required to detect a significant improvement in ORR_{12w}. **Results:** Between May 21, 2020, and August 8, 2022, 24 patients were randomly assigned to dx5 schedule while 22 to dx5x2 schedule, respectively. Median follow-up was 10.7 months (IQR 9.7–13.9) in the dx5 group and 8.3 months (IQR 4.4–15.3) in the dx5x2 group. ORR_{12w} was lower in dx5 group than in dx5x2 group (5 [20.8%] of 24 patients vs 12 [54.5%] of 22; $p=0.019$). There was no significant difference in PFS between the two groups (median PFS 2.3 months [95% CI 0.0–4.7] in dx5 group vs 4.3 months [2.7–6.0] in dx5x2 group; hazard ratio [HR] 0.956 [95% CI 0.84–1.09]; $p=0.434$). Also, there was no significant difference in OS (median OS 14.8 months [95% CI 12.0–17.6] vs 12.8 months [95% CI 6.9–18.7]; HR 0.957 [95% CI 0.81–1.12]; $p=0.594$). Patients in dx5 schedule reported more grade 3 and 4 adverse events (AEs) than dx5x2 schedule, including diarrhea/abdominal pain (23 [23.7%] of 97 courses vs 8 [8.4%] of 95 courses, $p=0.005$), vomiting/nausea (6 [6.2%] vs 1 [1.1%], $p=0.035$). Other common grade 3 and 4 AE ($> 5\%$) were similar between two schedules ($p > 0.05$), including fatigue (24 [24.7%] vs 14 [14.7%]), leukopenia (6 [6.2%] vs 8 [8.4%]), neutropenia (5 [5.2%] vs 8 [8.4%]), and anemia (5 [5.2%] vs 7 [7.4%]). Unfortunately, the isolation policy of COVID-19 significantly restricted the speed of recruiting and the sponsor stopped following support to our study. **Conclusions:** Protracted dx5x2 VIT schedule showed superior efficacy and favorable tolerability compared with the shorter dx5 VIT schedule in patients with relapsed or refractory Ewing sarcoma. Clinical trial information: NCT03359005. Research Sponsor: This work was funded by Project (RDX2019-09) supported by Peking University People's Hospital Scientific Research Development Funds.

PEPN1924, a phase 2 study of trastuzumab deruxtecan (DS-8201a, T-DXd) in adolescents and young adults with recurrent HER2+ osteosarcoma: A children's oncology group pediatric early-phase clinical Trial Network study. *First Author: Damon R. Reed, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Overall survival for patients (pts) with recurrent, unresectable osteosarcoma (OS) remains poor, and event free survival (EFS) based on historical benchmarks has been used to determine efficacy of investigational agents. HER2, a transmembrane receptor with kinase activity involved in cell signaling through the RAS pathway, is expressed in OS. T-DXd is a HER2 targeting antibody linked to DXd with preclinical in vitro studies demonstrating activity in OS correlating with the presence of HER2 expression. We report results of a Phase 2 study of T-DXd in adolescents and young adults with HER2 positive relapsed, unresectable OS. **Methods:** Pts (12–39 yrs) with relapsed, unresectable OS were eligible for screening. The most recent available tissue sample was centrally evaluated for HER2 expression by immunohistochemistry. Pts with greater than 10% of OS cells with cytoplasmic or membranous HER2 expression of any intensity were eligible to receive T-DXd at 5.4mg/kg IV every 3 wks for up to 2 yrs. The proportion of pts with an EFS at 24 wks was the primary endpoint estimated using a 9+15 Simon's optimal two-stage design assuming an unacceptable response rate of 12%, acceptable response rate of 40%, 5% type 1 error, and 90% power. **Results:** 50 pts were screened for HER2, and 41 samples met the membranous or cytoplasmic HER2 expression inclusion criteria. A single pt had an assay failure and 8 pts had tumor samples with less than 10% HER2+ cells. Nine eligible pts were enrolled (7 male) between April 15th and November 11th of 2021 and received T-DXd. 2 pts were < 18 yrs old and the median age was 19.3 years. Seven pts received 2 cycles and had progressive disease (PD) at the first evaluation. A single pt withdrew consent before the first evaluation. The final pt was event free at wk 24, meeting the protocol specified criteria for a response. With a single pt having more than 24 wks of stable disease (SD) of the 9 planned in the first stage, this study did not meet criteria to progress to stage 2. The estimated response rate is 11.1% (1-sided 95% CI LB: 0.6%). The single responder with SD for 12 cycles had 15% HER2 positive OS cells and the remaining pts had 30–100% HER2 staining. A single cycle 1 DLT of thrombocytopenia (GR4) was observed. No unexpected or at least possibly or greater related AE's were observed. Grade 3–4 at least possibly related AE's occurred in 3 of 9 patients and included nausea, vomiting, tumor hemorrhage, cytopenias ($n=3$), wound infection, and hypertension. **Conclusions:** T-DXd did not demonstrate sufficient response to expand enrollment to the planned second stage in pts with OS. None of the pts had significant HER2 membranous staining which may account for the limited efficacy. No new toxicities were observed. Further correlative studies including PK, anti-T-DXd analyses and circulating tumor DNA are ongoing. Clinical trial information: NCT04616560. Research Sponsor: U.S. National Institutes of Health.

Variations in the approach to lung metastases in osteosarcoma among pediatric and adult patients. *First Author: Victoria A Wytiacz, Department of Internal Medicine, University of Michigan, Rogel Cancer Center, Ann Arbor, MI*

Background: Osteosarcoma (OS) is most common in the pediatric (ped) and young adult population but can occur at any age. Amongst other factors, older age confers a worse prognosis, and it is uncertain whether this is due to inherent biologic differences or treatment approaches. Lung-only metastases (mets) is common, and metastasectomy is performed frequently to improve overall survival. Little is known about the differences in lung-only metastatic OS and approaches to metastasectomies between ped and adult populations. **Methods:** A single-institution retrospective chart review using a free-text search engine and keywords "osteosarcoma, "lung mets" and "pulmonary mets", generated 206 patients(pts) diagnosed from 2006-2021. Eligible pts had a diagnosis of lung-only metastatic disease, resection performed at the institution and at least one year of follow-up data. Data was analyzed in two cohorts based on age at OS diagnosis: ped (age<18) and adult (age > 18 years), as well as with age as a continuous predictor. **Results:** Fifty pts (27F/23M) with lung only mets were eligible for analysis with a median follow up of 10.4 years. Median age was 23 yrs (range 6-77); 20 pts (40%) were ≤18 years old; 31 pts (16 ped, 15 adult) had an extremity primary site. Rates of metachronous (67% vs 60%) and bilateral (50% vs 40%) lung mets were similar in ped vs. adult pts, respectively. The median number of lung mets was 2 (range 1 to > 25) with 50% of patients (35) having 2-6 metastases (8 ped, 20 adult). The median size of lung metastasis was 1.2 cm (range 0.1-4.0 cm). 15 ped pts (75%) underwent metastasectomy, compared to 19 adult (63.3%) (OR 1.74, p = 0.39). Probability of metastasectomy decreased with age when used as a continuous predictor (p = 0.11). Ped pts were more likely to have an open procedure as compared to thoracoscopic (OR 12.75, p < 0.01). There was no significant difference in relapse-free survival between ped and adult pts who underwent metastasectomy (p = 0.84). Median overall survival following lung metastasis detection was 5.8 years for ped pts compared to 3 years for adult pts (p = 0.15 from Cox model). **Conclusions:** Multiple tumor and patient-specific factors affect the decision to undergo metastasectomy in lung-only OS. In our single-center study we learned that timing, pattern, and number of lung mets in ped vs. adult pts were similar, but younger pts were more likely to undergo an open procedure. Our data trended towards a lower chance of undergoing metastasectomy with older age. Larger studies are required to further understand decision-making and therapeutic outcome and a randomized study of open vs. thoracoscopic metastasectomy for lung-only OS mets is underway. In this small study, many patients with lung-only metastatic OS had long-term survival. We showed that relapse-free survival post-metastasectomy was similar in ped and adult patients. Research Sponsor: None.

ALMB-0168, a novel Cx43 hemichannel agonist monoclonal antibody, for metastatic or unresectable osteosarcoma after standard chemotherapy: A multicenter, open-label, single-arm, phase 1 study. *First Author: Jingnan Shen, Department of Musculoskeletal Oncology, the First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: The treatment of metastatic or unresectable osteosarcoma after standard chemotherapy remains a significant clinical challenge. Connexin 43 (Cx43) hemichannel has been suggested to be a key regulator of bone homeostasis and represents a new target for bone and breast cancer. ALMB-0168, a first-in-class therapeutic antibody agonist for Cx43 hemichannel, has been shown to suppress the growth and migration of osteosarcoma and breast cancer bone metastases in preclinical studies. **Methods:** Patients ≥16 years with histologically confirmed osteosarcoma who progressed after standard chemotherapy were eligible. This study consists of accelerated titration followed by a 3+3 design with 7 planned ALMB-0168 dose levels (1, 3, 6, 12, 18, 24, and 30 mg/kg) administered intravenously once every 3 weeks and then dose expansion at the potential recommended phase 2 dose (RP2D). Primary endpoints are safety and tolerability. Adverse events are rated according to the NCI CTCAE v5.0. Key secondary endpoints are overall response rate (ORR) and disease control rate (DCR) assessed using RECIST v1.1. **Results:** As of August 21, 2022, 14 patients (10 males, 4 females) with median age 27.5 years (range 16-38 years) were enrolled; ECOG PS was 0 in 7 patients (50.0%), 1 in 6 patients (42.9%) and 2 in 1 patient (7.1%). 5 patients received ≥2 prior lines of therapy. Six dose levels (1-24 mg/kg) have been completed in this ongoing study with no dose-limiting toxicities reported. Treatment related adverse events (TRAEs) of any grade occurred in 10 (71.4%) patients and were Grade 3 in 1 patient (infectious pneumonia); no events were Grade 4 or 5. Common TRAEs (> 10%) were proteinuria (21.4%), anemia (21.4%), hematuria (14.3%), and increased aspartate aminotransferase (14.3%). No Cx43-related cardiac events or severe hepatic events were observed. A total of 13 patients were evaluable for response. ORR was 15.4% (2/13, 95% CI: 1.9-45.5%), including 2 partial responses (PR), 1 patient each at 6 mg/kg and 18 mg/kg. The patient at 6 mg/kg, who had ≥3 prior lines of therapy and lung metastases, achieved durable disease control with stable disease (SD) for 33 weeks followed by PR for 8+ weeks (at the time of analysis). The DCR was 53.8% (7/13, 95% CI: 25.1-80.8%) with 2 PRs and 5 SDs. **Conclusions:** ALMB-0168 demonstrated encouraging efficacy and tolerable safety in patients with metastatic or unresectable osteosarcoma after standard chemotherapy in a phase 1 dose-escalation trial. Dose escalation is ongoing and dose expansion will start at the potential RP2D levels. Clinical trial information: NCT04886765. Research Sponsor: Alimab Therapeutics (Shanghai) Inc.

Evaluation of local control strategies on patterns of treatment failure in patients with localized ewing sarcoma treated on AEWS1031: A report from the children's oncology group. *First Author: Safia K. Ahmed, Mayo Clinic Arizona, Phoenix, AZ*

Background: To evaluate clinical characteristics and patterns of treatment failure in patients with localized Ewing sarcoma (ES) treated on AEWS1031 according to local control (LC) strategies, tumor size, and tumor site. **Methods:** AEWS1031 was a phase 3 randomized trial comparing two interval compressed chemotherapy regimens. Patients who completed LC on AEWS1031 were analyzed. LC was with surgery alone (S), definitive radiation therapy (RT), or surgery plus radiation (S+RT), and determined by the treating investigator. Local failure (LF) and distant failure (DF) were defined as recurrence at primary tumor site or distant site, respectively. Fine and Gray method was used to estimate cumulative incidence of LF and DF from time LC was completed. P-values were calculated using logrank or Gray's test, as appropriate. A two-sided p-value of ≤0.05 was considered significant. **Results:** 588 patients completed LC. Median age at enrollment was 13.0 years (range: 0.6-33.9 years). Tumor sites were categorized as extremity (230; 39%), axial (142; 24%), extraosseous (110; 19%), and pelvis (106; 18%). At diagnosis, tumor volume (TV) was ≥200 mL in 170 patients (31%) and maximum tumor dimension (MTD) was ≥8 cm in 289 patients (52%). LC was with S in 320 patients (54%), RT in 160 (27%), and S+RT in 108 (18%). Eight patients received pre-operative RT. Fifty-three patients (13.1%) who received S+RT had an R1 resection. LC with S was more likely for extremity (58%), RT for pelvis (38%) and S+RT for axial (36%) and extraosseous (34%) primary tumors (p < 0.01). With median follow up of 67.6 months from LC, the 5-year cumulative incidences of LF and DF for the entire cohort were 6.0% (95% CI, 4.3-8.3%) and 11.0% (95% CI, 8.6-13.9%), respectively. Eleven patients experienced simultaneous LF and DF. LF incidence was 5.0% for S, 8.4% for RT, and 5.6% for S+RT (p=0.47). DF incidence was 11.8% for S, 6.4% for RT, and 15.1% for S+RT (p=0.16). LF incidence by tumor site was 3.6% for extremity, 8.7% for pelvis, 7.3% for axial, and 6.8% for extraosseous (p=0.08). LF incidence was higher for primary tumors ≥200 mL (11.3%) compared to tumors < 200 mL (3.9%; p<0.01) and for tumors ≥8 cm (7.8%) compared to tumors < 8 cm (4.4%; p=0.02). Tumor size was associated with a higher LF incidence for S and RT, but not for S+RT (Table). LF incidence was 4.0% for R0, 7.5% for R1 with RT, and 16.7% for R1 without RT (p=0.02). **Conclusions:** We report the lowest LF incidence to date for prospective ES trials conducted. Both larger TV and MTD were associated with higher LF. Future investigations will aim to evaluate the impact of chemotherapy dose-intensity on LC and identify risk-stratification variables for improved LC. Five-year LF incidence by LC and tumor size. Clinical trial information: NCT01231906. Research Sponsor: U.S. National Institutes of Health.

ETCTN/NCI 10330: A phase 2 study of belinostat with SGI-110 (guadecitabine) or ASTX727 (decitabine/cedazuridine) for the treatment of unresectable and metastatic conventional chondrosarcoma. *First Author: Kristine Peregrino Lacuna, Columbia University Irving Medical Center, New York, NY*

Background: Conventional chondrosarcoma (cCS) is the 2nd most common primary bone tumor and is resistant to chemotherapy and radiation. *IDH1/2* mutations (m) occur in 50% of cCS. Both *IDHm* and wild-type (wt) cCS harbor epigenetic dysregulation. In preclinical models of *IDHm* and wt cCS, combination treatment with HDAC and DNMT inhibitors (i) suppressed growth *in vitro* and *in vivo* by reversing the hypermethylated state and inducing tumor suppressors, interferon response genes and apoptosis (Sheikh T, Schwartz G. Mol Cancer Ther 2021;20). **Methods:** NCI 10330 is a single-arm, multicenter, phase 2 study evaluating the HDACi belinostat (B) with the DNMTi SGI-110 (S) or ASTX727 (A). A replaced S due to drug availability (pts were replaced). Pts had advanced cCS, ECOG PS ≤ 2 and could be treatment naïve. Progression was required for grade 1 cCS. Pts received B 1000mg/m² IV + S 45mg/m² SC both days 1-5 or B (same dosing) + A (cedazuridine 100mg/decitabine 35mg) PO both days 1-5, in 28-day cycles. 1° endpoint was objective response. A Simon 2-stage design was used. If ≥ 2/13 responses occurred in stage 1, the study would proceed to full accrual. Design had 85% power with α = 0.05 to test ORR 8% vs 28%. 2° endpoints included safety, PFS and OS. A safety lead-in was performed. Paired biopsies were collected. **Results:** Stage 1 is complete. 19 pts were treated: 6 on B+S and 13 on B+A. Median age was 50 and 67 years, respectively. All pts had prior surgery. 17% (B+S) and 38% (B+A) had prior radiation. 33% (B+S) and 55% (B+A) were *IDHm*. 67% (B+S) and 75% (B+A) were histologic grade ≥ 2. There were no objective responses. Best response (at 8 weeks) was stable disease (SD) in 4/6 pts (67%) on B+S and 6/10 pts (60%) on B+A. mPFS was 4.2 mos (95% CI 1.97-NR) for B+S and 3.8 mos (95% CI 2.17-NR) for B+A. mOS has not been reached. For B+A, mPFS for *IDHm* vs wt pts was 4.7 and 3.1 mos, respectively (p=0.21). One pt with *IDHm* grade 2 cCS who progressed on FT-2102 (*IDH1*) remains on B+A > 1 year. There were no DLTs during either safety lead-in. Grade 3/4 treatment-related adverse events (TRAEs) occurred in 17% (B+S) and 69% (B+A). For B+A, the most common grade 3/4 TRAE was neutropenia (54%) and the most common all-grade TRAEs were nausea (69%), leukopenia (61%), neutropenia (54%), anemia (46%) and fatigue (46%). Paired tumor biopsies are being evaluated with whole exome sequencing, RNAseq, methylation array and multiplex IHC with results forthcoming. **Conclusions:** Combination HDACi + DNMTi was well-tolerated in advanced cCS. There were no objective responses; however, a subset of pts experienced prolonged SD with a trend towards improved mPFS in *IDHm* pts. Correlative work is ongoing with a focus on differential effects on *IDHm* tumors and whether modulation of the immune microenvironment might support combinations with immunotherapy. Support: UM1CA186689. Clinical trial information: NCT04340843. Research Sponsor: U.S. National Institutes of Health.

Phase I study of the mutant *IDH1* inhibitor ivosidenib: Long-term safety and clinical activity in patients with conventional chondrosarcoma. *First Author: William D. Tap, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY*

Background: Chondrosarcomas (CS) are rare primary bone malignancies for which there are no approved systemic therapies. 85% of CS are the conventional subtype. Mutations in the isocitrate dehydrogenase 1 (*IDH1*) gene occur in ~50% of conventional CS. In a phase 1 study in patients (pts) with *IDH1*-mutated advanced solid tumors, ivosidenib (IVO), an oral potent inhibitor of mutant *IDH1*, demonstrated manageable toxicity (without dose-limiting toxicities), suppression of the oncometabolite 2-hydroxyglutarate at dose levels ≥ 300 mg/day, and disease control in pts with conventional CS. We report long-term safety, tolerability and efficacy of IVO in pts with conventional CS. **Methods:** In this phase I multicenter open-label dose-escalation and expansion study, IVO was administered orally (100 mg twice/day [BID] to 1200 mg once/day [QD]) in continuous 28-day cycles. Primary outcome was safety and tolerability; secondary outcomes included clinical activity (objective response rates [ORR, defined as complete response (CR) + partial response (PR)], stable disease [SD] and progression-free survival [PFS]). Adverse events (AEs) were assessed every visit and reported per the Common Terminology Criteria for Adverse Events (CTCAE version 4.03). Responses were assessed every other cycle using Response Evaluation Criteria in Solid Tumors (RECIST version 1.1). **Results:** 13 pts with advanced conventional CS were included in this analysis (data cut off 15 September 2022; women, n = 4; median age 54.0; AJCC tumor grade I [n = 2], II [n = 8], III [n = 1], unknown [n = 2]; 6 had received prior systemic therapy; received 100 mg IVO BID [n = 1], 400 mg QD [n = 1], 500 mg QD [n = 7], 800 mg QD [n = 2], and 1200 mg QD [n = 2]). Median treatment duration was 11.3 months (range: 0.5-92.6 months). Four pts (30.8%) have continued therapy for > 6 years (two of which were treated for > 7 years). Median relative dose intensity was 100%. The most frequent treatment emergent AEs (in > 4 pts; mostly grade 1/2) were diarrhea (n = 5) and nausea (n = 5). Six pts experienced grade ≥ 3 AEs. Three pts experienced serious AEs (none considered related to treatment). There were no discontinuations, dose reductions or deaths due to AEs. The ORR was 23.1%. Median duration of response was 42.5 months (range: 25.8-51.8 months). One pt with a base of the skull lesion achieved a CR (1200 mg IVO QD); two achieved PR (one 500 mg and one 1200 mg IVO QD); seven had SD (five received ≥ 500 mg IVO QD) and two had PD (both received ≥ 500 mg IVO QD). All responses occurred after > 2 years on treatment. Median PFS was 7.4 months (95% CI: 2.0-61.3). **Conclusions:** In pts with *IDH1* mutated advanced conventional CS, IVO demonstrates manageable toxicity and durable disease control including long-term responses, extending several years for a proportion of pts. Future studies are warranted to better understand the efficacy of IVO in pts with advanced conventional CS. Clinical trial information: NCT02703994. Prolonged 14-day continuous infusion of high-dose ifosfamide (14IFO) for relapsed/refractory high-grade osteosarcoma (R/R HOS): A retrospective multicenter cohort study. *First Author: Elisa Tirtel, Pediatric Onco-Hematology, Regina Margherita Children's Hospital, AOU Città della Salute e della Scienza, University of Torino, Torino, Italy*

Background: The prognosis of patients (pts) with relapsed/refractory (R/R) High-Grade Osteosarcoma (HOS) remains dismal without an agreement on systemic therapy. The use of 14IFO with an external pump in outpatient setting (1g/sqm/day x 14 days every 21) in R/R HOS pts is limited. This is the first retrospective cohort study focused on 14IFO activity and toxicity in this setting (NCT04651569). **Methods:** Five Centers of the Italian Association of Pediatric Onco-Hematology and Italian Sarcoma Group participated to the study. Primary aim is to investigate 14IFO activity in pts with R/R HOS younger than 40 years. Secondary aim is to evaluate toxicity, according to CTCAE v.5, and clinical benefit. Progression Free Survival (PFS) and Overall Survival (OS) analysis are performed using the Kaplan Meier method with 95% confidence interval (CI). **Results:** Between 2012 and 2021, 26 R/R HOS pts were treated with 14IFO (median follow-up: 17.5 months, range: 4.6 – 83 months). Median age is 19 years at the beginning of 14IFO; eleven pts (42%) are ≤ 18 years. Three pts (12%) have a localized HOS, twelve pts (46%) have pulmonary disease only and eleven pts (42%) have a pluri-metastatic HOS. Eleven pts (42%) have a relapsed HOS with a median disease-free interval (DFI) of 13 months before 14IFO, the remaining (58%) have a refractory disease to two or more treatments. Overall, thirteen pts (50%) receive 14IFO as second line therapy and fifteen pts (57%) are pre-treated with ifosfamide in first line. Disease Control Rate is 57.5% (5 Partial Response + 10 Stable Disease). Seven pts (27%) receive a local treatment after 14IFO (5 surgery, 1 Radiotherapy (RT), 1 Carbon Ion RT). The median PFS is 4.1 months (95% CI 2.13, 7.37). 6-month and 1-year PFS are 38% (95% CI 24-63) and 8% (95% CI 2-29), respectively. The median OS is 13.7 months (95% CI 10.6 – 23.7). 1-year and 2-year OS are 51% (95% CI 35-75) and 22% (95% CI 9.5-49), respectively. Relapsed pts have both longer median PFS and OS compared to pts with a refractory disease [PFS: 7.33 months vs 2.13 months (p = 0.02); OS: 19.4 months vs 10.7 months (p = 0.1)]. Sixteen pts (61%) receive at least 4 cycles and an amount of 101 cycles are evaluated for toxicity. Grade 4 hematological toxicity is reported in 15 cycles (14.8%) as follows: i) white-blood cell decrease in 6 cycles (6%); ii) neutropenia in 7 cycles (7%); iii) thrombocytopenia in 2 cycles (2%). One patient has one episode of febrile neutropenia. No grade 3-4 non hematological toxicities are reported. **Conclusions:** This trial shows a non inferiority activity of 14IFO compared to other treatments in this setting, despite the small number of pts. Therefore, 14IFO should be considered as a treatment option in R/R HOS, especially for its well tolerated toxicity profile and the home-administration that improve patient's quality of life and it could significantly reduce cancer care cost. Clinical trial information: NCT04651569. Research Sponsor: None.

A phase 2 study of an anti-PD-L1 antibody (atezolizumab) in dedifferentiated chondrosarcoma. *First Author: Mohamad Adham Salkeni, Developmental Therapeutics Clinic, Division of Cancer Treatment and Diagnosis, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Chondrosarcoma (CS) is one of the most common bone malignancies in adults. Contrary to the indolent nature of low-grade CS, the dedifferentiated subtype (dCS), representing 5-10% of all CS, is known for aggressive behavior, high risk of relapse following resection, and poor prognosis. Expression of PD-L1 has been demonstrated in dCS samples and correlated with high numbers of tumor-infiltrating lymphocytes (Kostine, et al., Mod Pathol, 2016). Response to anti-PD1 therapy has not been evaluated prospectively. We report here the outcomes of a dCS cohort treated with the anti-PD-L1 agent, atezolizumab (atezo). **Methods:** Patients (pts) 2 years of age or older received intravenous atezolizumab 1200 mg (15 mg/kg with a 1200 mg cap in pediatric pts) once every 21 days. Prior immune checkpoint inhibitor therapy was not allowed. Primary objective was response rate (ORR). Imaging was carried out at the end of cycle 3 and then every two cycles; responses were evaluated per RECIST 1.1. The study employed a Simon two-stage design. If no responses were observed within 9 months of the ninth patient being enrolled, the cohort was to be terminated early. Research biopsies for immuno-pharmacodynamic (IO-PD) studies were collected at baseline, prior to C3D1, and optionally at progression. **Results:** Nine pts were enrolled to the dCS cohort. Three pts were female, 8 pts were White (1 unknown), all had an ECOG performance score ≤ 1 , and their median age was 63 years (range, 53-85). Primary disease sites were pelvis (2); sternum (2); femur, hip, chest, scapula, and lung (1 each). Median duration of treatment for all pts was 9 weeks. Seven pts were evaluated for response, of whom 3 (42.9%) were documented to have stable disease (SD) as best response, lasting a median of 25.9 weeks (range, 15-38.3 weeks). Four pts had a best response of disease progression. Two pts died prior to first response assessment. No RECIST objective responses were observed; the cohort was closed due to futility. Reasons for treatment discontinuation included progression (n = 6), death (1, respiratory failure unrelated to treatment), withdrawal of consent (1), and SARS-CoV-2 infection (1). Treatment-related adverse events (TrAE), grades 1-3, occurred in 7 pts (78%). Grade 3 TrAEs occurred in 2 pts (22%), included infusion reaction, myonecrosis, and anemia. IO-PD studies are ongoing to elucidate changes within the tumor microenvironment. **Conclusions:** Though objective response was not seen, atezo showed stabilization of disease in 1/3 of the patients with this aggressive tumor. IO-PD results will be critical to identify determinants of atezolizumab resistance within this dCS cohort and to identify possible partners for combination therapy. Funded by NCI Contract No. HHSN2612015000031. This project was also supported in with funding and drug supply from Genentech Inc (a member of the Roche group). Clinical trial information: NCT04458922. Research Sponsor: U.S. National Institutes of Health.

Survival outcomes in pediatric patients with metastatic Ewing sarcoma who achieve a rapid complete response of pulmonary metastases. *First Author: Audra J Reiter, Ann & Robert H. Lurie Children's Hospital, Chicago, IL*

Background: Twenty-five percent of patients with Ewing Sarcoma (EWS) have metastatic disease at diagnosis, most commonly in the lungs. Our objectives were to compare overall (OS) and pulmonary disease-free survival (PDFS) between patients with metastatic EWS at diagnosis who achieve rapid complete response (RCR), defined as radiographic resolution of all pulmonary nodules at the end of induction chemotherapy, and those with residual pulmonary nodules after induction chemotherapy (non-RCR). **Methods:** This multi-center, retrospective cohort study included children under 20 years of age with metastatic EWS treated from 2007-2020 at 19 institutions participating in the Pediatric Surgical Oncology Research Collaborative. Chi-square tests were conducted for differences among groups, and p < 0.05 was considered significant. Kaplan-Meier curves were generated for OS and PDFS. Cox regression was performed for OS, controlling for whole lung irradiation (WLI), extrapulmonary metastases, and age. **Results:** Among 153 patients with metastatic EWS at diagnosis, 61 (40%) achieved RCR, and 87 (57%) did not (5 unknown). The median number of pulmonary nodules was 3.5 in the RCR vs 5 in the non-RCR groups (p = 0.02), while bilateral disease was present in 44 (72%) RCR vs 75 (86%) non-RCR patients (p = 0.03). Pulmonary relapse occurred in 58 (38%) patients, including 18 (29%) in the RCR and 36 (41%) in the non-RCR groups (p = 0.14). Factors associated with pulmonary relapse in the univariate analysis include median age [15 years (IQR: 12-17) with pulmonary relapse vs 12 years (IQR: 9-16) without (p = 0.03)] and extrapulmonary metastases at diagnosis [24 (41%) patients with pulmonary relapse vs 26 (27%) patients without pulmonary relapse (p = 0.05)]. WLI was performed in 100 patients and was not associated with a reduction in pulmonary relapse (p = 0.93). Complete surgical clearance of pulmonary disease was attempted in 29 (19%) patients, including 17 of the patients who met the criteria for RCR. On Kaplan-Meier analyses, 5-year PDFS did not significantly differ based on RCR (67%) vs. non-RCR (53%, p = 0.13), or WLI (61%) vs. no WLI (54%, p = 0.32). However, 5-year OS did vary significantly between patients with RCR and WLI (85%), RCR without WLI (55%), non-RCR with WLI (60%), and non-RCR without WLI (25%; p < 0.01). In Cox regression analysis, RCR was associated with improved OS after controlling for WLI, extrapulmonary metastases, and patient age (HR 0.51, p = 0.03). **Conclusions:** Patients with EWS who had pulmonary metastases at diagnosis had improved OS if they achieved RCR and received WLI, despite having no significant differences in rates of pulmonary relapse. Further research is needed to determine whether clearance of pulmonary disease achieved through surgical metastasectomy provides a comparable survival benefit and if any subsets of patients have a reduced risk of pulmonary relapse after resection. Outcomes in patients with advanced gastrointestinal stromal tumor who did not have baseline ctDNA detected in the INTRIGUE study. *First Author: Jonathan C. Trent, Sylvester Comprehensive Cancer Center, University of Miami Health System, Miami, FL*

Background: Ripretinib is a switch-control tyrosine kinase inhibitor approved for patients (pts) with gastrointestinal stromal tumor (GIST) who received prior treatment with ≥ 3 kinase inhibitors, including imatinib. Exploratory baseline circulating tumor DNA (ctDNA) next-generation sequencing (NGS) analysis from INTRIGUE showed pts with second-line advanced GIST with primary *KIT* exon 11 mutations and secondary resistance mutations exclusively in *KIT* exons 17/18 derived clinical benefit from ripretinib but not sunitinib (Bauer S et al. *J Clin Oncol*. 2023; Abs 397784). Outcomes in pts with advanced GIST with ctDNA not detected (ctDNA-ND) had not been evaluated. Here, we present exploratory data from INTRIGUE in pts who had baseline ctDNA-ND vs ctDNA detected (ctDNA-D). **Methods:** INTRIGUE is an open-label, phase 3 study that enrolled pts with advanced GIST who had disease progression on or intolerance to imatinib (NCT03673501). Pts were randomized 1:1 to ripretinib 150 mg once daily (QD) or sunitinib 50 mg QD (4 wks on/2 wks off) and stratified by mutation according to local pathology report. Baseline peripheral whole blood was analyzed by Guardant360, a 74-gene ctDNA NGS-based assay. Pts with ctDNA-D had ≥ 1 somatic alteration in the 74 genes analyzed. **Results:** Pts with ctDNA-ND (82/362, 22.7%) were younger (median: 55.5 vs 62.0 years) and had smaller sums of longest diameters of target lesions (median [range]: 57.6 [11–459] vs 108.8 [15–418] mm) vs ctDNA-D (280/362, 77.3%). Progression-free survival (PFS) was longer in pts with ctDNA-ND vs ctDNA-D and numerically higher with ripretinib vs sunitinib in pts with ctDNA-ND (Table). Pts with ctDNA-ND categorized as not having a *KIT* exon 9 mutation at randomization (*KIT* exon 11, other *KIT*/PDGFRA, or *KIT*/PDGFRA wild-type; n = 71) had longer PFS with ripretinib vs sunitinib (median not estimable [NE] vs 11 months; HR = 0.56; 95% CI 0.28 to 1.12). Objective response rate (ORR) and overall survival (OS) were higher with ctDNA-ND vs ctDNA-D. Safety was similar between groups and consistent with the primary analysis. **Conclusions:** Pts with ctDNA-ND had better efficacy outcomes vs pts with ctDNA-D in both treatment arms; PFS was numerically higher with ripretinib vs sunitinib in pts with ctDNA-ND. Although little is known about the biology driving ctDNA in GIST, these data suggest pts may have improved outcomes and different treatment sensitivity based on ctDNA detectability. Clinical trial information: NCT03673501. Research Sponsor: Deciphera Pharmaceuticals, LLC.

Combination targeted therapy with avapritinib and sunitinib in patients with refractory gastrointestinal stromal tumors after failure of standard treatments: A small prospective pilot study. *First Author: Yanzhe Xia, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: There is currently no standard treatment after ripretinib beyond the fourth-line setting for refractory gastrointestinal stromal tumors (GISTs). A combination of tyrosine kinase inhibitors (TKIs) is rational to be potentially effective after failure of standard therapies. The objective of this study was to explore the efficacy and safety of avapritinib plus sunitinib in refractory GISTs. **Methods:** This was a prospective cohort study in part of a real-world trial (NCT05461664) exploring avapritinib in GIST patients (pts) after failure of standard treatments. Participants received avapritinib 100–200 mg once a day (QD) combined with sunitinib 25–37.5 mg QD continuously in 28-day cycles until disease progression (PD) or discontinuation from January 2022 to January 2023. Clinical outcomes including objective response rate (ORR), survival and safety were assessed. **Results:** A total of 11 pts with a median age of 57 years were enrolled. Median follow-up duration was 4.1 months (range, 1.4–12.8 months). Median sum of target lesions was 28.2 cm (range, 6.6–47.0 cm). Four pts had primary *KIT* exon 11 mutation, 6 had exon 9 and one had exon 17, secondary mutation *KIT* exon 13 was in 2 pts, exon 14 in one, exon 16 in 2 and exon 17 in 7 pts. Seven pts received more than 4 lines of prior TKIs, three received 3 and one had 2 lines of prior TKIs. One patient (9.1%) achieved partial response (PR) with 48.7% lesion length reduction, 9 (81.8%) had stable disease (SD) with 8 out of 9 pts achieving tumor shrinkage (median sum of lesion reduction of 20.8% [range, 9.8–27.3%]), and one (9.1%) had PD according to mRECIST1.1. Eight pts (72.8%) achieved PR, one (9.1%) had SD, and 2 (18.2%) had PD according to the Choi criteria. Until last follow-up, 4 pts progressed, one withdrew from the study and one discontinued treatment after surgery. Five pts were still receiving treatment, one exceeded 1 year with 26.3% lesion reduction in the seventh line setting. Progression-free survival and overall survival results were immature. ORR and lesion reduction trended favorably in those with *KIT* activation loop (AL) mutations, but this was not statistically significant. The dose of avapritinib (100–150 mg/d) and sunitinib (25–37.5 mg/d) could be tolerated. Common adverse events (AEs) were anemia, leukopenia, diarrhea, fatigue, periorbital and face edema, and memory impairment. Common grade ≥ 3 AEs included anemia (54.5%), leukopenia (36.4%), diarrhea (36.4%), tumor hemorrhage (27.3%) and gastrointestinal hemorrhage (18.2%). **Conclusions:** The preliminary results from this study demonstrated meaningful clinical benefit with avapritinib plus sunitinib, achieving significant lesion reduction in refractory GISTs, especially those with *KIT*/AL secondary mutations. Further studies are warranted to determine the optimal dosing regimen of two targeted drugs. Clinical trial information: NCT05461664. Research Sponsor: None.

Poster Session

Safety, pharmacokinetics (PK), and clinical activity of bezucastatinib + sunitinib in previously-treated gastrointestinal stromal tumor (GIST): Results from part 1 of the phase 3 Peak study. *First Author: William D. Tap, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY*

Background: Patients with GIST often relapse after first line therapy with imatinib due to secondary resistance mutations in *KIT*. As the *KIT* mutation targeting profiles of bezucastatinib (type I TKI) and sunitinib are distinct and complementary, when combined they inhibit a broad spectrum of secondary *KIT* mutations. In a prior Phase 1b/2a study (NCT02401815), the combination of the original formulation (Form. A) of bezucastatinib + sunitinib had an acceptable safety profile and was associated with clinical activity at the RP2D (Wagner, JAMA Oncol 2021;7(9):1343-50). An optimized formulation (Form. B) of bezucastatinib with improved bioavailability was developed to reduce pill burden for GIST pts. PK and safety results from the Part 1a lead-in of Peak (NCT05208047) have been previously presented (Wagner, CTOS 2022, P320). Herein we intend to report comprehensive clinical results from Part 1a including duration of therapy, initial response assessment and updated safety. **Methods:** Peak, a randomized Phase 3, open-label study, aims to evaluate efficacy and safety of bezucastatinib + sunitinib vs sunitinib in pts with imatinib-resistant or intolerant GIST. In Part 1a of the 3-part study, bezucastatinib (Form. B) dosing was escalated in serial cohorts based on PK results until the target exposure, comparable to those achieved at the RP2D established in the Phase 1b/2a study, was achieved. Key inclusion: adult with locally advanced, metastatic and/or unresectable GIST, ≥ 1 measurable lesion according to modified RECIST v1.1, and ECOG PS 0 to 2. **Results:** Part 1a enrolled 19 pts. Five pts (Cohort 1) received the starting dose of once daily (QD) bezucastatinib 300 mg+ sunitinib 37.5 mg; dose was escalated to 600 mg with 14 pts receiving bezucastatinib 600 mg + sunitinib 37.5 mg. Median age - 60 yrs (range: 42-77); 68% male; 95% ECOG PS 0-1; 95% metastatic and 5% locally advanced. As of Sept 2022 data cutoff, the median (range) treatment duration was 6 weeks (3.1, 23.9). Due to AEs, one pt required dose reduction of bezucastatinib (Gr 3 diarrhea) and 1 pt discontinued (Gr 2 rash). The majority of TEAEs were low grade, with no $\geq$ Gr4. Most common TRAEs were diarrhea (37%), neutropenia (37%), ALT (32%) and AST (26%) increases. One pt experienced SAEs of Gr 2 neutropenia and pyrexia and Gr 3 thrombocytopenia. Steady state exposure in pts receiving QD doses of bezucastatinib 600 mg + sunitinib 37.5 mg in this study were similar to that at the RP2D established in the prior Phase 1b/2a study. **Conclusions:** Initial data from Peak shows an encouraging safety and tolerability profile with no unique safety signals when compared to the known safety profile for sunitinib monotherapy. A dose of bezucastatinib 600 mg QD + sunitinib 37.5 mg QD was confirmed for use in Peak study Part 2, for which enrollment is ongoing. Updated data from Part 1a, including response data, will be presented. Clinical trial information: NCT05208047. Research Sponsor: Cogent Biosciences.

Fluorine-18 fluorodeoxyglucose (¹⁸FDG)-uptake assessment of PDGFRA mutant gastrointestinal stromal tumors (GIST): A retrospective multicenter Italian study. *First Author: Maria Concetta Nigro, Oncology Unit, Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy*

Background: D842V PDGFRA mutation identifies a molecular subtype of GIST, primarily resistant to imatinib and characterized by higher indolent behavior and a prominent immune profile. Although functional imaging with ¹⁸FDG-PET plays a proven role in GIST, especially in early assessment tumor response, less is known about ¹⁸FDG-uptake according to the GIST molecular subtypes. Taking into account of clinical and molecular features of D842V mutant GIST, we assumed that this subset of GIST could also have a different ¹⁸FDG-uptake. Therefore, the aim of the present study has been to investigate the degree of FDG uptake of PDGFRA mutant GIST, focusing on D842V ones, in order to better define the role of functional imaging in this rare and peculiar subset of GIST. **Methods:** Patients with PDGFRA mutant GIST underwent ¹⁸FDG-PET were retrospectively included from seven GIST Italian reference centers. Data on maximum standardized uptake (SUVmax) value of primary tumor or metastatic disease were collected. **Results:** 71 patients have been included: 37 (55.1%) with D842V PDGFRA mutant GIST (group A) and 34 (47.9%) with PDGFRA non-D842V mutant GIST (group B). Additionally, 30 patients with exon 11 *KIT* mutant GIST have been included, as control (group C). SUVmax values were obtained from primary tumor and metastatic lesions in 55 (54.4%) and 46 (45.6%) patients, respectively. Considering the whole population of 101 patients, the global median SUVmax was 3.7 (IQR 0-9.1), while the median SUVmax for group A, B, and C was 0, 3.6, and 10.4, respectively. The median SUVmax of PDGFRA mutant GIST was significantly lower than the median value of exon 11 *KIT* mutant GIST (p < 0.001). Notably, median ¹⁸FDG-uptake was significantly lower in D842V PDGFRA mutant GIST compared to PDGFRA non-D842V mutant ones (p = 0.021). **Conclusions:** PDGFRA D842V-mutant GIST present an overall lower ¹⁸FDG uptake compared to other GIST subgroups. This feature could be related to their specific molecular background and is consistent with their higher tendency to an indolent behavior. Therefore, the role of functional imaging with ¹⁸FDG-PET in this subset of GIST is limited. Finally, the prognostic value of the ¹⁸FDG-uptake degree within all PDGFRA mutant GIST will be investigated in the future. Research Sponsor: None.

Antitumor activity of olverembatinib (HQP1351) in patients (pts) with tyrosine kinase inhibitor (TKI)-resistant succinate dehydrogenase (SDH)-deficient gastrointestinal stromal tumor (GIST). *First Author: Haibo Qiu, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Sun Yat-sen University, Guangzhou, China*

Background: Treatment of pts with GIST has been transformed by TKIs. However, treatment resistance is a challenge in managing locally advanced or metastatic disease. Pts with SDH-deficient GIST typically present with multifocal and multinodular disease that is insensitive to most TKIs. Olverembatinib is an investigational novel, potent, orally active third-generation TKI with promising activity against GIST in multiple preclinical models. **Methods:** The aim of this study was to evaluate the safety and efficacy (per RECIST v1.1) of olverembatinib in pts with TKI-resistant metastatic SDH-deficient GISTs (confirmed by immunohistochemistry). Olverembatinib was administered orally once every other day (QOD) in 28-day cycles. **Results:** As of January 15, 2023, 20 pts with SDH-deficient GIST had received ≥ 1 dose of olverembatinib (median age, 30 [14-56] years), and 19 had received 1 to TKIs (50% of pts ≥ 3 ; Table). The dose range of olverembatinib was 20 to 50 mg (50 mg cohort [n = 6]; 40 mg [n = 8]; 30 mg [n = 6]). The median (range) treatment duration was 7.8 (1.81-42.3) months. A total of 5 of 20 pts experienced partial response (PR) as the best response. Of 16 evaluable pts treated with > 4 cycles of olverembatinib, the clinical benefit rate (CBR; complete response + PR + stable disease > 4 cycles) was 93.8% (15/16); the longest treatment duration was 42 months. All pts experienced treatment-emergent adverse events (AEs; most, grade 1 or 2); 2 pts experienced grade 3 AEs; the only hematologic AE with an incidence rate $\geq 20\%$ was anemia (55%). A total of 15 (75%) pts experienced treatment-related AEs (grade 3 neutropenia [n = 1]). No treatment-related serious AEs were reported. **Conclusions:** Olverembatinib was well tolerated up to 50 mg QOD and showed antitumor activity in pts with TKI-resistant, SDH-deficient GIST. A total of 5 PRs were reported among 20 evaluable pts and 15 SDs among 16 pts treated for ≥ 4 cycles (98.3% CBR). These promising findings warrant further investigation. Internal study identifier: HQP1351SJ003. Clinical trial registration: NCT03594422. Research Sponsor: Ascentage Pharma Group.

Longitudinal follow-up and outcomes of pediatric and adult patients with SDH-deficient GIST. *First Author: Urania Dagalakis, Pediatric Oncology Branch, Center for Cancer Research, Bethesda, MD*

Background: Gastrointestinal stromal tumor (GIST) are gastrointestinal non-epithelial neoplasms most commonly driven by somatic mutations in *KIT* or *PDGFRA*. Approximately ten percent of GIST are due to germline mutations in *SDHx* or epigenetic loss of expression of *SDHC*. While *KIT* and *PDGFRA* driven GIST respond to treatment with tyrosine kinase inhibitors, effective systemic therapies for SDH-deficient GIST have not yet been identified. SDH-deficient GIST are indolent tumors that typically progress slowly over time. A better understanding of the natural history of patients with these neoplasms is critical to identify effective treatments and improve patient care. A cohort of patients with SDH-deficient GIST is followed at the NIH Clinical Center and through the NIH Pediatric and Wild-type GIST Clinic. The aim of this study is to characterize the long-term outcome of this cohort of patients. **Methods:** Data from patients with SDH-deficient GIST enrolled in a study Natural History and Biospecimen Acquisition for Children and Adults with Rare Solid Tumors (NCT03739827) from January 2019 through January 2023 at the NIH were evaluated. In addition to review of medical records and imaging, when available, tumors were characterized by sequencing of *SDH* genes. Germline analysis of *SDH* genes was offered to consenting patients and families. **Results:** Clinical information and specimens were collected from 77 GIST patients (median age at diagnosis 21.5, [range 7-57] years; 72.7% (56) female, 21.3% (21) male) were classified by molecular subtypes: 33.8% SDHC epimutation, 28.6% SDHA, 22.1% SDHB, 14.3% SDHC and 1.3% SDHD. Median age at presentation of SDHC epimutation was younger (14.5 years, range: 8-56) when compared to SDHA (27.5 years, range: 7-55), SDHB (22 years, range: 8-54), SDHC (18 years, range: 10-57) and SDHD (39 years, N = 1). Most commonly, patients had at least one surgery (55.8%) while a lower proportion had four or more (7.8%). Primary tumors occurred in the stomach with 26% having metastases at presentation the most common location being the liver (10.4%). Overall, 64.9% of patients were treated with imatinib, 39% were treated with sunitinib and 15.6% received other additional systemic therapies. Within the cohort there were 13% of patients with paragangliomas and 6.5% with chondromas while only 9.1% had a family history of GIST. **Conclusions:** Longitudinal follow-up of an SDH-deficient GIST patient cohort will allow for better understanding of the natural history including treatment history and survival of patients with this rare disease and will help to optimize strategies for treatment and follow-up of these patients. Clinical utility of liquid-based comprehensive genomic profiling (CGP) in gastrointestinal stromal tumors (GIST). *First Author: Lindsey Hildebrand, Boston Medical Center, Boston, MA*

Background: GIST is the most common mesenchymal cancer of the digestive tract. Beyond surgery, treatment for GIST focuses largely on tyrosine kinase inhibitors (TKI), whose selection and potential resistance depend on select mutations. We present the molecular landscape of GIST utilizing tissue and liquid biopsies with emphasis on the clinical utility of liquid biopsy in advanced GIST. **Methods:** Liquid (FoundationOne Liquid CDx [F1LCDx]) and tissue (FoundationOne CDx) CGP was performed by hybrid capture, targeted NGS at Foundation Medicine Inc. Tissue and liquid samples from 2,198 and 147 patients, respectively, were analyzed. A cohort of 27 paired tissue and liquid samples were also evaluated. The levels of circulating tumor DNA (ctDNA) in liquid biopsies was quantified by tumor fraction (TF), with a TF algorithm incorporating aneuploidy, variant allele frequency, and canonical alterations detected on F1LCDx. **Results:** Tissue CGP (n = 2,198) revealed the following prevalence of primary driver alterations: *KIT* (77%), *PDGFRA* (8%), *NF1* (6%), *SDHAB/C/D* (SDHx, 3%) and *BRAF* (1%). Rates of molecular markers previously associated with worse prognosis included: *CDKN2A* (29%), *RB1* (9%), *TP53* (6%) and *SETD2* (4%). 7% of cases had no reportable known pathogenic alterations in canonical GIST genes (wild-type GIST), while 2% of cases had a mutation in more than one driver. In a cohort of 147 liquid biopsies, TF was $< 1\%$ in 68.0%, 1-10% in 18.4%, $> 10\%$ in 13.6% of samples. In samples with elevated TF ($> 10\%$), the prevalence of targetable driver alterations in *KIT* (89%), *PDGFRA* (4%), *NF1* (4%) and *BRAF* (4%) was comparable to the tissue prevalence. In liquid, 58% (39/67) of samples with a *KIT*-driver mutation had a co-occurring imatinib-resistant *KIT* alteration. In addition, 4/147 patients (3%) were predicted to harbor a germline *KIT* mutation, including one patient (0.6%) with a potential imatinib-resistant *KIT* D820G germline mutation and another with clinical suspicion of germline *KIT* L576P mutation due to the presence of multiple primary GISTs, hyperplasia of myenteric plexus and dysplastic skin nevi. In paired tissue/liquid samples, liquid detected 2/2 driver mutations found in tissue when liquid TF was $> 10\%$, and 5/6 in specimens with TF $> 1\%$. In the overall cohort, the relative prevalence of *KIT* exon 9 and 11 driver alterations was comparable in tissue vs liquid, while imatinib-resistance *KIT* exon 13 and 17 mutations were enriched in liquid samples. **Conclusions:** Known driver and TKI-resistant mutations of both somatic and potential germline origin are identified in peripheral blood ctDNA of GIST patients. Liquid biopsy shows high concordance to tissue in identifying driver mutations in the presence of elevated TF and may exhibit TKI-resistant specific alterations. This study indicates that liquid biopsy may be useful in the molecular classification of GIST during the medical management of advanced GIST patients. Research Sponsor: Foundation Medicine, Inc.

Efficacy and safety of ripretinib in Chinese patients with advanced gastrointestinal stromal tumors (GIST) as ≥ 4 th line therapy: Long-term update from a single-arm, phase 2 trial. *First Author: Jian Li, Peking University Cancer Hospital & Institute, Beijing, China*

Background: In INVICTUS study (NCT03353753), ripretinib as ≥ 4 th line (4L) GIST therapy significantly improved median progression-free survival (mPFS) versus placebo (hazard ratio 0.15, 95% confidence interval [CI] 0.09-0.25; mPFS 6.3 vs 1.0 months) with a satisfactory safety profile. In the primary analysis (data cut-off: 26 Feb 2021) of the bridging study (NCT04282980) of INVICTUS, ripretinib as ≥ 4 L therapy showed consistent efficacy and safety profiles in Chinese GIST patients to those in INVICTUS, with mPFS of 7.2 months and objective response rate (ORR) of 18.4% (7/38 patients). The overall survival (OS) data was immature at the primary analysis. Here we report the long-term updates of this bridging study. **Methods:** Patients received ripretinib 150 mg once daily continuously in 28-day cycles until progressive disease or other protocol-specified events for treatment discontinuation. The primary endpoint was progression-free survival (PFS) by independent radiologic review (IRR) using Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 GIST-Specific Standard. Secondary endpoints included ORR by IRR, time to best response (TBR), duration of response (DOR), OS and safety. Adverse events were graded according to National Cancer Institute Common Terminology Criteria for Adverse Events v4.03. **Results:** Overall, 39 patients were enrolled. Thirty-eight patients received continuous ripretinib treatment and were included in the efficacy analysis set. All 39 patients received at least one dose of ripretinib and were included in the safety set. The updated data cut-off was 23 Aug 2022. The overall median follow-up (90% CI) was 23.00 (11.99, 24.87) months. In the efficacy analysis set, mPFS (90% CI) by IRR was 6.44 (2.89, 8.31) months and ORR was 21.1% (8/38 patients). Median TBR and median DOR for the 8 patients with confirmed partial response were 2.25 and 8.57 months, respectively. The median OS (95% CI) in the efficacy analysis set was 25.56 (11.73, not evaluable) months. In the safety set, 20.5% of patients experienced ≥ 1 grade 3/4 treatment-related treatment-emergent adverse events (TRAEs). Compared to the primary analysis, the increase in TRAEs and new TRAEs leading to dose modification were minimal after 18 months of additional follow-up. **Conclusions:** After long-term follow-up, the more mature results continued to support the clinically meaningful benefit in PFS and also demonstrated clinically meaningful benefit in OS in Chinese ≥ 4 L GIST patients, while the safety profile remained satisfactory. Clinical trial information: NCT04282980. Research Sponsor: Zai Lab (Shanghai) Co., Ltd.

Exploratory novel biomarker and resistance mechanism of milademetan, an MDM2 inhibitor, in amplified MDM2 intimal sarcoma from an open-label phase 1b/2 trial (NCC1806/MK004). *First Author: Takafumi Koyama, Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan*

Background: Amplified *Murine double minute 2 (MDM2)* is found in > 70% of intimal sarcoma, known as one of the ultra-rare sarcomas. Milademetan (DS3032, RAIN-32) is a novel, specific, small-molecule MDM2 inhibitor that disrupts MDM2 and the tumor suppressor protein p53 interactions in tumor cells. We conducted a phase 1b/2 trial (Trial registration No: JMA-IA00402) in patients with amplified *MDM2* wild-type *TP53* intimal sarcoma as a sub-study under the nationwide large registry for rare cancers in Japan (MASTERKEY Project). Eleven patients were enrolled, and ten were included in the efficacy analysis. Two (20%) patients had durable responses for > 15 months. Milademetan provided clinical benefits in patients with amplified *MDM2* intimal sarcoma. Predictive biomarkers other than amplified *MDM2* and acquired resistance mechanisms for milademetan are unknown. **Methods:** Whole-exome and RNA sequencing analyses of pre-treatment tissue samples were conducted to identify determinants of response. Genomic alterations were analyzed for 10 patients, and gene expression was analyzed for 9 patients using their pre-treatment tissue samples. Targeted sequencing of cell-free DNA (cfDNA) samples (liquid biopsy) was also conducted sequentially at three points [before treatment with milademetan (baseline), at Cycle 2 Day1, and at the time of disease progression] to identify determinants of response and resistance. **Results:** From whole-exome and RNA sequencing analyses of pre-treatment tissue samples, we could not find any molecular pathways associated with the anti-tumor activity of milademetan. Focusing on 8 genes (*CDK4*, *CDKN2A*, *CDKN2B*, *EGFR*, *ERBB3*, *MDM2*, *PDGFRA*, *TP53*) known to be frequently altered in intimal sarcoma and 10 genes (*AKT1*, *ATM*, *BBC3*, *CDKN1A*, *CDKN1C*, *CHEK2*, *MDM4*, *PMAIP1*, *PPM1D*, *TP53*) reported to be associated with MDM2 inhibitor responses; we found that anti-tumor activity correlated with amplified *TP53* (p -value = 0.028) and negatively with *CDKN2A* loss (p -value = 0.071). Eight of the 10 patients had their cfDNA collected sequentially at baseline, at Cycle 2 Day1 and disease progression; however, one did not consent to the exploratory analysis study using cfDNA, and one had cfDNA collected at baseline but not at disease progression due to ongoing treatment. Of the eight patients, *TP53* mutations in cfDNA were detected in one and five patients at baseline and disease progression, respectively. The cfDNA allele frequency of *TP53* mutations increased with disease progression. **Conclusions:** *CDKN2A* loss and amplified *TP53* could be associated with the anti-tumor activity of milademetan in patients with amplified MDM2 intimal sarcoma. Acquired *TP53* mutations were detected in sequential liquid biopsies as loss-of-function mutations, and these *TP53* mutations might compromise the anti-tumor activity. Clinical trial information: JMA-IA00402. Research Sponsor: None.

Alternative splicing (AS) regulation as a novel therapeutic target in soft-tissue sarcoma (STS). *First Author: David Silva Moura, Health Research Institute-Fundación Jiménez Díaz University Hospital, Autonomous University of Madrid (IIS-FJD, UAM), Madrid, Spain*

Background: There is an urgent clinical need to identify novel treatments for advanced STS, since all the clinical trials testing chemotherapy combinations have failed to improve survival compared to doxorubicin (dox) alone. AS deregulation has been associated with cancer initiation, progression and resistance to therapy. This deregulation can occur due to mutations or imbalanced expression or activity of splicing factors (SF). The alteration SF can alter thousands of pre-mRNAs, increasing cellular complexity and facilitating tumour progression. CDC-like kinases (CLK) that phosphorylate serine-arginine-rich SF (SRSFs), are key regulators of AS. SM09419 is an oral pan CLK/DYRK inhibitor that has been shown to inhibit SRSF phosphorylation, selectively modify spliceosome activity and decrease tumour growth by multiple mechanisms including the downregulation of Wnt/ β -catenin signalling, a pathway that we reported to be important in sarcoma. **Methods:** A panel of 9 STS cell lines, including LMS (CPO024, IEC005, AA, SK-UT-1), LPS (93T449), synovial sarcoma (MCP037) and UPS (MCP016, MCP021, MCP025) were used to analyse the effect of SM09419 (provided by Biosplice) or PRI-724 (Wnt/ β -catenin inhibitor) on cell viability (MTS assays). TOP flash β -catenin/TCF-responsive reporter assay was performed to evaluate the inhibition of the Wnt/ β -catenin pathway in response to SM09419. *In vivo* experiments tested the combination of SM09419 (25mg/kg 5 days on and 2 off, for 21 days cycle) plus IP dox (5mg/kg once a week for 21 days cycle) in LMS (IEC005) and synovial sarcoma (FJD-SS-001) PDX models. **Results:** Our results showed that SM09419 had superior activity in STS cells compared to specific Wnt/ β -catenin inhibitors with IC_{50} values starting at 29.8 nM in SK-UT-1 cell line, whereas PRI-724 IC_{50} values were clearly higher, starting from 5.18 μ M in 93T449 cells. SM09419 treatment significantly inhibited the transcriptional activity of β -catenin by 40% in the MCP021 cells, demonstrating the regulatory activity of AS inhibitors on this pathway. *In vivo* studies confirmed the higher efficacy of SM09419 in monotherapy compared to dox, in inhibiting tumour growth ($p < 0.05$), which was potentiated when combined with dox. The combination was increasingly active in synovial sarcoma with tumour regressions in 3 out of 4 mice, including one complete response. Treatment schedule was adapted to a single IP administration of dox (5mg/kg) and 5 administrations of SM09419 (25mg/kg), to improve the tolerability of the combination. **Conclusions:** The effects of pan CLK/DYRK inhibition on growth and survival of STS cancer cell lines and PDX models, indicate that can STS may be therapeutically addressed with these AS-modulators. The combination of SM09419 with dox was active in STS preclinical models known for their resilience toward treatment. Based on these results, the exploration of such combinations in clinical trials is warranted. Research Sponsor: Foundation AECC - GEACC19007MA.

Large versus limited molecular profiling panel screening program in patients with metastatic sarcoma: An exploratory subgroup analysis from the Profiler 02 trial. *First Author: Mehdi Brahmi, Centre Léon-Bérard, Lyon, France*

Background: Profiler 02 (NCT03163732) is a multicentre, randomized molecular screening clinical trial aiming to evaluate the feasibility and the benefit of a large NGS (Next-generation sequencing) panel (FoundationOne Medicine NGS panel or FOne, 324 cancer-related genes) compared to a limited one (Control panel or CTRL, 87 cancer-related genes) in terms of clinical, quality of life and health economic outcomes. We present here the results of the patients with advanced/metastatic sarcoma included in the Profiler 02 trial. **Methods:** Patients (pts) were enrolled during their first-line of standard therapy for an advanced sarcoma. All sarcomas diagnosis were performed within the RRePS network (French pathology network of reference for sarcomas) and a central pathological review confirmed if quality and quantity of material were acceptable for molecular analysis. Patients were randomized within the two study arms (FOne versus CTRL) and DNA was analysed using both panels. The primary objective of the study was to compare the proportion of patients for whom a genomically driven recommended therapy (RT) could be initiated based on the FOne versus CTRL panels. A dedicated Molecular Tumour Board (MTB) reviewed tumour genomics data of both panels independently to propose a RT. **Results:** From January 2018 to July 2019, 39 pts with sarcoma (20F, 19M), with a median age of 54 years [21-81], were randomized between FOne Arm (17 pts) and CTRL Arm (22 pts). Pathological subtypes per arm are presented in the table. Overall, 19 pts (49%) had at least one genomically driven RT, 11 according to both panels and 8 according to FOne panel exclusively (McNemar's test, $p=0.01$). Main RT were CDK4/6 inhibitors ($n=5$), PI3K/AKT/mTOR inhibitors ($n=4$), and immunotherapy ($n=4$). After the MBT, a RT was initiated for seven patients, four according to FOne panel only and three according to both panels. Importantly, a complete response was observed for a metastatic MPNST (Malignant Peripheral Nerve Sheath Tumor) with a high tumour mutational burden (TMB) detected by the FOne panel (37 mutations per megabase) and treated with durvalumab (anti-PDL1) + tremelimumab (anti-CTLA4). **Conclusions:** Although from an exploratory subgroup analysis, these results suggest that a large molecular profiling panel including TMB (FOne panel) might increase the number of RT and the number of sarcoma patients treated. Studies of precision medicine in rare cancers such as sarcomas are feasible, this approach could benefit to patients. Clinical trial information: NCT03163732. Novel genomic alterations and transcriptomic-based tumor microenvironment classification of sarcoma and their impact on treatment decision making. *First Author: Irina Zhuk, BostonGene, Corp., Waltham, MA*

Background: Sarcomas are rare tumors of mesenchymal origin, with over 50 different histological sarcoma subtypes. The heterogeneous molecular and immunologic characteristics of sarcomas present many challenges for diagnostics and treatment plans. We aim to provide a more comprehensive molecular testing and immune profiling of sarcoma patients. **Methods:** The cohort consisted of samples from 200 patients diagnosed with sarcomas. WES and whole transcriptome analysis were performed on all samples. Tumor Portrait test identified genomic alterations of sarcomas and classified tumor microenvironment (TME) subtypes. The actual response to immune checkpoint inhibitor (ICI) treatment was determined using RECIST criteria and compared to response predictions by the Tumor Portrait test. **Results:** Across sarcoma subtypes, the most common mutations were in tumor suppressors including *TP53*, *RB1*, *CDKN2A*, and *TSC1/2*. We report fusions in 20.5% of cases, with commonly described diagnostic fusions accounting for 34/41 cases. In one case, the detection of the *ZC3H7B-BCOR* fusion suggested a change in diagnosis from uterine leiomyosarcoma to endometrial stromal sarcoma. Several previously unreported fusions were detected, including potentially targetable (*ARID1A-NUDC*, *MICAL3-MAPK*) and prognostic (*YWHE-CIC*) fusions. DNA damage response related genes were mutated in 12% of cases. Other less commonly detected targetable alterations were found in the following genes: *MDM2*, *CDK4*, *SMARCB1*, *NF1*, *PIK3CA*, *NTRK1-3*, *FGFR1-4*. Transcriptomic-based TME classification found that 52% of patients had an Immune-Enriched (IE) TME, with 26.5% and 25.5% grouped in the IE-Fibrotic and IE-non-Fibrotic subtype, respectively, which we previously showed is associated with good response to ICI treatment. In contrast, 48% of the patients presented with a Fibrotic (F, 30%) or Desert (D, 18%) subtype, are predicted to have a poor response to ICI treatment. Our classification of sarcomas based on TME subtypes conforms well with predicted responses of tumors to ICI therapy found in previous reports. Soft-tissue angiosarcomas, undifferentiated pleomorphic sarcoma, and myxofibrosarcomas presented TMEs of the IE subtype in 75% of cases, significantly more compared to 34% of the bone neoplasm cases, which are known for their favorable and unfavorable response to ICI therapy, respectively (Chi-squared test, $p = 0.001$). In retrospective chart review, we had response data on 24 patients who received ICI treatment. The disease control rate, defined as CR+PR+SD as best response, was significantly higher in the IE subtype compared to the F/D subtype (85.7% vs 20%, Chi-squared test, $p < 0.003$). **Conclusions:** Together, our findings identify actionable and diagnostic alterations in diverse mesenchymal tumors and suggest that ICI treatment may be beneficial in immune-enriched sarcomas. Next generation sequencing reveals targetable mutations in multiple sarcoma histologies. *First Author: Rodney Dixon Dorand, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: Sarcomas are a rare and heterogeneous group of cancers that arise from bone or soft tissue, and two thirds have poorly defined mutational profiles. Given their rarity, few comprehensive studies have fully characterized mutations and gene expression across sarcoma histologies correlated with clinical outcomes. Further studies are needed to determine the presence of targetable mutations that may improve patient outcomes. In this study, we explored the genomic landscape and clinical actionability of sarcoma mutations from patients enrolled in our CAUSAL (Cohort to Augment the Understanding of Sarcoma survivorship Across the Lifespan) study. **Methods:** Between 04/01/2022 and 01/01/2023, 481 participants, treated from 2012 – present with multiple sarcoma histologies were enrolled on CAUSAL. Next Generation Sequencing (NGS) was performed on primary or metastatic tumors from 76 patients to determine DNA mutations within a 648 gene panel. Whole transcriptome RNA sequencing (seq) provided expression profiles and RNA fusion products. Further analysis was performed using principal components analysis of RNA seq data to explore correlates amongst sarcoma subtypes. Tumor mutations were queried in ClinVar for relevance to known variants and were assigned to tiers I-IV based on the ESMO scale for clinical actionability of molecular targets (ESCAT). Tier I mutations have drug-mutation matched evidence of actionability while tier IV have only pre-clinical evidence. **Results:** NGS has been completed on 76 tumor samples. Sequenced tumors represented 19 histologies, with the most common ones as follows: undifferentiated pleomorphic sarcoma (15.8%), liposarcoma (9.2%), gastrointestinal stromal tumor (9.2%), osteosarcoma (7.9%), and leiomyosarcoma (7.9%). Of 76 patients, 66 (87%) had at least one mutation detected with an mean frequency of 2.74. *TP53* (20/66), *RBI* (14/66), and *ATRX* (9/66) were most commonly mutated genes. Mean (std) tumor mutation burden (TMB) was 3.4 m/MB (3.5m/MB) and one tumor had TMB of 25.3 m/MB. Of the 76 samples, 68 had RNA expression and fusion data available, of which 42 (62%) had anomalous expression changes and 11 had RNA fusions. The most overexpressed genes were *NY-ESO-1* (13), *LAGE-1* (9), and *RET* (7); the most under-expressed genes were *SMARCB1* (9) and *MGMT* (6). 30.2% (23 of 76) of patients had potentially actionable DNA mutations, 9 had ESCAT tier I DNA mutations, 3 had tier II, 10 had tier III, and 1 had tier IV. 29.4% (20/68) of patients had potential targets based on RNA expression. 51.3% (39/76) patients had either a potential DNA or RNA target, and 6.6% (5/76) had multiple RNA or DNA targets. **Conclusions:** NGS revealed potentially actionable targets in over half of sarcoma patients based on ESCAT criteria. With ongoing accrual and sequencing of additional tumor specimens future analysis of CAUSAL will focus on assessing the correlation between targetable mutations and clinical outcomes. Aristolochic acid (AA) exposure and telomere maintenance mechanism in liver angiosarcoma (AS). *First Author: Tom Wei-Wu Chen, Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan*

Background: Liver AS has a grave prognosis and our previous study (Chen TW et al. Cancer 2022) showed that the incidence of liver AS is higher in Asia. We aimed to investigate the etiology of liver AS and its molecular characteristics. **Methods:** We performed whole exome (WES) and transcriptome sequencing (RNA-seq) of AS (liver 10, scalp 5, breast 2, trunk 1, heart 1) and hepatocellular carcinoma (HCC, 9) from National Taiwan University Hospital (NTUH) and re-analyzed WES & RNA-seq of AS from the Count Me In Project (CMI, 46). Somatic mutations and copy number alternation were called by Mutect2 and Sequenza from tumor-normal matched WES. Non-negative matrix factorization was used to determine mutational signature profiles and the contributions of each signature to each sample. Telomere length was estimated using TelSeq. **Results:** We identified four single-base-substitution (SBS) signatures using somatic mutations from 74 (AS/HCC 65/9) WES data. The dominated signature in liver AS had exceptionally high cosine similarity (93.08%) with COSMIC SBS22 (ver 3.2), which is related to AA exposure. The AA-mutation signature contributed significantly (adjusted $p < 0.01$) to the DNA mutations in 70% (7/10), 0% (0/9), 7% (3/46), and 56% (5/9) of liver AS (NTUH), nonliver AS (NTUH), CMI AS, and HCC (NTUH), respectively. *TP53* (60% vs 22% vs 32%) and *ATRX* (40% vs 0% vs 11%) mutations were more common in liver than nonliver AS (NTUH) or CMI, while *KDR* mutation rates were similar (30% vs 44% vs 22%). Among *TP53* mutations from liver AS with AA signature, 86% (6/7) showed the typical A:T > T:A mutation caused explicitly by AA-induced DNA damage. In liver vs nonliver AS, the median number of mutations and neoantigen burdens were 6.55 vs 0.98 ($p = 0.0076$) and 1572 vs 544 ($p = 0.095$), respectively. Although liver AS and HCC were highly associated with AA-mutation signature, liver AS had significantly longer telomeres in terms of tumor/normal telomere ratio (median 1.27 vs 1.16, $p = 0.0009$) but a significantly lower telomerase enzyme activity ($p = 0.016$). We did not find an association between *ATRX* mutation, or its mRNA expression level, with the extended telomere length in liver AS. Compared to nonliver AS, the activity of the telomere replication molecule *BUB1* was significantly higher in liver AS ($p = 0.0029$). **Conclusions:** Our study is the first to connect AA exposure to the etiology of liver AS. The high mutation rate and distinct telomere maintenance mechanism of liver AS provides insights into future treatments. Research Sponsor: National Taiwan University Hospital; Good Liver Foundation.

Loss of the DNA repair gene RNase H2 and a unique subset of DDR-deficient leiomyosarcomas. *First Author: Michael Nakazawa, University of Texas MD Anderson Cancer Center Hematology/Oncology Fellowship, Houston, TX*

Background: Targeting the DNA damage response (DDR)/Homologous Recombination (HR) pathway is an emerging therapeutic approach for leiomyosarcoma (LMS). Loss of RNase H2 decreases DNA repair via the Non-Homologous End-Joining (NHEJ) pathway, leading to increased double stranded breaks, replication stress, and increased cell death. Therefore, we developed an assay to screen for RNase H2 loss in STS patient samples to determine its prevalence and prognostic significance, particularly in LMS patients. **Methods:** *RNASEH2B* homozygous deletion (HomDel) calls from TCGA samples were based on the Allele-Specific Copy number Analysis of Tumors (ASCAT2) algorithm. Immunohistochemistry (IHC) of RNase H2 was performed on tissue microarrays (TMAs) of uterine (U-LMS) and soft tissue (ST-LMS) leiomyosarcoma samples from MD Anderson Cancer Center (MDACC) using a selective antibody developed by Repare Therapeutics. RNase H2 loss was defined as $\leq 10\%$ cells without nuclear IHC staining and scored by experienced pathologists in 2 separate cohorts. Genomic analysis was performed using SNIpDx™, a targeted-NGS assay designed to detect allelic loss of function in select DDR related genes and whole genome sequencing (WGS). MDACC TMA samples were clinically annotated by retrospective review. **Results:** Using TCGA data, *RNASEH2B* HomDels were seen in 6% (5/80) of all LMS cases, with a higher proportion in U-LMS (15%; 4/27) as compared to ST-LMS (2%; 1/53). In a pan-tumor TMA, RNase H2 loss by IHC was found in 3.8% (32/843) of samples overall, and in 10% (9/88) of LMS samples. This proportion of RNase H2 loss was higher in a larger MDACC LMS cohort, where negative staining of RNase H2 was found in 30% (33/110) of U-LMS and 38% (39/102) of ST-LMS cases. 30 MDACC LMS cases (15 U-LMS and 15 ST-LMS) were analyzed for *RNASEH2B* HomDels by SNIpDx. In U-LMS, *RNASEH2B* HomDels were detected in 64% (7/11) of RNase H2 IHC loss cases vs. 0% (0/3) in RNase H2 IHC intact cases. No *RNASEH2B* HomDels were detected in ST-LMS cases (10 IHC loss, 5 intact). The median overall survival (mOS) of MDACC U-LMS patients ($n = 109$) was 4.3 years. No significant mOS difference was seen in RNase H2 IHC intact cases versus loss (mOS 4.4 v 3.3 years, $p = 0.54$). In a separate cohort, 45 U-LMS samples were screened by IHC; 22% (10/45) had RNase H2 loss. *RNASEH2B* HomDels were detected in 70% (7/10) of RNase H2 IHC loss cases using SNIpDx and confirmed using WGS. In contrast, *RNASEH2B* HomDels were detected in 3% (1/33) of RNase H2 IHC intact cases. In the combined U-LMS cohort with IHC and SNIpDx results ($n = 71$), the diagnostic accuracy, sensitivity and specificity of RNase H2 IHC for detecting *RNASEH2B* HomDels was 76%, 93% and 71% respectively. **Conclusions:** RNase H2 loss via *RNASEH2B* HomDels is prevalent in U-LMS and is unique from other DDR pathway alterations. RNase H2 IHC is an effective screening tool and is being developed for future clinical trials targeting DDR in LMS. Research Sponsor: Repare Therapeutics.

Phase 1 trial of avelumab with hypofractionated thoracic radiation therapy (HT-RT) in patients with metastatic soft-tissue sarcomas (mSTS). *First Author: Shane H Zaidi, Royal Marsden Hospital, London, United Kingdom*

Background: Combining HT-RT with anti PD-L1 therapy may enhance local and distant tumour control in mSTS. This was a Phase 1 trial to evaluate the safety, tolerability, and efficacy of avelumab in patients with mSTS. **Methods:** This was a single centre phase 1 trial of avelumab with HT-RT in patients with mSTS (NCT03602833). Patients > 18 years with at least 2 pulmonary metastases, ECOG performance status 0-1 were eligible between Oct 2018-Apr 22. Patients received HT-RT (36 Gy in 12 fractions), with concurrent intravenous avelumab (10 mg/kg q14d) until disease progression. The primary end point was safety of avelumab with HT-RT. Secondary endpoints included local control rate at 3 months. Dose limiting Toxicity (DLT) assessed from start of HT-RT and avelumab up to Cycle 7 avelumab and defined as: $\geq$ G2 pneumonitis, $\geq$ G2 myelitis, $\geq$ G3 non-haem toxicity, $\geq$ any other G4 and/or HT-RT interruption > 5 days. Response was evaluated using the Response Evaluation Criteria in Solid Tumors (RECIST). **Results:** 12 patients were treated in this trial. Histological subtypes: leiomyosarcoma ($n = 2$), undifferentiated pleomorphic sarcoma ($n = 2$), and spindle cell sarcoma ($n = 2$). The median age was 57.5 (37-68) years, 7 were female (58%). All patients had lung metastases. 1 previously received SBRT to the lung, and 5 (42%) patients had received prior systemic treatment. 12 patients received at least one cycle of avelumab, median 9 (range: 1-37), and treatment was discontinued in 11 (92%) patients; 10 (83%) stopping for progressive disease, 1 (8%) patient for G4 immune-mediated hepatitis after DLT period and 1 patient completed and continues on compassionate-use avelumab. Eleven (92%) completed radiotherapy (36 Gy, 12 fractions). No DLTs or treatment-related deaths were observed. HT-RT toxicity: 3 G2 acute (1 oesophagitis, 2 skin) noted up to 11 weeks. 13 G1 late toxicities (5 pneumonitis, 5 skin, 1 cardiac, 1 myelitis, 1 oesophagitis) reported. Avelumab toxicities: 2 G3 (1 ALT rise, 1 viral infection) and 3 G4 (1 AST rise, 1 hepatitis, 1 sepsis) reported after DLT observation period. The median follow-up was 21.8 (range 3.2-31.9) months with a 3-month local control rate of 50% (95% CI, 21%-74%). RECIST responses at 3 months were 0 CR, 1 (8%) PR, 5 (42%) SD and 5 (42%) PD. **Conclusions:** Avelumab in combination with thoracic radiotherapy was safe with encouraging anti-tumour activity in patients with metastatic soft-tissue sarcomas. Additional molecular biomarker analyses are in progress. Clinical trial information: NCT03602833. Research Sponsor: Merck Serono Ltd. (CrossRef Funder ID: 10.13039/100009945); Royal Marsden/ Institute of Cancer Research London BRC.

Efficacy and safety of anlotinib combined with anthracycline and ifosfamide followed by anlotinib maintenance in advanced soft tissue sarcoma: A single-arm, phase 2 trial. *First Author: Zengjun Liu, Rare tumors Department, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Huaiyin District Jinan, China*

Background: Anthracycline plus ifosfamide is the standard first line treatment regime for advanced soft tissue sarcoma (STS). Anlotinib, a multikinase angiogenesis inhibitor, has evolved as a standard second line treatment option in Chinese advanced STS patients. This study was performed to evaluate the efficacy and safety of anlotinib combined with anthracycline and ifosfamide followed by anlotinib maintenance in the first line treatment of patients with advanced STS. **Methods:** This prospective, open-label, single-arm, phase 2 trial was conducted in Shandong Cancer Hospital and Institute (ChiCTR2100054711). The key inclusion criteria included: (a) age was 18-70 years; (b) ECOG performance state of 0-1; (c) histologically confirmed high-grade STS; (d) unresectable or metastatic STS; (e) previously untreated, and sensitive to chemotherapy; (f) having measurable lesions according to RECIST 1.1. All patients received up to 6 cycles of anlotinib (12 mg QD on day1-14, 21 days per cycle) combined with anthracycline (epirubicin 40mg/m²/d on day 1-2, 21 days per cycle; or liposomal doxorubicin 30mg/m²/d on day 1, 21 days per cycle) and ifosfamide (2g/m²/d on day 1-3, 21 days per cycle) followed by anlotinib maintenance until disease progression, unacceptable toxicity or death. Pegylated recombinant human granulocyte colony-stimulating factor was administered following chemotherapy. The primary endpoint was objective response rate (ORR). The secondary endpoints included progression-free survival (PFS), overall survival (OS), and adverse effect (AE). **Results:** From December 2021 to December 2022, 31 patients (median [range] age, 53 [18-69] years; 20 [64.5%] male) were enrolled. 29 were evaluable for objective response, and the ORR and DCR were 31.03% (95%CI, 17.28-49.23%) and 82.76% (95%CI, 65.45-92.4%), respectively. With a median follow-up duration of 6.3 months (range, 0.8-14.0), the median PFS for all 31 patients was 6.9 months (95% CI, 2.62-11.17). The median OS was not reached. Treatment-related AEs of any grade occurred in all patients. The most common AEs included nausea/vomiting (88.46%), anemia (23.08%), leukopenia (19.23%), venous thrombosis (15.38%), hand-foot syndrome (11.54%) and elevated alanine aminotransferase or aspartate aminotransferase (11.54%). The most frequent $\geq$ grade 3 AEs were leukopenia (11.54%) and thrombocytopenia (7.69%). 2 serious AEs (1 left heart failure and 1 intestinal obstruction) were recorded. No treatment-related death occurred. **Conclusions:** This study suggested that anlotinib combined with anthracycline and ifosfamide followed by anlotinib maintenance demonstrated encouraging efficacy with a manageable safety profile in the first line treatment of patients with advanced STS. Clinical trial information: ChiCTR2100054711. Research Sponsor: Beijing Lize Charity Foundation.

Results of SOC-2082 phase 2 study using metronomic gemcitabine, doxorubicin and docetaxel plus nivolumab as second/third-line therapy for advanced sarcoma. *First Author: Nadezhda Omelchenko, Sarcoma Oncology Research Center, Santa Monica, CA*

Background: Metronomic dosing of gemcitabine, doxorubicin and docetaxel causes less severe side effects than standard chemotherapy for advanced sarcoma. The addition of nivolumab to this regimen has potential to have synergistic effects and improve treatment outcomes. **Methods:** Primary objective: To assess progression-free survival (PFS); Secondary objectives: (1) To evaluate best overall response during treatment period confirmed in a 6-week follow-up, (2) PFS rate at 6 and 9 months, (3) Overall survival (OS) rate at 6, 12 months, and (4) Incidence of treatment-related adverse events (TRAEs). Inclusion criteria: Previously treated male and female subjects, $\geq$ 18 years of age, pathologically confirmed diagnosis of locally advanced, unresectable, or metastatic sarcoma, measurable disease by RECIST v1.1, and acceptable hematologic and organ functions. Exclusion Criteria: History of autoimmune disorder. Treatment schedule: Metronomic doses of gemcitabine (600 mg/m² max:1000 mg), doxorubicin (18 mg/m²; max: 32 mg), docetaxel (25 mg/m²; max:42 mg) on Day 1 and Day 8, and nivolumab (240 mg) on Day 1 only. Repeat treatment cycles are continued every three weeks if the toxicity grade is $\leq$ 1. **Results:** This report on the modified intent-to-treat population (n=59). This population completed at least one treatment cycle and had a follow-up CT or MRI scan at week 6. Best Overall Response = 8 PR, 44 SD, 7 PD. The disease control rate (CR+PR+SD) was 88.1%. Median PFS was 5.1 (95% CI: 2.837-7.363) months; 6 month PFS rate 52.5%. Median OS, 15.3 (95% CI: 5.48-25.12) months, with 6-month OS 88%. Safety analysis: Grade 3/4 TRAEs include fatigue (n=18), nausea (n=13), neutropenia (n=10), thrombocytopenia (n=9), anemia (n=9), diarrhea (n=1). There were no unexpected adverse events. **Conclusions:** Taken together, the data suggests that nivolumab in combination with metronomic doses of gemcitabine, doxorubicin and docetaxel (1) may have synergistic activity, and (2) by indirect comparison, may be as effective as standard first line therapy for advanced sarcoma with manageable toxicity. Clinical trial information: NCT04535713. Research Sponsor: None.

A phase Ia/Ib, dose-escalation/expansion study of the MDM2-p53 antagonist BI 907828 in patients (pts) with solid tumors: Safety and efficacy in patients with dedifferentiated liposarcoma (DDLPS). *First Author: Patricia LoRusso, Yale University School of Medicine, Yale Cancer Center, New Haven, CT*

Background: Inactivation of p53 is a key mechanism which promotes tumor survival and proliferation. p53 inactivation can be due to mutations in *TP53* or downregulation of wild-type (wt) p53 by the key negative regulator mouse double-minute 2 (MDM2). BI 907828 is a highly potent MDM2-p53 antagonist which has demonstrated preclinical antitumor activity, particularly in *TP53*-wt *MDM2*-amplified DDLPS models. In this phase I study (NCT03449381), BI 907828 monotherapy is being evaluated in pts with advanced solid tumors, including DDLPS. During dose escalation (phase Ia), BI 907828 had a manageable safety profile and the selected recommended dose for expansion (RDE) was 45 mg q3w. Here we report safety data in all pts who received the RDE of 45 mg q3w and present efficacy data in the subgroup of pts with DDLPS. **Methods:** In Phase Ia, pts received one of two BI 907828 dosing schedules: Arm A, day 1 of 21-day cycles (q3w); Arm B, days 1 and 8 of 28-day cycles. During Phase Ib (dose expansion), pts were enrolled to Cohort 1 (*TP53*wt, *MDM2*-amplified sarcoma) or Cohort 2 (other *TP53*wt, *MDM2*-amplified solid tumors). Here we focus on Cohort 1 (received BI 907828 45 mg q3w). The primary endpoint (phase Ib) was progression-free survival (PFS). Secondary endpoints/objectives included overall response rate (ORR) and grade $\geq$ 3 treatment-related AEs (TRAEs). **Results:** As of December 22, 2022, a total of 137 pts had been enrolled; 72 (52.6%) were male, 77 (56.2%)/59 (43.1%) had ECOG PS 0/1, and the median number of prior systemic therapies was 2 (range, 0-11). In the 73 pts who received the RDE of 45 mg q3w, the most common any-grade TRAEs were nausea (74.0%) and fatigue (61.6%). 33 (45.2%) pts had grade $\geq$ 3 TRAEs; the most common were thrombocytopenia (23.3%), neutropenia (21.9%), anemia (11.0%), and leukopenia (11.0%). 22 (30.1%) pts had TRAEs leading to dose reductions and 6 (8.2%) had TRAEs leading to treatment discontinuation. 20 pts (27.4%) had serious AEs; the most common were nausea, pulmonary embolism (each 4.1%), sepsis, small intestine obstruction, vomiting, thrombocytopenia, and pyrexia (each 2.7%). 50/73 pts who received 45 mg q3w had advanced DDLPS; all had *MDM2*-amplified disease. Of the 42 evaluable DDLPS pts, 8 achieved a confirmed PR (ORR 19.0%; locally assessed) and a further 29 achieved a best response of stable disease (including 2 with unconfirmed PR), giving a disease control rate of 88.1%. Preliminary median PFS was 8.1 months. **Conclusions:** BI 907828 demonstrated a manageable safety profile overall and encouraging preliminary efficacy was seen in pts with advanced *MDM2*-amplified DDLPS; Phase Ib is ongoing. BI 907828 is also being evaluated versus doxorubicin as first-line treatment for pts with advanced DDLPS in the ongoing Phase II/III Brightline-1 study (NCT05218499), for which the FDA has granted a Fast Track Designation. Clinical trial information: NCT03449381. Research Sponsor: Boehringer Ingelheim.

Interim results of a phase 2 study using talimogene laherparepvec, nivolumab, and trabectedin for advanced leiomyosarcoma. *First Author: Neal Shiv Chawla, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Intratumoral injection of Talimogene Laherparepvec (TVEC) has a local oncolytic effect and evokes a cytotoxic immune response. The combination of Trabectedin (T) and Nivolumab (N) is a safe and effective therapy in soft tissue sarcoma (STS). This study aims to determine the safety and efficacy of adding TVEC to the combination of T and N in advanced leiomyosarcoma (LMS). **Methods:** Objectives: Primary: To assess progression-free survival (PFS). Secondary: (1) To evaluate the best overall response, (2) PFS rate at 6 and 9 months, (3) Overall survival (OS) rate at 6, 9, and 12 months, (4) Incidence of conversion from unresectable to the resectable tumor, and (5) Incidence of treatment-related adverse events (TRAEs). Patients and Methods: Eligible patients included patients $\geq$ 18 years of age with locally advanced unresectable or metastatic LMS, measurable disease by RECIST v1.1, and at least one accessible tumor for TVEC intratumoral injection. N (3 mg/kg q2 weeks), T (1.2 mg/m² q3 weeks), and TVEC (1x10⁸ PFU/ml q 2 weeks depending on tumor size) were administered. A starting dose of TVEC (1x10⁶ PFU/ml) was initially given, followed by a total dose of 1x10⁸ PFU/ml q 2 weeks depending on tumor size) three weeks later. **Results:** Efficacy: Per protocol, there were 11 evaluable subjects (Modified Intention to Treat [mITT] patients who had completed at least one treatment cycle and had a follow-up CT scan). The median number of prior lines of therapy was 4 (range 1-8). Confirmed Best Overall Response (BOR) by RECIST v1.1 = 2 PR, 9 SD (BOR Rate 18.2%). The disease control rate (PR+SD) at week 6 was 100%. The median PFS was 7 months (range: 3-18); 6-month PFS rate, 55%; median OS 18.2 months (range: 4- 32); 6-month OS rate, 91%. There was no conversion from unresectable to resectable tumor. Response was not related to PD-L1 positivity but both patients with PR were ER+/PR+ and had uterine LMS. There were 15 evaluable subjects for OS analysis under the Intention-to-Treat (ITT) population who received at least one dose of study drug. The median OS was 12 (range 0-32) months; 6-month OS rate, 60%. Safety: Eight of 15 (53.3%) patients experienced at least one $\geq$ Grade 3 treatment-related adverse event (TRAE). Grade 3 TRAEs include anemia (n=3), thrombocytopenia (n=2), neutropenia (n=1), increased ALT (n=1), increased GGT (n=1), decreased LVEF (n=1), myalgia (n=1). Grade 4 TRAE include thrombocytopenia (n=1). The TRAEs were related to Trabectedin use. No new safety signals noted in this study. **Conclusions:** These results suggest that (1) By indirect comparison, the combination regimen using Talimogene laherparepvec, Nivolumab & Trabectedin may be more effective as second/third-line/fourth therapy for advanced leiomyosarcoma with manageable toxicity (Trabectedin alone for LMS= 4.3 mos; Dacarbazine alone = 1.6 mos; Demetri 2015), and (2) The best responders are patients with HR+ uterine LMS. Clinical trial information: NCT03886311. Research Sponsor: Amgen.

Metronomic dosing of selinexor in select soft tissue sarcomas (STS). *First Author: Aisha Alshibany, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Selinexor (S) is a first-in-class, oral, selective inhibitor of nuclear export (SINE). S has a demonstrated anti-tumor activity in STS. However, the use of S can be associated with toxicities, such as nausea, anorexia and fatigue. A modified dosing schedule may improve the tolerability of S without compromising its efficacy. **Methods:** We evaluated S when given metronomically in patients (pts) with advanced metastatic leiomyosarcoma, endometrial stromal sarcoma, and malignant peripheral nerve sheath tumors. S was administered daily for 4-days in a row followed by 3-days break, repeated weekly in a 28-days cycle. Dose levels (DL) were escalated using a 3+3 design to determine maximum tolerated dose. DL included 2.5mg (DL1), 5mg (DL2), 7.5mg (DL3), 10 mg (DL4), 12.5 mg (DL5), 15 mg (DL6) and 17.5 mg (DL7). S was administered until unacceptable toxicities or disease progression. Imaging was performed every 8 weeks. Primary objectives were safety and tolerability as well as the determination of the recommended phase II dose. Secondary objectives were anti-tumor activity, toxicity profile, and pharmacokinetics (PK) profile. **Results:** Twenty-five pts (22 females/3 males, median age 59 years [range 35-84]) were enrolled at different DL (3, 3, 4, 6, 6, 3 pts at DL1 to DL6 respectively). The most common adverse events (AE) of any grade were constipation (n = 11, 50%), nausea (n = 11, 50%), and dysgeusia (n = 10, 45%). Eight (36%) pts experienced G3/4 AE while on trial; most were hematological toxicities seen in 3 (14%) pts (anemia, neutropenia, and leukopenia, n = 1 each). Non-hematological G3/4 AE were seen in 5 (23%) pts (Including: colonic obstruction, atrial fibrillation, and spinal cord compression, n = 1 each). Two Dose limiting toxicities were experienced, at DL4 (thrombocytopenia) and DL5 (transaminitis). Twenty-two pts were evaluable for response; 10 (45%) pts had stable disease (SD) as best response. Eight pts with SD had disease stability of > 4 months. Twelve pts (55%) had progressive disease. Median progression-free survival was 2.4 months (95% CI 1.7-5.3 months). PK data is awaiting final analysis. **Conclusions:** Metronomic S demonstrated tolerability in selected sarcoma pts. Signs of potential clinical benefit was seen in the form of SD. Further data comparison with historical controls and PK analysis are needed to put this finding into perspective. Clinical trial information: NCT04811196. Research Sponsor: University Health Network, Toronto.

Efficacy and safety profile of pimicotinib (ABSK021) in tenosynovial giant cell tumor (TGCT): Phase 1b update. *First Author: Hairong Xu, Department of Orthopaedic Oncology Surgery, Beijing Ji Shui Tan Hospital, Peking University, Beijing, China*

Background: TGCT is a rare type of locally aggressive neoplasm that is mainly caused by overexpression of colony-stimulating factor 1 (CSF1) gene. Pimicotinib is an oral, highly potent, and selective small-molecule antagonist of CSF-1R with minimum inhibition of c-Kit and PDGFR, and has been granted Breakthrough Therapy Designation for TGCT by FDA in Jan 2023. Here, we report the updates from 50 mg QD cohort as well as the preliminary data from 25 mg QD cohort in TGCT pts. **Methods:** The study (NCT04192344) is to evaluate the safety and preliminary antitumor activity of Pimicotinib at 50 mg QD and 25 mg QD in TGCT pts not amenable to surgical resection. **Results:** As of December 31, 2022, 49 TGCT pts were enrolled, including 37 pts treated with 50 mg QD and 12 pts with 25 mg QD. Median age was 39 y (range: 19-76) and 40.8% were male. The tumor location was mainly in knee (53.1%), hip (18.4%) or ankle (12.2%). Thirty-one pts received at least one prior surgery, and 1 pt received prior exploratory systemic therapy (Anlotinib). Median treatment duration was 7.9 mos (range: 0.4-12.5), and 89.8% remained on treatment. The ORR was 77.4% (24/31, including 2 CR) in 50 mg QD and 40% (4/10, including 1 CR) in 25 mg QD by IRC based on RECIST 1.1. Most responses were achieved within 25 wks and median DOR in both cohorts was not reached. Average improvement of flexion range of knee at wk 13 from baseline was 30.2 degrees (n = 13, range: 2, 105) in 50 mg QD and 4.8 degrees (n = 5, range: -12, 24) in 25 mg QD. Proportion of responders based on BPI-30 at wk 25 was 66.7% (16/24) in 50 mg QD and 60% (3/5) in 25 mg QD, along with a similar trend of stiffness. Most TEAEs were Gr 1 or 2. Four Gr 3/4 TEAEs were reported (2 drug-related), including 1 Gr 3 serious TEAE. Most common TEAEs (≥20%) include LDH increase (75.5%), CPK increase (67.3%), α-HBDH increase (63.3%), AST increase (42.9%), amylase increase (26.5%), ALT increase (24.5%), pruritus (20.4%) and rash (20.4%). No hair color changes or serious liver injuries were reported. CPK and transaminase elevations were asymptomatic, on-target and quickly recovered after drug interruptions. Under steady-state, 50 mg QD resulted in ~ 2-fold higher C_{max} and C_{trough} compared to 25 mg QD, in sync with findings from escalation phase. Significant PD changes were observed in both cohorts, such as increase in plasma CSF-1 levels, decrease in non-classical monocytes and C-terminal telopeptide (CTX). Changes from baselines in both CSF-1 and CTx showed a correlation with pimicotinib plasma concentrations. **Conclusions:** Pimicotinib has demonstrated a significant antitumor activity, favorable safety, and PK profiles at both 50 mg QD and 25 mg QD with no apparent hepatotoxicity. The changes in PD biomarkers indicate significant CSF-1R inhibition in TGCT pts. Updated data from 50 mg QD cohort showed higher ORR and continuous improvement over a longer treatment time, which supports the further evaluation of Pimicotinib in a phase 3 study. Clinical trial information: NCT04192344. Research Sponsor: Abbisko Therapeutics Co, Ltd.

Results from phase I/II study of NY-ESO-1-specific TCR gene-transduced T cell therapy (TBI-1301, mipetresgene autoleucel) in patients with advanced synovial sarcoma. *First Author: Akira Kawai, Department of Musculoskeletal Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Synovial sarcoma is one of malignant soft tissue tumors with a poor prognosis. A cancer-testis antigen NY-ESO-1 is expressed in the tumors of 50-80% synovial sarcoma patients. The purpose of this study was to evaluate the safety and the efficacy of gene engineered autologous T cell product with NY-ESO-1 siTCR retroviral vector which expressed affinity-enhanced NY-ESO-1-specific TCR and siRNA to silence endogenous TCR (TBI-1301). **Methods:** This was an open label phase I/II study to evaluate safety, appearance of replication competent retrovirus (RCR), appearance of clonality, *in vivo* cell kinetics and clinical responses. TBI-1301 were manufactured from each subject's leucocytes stimulated with anti-CD3 antibody and Retronectin and transduced with NY-ESO-1 siTCR retroviral vector. TBI-1301 was infused at split dose of 5×10^9 cells following cyclophosphamide treatment at 750 mg/m² for two days to HLA-A*02:01 or HLA-A*02:06 positive subjects with synovial sarcoma expressing NY-ESO-1, which were surgically unresectable and refractory to anthracycline therapy. **Results:** Eight subjects were enrolled and treated with TBI-1301. The objective response rate was 50.0% with best overall partial response in 4 of 8 subjects according to RECIST v1.1/irRECIST and the median overall survival was 650 days. Cytokine release syndrome (CRS) occurred in 50.0% (4/8) and consisted of 1 subject with grade 1 CRS and 3 subjects with grade 2 CRS. All subjects who developed CRS recovered with prespecified treatment, in which 2 subjects were treated with symptomatic therapy, 1 subject was treated with tocilizumab and 1 subject was treated with both tocilizumab and corticosteroid. No subjects had immune effector cell-associated neurotoxicity syndrome (ICANS). RCR and clonal dominance were not detected in any subjects throughout the study period. **Conclusions:** Adoptive immunotherapy with TBI-1301 to selectively target NY-ESO-1 positive tumors will become a promising treatment for advanced or recurrent synovial sarcoma with acceptable toxicity. Clinical trial information: NCT03250325. Research Sponsor: Takara Bio Inc.

Evaluation of hyperprogression in patients with sarcoma treated with targeted therapy and/or immunotherapy in early-phase clinical trials. *First Author: Aisha Alshibany, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Hyper-progressive disease (HPD) is an adverse outcome with acceleration of tumor growth, often accompanied by clinical deterioration. This phenomenon is described with immunotherapy (IT) but its incidence in sarcoma and/or in the context of targeted therapy (TT) remains unknown. Tumor growth rate (TGR) allows for dynamic evaluation of tumor volume change over time and may complement RECIST. We evaluated HPD in sarcoma patients (pts) treated in early-phase trials by assessing TGR and describing their subsequent clinical outcomes. **Methods:** We retrospectively reviewed medical records from advanced soft tissue sarcoma (STS) pts enrolled in early phase trials at the Princess Margaret Cancer Centre between January 2012 and December 2022. TGR was calculated based on tumor measurements taken at pre-baseline, baseline, and on-treatment CT scans. We used the Champiat formula (Clin Cancer Res 2017) to calculate TGR ratio. Primary objective was to describe the incidence of HPD, defined as a TGR ratio of > 50%. Secondary objective was to investigate the correlation between HPD with progression-free survival (PFS) and overall survival (OS). **Results:** We identified a total of 192 pts involved in STS early phase trials from 2012-2022. Most common histology was leiomyosarcoma seen in 72 pts. Eighty-four pts (43.8%) received TT, 75 (39%) pts received IT-based, and the rest had combined TT/IT regimens (n = 33, 17.2%). The incidence of HPD was 6.8% (n = 13), including IT-based (n = 9) and non-IT-based (n = 4) regimens. HPD was associated with a worse PFS, and OS compared to non-HPD pts (median PFS 1.6m vs 4.6m HR: 5.5, 95%CI 2.8-10.6, P < 0.001; median OS 5.5 vs 16.1 months; HR: 3.7, 95%CI: 2.0-7.1, P < 0.001). On multivariable analysis, only IT was significantly associated with HPD (OR 3.9, 95%CI: 1.1-13, P = 0.021). There was no association between HPD and new lesions or sarcoma histology subtype. **Conclusions:** HPD occurs in a small subset of sarcoma patients undergoing clinical trials with TT or IT. Exploring TGR provides clinically meaningful data as it pertains to HPD as it predicts OS and PFS in sarcoma patients undergoing early-phase clinical trials. Research Sponsor: None.

Novel MRI scoring system to assess osseous malignancy in patients with soft tissue sarcoma following radiotherapy. *First Author: Gayathri Vijayakumar, Rush University Medical Center, Chicago, IL*

Background: Although radiotherapy is an important component of STS management, radiation induced changes such as radiation osteitis are commonly identified on magnetic resonance imaging (MRI). These imaging findings may be concerning for malignancy and sometimes require biopsy for investigation. This study proposes a novel MRI scoring system to assess osseous lesions and predict potential for malignancy based on MRI score in STS patients who received radiotherapy. **Methods:** The MRI score consisted of 3 parameters: morphology, signal intensity, and progression. Interobserver reliability between the total score of MRI examinations scored by two senior musculoskeletal radiologists were analyzed with Cohen's kappa coefficient. Receiver operating curve (ROC) analysis was performed to determine a predictive MRI score for malignancy. **Results:** 156 MRI's from 30 STS patients who received radiotherapy were retrospectively reviewed. Two (6.7%) patients developed regional osseous metastasis identified on MRI. The kappa coefficient of the scoring system was 0.785 demonstrating substantial interobserver agreement ($p < 0.001$). ROC analysis demonstrated that the optimal cut-off value for malignant lesion on MRI was 5.5 (area under the curve 0.998 [95% CI 0.993-1.000] $p < 0.001$). **Conclusions:** This novel MRI scoring system recommends lesions with a score of six and above to be biopsied to distinguish if malignancy is present. We believe this scoring system can be utilized by multidisciplinary care teams to guide clinical recommendations for patients with STS and MRI findings concerning for malignancy versus radiation induced changes. Research Sponsor: None.

The SPEARHEAD-1 trial of afamitresgene autoleucel (afami-cel [formerly ADP-A2M4]): Analysis of overall survival in advanced synovial sarcoma. *First Author: Brian Andrew Van Tine, Washington University School of Medicine, St. Louis, MO*

Background: Afami-cel is an autologous, T-cell receptor (TCR) T-cell therapy to treat human leukocyte antigen (HLA) A*02-eligible patients (pts) with advanced solid tumors positive for the cancer testis antigen melanoma-associated antigen A4 (MAGE-A4). The efficacy and safety of afami-cel in pretreated pts with advanced/metastatic synovial sarcoma or myxoid/round cell liposarcoma are being evaluated in the Phase 2, two-cohort, open-label, SPEARHEAD-1 (NCT04044768) trial. Here we report interim overall survival (OS) data in the pts with advanced synovial sarcoma in Cohort 1. **Methods:** Pts who were HLA-A*02 positive with advanced synovial sarcoma (with evidence of clinical/radiological progression) positive for MAGE-A4 received afami-cel after lymphodepleting chemotherapy containing fludarabine and cyclophosphamide. The primary endpoint was overall response rate per RECIST v1.1 by independent review. Secondary endpoints included OS and progression-free survival (PFS), estimated utilizing the Kaplan-Meier method. **Results:** As of August 29, 2022, 44 pts with synovial sarcoma received afami-cel ($2.68-9.99 \times 10^9$ transduced T-cells) in Cohort 1. The median age was 41 years (range: 19-73 years), 50% of pts were female, 89% of pts were white, 96% of pts were typed as HLA-A*02:01P, and median tumor MAGE-A4 expression H-score was 257 (132-300). Pts were heavily pre-treated with a median of 3 prior lines of therapy (range: 1-12). The median follow-up time at the data cut-off was 20.8 months. Median PFS was 3.8 months (95% CI: 2.8, 5.8) and 4.1 months (95% CI: 2.8, 6.9) by independent and investigator review, respectively. Median OS by independent review was 15.4 months (95% CI: 10.9, not estimable) with 52% of pts censored at the data cut-off. The 12-month OS probability was 60% and 24-month OS probability was 40%. Twenty-one pts received additional therapy during long term follow up (systemic therapy, $n = 20$; radiation, $n = 6$; other, $n = 4$). In the 17 pts who had a RECIST response by independent review, the median OS was not reached, the 12-month OS probability was 90%, and 24-month OS probability was 60%. **Conclusions:** Pts with advanced synovial sarcoma treated with afami-cel in SPEARHEAD-1 had encouraging survival, especially those pts with a RECIST response. Clinical trial information: NCT04044768. Research Sponsor: This study was sponsored by Adaptimmune. Writing/editorial support was provided by Excel Scientific Solutions and was funded by Adaptimmune.

HH2853, an EZH1/2 inhibitor, in patients with epithelioid sarcoma: Preliminary results from the phase 1 part of a first-in-human phase I/II study. *First Author: Zhengfu Fan, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Epithelioid sarcoma (ES) is a rare and aggressive subtype of soft-tissue sarcoma. Over 90% of tumors have lost INI1 expression, leading to oncogenic dependence on the transcriptional repressor EZH2. Tazemetostat (an EZH2 inhibitor) has been approved by FDA for clinical use in ES. HH2853 is a novel selective EZH1/2 dual inhibitor, which has demonstrated superior anti-tumor efficacy to tazemetostat in INI1-loss preclinical models. **Methods:** This is a first-in-human, open-label, multicenter, Phase (Ph) I/II study in patients (pts) with relapsed/refractory non-Hodgkin lymphomas or advanced solid tumors. Ph I is composed of two parts: dose escalation and dose extension part. Local pathologically documented, advanced recurrent or metastatic ES pts who received prior systemic anti-tumor therapies or have no standard therapy are eligible. HH2853 was administered orally twice daily (BID) on a continuous 28-day treatment cycle. Safety and clinical activity of HH2853 were assessed in pts with ES from the Ph I part. **Results:** Between Dec 2, 2021 and Nov 7, 2022, 32 pts with pre-treated ES were enrolled to three dose levels (400, 600, and 800 mg BID) from 4 sites in China. Median prior lines of therapy was two. 12 (37.5%) pts received ≥ 3 lines of prior therapies. 30 (93.8%) pts had documented loss of INI1 expression by local immunohistochemical analysis. There were 18 (56.3%) pts with proximal subtype. As of Jan 4, 2023, at a median treatment duration of 124 days, the most common treatment-related adverse events (TRAE) were diarrhea (59.4%), blood bilirubin increased (43.8%), white blood cell count (WBC) decreased (34.4%), rash (31.3%), anemia (25.0%), hypokalemia (21.9%), and platelet count (PLT) decreased (21.9%). TRAEs of $\geq$ Grade 3 included diarrhea, WBC decreased, anemia, hypokalemia, and neutrophil count decreased (6.2%, each), and blood bilirubin increased, PLT decreased, blood creatine phosphokinase increased, and hyperglycemia (3.1%, each). TRAEs leading to dose interruption or reduction were reported in 21.9% and 12.5% pts, respectively. No TRAE led to dose discontinuation or death. Tumor responses were observed from 400 to 800 mg BID. Overall response rate (ORR) was 15.6% (5/32) per investigator assessment according to RECIST 1.1. Three pts had unconfirmed response waiting to be confirmed at the next scheduled assessment, expecting to bring the total ORR to 25% [95% CI 11.5 - 43.4]. Median time to response was 1.9 months. One patient with complete response (CR) has responded for 222 days from the initial response. Disease control rate (DCR) (DCR = CR + partial response + stable disease at 6 weeks) was 78.1% [95% CI 60-90.7]. **Conclusions:** HH2853 showed an acceptable safety profile and promising anti-tumor activity in heavily pretreated ES pts with a wide therapeutic window, providing evidence for further investigation. Clinical trial information: NCT04390737. Research Sponsor: Haihe Biopharma Co., Ltd., Shanghai, China.

Impact of nirogacestat on pain, a key symptom in patients with desmoid tumors (DT): Results from the phase 3 DeFi study. *First Author: Winette T.A. Van Der Graaf, Department of Medical Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Pain reduction is a key treatment goal in DT (aggressive fibromatosis): 60% of patients (pts) experience chronic pain. In the phase 3 DeFi trial, nirogacestat (NIRO; $n = 70$) significantly improved progression-free survival compared with placebo (PBO; $n = 72$) in pts with progressing DT (HR: 0.29 [95% CI, 0.15-0.55]; $P < 0.001$). Also as previously reported, NIRO significantly reduced pain severity by 1.50 points (on a 10-point scale) compared with PBO at cycle 10 (28-day cycles; $P < 0.001$) per the prespecified secondary endpoint of "worst pain" from the Brief Pain Inventory Short Form (BPI-SF). Additional aspects of pain were collected in DeFi to further characterize treatment impact and consistency across multiple pain assessment tools. **Methods:** In DeFi, pts completed 3 prespecified pain assessment tools through end of treatment: BPI-SF (worst pain), Gounder/Desmoid Tumor Research Foundation Desmoid Symptom Scale (GODDESS-DTSS pain scale: worst pain, dull pain, shooting pain), European Organisation for Research and Treatment of Cancer Core Quality of Life Questionnaire (QLQ-C30 pain scale: pain, pain interference with daily activities). Change from baseline (BL) in pain scores was compared between arms; analyses included mixed models for repeated measures to compare change from BL and stratified Cochran-Mantel-Haenszel to compare proportions of pts with clinically meaningful pain reduction (defined using prespecified thresholds) at cycle 10. Cycle 10 was preselected to allow adequate time for a treatment effect to be observed. **Results:** Statistically significant and clinically meaningful pain reductions were observed with NIRO compared with PBO at cycle 10 across all assessment tools; statistically significant differences between arms occurred as early as cycle 2 and were sustained throughout treatment. At cycle 10, NIRO reduced mean BL pain per GODDESS-DTSS (0-10 range) by 1.78 points (SE = 0.26) and PBO increased pain by 0.32 points (SE = 0.27; $P < 0.001$). At cycle 10, NIRO reduced mean BL pain per QLQ-C30 (0-100 range) by 22.05 points (SE = 3.38) and PBO increased pain by 7.19 points (SE = 3.64; $P < 0.001$). Clinically meaningful pain reduction (by ≥ 2.0 points) per BPI-SF worst pain (0-10 range) was achieved by 72% of pts with NIRO vs 29% of pts with PBO at cycle 10 ($P < 0.001$). Per GODDESS-DTSS, clinically meaningful pain reduction (by ≥ 1.9 points) was achieved by 62% of pts with NIRO vs 19% of pts with PBO at cycle 10 ($P = 0.002$). **Conclusions:** Rapid, sustained, and consistent reductions in different aspects of pain were observed with NIRO compared with PBO across multiple assessment tools in pts with DT. Furthermore, a significantly greater proportion of pts achieved clinically meaningful reductions in pain with NIRO than with PBO. As pain is the most commonly reported symptom, pain reduction should be a key clinical trial endpoint and a key treatment goal in DT. Clinical trial information: NCT03785964. Poster Session

A phase II trial with safety lead-in to evaluate the addition of sotigalimab, a CD40 agonistic monoclonal antibody, to standard-of-care doxorubicin for the treatment of advanced sarcoma. *First Author: Sminu (Sam) Bose, Columbia University Irving Medical Center, New York, NY*

Background: Immune checkpoint inhibitors have limited efficacy in soft tissue sarcoma (STS) due to insufficient T-cell activation and infiltration by immunosuppressive macrophages. Sotigalimab (S), a high-affinity humanized monoclonal antibody for CD40, promotes antigen presentation, stimulates T-cell responses, and reprograms immunosuppressive macrophages. Preclinical studies with CD40 agonists revealed efficacy in immune “cold” tumor types and synergy with chemotherapy. Standard first-line doxorubicin (D) provides objective response rate (ORR) < 15% and median progression free survival (mPFS) of 4–6 mos in advanced STS. We therefore conducted this first-in-human study of D+S in STS. **Methods:** An open-label, single-arm, multi-center, phase 2 study evaluated D+S in advanced STS. Pts had ECOG PS ≤ 1 and any number of prior lines (but were anthracycline-naïve). The study initially enrolled all STS subtypes (except KS and GIST) but was amended in 12/2020 to limit enrollment to dedifferentiated liposarcoma (DDLPS), leiomyosarcoma (LMS), and undifferentiated pleomorphic sarcoma (UPS). Pts received D 75 mg/m² IV D1 + S 0.3 mg/kg IV D1 for eight 21-day cycles, followed by S monotherapy. A safety lead-in was performed (first 6 patients). Primary endpoint was ORR. Secondary endpoints included PFS and safety. A Simon two-stage design was used. If ≥ 7/32 responded overall, the treatment would be considered promising (85% power, α = 0.05). A subset of patients underwent paired tumor biopsies. **Results:** 32 pts have enrolled (median age 62; 10 LMS, 10 UPS, 9 DDLPS, 3 other). 4 pts remain on treatment with median follow-up of 2.8 mos (1 UPS pt has not reached first imaging). D (75 mg/m²) + S (0.3 mg/kg) was safe and tolerable without dose limiting toxicity. Overall ORR was 16% (5/31). Objective responses occurred in UPS (2), LMS (1), other LPS (1), and epithelioid hemangioendothelioma (1). Overall mPFS was 7.5 mos (95% CI 5.6–14.9 mos) and PFS rate at 6 and 12-mos was 55% and 31%, respectively. mPFS by STS subtype was 11.9 mos (95% CI: 10.3–NE) for DDLPS, 7.5 mos (95% CI: 1.4–NE) for UPS and 5.6 mos (95% CI: 1.3–NE) for LMS. Overall, 17/31 (55%) pts experienced grade 3 or 4 adverse events (AEs): most commonly, neutropenia (32%), febrile neutropenia (19%), and anemia (16%). 16% of pts experienced cytokine release (all low-grade). Correlative analysis of biopsies with high-definition spatial proteomics is ongoing. **Conclusions:** D (75 mg/m²) + S (0.3 mg/kg) every 21 days is safe and tolerable in STS. Final analysis of the primary endpoint awaits further follow-up on recently enrolled patients. Subtype-specific analysis suggests improvement in median PFS for DDLPS over historical controls: 11.9 mos vs 4 mos (Stacchiotti S. Ann Oncol 2020; Livingston M. Sci Rep 2017). An expansion of the DDLPS cohort is planned. Clinical trial information: NCT03719430. Research Sponsor: Apexigen, Inc.

Immune correlates of outcome in patients with leiomyosarcoma (LMS) treated with durvalumab plus olaparib or cediranib: Transcriptome analysis from the DAPPER study. *First Author: Abdulazeez Salawu, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Immune checkpoint blockade (ICB) as monotherapy has not shown clinical benefit in non-inflamed (cold) tumors such as LMS. Combining ICB with angiogenesis, or poly-ADP ribose polymerase (PARP) inhibitors may increase tumor immunogenicity by altering the immune cell composition of the tumor microenvironment (TME). In the DAPPER trial [NCT03851614], advanced LMS pts were randomized to receive ICB (Durvalumab 1500mg IV q4w) with either angiogenesis (Cediranib 20mg qd PO on 5 days/week) or PARP inhibition (Olaparib 300mg bid PO) until unacceptable toxicity or disease progression (Ayodele et al, *J Clin Oncol*, 2021). Here, we present the results of transcriptomic and immune biomarker analyses of patients (pts) in the whole cohort. **Methods:** Radiologic responses were assessed using RECISTv1.1 and survival analysis performed by Kaplan-Meier method. Transcriptome analysis by RNAseq was performed on fresh tumor biopsies obtained from all pts at screening. Relative fractions of 22 immune cell subsets in the TME were inferred from gene-expression profiles using CIBERSORT v1.06. Gene set variation analysis (GSVA) to identify transcriptomic signatures associated with progression-free (PFS) or overall survival (OS) benefit was performed using GSVA R package v1.42. For comparison with an independent cohort, GSVA was also performed using transcriptome data from LMS pts (n = 104) in the cancer genome atlas (TCGA) dataset. **Results:** Among 28 response-evaluable pts, 1 (3.6%) had partial response; 10 (35.7%) had stable disease (SD); and 17 (60.7%) had progressive disease. Median PFS and OS were 2.8 months (95% CI, 2.8–5.4) and 14.6 months (95% CI 10.7–NR), respectively. RNAseq data of adequate quality was available for 17 pts. Using the median CIBERSORT score as cut-off, pts with high M1 macrophage levels at baseline had significantly longer OS (p = 0.0019). High M1/M2 macrophage ratio score was also associated with longer OS (p = 0.05). GSVA identified 7 immune- and angiogenesis-related signatures that were associated with significantly longer OS. After false discovery rate correction, 1 signature comprising genes reflective of high overall B-cell activity remained significant. No transcriptomic signatures were associated with OS in the TCGA LMS cohort where pts did not receive ICB. **Conclusions:** Transcriptomic analysis shows that macrophage presence in the TME is associated with longer OS. Association of the B-cell activity signature with longer OS in LMS pts on the DAPPER trial, but not in the ICB treatment-naïve TCGA cohort suggests that high B-cell activity may identify pts who are more likely to have favorable outcomes with ICB and supports previous reports in sarcoma (Petitprez et al, *Nature*, 2020). Our results support ongoing further evaluation and integration of these biomarkers in LMS. Clinical trial information: NCT03851614. Research Sponsor: University Health Network; AstraZeneca.

A phase II clinical trial of chidamide in combination with toripalimab in patients with advanced soft tissue sarcoma. *First Author: Xing Zhang, Department of Medical Melanoma and Sarcoma, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University, Guangzhou, China*

Background: Chidamide is an oral subtype-selective histone deacetylase inhibitor which is effective on the patients with hematological tumors and reported to enhance the efficacy of checkpoint blockade therapies and regulate the host immune response. Here, we report preliminary results of Chidamide in combination with Toripalimab in soft tissue sarcoma (STS) patients. **Methods:** An open, single arm, phase II study of Chidamide with Toripalimab in patients with advanced soft tissue sarcoma after failure of standard treatment was conducted. Eligible patients could have any number of prior therapies, excluding HDAC inhibitors and immune checkpoint inhibitors treatment. All patients received Chidamide orally at 30mg twice weekly in combination with intravenous Toripalimab 240mg every 21 days until progression or unaccepted toxicity. The primary endpoint was RECIST1.1 objective response rate (ORR). The secondary endpoint included progression free survival (PFS), overall survival (OS), disease control rate (DCR) and safety. **Results:** Forty-six patients with advanced soft tissue sarcoma were enrolled. The median age of the patients was 47 years and the median prior lines of therapy were 3. The main subtypes included leiomyosarcoma (30.4%), well/differentiated liposarcoma (30%), myxoid/round cell liposarcoma (7%), undifferentiated sarcoma (9%), and osteosarcoma (7%). Treatment was well tolerated with the most common adverse events mainly in grade I and grade II, including thrombocytopenia (43.5%), nausea (28.3%), neutropenia (23.9%), fatigue (17.4%) and hypothyroidism (15.2%). Among 46 efficacy-evaluable patients, the overall response rate and disease control rate were 23.9% and 80.4%, respectively. The median time to an initial response was 3 months (range, 2 to 14), and the 3-mon and 6-mon progression-free survival rate were 92.7% and 58.9%, respectively. **Conclusions:** Chidamide with Toripalimab every 21 days was well tolerated and showed promising efficacy in patients with advanced STS. Clinical trial information: NCT04025931. Research Sponsor: Shenzhen Chipscreen Biosciences Co., Ltd. and Shanghai Junshi Biosciences Co., Ltd.

Intratumoral INT230-6 (cisplatin, vinblastine, shao) alone or with ipilimumab prolonged survival with favorable safety in adults with refractory sarcomas. *First Author: Christian Frederick Meyer, Johns Hopkins Hospital, Baltimore, MD*

Background: Sarcomas are a rare and diverse group of solid tumors from mesenchymal cells; chemotherapy provides limited benefit for metastatic disease. INT230-6 is a novel formulation of cisplatin (CIS), vinblastine (VIN) and a tissue dispersion enhancer (SHAO) designed for intratumoral (IT) delivery. The drug diffuses into cancer cells, causes apoptosis and recruits dendritic and T-cells to the tumor. Adding ipilimumab (IPI) appears to improve INT230-6 responses in models and clinically. The study evaluated INT230-6 for safety and efficacy alone and with intravenous (IV) IPI. Previously reported results showed INT230-6 alone induced tumor regression, T-cell influx and abscopal effects in uninjected lesions^{1,2}. **Methods:** IT-01 is an open-label phase 1/2 study in adults with locally advanced, unresectable or metastatic solid tumors, including sarcoma. INT230-6 dose was set by tumor diameter or volume. INT230-6 was dosed IT Q2W for up to 5 doses alone or with IPI at 3mg/kg Q3 weeks for 4 doses. Maintenance INT230-6 dosing was Q9W. **Results:** The study enrolled 29 sarcoma patients with 11 subtypes (mainly leiomyosarcoma, liposarcoma, pleomorphic, chondrosarcoma and chordoma). The maximum INT230-6 dose at a single visit was 175 mL (87.5 mg of CIS, 17.5 mg VIN) in 1 or more tumors, an amount that exceeds an IV dose of VIN or CIS. PK analysis shows that >95% of VIN stays in the tumor. The >20% treatment-related adverse events (TRAEs) in evaluable monotherapy patients (n=15) were localized pain (80%), nausea (40%), fatigue (33%), decreased appetite (27%), and vomiting (20%). The >20% TRAEs in evaluable IPI/INT230-6 patients (n=14) were fatigue (39%), localized pain (39%), nausea (31%), pruritus (23%), rash (23%) and vomiting. G3 TRAEs occurred in 20% and 7% of patients in the INT230-6 and combination arms respectively with no grade 4 or 5 events in either arm. RECIST metrics are confounded by IT injections due to the large volume of highly retained INT230-6 and the influx of immune infiltrates. Analysis of median overall survival (mOS) for INT230-6 alone (n=15) was 649 days. For INT230-6 dosed at a volume/total tumor burden (TTB) ratio of ≥40%, the mOS was 715 days. The mOS of the combination has not been reached with over 1 year of median follow-up. OS data compare favorably to a synthetic control (mOS of 205 days) based on historical data³. The hazard ratios of INT230-6 alone or with IPI for OS to the synthetic control were 0.446 and 0.270, p-values <0.01. **Conclusions:** INT230-6 dosed IT alone or with IPI was well-tolerated in diverse sarcomas. INT230-6 use was associated with immune infiltration and favorable mOS as compared to a synthetic control, particularly when ≥40% of the TTB was injected. A randomized phase 3 trial vs. SOC in selected sarcoma subtypes with an OS endpoint is planned. References: 1. Oncoimmunology. 2019 Jul 16;8(10). 2. ASCO 6/2022. 3. Sci Rep. 2016;6:35448. Phase I/II study to evaluate penpulimab combined with anlotinib and epirubicin in the first-line treatment of soft tissue sarcoma: Updated. *First Author: Yuhong Zhou, Liver Cancer Institute, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Anthracycline-based chemotherapy regimens are the cornerstone of first-line treatment of recurrent/metastatic unresectable soft tissue sarcoma(STS), while the efficacy was not satisfactory (the median PFS: 4-8 months). Anti-angiogenesis TKI hypothetically can improve the efficacy of chemotherapy by remodeling the immunosuppressive TME. We conducted this trial to explore the safety and efficacy of PD-1 antibody Penpulimab(P) plus anlotinib(A) and epirubicin(E) in the first-line treatment of STS. The results of the phase I study were reported (2022 ESMO). We updated the latest efficacy and safety data. **Methods:** This ongoing phase I/II, open-label trial (ChiCTR2100048014) enrolled patients (pts) aged 16-75 years old with pathologically confirmed metastatic or unresectable locally advanced STS. Pathologic types are moderately sensitive or above to anthracycline chemotherapy. Pts who met the inclusion criteria were treated with phase I dose results (E 60 mg/m² + A 10 mg and P 200 mg ; E: IV, D1-3, Q3W, A: PO, QD, D1-14, Q3W, P: IV, Q3W) for a total of 6 treatment cycles (3 weeks each). A+P was maintained for 2 years until progressive disease or unacceptable toxicity. The primary endpoint was PFS(progression-free survival) and secondary endpoints were ORR(objective response rate), DCR(disease control), OS(overall survival), 2-year OS and PFSR at 3 and 6 months. The response to treatment was evaluated according to RECIST version 1.1. In addition, adverse events were evaluated by CTCAE v5.0. **Results:** From September 2021 to December 2022, 32 pts (14 males and 18 females) were enrolled with the median age is 53.5 (range 29-73) years old. Pathological types included liposarcoma (DDLPS 14, PLS 1, n = 15), undifferentiated sarcoma (n = 4), leiomyosarcoma (n = 5), angiosarcoma (n = 3), fibrosarcoma (n = 2), and others (n = 3). At the data cut off date on December 20, 2022, Median follow-up time was 3.5 months (range 0.03-15.38), Median PFS was 10.55 months [95%CI 4.60, 14.59]. Median OS was not reached. The PFS at 3 months and 6 months was 86.76%, 68.16%, respectively, and the OS at 12 months was 92.64%. 24 pts were eligible for the evaluation of tumor response, the objective response rate (ORR) was 12.50% (4/24) and the disease control rate (DCR) was 68.75% (14/24). The incidence of treatment-related adverse events of grade 3 was 31.25%, with a higher incidence of hypertriglyceridemia (9.38%), Neutrophil count decreased (6.25%), palmar-plantar erythrodysesthesia syndrome (6.25%), febrile neutropenia (6.25%), respectively. The incidence of Severity Adverse Event was 12.5%. 50 pts are expected to be enrolled in the study, and the data will be mature after the follow-up is completed. **Conclusions:** Penpulimab(P) plus anlotinib(A) and epirubicin(E) has shown encouraging activity as first-line treatment for STS, which significantly prolong the PFS with well tolerance. Clinical trial information: ChiCTR2100048014. Research Sponsor: None.

Trabectedin (T) versus adriamycin plus dacarbazine (A-DA) in advanced solitary fibrous tumor (SFT): Results from a phase II randomised clinical study (STRADA). *First Author: Silvia Stacchiotti, IRCCS Foundation National Cancer Institute, Milan, Italy*

Background: T and A-DA showed antitumor activity in a PDX model of dedifferentiated-SFT (D-SFT) and a few cases of activity in advanced SFT pts have been reported. The efficacy of these agents in advanced typical- (T-) malignant- (M-) SFT is unclear. A phase 2 randomised (R) study was conducted within the Italian Sarcoma Group (ISG) to investigate the activity of T and A-DA in advanced T-, M- and D-SFT (Clin-Gov: NCT03023124). **Methods:** An Italian, multicentre, investigator-initiated prospective open-label, R, non-comparative, phase 2 trial was started in July 2017 involving 6 ISG sites, to evaluate the activity of front-line T (1,5-1,3 mg/sqm at investigator's discretion, day 1 every 3 wks; arm A) vs A-DA (A 75 mg/sqm day 1 + DA 400 mg/sqm days 1,2 every 3 wks; arm B) in > 18 years-old pts with advanced SFT (T-SFT, M-SFT, D-SFT) until progression or limiting toxicity; in arm B, a maximum number of 6 cycles was foreseen, given the constrain of the maximum tolerated dose of A. Eligible pts had to show RECIST progression in the 6 mos prior to study entry. Centralized pathologic and radiologic review was performed. Pts were randomly assigned to Arm A or Arm B (1:1 ratio), with cross over in case of progression (PD) or unacceptable toxicity prior to the completion of the 6 cycles (arm B in case of randomization to arm A and vice versa). An interim analysis was pre-planned after reaching 10 evaluable pts in each arm, and at least 1 response in arm A was required to continue the study. Primary end-point was the overall response rate (ORR) by RECIST; secondary end-points ORR by Choi, progression-free survival (PFS), overall survival (OS). **Results:** Enrollment for the interim analysis was completed in September 2022. 30 pts were screened and 23 were enrolled (7 screening failure): T-SFT = 7, M-SFT = 14, D-SFT = 2. All pts were naïve; 3 pts are ongoing, 20 completed their treatment (12 = PD, 8 = other). All pts were evaluable for RECIST. No responses by RECIST were seen in each arm (ORR 0%), while stable disease (SD) and PD were 9 (45%) and 1 (5%) in arm A and 8 (40%) and 2 (10%) in arm B, respectively. At a 15.9-mo (I.Q. range 11.3-29.0) m-FU, m-PFS by RECIST was 9.2 (2.7-not assessable) mos in arm A and 8.0 (1.1-not assessable) mos in Arm B, with 29.6% progression-free pts at 1 year in arm A and 18.7% in arm B. Median OS was 34.3 (9.3-not assessable) mos in arm A, 31.5 (4.2-31.5) mos in arm B. **Conclusions:** No responses were seen neither to T nor to A-DA across all SFT subtypes; therefore, the study was closed to enrolment for T-SFT and M-SFT after the interim analysis. Noteworthy, both T and A-DA stabilised the disease in about 40% of previously progressive pts, and nearly 30% of pts treated with T were free from progression at 1 year. On the other hand, no conclusion can be drawn yet on the activity of T/A-DA in this SFT subtype, since D-SFT cases who entered the study were only 2 and the enrolment of D-SFT is still ongoing. Clinical trial information: NCT03023124. Research Sponsor: Pharmamar.

A phase II study of talimogene laherparepvec (T-VEC) and pembrolizumab in patients with advanced sarcoma: Results of expansion cohorts. *First Author: Ciara Marie Kelly, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The open-label, single-center phase II study of T-VEC and pembrolizumab in patients with advanced sarcoma met its primary endpoint and demonstrated a best objective response rate of 30% at 24 weeks per RECIST v1.1 (Kelly CM, et al, Jama Oncology, 2020). Responses were seen in undifferentiated pleomorphic sarcoma (UPS), myxofibrosarcoma (MFS), epithelioid sarcoma (ES), cutaneous angiosarcoma (AS), and undifferentiated sarcoma not otherwise specified. Here, we report the efficacy observed in three histology specific expansion cohorts: 1) UPS/MFS, 2) cutaneous AS and 3) ES. **Methods:** Patients refractory to ≥ 1 prior line of systemic therapy or declined standard of care systemic therapy received pembrolizumab intravenously and intratumoral T-VEC injections on day 1 of a 21-day cycle. The primary endpoint was best objective response (ORR, complete and partial responses per RECIST v 1.1) by 24 weeks estimated for each subtype-specific cohort. Secondary objectives included: adverse events (AEs, TRAEs), median PFS and correlatives. **Results:** Twenty-one patients enrolled in the expansion cohorts: median age 72 years (range: 39-85), male 57%, ≥ 1 prior line of therapy (43%). Treatment was well tolerated in twenty patients; one patient discontinued study therapy due to grade 3 immune mediated hepatitis. Nineteen patients were evaluable for efficacy (one patient withdrew from the study and another discontinued treatment before week 24). Subtype specific best ORR by 24 weeks per RECIST v 1.1: UPS/MFS – 11% (n = 1/9)[95% CI: 0.0-0.48]; AS – 43% (n = 3/7)[95% CI: 0.1-0.82]; ES – 0% (n = 0/3). The best ORR overall for the AS cohort was 71% (n = 5/7)[95% CI: 0.03-0.95]. Median PFS (weeks) was 14.9 [CI: 7-11] for UPS/MFS and 54 [95% CI: 3- not reached] for AS (Table). **Conclusions:** TVEC and pembrolizumab demonstrated acceptable safety and promising anti-tumor activity in cutaneous AS (head & neck (n = 4) and Stewart-Treves syndrome involving the upper extremity (n = 1)). Five AS patients experienced a partial response with durable disease control, remaining on study for 1-2 years or more. Two delayed responses were observed in the AS cohort after the pre-specified 24-week criteria. One AS responder progressed on immune checkpoint inhibition prior to study entry. Correlative analyses are ongoing. Clinical trial information: NCT03069378. Research Sponsor: Merck and Amgen; Cycle for Survival; from NIH/NCI Cancer Center Support Grant p30 CA008748; Angiosarcoma Awareness, Inc foundation provided funding for travel reimbursement for angiosarcoma participants in the expansion cohort.

	UPS/MFS (n = 10*)	Cut. AS (n = 8*)	ES (N = 3)
Median Age (range)[years]	69 (48-81)	80 (72-85)	63 (39-70)
Prior treatment (%)			
≤ 2 regimens	7 (70)	4 (50)	2 (66.6)
≥ 3 regimens	3 (30)	4 (50)	1 (33.3)
Prior immunotherapy (%)	2 (20)	1 (12.5)	0 (0)
≥ Grade 3 TRAE (%)	0 (0)	1 (hepatitis) (12.5%)	0 (0)
Best ORR at 24 weeks n (%) [CI]	1 (11) [0.0-0.48]	3 (43) [0.1-0.82]	0 (0)
Best ORR overall n (%)	1 (11)	5 (71)	0 (0)

Efficacy of eribulin administered in combination with an immune checkpoint inhibitor (ICI) and anlotinib as salvage treatment for patients (pts) with advanced adult soft tissue sarcoma (STS). *First Author: Xi Guo, Department of Medical Oncology, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Eribulin combined with a multi-targeted antiangiogenic tyrosine kinase inhibitor has shown efficacy in STS. ICIs have also exhibited improved survival in some STS subtypes. We investigated the efficacy and safety of triple combination therapy with eribulin, an ICI and anlotinib in the treatment of advanced STS in an adult Chinese population. **Methods:** This study retrospectively analyzed data from patients diagnosed with advanced STS who received combination therapy with eribulin, an ICI and anlotinib at the Department of Oncology, Zhongshan Hospital affiliated to Fudan University. The primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR) by RECIST v1.1, disease control rate (DCR), and treatment-related adverse events (TRAEs) by CTCAE v5.0. **Results:** Medical records from 32 pts treated between August 15, 2020 and January 31, 2023 were included; the median age was 56 years, 71.8% (23/32) were female, 75.0% (24/32) had an Eastern Cooperative Oncology Group (ECOG) performance status (PS) of 0 or 1, and 25.0% (8/32) had an ECOG PS of 2. Pts had received a median of 2 (range 0-6) prior regimens and the median follow-up was 4.1 months. Among the patients, 50.0% (16/32) had liposarcomas (including 1 with pleomorphic liposarcoma and 15 with dedifferentiated liposarcoma [DDLPS]), 31.3% (10/32) had leiomyosarcomas (LMS), 3 had undifferentiated pleomorphic sarcoma (UPS), and 1 each had angiosarcoma, rhabdomyosarcoma and desmoplastic small round cell tumor. In a preliminary analysis, 29 pts were evaluable for clinical activity; partial responses (PRs) were achieved in 3 pts (2 DDLPS, 1 UPS), the ORR and DCR were 10.3% (3/29) and 62.1% (18/29) respectively, and the median PFS was 5.7 months (95% CI 2.7-9.8). Of the 15 pts with DDLPS (median 1 prior line of therapy; median follow-up 6.3 months), 13 were evaluable for clinical activity; a PR was achieved by 15.4% (2/13), the DCR was 61.5% (8/13), the median PFS was 9.8 months (95% CI 1.8-28.5) and treatment was ongoing in 46.7% of pts (n = 7). Among the 9 evaluable pts with LMS, 0 achieved a PR, the DCR was 44.4% (4/9), median PFS was 3.9 months and 3 pts were still receiving treatment. In the overall cohort (n = 32), TRAEs of any grade occurred in 56.3% of pts (n = 18), the most common were myelosuppression (28.1%), fatigue (15.6%), fever (12.5%) and rash (12.5%). Grade 3/4 TRAEs occurred in 12.5% of pts, with no grade 5 events. **Conclusions:** This study demonstrates the potential efficacy of combination therapy with eribulin, an ICI and anlotinib in patients with advanced STS, especially in those with the DDLPS subtype. Our data suggest that this combination has good tolerability and a prospective trial is warranted. Clinical trial information: ChiCTR2100053594. Research Sponsor: None.

Trabectedin failure-free survival (TFFS) after resuming trabectedin (T) in advanced myxoid liposarcoma (MLPS) patients. *First Author: Chiara Fabroni, Italian National Cancer Institute, Milan, Italy*

Background: To explore the time to trabectedin failure-free survival after resumption of T in advanced MLPS patients who were stable or responding to T at the time of discontinuation. **Methods:** We retrospectively collected the cases of all patients with advanced MLPS treated with T at our institution from September 2002, highlighting those who were free from progression (according to RECIST) after 6 cycles of T. Trabectedin failure-free survival (TFFS) was defined as time from the first cycle of T to progression (PD) or death, whichever occurred first. Survival analyses were performed using the Kaplan-Meier method. **Results:** Since September 2002, 75 patients with recurrent myxoid liposarcoma received T at our institution. A total of 56 patients were free from progression (according to RECIST) after 6 cycles of T and were included in this analysis. Among them, 25/56 (45%) interrupted their treatment in absence of progression, while 31/56 (55%) patients received T until progression of disease. In the former group, 11/25 had surgery of their residual disease, 3/25 received radiotherapy, 5/25 interrupted T for toxicity and 6/25 patients shared the decision to stop with the clinician. Among patients who received surgery, 2/11 had monofocal disease (longest diameter < or = 5cm), 4/11 had monofocal disease (longest diameter between 10-18 cm) and 5/11 had plurifocal disease. The interruption of T in these 25 patients occurred after a median of 12 cycles (interquartile range = 9-14). Median TFFS was 43.4 months (95%CI 38.7-NA). In the concurrent group of patients who received T continuously, the median TFFS was 14.2 months (95% CI: 10.8-21.9). **Conclusions:** While the longer TFFS of patients undergoing discontinuation cannot be compared with the shorter of those who did not interrupt, the former group being biased favorably (feasibility and exploitation of surgery, other likely determinants of physician's decision to stop), we speculate that there may be a subgroup of selected patients with advanced myxoid liposarcoma primarily responding to T, who could benefit from a "stop and go" policy, thus prolonging the overall time interval within which T remains active. Prospective studies in selected subgroups of MLPS patients on optimization of treatment strategy with T are worthwhile. Research Sponsor: None.

Risk stratification tools to help decide on adjuvant chemotherapy usage in resected soft tissue sarcomas: A 10 year review of an Irish sarcoma centre experience. *First Author: Catherine Weadick, Department of Medical Oncology, Cork University Hospital, Cork, Ireland*

Background: Soft tissue sarcoma (STS) is comprised of 80 pathologic subtypes based on a combination of distinctive morphological, immunohistochemical and molecular features. Adult-type soft tissue and visceral sarcomas are rare, with an estimated incidence of 4-5/100,000/year in Europe. The National Comprehensive Cancer Network (NCCN) guidelines recommend consideration of neo-adjuvant or adjuvant systemic treatment in resectable stage III (high grade tumours which are >5cm) and also in those who need to undergo an amputation or radical resection with adverse functional outcomes. The Sarcuator risk prediction tool has identified a threshold of risk above which the administration of chemotherapy may provide an overall survival benefit. This can be applied to the most common histologic subtypes. Patients affected by these subtypes and with a 10-year predicted OS likelihood <60% are considered as high risk and therefore, should be considered for adjuvant chemotherapy. Alternatively, tumours considered at high risk of recurrence based on size >5cm and high grade histology, may benefit from adjuvant chemotherapy. Therefore, the aim of this project is to review the outcomes of resected extremity/trunk soft tissue sarcoma and assess the prognostic accuracy of these risk prediction methods. **Methods:** All new patients with resected STS discussed in the STS MDT in Cork University Hospital between Jan 2012 – Dec 2021 were identified. The histology and imaging of the identified patients were reviewed. Data regarding demographics, histology, treatment and outcomes was collected. Risk assessment using AJCC and Sarcuator score was done on all patients with an extremity or trunk sarcoma. Overall survival was recorded and assessed including Kaplan Meier method for time to event analysis. **Results:** 200 patients were identified as having an STS resected - 134 of these were located on the trunk or extremities representing 24 different histological subtypes. Sarcuator score was calculated for 60 of these (well differentiated liposarcomas, desmoid tumours, and dermatofibrosarcoma protuberans were excluded). 3 patients received adjuvant chemotherapy and 4 patient neoadjuvant chemotherapy. Overall survival data is presented below. **Conclusions:** Our cohort is representative of the broad histological subtypes expected in sarcoma. Sarcuator score results correlate with international outcomes, with higher scores associated with increased mortality. In our cohort, sarcuator score was more predictive of outcome than tumour grade/size alone. Research Sponsor: None.

Sarcuator score – risk assessment	No. patients	No. of deaths	5 yr OS rate (n = 30)
High risk	19	8 (42.1%)	60.2%
Low risk	41	6 (14.6%)	87.1%
AJCC staging - risk assessment	No. patients	No. of deaths	5 yr OS rate (n = 30)
High risk	25	8 (32%)	67.6%
Low risk	35	6 (17%)	86.3%

Outcome of patients (PTS) with advanced epithelioid hemangioendothelioma (EHE) after failure on sirolimus (S). *First Author: Claudia Giani, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

Background: EHE is an ultra-rare sarcoma, showing a highly variable clinical behavior, from indolent to very aggressive. Systemic agents available for treatment of sarcoma have marginal activity in EHE. S showed antitumor effect in PDX models and pts affected by advanced EHE. However, clinical data on S in EHE are only retrospective and uncontrolled. This makes it difficult to interpret if the median progression-free survival (m-PFS) of 13 mos and the m-overall survival (m-OS) of 18.8 mos observed in the 38 progressive pts included in the largest series available (Stacchiotti et al, doi:10.1002/cncr.33247) were attributable to the antitumor effect of S or to EHE natural history. To fill this gap, we reviewed the outcome of pts included in this series who went off S. **Methods:** Clinical data of all EHE pts included in the above-mentioned retrospective study and treated with S for advanced disease between 2010 and 2019 were reviewed, focusing on pts who discontinued S for any reason. Progression was retrospectively categorized by RECIST 1.1 progressive disease (PD) and as "clinical progression" (CP), CP being defined as worsening of systemic symptoms and/or serosal effusion without criteria for RECIST PD. Survival analyses were performed by Kaplan-Meier method. OS was defined as the time from S start until death or last follow-up (FU), post-discontinuation OS (pOS) as the time from S discontinuation until death or last FU, post-discontinuation PFS (pPFS) as the time from S discontinuation until first evidence of progression (PD or CP) or death, post-re-challenge PFS (pR-PFS) as the time from S re-challenge until first evidence of progression (PD or CP) or death. **Results:** Of the 38 pts, 24 stopped S and were included in this analysis (median age = 47 yrs; serosal effusion yes/no = 9/15; S discontinuation due to: RECIST PD = 12, CP = 3, toxicity = 7; other = 2). After S discontinuation all pts had an event (PD or CP or death), and 13/24 (54%) pts did not receive further treatments, while 11/24 (46%) started again a systemic treatment. In particular, 6/24 (25%) restarted S (all after interval progression, PD or CP) with a new stable disease in 5/6 cases. At last FU, 6/24 (25%) pts were alive, 18/24 (75%) dead. At 62.2-mo m-FU (IQR 46-124), m-OS was 14.3 mos (95% CI, 7.3-21.2). Overall m-pPFS was 3.02 mos (95% CI, 1.6-4.4), m-pOS was 7.15 mos (95% CI, 4.4-9.9). m-pPFS of pts who discontinued S without evidence of progression (PD or CP) was also 3.02 mos (95% CI, 2.9-3.1). m-PFS following the re-challenge of S (m-pR-PFS) was unreached; 1 pt died following PD after 19 mos, 1 pt was alive and showed CP at 40 mos, 4 were alive and progression-free after 27, 31, 55, 94 mos. **Conclusions:** In our study the outcome of EHE pts who discontinued S was poor, with a m-pPFS of 3 mos and a m-pOS of 7 mos. However, pts who discontinued S for reasons other than progression benefited from S re-challenge, suggesting that in advanced EHE there is a subset of long-responders to S. Research Sponsor: None.

Clinical implications of recurring mutations in myxoid liposarcoma (MLS). *First Author: Prapassorn Thirasastr, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MLS is a subset of liposarcoma characterized by a translocation, t(12;16), FUS-DDIT3 or less frequently t(12;22), EWSR1-DDIT3. Additional mutations have been reported in *TERT* promoter, *PIK3CA*, and *PTEN* and some were associated with the more aggressive round cell phenotype. Our study aimed at analyzing the clinical significance of these recurring mutations. **Methods:** MLS patients (pt) with available next-generation sequencing (NGS) data (any clinical grade) between Jan 2014 to Oct 2022 were included. Baseline characteristics, chemotherapy (CMT) response (partial response [PR] and stable disease [SD]), and survival were collected for doxorubicin-ifosfamide (AI), doxorubicin-dacarbazine (ADIC), trabectedin (T), and eribulin (E). Binary logistic regression was used to evaluate mutations associated with response. Cox proportional-hazard regression was used to investigate associations of variables with progression-free survival (PFS) and overall survival (OS). The Kaplan-Meier method was used to estimate survival and log-rank tests were used to compare survival between groups. **Results:** Of 18 MLS pt included, median age at diagnosis was 42 years (R 30-65). Majority were male (12/18, 67%), had localized disease at diagnosis (13/18, 72%), and had lower extremities as primary location (10/18, 56%). Eight (44%) had round-cell > 5% and 15 (83%) had primary tumor > 5 cm. Somatic mutations were reported in 15 pt (83%); the most common were *TERT* promoter (61%), *PTEN* (28%), *PIK3CA* (22%), and *TP53* (17%). None showed significant association with clinical factors (age, sex, size, stage, round cell > 5%, primary location). Forty-eight records (18 AI, 6 ADIC, 19 T, and 5 E; 3 pt received AI and T twice for different recurrences), were evaluated for PFS and 47 records had response data available. For AI, ADIC, T, and E, PR rate was 39% (7/18), 17% (1/6), 32% (6/19), and 40% (2/5), while clinical benefit (CBR: PR + SD ≥ 3 mo) was 67% (12/18), 50% (3/6), 63% (12/19), and 80% (4/5), respectively. PR or CBR were not associated with the common mutations for any regimen. Median follow up (FU) from start of CMT was 4 mo (R 0.5-31). PFS (95%CI) was 11 (6.7- Not Reached [NR]), 1.2 (1.1-NR), 23 (6.3-NR), and 8 (1.3-NR) mo for AI, ADIC, T, and E, respectively. *PIK3CA*m (n = 15) was associated with improved PFS with CMT (PFS [95%CI]: *PIK3CA*w 7.8 [6.3-11.2] vs. *PIK3CA*m 23 mo [1.3-NR]; multivariate hazard ratio [HR] 0.23, p = 0.036, adjusted by gender and ADIC regimen). This appeared to be mainly driven by the *PIK3CA*m/*TERT*wt (n = 8, HR 0.07, p = 0.006). For T, *PIK3CA*m/*TERT*m (n = 3) showed a trend for lower PFS (1.3 mo) in contrast to other groups (23 mo). **Conclusions:** *TERT* promoter mutation was the most frequent mutation but was not associated with outcome in our small series. *PIK3CA*m suggested PFS benefit from CMT while, on the contrary, dual *PIK3CA*m/*TERT*m showed a trend towards shorter PFS with T. The predictive and prognostic role of these mutations in MLS warrant further study. Research Sponsor: None.

DKC expression by RNAseq as a potential biomarker of gemcitabine response in sarcoma. *First Author: David A. Liebner, The Ohio State University, Columbus, OH*

Background: Deoxycytidine kinase (DKC) is responsible for activation of gemcitabine by phosphorylation of gemcitabine to its monophosphate form. Studies have suggested that DKC expression may be correlated to response to gemcitabine in various solid tumors, and that downregulation of DKC may be at least partly responsible for gemcitabine-resistance *in vitro*. However, the significance of DKC expression in sarcomas as a biomarker of response to gemcitabine remains poorly characterized. **Methods:** Participants enrolled in the prospective Electronic Health Record (EHR)-Based Comprehensive Bone and Soft Tumor Registry (NCT02677961) at The Ohio State James Cancer Center who had received gemcitabine-based chemotherapy for the treatment of bone and soft tissue sarcoma were eligible for this study. A total of 179 patients were identified who had received at least one cycle of gemcitabine-based chemotherapy, between January 1st, 2014, to December 31st, 2022. Whole exome RNAseq expression data was available for 36 of these patients who had received gemcitabine-based chemotherapy in the setting of active disease. **Results:** Of the 36 patients included in this study, 22 were female and 14 were male. Nine different main disease types were identified in the patient subset. These include angiosarcoma (8), chondrosarcoma (1), leiomyosarcoma (16), liposarcoma (3), malignant peripheral nerve sheath tumor (1), myxofibrosarcoma (2), osteosarcoma (2), undifferentiated pleomorphic sarcoma (3), and undifferentiated spindle cell sarcoma (1). The median time to treatment discontinuation (TTD) among all patients was 178 days. Among DKC low-expressors (n = 16), the median TTD was 86 days; among high-expressors (n = 16), the median TTD was not reached. Differences between groups did not reach statistical significance (HR = 0.55, p = 0.14). **Conclusions:** DKC expression by clinical RNAseq is a potential biomarker of gemcitabine-response in sarcoma, but larger studies are necessary to evaluate the potential clinical significance and possible role of DKC expression in identifying patients most likely to benefit from gemcitabine-based chemotherapy. AOST2031: An in-progress COG phase 3 randomized controlled trial comparing open vs thoracoscopic management of pulmonary metastases in patients with osteosarcoma. *First Author: John J Doski, University of Texas Health Sciences Center at San Antonio, San Antonio, TX*

Background: Pulmonary metastasectomy is considered a necessary component of curative therapy in pulmonary metastatic osteosarcoma, however the optimal surgical approach is unknown. Two approaches include open surgery (OSY) including thoracotomy or sternotomy and minimally invasive surgery (MSY) by thoracoscopy. No randomized trial has been completed comparing these approaches in patients with osteosarcoma, however randomized controlled trials in other cancers have not identified superior outcomes in patients undergoing OSY. OSY allows for direct palpation of all lung surfaces and more pulmonary metastatic nodules can be identified during OSY compared to the number predicted by pre-operative imaging. MSY offers the benefit of faster patient recovery, improved quality of life and potential for equivalent surgical control of relevant metastatic disease. Given wide variability in surgical approach and willingness of both surgical oncology and patient advocacy communities to participate in a randomized trial, AOST2031 was developed to address this clinical equipoise. **Methods:** Eligibility for AOST2031 includes patients < 50 yrs with a histological diagnosis of osteosarcoma and evidence of pulmonary metastases at initial diagnosis or at first recurrence. Patients must have oligometastatic lung metastasis considered resectable by either OSY or MSY, with rapid central review of chest CT images to confirm eligibility. Systemic therapy considered equivalent to methotrexate, cisplatin and doxorubicin is required to be ongoing in newly diagnosed and completed in patients with recurrence. Exclusion criteria include unresectable primary disease, metastatic disease requiring anatomic lung resection, pleural or mediastinal lesions or pleural effusions, progression while receiving initial therapy, extra-pulmonary metastases and prior chest surgery for pulmonary metastases. Patients are randomized 1:1 to either OSY or MSY, with randomization stratified by disease status and risk. The primary outcome is thoracic event free survival, defined as intrathoracic tumor recurrence or death that results from the procedure or a complication related to the procedure. Two-hundred and twenty-five eligible patients are anticipated to answer the primary objective. Secondary objectives include event free, overall survival and . Exploratory objectives include surgical complication rates, patterns of recurrence, use of surgical localization techniques, comparison of CT findings to pathology of resected specimens, and patient reported outcomes. Biologic objectives include the collection of metastatic tissues to facilitate the study of metastatic disease and serial blood samples for future tumor profiling, germline and circulating tumor DNA studies. AOST2031 opened to enrollment at NCTN sites in February 2022. Clinical trial information: NCT05235165. Research Sponsor: U.S. National Institutes of Health.

A randomized, open-label, phase 2 study evaluating abemaciclib in combination with irinotecan and temozolomide in participants with relapsed or refractory Ewing sarcoma. *First Author: Gertjan VAN HAL, Eli Lilly and Company, Indianapolis, IN*

Background: Ewing's sarcoma (ES) is the second most common malignant bone tumor affecting children and young adults. Patients with relapsed disease have a poor prognosis and need effective therapies. *EWS-FLI1*, the most common ES fusion gene (90-95% of cases), is an oncogenic transcription factor that downregulates intrinsic cyclin-dependent kinase (CDK) inhibitors, *CDKN1A* and *CDKN1C*, which promote cell cycle arrest and upregulates *CDK4*, which drives entry into the cell cycle. This provides a biological rationale for the clinical evaluation of CDK4/6 inhibitors in ES. Abemaciclib is a selective CDK4/6 inhibitor approved for the treatment of breast cancer. It is approximately 14 times more potent against CDK4/cyclin D1 than CDK6/cyclin D3 in enzymatic assays and has the advantage of continuous dosing schedule without breaks for neutrophil recovery. Abemaciclib is currently also in clinical development for paediatric patients with relapse/refractory solid tumors in combination with irinotecan and temozolomide (JPCS study, NCT04238819). This study, NCT05440786, will evaluate the potential benefit of adding abemaciclib to irinotecan plus temozolomide for the treatment of relapsed/refractory ES. **Methods:** This randomized, open-label, Phase 2 study is part of the CAMPFIRE master protocol. It is enrolling paediatric and young adult patients (1-39 years) with relapsed/refractory ES or ES-like tumors. Approximately 45 patients will be randomized 2:1 between 2 arms: irinotecan and temozolomide with or without abemaciclib. Stratification factors include age, pulmonary/non-pulmonary site of metastases, and time to recurrence from initial diagnosis. Patients will receive irinotecan (50 mg/m²/day intravenously) and temozolomide (100 mg/m²/day orally) on days 1-5. Abemaciclib will be administered orally twice-daily on a continuous 21-day cycle. The abemaciclib dose will be 55mg/m² BID for patients < 18 years and 100mg BID for those ≥ 18 years. Besides 25 and 50mg tablets, abemaciclib will be available as 2.5mg granules allowing administration of doses as low as 10mg to patients with a body surface area lower than 0.2m². Treatment continues until disease progression or other discontinuation criteria are met. The primary endpoint is progression-free survival (PFS) determined by a blinded independent review committee using Response Evaluation Criteria in Solid Tumors, Version 1.1. Key secondary endpoints include overall survival, objective response rate, duration of response, disease control rate, PFS determined by investigator assessment, safety, and pharmacokinetics. Additional analysis includes exploratory biomarker testing. This study is open and actively enrolling in Australia, Europe, Japan, and United States. Clinical trial information: NCT05440786. Research Sponsor: Eli Lilly and Company.

ENLIGHTEN-01: A phase 1 study of fluorescein-specific (FITC-E2)-CAR T cells in combination with folate-fluorescein (UB-TT170) for osteosarcoma. *First Author: Catherine Michelle Albert, Seattle Children's Research Institute, Seattle, WA*

Background: Outcomes for relapsed osteosarcoma (OS) remain poor and there are no systemic therapies that have been shown to provide a survival benefit. Chimeric Antigen Receptor (CAR) T cell immunotherapy involves the adoptive transfer of T-lymphocytes that have been engineered to recognize tumor-specific antigens, resulting in targeted lysis of malignant cells. Folate receptors (FR) are membrane-bound surface proteins that bind folates with high affinity. FRs are overexpressed in OS and have very limited expression in normal tissue. UB-TT170 (Umoja Biopharma) is a small molecule bispecific "adapter" consisting of folate conjugated to fluorescein (FL). It penetrates tumors in minutes and is retained for long periods of time due to high affinity for the FR, while unbound UB-TT170 rapidly clears from the blood and from FR- tissues. We hypothesize that administration of fixed dosing anti-FL(FITC-E2) CAR T cells followed by escalating doses of UB-TT170 will deliver personalized immunotherapy to OS patients. In addition, this approach offers an attractive safety mechanism since administration of NaFL should reverse CAR T cell reactivity. **Methods:** We designed a Phase I study for young adult (15-30 yr) patients with recurrent/refractory OS to examine the safety and feasibility of administering autologous, peripheral blood-derived T cells that have been genetically modified to express a 2nd generation FL-specific CAR in combination with intra-subject dose escalation of UB-TT170. The primary objective is to identify a recommended dose escalation sequence of UB-TT170 to move forward in clinical development. A 3+3 design will be used to investigate 3 possible dosing sequences. The trial opened in July 2022. As of January 5, 2023, 5 subjects have enrolled and one subject has been treated on dose regimen 1. T cell products have been successfully manufactured for all enrolled subjects. The trial remains open to enrollment. Clinical trial information: NCT05312411. Research Sponsor: Umoja Pharma; Seattle Children's Therapeutics.

INSIGHT: A phase 3, randomized, multicenter, open-label study of ripretinib vs sunitinib in patients with advanced gastrointestinal stromal tumor previously treated with imatinib harboring *KIT* exon 11 + 17 and/or 18 mutations. First Author: Suzanne George, Dana-Farber Cancer Institute, Boston, MA

Background: Gastrointestinal stromal tumor (GIST) is the most common gastrointestinal sarcoma, with approximately 80% of cases driven by *KIT* mutations. Most patients (pts) with advanced GIST develop disease progression following first-line treatment with imatinib due to *KIT* secondary resistance mutations occurring most commonly in the ATP-binding pocket (exons 13/14) and/or activation loop (exons 17/18). Sunitinib is approved as second-line therapy for advanced GIST. Ripretinib is a switch-control tyrosine kinase inhibitor approved for pts with GIST who received prior treatment with 3 or more kinase inhibitors, including imatinib. In the phase 3 INTRIGUE study (NCT03673501) in second-line advanced GIST, ripretinib was not superior to sunitinib in terms of progression-free survival (PFS); however, a more favorable safety profile was observed with ripretinib vs sunitinib (Bauer S et al. *J Clin Oncol*. 2022). Exploratory mutational analysis from INTRIGUE using baseline circulating tumor DNA (ctDNA) demonstrated that pts harboring primary *KIT* exon 11 mutations with secondary resistance mutations exclusively in *KIT* exons 17 and/or 18 derived PFS benefit with ripretinib vs sunitinib (median, 14.2 vs 1.5 months; HR = 0.22, 95% CI 0.11 to 0.44, nominal $P < 0.0001$; Bauer S et al. *J Clin Oncol*. 2023; abstract 397784). Here, we describe a planned phase 3 study for pts with advanced GIST previously treated with imatinib harboring *KIT* exon 11 + 17 and/or 18 mutations. **Methods:** INSIGHT is a phase 3, randomized, open-label study that aims to evaluate the efficacy of ripretinib vs sunitinib in pts with advanced GIST previously treated with imatinib and who harbor *KIT* exon 11 + 17 and/or 18 mutations. Eligible pts must be ≥ 18 years old with histologically confirmed GIST and co-occurring *KIT* exon 11 + 17 and/or 18 mutations confirmed by ctDNA analysis. Pts must also have advanced disease with ≥ 1 measurable lesion per modified Response Evaluation Criteria in Solid Tumors (mRECIST) v1.1, radiologic progression on imatinib, and an Eastern Cooperative Oncology Group Performance Status ≤ 2 . Key exclusion criteria include a *KIT* exon 9, 13, or 14 mutation via ctDNA at screening and prior treatment with another line of therapy in addition to imatinib for advanced GIST. A total of 54 pts will be randomized (2:1) to receive ripretinib 150 mg once daily (QD; continuous) or sunitinib 50 mg QD (4 weeks on/2 weeks off) in 6-week cycles. The primary endpoint is PFS by independent radiologic review (IRR) per mRECIST v1.1; key secondary endpoints are objective response rate by IRR using mRECIST v1.1 and overall survival. Safety and patient-reported outcome measures will also be assessed. Pts randomized to the sunitinib arm may cross over to the ripretinib arm upon disease progression. Clinical trial information: NCT05734105. Research Sponsor: Deciphera Pharmaceuticals, LLC.

Alliance A092104: A randomized phase 2/3 study of olaparib plus temozolomide versus investigator's choice for the treatment of patients with advanced uterine leiomyosarcoma after progression on prior chemotherapy. First Author: Kristine Peregrino Lacuna, Columbia University Irving Medical Center, New York, NY

Background: Uterine leiomyosarcoma (uLMS) is an aggressive sarcoma subtype with frequent metastatic relapse. Advanced uLMS is treated with gemcitabine/docetaxel or anthracycline-based regimens. After failure of initial chemotherapy, remaining options provide limited benefit (trabectedin: objective response rate (ORR) 11%, median progression-free survival (mPFS) 4.0 months (mo); pazopanib: ORR 11%, mPFS 3.0 mo; dacarbazine: ORR 9%, mPFS 1.5 mo). 18-23% of uLMS harbor deleterious alterations in homologous recombination (HR) DNA repair genes. HR-deficient cancers are unable to effectively repair double-stranded DNA breaks and may be sensitive to poly ADP-ribose polymerase (PARP) inhibitor-based strategies. In preclinical studies, the combination of temozolomide (T), an alkylating agent, and olaparib (O), a PARP inhibitor, markedly suppressed proliferation of uLMS models. Among 22 uLMS patients with median 3 prior lines, O+T demonstrated mPFS 6.9 mo and ORR 27% (Ingham M. et al. ASCO 2021: #11506). In correlative analysis, alterations in HR genes including *PALB2* and *RAD51B* or absence of *RAD51* foci formation by a functional assay were observed in patients with prolonged PFS (Bose S. et al. ASCO 2022: #11509). Based on these results, we designed a randomized phase 2/3 study to further evaluate O+T in advanced, pretreated uLMS. **Methods:** Alliance for Clinical Trials in Oncology A092104 is a randomized, open-label phase 2/3 clinical trial of O+T versus investigator's choice in advanced uLMS. Eligible patients have ECOG performance status ≤ 2 , progression on ≥ 2 prior treatment lines and measurable disease. Patients are randomized 1:1 to receive T 75 mg/m² orally daily + O 200 mg orally twice daily on days 1-7 in 21-day cycles (Arm 1) or investigator's choice of trabectedin 1.5 mg/m² over 24 hours every 21 days or pazopanib 400-600 mg orally daily (Arm 2). For phase 2, the primary endpoint is PFS. The design evaluates for an improvement in PFS from 4 mo to 8 mo, requires 70 patients, and yields 90% power and 1-sided alpha 0.10. If phase 2 is positive, phase 3 will enroll. For phase 3, the primary endpoint is overall survival (OS). The design evaluates for an improvement in OS from 13 mo to 23 mo, requires 165 patients (including 70 from phase 2) and yields 90% power with 1-sided alpha 0.025. Secondary endpoints include ORR, duration of response, safety and patient-reported outcomes. Archival tissue will be collected and evaluated with a *RAD51* foci formation assay. Genomic sequencing results will be obtained where available. The study opened to accrual in 1/2023. Support: U10CA180821, U10CA180882, U24 CA196171; <https://acknowledgments.alliancefound.org>. Clinical trial information: NCT05633381. Research Sponsor: U.S. National Institutes of Health.

ENVASARC: A pivotal trial of envafolelimab and envafolelimab in combination with ipilimumab in patients with advanced or metastatic undifferentiated pleomorphic sarcoma or myxofibrosarcoma who have progressed on prior chemotherapy. First Author: Richard F. Riedel, Duke Cancer Institute, Duke University Medical Center, Durham, NC

Background: Metastatic undifferentiated pleomorphic sarcoma (UPS) and the genetically related myxofibrosarcoma (MFS) are soft tissue sarcoma (STS) subtypes with poor prognoses. While responses to first-line chemotherapy can approach 20%, efficacy remains limited in the 2nd-line setting and beyond. Pazopanib, the only FDA approved treatment in the refractory setting, has demonstrated an objective response rate (ORR) of 4%. Envafolelimab is a single domain PD-L1 antibody administered by rapid subcutaneous (SQ) injection that is approved for the treatment of microsatellite instability-high (MSI-H) cancer in China. The activity of envafolelimab appears to be similar to other PD-1 antibodies administered intravenously (i.v.). Envafolelimab demonstrated a 32% ORR in MSI-H colorectal cancer patients with progressive disease following three approved chemotherapeutics, similar to the ORR of 28% and 33% with nivolumab and pembrolizumab in these patients, respectively. The rationale for the ENVASARC is based on envafolelimab activity in STS in phase 1 trials and previously reported activity of checkpoint inhibition in UPS/MFS: single-agent pembrolizumab demonstrated a 23% ORR, while the combination of nivolumab and ipilimumab demonstrated a 29% ORR in refractory UPS/MFS. **Methods:** ENVASARC (NCT 04480502) is a pivotal multicenter (at 30 U.S. and U.K. centers) open-label, randomized, non-comparative, parallel cohort study of envafolelimab 600 mg every 3 weeks by SQ injection (n = 80) or envafolelimab 600 mg every 3 weeks by SQ injection combined with ipilimumab 1 mg/kg every 3 weeks i.v. for four doses (n = 80) in patients with locally advanced, unresectable or metastatic UPS/MFS with disease progression on one or two lines of prior therapy. The primary objective of each of parallel cohort is to demonstrate an ORR with a lower limit of the 95% confidence interval that excludes 5.0% in each cohort. If ≥ 9 responders are observed among the 80 patients enrolled in each cohort, then the lower bound of the 95% confidence interval will exclude 5.0%. Secondary endpoints include duration of response, PFS and OS. Key inclusion criteria: ≤ 2 prior lines of therapy (neoadjuvant therapy excluded), ECOG ≤ 1 . Clinical trial information: NCT04480502. Research Sponsor: TRACON Pharmaceuticals.

Poster Session

A phase 2, open-label, adaptive, dose-ranging study with long-term extension to evaluate the safety, tolerability, efficacy, and pharmacokinetics of intra-articular AMB-05X injections in patients with tenosynovial giant cell tumor. First Author: Hans Gelderblom, LUMC Leids Universitair Medisch Centrum, Leiden, Netherlands

Background: CSF1R is a clinically validated target for Tenosynovial Giant Cell Tumor (TGCT). CSF1 is overexpressed in TGCT and, via action at the colony-stimulating factor 1 receptor (CSF1R), leads to the proliferation of synovial-like mononuclear cells and recruitment of multinucleated giant cells, foam cells, siderophages, and inflammatory cells, which compose the bulk of the neoplasm. Although non-metastatic in nature, TGCT can develop into locally destructive lesions that cause significant local tissue injury, loss of joint function, and impaired quality of life. When complete resection is achievable without significant morbidity, the standard of care for patients with TGCT is surgical resection. Recurrence after surgery occurs in up to 30% of patients with localized TGCT and 83% of patients with diffuse TGCT (Mastboom 2019, Patel 2017). Repeat surgeries may be necessary but often leads to further morbidity, complications, and reduced function of affected joints. A safe, effective, and convenient pharmacotherapy is a desirable addition to the therapeutic armamentarium for TGCT. AMB-05X is a potent and selective anti-CSF1R monoclonal antibody in development for local treatment of TGCT. Intra-articular (IA) injection of AMB-05X enables high drug concentration at the tumor site while minimizing systemic exposure and toxicity. A proof-of-concept study of IA AMB-05X for TGCT found clinically meaningful improvement in objective response rate, functional (pain, stiffness, range of motion) and quality of life measures after 12 weeks of therapy with no serious and a low number of adverse events associated with targeting CSF1R. This phase 2 study aims to establish the optimal dosing regimen and local administration of AMB-05X and confirm the efficacy and safety of 24 weeks and longer treatment. **Methods:** AMB-051-07 (NCT05349643) is an open-label, multicenter, phase 2 study of AMB-05X in patients with TGCT. The trial is being conducted at multiple sites in North America, Europe, and Australia. The dosing schedule includes an injection interval of every 4 weeks and longer, including an extended dosing period. Adult patients with histologically confirmed symptomatic TGCT with one joint involvement whether surgically amenable or non-amenable with measurable disease and adequate organ function are being enrolled. After the initial cohort of patients with TGCT of the knee, other joints may be enrolled pending evaluation by the DMC. The primary study outcome measures are objective response rate (ORR) per RECIST v1.1 by central radiology review and safety. Secondary outcome measures include ORR per modified RECIST and Tumor Volume Score, duration of response, time to response, PRO/QOL (including range of motion, stiffness, pain), pharmacodynamics and pharmacokinetics. Clinical trial information: NCT05349643. Research Sponsor: AmMax Bio, Inc.

PEMBROCABOSARC: Combination of pembrolizumab and cabozantinib in patients with advanced sarcomas. *First Author: Sabrina Sellan-Albert, Institut Bergonie, Bordeaux, France*

Background: Despite optimal treatment, up to 40% of patients with sarcomas will develop locoregional and/or distant relapse and median survival in this setting is less than two years. There are very few options in the treatment of undifferentiated pleomorphic sarcomas whereas there is no specific treatment regimen established for recurrent osteosarcoma (OSS) and Ewing sarcoma (ES). Innovative strategies are therefore urgently needed in these settings. In preclinical studies, while immune checkpoint inhibitors were insufficient in controlling tumour growth, combining them with M2 macrophage or angiogenesis targeting resulted in superior tumour control (Mao et al, Clin Cancer Res 2016; Zhu et al, Cancer Res 2014). Combining both antiangiogenic and MET inhibition properties, cabozantinib has shown both preclinical and clinical activity, notably in osteosarcoma and Ewing sarcoma (Italiano et al. ESMO 2018). Interestingly, cabozantinib has also recently been shown to trigger an innate immune response in a preclinical model (Patnaik et al, Cancer Discov 2017). Altogether, these findings pave the way for studies assessing the impact of targeting angiogenesis, MET and immune response in soft-tissue and bone sarcomas. **Methods:** PEMBROCABOSARC (NCT05182164) is a multi-stratum, three single-arm phase 2, multicenter, open-label study investigating pembrolizumab combined with cabozantinib in patients with advanced selected sarcomas: undifferentiated pleomorphic sarcoma (stratum 1), osteosarcoma (stratum 2), Ewing sarcoma (stratum 3). Strata 1 and 2 will enroll ~32 patients and stratum 3 ~55 patients, respectively. Each stratum phase II will be conducted using a Simon's optimal two-stage design. Eligible and consented patients must be ECOG PS 0-1, have measurable and progressive disease according to RECIST 1.1 and have received less than 3 previous lines of systemic therapy for advanced disease and consent also to baseline and per treatment biopsies. Cabozantinib will be administered orally, once daily at a fixed dose of 40 mg, continuously. Pembrolizumab will be administered by intravenous infusion every 3 weeks on Day 1 of each cycle, at a fixed dose of 200 mg. Both treatments will start on Day 1 (of cycle 1). The primary endpoint is 6-months non progression rate as per RECIST 1.1. Secondary endpoints include adverse events (AEs)/serious AEs, best overall response, and progression-free survival. Pharmacodynamic and other biomarkers will be explored on blood and tumor tissue. The first patient received study drug on May, 31, 2022; 8 of planned 119 patients have been enrolled and 5 sites across France among the planned 10, are currently enrolling patients. Clinical trial information: NCT05182164. Research Sponsor: IPSEN PHARMA; French DGOS.

Engagement of patient participation in genomics research by the Osteosarcoma and Leiomyosarcoma Count Me In Projects of the Cancer Moonshot funded PE-CGS Network. *First Author: Suzanne George, Dana-Farber Cancer Institute, Boston, MA*

Background: Osteosarcoma (OS) and Leiomyosarcoma (LMS) are sarcomas with complex genomes for which there has been limited progress in identifying new treatments and improving outcomes. Slow progress in OS and LMS is partially due to insufficient characterization of the genomic landscape. Generating large genomic datasets in OS and LMS is challenging because of the rarity of these sarcomas and recruitment barriers such as care fragmentation between institutions and specialties. The OS and LMS Project research studies aim to: 1) establish a network of engaged pediatric and adult participants with OS and LMS who will co-create a shared database of clinical, genomic, molecular, and patient reported data to enable research; 2) define the clinicogenomic landscape of OS and LMS; and 3) optimize the approach to direct patient engagement in cancer research. **Methods:** Count Me In, a research initiative with prior success in angiosarcoma, working with patients and advocates created websites (OSProject.org and LMSProject.org) where patients register and consent to participation. Projects were launched in September, 2022. After 5 months of accrual, 306 patients age 6-79 from 149 Institutions have consented. Blood and saliva are collected from consented participants, tumor samples are obtained from pathology departments and medical records are requested from treating hospitals. WES and WGS of tumor and normal, and RNASeq of tumor is performed. ctDNA is obtained and sequenced. Results are shared with patient, advocacy, physician and research communities in several ways. Individual participants receive a shared learning report describing the somatic variants identified in their tumor from paired tumor-normal WES and are offered genetic counseling and clinical germline testing. Registered participants receive updates via email and Project websites. There are regular pre-publication data releases to the genomic data commons and to cBioPortal. A physician engagement committee meets regularly to discuss clinical insights and conundrums from shared learning reports and germline testing. Patient accrual over the next 3 years is anticipated to result in sequencing of 750 tumor-normal pairs and 500 ctDNA samples. Research Sponsor: U.S. National Institutes of Health.

SARC041: A phase 3 randomized double-blind study of abemaciclib versus placebo in patients with advanced dedifferentiated liposarcoma. *First Author: Mark Andrew Dickson, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Recurrent or metastatic dedifferentiated liposarcoma (DDLs) remains a difficult disease to treat. Available agents such as doxorubicin, eribulin, trabectedin, ifosfamide, dacarbazine, or gemcitabine-based regimens are associated with low response rates and only modest improvements in progression free or overall survival. The oncogene CDK4 is ubiquitously amplified in this disease and represents a rational therapeutic target. In single-arm phase 2 studies, treatment with selective CDK4 inhibitors resulted in clinical benefit (12-week progression-free survival (PFS) of 57% with palbociclib and 74% with abemaciclib). We hypothesize that treatment with abemaciclib will improve PFS compared to placebo in patients with recurrent or metastatic DDLs. **Methods:** This is a phase 3 randomized double-blind study of abemaciclib versus placebo. Eligible patients have recurrent or metastatic dedifferentiated liposarcoma (purely well-differentiated liposarcoma excluded), progression of disease by RECIST 1.1 in the 6 months prior to study entry, any number of prior systemic therapies, and adequate organ function and performance status. Patients are stratified by number of prior lines of therapy (0 vs 1 or more) and randomized 1:1 between abemaciclib 200 mg PO twice a day and matching placebo. Patients are followed with scans every 6 weeks (every 12w after 36w) and those with progression of disease on placebo may cross over to open label abemaciclib. The primary endpoint is PFS. Target enrollment is 108 evaluable patients which provides 80% power with two-sided 10% significance level to detect a hazard ratio of 0.6. Secondary endpoints include response rate, PFS and response rate after crossover, and overall survival. Archival tissue will be collected to explore potential biomarkers. As of Feb 1, 2023, 43 patients have been accrued at 9 participating centers. Clinical trial information: NCT04967521. Research Sponsor: Eli-Lilly.

Phase 1 dose-expansion study of oral TP-1287, a cyclin-dependent kinase 9 (CDK9) inhibitor, in patients with Ewing sarcoma (EWS). *First Author: Gregory Michael Cote, MGH Cancer Center, Boston, MA*

Background: Cyclin-dependent kinase 9 (CDK9) blockade inhibits tumor growth and progression by impairing the transcription of key oncogenes, such as myeloid cell leukemia-1 (MCL-1) and c-MYC. CDK9 overexpression has been observed in sarcoma patients (pts), and CDK9 has emerged as a potential therapeutic target in pts with sarcoma. TP-1287 is an investigational orally delivered phosphate prodrug of the CDK9 inhibitor alvocidib. In preclinical studies, TP-1287 has been shown to decrease MCL-1 expression and phosphorylation of RNA polymerase II (RPB1), and inhibit tumor growth in an Ewing sarcoma (EWS) mouse model. Phase 1 dose-escalation in solid tumors has completed and TP-1287 is being investigated in a dose expansion cohort in pts with EWS (NCT03604783). The design of the expansion part of the trial in pts with EWS is herein described. **Methods:** Up to thirty pts with EWS will be enrolled in this dose expansion cohort. Key eligibility criteria are age ≥ 18 years (≥ 12 years, if weight ≥ 40 kg); histologically confirmed locally advanced or metastatic unresectable EWS; received 1 to 5 prior lines of treatment including an anthracycline; one or more measurable tumors per the RECIST v1.1; ECOG performance status of ≤ 1 ; acceptable liver and renal function, and acceptable hematologic and coagulation status; no treatment with surgery, chemotherapy, or investigational therapy within 28 days or 5 half-lives. Eligible pts will be treated with oral TP-1287 monotherapy RP2D established from the dose escalation part (11 mg BID, continuous dosing in a 28-day treatment cycle) and will continue treatment until treatment-related adverse event or disease progression. Assessments will be performed on Day 1 and Day 15 of each cycle. Tumor response assessment will be done after Cycle 2 and at the end of every other cycle thereafter. The primary objectives are objective response rate (ORR) and clinical benefit rate (CBR); secondary objectives are median progression-free survival (PFS), PFS rate at 16-weeks and 24-weeks and safety; and exploratory objectives include evaluation of systemic exposure and pharmacodynamics. Safety data will be reviewed on an ongoing basis and a Bayesian approach will be used to assess the efficacy data. Statistical analysis for safety and efficacy parameters will be primarily descriptive in nature. EWS dose expansion cohort is currently recruiting in the United States. Clinical trial information: NCT03604783. Research Sponsor: Sumitomo Pharma Oncology.

Poster Session

A phase II study of palbociclib combined with retifanlimab in patients with advanced dedifferentiated liposarcoma. *First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Dedifferentiated liposarcoma (DDLPS) is characterized by near universal amplification of the cyclin-dependent kinase 4 (*CDK4*) gene. Palbociclib (P) is a selective CDK4/6 inhibitor that has demonstrated promise in phase II studies of DDLPS. Anti-PD-1 therapy has also shown signals of efficacy, with an approximate overall response rate of 10% in DDLPS patients. CDK4/6 inhibitors upregulate antigen processing and presentation, suppress regulatory T cells, and increase inflammation within the tumor microenvironment. Combined with anti-PD-1 blockade, they can induce an inflamed T cell phenotype and tumor regression in pre-clinical models. We hypothesize that P combined with the anti-PD-1 inhibitor retifanlimab (R) will be safe and tolerable and have synergistic activity leading to activation of T cells and resultant clinical responses. **Methods:** NCT04438824 is a phase II study of P plus R with a safety lead-in phase. Patients with unresectable or metastatic DDLPS who have received any number of prior therapies are eligible to enroll. On the safety lead-in phase, 6 patients received P (125 mg once daily orally for 21 days followed by 7 days off) plus R (500 mg IV flat dose), repeated in 28-day cycles. P was initiated as monotherapy two weeks prior to initiation of R. The primary endpoint of the safety lead-in was to confirm the recommended phase two dose of the combination. Accrual to the safety lead-in has been completed and a pre-planned phase II expansion portion was opened to accrual. A study amendment was passed that revised the treatment schedule on the expansion cohort to start both P and R concomitantly on day 1 of each cycle. This revised schedule was based on recent data demonstrating the superior safety of a concurrent, rather than staggered, dosing schedule. The primary endpoint of the expansion phase is to estimate the best overall response rate (ORR) by RECIST 1.1. Secondary endpoints include describing the safety and estimating clinical benefit rate, duration of response, progression-free, and overall survival. A total of 30 patients treated with the revised dosing scheme will be enrolled onto the expansion phase. Twelve patients have been enrolled to date. An ORR of 5% will be considered not promising, while an ORR of 25% will be considered promising. The null hypothesis will be rejected if 4 or more patients have a confirmed objective response to treatment. This design has a type I error rate of 0.06 and a type II error rate of 0.04. Mandatory pre- and on-treatment biopsies will be performed for correlative analyses. Clinical trial information: NCT04438824. Research Sponsor: Incyte; U.S. National Institutes of Health.

Oral Abstract Session

A multicenter randomized controlled trial (RCT) for the effectiveness of comprehensive geriatric assessment (CGA) with extensive patient coaching on quality of life (QoL) in older patients with solid tumors receiving systemic therapy: G-oncoCOACH study. *First Author: Cindy Kenis, Department of General Medical Oncology and Geriatric Medicine, University Hospitals Leuven & Department of Public Health and Primary Care, Academic Centre for Nursing and Midwifery, KU Leuven - University of Leuven, Leuven, Belgium*

Background: CGA is internationally recommended in the care for older patients with cancer (e.g. ASCO). Only a few recent RCTs have examined the impact on patient's QoL. Aim of this study is to evaluate the effectiveness of CGA coordinated by a geriatric team combined with intensive patient coaching (= intervention group (IG)) versus standard of care, which is CGA coordinated by an oncology team (= control group (CG)) on QoL in older patients with solid tumors receiving systemic therapy. **Methods:** The G-oncoCOACH study was a multicenter RCT in two academic Belgian hospitals (NCT04069962). Eligibility criteria were 70+ years, solid tumor, systemic therapy with curative or non-curative intent (first/second-line), and physician-estimated life expectancy > 6 months. IG patients received CGA coordinated by the geriatric team in close collaboration with the oncology team, increasing multidisciplinary care and in combination with intensive patient coaching to increase patient compliance. This supports patient empowerment by improving self-efficacy and supporting self-management of age-related problems. It included an individual counselling session at start of systemic therapy to discuss CGA results and recommendations with the patient and to determine their priorities, followed by individual counselling organized at 2, 4, 5, 8 and 10 months. Primary endpoint was global health status (GHS) of the European Organisation for Research and Therapy of Cancer (EORTC) QoL questionnaire measured at 6 months after start of systemic therapy. Sample size calculation required > 195 included patients for primary endpoint (≥10 points QoL change at 6 months) for 80% power at 2-sided 5% significance level. After exclusion of multicollinearity, the change in QoL GHS between baseline and 6 months follow-up was analyzed with a mixed model. **Results:** From 10/2019 to 9/2021, 212 participants were enrolled (CG (n = 107); IG (n = 105)). Mean age was 76.8 years; 52.4% were female (n = 111). The 3 most common tumor types were digestive (n = 65; 30.7%), thorax (n = 44; 20.8%), and urogenital (n = 33; 15.6%). Cancer therapy was started mostly with non-curative intent. After 6 months, the difference between CG and IG in change of adjusted QoL GHS versus baseline amounted 12.8 points in favor of the IG (95%CI 6.7-18.8; p < 0.0001). This difference consisted of an improvement of 4.5 point versus baseline in the IG and decline of 8.2 points in the CG. Secondary endpoints (e.g. QoL at 3 and 12 months, patient satisfaction, severe systemic therapy-related adverse events, survival) will be presented at the meeting. **Conclusions:** CGA coordinated by a geriatric team combined with extensive patient coaching improves QoL GHS in older patients with cancer compared to CGA coordinated by an oncology team. Clinical trial information: NCT04069962. Research Sponsor: Stand Up Against Cancer.

Oral Abstract Session

Results of a tailored multimodal lifestyle follow-up care program focusing on physical activity, nutritional behavior and psychological processes in adolescent and young adult cancer survivors: The CARE for CAYA multicenter, randomized clinical trial. *First Author: Simon Elmers, Hubertus Wald Tumor Center - University Cancer Center Hamburg, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: The aim of the CARE for CAYA-program (CFC-P) was to implement a multimodal lifestyle program in addition to medical follow-up care for child, adolescents and young adult cancer survivors (CAYAs). **Methods:** The CFC-P was a multicenter program with an initial randomized clinical trial (RCT) comparing need-based modular interventions to usual care for CAYAs aged between 15 and 39. A comprehensive assessment (questionnaires and medical examination) was conducted to determine individual needs regarding nutrition, physical activity and psychoneurology. If "high need" was identified, CAYAs could take part in up to three modules over 12 months. In the intervention group (IG), each module included five consultations plus newsletters. The control group (CG) included one baseline counselling in each module. The primary outcome was defined as the rate of CAYAs with "high need(s)" after 12 months of intervention. Secondary outcomes included feasibility, cost-effectiveness, modular-specific endpoints, quality of life (QoL) and fatigue. **Results:** 791 CAYAs were included at 14 German CAYA survivorship clinics from December 2017 to March 2021. Most common tumor types were lymphoma 26.8% (n = 211), sarcoma 13.2% (n = 104) and leukemia 10.0% (n = 79). 58.0% (n = 457) were female, median age was 23.9 years, time since end of tumor specific therapy was < 5 years in 54.4%, > 5 years in 21.2%, > 10 years in 11.5% and > 15 years in 12.9% of patients (median: 57.0 months). 86.2% (n = 679) reported an initial "high need" in at least one module. After 52 weeks, 83.9% (n = 396) of 472 evaluable participants continued to report or developed a "high need": 59.3% (n = 235) in IG and non-randomized cohort, 28.8% (n = 114) in CG and 12.7% (n = 47) with no initial "high need". 357 participants were evaluable in the RCT (63% (n = 226) female, median age 25.0 years). 26.2% (n = 94) reported a "high need" in one, 35.7% (n = 128) in two and 37.6% (n = 135) in three modules. 271 patients could be analyzed at 52 weeks, 87.0% of IG (n = 120 of 138) and 86.5% of CG (n = 115 of 133) continued to have at least one "high need". The primary outcome did not differ significantly between groups (p = .905). However, both showed an increase of QoL and a reduction of fatigue. **Conclusions:** In the CFC-P, the feasibility of a large trial to regularly assess lifestyle habits and the psychosocial situation and determine the efficacy of a need based multimodal interventions in CAYAs was demonstrated. Although a high need for support was revealed in this population, no significant changes with the applied interventions were noted after 12 months. The obtained data will guide the development and implementation of multimodal interventions in long term follow up of CAYAs. Clinical trial information: DRKS00012504. Oral Abstract Session

Effect of a telephone-based weight loss intervention (WLI) on weight at 12-months in women with early breast cancer: Results from the Breast Cancer Weight Loss (BWEL) trial. *First Author: Jennifer A. Ligibel, Dana-Farber Cancer Institute, Boston, MA*

Background: Obesity is a poor prognostic factor in early breast cancer. The Breast Cancer Weight Loss (BWEL) trial (Alliance for Clinical Trials in Oncology A011401; NCT02750826) evaluates the impact of a WLI on invasive disease-free survival in breast cancer patients (pts) with a body mass index (BMI) ≥27 kg/m². Here we report the impact of the WLI on weight change. **Methods:** Eligible pts were within 14 months of diagnosis of stage 2-3 HER2-negative breast cancer, had completed chemotherapy and radiation (if administered), and were randomized 1:1 to a telephone-based WLI plus health education (HE) or an HE alone control group. The WLI was delivered by telephone-based health coaching and focused on caloric restriction and increased exercise. Height and weight were measured at baseline and 12 months. Changes in weight were compared between groups. Analysis was performed with univariable and multivariable (including arm, baseline weight, menopausal status, race/ethnicity, and hormone receptor [HR] status) regression models. A 0.05 level of significance was used. **Results:** 3181 women were randomized between 8/2016 and 2/2021. At baseline, mean BMI was 34.5 (±5.74) kg/m², mean age was 53.4 (±10.58) years, and 57% of pts were postmenopausal at the time of diagnosis. 80.3% of participants were White, 12.8% were Black, and 7.3% were Hispanic. Follow-up weight was available from 2293 pts alive and disease-free at 12 months. The WLI led to a significant decrease in weight relative to controls; pts randomized to WLI lost an average of 4.8% (±7.9) of baseline body weight at 12 months vs. 0.8% (±6.4) weight gain in controls (p<0.0001). Pts randomized to WLI experienced significant weight loss (vs controls) across demographic and tumor factors (Table). WLI effect differed significantly by menopausal status (interaction p value = 0.0057) and race/ethnicity (interaction p-value = 0.019), but not HR status (interaction p-value = 0.17). **Conclusions:** A telephone-based WLI induced significant, clinically meaningful weight loss in breast cancer pts with overweight and obesity across demographic and tumor factors. Additional tailoring of the WLI could be useful to enhance weight loss in Black and younger pts. Further follow-up of the BWEL trial will evaluate whether the WLI improves disease outcomes. Oral Abstract Session

Chemotherapy induced peripheral neuropathy (CIPN) due to paclitaxel versus docetaxel in patients with early-stage breast cancer receiving taxane therapy: SWOG S1714. *First Author: Meghna S. Trivedi, Columbia University, New York, NY*

Background: Paclitaxel (Pac) and docetaxel (Doc) are used to treat early-stage breast cancer (BC). CIPN due to taxane therapy can cause sensory and motor deficits. CIPN symptoms caused by Pac versus Doc are not well described. **Methods:** SWOG S1714 enrolled patients ≥ 18 years with Stage I-III primary NSCLC, BC, or ovarian cancer starting treatment with a taxane-based regimen. CIPN was assessed by the patient-reported EORTC QLQ-CIPN20 (CIPN-20) and clinician-assessed NCI-CTCAE. Assessments occurred at baseline and 4, 8, 12, and 24 weeks after registration. Increase in CIPN-20 sensory subscale score ≥ 8 points was considered clinically meaningful. Chi-square and Fisher tests were used for baseline comparisons; logistic regression was used for multivariable analyses. **Results:** Among 1336 enrolled patients, 1106 of eligible patients had a diagnosis of BC, with median age 54.8 y (range 23.9-84.2 y), 99.3% female, and 72.3% White/11.3% Black/4.6% Asian/11.1% Hispanic/Latino. Pac was administered to 615 (55.6%) and Doc to 491 (44.3%) patients. Between the Pac and Doc cohorts, there were significant baseline differences in median age, diabetes, and performance status. At 24 weeks, the proportion of patients with ≥8 point increase in CIPN-20 sensory score was lower for Doc (40.5%) vs Pac (50.2%) (odds ratio [OR] 0.64, 95% CI 0.50, 0.82; multivariable adjusted p<.001). At nearly every timepoint through 24 weeks, patients treated with Pac had more sensory and motor neuropathy as measured by both the CIPN-20 and NCI-CTCAE (Table). **Conclusions:** In this diverse cohort of patients with BC, the frequency of CIPN was higher than expected for both Pac and Doc and more severe in patients receiving Pac. These findings based on CIPN-20 can assist in treatment decision-making about taxane therapy. Long term follow up will better characterize the differences in the trajectory of CIPN between Pac and Doc. Funding: NIH/NCI/NCORP grant UG1CA189974. Clinical trial information: NCT03939481. Research Sponsor: U.S. National Institutes of Health.

Oral Abstract Session

Phase 3 randomized placebo-controlled trial of donepezil for late cancer-related cognitive impairment in breast cancer survivors exposed to chemotherapy from the Wake Forest NCORP Research Base REMEMBER trial (WF97116). *First Author: Steve R. Rapp, Wake Forest University School of Medicine, Winston-Salem, NC*

Background: Cancer-related cognitive impairment (CRCI) is common among breast cancer survivors (BCS). Prior studies of late CRCI suggest repurposing cognitive enhancing medication may benefit survivors. The REMEMBER prospective, randomized, double-blind, placebo-controlled trial compared the efficacy of donepezil, an acetylcholine esterase inhibitor, versus placebo to reduce late CRCI among BCS previously exposed to chemotherapy. (Clinical Trials #NCT02822573). **Methods:** Women ≥ 18 years of age, with a history of breast cancer who completed ≥ 4 cycles of chemotherapy 1 to 5 years prior to enrollment, self-reported CRCI, with evidence of a memory deficit on the Hopkins Verbal Learning Test-Revised (HVLT-R) were eligible. Women were randomized to a 24-week course of donepezil (5mg/daily x 6 wk. titrated to 10mg/daily x 18 wk.) or placebo. A cognitive battery assessing memory, attention, executive function, verbal fluency, and processing speed was administered at baseline, week 12, 24 (end of intervention), and 36 (wash-out) along with patient-reported outcome measures and adverse events. There was 90% power to detect a treatment difference of 2 words for HVLT-IR (effect size=0.47) Mixed effects repeated measures analysis of covariance (RMANCOVA) models were utilized to assess treatment differences in memory (primary outcome) and other cognitive domains (secondary outcomes) with model covariates of treatment, time, time by treatment interaction, baseline outcome level, age stratification and an unstructured covariance matrix to account for within participant correlation over time. **Results:** A total of 276 patients from 87 NCORP sites (mean age=57.1yr, SD=10.5) an average of 29.6 months post-chemotherapy completion were randomized to donepezil (n=140) or placebo (n=136). The primary outcome of memory (HVLT-R total) at 24 weeks was not different between treatments (donepezil mean=25.98, placebo = 26.50, p=0.32). There were no statistically significant differences between treatments at 12, 24, or 36 weeks on attention, executive function, verbal fluency, or processing speed. Exploratory analyses additionally adjusting for education, baseline fatigue and depression as well as independent analyses considering treatment interaction with endocrine therapy and menopausal status also did not result in any differences by group for any outcomes. Twenty-five grade 3 or 4 adverse events were reported with no differences by treatment. **Conclusions:** BCS 1-5 years after completing chemotherapy, randomized to 24 weeks of a daily dose of 5-10mg of donepezil, did not perform differently at the end of treatment on tests of memory or other cognitive functions than survivors randomized to placebo. Funding: NIH/NCI 2UG1CA189824. Clinical trial information: NCT02822573. Research Sponsor: U.S. National Institutes of Health.

Oral Abstract Session

Reduced symptom burden after implementation of an electronic symptom management program. *First Author: Jessica J Bian, MaineHealth Cancer Care, South Portland, ME*

Background: The SIMPRO consortium implemented an electronic patient reported outcomes (ePRO) symptom management program as part of routine clinical care for patients (pts) receiving systemic cancer therapy or surgery across six health systems including rural and community cancer centers. To evaluate impact of the Epic-integrated electronic symptom management (eSyM) program on quality of life, pre- and post-implementation surveys were sent to a subset of gastrointestinal, thoracic, and gynecologic medical oncology (MO) and surgical (Surg) patients at all sites. **Methods:** A survey assessing symptom burden, health literacy, and self-efficacy was administered to separate groups of MO and Surg pts before (Pre-Implementation) and after (Post-Implementation) eSyM deployment. A waiver of documentation of consent was obtained for participation. Questions were derived from validated instruments including PROMIS, a standardized measurement tool for patient-reported symptoms. Surveys were completed 30-90 days after surgery or start of systemic therapy. PROMIS item responses were scored individually then translated into standardized T-scores with a mean of 50 based on an established reference population. Mean T-scores for PROMIS depression, anxiety, fatigue, and pain interference were calculated. Higher T-score correlated with greater symptom burden. Comparison between groups utilized non-parametric Kruskal-Wallis testing. **Results:** The number of survey responses were 498 MO Pre-Implementation, 518 MO Post-Implementation, 566 Surg Pre-Implementation, and 507 Surg Post-Implementation. MO pts reported significantly lower PROMIS mean T-scores for depression, anxiety, fatigue, and pain interference after eSyM compared to a similar group of MO pts prior to eSyM. Surg pts reported lower T-scores for depression, anxiety, fatigue, and pain interference after eSyM compared to a similar group of Surg pts prior to eSyM, although reduction in pain interference was not statistically significant. **Conclusions:** eSyM deployment in MO was associated with a significant reduction in patient reported depression, anxiety, fatigue, and pain interference. Surgical pts after eSyM deployment reported significantly lower rates of depression, anxiety, and fatigue. External validation with PROMIS based surveys demonstrated small but meaningful benefits of ePRO symptom monitoring as part of routine clinical care across six diverse health systems. Clinical trial information: NCT03850912. Research Sponsor: U.S. National Institutes of Health.

Oral Abstract Session

Randomized double-blind, placebo-controlled study of topical diclofenac in prevention of hand-foot syndrome in patients receiving capecitabine. *First Author: AKHIL Santhosh, All India Institute of Medical Sciences, Delhi, New Delhi, India*

Background: Capecitabine induced HFS is associated with deterioration of quality of life of patients and dose of capecitabine is often reduced to manage this adverse event. Celecoxib is the only effective intervention in preventing HFS; however, its widespread use is limited due to its own safety concerns. We conducted this study to assess the efficacy of topical diclofenac in preventing capecitabine induced HFS. **Methods:** Patients with breast and gastrointestinal (GI) cancers, planned for capecitabine (monotherapy or combination) treatment were randomized in 1:1 to receive topical diclofenac or placebo gel for 4 cycles or until development of HFS, whichever was earlier. Stratified (male or female; capecitabine monotherapy or combination therapy) permuted variable size block randomization was done using a computer-generated random numbers sequence. Primary objective was to compare the incidence of grade 2 or higher HFS in diclofenac and placebo arms. Secondary objectives were incidence of any grade HFS, capecitabine dose changes due to HFS and self-reported adherence with application. **Results:** A total of 263 patients were randomized to apply topical diclofenac gel (n=130) or placebo (n=133). Baseline characteristics were similar in both the arms (Table). The incidence of grade 2 or higher HFS was 3.8% (95% CI, 1.6%-8.9%) in the diclofenac arm compared with 15.0% (95% CI, 9.9%-22.2%) in the placebo arm (P=0.003). Any grade HFS was significantly lower in the study arm compared with the placebo arm (6.1% vs 18.1%; P=0.003). A lower incidence of HFS was observed in the diclofenac arm across the subgroups (breast and GI cancers; males and females). Capecitabine dose reductions were less frequent in the diclofenac arm (3.8%) compared with the placebo arm (15%) (P=0.002). Adherence to topical treatment was similar in the diclofenac arm (96.7 +/- 19.1%) compared with the placebo arm (94.0 +/- 28.3%) (P=0.36). Other capecitabine associated adverse events, including diarrhea, mucositis, and myelosuppression were not significantly different in both the arms. **Conclusions:** Topical diclofenac is effective in preventing all grades of HFS in patients receiving capecitabine. Diclofenac application was also associated with lesser dose reductions of capecitabine. This trial establishes topical diclofenac as the new standard of care to prevent capecitabine associated HFS. Clinical trial information: CTRI/2021/01/030592. Research Sponsor: Indian Association for Supportive Care in Cancer (IASCC); Alkem Laboratories provided diclofenac gel and placebo.

Oral Abstract Session

Telehealth-based psychological intervention for caregivers of patients with primary malignant brain tumors: A randomized controlled trial. *First Author: Deborah Anne Forst, Massachusetts General Hospital, Boston, MA*

Background: Caregivers of patients with primary malignant brain tumors (PMBT) face unique challenges caring for someone with a progressive neurological illness. In preliminary studies, we found that 50% or more of caregivers had clinically significant anxiety symptoms in the months following the patient's PMBT diagnosis. However, few interventions have been developed to specifically target anxiety symptoms in this population. **Methods:** We conducted a randomized controlled trial evaluating the efficacy of NeuroCARE, a population-specific intervention addressing anxiety in caregivers of patients receiving treatment at two academic centers. Eligible caregivers were within six months of the patient's PMBT diagnosis and had clinically significant anxiety symptoms (score ≥ 5 on the Generalized Anxiety Disorder-7 tool). Participants were randomized 1:1 to NeuroCARE or usual care. NeuroCARE consisted of six one-on-one telehealth sessions with a mental health clinician or trainee and incorporated evidence-based skills for 1) coping with worry, 2) using assertive communication techniques, 3) optimizing social support, and 4) promoting relaxation and healthy sleep. Participants completed questionnaires at baseline, 11 weeks (immediately post-intervention) and 16 weeks (1 month post-intervention). Our primary endpoint was anxiety symptoms at 11 weeks (Hospital Anxiety and Depression Scale (HADS) – Anxiety Subscale score). We also assessed depression symptoms (HADS – Depression Subscale), quality of life (QOL; Caregiver QOL survey), caregiver burden (Caregiver Reaction Assessment), self-efficacy (Lewis Cancer Self-Efficacy scale), coping (Measure of Current Status) and post-traumatic stress disorder (PTSD) symptoms (PTSD Checklist for DSM-5). We used analysis of covariance to evaluate the effect of NeuroCARE versus usual care on these outcomes. **Results:** We enrolled 120 caregivers (60 per arm, mean age = 53 years, 83% female), the majority of whom were caring for their spouse/long-term partner (70%), child (17%), or parent (7%). At 11 weeks, NeuroCARE participants reported significantly lower anxiety symptoms than those assigned to usual care (means: 8.87 vs 10.69, $p = 0.008$). NeuroCARE caregivers also reported significantly lower depression symptoms (6.08 vs 7.77, $p = 0.004$) and better self-efficacy (128.81 vs 111.17, $p < 0.001$) and coping (32.25 vs 25.65, $p < 0.001$) at 11 weeks. Study groups did not differ with respect to caregiver burden, PTSD symptoms, or QOL at 11 weeks. **Conclusions:** A population-specific telehealth-based psychological intervention (NeuroCARE) led to significantly lower anxiety and depression symptoms and better self-efficacy and coping among caregivers of patients with PMBT compared with usual supportive care. Clinical trial information: NCT04109209. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Clinical Science Symposium

Frailty status determined by an electronic health record embedded frailty index and hospitalization risk among older adults following the initiation of cancer chemotherapy. *First Author: Heidi D. Klepin, Wake Forest University School of Medicine, Winston-Salem, NC*

Background: Novel strategies are needed to efficiently identify older adults at high risk for hospitalization before and after chemotherapy initiation. An electronic frailty index (eFI) holds promise as a passive digital marker for frailty available to estimate risk at the point of care. The objective of this study was to evaluate the association of pre-treatment eFI with risk of hospitalization after receipt of cancer chemotherapy among older adults. **Methods:** Consecutive patients ($N = 509$ aged 65+ with newly diagnosed lung, colorectal or breast cancer treated with chemotherapy) were identified from our cancer registry between 2017 and 2020. Calculation of the eFI is automated in the EMR. It requires at least two ambulatory visits over a 2-year period and utilizes demographic information, vital signs, smoking status, ICD-10 diagnosis codes, select outpatient laboratory measurements, and functional information (if available from Medicare Annual Wellness Visits) during the 2 years prior to diagnosis. Frailty status is categorized as fit ($eFI \leq 0.10$), pre-frail ($0.10 < eFI \leq 0.21$), and frail ($eFI > 0.21$) based on the proportion of deficits present over the total number evaluated (score range 0-1). Non-calculable scores indicate insufficient historical primary care data within two year prior to cancer diagnosis. Outcomes were hospitalization at 3 and 6 months post chemotherapy initiation. Time to first hospitalization was estimated by eFI category, using Cox regression models to estimate the adjusted association between frailty status and hospitalization. **Results:** The cohort included 509 adults (median age 72.2 yrs, 55% female, 83% white, 13% black, 45.8% stage 4) with lung ($N = 312$), colorectal ($N = 111$), and breast ($N = 86$) cancers. Distribution of eFI categories at diagnosis were fit (26.3%), pre-frail (42.4%), frail (16.3%) and not calculable (14.9%). Hospitalization rates at 3 and 6 months post chemotherapy were 12.0% (fit), 29.9% (pre-frail), 46.3% (frail), 45.9% (not-calculable) and 24.4% (fit), 41.3% (pre-frail), 59.8% (frail) and 49.8% (non-calculable), respectively ($p < 0.0001$). Adjusting for age, gender, race, stage, and cancer type, the incidence of hospitalization was higher for frail (Hazard Ratio (HR) 2.96, 95% Confidence Interval (CI) 2.05, 4.27), pre-frail (HR 1.41, 95% CI 1.03, 1.94), and not calculable eFI categories (HR 2.01, 95% CI 1.33, 3.03) compared to fit patients. **Conclusions:** Over forty percent of frail older adults with lung, colorectal, or breast cancer identified by eFI were hospitalized within the first 3 months of chemotherapy initiation. The eFI can inform real-time shared treatment decision-making and identify a sub-set of patients who may benefit from care delivery interventions to decrease unplanned hospitalization and improve quality of care. Clinical Science Symposium

Electronic frailty index predicts 30-day mortality from chemotherapy in breast, colorectal and lung cancer. *First Author: Agnieszka Michael, University of Surrey, Guildford, United Kingdom*

Background: Older and frail patients with cancer (Ca) often receive less aggressive treatment and as a result have worse survival. Current methods of assessing fitness (performance status) for intensive treatment such as chemotherapy are inadequate. The complexity of geriatric assessments, lack of training and time pressures in busy clinics, mean that better solutions are needed. A UK initiative - the electronic frailty index (eFI) - is derived from a cumulative deficit frailty model and provides a measure of frailty alongside pre-existing conditions such as issues with mobility, fractures, falls, memory, sight, hearing, anaemia, tremor, diabetes, heart, thyroid, skin, respiratory, cerebrovascular, circulation, social vulnerability, and polypharmacy (36 fields) (Clegg et al). Patients are classified into the following groups: no frailty, mild, moderate or severe frailty. We used the same methodology to investigate whether eFI predicts adverse outcomes of chemotherapy in frail patients with Ca. **Methods:** The study conducted retrospective data analysis of Ca patients treated with chemotherapy from Public Health England (PHE) Systemic Chemotherapy Dataset (SACT) years 2015-2018. Eligible patients had stage II - III breast Ca, stage III colon Ca or stage IIB-IV non-small-cell lung Ca (NSCLC). The data from SACT was linked with hospital episodes' statistics (obtained from NHS-Digital) to calculate 30-day SACT mortality, overall survival and hospital admissions. eFI was calculated from the above 35 fields; polypharmacy was not available from NHS-Digital data. **Results:** The eFI was calculated for 78799 patients: colorectal 17951, lung 22052, and breast 38796. 20388 patients were ≥ 70 y.o. and 58411 were < 70 y.o. Most patients were fit with an eFI score of 0-69% (54563), 19% (15,295) had mild frailty, 7.7% (6104)-moderate, and 3.6% (2837) had severe frailty. 4.2% (3356) of patients died within 30 days of SACT. For colorectal Ca patients the risk of dying within 30 days of SACT in patients ≥ 70 y.o. was twice that of the < 70 y.o. (OR 2.04 -CI 1.58 - 2.64); patients with mild eFI did not differ - OR: 1.07 (CI 0.78-1.45), moderate frailty: 1.6 (CI 1.1-2.33) and severe frailty: 2.13 (CI 1.34-3.39). In breast Ca patients, 30-day mortality for ≥ 70 y.o. was 6.38 times higher than for < 70 y.o. (95% CI 4.29-9.49); eFI for mild frailty - OR of 1.45 (95% CI 0.78-2.71), moderate frailty-OR of 3.5 (95%CI 1.82-6.75) and severe frailty 5.73 (95% CI 2.66-12.3). The 30-day mortality in lung cancer in ≥ 70 y.o. and < 70 y.o. did not differ with OR 0.95 (95% CI 0.88-1.03) for ≥ 70 y.o. Patients with mild frailty had OR for 30-day mortality of 1.17 (95% CI 1.07-1.28), moderate frailty-OR of 1.28 (95%CI 1.15-1.44) and severe frailty 1.48 (95% CI 1.28-1.77). **Conclusions:** The eFI closely predicts poor outcomes from SACT, particularly in early breast and colon cancer, and requires further evaluation in a prospective study. Research Sponsor: Research for Patient Benefit, National Institute of Health Research.

Web-based patient-reported outcome measures (PROMs) in elderly cancer patients: A French multicentric prospective feasibility trial (the FASTOCH study). *First Author: Mathilde Cancel, Department of Medical Oncology, CHU Bretonneau Centre, Tours University, Tours, France*

Background: Web-based PROMs in cancer care improve overall survival and quality of life. There is, nonetheless, no data available on this type of follow-up in the elderly population. **Methods:** From February 2021 to April 2022, 75 or more years-old patients ongoing any active anti-cancer treatment (such as chemotherapy, targeted therapy, hormonotherapy, immune therapy) were included, in six French cancer centers. Feasibility of the web-based PROMs was assessed as the part of the population included that could use the Ana-Health's web-based application "ANA" to monitor their symptoms, the others being considered as in "primary failure" due to technological barriers or refusal to participate. Among the patients that agreed to participate, we then defined as "active" those who filled at least one form during the three months follow up. We also searched for factors restraining elderly patients to use "ANA" and evaluated their satisfaction. **Results:** Overall, 473 patients were included in the study. There were 288 patients in "primary failure" (233 without Internet access, 17 not comfortable enough to use web-based PROMs, 38 refusals to participate). Among the 185 patients "willing to participate", there were 122 "active" patients and 63 "inactive" ones, leading to a 26% feasibility in intention-to-test and a 66% feasibility in per protocol analysis. Patients "willing to participate" were from higher socio-professional category ($p = 0.002$) and had a significantly higher G8 score (13.5 versus 12, $p < 0.001$), particularly when considering the autonomy ($p = 0.028$), cognitive assessment ($p = 0.003$) and general condition ($p < 0.001$) items. In the multivariate analysis, the socio-professional category and the general condition were still significantly different ($p = 0.009$ and 0.002 respectively). The only factor that remained significantly different between the "active" and "inactive" populations was the better general condition in the "active" group ($p < 0.001$). The "inactive" patients prematurely ended their participation because they lost interest in the web-based follow up significantly more than the "active" group (28 "inactive" patients, i.e. 44%, vs 5 "active" patients, i.e. 4%, $p < 0.001$). Similarly, the "active" patients were significantly more satisfied with "ANA" than the "inactive" (71% vs 29%, $p < 0.001$). **Conclusions:** Our study shows that, in the elderly population treated for a cancer, a web-based application to measure PROs is feasible, however socio-professional category, general condition and above all technological barriers are of some concern. Cost-utility of geriatric assessment in older adults with cancer: Results from the 5C trial. *First Author: Yeva Sahakyan, University Health Network, Toronto, ON, Canada*

Background: Geriatric assessment is a guideline-recommended approach to optimize cancer management in older adults. We conducted a cost-utility analysis alongside the recently published 5C randomized controlled trial to compare geriatric assessment and management (GAM) with usual care in older adults with cancer. **Methods:** The economic evaluation was conducted from a societal perspective, using a 12-month time horizon. The 5C study enrolled patients age 65+ from 8 Canadian hospitals and randomly assigned them to receive GAM or usual care. Patients were initiating systemic therapy with curative or palliative intent. Quality-adjusted life years (QALYs) were measured using the EQ-5D-5L questionnaire. Healthcare utilization was evaluated using cost diaries and chart reviews. The primary outcome, an incremental monetary benefit (INMB), was evaluated for the full sample and for prespecified subgroups. Multiple imputation was used to account for missing data. The 95% confidence intervals (CI) were computed using bootstrapping. **Results:** The study included 350 patients, of which 173 received GAM and 177 received usual care. At 12 months, the average QALYs per patient were 0.747 and 0.753 for GAM and usual care respectively (Δ QALY = -0.006, 95%CI: -0.06 to 0.05). The total average costs per patient were \$48,397 and \$45,342 for GAM and usual care (Δ Cost = \$3,078 (95% CI: -\$5,336 to \$12,050). At a cost-effectiveness threshold of \$50,000/QALY the INMB was negative (-\$3,962; 95% CI: -\$7,117 to -\$794) meaning that GAM was not cost-effective compared to usual care. In a subgroup analysis the INMB was positive (\$4,639, 95% CI: \$61 to \$8,607) for patients treated with curative intent, and the intervention was cost effective in 78% of simulations, but remained negative (i.e. not cost-effective) for patients treated with palliative intent (INMB -\$13,307, 95% CI -\$18,063 to -\$8,264). **Conclusions:** This is the first cost-utility analysis of GAM in cancer. The findings showed that GAM was cost-effective for cancer patients treated with curative intent but not for patients with palliative intent. Although the primary results of the 5C trial were negative, extrapolating our costing data to positive GAM trials like GAIN, GAP70, and INTEGRATE will provide a more complete picture of the cost effectiveness of GAM in this setting. Clinical trial information: NCT03154671. Research Sponsor: Canadian Cancer Society.

Poster Discussion Session

Fertility post immune checkpoint blockade. *First Author: Martinique Ogle, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Immune checkpoint blockade (ICB) is radically altering the treatment paradigm for a wide range of malignancies. Consequently, the proportion of ICB exposed pts will expand and the impact of ICB on fertility is of increasing importance. We sought to evaluate fertility outcomes post ICB exposure at our institution. **Methods:** Pts <45 years old post ≥ 1 cycles of ICB at MSK who consented to the MSK-IMPACT protocol (NCT01775072) were screened for eligibility (n = 537). Pts in receipt of prior cytotoxic chemotherapy or tyrosine kinase, BRAF or MEK inhibitors were excluded. 96 eligible pts were emailed a 28-question survey; 65% were followed up by phone. **Results:** 50/96 pts responded to the survey, male to female ratio was 27:23. 5 pts were excluded from final analysis due to additional systemic agent use pre-conception. Median age at ICB exposure was 35 (range 19-44). 53% (25/45) of pts received ICB in the metastatic setting. 40% (17/42) of pts received fertility counseling pre-ICB use. There was no statistically significant difference between rates of fertility counseling in metastatic vs non-metastatic settings (p = 0.14). 7 pts (14%) conceived and 2 pts (4%) are currently trying to conceive children post ICB. 4 pts (3 female, 1 male) conceived children with reproductive technology. 3/4 pts used sperm or embryos frozen prior to ICB and IVF leading to successful pregnancies, 2 of which are currently ongoing. One patient froze embryos 6 months after 2 years of PD1 inhibitor (PD1i) monotherapy and embryo implantation led to a currently ongoing pregnancy. Notably this pt developed hypothyroidism with ICB use, controlled with levothyroxine, and has remained euthyroid during pregnancy to date. 3 pts (2 female, 1 male) receiving single agent PD1i in the localized setting conceived naturally at 2 yrs, 9 months and 2 months respectively post ICB. 4/8 pregnancies are currently ongoing without reported immunological complications. 3 deliveries have resulted in 4 children (including 1 set of twins). 1 of these pts had a 1st trimester miscarriage of unclear cause followed by successful pregnancy complicated by gestational diabetes. First pregnancies occurred a median of 1 year post ICB (range 2-24 months). No autoimmune conditions in progeny were reported. **Conclusions:** Successful conception occurred both naturally and with reproductive assistance technologies post ICB. Most pts did not receive fertility counseling pre-ICB use, possibly reflective of nascent appreciation of complete and durable ICB responses. There were no definite adverse immunological complications reported in pregnancy or progeny of these pts. As ICB indications expand prospective evaluation of ICB impact on fertility in pts desirous of a family is critical and consequently we are integrating longitudinal fertility analysis in neoadjuvant ICB protocols. Impact of immune checkpoint inhibition on ovarian reserve in patients with melanoma enrolled in the ECOG-ACRIN E1609 adjuvant trial. *First Author: Elizabeth Iannotti Buchbinder, Dana-Farber Cancer Institute, Boston, MA*

Background: Immunotherapy with immune checkpoint inhibition (ICI) is being widely adopted in the treatment of patients with a wide range of malignancies. However, we have no data on how these therapies influence fertility or ability to undergo fertility treatments after therapy. Within the melanoma community numerous women of childbearing age have been treated with ICI including ipilimumab, nivolumab and pembrolizumab. Anti-mullerian hormone (AMH) is a biomarker of ovarian reserve and a predictor of response to fertility treatments, including in vitro fertilization (IVF). In women under the age of 35 who have no reproductive pathology, AMH should be detectable and remain relatively stable over time. Above the age of 35 AMH decline accelerates as the number of eggs decreases more rapidly due to normal ovarian aging. **Methods:** Pre and post-treatment samples from women aged 20-35 whose melanoma was treated with 3 mg/kg ipilimumab (57%) or 10 mg/kg ipilimumab (43%) in the adjuvant setting on trial ECOG-ACRIN E1609 were analyzed in collaboration with the BWH Reproductive Endocrine Laboratory. Serum samples were tested for luteinizing hormone (LH), follicle stimulating hormone (FSH), estradiol, AMH and prolactin. **Results:** Samples from E1609 were available from 28 female patients with a median age of 28 (min 20, max 35). The median time between samples was 8.0 months (min 0.7, max 16.4). 53% of patients had stage IIIB melanoma, 43% stage IIIC and one patient had M1a disease. AMH, estradiol and LH significantly decreased after treatment (p < 0.001, p = 0.016, p = 0.012, respectively) (Figure 1); there was no significant difference in the level of FSH and prolactin before and after the treatment (p = 0.68, p = 0.12, respectively). The median AMH was 4.24 ng/mL in the pre-treatment group and 3.51 in the post-treatment group. **Conclusions:** In this study of young women treated with ipilimumab there was a significant decrease in AMH before and after ICI therapy suggesting that ovarian reserve and possibly female fertility may be impacted by immune checkpoint inhibition. Further investigation is needed to look at PD-1 inhibition and combination immunotherapy effects on ovarian reserve and female fertility. In addition, there is a similar need to examine ICI effects on male fertility. Research Sponsor: None.

Effect of flibanserin on libido in women with breast cancer on adjuvant endocrine therapy. *First Author: Shari Beth Goldfarb, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Breast cancer and its treatment can cause decreased libido. This study evaluates the use of Flibanserin in women with breast cancer on endocrine therapy who are experiencing decreased libido. It is the first study evaluating Flibanserin for medically induced decreased libido. **Methods:** 37 women (mean age of 49) with stage 0-III ER+ breast cancer on endocrine therapy for at least three months were enrolled on a longitudinal IRB-approved trial from both an academic center and an alliance community site. All patients met criteria for the diagnosis of HSDD as defined by the DSM-IV and ISSWSH consensus paper. Patients took Flibanserin 100mg at bedtime for 24 weeks and were followed for 52 weeks. Patients were monitored closely with medical exams and questionnaires at baseline, weeks 4, 8, 16, 24 and 52. Feasibility and efficacy of Flibanserin was measured by patient reported validated instruments such as Female Sexual Function Index (FSFI), Pittsburg Sleep Quality Index (PSQI), PROMIS, and EQ5D. **Results:** A statistically significant improvement in the sexual domains of desire, arousal, lubrication, orgasm, satisfaction, and pain were seen as measured by the FSFI while on Flibanserin, which declined after discontinuing the medication. At baseline, patients had an average libido of 1.7, which increased to 2.8 at 24 weeks and declined to 2.5 after discontinuing treatment. Sexual confidence and satisfaction at baseline were an average of 1.2 and 1.6 respectively and increased to an average of 2.5 and 2.6 after treatment. Ability to become lubricated was 1.3 at baseline and increased to 4.4 at 24 weeks. Ability to maintain lubrication and ease of lubrication both averaged 1.6 at baseline and increased to 3.4 at week 24. Ease and frequency of climax scored an average 1.4 at baseline, then increased to 2.6 and 2.9 respectively at week 24. Patients reported less pain and distress with sexual intercourse throughout the study and an increased number of sexually satisfying events. At baseline, the average score for overall state of health was 78/100. At 24 weeks, the average score increased to 93 and declined to 82 at week 52 (after medication was discontinued). Patients slept an average of 6.7 hours per night at baseline, which increased to 7.7 hours on Flibanserin and decreased to 5.5 hours after discontinuing the medication. **Conclusions:** Our study found statistically significant improvement in the sexual domains of desire, arousal, lubrication, orgasm, satisfaction, and pain as measured by the FSFI from baseline to week 24 while on Flibanserin. It also showed improved overall health-related quality of life and sleep. Flibanserin is an effective treatment option for women with breast cancer. A larger randomized placebo-controlled study is still needed to further evaluate Flibanserin in women with breast cancer and medically induced decreased libido. Clinical trial information: NCT03707340. Research Sponsor: Sprout Pharmaceuticals.

Long-term outcomes of adolescents and young adults with testicular germ cell tumors: A population-based retrospective matched cohort study. *First Author: Rand Ajaj, The Hospital for Sick Children Research Institute, Child Health Evaluative Sciences, Toronto, ON, Canada*

Background: Testicular germ cell tumor (TGCT) survival exceeds 90%, but survivors of adult TGCT are at risk of developing late effects. Little is known about the risk for late effects in survivors of TGCT in children, adolescents, or young adults (CAYA). **Methods:** We identified all CAYA aged 11-21 years at TGCT diagnosis in Ontario, Canada, between 1992-2021. Those with complete treatment records were matched 1:5 by birth date and postal code at diagnosis to individuals from the general population (controls). Controls' index date was defined as the diagnosis date of their survivor match. Participants were linked to health administrative databases to identify second malignant neoplasms (SMN); cardiovascular disease (CVD: congestive heart failure [CHF], myocardial infarction, coronary artery disease, pericardial disease, valvular abnormalities, arrhythmia, stroke, hypertension); renal disease (dialysis, kidney transplant); and hearing loss (physician-diagnosed hearing loss, hearing aid use). Cumulative incidences were compared between survivors and controls, and between chemotherapy and surgery treated survivors using Gray's test. Cox proportional hazard models compared the risk of late effects between survivors and controls. **Results:** 521 TGCT survivors (296 chemotherapy treated, 225 treated with surgery only) were matched to 2605 controls. Median age at diagnosis/index date was 19 years. Survivors' median follow-up time was 14.8 years (interquartile range: 10.7-21.7). Compared to controls, survivors had higher 15-year incidence and hazard ratio (HR) of all SMN (5.0% vs 0.5%; HR 8.4, $p < .0001$), non-testicular SMN (2.1% vs 0.5%; HR 3.8, $p = 0.0003$), dialysis (1.0% vs 0.04%; HR 12.4, $p = 0.003$), kidney transplant (0.4% vs 0.0%, $p = 0.002$), hearing loss (7.1% vs 3.1%; HR 1.8, $p = 0.005$), and hearing aid use (1.0% vs 0.2%; HR 4.1, $p = 0.02$). Survivors were at substantially increased risk of any CVD (8.2% vs 5.5%; HR 1.4, $p < 0.03$), CHF (1.2% vs 0.2%; HR 5.0, $p = 0.006$), arrhythmia (1.8% vs 0.5%; HR 3.4, $p = 0.002$), and stroke (0.8% vs 0.05%; HR 8.7, $p = 0.0006$) despite no anthracycline exposure. Compared to surgery only treated survivors, chemotherapy treated survivors had higher 15-year incidence of any CVD (13.1% vs 2.0%, $p < 0.0001$), CHF (2.1% vs 0.0%, $p = 0.03$), arrhythmia (3.3% vs 0.0%, $p = 0.02$), stroke (1.4% vs 0.0%, $p = 0.02$), hypertension (7.4% vs 2.0%, $p = 0.009$), and hearing loss (10.2% vs 3.0%, $p = 0.02$). **Conclusions:** Survivors of TGCT during CAYA are at considerable risk for late effects affecting multiple organ systems. In addition to previously described morbidities like hearing loss, survivors (particularly those who received chemotherapy) are at higher risk of CVD. Despite excellent rates of cure, TGCT survivors diagnosed at a young age require life-long risk-directed follow-up to maximize their long-term health. Predicting therapy-induced cardiomyopathy in long-term survivors of childhood cancer: A report from the St. Jude Lifetime Cohort (SJLIFE) and the Childhood Cancer Survivor Study (CCSS). *First Author: Kateryna Petrykey, St Jude Childrens Research Hospital, Memphis, TN*

Background: Cancer-therapy-induced cardiomyopathy (CCM) is the leading non-cancer cause of mortality among long-term survivors of childhood cancer, the prevalence of which increases with age. Early identification of survivors at risk provides opportunities for targeted prevention strategies. Here, we developed and validated a clinically applicable CCM prediction model based on survivor characteristics, treatment exposures and inherited genetic variation among long-term survivors of childhood cancer. **Methods:** Long-term survivors from SJLIFE (training cohort; $n = 3,350$; median age 34 years, range 8-72 years) and CCSS (validation cohort; $n = 7,008$; median age 36 years, range 11-64 years) were assessed by the five different general population polygenic risk scores (multiPRS) for dilated cardiomyopathy, hypertrophic cardiomyopathy, heart failure, ejection fraction and left ventricular end systolic volume. Multivariable logistic regression was used to predict 15-year risk of the CCM (defined as CTCAE grade ≥ 3 cardiomyopathy requiring heart failure medications or heart transplantation or leading to death). Model performance was assessed by the area under the receiver operating characteristic curve (AUC). **Results:** CCM was clinically identified in 150 (4.5%) SJLIFE and self-reported in 156 (2.1%) CCSS survivors, respectively. AUC of clinical models with attained age, sex, age at primary cancer diagnosis, cumulative anthracycline dose, mean heart radiation dose (heart RT), and genetic ancestry was 0.81 (95% CI, 0.78-0.85) in SJLIFE and 0.78 (95% CI, 0.74-0.81) in CCSS. Inclusion of cardiovascular risk factors (hypertension, dyslipidemia, and diabetes) significantly increased AUC to 0.83 (95% CI, 0.80-0.87; $P = 0.011$; SJLIFE) and 0.84 (95% CI, 0.80-0.87; $P < 0.001$; CCSS). The addition of the multiPRS further provided significant but modest increases in AUC in SJLIFE (0.84; 95% CI, 0.81-0.87; $P = 0.022$) and CCSS (0.85; 95% CI, 0.81-0.88; $P = 0.031$). In low-risk survivors (exposed to $< 100 \text{ mg/m}^2$ anthracyclines and < 15 Gray heart RT), we observed a possibly larger magnitude AUC increase after adding multiPRS, 0.73 (95% CI, 0.65-0.82) to 0.76 (95% CI, 0.68-0.83; $P = 0.11$) in SJLIFE and 0.77 (95% CI, 0.65-0.90) to 0.82 (95% CI, 0.69-0.94; $P = 0.073$) in CCSS. **Conclusions:** Inherited polygenic factors contributed significantly to improve CCM prediction over available clinical risk factors and may be of benefit to low-risk survivors for whom routine cardiac surveillance is not currently recommended. Poster Discussion Session

Social determinants of health burden among adolescent and young adult cancer patients and impact on overall survival. *First Author: Elizabeth Rodriguez, McGovern Medical School, Houston, TX*

Background: The 5-year survival rates for adolescents and young adults (AYA) with cancer have steadily improved, yet disparities by race/ethnicity persist. The drivers of these disparities remain unclear. Neighborhood socioeconomic deprivation has been linked to adverse health outcomes independent of the effects of individual-level measures of social determinants of health (SDOH). We evaluated the impact of neighborhood SDOH on overall survival (OS) in a diverse AYA cancer patient population treated in a single academic setting. **Methods:** This study utilized a multi-ethnic cohort of AYA cancer survivors ($N=10,261$) diagnosed between ages 15-39 seen at MD Anderson Cancer Center between 2000 and 2016. Patient demographics, zip code at presentation, cancer characteristics, and follow-up were obtained from our institutional tumor registry. Zip codes were linked to Area Deprivation Index (ADI) values, a validated neighborhood-level SDOH measure, with higher ADI representing worse SDOH. **Results:** The cohort included 6,361 (62%) non-Hispanic White, 1,112 (10.8%) non-Hispanic Black, and 2,133 (20.8%) Hispanic AYA cancer patients, with 655 (6.4%) of other ethnicities or missing information. The mean ADI value was significantly higher ($p < 0.05$) for Black (61.7) and Hispanic (65.3) patients, compared to White (51.2) patients. Analysis of ADI by cancer type showed significant differences, mainly driven by the significantly higher ADI in patients with cervical cancer (62.3) than other cancer types. In contrast, AYA patients diagnosed with breast cancer (53.0) and CNS tumors (52.9) resided in neighborhoods with the lowest ADI values. ADI was a significant predictor of OS overall. In multivariable models that included gender, age at diagnosis, cancer diagnosis, and race/ethnicity, risk of death for AYA cancer patients residing in neighborhoods with ADI in the highest quartile was greater than that for patients in the lowest quartile (HR: 1.09, 95% CI: 1.00-1.19, $p=0.043$). **Conclusions:** Our results in this large multi-ethnic cohort indicate that non-White AYA patients with cancer more commonly live in neighborhoods associated with higher ADI compared to their White counterparts. Even when treated in the same academic setting, AYA cancer patients with higher ADI experienced worse OS across cancers. Although the magnitude of the effect was moderate, the presence of this effect within a tertiary cancer center with existing barriers to care suggests that ADI is a meaningful risk factor impacting survival. Further analysis is warranted to determine the generalizability of these findings to the patient population more broadly. However, the results provide intriguing evidence for potential interventions aimed at supporting AYA cancer patients from disadvantaged backgrounds. Cannabis extract for secondary prevention of chemotherapy-induced nausea and vomiting: Results of a phase II/III, placebo-controlled, randomised trial. *First Author: Antony Mersiades, NHMRC Clinical Trials Centre, The University of Sydney; Northern Beaches Hospital, Sydney, NSW, Australia*

Background: The aim of this multi-centre, randomised, placebo-controlled, phase II/III trial was to determine the efficacy of adding an oral THC/CBD (tetrahydrocannabinol/cannabidiol) cannabis extract in adults who experience CINV during moderate and highly emetogenic intravenous chemotherapy regimens despite guideline-consistent anti-emetic prophylaxis. The phase II crossover component has been published (Grimson et al, AnnOnc 2020). Here we report the definitive results from the combined phase II/III components with a planned sample size of 250 patients. **Methods:** For the definitive phase III component, participants were randomised 1:1 to receive, oral THC 2.5mg/CBD 2.5mg (Tilray TN-TC11M) capsules TDS days -1 to 5, or placebo (in addition to guideline-consistent anti-emetics including rescue medications) for cycles A, B and C. Primary endpoint was the difference in gaining a 'complete response' (no emesis and no use of rescue medications) during 0-120 hours from chemotherapy for cycle A. **Results:** Complete response was achieved in 24% and 8% with THC/CBD and placebo, respectively (absolute difference 16%, P -value 0.01). The study closed early due to slow accrual without knowledge of study outcomes, with a total of 147 patients recruited 2016-22 (pilot $n=78$, definitive $n=69$). Median age was 56 years (range 25 to 80), 78% were females, 39% reported historic cannabis use, 65% were treated with curative intent. Most common regimens were doxorubicin/cyclophosphamide (AC, 31%), and fluorouracil/oxaliplatin (FOLFOX, 17%), 97% received corticosteroid & 5-HT3 antagonist, 80% received NK-1 antagonist, 10% received olanzapine. Efficacy and safety are shown in the table. No SAEs were attributed to THC/CBD. **Conclusions:** Oral THC/CBD was associated with a significant increase in the proportion of patients achieving a complete response in chemotherapy-induced nausea and vomiting and was well tolerated, representing an effective new treatment in the management of this condition. Future analyses will report quality of life and cost-effectiveness. Funding from NSW Government Dept of Health. Drug supply by Tilray. Clinical trial information: ACTRN12616001036404. Research Sponsor: NSW Health.

Safety and efficacy of cannabidiol in the management of chemotherapy-induced peripheral neuropathy. *First Author: Marisa C. Weiss, Lankenau Institute for Medical Research, Wynnewood, PA*

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common dose-limiting complication of cancer treatment that can negatively impact survival and quality of life. Cannabidiol (CBD) has been shown to attenuate CIPN in rodent models although its ability to reduce CIPN symptoms in humans is unexplored. **Methods:** A phase 3 randomized double-blind, placebo-controlled clinical trial was conducted between 6/1/2020 and 8/8/2022. Participants with nonmetastatic breast, colorectal, endometrial, and ovarian cancer (all stages) experiencing grade 2-3 CIPN (duration $\leq$ 2 years) were enrolled after completing taxane or platin-based chemotherapy. They were randomized into active and placebo groups, and followed x 16 weeks. The active group received 135 mg/day of CBD, provided as hemp-based whole plant extract in gelpcaps, while placebo consisted of coconut oil gelpcaps, delivered x 12 weeks. Participants were evaluated every 2 weeks using the EORTC QLQ-CIPN20, which assesses three categories of symptoms: sensory (numbness, tingling, pain), motor (weakness, difficulty walking), and autonomic (blurriness, hearing loss). Side effect and safety data were logged daily. **Results:** Of 230 participants with CIPN identified, 124 met eligibility, 54 consented and enrolled, and 46 completed $\geq$ 8 of the 12-week treatment phase and were included in the analysis. Mean age was 59.6 years; 89.1% were female. Of those participants, 63% had breast cancer, 19.6% colorectal, 15.2% ovarian, and 2.2% uterine. CIPN20 scores were summated and standardized. With placebo as the reference group, main effects for sensory and motor scales were adjusted for time from enrollment and baseline CIPN grade. Participants receiving CBD had greater improvement of sensory function ($p=0.048$), with reduced numbness and tingling, but without significant pain reduction ($p=.282$) or change in motor function ($p=.158$) vs placebo. No autonomic changes were observed. CBD was well tolerated without serious adverse events. **Conclusions:** CBD reduced numbness/tingling and improved sensory function vs. placebo, as assessed by the CIPN20 scale. These symptoms are among the most common and challenging symptoms of CIPN, for which there are limited available treatment options. However, CBD did not affect pain and motor function. Thus, this preliminary study provides evidence that CBD, dosed at 135 mg/day, might serve as a treatment for some CIPN symptoms without serious adverse events. Further research is needed to confirm these results and to assess the safety and efficacy of CBD combined with chemotherapy to prevent or attenuate CIPN. Such an advance could deliver a survival benefit by helping more people complete and better tolerate chemotherapy. Clinical trial information: NCT04398446. Research Sponsor: Ecofibre/Ananda Health.

Neurocognitive function outcomes in NRG/RTOG 0534, the SPPOINT trial. *First Author: Jeffrey Scott Wefel, MD Anderson Cancer Center, Houston, TX*

Background: RTOG 0534 established the benefit of adding of short term androgen deprivation therapy (PBRT+STADT, Arm 2) to prostate bed salvage radiotherapy (PBRT, Arm 1), and demonstrated that elective pelvic lymph node irradiation combined with STADT (PBRT+STADT+PLNRT, Arm 3) results in further reductions in progression. Longitudinal monitoring of neurocognitive function (NCF) was conducted to evaluate the hypothesis that patients treated with STADT will demonstrate greater decline in NCF compared to patients receiving PBRT alone. **Methods:** Patients were administered the Clinical Trial Battery [Hopkins Verbal Learning Test – Revised (HVLT-R), Trail Making Test (TMT), and the Controlled Oral Word Association (COWA) test] by certified test administrators at baseline, and at 6 weeks (6w), 1 year (1yr), and 5 years after the end of RT (5yr). Raw NCF tests scores were converted to standardized z-scores adjusted for age and education when necessary. Analyses included z-score change and reliable change index (RCI) determined decline compared to baseline, and longitudinal mixed effect regression models using z-scores. To control for multiplicity, $p < 0.025$ is required for statistical significance. **Results:** Among the 1716 analyzable patients, 429 consented to NCF monitoring. There were no significant differences in sociodemographic or clinical characteristics between arms. NCF test completion was 82, 76, 63 and 30% at baseline, 6w, 1yr, and 5yr, respectively. RCI-based NCF deterioration was more frequent in Arm 3 compared to Arm 1 at 6 weeks on Delayed Recall (16% vs. 7%, $p = 0.023$). Patients in Arm 3 evidenced greater z-score decline compared to patients in Arm 1 at 6w on HVLT-R Total Recall [M(SD) Z-score Δ = -0.1(1.0) vs 0.2(0.9), ($p = 0.020$)] and Delayed Recall [M(SD) Z-score Δ = -0.4(1.5) vs 0.1(1.2), ($p = 0.012$)]. Mixed effects models identified statistically significant differences in z-scores between Arm 3 and 1 at 6w on Delayed Recall [-0.541 (SE 0.178, $p = 0.002$)]. A statistically significant difference was observed between Arm 2 and 1 at 6w on TMTB [1.498 (SE 0.626, $p = 0.017$) favoring Arm 2]. Between arm differences were not seen at any other time point, or on other NCF outcomes. **Conclusions:** Compared to patients treated with PBRT alone, patients treated with PBRT+STADT+PLNRT exhibited greater worsening in episodic verbal learning and memory processes at 6 weeks after the end of RT, while patients treated with PBRT+STADT exhibited greater improvement in processing speed. The absence of long term or progressive cognitive decline associated with STADT-containing regimens is promising but limited by substantial missing data at year 5. Long term efficacy of psilocybin in patients with cancer and major depressive disorder (MDD). *First Author: Manish Agrawal, Sunstone Therapies, Rockville, MD*

Background: Up to 25% of people living with cancer have depression. Existing psychological interventions have limited efficacy in treating depression. Psilocybin, a 5-hydroxytryptaminergic psychedelic, coupled with group therapy is safe and effective in ameliorating symptoms of depression (Agrawal et al, ASCO 2022). Response to psilocybin treatment was observed in 83.3% of patients at 8 weeks, and 50% of patients showed full remission of depressive symptoms. This study evaluates the efficacy of psilocybin-assisted group therapy in relieving depression in cancer patients over 18 months. **Methods:** Adults with curable or metastatic cancer and MDD (according to DSM-5) underwent psychological assessments at baseline. They were treated with single-dose psilocybin 25 mg administered simultaneously in group cohorts of 3-4, supported with group and individual psychological therapy, and evaluated at 8 weeks and 18 months. Primary objectives were long-term effectiveness on depression and anxiety severity (as measured by change in Montgomery Asberg Depression Rating Scale [MADRS] and Hamilton Depression Rating Scale [HAM-A] scores by independent rater assessments) as well as clinical response ($\geq 50\%$ decrease in MADRS total score from baseline to 18 months) and remission (defined as patients with a MADRS total score ≤ 10 at 18 months). **Results:** Of 30 patients enrolled in the parent study, 2 died and 4 were lost to follow-up. Clinical response was demonstrated in 18/28 patients (64.2%) from baseline to 18 months follow-up (see table); 16/28 patients (57.1%) demonstrated remission of depression at 18 months. In 24 evaluable patients, continued reduction in mean depression severity scores was also demonstrated from baseline to week 8 (MADRS by 20.6 points [95% CI 23.2, 18.0, $p < 0.001$] and HAMA-A by 16.7 points [95% CI 19.7, 13.7, $p < 0.001$]) and from baseline to 18 months (MADRS by 16.7 points [95% CI 20.4, 12.9, $p < 0.001$] and HAMA-A by 14.4 points [95% CI 17.3, 11.4, $p < 0.001$]). **Conclusions:** Long-term follow-up suggests continued robust clinical response and remission from depression with a single dose of psilocybin and simultaneous psychological support in patients with cancer and MDD. These findings indicate psilocybin may play a role in treatment of depression in cancer patients, and further investigations are ongoing. Research Sponsor: Sunstone Medical, PC.

Yoga vs. behavioral placebo for fatigue and quality of life among older cancer survivors. *First Author: Evelyn Arana, Wilmet Cancer Institute, University of Rochester Medical Center, Rochester, NY*

Background: Older cancer survivors consistently express the need for interventions to reduce fatigue and maintain quality of life (QOL). We previously showed that yoga, compared to standard care, effectively improved fatigue and QOL among older survivors. Whether yoga is superior to a rigorous behavioral placebo for improving fatigue and QOL in older survivors is unknown. To examine the efficacy of yoga vs a behavioral placebo for improving fatigue and QOL in older survivors. **Methods:** Older cancer survivors (age 60+) 2-60 months post-treatment were randomized to receive Yoga for Cancer Survivors (YOCAS; 75-minute sessions 2x/week for 4 weeks) or a behavioral placebo (Survivorship Health Education – SHE; 75-minute sessions 2x/week for 4 weeks). The YOCAS intervention includes breathing exercises, yoga poses, and mindfulness activities. The SHE placebo includes education based on ASCO cancer survivorship recommendations. Fatigue and QOL (i.e., overall, physical, emotional, and functional) were assessed pre- and post-intervention with the Functional Assessment for Chronic Illness Therapy-Fatigue (FACIT-F). The within-group and between-group intervention effects on fatigue were examined by 2-tailed t tests and ANCOVAs. **Results:** 173 older survivors were enrolled (91% women, mean age 67 [range=60-85], 90% White, 10% racial minority, 2.3% Hispanic, 71% breast cancer). On average, participants completed 6 in-person yoga sessions and 1 additional weekly, home-based yoga practice, for an average of 183 minutes of yoga/week with no intervention-related adverse events. There were significant between group differences on fatigue, where yoga participants reported significantly more improvement in fatigue than controls (1.6 $\pm$ 0.9, $p<0.05$). There were also significant between group differences on the emotional component of QOL, where yoga participants reported significant improvement in the emotional component of QOL but controls did not (0.8 $\pm$ 0.4, $p<0.045$). Moreover, there were statistical trends for between group differences on the physical and functional component of QOL, where yoga participants reported improvements in the physical (0.8 $\pm$ 0.4, $p<0.063$) and functional components of QOL (0.9 $\pm$ 0.5, $p<0.089$) but controls did not. There were significant between group differences on overall QOL, where yoga participants reported significant improvement in overall QOL but controls did not (3.8 $\pm$ 1.4, $p<0.007$). 94% of participants reported the intervention useful for symptom management and would recommend it to others. **Conclusions:** Results suggest that older survivors: 1) can safely utilize yoga for treating side effects, 2) experience improvements in fatigue and QOL via yoga therapy, and 3) find yoga a useful treatment for side effects and recommend it to others. Future research is needed to confirm these results and increase uptake by older, and ethnically and racially diverse survivors. Clinical trial information: NCT02613364. The menopause after cancer study: A multimodal technology assisted intervention for the management of menopausal symptoms after cancer. *First Author: Fionán Donohoe, UCD Gynaecological Oncology Group, Dublin, Ireland*

Background: Vasomotor symptoms (VMS) of menopause represent a significant challenge for many patients after cancer treatment, particularly if menopausal hormone therapy (MHT) is contraindicated. **Methods:** The Menopause after Cancer (MAC) Study (NCT04766229) was a single arm phase II trial examining the impact of a composite intervention on quality of life (QoL) in women with moderate to severe VMS after cancer. The intervention consisted of: (1) use of non-hormonal pharmacotherapy to manage VMS (citalopram for predominantly daytime VMS and/or gabapentin for predominantly nocturnal VMS) (2) digital cognitive behavioural therapy for insomnia using Sleepio (BigHealth), (3) self-management strategies for VMS delivered via a mobile application called myPatientSpace and (4) nomination of an additional support person/partner. The primary outcome was cancer specific QoL assessed by the EORTC QLQ C30 version 3 at 6 months. Secondary outcomes included frequency of VMS, bother/interference of VMS (hot flush rating scale [HFRS]) and prevalence of insomnia (sleep condition indicator [SCI] ≥ 16) at 6 months. **Results:** 205 women (82% history of breast cancer) with a median age of 49 years (range 28-66) were recruited. Date of diagnosis ranged from January 2004 until January 2022, with 65% of participants diagnosed from 2019 onwards. Participants had a median of 10 hot flashes in a day (SD 9.2) and 4 night sweats each night (SD 4.9). 17.1% were prescribed citalopram, 62.8% gabapentin alone and 20.1% were prescribed both medications. 120 women completed the protocol. In the intention to treat (ITT) cohort (n = 205) mean QoL scores increased from 62.2 (SEM 1.4) at baseline to 70.4 (SEM 1.7) at 6 months (p < 0.001). In the per protocol (PP) cohort, (n = 120) mean QoL scores increased from 62 (SEM 1.7) to 70.4 (SEM 1.7) at 6 months (p < 0.001). Clinically meaningful improvements were seen across multiple domains of the EORTC QLQ C30 including cognitive function, emotional function and social functioning. Frequency of VMS decreased by 50% at 6 months in the ITT and PP cohorts. Mean HFRS scores decreased from 7.6 (SEM 0.1) to 3.4 (SEM 0.2) at 6 months (p < 0.0005) in the ITT cohort (7.5 (SEM 0.1) to 3.4 (SEM 0.2) (p < 0.001) in the PP cohort) demonstrating reduction in bother/interference of VMS. The prevalence of insomnia reduced from 92% at baseline to 38.7% at 6 months (p = 0.006) in the ITT cohort (95.2% to 38.7% in the PP cohort (p = 0.006)). Mean SCI scores increased from 8.5 (SEM 0.4) at baseline to 17.3 (SEM 0.5) at 6 months (p < 0.0005) in the ITT cohort (7.9 (SEM 0.4) to 17.3 (SEM 0.5) (p < 0.001) in the PP cohort). Significant reductions in wakefulness after sleep onset and sleep onset latency were major contributors to this improvement in insomnia symptoms. **Conclusions:** The MAC study demonstrates that improvements in QoL can be achieved using this multimodal intervention to target VMS and insomnia after cancer. Interventions to improve outcomes for caregivers of patients with advanced cancer: A systematic review and meta-analysis. *First Author: Ronald Chow, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: More than one in ten adults in the US are family caregivers, with cancer among the most common diagnoses of care recipients. Family caregivers of patients with advanced cancer often have poor quality of life (QOL) and mental health. We examined the effectiveness of interventions offering support for caregivers of patients with advanced cancer on caregiver QOL and mental health outcomes. **Methods:** We searched Ovid MEDLINE, EMBASE, Cochrane CENTRAL, and CINAHL databases from inception through 6/2021. Eligible studies reported on randomized controlled trials for adult caregivers of adult patients with advanced cancer. Meta-analysis was conducted for primary outcomes of QOL, physical well-being, mental well-being, anxiety, and depression, from baseline to follow-up of 1-3 months; secondary endpoints were these outcomes at 4-6 months and additional caregiver burden, self-efficacy, family functioning and bereavement outcomes. Random effects models were used to generate summary standardized mean differences (SMD). Meta-regression was conducted for primary outcomes that were significant for the intervention, assessing for mediation effect modification by caregiver sex and age of patient and caregiver. Type I error was 0.05. PROSPERO Registration: CRD42019136321. **Results:** Of 12,193 references identified, 56 articles reporting on 49 trials involving 8,554 caregivers were eligible for analysis; 16 (33%) targeted caregivers (mostly psychoeducational or problem-solving interventions), 19 (39%) patient-caregiver dyads (mostly counseling/therapy), and 14 (29%) patients and their families (mostly palliative care teams). At 1-3 month follow-up, interventions had a significant effect on overall QOL (SMD 0.24 (0.10 to 0.39), $I^2 = 52.0\%$), mental well-being (SMD 0.14 (0.02 to 0.25), $I^2 = 0.0\%$), anxiety (SMD 0.27 (0.06 to 0.49), $I^2 = 74.0\%$), and depression (SMD 0.34 (0.16 to 0.52), $I^2 = 64.4\%$), compared to standard care. At 1-3-month follow-up, a larger age difference (older patient and younger caregiver) was associated with a greater positive effect on QOL (p = 0.04) and depression (p = 0.02). In narrative synthesis, interventions demonstrated improvements in caregiver self-efficacy and grief. **Conclusions:** Interventions targeting caregivers, dyads, or patients and families led to improvements in caregiver QOL and mental health outcomes. These data support the routine provision of available interventions to support caregivers of patients with advanced cancer. A meta-analysis studying the utility of cryotherapy in the prevention of peripheral neuropathy in breast cancer patients receiving paclitaxel and nab-paclitaxel. *First Author: Prashanth Ashok Kumar, Upstate University Hospital, Syracuse, NY*

Background: Debilitating Peripheral Neuropathy (PN) caused by paclitaxel adversely impacts the quality of life in Breast Cancer (BC) patients. Cryotherapy using cooling devices during taxane infusion is a non-invasive strategy to prevent PN, but its efficacy has not been established. We hope to answer this question through our meta-analysis. **Methods:** A systematic search with keywords and controlled vocabulary encompassing BC, antineoplastics, and paclitaxel was conducted in PubMed, CINAHL, Embase, Scopus, Web of Science Collections, and CENTRAL. All databases were searched on March 7, 2022. There were no search restrictions on date, language, status, or outcomes. 405 records were identified, and duplicates were removed using EndNote 20. The remaining 372 records were imported into Covidence, and the titles and abstracts were screened independently by 2 reviewers. 22 out of 63 full texts were relevant to our question of which 14 [12 Randomized control studies and 2 retrospective studies] were included for the meta-analysis using R package meta. Only studies that analyzed cryotherapy use in BC patients who received paclitaxel or nab-paclitaxel were included. Relative risk (RR) derived from random effects model with Mantel-Haenszel method was used to compare the occurrence of PN between cryotherapy vs placebo groups. **Results:** Pooled incidence of Common Terminology Criteria for Adverse Events (CTCAE) grade ≥ 2 PN was 24.85% (81/326) in the cryotherapy arm and 42.35% (72/170) in the placebo arm. Overall RR for CTCAE grade ≥ 2 PN with cryotherapy compared to placebo was 0.45 [0.27,0.77, p = 0.0031]. RR for sensory PN was 0.19 [0.05, 0.66, p = 0.009] and for motor PN was 0.18 [0.03, 0.99, p = 0.0491]. RR for Patient Neurotoxicity Questionnaire (PNQ) score $\geq D$ which connotes severe neuropathy was 0.24 [0.09,0.62, p = 0.0035]. Cold intolerance was the predominant adverse effect at 15% (37/247). Fingernail paronychia and skin irritation were reported at 0.8% (2/247) each. 5.1% (15/294) stopped cryotherapy use prior to completion. However, this number was driven by a single study (10/16 patients stopped using cryotherapy due to cold intolerance) and 7/11 studies had no discontinuations. Visual inspection of our funnel plots revealed no publication bias. **Conclusions:** Use of cryotherapy decreased the occurrence of CTCAE grade ≥ 2 PN by 55% in BC patients getting paclitaxel or nab-paclitaxel. Occurrence of both sensory and motor PN were lower. Cold intolerance was the most frequently reported issue with its use but lead to relatively low discontinuation rates in most studies. Given the lack of any severe adverse effect, cryotherapy use must be encouraged for patients receiving paclitaxel and nab-paclitaxel. Further studies are needed establish a standardized way of applying cryotherapy in terms of the device to use, timing and other logistical factors. Research Sponsor: None.

Use of clinical pathways to identify patients with cancer who may benefit from serious illness conversations. *First Author: Cody E Cotner, Department of Medicine, Brigham and Women's Hospital, Boston, MA*

Background: Treatment pathways are widely used to provide decision support and encourage guideline adherence. Pathways data may be used to identify patients for targeted interventions to improve cancer care. For example, pathways data may enable the identification of patients with poor prognoses for whom serious illness conversations (SICs) should be prioritized to ensure goal-concordant care. **Methods:** For patients starting new therapies at Dana-Farber, oncologists select a node in clinical pathways to indicate the line of treatment. Subspecialty oncologists identified "poor prognosis" nodes in pathways, defined as therapies for patients with expected survivals of < 12 months and for whom an SIC would be appropriate (e.g., 3rd-line treatment for metastatic colon cancer). Pathway node navigations for patients with metastatic solid tumor malignancies with poor prognosis nodes (n = 21 disease pathways) were combined with electronic medical record data to identify SIC documentation in an advance care planning module within 6 months of pathway navigation and patients' dates of death if present. For each node, we calculated the median overall survival (OS), the proportion of patients with an SIC, and the proportion of patients who died before reaching the next node. **Results:** There were 10,132 navigations for 7,031 patients (median age 67 years, 52% female, 86% White) between 8/16/2019 and 1/4/2023. With each treatment line, patients' median OS decreased and SIC rates increased (examples for 3 diseases in Table). Among patients who reached poor prognosis nodes, the median OS was 4.9 months, mean SIC rate was 43.8%, and 60.2% of patients died without reaching a subsequent node. For nodes immediately prior to poor prognosis nodes, the median OS was 7.1 months, the mean SIC rate was 25.2%, and 31.3% of patients died without reaching the next node. 46.3% of patients died without reaching a poor prognosis node. The proportion of patients having an SIC at death was 40.9% among all decedents, 50.8% for decedents reaching a poor prognosis node, and 29.3% for decedents who do not reach a poor prognosis node. **Conclusions:** Clinical pathways can be used as a scalable method to identify patients with metastatic solid tumors and poor prognoses. In our study, only half of patients who reached a poor prognosis node had an SIC before death and nearly half of decedents never reached a poor prognosis node, underscoring the importance of identifying this population to improve end-of-life care. A clinical trial using pathways to identify and deliver interventions to increase SICs is ongoing. Research Sponsor: None.

Quality for all: Clinical trial enrollment and end-of-life care in solid and hematologic malignancies. *First Author: Melissa R Rosen, Duke University School of Medicine, Durham, NC*

Background: All patients with cancer deserve quality end-of-life (EOL) care. Despite established EOL quality metrics, many patients with cancer receive futile, aggressive EOL care with infrequent palliative care involvement and advanced care planning (ACP) documentation. Clinical trials are critical to advancing cancer care; at National Cancer Institute-designated cancer centers, ~20% of patients participate in clinical trials at some point. We aim to identify associations between trial enrollment in the last year of life (YOL) and EOL quality metrics for adults with solid or hematologic malignancies to identify opportunities to advance cancer care near death. **Methods:** This is a retrospective review of patients with solid or hematologic cancers treated at a single academic institution who died of disease between 2018 – 2022. Patients were identified using institutional registries. Inclusion criteria were ≥18 years of age with active disease at death. Outcomes include: initiation of new anti-cancer therapy, Intensive Care Unit (ICU) admission, hospitalization, or Emergency Department (ED) visit in the last 30 days of life (DOL), referral to hospice, palliative care involvement, and documentation of goals of care (GOC) and ACP paperwork. **Results:** Among 9,384 patients, 637 (6.8%) enrolled in clinical trials in the last YOL. Most common disease sites were gastrointestinal, thoracic, and genitourinary. Patients enrolled in clinical trials were more likely to initiate new anti-cancer treatments in the last 30 DOL ($p < 0.001$), less likely to be referred to palliative care ($p = 0.008$) or have GOC documentation ($p = 0.001$), and less likely to visit the ED ($p = 0.016$) or die in an inpatient setting ($p = 0.02$). No differences were noted in referrals to hospice, ICU or hospital admissions in last 30 DOL, or ACP paperwork. **Conclusions:** Enrollment in a clinical trial in the last YOL was associated with several measures of aggressive EOL care. Low rates of palliative care and hospice engagement and infrequent documentation of ACP decisions across the study population suggest opportunities for improvement for all patients, regardless of trial enrollment. Research Sponsor: None.

End-of-life outcomes of patients with advanced cancer enrolled in palliative care. *First Author: Andrew Lynch, Kaiser Permanente Oakland Medical Center, Oakland, CA*

Background: Palliative Care (PC) integration improves end-of-life (EOL) outcomes for patients with advanced cancer. However, there is limited evidence in real world settings of the impact of PC enrollment on EOL outcomes and the presence of racial disparities in PC enrollment. We sought to understand how PC enrollment differs between certain patient demographics and whether enrollment affects EOL outcomes in a large integrated health system. **Methods:** This retrospective cross-sectional study included adults 18 years and older diagnosed with Stage IV solid cancers who died within 1 year of diagnosis at 21 cancer centers within Kaiser Permanente Northern California between 2018-2020. Demographics, clinical variables and EOL outcomes were compared by PC enrollment status. Categorical and continuous comparisons were made using Chi-squared and t-tests, respectively. **Results:** Among 3,575 patients diagnosed with stage IV solid cancers who died within 1 year of diagnosis (mean age 73.2), 52.8% were male; 8.2% were Black, 11.0% Hispanic, 12.3% Asian, and 67.7% non-Hispanic White. Most patients (93.0%) selected English as their preferred language. The most common cancer subtypes were thoracic (33.2%), upper GI (32.4%), and lower GI (10.6%). Overall, 1613 patients (45.1%) were enrolled in PC. Baseline demographics were similar between the PC and no-PC groups including gender ($p = 0.58$), race ($p = 0.32$), and preferred language ($p = 0.23$). There was a difference in mean age between groups (72.0 vs. 74.2, $p < 0.01$). Patients enrolled in PC were more likely to enroll in hospice (42.9% vs. 25.7%, $p < 0.01$, Table) and less likely to be hospitalized in the last 30 days of life (35.5% vs. 45.7%, $p < 0.01$, Table). Short hospice stays (< 3 days) were uncommon in both groups, and there was no statistically significant difference between groups (4.5% vs. 5.4%, $p = 0.49$, Table). There was no significant difference in the proportion of patients with multiple ED visits in the last 30 days of life between groups (21.0% vs. 21.8%, $p = 0.56$, Table). **Conclusions:** PC enrollment is associated with significant improvement in some EOL outcomes with higher rates of hospice enrollment and lower rates of hospitalization at the EOL. These outcomes were seen without racial disparities in PC enrollment. Future studies are needed to assess other outcomes related to goal-concordant care and to determine which patients benefit most from PC enrollment. Research Sponsor: None.

Trends in place of death in adolescents and young adults dying from cancer in the US, 2003-2019. *First Author: S. M. Qasim Hussaini, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins Hospital, Baltimore, MD*

Background: Adolescents and Young Adults (AYAs) face unique social challenges in navigating care at end-of-life (EOL). Place of Death (PoD) is an important determinant of patient and caregiver preference, access to home-based supportive care, and cost of caregiving at EOL. We sought to describe disparities in PoD in AYAs who died from cancer between 2003-2019. **Methods:** We used deidentified death certificate data via the CDC Wonder database. We included decedents aged 15-44 years with an underlying cause of death from cancer (through ICD codes) from 2003-2019. We stratified findings by age, race/ethnicity, sex, cancer site, and urban/rural metro status. We classified PoD as (1) medical facility (2) nursing home (3) home, or (4) hospice facility. Odds ratios (OR) for the association between PoD and geographic region were calculated using multinomial regression, adjusting for year of death. **Results:** We included 301,886 AYA deaths from cancer (53.9% female, 15.6% non-Hispanic Black, 18.4% Hispanic, 15.6% rural, 28.6% breast, 19.9% colorectal, 18.4% lung, 16.9% brain, 16.2% leukemia). From 2003-2019, deaths in a medical facility reduced from 11,579 (52.7%) to 7,952 (49.5%), home from 8,630 (39.3%) to 6032 (37.5%), and in a hospice facility increased from 152 (0.7%) to 2,245 (14.0%). Compared with older adults (>45), AYAs were 42% and 37% less likely to die at home or in a hospice facility than a medical facility. Within AYAs, similar trends were noted for Hispanic and non-Hispanic Blacks when compared to non-Hispanic Whites, and rural residents when compared to urban residents. AYAs with leukemia were most likely to die in a medical facility and least likely in hospice, brain cancer most likely to die at home or in a nursing facility, while colorectal and breast cancers had equal uptake of hospice. **Conclusions:** AYAs have lower hospice uptake at EOL with notable sociodemographic, geographic and disease-site specific variation. These data likely reflect complex treatment planning and care access/preference at EOL. Dying at home may be unattainable for AYAs, unless they are able to afford help or have family who are willing to be caregivers. Future work investigating whether the offerings of hospice meet the basic care needs of AYA with cancer at EOL is necessary. Research Sponsor: None.

Patient characteristics associated with psychosocial distress about end-of-life. *First Author: Ana Isabel Tergas, City of Hope, Duarte, CA*

Background: A cancer diagnosis and subsequent treatment can cause significant psychosocial distress, including fear about the end of life (EoL). Although distress is common, it often goes unrecognized due to the challenge of routine psychosocial distress screening. This study sought to determine patient characteristics associated with EoL-related distress. **Methods:** A validated psychosocial distress screening tool (SupportScreen) was administered to patients prior to treatment at an NCI-designated cancer center between 2009-2017. Fear about EoL was measured on a 5-point Likert scale with scores of ≥3 indicating “high” distress. Multivariable logistic regression was used to test the association between fear of EoL and patients’ characteristics (age, sex, education, household income, survey language, race/ethnicity, and cancer diagnoses). Pairwise comparisons were run for cancer types and p-values were adjusted. **Results:** A total of 4,198 patients with cancer were included. Of these, 21.5% reported high distress from fear about EoL. Most patients were women (61%) and non-Latino white (60%). The average age was 59.9 years (SD = 13.9). About 29% of the participants had household income < \$40,000. The most common cancers in this sample were breast (22%), hematological (15%), gastrointestinal (14%) and gynecological (13%). Adjusted analyses showed that being a woman (OR = 1.30, $p < 0.042$), taking the survey in Spanish (OR = 1.71, $p = 0.020$) and having a household income < \$40,000 (OR = 1.80, $p < 0.001$) were all associated with high distress for EoL. Among cancer types, lung cancer (versus breast, digestive, gynecological, hematological, and prostate cancers) was significantly linked to high distress (p -values < 0.05). Conversely, older age (OR = 0.99, $p = 0.009$) was associated with low distress. **Conclusions:** In this study, we identified patient clinical and demographic characteristics associated with high levels of distress due to fear of EoL. Patients who have lower household income, limited English proficiency, are younger, and female, as well as patients with lung cancer, may benefit from targeted screening for EoL distress, to facilitate early identification and tailored supportive care assistance. Psychosocial health of patients engaging in medical aid in dying and their family members: A prospective descriptive analysis. *First Author: Chloe Turner, Texas Tech University, Lubbock, TX*

Background: Medical Aid in Dying (MAID) allows patients (pts) with a terminal illness and less than 6 months prognosis to request a prescription that will end their life. MAID is controversial; opponents argue that negative psychological health underlies the choice, and that participation adversely affects pts and FMs. This is the first study to prospectively examine psychological health of pts and Family Members (FMs) who engaged in MAID and compare this to the psychological health of pts and FMs who did not utilize MAID. **Methods:** Pts and FMs were recruited prospectively from End-of-Life Washington (largest non-profit, public MAID advocacy/assistance organization in Washington State) from September 2022-January 2023 to a self-report, longitudinal study. Pts, FMs or the dyad were enrolled. Results of this study are compared to previously published results: *means (standard deviation, SD) taken from *Singer, et al. 2021; **Frikkel, et al. 2021; ^Robinson, et al. 2016 and ~Trevino, et al. 2013. + indicates no significant difference between MAID and non-MAID subjects at $p > .05$ level. **Results:** 16% (8/51) of eligible pts and 49% (20/41) of eligible FMs were recruited. 55% (n = 11) of FMs were spouses. There was no difference in sex and subjects were mostly white (pts 87.5%; FMs 95%) with college or higher degrees (pts 62.5%; FMs 85%). Most pts reported having cancer (n = 6 [75%]; neurologic condition, n = 1 [12.5%]; cirrhosis, n = 1 [12.5%]); most FMs also reported their pt had cancer (n = 17 [85%]; neurologic condition, n = 3 [15%]). There were no differences in psychological health between terminal cancer pts and FMs who engaged in MAID and advanced cancer pts & FMs who did not (see table). **Conclusions:** In this study, FMs and pts participating in MAID appear to have rates of negative psychological states that are in the low to moderate range. These rates appear similar to pts with advanced cancer and their FMs who are not engaging in MAID. Future research should study larger, heterogeneous populations earlier in the illness trajectory. The impact of patient age on palliative care utilization and end-of-life outcomes among patients with metastatic breast cancer. *First Author: Carley Mitchell, University Hospitals, Department of Medicine, Cleveland, OH*

Background: Among patients with advanced cancer, palliative care (PC) utilization is frequently associated with improved quality of life, less aggressive end of life (EOL) measures, and hospice enrollment at the time of death. While older age is often associated with less PC utilization. The interplay between patient age, site and timing of PC with resultant EOL trends is not well understood. We aimed to assess these variations within a single institution's metastatic breast cancer (mBC) population. **Methods:** An IRB approved retrospective study was conducted. All adult, decedent, mBC patients from 2011-2022 were analyzed. Manual chart review extracted demographic and clinical data related to diagnosis, treatment, PC utilization and death. The relationship of patient age with PC utilization (including setting and timing), aggressive EOL measures, hospice care at the time of death, and hospice duration were evaluated. Univariate analyses were conducted and factors with a significance level $p < 0.15$ were further evaluated on multivariable logistic regression. **Results:** 278 decedent mBC patients met inclusion criteria. Any form of PC interaction from date of metastatic diagnosis to date of death, and utilizing outpatient (OP) PC (i.e., only OP or OP + inpatient (IP)) during the last year of life were significantly associated with hospice enrollment at the time of death. Similarly, utilizing only OP PC (i.e., no IP) was significantly associated with a longer time on hospice care. There was a trend toward shorter hospice durations in mBC patients who received only IP PC, and patients who received any IP PC or had their first PC interaction < 4 months prior to the time of death were more likely to experience ≥ 1 aggressive EOL measure. Young adults (< 40) were significantly more likely to receive some form of PC throughout their disease course, with a trend toward receiving only IP PC. While no significant relationships were identified between age and EOL factors, there were trends toward young and middle-aged adults (40-64) receiving ≥ 1 aggressive EOL measure and less time on hospice compared to older adults (≥ 65). **Conclusions:** This study gives important insight into a breast cancer-specific female population. Results highlight the importance of PC, especially in the OP setting, and its effect on hospice enrollment prior to death. However, there appears to be an interesting dichotomy between young adults receiving more PC and worse EOL experiences compared to older adults receiving less PC and better EOL experiences. These results should guide and promote, early OP focused PC specifically for young and middle-aged adults to help improve challenging EOL transitions. Research Sponsor: None.

Risk of malnutrition and predisposing factors among Mexican patients with advanced cancer. *First Author: Sergio Contreras, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán (Mexico), México City, Mexico*

Background: Malnutrition is a predictor of cancer survival independent of cancer site. However, routine screening for malnutrition is underutilized. Advanced cancer accounts for 60% of cancer cases in developing countries of which approximately 52 % have malnutrition. This study aimed to describe factors associated with risk of malnutrition among patients with advanced cancer. **Methods:** We conducted a cross-sectional analysis of baseline data from patients with recently diagnosed advanced cancer included in a multidisciplinary patient navigator-led supportive care program in Mexico City (Te Acompañamos). At the time of enrollment in the program, patients completed a series of questionnaires including assessments of quality of life (FACT-G), various symptoms and the validated malnutrition screening tool (MST). Clinic and demographic characteristics were obtained from the patient chart. Descriptive statistics were used for analysis and factors associated with risk of malnutrition were analyzed by bivariate testing. **Results:** Between August 2017 and December 2022, a total of 601 patients were included. Mean age was 62 years (range 18-94), 57.2% were women, 56% had gastrointestinal and 28% gynecological malignancies. 72 % screened positive for malnutrition on the MST and 49 % reported nausea on FACT-G. Patients with an ECOG performance status ≥ 3 were more likely to screen positive for malnutrition (OR 5.9 95%CI 2.5- 13) as well as those with baseline nausea (OR 2.99; 95%CI 1.9-4.7). On the other hand, patients with active chemotherapy (OR 1.4 95%CI, 1.016-1.95) and those receiving antiemetic treatment with a single medication (OR 1.63 95%CI, 1.1-2.4) were more likely to have nausea. No other clinical or demographic characteristics were significantly associated with screening positive for malnutrition or reporting nausea, including gender, age, history of smoking or alcohol abuse, type of neoplasia, or oncologic treatment. **Conclusions:** Our results show that a high proportion of patients with advanced cancer are at increased risk for malnutrition and report nausea. Poor functional status and nausea were strongly associated with a higher risk of malnutrition, while receiving insufficient antiemetic medication was associated with increased odds of nausea. This suggests that appropriate treatment of nausea and nutritional interventions should be prioritized early in the management of patients with advanced cancer regardless of the type of cancer treatment in order to avoid malnutrition and improve patient well-being. Falls and hospitalization during chemotherapy in older women with early breast cancer. *First Author: Jingran Ji, City of Hope, Duarte, CA*

Background: Hospitalizations are frequent, burdensome, and potentially avoidable complications of cancer treatment in older adults. While geriatric assessments can identify older patients at risk for hospitalization, the use of these assessments in clinic is limited by time and resources. Screening for falls in the past 6 months is a quick and simple question that clinicians can ask in clinic and fall history has been linked to chemo-related toxicity. Here, we hypothesized that in older adults with cancer fall history prior to chemo is associated with an increased risk of hospitalization during chemo. **Methods:** In a prospective multicenter study of 497 women age ≥ 65 with stage I-III breast cancer treated with neo/adjuvant chemo, we assessed baseline self-reported fall history in the past 6 months as a dichotomous (yes/no) and continuous variable (no. of falls). Our primary endpoint was hospitalization during chemo (yes/no, yes defined as incident hospitalization assessed from start to end of chemo and attributed to toxicity from chemo). We used multivariable logistic regression to examine the association between fall history and hospitalization during chemo, adjusting for socio-demographic and clinical covariates. **Results:** The median age was 70 (65-86), 65% had stage II/III disease, 37% had anthracycline, and 72% received primary prophylaxis with G-CSF. Of the 497 participants, 60 (12%) reported falls (median 1.0 [1-6]) at baseline, and 114 (23%) were hospitalized during chemo (median 1.0 [1-4]). The most common toxicities that resulted in hospitalization were febrile neutropenia (25%), anemia (13%), dehydration (13%), and fatigue (13%). Women who fell in the 6 months prior to chemo had greater odds (adjusted OR = 2.69, 95% CI 1.42-5.11, $p = 0.003$) of being hospitalized during chemo compared to women who did not fall. **Conclusions:** In this cohort of older women with early breast cancer, fall history prior to chemo was associated with an increased risk of hospitalization during chemo, independent of sociodemographic and clinical factors. Oncologists do not routinely assess fall history when considering chemo in older adults. Screening for falls is a quick, simple, and important indicator of vulnerability that oncologists may use to identify patients at risk for hospitalization during chemo and inform personalized, patient-partnered treatment decisions. Clinical trial information: NCT01472094. Research Sponsor: U.S. National Institutes of Health; Breast Cancer Research Foundation; Center for Cancer and Aging.

The association of the comorbidity polypharmacy score (CPS) with functional limitations, frailty, and mortality in older adults with gastrointestinal malignancies. *First Author: Brian Westbrook, University of Alabama at Birmingham, Birmingham, AL*

Background: Older adults share a growing burden of cancer morbidity and mortality. The presence of comorbid medical conditions and polypharmacy may present significant challenges to cancer management for older adults. Although geriatric assessment (GA) is recommended to personalize treatment for older adults with cancer, it remains underutilized in routine oncology practice, and how best to measure comorbidity and polypharmacy remain unknown. The Comorbidity Polypharmacy Score (CPS), which is the sum of the number of comorbid medical conditions and medications for a patient, has been validated in other medical fields. Here we review the association of CPS with key outcomes among older adults with gastrointestinal (GI) malignancy. **Methods:** The Cancer and Aging Resilience Evaluation (CARE) tool is a brief, patient-completed GA developed for older adults with cancer at the University of Alabama at Birmingham (UAB). For patients enrolled in the CARE registry, diagnosed with a new GI malignancy between September 2017 and April 2021, we calculated a CPS based upon the number of patient-reported medical comorbid conditions and daily medications. Patients were separated into two groups, those with CPS ≥ 15 , or high-risk, and those with CPS < 15 . Multivariable analyses were adjusted for age, sex, race, cancer type, and cancer stage, and were performed to examine the potential association between high-risk CPS and falls, functional limitations, frailty, and mortality. **Results:** 548 patients were included in this study with a mean age of 69.7 years; 44.9% female and 23.9% Black. Common GI malignancies included colorectal (30.8%), pancreatic (25.5%), hepatobiliary (17.7%), and gastroesophageal (10.8%). Patients with CPS ≥ 15 were more likely to report falls (adjusted odds ratio [aOR] 3.39, 95% CI 1.91-6.02), dependence in activities of daily living (ADL) (aOR 3.07, 95% CI 1.67-5.66) and instrumental ADL (aOR 3.81, 95% CI 2.02-7.20), and have frailty (aOR 5.17, 95% CI 2.84-9.39). There was not a statistically significant association with either six-month or twelve-month survival. **Conclusions:** CPS was associated with falls, functional limitations, and frailty, but not survival, among older adults with GI malignancies. This association highlights the potential role of CPS as an efficient screening tool for older adults with cancer who would benefit from more comprehensive comorbidity and medication review. Association of sarcopenia and treatment tolerability in older adults with advanced cancer: Secondary analysis of a nationwide NCI Community Oncology Research Program (NCORP) randomized clinical trial. *First Author: Richard Francis Dunne, Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY*

Background: Sarcopenia (sarc) is defined by reduced muscle function paired with low muscle mass or quality. Sarc is common in older adults, but the relationship between sarc and treatment tolerability in older patients (pts) with cancer has not been established. This secondary analysis of our nationwide University of Rochester NCORP Research Base randomized trial examines whether pre-treatment sarc was associated with treatment toxicity and survival in older pts with advanced cancers. **Methods:** Pts aged 70 and older with incurable solid tumors and lymphoma initiating a new high-risk systemic treatment were enrolled in GAP70+ (NCT02054741). GAP70+ was a cluster randomized trial evaluating whether a geriatric assessment intervention can reduce cancer treatment toxicity. This secondary analysis included 161 pts with baseline computed tomography (CT) scans and physical function testing. Sarc was defined as low muscle strength (5-time Chair Stand Test > 16.7 seconds) with reduced muscle mass (BMI and sex-specific cutoffs, cm/m²) or low muscle quality (Hounsfield units [HU] average radiodensity thresholds) utilizing validated cross-sectional CT imaging metrics. Sarc was defined as severe in presence of reduced physical performance (Timed-Up-And-Go > 13.5 seconds). We evaluated if the proportion of pts experiencing any grade 3-5 toxicity in the first 3 months of treatment using Common Terminology Criteria for Adverse Events (CTCAE) V4.0 was higher in those with sarc than those without sarc. Multivariate logistic regression was used to further explore this relationship. Multivariate Cox regression analysis was performed to evaluate the association of sarc and severe sarc with 1-year survival. **Results:** Mean age of the 161 participants included in this cohort was 76.6 years and 60.9% of were male; over half had gastrointestinal (34.8%) or lung cancer (23.6%). Sarc was found in 91 of 161 (56.5%) pts; 54 had severe sarc. Pts with sarc did not experience significantly more grade 3-5 toxicity compared to those without sarc (79.1% vs. 71.4%, $p = 0.26$). However, pts with sarc experienced more grade 3-5 non-hematologic toxicity (63.7% vs. 44.3%, $p = 0.01$) on univariate and multivariate analysis (OR 2.2, CI 1.1-4.5, $p = 0.02$). The association between sarc and worse survival at 1-year was not statistically significant (OR 1.5, CI 0.9-2.4, $p = 0.13$). Those with severe sarc did demonstrate significantly worse 1-year survival on multivariate analysis (HR 1.8, CI 1.1-2.9, $p = 0.02$). **Conclusions:** Older pts with cancer and sarc were more likely to suffer serious non-hematologic toxicity from cancer treatment. Furthermore, those with severe sarc had significantly worse survival. Evaluation for sarc before initiating treatment in older adults could help oncologists identify pts at higher risk of toxicity and poor survival. Clinical trial information: NCT02054741. Biologic profile to predict overall survival in non-metastatic breast cancer: A latent class analysis on aging biomarkers. *First Author: Claire Falandry, Unité d'Oncogériatrie, Centre Hospitalier Lyon Sud and CarMeN laboratory of Lyon University, Pierre-Benite, France*

Background: The aging process is heterogeneous and the result of different biological mechanisms. Blood biomarkers involved in the aging process, aside from comprehensive geriatric assessment, may help clinicians when facing equivocal therapeutic decisions, for example adjuvant treatment at high risk of toxicities. **Methods:** This study was conducted on a previously published cohort (PMID 25989735) including 162 patients aged ≥ 70 years ("Old") and 82 patients aged ≤ 60 years ("Young") with newly diagnosed non-metastatic breast cancer. Serum samples collected from all patients at breast cancer diagnosis, before any treatment were available from the extensive Leuven blood biobank. Overall survival was evaluated with October 7, 2022 as data cutoff. A panel of blood aging biomarkers attributed to inflammation: IL6, MCP1, RANTES, telomere shortening: telomeric DNA ratio T/S, telomeric dysfunction: CRAMP, chitinase activity, and anabolism : IGF1. Considering a high risk of collinearity, we performed a latent class analysis (LCA) on the whole cohort, to delineate the respective roles of inflammaging, replicative senescence and sarcopenia on patient clusters. **Results:** In univariate analysis were significantly associated with a poorer survival: high MCP1, hazard ratio (HR) = 1.57 (95%CI 1.32-1.87), high chitinase activity, HR = 1.33 (95%CI 1.12-1.57), and low IGF1, HR = 1.76 (95%CI 1.47-2.11). The biomarkers correlation matrix identified a significant correlation of Chitinase activity with MCP1, IGF1, CRAMP; of CRAMP with IL6; and IGF1 with T/S ratio. LCA identified 2 biologic profiles within the population, representing 137 (56.1%, class 1) and 107 (43.9%, class 2) patients. Class 1 was associated with a significantly poorer overall survival: HR = 3.52 (95%CI 2.28-5.45), and age-adjusted HR = 1.77 (95%CI 1.12-2.80). The best predictors for class 1 membership were low IGF1 (89%), high MCP1 (82%), high chitinase activity (79%), high IL6 (69%). Class 1 represented 77% of the "Old" and 15% of the "Young" populations. **Conclusions:** Our results delineate an unfavorable biologic profile that transcends chronological age and significantly predicts a poorer overall survival, underpinned by markers of both inflammaging, telomeric dysfunction and sarcopenia. The strong correlation between markers argues for a unique underlying biological pathway. Noteworthy, high IGF1, usually considered as a risk factor for breast cancer progression, was associated with a better prognosis. Low IGF1, high chitinase activity and high MCP1 appear as promising predictive biomarkers. Defining an abnormal geriatric assessment for older adults with cancer: Which deficits matter most? *First Author: Anthony Carrozzi, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: At present, there is no universal, objective, and evidence-based definition of what constitutes an abnormal geriatric assessment (GA) in geriatric oncology (GO). In the literature, a threshold number of abnormal GA domains (ranging from 1-4) is often used to define an abnormal GA. However, it is not well-established whether having a specific number of abnormal domains more frequently leads to treatment plan modification (TPM), a key goal of GA, or if particular domains have a greater impact on TPM. The primary objectives of this study are: (1) to determine how well the current definitions of an abnormal GA predict TPM following GA, and (2) to identify particular GA domains associated with TPM. **Methods:** A retrospective review of the GO clinic database at Princess Margaret Cancer Centre was conducted. All new patients seen in clinic from May 22, 2015 to June 10, 2022 who met the following criteria were included: (1) referred for treatment decision making, (2) received a complete GA, and (3) had a proposed oncologic treatment plan. Demographic, oncologic, and GA-domain variables were extracted. Univariate and multivariate logistic regression modelling was conducted using SPSS to determine each variable's association with TPM; age, sex, frailty (VES-13) score, and treatment intent were included in all multivariate models. Area under the curve (AUC) was calculated for each model. **Results:** The study cohort ($n = 736$) had a mean age of 80.7 years (61-100), 46.1% was female, and 78.3% had a VES-13 score indicating vulnerability. In univariate analysis, age, VES-13 score, disease stage, treatment intent, all GA domains (except Medication Optimization and Social Supports), and all threshold numbers of abnormal domains (except 1 and 7) were significantly associated (p -value < 0.050) with TPM. The best-performing threshold number of abnormal domains in univariate analysis was 4 (AUC 0.628). Overall, the best-performing multivariate model based on AUC was the model containing all 6 significant GA domains (AUC 0.710). In this model, age, treatment intent, Comorbidities, Falls Risk, and Cognition were independently associated with TPM (p -value < 0.05). The multivariate model with a threshold of 4 abnormal domains alone had an AUC of 0.689 and age, VES-13 score, treatment intent, and the threshold were independently associated with TPM. Of the models which included a single GA domain plus the threshold, the models with Comorbidities and Cognition performed best, having AUCs of 0.699 and 0.700, respectively. **Conclusions:** Overall, our results suggest that an abnormal GA (leading to TPM) may be best defined as one with abnormalities in the domains of Comorbidities, Falls Risk, and Cognition. In terms of a strictly numerical threshold, a GA may be best defined as abnormal if at least 4 GA domains are abnormal. When at least 4 GA domains are abnormal, abnormalities in Comorbidities and Cognition appear to best predict TPM. Associations of frailty with overall survival (OS) and functional decline among older adults with non-small-cell lung cancer (NSCLC) receiving chemotherapy, immunotherapy, and/or targeted therapy. *First Author: Howard Jinsoo Lee, University of California, San Francisco, San Francisco, CA*

Background: Among older adults with cancer receiving chemotherapy, frailty indices can predict poor outcomes including survival and toxicity. Given the increasing use of immunotherapy and targeted therapy to treat NSCLC, we assessed the prognostic importance of frailty among older adults with NSCLC receiving systemic therapy. **Methods:** This multi-site prospective cohort study enrolled adults age ≥ 65 with advanced NSCLC starting chemotherapy, immunotherapy, and/or targeted therapy with non-curative intent. Patients completed geriatric assessments pretreatment and at 1, 2, 4, and 6 months. We constructed a 47-item deficit-accumulation frailty index including pretreatment demographic, geriatric assessment, and clinical factors using established methodology. Frailty scores ranged from 0 (no frailty deficits) to 1 (all frailty deficits present). We categorized patients as robust (< 0.2), pre-frail ($0.2-0.34$), or frail (≥ 0.35). The primary outcome was OS. Secondary outcomes included treatment-related grade ≥ 3 adverse events (AE), unplanned hospitalization, and functional decline in instrumental activities of daily living (IADL). We conducted a Kaplan-Meier survival analysis to estimate OS by frailty group and Cox proportional hazards models adjusting for treatment type. We used logistic regression models to evaluate the association of frailty with secondary outcomes adjusting for treatment type. **Results:** Among 149 patients, median age was 73 (range 65-94). During the study, 32% received targeted therapy, 29% immunotherapy, 27% chemoimmunotherapy, and 12% chemotherapy. Overall 43% of patients were robust, 38% pre-frail, and 19% frail. Frailty was associated with Asian race, lower education, Medicaid insurance, and no prior NSCLC surgery. Notably, frailty was not associated with age or treatment type. Median OS was 18.7 months overall: not reached for robust patients, 8.9 months for pre-frail, and 5.6 months for frail patients. Adjusting for treatment type, pre-frail (HR 2.11, 95% CI 1.24-3.60; $p = 0.006$) and frail (HR 2.86, 95% CI 1.52-5.39; $p = 0.001$) patients had worse OS compared to robust patients. During treatment, 29% developed a grade ≥ 3 AE, 31% had an unplanned hospitalization, and 41% developed IADL decline. Pre-frail/frail patients were more likely to develop IADL decline (HR 2.18, 95% CI 1.02-4.68; $p = 0.04$) than robust patients, but there were no differences in toxicity or hospitalization. **Conclusions:** Frailty is prognostic for OS among older adults with advanced NSCLC receiving systemic therapy across treatment types and predicted IADL decline. Frailty assessment before initiation of systemic therapy may help identify older adults with advanced NSCLC at higher risk of poor outcomes to inform decision making, individualize anticipatory guidance, and optimize supportive care. Poster Session

Exploring decisional control preferences in older patients with cancer and their caregivers. *First Author: Sofiia Hryniv, University of Rochester, Rochester, NY*

Background: Shared decision making is preferred by many patients but it is often viewed from the lens of the patient and physician dyad only. Caregivers often support cancer decision-making, although their decision control preferences are not typically considered. We explored decisional control preferences of older patients with cancer and their caregivers, and examined concordance in preferences of the dyad, as well as patient, caregiver, physician factors associated with concordance. **Methods:** We utilized data from a national geriatric assessment (GA) cluster-randomized trial (NCT 02054741; PI: Mohile; funding NCI UG1CA189961) that recruited patients aged ≥ 70 with incurable cancer, their caregivers, and oncologists. Controlled Preferences Scale (CPS) was used to assess shared decision making preferences. Both patients and caregivers were asked about the role of patients (Patient-role CPS) and caregiver (Caregiver-role CPS) in the decision making process. Patient-role CPS options were 1) doctor makes the decisions, 2) doctor makes the decisions with patient's input, 3) equally shared decision, 4) patient makes the decisions with doctor's input, 5) patient makes the decisions. Caregiver-role CPS options were 1) doctor makes the decisions, 2) patient makes the decision with doctor, 3) patient and caregiver make the decisions with doctor, 4) caregiver makes the decisions with doctor. Matching responses of the dyads for each CPS question were considered concordant. We used descriptive statistics to summarize CPS for patients and caregivers and the concordance between them. We utilized logistic regression to assess dyads' sociodemographic information, patients' GA and physicians' practice characteristics associated with patient-caregiver CPS concordance. **Results:** Enrolled dyads with completed CPS were included ($N=332$); mean age (SD) of patients and caregivers was 76.6 (5.3) and 66.6 (12.2). Women constituted 39% of patients and 76% of caregivers. Patient-role CPS for patients' (and caregivers') were 11% (6%) for doctor makes the decisions, 33% (28%) for doctor makes the decisions with patient's input, 45% (49%) for equally shared, 9% (14%) for patient makes the decisions with doctor's input, 2% (3%) for patient makes the decision. Patients' (and caregivers') answers on caregiver-role CPS were 20% (19%) for doctor makes the decisions, 18% (28%) for patient makes the decisions with doctor, 61% (52%) for patient and caregiver make the decisions with doctor and 1% (1%) for caregiver makes the decisions with doctor. Dyads concordance occurred in 46% of patient-role CPS and 54% of caregiver-role CPS, indicating moderate concordance. No baseline factors were associated in dyad concordance for either the patient-role or caregiver-role CPS. **Conclusions:** Clinicians should inquire about decisional control preferences of patients and caregivers in order to optimally support shared decision making. Clinical trial information: NCT02054741. Research Sponsor: U.S. National Institutes of Health.

Satisfaction in older patients by geriatric assessment using a novel tablet-based questionnaire system: A cluster-randomized, phase III trial of patients with non-small-cell lung cancer (ENSURE-GA study; NEJ041/CS-Lung001). *First Author: Sayo Soda, Department of Pulmonary Medicine and Clinical Immunology, Dokkyo Medical University School of Medicine, Tochigi, Japan*

Background: To provide optimal treatment for older cancer patients, it is necessary to carry out a geriatric assessment (GA) to evaluate geriatric syndrome. However, GA is not widely performed because it requires expertise. In this ENSURE-GA study, we evaluated if providing a GA summary and recommendations for GA-guided interventions using a novel tablet-based questionnaire system improved satisfaction about communication with physicians for older patients with non-small-cell lung cancer (NSCLC). **Methods:** Patients with NSCLC who were incapable of radical treatment aged 75 or older were enrolled. All patients underwent a standardized GA using a tablet before starting treatment. Participating institutions were cluster-randomized into the intervention group and the control group. In the intervention group, GA summary and recommendations for GA-guided interventions were immediately returned to guide physicians in selecting treatments and interventions. The control group did not provide a GA summary. The primary outcomes were difference in patient satisfaction pre-treatment and percent change pre- and post-treatment according to the HCCQ questionnaire. **Results:** A total of 1,021 patients from 78 institutions in Japan were enrolled between 2019–2022. There were no differences in patient backgrounds between the intervention group and the control group: mean age 80.1 yrs. vs. 80.0 yrs.; male 64.1% vs. 66.8%; adenocarcinoma 70.4% vs. 64.8%; and performance status 0-1, 82.4% vs. 79.0%, respectively. All GA domain evaluation results, such as ADL and cognitive function, also did not differ between the two groups. Pre-treatment satisfaction scores were significantly higher in the intervention group than in the control group (29.9 vs. 29.1, $p = 0.003$). There was no significant difference in the mean percent change between the two groups (-0.13 vs. 2.38 , $p = 0.165$). **Conclusions:** Providing the oncologist with a GA summary and recommendations for GA-guided interventions improved patient satisfaction from the start of treatment. A novel system using a tablet may be effective at promoting GA more widely. Clinical trial information: UMIN0000037590. Research Sponsor: Japan Agency for Medical Research and Development.

Association of nutrition with psychological health and quality of life among older adults with advanced cancer. *First Author: Surbhi Singhal, Stanford Hospital & Clinics, Stanford, CA*

Background: Impaired nutrition is associated with greater treatment toxicity and reduced overall survival in patients with advanced cancer. We aimed to evaluate the association of impaired nutrition with psychological health and quality of life among older adults with advanced cancer who were starting cancer treatment with palliative intent. **Methods:** This secondary analysis was performed on baseline data from a nationwide cluster randomized clinical trial (ClinicalTrials.gov identifier: NCT02107443; PI: Mohile; funding NCI UG1CA189961). Adults age ≥ 70 with advanced cancer and ≥ 1 geriatric assessment impairment were enrolled from 2014 to 2017. Patients with BMI < 21 kg/m², $> 10\%$ involuntary weight loss in the past 6 months, or Mini Nutritional Assessment Short Form (MNA-SF) score of ≤ 11 were considered to have impaired nutrition. We used separate multivariable linear regressions to evaluate the association of impaired nutrition with each measure of psychological health and quality of life, which included Geriatric Depression Scale (GDS-15, range 0-15), Generalized Anxiety Disorder-7 (GAD-7, range 0-21), NCCN Distress Thermometer (NCCN DT, range 0-10) and Functional Assessment of Cancer Therapy-General (FACT-G, range 0-108). Analyses were adjusted for baseline patient demographics, clinical characteristics, and geriatric assessment. **Results:** Among 541 patients, mean age was 77 (range 70-96) and 60% had impaired nutrition. Among the 326 patients with impaired nutrition, 95% had MNA-SF ≤ 11 , 23% had $> 10\%$ weight loss in the last six months, and 20% had BMI < 21 kg/m². Mean baseline GDS-15 was 3.1 (standard deviation [SD] 2.7), GAD-7 was 2.9 (SD 4.0), NCCN DT was 2.9 (SD 2.7), and FACT-G was 80 (SD 14). In the adjusted model, compared to those with normal nutrition, older adults with impaired nutrition had greater depression (mean 0.65 points higher on the GDS-15, $p < 0.01$) and lower quality of life (mean 6.0 points lower on the FACT-G, $p < 0.01$). There was insufficient evidence of an association between nutrition and anxiety ($\beta = 0.67$, $p = 0.06$) or distress ($\beta = 0.26$, $p = 0.28$). **Conclusions:** Recognition of malnutrition by oncology providers is crucial for older adults with advanced cancer. Impaired nutrition is associated with greater depression and lower quality of life among older adults with advanced cancer. Tailored resources to improve psychological health and quality of life are needed to support older adults with impaired nutrition receiving cancer treatment. Racial differences in muscle measures and survival among older adults with GI malignancies. *First Author: Gabriel Aleixo, Cleveland Clinic Foundation, Cleveland Heights, OH*

Background: Sarcopenia (low muscle mass) and myosteatosis (fat infiltration of muscle) can be assessed from routinely obtained Computed tomography (CT) images and are independent predictors of chemotherapy toxicities and survival among patients with gastrointestinal (GI) malignancies. However, most studies to date have consisted of predominantly white populations. Therefore, the role of sarcopenia and myosteatosis among racial minority populations is unknown. Our objective was to examine racial differences in muscle measures and their association with survival among older adults with GI malignancies. **Methods:** This is a prospective cohort study of older adults with GI cancers from the University of Alabama at Birmingham. Single slices of axial CT images from L3 segments were analyzed using Slice-O-Matic software. Skeletal muscle area (cm²) was divided by height to obtain the skeletal muscle index (SMI, cm²/m²). Skeletal muscle radiodensity (SMD) in Hounsfield units (HU) was used to approximate muscle composition. Sarcopenia (low SMI) and myosteatosis (low SMD) were defined based on standard cut-offs developed in a cohort of GI malignancies (Martin et al., JCO 2013). We compared differences in muscle measures between non-Hispanic (NH) White and NH Black participants. We utilized Cox models, separated by race, to examine the impact of muscle measures on survival. We adjusted for age, sex, education, cancer type, cancer stage, lines of therapy, and comorbidities. **Results:** Six hundred sixty patients were included, 76% NH White and 24% NH Black. The median age was 69.4 years, 35% had colorectal cancer, and 42% had stage IV disease. NH Black patients had higher SMD (41.7 vs. 38.3 HU; $p < 0.001$) and lower rates of myosteatosis (40% vs. 27%; $p = 0.04$) but similar SMI (42.3 vs. 41.1 cm²/m²) and rates of sarcopenia (58% vs. 55%). In stratified Cox models, each 5 HU unit increase in SMD was associated with reduced risk of all-cause mortality of NH black patients (HR 0.88; 95% CI 0.80-0.98 $p = 0.02$) and not in NH White patients (HR 0.95; 95% CI 0.88-1.01; $p = 0.14$). Meanwhile, each 5-unit increase in SMI was associated with improved survival in NH White patients (HR 0.91; CI 0.85-0.98; $p = 0.03$) but not in NH Black patients (HR 0.89 CI 0.78-1.03 $p = 0.13$). When using existing cut points for sarcopenia and myosteatosis, NH White patients with sarcopenia had worse survival (HR 1.42; CI 1.04-1.92; $p = 0.02$), but sarcopenia among NH black patients was not associated with worse survival (HR 1.16 95% CI 0.62-2.16 $p = 0.64$). Myosteatosis was not associated with worse survival in either NH white (HR 95%CI 0.95-1.68 $p = 0.10$) or NH black patients (HR 1.61 95%CI 0.88-2.95 $p = 0.12$). **Conclusions:** Muscle measures may differ by race and have different associations with survival by racial group. Therefore, it is essential to develop cut points for muscle measures incorporating race. Research Sponsor: U.S. National Institutes of Health; Doris Duke Charitable Foundation; CARES program at UAB.

Association between food insecurity and frailty among older adults with gastrointestinal malignancies: The CARE Registry. *First Author: Mackenzie Elisha Fowler, University of Alabama at Birmingham, Birmingham, AL*

Background: Food insecurity is associated with higher gastrointestinal (GI) cancer mortality, but its association with frailty, a known predictor of premature mortality among older adults with cancer, is less understood. Our objective was to evaluate the association between food insecurity and frailty among older adults with GI malignancies. **Methods:** In this cross-sectional analysis, we included 424 older adults ≥ 60 y recently diagnosed with GI cancer undergoing self-reported geriatric assessment (GA) at their first pre-chemotherapy visit to the University of Alabama at Birmingham oncology clinic. Food insecurity was the exposure of interest, defined using the 2019 United States Department of Agriculture Economic Research Service (USDA ERS) Low-Income, Low-Access (LILA) measure, which classifies census tracts based on income and/or access to food stores at various distances by urban-rural status. The primary outcome was frailty measured via the CARE Frailty Index, a composite measure based on the proportion of deficits across several GA measures (44 items in total). Frailty was dichotomized as frail or robust/pre-frail. We examined the association between LILA and frailty with modified Poisson regression accounting for census tract clustering. **Results:** Median age at study participation was 69 (IQR: 64, 76), 56.6% were male, 27.2% were non-Hispanic black, 31.4% had colorectal, 28.1% had pancreatic cancer, and 71.7% presented with stage III/IV disease. LILA versus non-LILA had a higher proportion of participants who were non-Hispanic Black (52.1% vs. 11.0%, $p < 0.001$) and lower educated (high school or less: 50.6% vs. 35.0%, $p = 0.020$). After adjustment for age, race, sex, cancer type and stage, LILA was associated with 37% higher risk of frailty (RR: 1.37, 95% CI: 1.05, 1.80) versus non-LILA. Analysis of LILA sub-categories revealed that the overall effect may be driven by low income + low access at 1 mile for urban/10 miles for rural areas (RR: 1.47, 95% CI: 1.12, 1.94) and low income + low access at 0.5 mile for urban/10 miles for rural areas (RR: 1.39, 95% CI: 1.05, 1.85). Low income + low access at 1 mile for urban/20 miles for rural areas, low income + low access with a vehicle or at 20 miles, low income only, or low access only did not demonstrate a significant difference. **Conclusions:** Low income and low access to food stores is associated with higher risk of frailty among newly diagnosed older adults with GI cancers prior to systemic treatment. Intervening on food insecurity at the local level, particularly in areas with low income and low access, may be a target for improving rates of frailty among older adults with GI cancers. Future studies are needed to determine causality. Research Sponsor: U.S. National Institutes of Health; Agency for Healthcare Research and Quality.

Peaceful acceptance of illness among older adults with cancer. *First Author: Elizabeth Gilbride, University of Rochester, Rochester, NY*

Background: Greater illness acceptance is associated with lower levels of psychological distress and higher rates of completion of advance care planning in adults with advanced cancer. However, studies on factors associated with illness acceptance among older adults with advanced cancer are limited and historically have not explored its relationship with caregiver or physician characteristics, despite the important role caregivers and oncologists play in patient illness acceptance. We aimed to evaluate the associations of patient, caregiver, and physician-related factors with illness acceptance among older adults with cancer. **Methods:** We utilized data from a national geriatric assessment cluster-randomized trial (NCT 02054741; PI: Mohile; funding NCI UG1CA189961). We recruited patients aged 70 years or over with stage III or IV incurable solid tumors or lymphoma and at least one geriatric assessment domain impairment as well as their caregivers. Illness acceptance was assessed using the 5-item Peace, Equanimity, and Acceptance in the Cancer Experience (PEACE) questionnaire (range 5-20). Higher PEACE score indicates greater illness acceptance. Multiple linear regression was used to assess the associations of patient, caregiver, and physician-related variables with PEACE. Variables included patient sociodemographic factors, geriatric assessment variables, and estimated life expectancy; caregiver sociodemographic variables, anxiety, depression, and physical function; and oncologist years in practice and comfort with geriatrics. **Results:** We included 333 patient-caregiver dyads; mean age (SD) of patients and caregivers, respectively, were 76.8 (5.4) and 66.6 (12.1). Approximately 27%, 26%, and 16% of patients had lung, gastrointestinal, and genitourinary cancers, respectively. Mean PEACE score was 17.4 (2.5), indicating relatively high illness acceptance (Table). On regression analysis, patient psychological impairment domain (including both anxiety and depression) ($B = -0.89$; $p > 0.01$), patient's lower estimated life expectancy (≤ 1 vs. > 5 years, $B = 1.19$, $p = 0.02$), and lower caregiver education attainment ($\leq$ high school vs. college; $B = -0.86$; $p < 0.01$) were associated with a lower illness acceptance. No physician variables were associated with PEACE. **Conclusions:** A better understanding of illness acceptance and its associated factors can facilitate patient-caregiver dyadic interventions to improve illness acceptance. Research Sponsor: U.S. National Institutes of Health; PCORI.

PEACE questionnaire.				
	Not at all	To a slight extent	To some extent	To a large extent
To what extent are you able to accept your diagnosis of cancer?	0.3%	3.3%	25.5%	70.9%
To what extent would you say you have a sense of inner peace and harmony?	3.3%	8.1%	43.5%	45.0%
To what extent do you feel that you have made peace with your illness?	4.5%	8.7%	39.0%	47.7%

Regorafenib in older adults with metastatic colorectal cancer: A multi-center, single arm phase II trial. *First Author: Nabeel Badri, Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY*

Background: Metastatic colorectal cancer (mCRC) is a leading cause of death, particularly in older adults. Regorafenib (REGO) is an FDA-approved oral multi-kinase inhibitor for refractory mCRC based on the CORRECT trial results, but older adults were underrepresented with a median age of 61 (54–67). This study aimed to evaluate REGO safety in older adults with mCRC and assess the feasibility of using geriatric assessment (GA) to predict toxicity risk. **Methods:** 27 subjects (PTs) enrolled (median age 73, range 65-85) and started at 120mg of REGO for 21 days of a 28-day cycle with provider discretion to escalate to full dose of 160mg after cycle 1. GA was conducted at enrollment, 4 weeks later, and then every 3 months to monitor for any deterioration. GA assessed 8 geriatric domains (comorbidity, functional status, physical performance, cognition, psychological state, nutrition, medication review, and social support) using validated tools. Primary objective was to assess grade 3-5 toxicity rate, with secondary objectives evaluating REGO efficacy and exploring baseline GA and toxicity risk associations. Kaplan-Meier method was used to estimate median overall survival (OS) and progression-free survival (PFS) from date of consent. Continuous GA measures were compared using non-parametric Wilcoxon rank-sum test, and binary GA measures were compared using Fisher's exact test. **Results:** Of 27 PTs enrolled, 15 were male, 12 were female, and 19 identified as white. At baseline, 77.7% of PTs had at least 3 (1-9) GA impairments. Physical performance (80.8%), comorbidity (75%), and cognition (69.2%) were the most prevalent impaired GA domains. 40% required dose reduction by end of cycle 2, and none escalated to full dose. 55% of PTs completed cycle 3. Main reasons for drug discontinuation were disease progression (80%) and toxicity (12%). 74.1% of PTs experienced at least one treatment-related grade 3-4 toxicity. Fatigue (33%), hypertension (30%), and hand-foot syndrome (15%) were the leading grade 3-4 toxicities. Median OS was 5.6 months (95% CI: 3.6-12.2m), and median PFS was 2.8 months (95% CI: 2.5-3.4m). There was no significant difference in baseline GA measures between those who experienced toxicities and those who did not. No statistically significant toxicity risk was associated with any baseline GA impairment. The prevalence of impaired mini-nutritional assessment increased over 4 weeks (58% to 91%, $p < 0.01$), and median Short Physical Performance Battery (SPPB) scores decreased (7 to 6, $p = 0.03$). **Conclusions:** The study found that older adults with mCRC had comparable survival with REGO but experienced high toxicity. This may be ameliorated by recently published step-wise REDOS dosing method and should be considered in older adults with mCRC. The study confirms the feasibility of implementing GA within clinical trials. More data is needed on the role of GA in predicting toxicity with targeted therapies. Clinical trial information: NCT02466009. Research Sponsor: Bayer.

An evaluation of the financial toxicity amongst older patients with cancer in India. *First Author: Anant Ramaswamy, Tata Memorial Hospital (HBNL), Mumbai, India*

Background: Financial toxicity (FT) of cancer is prevalent among older patients in high-income countries, but there is no data about the financial burden faced by older patients in India. This study aimed to explore the FT of cancer among older Indian patients. **Methods:** This was a cross-sectional observational study conducted in the geriatric oncology clinic of Tata Memorial Hospital (Mumbai, India). Patients aged 60 years and above with cancer were included. Patients and their relatives were enquired regarding their occupations, monthly income, and source of funding for cancer treatment. The modified Kuppuswamy scale was used for stratification of socio-economic status (SES). The financial burden was evaluated using the Comprehensive Score for Financial Toxicity-Functional Assessment of Chronic Illness Therapy (COST-FACIT) scale. In addition, the Consumer Financial Protection Bureau Financial Well-Being Scale and the 28th question of QORTC QLQ-C30 were used to assess the financial quality of life. **Results:** Between June 2022 and January 2023, 498 patients were included. The median age was 67 (IQR, 63-72) years, and 360 (72.3%) were male. Common malignancies included gastrointestinal (199, 40.0%), lung (169, 34.0%) and urological (63, 12.7%); 320 (64.4%) had metastatic disease. According to the modified Kuppuswamy scale, most of the participants belonged to upper-lower SES (223, 44.8%), followed by lower-middle (115, 23.1%), upper-middle (97, 19.5%), lower (59, 11.8%) and only 4 (0.8%) belonged to upper SES. The source of funding was mostly from family members (264, 53.9%), insurance (72, 14.7%), while 59 patients (12.0%) did not require external support. Sixty-one (12.4%) had to borrow money, twenty-one (4.3%) participants had taken a loan, and 13 (2.6%) had sold their assets for the purposes of treatment. Moderate-severe burden on COST-FACIT was present in 165 (33.1%), whereas 333 (66.9%) experienced no or mild burden. High FT was associated with lower socioeconomic status (OR: 4.69, 95%CI 2.47-8.91, p-value < 0.001), poor financial well-being (OR: 9.35, 95%CI 5.52-16.46, p-value < 0.001) and poor score on Financial quality of life (OR: 5.16, 95%CI 3.39-7.86, p-value < 0.001). **Conclusions:** In older Indian patients with cancer, there is a high prevalence of financial burden and is associated with poor socioeconomic status, poor financial well-being and poor financial quality of life. More than half the patients depended on their family members to meet the cost of cancer treatment. Research Sponsor: None.

Association of emotional support with quality of life, mental health, and survival among older adults with gastrointestinal (GI) malignancies. *First Author: Daniel Clausing, University of Alabama at Birmingham, Birmingham, AL*

Background: Emotional support (ES) is the most frequently reported support need among older adults with cancer. Yet, the association of ES with cancer outcomes is largely unknown. This study examined the association of ES with health-related quality of life (HRQoL), mental health, and survival among older adults with GI malignancies. **Methods:** We included older adults (≥60y) newly diagnosed with GI cancer and undergoing a self-reported geriatric assessment (GA) at first clinic visit. Self-reported ES, measured by the Medical Outcomes Survey was the primary exposure. Outcomes included physical and mental HRQoL as measured by the Patient-Reported Outcomes Measurement Information System® (PROMIS) 10-item global assessment, anxiety and depression as measured by the PROMIS Anxiety and Depression Short Form 4a, respectively, and one-year, two-year, and overall survival. Linear regression evaluated the association between ES and t-scores of physical/mental HRQoL. Logistic regression evaluated the association of ES with anxiety and depression. Models were adjusted for age, race, sex, and cancer type/stage. Kaplan-Meier curves and log-rank tests evaluated the association between ES and survival outcomes. **Results:** Overall, 795 participants were included. The median age was 68 (IQR: 64-74) and patients were 58.0% male, and 74.6% White. The most common cancers included colorectal (37.9%) and pancreatic (30.8%), with mostly advanced staged disease (Stage III/IV: 72.1%). A majority (77.6%) had adequate ES. Patients with inadequate ES were more likely to be Black (31.5 vs. 20.8%, p=0.005), disabled (24.1 vs. 10.4%, p<0.001), and widowed/divorced (54.2 vs. 24.8%, p<0.001). After adjustment, patients with inadequate ES had lower physical and mental HRQoL t-scores (Physical β: -3.35, 95% CI: -5.25, -1.46; Mental β: -2.46, 95% CI: -4.11, -0.81) and higher odds of depression (aOR: 2.22, CI: 1.34-3.69). There was no statistically significant association with anxiety (aOR: 1.15, CI: 0.73, 1.81). No differences were observed between patients with inadequate versus adequate ES in one-year, two-year, or overall survival (Log-Rank tests: one-year, p=0.952; two-year, p=0.606; overall, p=0.584). **Conclusions:** Older adults with inadequate ES have higher odds of poor physical and mental HRQoL and depression, but no difference in survival compared to those with adequate ES. Further work is necessary to determine if interventions to improve ES also improve HRQoL and depression. Research Sponsor: U.S. National Institutes of Health; Doris Duke Charitable Foundation.

Overall survival outcomes in older patients with metastatic breast cancer: A National Cancer Database analysis. *First Author: Rima Patel, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Over the last few decades, improvements in healthcare have increased life expectancy by nearly 10 years resulting in a rise in America's older population. As age is one of the most significant risk factors for the development of cancer, there is a projected increase in the incidence of cancer in the elderly population, with the largest absolute and relative increases in breast cancer (BC). Although treatment advances have improved outcomes for patients with metastatic breast cancer (MBC), patients in clinical trials are often younger and there is limited data for the older population. The goals of this study were to use the National Cancer Database (NCDB) to assess overall survival (OS) in older patients over 75 years of age with MBC and evaluate the impact of tumor features and demographic factors. **Methods:** Women with a diagnosis of BC at age ≥75 years and with metastases at time of initial diagnosis from 2010 to 2019 were identified from the NCDB. Patients were stratified into age subgroups of 75-79, 80-84, and ≥85 years. Chi-square tests were used to compare categorical variables. Kaplan Meier curves were used to determine OS distributions for patients by age, BC subtype and year of diagnosis. Log-rank tests and multivariable cox proportional hazards modeling was performed to assess the difference in OS by BC subtype. **Results:** Of 17,325 eligible women included in the final analysis, 39.4% were 75-79, 30.1% 80-84, and 30.4% ≥85 years of age. We observed an improvement in OS over time, with 5-year OS rates improving from 13.7% in 2010 to 15.2% in 2015, p = 0.017. Three-year OS rates were higher in patients aged 75-79 (34.2%) compared with patients aged 80-84 (28.7%) and ≥85 years (18.6%), p < 0.001. Outcomes varied by BC subtype with better prognosis in patients with hormone receptor (HR)+, HER2-negative BC (3-year OS 35.1%), followed by HR+, HER2+ (32.8%), HER2+, HR-negative (20.6%) and lastly, HR-negative, HER2-negative BC (9.7%), p < 0.001. Based on multivariable analyses, a higher comorbidity index was associated with worse outcomes (HR 1.654 [1.48-1.849], p < 0.0001). Higher income (≥\$63,000) was associated with decreased mortality (HR 0.859 [0.784-0.941], p = 0.0011) compared with lower income (< \$38,000). While the type of cancer facility (academic, community, etc) did not impact mortality, older patients living in metropolitan areas (> 1 million) had improved outcomes (HR 0.829 [0.689-0.996], p = 0.046), compared to those in rural areas. **Conclusions:** We observed a modest though significant improvement in survival outcomes over time in older patients with MBC. Prognosis was better in patients with HR+ BC compared with HR-negative, HER2+, and HR-negative, HER2-negative subtypes. However, outcomes in patients ≥85 years remain poor. Given the lack of clinical trial data in older patients with cancer, future studies should specifically focus on improving outcomes in this population. Research Sponsor: None.

Toxicity and outcomes of ipilimumab plus nivolumab in patients 80 years and older. *First Author: Haley M Meyer, Mayo Clinic in Arizona, Phoenix, AZ*

Background: The combination of ipilimumab and nivolumab (Ipi-Nivo) is a standard of care regimen in many malignancies. However, immune-related adverse events (irAE) are common and are of great concern, especially when treating the elderly population. This subgroup of patients may be at greater risk for serious irAEs and be less able to tolerate the potential treatment side effects. We sought to retrospectively evaluate our experience treating elderly patients ≥ 80 years with Ipi-Nivo to characterize adverse events. **Methods:** A retrospective chart review of the electronic medical records of all patients treated with Ipi-Nivo at the Mayo Clinic Health System was performed. Patients with any solid tumor who received their first dose of Ipi-Nivo at the age of ≥ 80 were included. Records were analyzed for baseline characteristics, cancer type, toxicity, and response to therapy. Differences between continuous and categorical variables were assessed using the students' t-test and the chi-squared test, respectively. Overall survival (OS) was estimated using the Kaplan-Meier method. Cox proportional hazard models assessed the relative contribution of factors to survival after treatment. P values < 0.05 were considered statistically significant. All analyses were performed using SAS V.9.4. **Results:** Forty-six patients met inclusion criteria, 13 females and 33 males. Median age of first dose was 83 (Range: 80 - 94). Sixty-seven percent had an ECOG performance status (PS) 0-1 and 33% had an ECOG PS 2-3. Thirteen (28.3%) patients received 4 cycles of Ipi-Nivo. Cancers included: 18 (40%) melanomas, 10 (21%) mesothelioma, 9 (19.5%) lung cancers, and 9 (19.5%) other types. Thirty-one patients (67%) developed at least one irAE. Of the irAEs, 8 (17.4%) were grade 1, 20 (43.5%) were grade 2, 14 (30.4%) were grade 3, and 3 (6.5%) were grade 4. Systemic steroids were used in 29 (63%) patients. Twenty-six (56.5%) patients were hospitalized for any cause, and 12 (26.1%) were hospitalized due to an irAE. Of the 26 patients hospitalized during treatment, 19 (73%) died within 1 year of discharge; 11 (42%) died within < 1 month of discharge and 3 (12%) died within 1-3 months of discharge. Median OS from the date of first Ipi-Nivo dose was 14.6 months in the ECOG PS 0-1 and 6.5 months in the ECOG PS 2-3. ECOG PS of 0-1 was associated with a significantly decreased risk of mortality (HR [hazard ratio] 0.33, 95 % CI [confidence interval]: 0.15-0.70; p=0.0025) compared to ECOG PS of 2-3. **Conclusions:** This is the first analysis to evaluate the outcomes of Ipi-Nivo in patients ≥ 80 years. Approximately 60% of the patients required systemic steroids and a quarter were hospitalized with grade 3-4 irAEs. As expected, patients with ECOG PS 2-3 did significantly worse than ECOG PS 0-1. Ipi-Nivo should be used with caution in patients ≥ 80 years. Research Sponsor: None.

Association of frailty and high-risk immuno-nutritional score with outcomes in patients with relapsed and refractory multiple myeloma treated with chimeric antigen receptor T-cells. *First Author: Karnav Modi, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Multiple myeloma is a disease of older adults with a median age at diagnosis of 68 years (y). Patients (pts) receiving chimeric antigen receptor T-cell (CAR-T) therapy for relapsed/refractory MM (RRMM) often experience detrimental effects due to frailty, comorbidity, and cumulative toxicities. In this study, we evaluated the prevalence and impact of frailty, defined by the simplified frailty score, (SFS; Facon et al, Leukemia 2020), and immuno-nutritional status, using Glasgow prognostic score (GPS; Proctor et al, Br J Cancer 2011) in a real-world cohort of pts receiving CAR-T therapy for RRMM. **Methods:** We included all pts treated with commercial CAR-T therapy for RRMM between 2021 - 2023 at Moffitt Cancer Center. The SFS and GPS (CRP > 10 mg/dL, 1 point; albumin < 3.5, 1 point) were calculated for all pts at lymphodepletion. Primary endpoints included overall survival (OS) and progression free survival (PFS). Pearson's chi-squared tests or Fisher's exact tests were used to compare association between categorical variables. OS and PFS were estimated using Kaplan-Meier methods; the log-rank test was used to compare OS and PFS, and a cox-proportional model was used for multivariable analysis (MVA). **Results:** A total of 139 pts were included, with a median follow up of 6.3 months (m; range, 0.2 to 20.3 m). Median age was 66 y (IQR, 58-72 y); 38% were ≥ 70 y. Pts were treated with either idecabtagene vicleucel (83%) or ciltaabtagene autoleucel (17%). Around 1/3rd of pts had features of high-risk disease [high disease burden, 30%; high-risk cytogenetics (HR-Cyto), 37%; extramedullary disease (EMD), 37%]. Overall, 30% of pts were categorized as frail and 14% were classified as high-risk GPS (score = 2). There were no significant differences in GPS between older (≥ 70 y) and younger pts (< 70 y; $p = 0.8$). Median OS in the cohort was not reached (NR) and median PFS was 11.7 m. Both frailty and high-risk GPS were associated with inferior PFS (frail vs non-frail, HR 2.0, $p = 0.03$, high GPS vs low/int, HR 1.7 $p = 0.009$) and OS (frail vs non-frail, HR 3.0, $p = 0.006$, high GPS vs low/intermediate, HR 2.1 $p = < 0.001$). The association of GPS with OS remained significant in a MVA, even after adjusting for high-risk disease factors (high disease burden, HR-Cyto and EMD) and frailty. Pts categorized as frail had a lower median PFS of 5.4 m (vs 12.7m non-frail group, $p = 0.025$), and inferior median OS of 9.7 m (vs NR in non-frail, $p = 0.0039$). **Conclusions:** In a real-world setting, frailty affects almost a third of pts with RRMM receiving CAR-T therapy and is associated with inferior PFS and OS. The GPS, a simple immuno-nutritional score, is highly predictive of survival even after adjusting for the presence of high-risk disease. Studies looking at role of pre-habilitation and other modalities to reduce inflammatory burden prior to CAR-T therapy are warranted. Research Sponsor: None.

Understanding treatment toxicity patterns through remote symptom monitoring and examining the effect of frailty in older men with metastatic prostate cancer. *First Author: Mithy Parthipan, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Advancements in metastatic prostate cancer (mPC) treatments have increased survival, but using multiple lines of therapy has increased the prevalence and severity of toxicities. Older men and those living with frailty experience higher symptom burden associated with treatment. Although toxicities have been described in previous trials, much of the focus has been on pain and fatigue among fit and younger men, and only a few trials have examined the effects of frailty on toxicity. Thus, the aims of this study were to (1) understand the prevalence, duration, and changes in symptom severity among older men receiving mPC treatments; and (2) examine differences among frail and non-frail men. **Methods:** Men aged 65+ with mPC starting chemotherapy (chemo), androgen receptor-axis-targeted (ARAT) therapies, or radium-223 (Rad223) from two academic Canadian cancer centres were enrolled in a prospective cohort study. Participants self-reported symptoms daily using the Edmonton Symptom Assessment Scale (ESAS) for the first treatment cycle via internet or telephone. Frailty status was determined using the Vulnerable Elders Survey (VES-13). Study outcomes were the development of moderate-to-severe symptoms (ESAS ≥ 4), their duration, and the proportion of participants who had improvements in symptom severity (ESAS < 4) after reporting moderate-to-severe symptoms at baseline. Outcomes were determined using descriptive statistics. Associations between symptom prevalence, duration, and frailty were assessed using t-tests and chi-square tests. **Results:** 90 men (mean age = 77 $\pm$ 6.1 years, 58% frail (VES-13 ≥ 3)) starting chemo ($n = 34$), an ARAT ($n = 43$), or Rad223 ($n = 13$) were included. The most common moderate-to-severe symptoms across cohorts were fatigue (46.8%), insomnia (42.9%), poor wellbeing (41.2%), decreased appetite (37.1%), and pain (35.9%). These symptoms were numerically higher in frail men, but differences between frail and non-frail were only statistically significant for poor wellbeing (62.5% in frail vs. 31.4% in non-frail, $p = 0.039$). On average, poor wellbeing lasted 6.5 days (SD = 7.6) days, decreased appetite lasted 5.5 days (SD = 4.9), fatigue lasted 5.1 days (SD = 7.3), pain lasted 4.7 days (SD = 5.6), and insomnia lasted 4.6 days (SD = 6.2) across cohorts. Fatigue and pain lasted numerically longer in frail men whereas insomnia, poor wellbeing, and decreased appetite lasted numerically longer in non-frail men, but these differences were not statistically significant. Among participants who reported moderate-to-severe symptoms at baseline, 15.4%, 10.7%, 7.7%, 5.3% and 3.6% had improvements in pain, appetite, wellbeing, insomnia, and fatigue, respectively. **Conclusions:** Understanding temporal patterns of symptoms and the impact of frailty in older men receiving mPC treatments may help inform supportive care approaches. Clinical trial information: NCT04193657. Research Sponsor: Prostate Cancer Canada.

The influence of sex on the impact of age and frailty on acute care use among older adults receiving immune checkpoint inhibitor (ICI) treatment: A population-based study. *First Author: Elizabeth Faour, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: ICIs are commonly used across solid tumors and although better tolerated than chemotherapy, patients may develop immune related adverse events (irAEs) requiring hospitalization. Older adults were poorly represented in trials evaluating ICIs. We previously demonstrated that among older adults receiving ICIs, increasing age was associated with reduced risk of irAE hospitalizations, while frailty was associated with increased acute care use (ASCO 2022). However, sex may impact irAE rates. Here, we evaluated sex-specific differences based on age and frailty, on acute care use and irAEs among older adults receiving ICIs. **Methods:** We performed a retrospective, population-based study of a cohort of patients with cancer, age ≥ 65 , receiving ICIs between June 2012 and October 2018 in Ontario, Canada using administrative data. Databases were deterministically linked to obtain socio-demographic and clinical covariates, and acute care outcomes. Acute care use was defined as emergency department visits or hospitalizations from the start of ICIs to 120 days following last dose; irAE specific hospitalizations were identified using ICD-10 codes. Frailty was assessed using the McIsaac Frailty Index. Using death as the competing risk, multivariable competing risk analyses with Fine Gray sub-distribution hazards evaluated the effect of age and frailty on both acute care use and irAE hospitalizations, adjusted for body mass index (BMI), history of autoimmune condition, comorbidity score, rurality, and hospitalization within 60 days prior to starting ICI, stratified by sex. **Results:** 2737 patients were identified; 60% male. Median age 73 (IQR 69-78); 43% received Nivolumab, 41% Pembrolizumab and 13% Ipilimumab; 53% had lung cancer, 34% melanoma. 70% were robust (R), 26% pre-frail (PF) and 4% frail (F). 72% of patients had an acute care episode and 8% had an irAE hospitalization, which did not differ by sex (72%/8% male; 71%/8% female). Increasing frailty was associated with greater acute care use in males (PF vs R aHR 1.20 [95% CI 1.02-1.40] $p = 0.03$, F vs R aHR 1.42 [1.05-1.91] $p = 0.02$) and females (PF vs R aHR 1.24 [1.03-1.49] $p = 0.02$, F vs R aHR 1.55 [0.99-2.40] $p = 0.05$) but was not associated with irAE hospitalization in either sex. Using age as a continuous variable, increasing age was associated with reduced irAE hospitalizations in males (aHR 0.97 per year [0.94-0.99] $p = 0.04$), but not in females ($p = 0.18$); no significant associations were identified modelling age as a categorical variable. **Conclusions:** Among older adults receiving ICIs, increasing age was associated with reduced rates of irAE related hospitalization in males but not in females, while increasing frailty was associated with increased acute care use among both sexes. Sex should be taken into consideration when evaluating potential toxicity among older adults receiving ICIs. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Feasibility of daily physical activity monitoring and associations with treatment toxicity in older adults with metastatic prostate cancer. *First Author: Gregory Feng, University Health Network, Toronto, ON, Canada*

Background: Accelerometry research suggests physical activity may be associated with treatment toxicity, but generalizability to geriatric oncology is unclear. As many older adults have low levels of physical activity and technology use, further exploration is warranted. This study explores the feasibility of daily physical activity monitoring and the association between step counts and symptoms. **Methods:** Older adults aged 65+ starting treatment (chemotherapy, enzalutamide/abiraterone, or Radium-223) for metastatic prostate cancer were enrolled in a prospective cohort study. Participants reported step counts (measured via smartphone and a free commercial app) and symptoms (Edmonton Symptom Assessment Scale (ESAS)) daily for their first treatment cycle (~1 month). The feasibility of daily monitoring was assessed with descriptive statistics and thematic analysis. The association between a 15% decline in steps (compared to pre-treatment baseline) and the emergence of moderate-to-severe symptoms and pain (ESAS ≥ 4) in the next 24 hours was assessed using logistic regression. The utility of a 15% step count decline in predicting the development of moderate-to-severe symptoms and pain was evaluated using sensitivity and positive predictive value (PPV). **Results:** Of 90 participants, 47 engaged in step count monitoring (mean age 75y; 52.2% participation rate). Daily physical activity monitoring was found to be feasible (90.5% median response rate; 94% retention rate) with numerous patient-reported benefits including increased self-awareness and motivation to engage in physical activity. During the first treatment cycle, instances of a 15% decline in steps were common ($n = 37$, 78.7%), as was the emergence of moderate-to-severe symptoms overall ($n = 40$, 85.1%) and pain ($n = 26$, 55.3%). Overall, daily physical activity did not appear to be significantly predictive of symptoms (OR = 1.8, 95% CI = 0.42-7.74) overall or pain (OR = 0.95, 95% CI = 0.22-3.81). Predictive validity estimates revealed reasonable sensitivity for both moderate to severe symptoms overall (sensitivity = 88.8%, 95% CI = 68.7-95.0; PPV = 73.0%, 95% CI = 58.7-87.3) but poor PPV for pain (sensitivity = 77.8%, 95% CI = 58.6-97.0; PPV = 37.8%, 95% CI = 22.2-53.5). **Conclusions:** Despite recent studies framing physical activity changes as predictive of toxicity, PPV was only poor to fair. However, daily activity monitoring in older cancer patients appears feasible and may have other uses. Clinical trial information: NCT04193657. Research Sponsor: Prostate Cancer Canada.

Associations between sarcopenia and clinical outcomes in men with metastatic castrate-resistant prostate cancer. *First Author: Efthymios Papadopoulos, University Health Network, Toronto, ON, Canada*

Background: Understanding the impact of sarcopenia on clinical outcomes in patients with metastatic cancer will assist clinicians with risk stratification, treatment decision-making, and inform the need for targeted supportive care strategies. Our objective was to comprehensively assess sarcopenia using measures of muscle mass (radiographically) and function (i.e., muscle strength and walking speed) and examine its impact on severe treatment toxicity, time to first emergency room (ER) visit, prostate-specific antigen (PSA) progression, radiographic progression, and overall mortality in men initiating androgen receptor-axis targeted therapy (ARAT) or chemotherapy for mCRPC. **Methods:** This was a secondary analysis of a prospective observational study of older men with mCRPC at the Princess Margaret Cancer Centre. Sarcopenia was defined as the combination of low muscle strength (grip strength < 35.5kg), slowness (walking speed < 0.8m/s), and low muscle quantity or quality prior to treatment initiation. The skeletal muscle index and skeletal muscle density were assessed through computed tomography scans prior to ARAT or chemotherapy initiation to determine muscle quantity and quality, respectively, using published cut-offs. Severe treatment toxicity, unplanned healthcare use, and disease progression were assessed from treatment initiation until treatment termination or loss to follow up. The associations between sarcopenia and severe treatment toxicity (i.e., grade 3+ toxicity) were assessed using multivariable logistic regression. Survival analyses were used to assess the impact of sarcopenia on the time to first ER visit, PSA progression, radiographic progression, and overall mortality. An interaction term for sarcopenia by treatment was introduced in all multivariable models and when necessary, an analysis by treatment was performed. **Results:** In total, 110 men participated, of whom 30 (27.3%) had sarcopenia prior to initiating treatment. Sarcopenia was associated with severe treatment toxicity (adjusted odds ratio (aOR) = 6.26, 95%CI = 1.17-33.58, P = 0.032) and time to first ER visit (adjusted hazard ratio (aHR) = 4.41, 95%CI = 1.26-15.43, p = 0.020) in the group that was initiating ARAT but not chemotherapy. Sarcopenia was a significant predictor of radiographic progression (aHR = 2.39, 95% CI = 1.06-5.36, p = 0.035) and overall mortality (aHR = 2.44, 95%CI = 1.17-5.08, p = 0.018) in the entire cohort. **Conclusions:** Sarcopenia may predict severe treatment toxicity and emergency room visits in men starting ARAT for mCRPC. Additionally, sarcopenia predicts radiographic progression and overall mortality regardless of treatment type in men with mCRPC. Confirmation is needed from large-scale studies. Assessment of sarcopenia can assist clinicians in treatment decision making while identifying high-risk patients that require targeted supportive care strategies. Sedentary lifestyle as a predictor of early death in older adults with cancer: A prospective cohort study with 2692 patients. *First Author: Jurema Telles O Lima, IMIP-Instituto de Medicina Integral Professor Fernando Figueira, Recife, PE, Brazil*

Background: Physical activity is an important aspect of the global health of older adults with cancer (OAC). The aim of this study was to determine sedentary lifestyle as a predictor of early death in OAC. **Methods:** Prospective cohort involving elderly (60+) with cancer, cared for in a public hospital in Pernambuco, from January 2015 to December 2021. Sociodemographic, clinical, and lifestyle variables were considered. The level of physical activity was assessed before cancer treatment by the International Physical Activity Questionnaire (IPAQ), short version, with classification into active (active/very active) and inactive (sedentary/inadequately active) and comprehensive geriatric assessment (CGA). The outcome was death within 180 days. Kaplan-Meier survival curves and Cox multivariate analysis were performed. **Results:** 2692 patients were included, most were men, with family income less than 01 minimum wage in almost 30%. The presence of two or more comorbidities was observed in 70.1% of patients. The main primary sites were prostate (30.8%), breast (17%) and digestive system (25.8%), gynecological system (10.6%), lung (5.9%), and the majority (67.6%) had no metastatic disease. There were 461 deaths (25.7% sedentary and 9.7% non-sedentary). Sedentary lifestyle was an independent risk factor for early death (HR=1.28, 95% CI=1.07-1.64 p< 0.036), controlled by tumor topography and presence or absence of metastasis, presence of polypharmacy and Karnofsky performance scale, recent hospitalization and nutritional status. At 180 days, survival among patients with some level of physical activity was higher (90% (0.88 - 0.92)) than among sedentary patients (74% (0.72 - 0.77, p < 0.01). **Conclusions:** Sedentary lifestyle at the time of cancer diagnosis was an independent risk factor for early death among Older adults with cancer. Encouraging physical activity is an important public health action to face aging-related health problems, such as cancer. Research Sponsor: facepe/CNPQ.

A study of frontline therapy in adults >80 years with chronic lymphocytic leukemia (CLL). *First Author: Mazie Tsang, Mayo Clinic, Phoenix, AZ*

Background: Although CLL primarily affects older adults (median age 71 years), limited data exists about the outcomes of adults who are ≥80 years old because they are under-enrolled on clinical trials. **Methods:** The Mayo Clinic CLL Database was used to conduct a retrospective cohort study of adults ≥80 years at the time of frontline CLL treatment. Kaplan-Meier analysis was used to plot OS, and cumulative incidence was used to plot TTNT, accounting for competing risk of death. The Mayo Clinic IRB approved the study. **Results:** Our study included 216 patients with CLL who were age ≥80 years at the time of frontline CLL therapy between 1/1995 and 11/2022 (Table). The median time from CLL diagnosis to initiation of frontline therapy was 3.1 years. The median OS after start of frontline therapy was 3.9 years. The median OS was 3.3 years (95% CI 2.6-4.2) for patients who received alkylating agents (e.g., chlorambucil, n=96), 3.8 years (95% CI 2.8-not reached [NR]) for purine analogues (e.g., fludarabine, n=11), 3.9 years (95% CI 3.2-4.9) for anti-CD20 monoclonal antibody monotherapy (e.g., obinutuzumab, n=64), and not reached (95% CI 3.3-NR) for novel agents (n=43) (P=0.02). The types of novel agents included ibrutinib (n=19), acalabrutinib (n=16), venetoclax (n=7), and orelabrutinib (n=1). There was no difference in OS between 36 patients who received a BTKi compared to the 7 patients who received venetoclax-based therapy. At a median follow-up time of 6.7 years from the first visit, 143 patients died from the following: progressive CLL (n=63), infections (n=12), other cancer (n=11), non-CLL reasons (n=21). Cause of death was unavailable for 36 patients. On multivariable analyses, older age (i.e., any 5-year increase in age) was associated with a 50% increased risk of death (HR 1.5, 95% CI 1.2-1.9, p=0.001), and treatment with non-novel agents was associated with 3.2 times increased risk of death (HR 3.2, 95% CI 1.2-8.9, p=0.02). Of the 216 patients, 76 patients required second-line therapy; the median TTNT was 4.2 years (95% CI 2.9-NE). The most used second-line agents were monoclonal antibodies alone (20/76, 26%) and single-agent alkylators (18/76, 24%). **Conclusions:** When compared to all other CLL treatments, novel agents such as BTKi and venetoclax-based treatments are associated with significantly improved OS in patients with CLL ≥80 years old when used in the frontline setting. Safety of checkpoint inhibitors in older patients with genitourinary cancers. *First Author: Brian Hemendra Ramnarain, University of Florida/UF Health Cancer Center, Gainesville, FL*

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the care of patients with genitourinary (GU) cancers however many of the clinical trials that have led to the approval of ICIs in GU cancers often have low enrollments of older patients aged 65 and above for which safety data in this cohort is limited. **Methods:** A retrospective study was performed that included all patients aged 65 and older with kidney, bladder, and upper tract urothelial carcinoma (UTUC), who were treated at the University of Florida Health Cancer Center between January 2018 and September 2022, and received at least one dose of ICI (pembrolizumab, nivolumab, ipilimumab with nivolumab, avelumab, or atezolizumab). Data was collected on all documented immune related adverse events (irAEs) that were deemed attributable to the checkpoint inhibitor by the treating provider. The grading of toxicities was determined by the Common Terminology Criteria for Adverse Events (CTCAE) version 5.0. **Results:** We identified a total of 139 patients who met the inclusion criteria of our study. The ages of patients ranged from 65 to 93 and the median age was 74. Females accounted for 31 patients (22%) while 108 patients (78%) were male. There were 56 patients (40%) with bladder cancer, 58 patients (42%) with kidney cancer, and 25 patients (18%) with UTUC. An irAE was documented in 76 patients (55%) while 63 patients (45%) had no documented irAE. Patients were categorized by the highest grade of toxicity experienced. A Grade 1 toxicity was found in 15 patients (11%), while a grade 2 toxicity was found in 41 patients (29%), with 18 patients (13%) having a grade 3 toxicity, and 2 patients (1%) experiencing a grade 4 toxicity. There were no documented grade 5 toxicities, i.e. no deaths were directly attributed to treatment. We found that 27 patients (19%) required either oral or intravenous steroids to manage their irAE. Discontinuation of treatment due to an irAE was observed in 16 patients (12%). Inpatient hospitalization due to an irAE occurred in 12 patients (9%). **Conclusions:** Our study demonstrates that the majority of patients aged 65 and older either have no irAEs or developed mild irAEs when treated with ICIs. Severe and life-threatening adverse events are uncommon, rarely require hospital admission, and did not lead to any deaths. This study should help to provide valuable information on the safety of checkpoint inhibitors in older patients with GU cancers and assist in the shared decision-making process for cancer treatment. Research Sponsor: None.

Age Group	Patients	Patients with no reported irAE	Patients experiencing an irAE (G1-2)	Patients experiencing an irAE (G3+)	Need for Oral or IV steroids	Discontinuation due to irAE	Hospitalization due to irAE

Demographic stratification, evaluation of symptoms burden on basis of gender, and implications of G8 questionnaires in elderly patients with cancer in Bangladesh. *First Author: Muhammad Rafiqul Islam, National Institute of Cancer Research and Hospital, Dhaka, Bangladesh*

Background: Geriatric oncology is a new concept worldwide, as well as in Bangladesh. Presently, there is a scarcity of data regarding the geriatric perspective of malignant patients in Bangladesh. Our study investigated the demographic differentiation, evaluation of symptoms burden on the basis of gender, and implications of the G8 questionnaires in elderly cancer patients from a tertiary cancer care center in Bangladesh. This will help physicians to understand cancer in the elderly better, integrate their biological and epidemiological characteristics, and promote a longer life expectancy without compromising their quality of life in resource-constrained regions. **Methods:** This study included all the newly diagnosed and histologically confirmed primary solid tumors among age ≥ 60 years at the National Institute of Cancer Research & Hospital (NICRH), a tertiary care center in Bangladesh, during the year 2019 and 2020. For all statistical analyses, $P < 0.05$ was considered significant. **Results:** Of 8057 solid tumor patients, 2823 were geriatric patients (35.04%). Male dominant patients' mean BMI was $20.23 \pm SD 4.26$ and 35.4% were malnourished. The low SES was 63.7% and 68.5% of patients were illiterate. Pain was the most common symptom (37.44%), followed by GI symptoms (31.77%), whereas 33.1% suffered from more than one symptom. In the disease distribution, lung cancer was 52.4% irrespective of sex, followed by GIT 17% and HBS cancer 10%. Breast 24.58% and GIT 17.77% were the second most common malignancy in females and males, respectively. Among them, 22.1% of patients were metastatic at presentation and 25% had a comorbid condition. About 17.4% of patients were completely disabled. Low BMI with high ECOG status had more symptoms ($p = .004$). Gender, nutrition and socioeconomic condition strongly correlated with the patient's functional status and symptomatic presentation. Females were more comorbid with symptomatic metastases at presentation ($p = 0.020$), and males presented with late-stage cancer ($p = 0.002$). Compared to male elderly patients, female elderly patients suffered more from malnutrition and obesity ($p < .000$). Polypharmacy rates for elderly males were lower than those for elderly females ($p = 0.000$). Food intake behavior, weight loss, mobility, and health-related perception did not differ based on gender during or after treatment. Based on G8 scoring, we found that 12.3% were in the worse group, 70.2% in the intermediate group and the good group contained 17.5%. According to the cut-off value (≤ 11), 71.9% of patients needed the CGA evaluation. **Conclusions:** A high number of elder patients with multiple symptoms makes comprehensive management more challenging. A frail elderly patient's gender, SES, education, disease type, and stage along with performance status at the time of presentation of their disease are important prognostic factors. Frailty IO: Frailty parameters and incidence of immune related adverse events in older patients treated with immune checkpoint blockers (ICB). *First Author: Capucine Baldini, Drug Development Department (DITEP), Gustave Roussy, Villejuif, France*

Background: Immune checkpoint blockers (ICB) are one of the cornerstone of cancer treatment. The favorable tolerance profile makes it an interesting option in older patients with cancer. However, few evidence is available in patients aged 70 years and older according to geriatric parameters. We aimed to determine the impact of frailties on immune related adverse events (irAEs) in a real-life population of older patients treated with ICB. **Methods:** This retrospective French multicentric cohort study enrolled all patients aged 70 years or over who underwent a geriatric assessment before the start of ICB in monotherapy or in combination between January 1st 2016 and December 31st 2021. Main endpoint was to assess frailty and incidence of irAEs. **Results:** In total, 224 patients were included. Median age was 82 years old (Q1:77-Q3:87). Patients were mostly men (66%), 40% were treated for a skin cancer (melanoma or squamous), 35% lung and 15% genitourinary. Median number of comedications was 5 (3-8) and median G8 was 12 (9-14). Median ADL (6) was 6 and IADL (4) was 3 (2-4). Most patients were treated with ICB in monotherapy (80%). Altogether, 49% of patients experienced all-grade toxicity and 25% had more than 1 adverse event during the treatment course. The incidence of high-grade toxicity (≥ 3) was 14%. The most frequent types of toxicity were gastro-intestinal (17%), skin (13%), thyroid (9%) and rheumatoid (7%). Male gender ($p < 0.02$), normal IADL ($p < 0.01$), normal Timed up and go test ($p < 0.02$), not having falls in the last 6 months ($p < 0.001$) and visual impairment ($p = 0.02$) were significantly associated with toxicity in univariate analysis. Multiple toxicities were associated with male gender ($p = 0.03$), vision impairment ($p < 0.001$), normal IADL ($p < 0.05$), normal Timed up and go test ($p < 0.02$) not having falls in the last 6 months ($p < 0.001$). There were no association with 4-month hospitalization ($p = 0.73$). Median overall survival (OS) was 16.33 months [95%CI 12.78 - 20.63] and the 3-month OS rate 84.83% [95%CI 79.26 - 89.11]. Median progression free survival (PFS) was 6.08 [95%CI 5.13 - 8.71] in the overall population. Toxicity was associated with better PFS compared to no toxicity (logrank test : $p < 0.01$) with a median PFS (toxicity group) of 6.14 months [95%CI 5.13 - 8.94] versus median PFS (no toxicity group) of 5.26 months [95%CI 3.25 - 8.41]. Median PFS for patients with multiple toxicity was longer 9.86 months [95%CI 5.13 - 23.92] ($p < 0.01$). **Conclusions:** Older patients without IADL or walk impairments but with visions problem had increased incidence of irAEs. The PFS analysis shows a positive association of toxicity confirming that longer exposure to ICB might result in higher risk of irAE. The absence of IADL or mobility impairment may be associated with longer benefit from ICB. Further analysis will be presented at the meeting. Research Sponsor: BMS.

Poster Session

Impact of comorbidity burden on immune-related adverse events and survival among older adults with cancer on immunotherapy. *First Author: Andrew T. Fauchaux, Wake Forest Baptist Medical Center, Winston-Salem, NC*

Background: Comorbidities are more prevalent among older adults and predict worse outcomes for cytotoxic chemotherapy. Immunotherapies are increasingly used to treat various cancers and have a milder but less predictable toxicity profile. This study aimed to evaluate the association of comorbidity burden with immune-related adverse events (irAEs) and survival among older adults treated with these immunotherapies for any cancer type. **Methods:** We created a retrospective registry of consecutive patients ≥ 70 years old treated with one or more doses of an immune checkpoint inhibitor for any cancer indication between 2/1/2011- 4/7/2022 at our comprehensive cancer center. Treatment outcomes, including treatment-emergent adverse events, were captured via chart review. The comorbidity burden at the time of immunotherapy initiation was captured by chart abstraction and classified using the Charlson Comorbidity Index (CCI). We compared patients with high CCI scores (≥ 4) to patients with low CCI scores (CCI < 4) on the outcome of any irAE yes/no, using chi-square tests. We used the Kaplan-Meier method to compare progression-free survival (PFS) and overall survival (OS) between the two CCI groups. Survival analyses were calculated from the first dose of immunotherapy to death, last follow-up, or disease progression. A two-sided alpha of 0.05 was used for analyses. The study had institutional IRB approval. **Results:** Our cohort consisted of 1,216 patients (median age 76 years [interquartile range 73 to 80]), of which 217 (18%) had a high CCI score. The most common comorbidities were chronic obstructive lung disease (45%), coronary artery disease (29%), and diabetes (29%). The most common cancer type was lung cancer (46%), followed by melanoma (15%). Patients with a high CCI score had a shorter median overall survival than patients with a low CCI (11.2 vs. 13.8 months, respectively, $p = 0.049$). However, there was no significant difference in PFS between the high and low CCI groups (median PFS 27.1 vs. 25.0 months, $p = 0.32$). There was no association between the CCI group and the incidence of any-grade irAEs (39% vs. 40%, $p = 0.82$). There was also no association between CCI group and high-grade (grade ≥ 3) irAEs (17% vs. 15%, $p = 0.35$). We did not find any associations between any individual CCI comorbid condition and risk of irAE. **Conclusions:** A high comorbidity burden, as measured by the CCI, was not associated with increased immunotherapy toxicity or shorter PFS among older adults. The presence of comorbidities was associated with shorter OS. These data can support informed decision-making for older adults with comorbidity considering immunotherapy. Reference: 1. Older patients with early-stage triple-negative breast cancer: The Memorial Sloan Kettering Cancer Center experience. *First Author: Iris Zhi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Approximately 15% of cases of early-stage triple-negative breast cancer (TNBC) are diagnosed in individuals over the age of 70. Despite studies indicating that older patients derive similar benefits from polychemotherapy as younger patients, breast cancer specific mortality among older patients remains disproportionately high. Use of the comprehensive geriatric assessment (CGA) and individualized risk tools can help tailor treatment and minimize negative side effects while preserving quality of life. We performed a retrospective analysis of patients ≥ 70 years of age diagnosed with stage I-III TNBC at Memorial Sloan Kettering Cancer Center between 2015 and 2019 to describe clinical practices for managing this population. **Methods:** Demographics, CGA, systemic therapy data were collected from electronic medical records. A multivariable logistic regression model was used to identify factors that were independently associated with the probability of receiving chemotherapy. **Results:** We included 159 women, with a median age of 74.5 years (range 70-96). 67 (42%) had stage I disease, 71 (45%) had stage II, and 21 (13%) had stage III. 29 (18%) reported difficulty in Activities of Daily Living (ADL), 34 (21%) reported difficulties in Instrumental Activities of Daily Living (IADL), and 40 (26%) were identified as having a high risk for falls. 25 (17%) patients underwent CGA per physician's choice. The prevalence of cardiac risk factors was as follows: hypertension in 80 patients (50%), diabetes in 25 (16%), obesity in 7 (4.4%), heart failure in 1 (0.6%). 147 underwent breast surgery, with 106 (67%) receiving lumpectomy and 41 (26%) mastectomy. 97 (61%) patients received chemotherapy: 35 (22%) neoadjuvant and 62 (40%) adjuvant. Anthracycline, Cyclophosphamide, Paclitaxel (AC-T) and Cyclophosphamide, Methotrexate, Fluorouracil (CMF) were the most common regimens. In multivariable logistic regression analysis, use of chemotherapy was associated with younger age (odds ratio [OR] 0.84 for one year increase in age, 95% confidence interval [CI] 0.75-0.93, $p = 0.001$) and higher disease stage (stage II vs. I OR 4.97, 95% CI 1.66-16.4, $p = 0.006$; stage III vs. I OR 22.0, 95% CI 3.3-312, $p = 0.006$). No significant difference was found in geriatric referrals, cardiovascular risk factors, or difficulties with ADL or IADL between those receiving or not receiving chemotherapy. **Conclusions:** In our single center experience, 61% of older patients with early-stage TNBC received chemotherapy, with AC-T and CMF being the most common regimens. The referral rate for CGA was low. Age < 75 years and higher disease stage were significantly associated with receiving chemotherapy. Overcoming barriers to incorporating CGA and toxicity prediction into routine clinical practice is crucial for personalized treatment in this population. Frailty and pre-frailty associated with physical functional performance and quality of life in breast cancer and bone marrow transplant survivors. *First Author: Shuo Wang, University of Minnesota, Minneapolis, MN*

Background: Frailty in cancer survivors poses a great challenge to health care providers. Frailty is associated with premature mortality, functional decline, and poor quality of life (QOL). We aimed to examine the associations of frailty and pre-frailty with physical functional performance and QOL in breast cancer survivors and bone marrow transplant (BMT) survivors. **Methods:** 43 breast cancer survivors and 55 BMT survivors who had received chemotherapy and did not have active cancer were recruited to the study. Based on Fried frailty phenotype, survivors were classified as frail if 3 or more criteria were present: unintentional weight loss, exhaustion, slow walking speed, low physical activity, and weakness. Pre-frail was classified if 1 or 2 criteria were present. Physical functional performance was assessed by Karnofsky performance scale (KPS) and continuous summary performance score (CSPS, comprises walking speed, standing balance, and repeated chair stands tests). $p16^{INK4a}$, a marker for cellular senescence, was measured from survivors' blood samples. QOL was measured using the 36-Item Short Form Survey. Groups were compared using chi-square test for categorical variables and rank-sum test for continuous variables. **Results:** Median age of survivors was 59 yrs (39% male). 13% of survivors (N = 13) were frail and 26% (N = 25) were pre-frail. Frail/pre-frail survivors tended to be older, male, and BMT survivors and had worse results for KPS, walking speed, repeated chair stands, and CSPS (p-values<0.03). Frail/pre-frail versus non-frail survivors had a higher $p16^{INK4a}$ expression (p-value<0.01). For QOL, frail/pre-frail survivors had lower median scores of physical functioning, role limitations due to physical health, role limitations due to emotional problems, energy/fatigue, social functioning, bodily pain, and general health (p-values<0.04), but the median scores of emotional well-being for frail/pre-frail and non-frail survivors were similar (p-value=0.06). **Conclusions:** Frailty and pre-frailty in a study of breast cancer and BMT survivors were associated with worse physical functional performance, higher $p16^{INK4a}$ expression, and lower quality of life. Research Sponsor: Division of Hematology/Oncology/Transplantation University of Minnesota.

Summary of characteristics among frail/pre-frail and non-frail survivors.

	Frail/Pre-frail (n=38) 62 (40-81)	Non-frail (n=60) 55 (27-79)	P-value <0.01
Age, median yrs (min-max)	47.6	25.0	0.02
Male, %			
Walking speed [1 - (9/speed in cm/s)], median (min-max)	0.91 (0.85-0.94)	0.93 (0.86-0.98)	<0.01
Standing balance [time in s/30], median (min-max)	1.00 (0.00-1.00)	1.00 (0.77-1.00)	0.02
Repeated chair stands [1 - time in s/32.1], median (min-max)	0.57 (-0.60-1.00)	0.67 (0.31-1.00)	<0.01
CSPS, median score (min-max)	2.48 (0.81-2.91)	2.60 (2.21-2.78)	<0.01
$p16^{INK4a}$ expression, median (min-max)	2.00 (0.11-9.84)	0.51 (0.02-5.72)	<0.01

Dissecting the prognostic role of baseline body mass index (BMI) in early breast cancer (BC): Individual patient-level analysis from five mammella interGruppo (MIG) and gruppo italiano mammella (GIM) randomized clinical trials (RCTs). *First Author: Davide Soldato, IRCCS Ospedale Policlinico San Martino, Università degli Studi di Genova, Genova, Italy*

Background: Nearly half of patients (pts) are overweight or obese at BC diagnosis (dx). Higher BMI at dx has been associated with cardiometabolic comorbidities, higher risk of severe treatment-related sequelae, and worse quality of life. Previous studies showed inferior survival outcomes among patients with early BC and high BMI, although not consistently. The aim of this study was to explore the prognostic role of BMI at dx using data from five RCTs of adjuvant therapy for early stage BC with long-term follow-up. **Methods:** Pts with known BMI at dx, randomized in the MIG-1, MIG-5, GIM-2, GIM-3 and GIM-6 phase III RCTs were included. BMI was categorized as lean (< 25 kg/m²), overweight (25-30 kg/m²) or obese (≥ 30 kg/m²). Outcomes included disease-free survival (DFS), breast cancer free-interval (BCFI) and overall survival (OS). Survival estimates were compared using the Kaplan-Meier method and log-rank test. Multivariable Cox proportional hazard models stratified by trial and relevant prognostic factors assessed associations between BMI and outcomes. **Results:** Among 7334 pts in the overall population, mean age was 56.4 years (SD 11.2), 67.8% had node-positive disease, 76.9% received chemotherapy and 83.0% endocrine therapy. Most pts were overweight (33.1%) or obese (21.0%) and 45.9% were lean. Higher BMI was associated with older age, larger tumor size, higher nodal status, and HR+/HER2- subtype. At a median follow-up of 10.0 years (IQR 6.1-15.1) there were 2165 DFS, 1674 BCFI and 1354 OS events. Pts with higher BMI had worse DFS and OS (log-rank p = 0.007 and p < .0001, respectively), but similar BCFI (p = 0.48). BMI at dx was an independent risk factor for worse OS, but not for DFS and BCFI (Table). Results in the HR+/HER2- population (n = 4093) were consistent: pts with higher BMI had worse DFS, BCFI, and OS (log-rank p = 0.001, p < .006, and p < .0001, respectively) and BMI at dx was an independent risk factor only for worse OS (aHR [95%CI] 1.06 [0.84-1.32] and 1.31 [1.02-1.67] for overweight and obese vs lean pts, respectively). **Conclusions:** In this large study of pts with early BC treated in RCTs with long-term follow-up, higher BMI at dx was an independent risk factor for overall mortality but not for BC-specific outcomes. Weight loss interventions may mitigate the detrimental effect of excess body weight on outcomes of BC survivors, including by reducing the burden and risks of associated cardiometabolic comorbidities. Research Sponsor: "Associazione Italiana per la Ricerca sul Cancro", AIRC (MFA 2020 ID 24698).

Geriatric-assessment-guided interventions for older adults with multiple myeloma: A feasibility study. *First Author: Christopher Edward Jensen, University of North Carolina School of Medicine, Chapel Hill, NC*

Background: Multiple myeloma (MM) is disproportionately a disease of older adults, and aging-related impairments are common in this population. Geriatric assessment (GA) guided supportive care programs have been linked to improved treatment outcomes among older adults with solid-organ cancers. We sought to evaluate the feasibility of a GA-guided supportive care program among older adults treated for MM. **Methods:** We leveraged an existing registry of adults with plasma cell disorders at the University of North Carolina. Registry participants meeting inclusion criteria were offered referrals to supportive care resources by their MM provider during routine visits in 2021-2022. Inclusion criteria were diagnosis of MM, age ≥60, and presence of ≥1 selected problem areas (physical function, polypharmacy, mental health) on the GA. Function deficits were defined as self-report of requiring assistance with ≥1 instrumental activities of daily living or recent fall(s), polypharmacy as ≥10 daily medications, and anxiety/depression on the Mental Health Index 13. Individuals with physical function deficits were offered referral to physical therapy (PT). Those with polypharmacy were offered referral to an oncology Clinical Pharmacist Practitioner (CPP) for comprehensive medication reconciliation and evaluation for de-prescribing. Patients with mental health symptoms were offered referral to our center's Comprehensive Cancer Support Program (CCSP). **Results:** 59 individuals were identified as having at least one deficit on the GA (Table). Of these, 14 were already utilizing all relevant resources, leaving 45 individuals eligible for a new resource. Among these, 16 accepted a referral to at least one resource. An additional 16 were approached and declined all offered referrals. For the remaining 13 screened individuals, providers were prompted regarding a referral recommendation prior to the patient's visit, but a referral was not offered during the visit. Physical therapy was the most commonly identified relevant resource (n = 46), followed by CPP visits (n = 33). Referral acceptance rates were highest among those recommended for a pharmacy visit (55% of those approached) and lowest for CCSP (0%). **Conclusions:** Given the prevalence of polypharmacy or physical function deficits and acceptance rates for related interventions, future interventions focusing on collaboration with CPPs or physical therapists appear feasible in this setting. Methods to direct patients to supportive care resources that do not rely on provider recommendations during the limited window of clinic visits may also be beneficial. Clinical trial information: NCT04999085. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology; AHRQ.

A pilot study of intraneural facilitation versus standard physical therapy for prevention of chemotherapy-induced peripheral neuropathy. *First Author: Dan Ran Castillo, Division of Medical Oncology and Hematology, Loma Linda University of Medicine, Loma Linda, CA*

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a debilitating side effect necessitating chemotherapy (CT) dose adjustments or early termination. Intraneural Facilitation (INF) is a novel form of manual physical therapy (PT) developed to mitigate CIPN-related symptoms and improve patients' functional outcome. We conducted a randomized pilot study evaluating the efficacy of INF vs. standard PT in the prevention of CIPN (NCT 03272919). **Methods:** Eligible participants were patients with newly diagnosed breast cancer (stages I-III) and gynecologic cancer without preexisting peripheral neuropathy planning to receive platinum-based and/or taxane-based CT. Participants were randomly assigned to either INF or PT arm and received two 45-minute treatments twice a week for six weeks during their CT course. Outcomes reported here are a) assessment of pain between the 2 arms using the Pain Quality Assessment Scale (PQAS), and b) measurement of vascular patterns using ultrasound (US), evaluating pulsatility index, volume flow and peak systolic velocity between the 2 arms. Participants were evaluated at baseline, week 3 (W3), week 6 (W6), and month 3 (M3). PQAS scores ranged from 0 to 10 with subscale evaluations of paroxysmal, surface, and deep pain. Pain scores on a scale from 0 to 10 were grouped into none (0), mild (1-3), moderate (4-6) and severe (7-10). The use of neuropathy medications, CT dose reductions, premature CT discontinuation and participant satisfaction surveys between the two groups were previously reported at SABCS 2022. **Results:** Of 104 screened participants, 44 met the eligibility criteria, with 38 eligible for analysis (n=20 INF arm and n=18 PT arm). Participants reporting moderate or severe pain in either arm were combined (Table). Pain symptoms peaked at W6 coinciding with cumulative CT effects. At M3, none in the INF arm reported moderate or severe paroxysmal pain compared to two participants in the PT arm. One participant in each arm reported moderate or severe surface or deep pain at M3. The US results showed physiologic impact in both arms at W3 and W6, suggesting their role in preserving neural tissue blood flow and reducing vascular damage. **Conclusions:** Our study shows fewer number of participants on both intervention arms reporting pain, with numerically lower scores on PQAS in INF arm compared to PT arm, especially during ongoing CT. The US results suggest that INF has a unique pathophysiological impact on the microvasculature compared to standard PT; further studies are needed to validate these findings and potentially address their clinical significance as a combined modality. Clinical trial information: NCT03272919. Research Sponsor: GRASP grant.

Type of Pain	INF n =20(%)	PT n= 18(%)

The effect of exercise on physical function and medication adherence in women receiving endocrine therapy for breast cancer: The breast cancer endocrine therapy fitness (BE-FIT) randomized controlled trial. *First Author: Samantha Myers, University of British Columbia, Vancouver, BC, Canada*

Background: Approximately 20% of women receiving endocrine therapy (ET) for early-stage breast cancer (BrCa) discontinue their regimen due to side effects, including vasomotor symptoms and arthralgias, subjecting them to higher rates of disease recurrence. Exercise is one approach to mitigate ET-related toxicity and potentially improve medication adherence by mitigating ET-related symptoms. However, only 11% of women with BrCa adhere to recommended exercise guidelines. **Purpose:** To examine the effect of a virtual supervised exercise program for women receiving ET for early-stage BrCa on physical function (PF) (primary outcome) and adherence to ET (secondary outcome). **Methods:** Participants were recruited through referral by oncology care providers from multiple BC Cancer sites and self-referral. Eligible participants were: females with stage I-III BrCa being treated with curative intent, 19-75 years, taking ET for at least 3 months up to 3 years. Using a partial cross-over design (NCT04824339), participants were randomized to the immediate exercise group (INT) or the delayed exercise group (CON), which crossed over at 8 weeks. The 8-week intervention was comprised of a 50-minute resistance exercise circuit, delivered virtually by an exercise physiologist twice per week via Zoom, and self-directed aerobic exercise (progressing to 90 minutes or more per week of at least moderate intensity). PF was assessed using the 30-second chair stand test. ET adherence was measured by the Voils self-reported medication non-adherence questionnaire. Values reported as means and standard deviations. The difference at 8 weeks by intervention arm was examined using two sample t-test (continuous) or kappa measure of agreement (categorical). **Results:** A total of 132 women were randomized. On average, women were 54 years, White (European) (47%), married (64%), had at least a bachelor's degree or higher (51%), and had a body mass index of 27.7 kg/m². The most common type of ET women received was Letrozole (43%), followed by Tamoxifen (36%). At 8 weeks, there was a significant improvement in PF for INT versus CON (mean change +2.5±2.9 vs. +0.7±2.2 stands, $p < 0.001$). There was no difference between groups in change in medication adherence status ($k = 0.35$). **Conclusions:** An 8-week virtual supervised exercise program for women receiving ET for early-stage BrCa significantly improved PF but did not change medication adherence at 8 weeks. The potential impact of the intervention on long-term medication adherence will be explored up to one year and with covariates. Based on improvement in PF, future trials to establish effectiveness and inform implementation are warranted. Clinical trial information: NCT04824339. Research Sponsor: BC Cancer Foundation.

Preliminary outcomes of a financial navigation program among lower socioeconomic patients with cancer. *First Author: Chiu Yi Joey Tan, School of Social Policy & Practice, University of Pennsylvania, Philadelphia, PA*

Background: Cancer patients receiving treatment are at risk of experiencing financial hardship, especially among those from lower socioeconomic status (SES) households. Patients experiencing financial toxicity are more likely to report poorer physical-wellbeing, higher anxiety, housing or food insecurity, and treatment non-adherence. While financial navigation programs are present, there is a lack of standardized practice to mitigate financial hardship among cancer patients. The purpose of this study is to evaluate the preliminary efficacy of Family Reach's oncology financial treatment program (FTP) on financial toxicity, quality of life, and anxiety in low SES patients. FTP consists of individualized resource navigation, financial education services, and a \$1000 patient assistance grant that was used towards non-treatment related expenses. **Methods:** 152 cancer patients undergoing active treatment, with household incomes under the 400% poverty line were recruited from two NCI-designated cancer centers. 99 participants completed the baseline and 2-month follow-up survey, consisting of these measures: COST: A FACIT Measure of Financial Toxicity (COST), Hospital Anxiety and Depression Scale (HADS), 36-Item Short Form Health Survey (SF-36), poverty exposure and treatment adherence items (secondary outcomes). **Results:** Participants were 69% female; roughly half (51%) were African American/Black, 34% were white, 4% were mixed, 3% were Asian and 8% reported 'other' or preferred not to answer. COST score at baseline (M=10.5, SD=6.4) significantly increased after 2 months (M=12.9, SD=7.9), $t(176.2) = -2.3$, $p < .05$. HADS-Anxiety score at baseline (M=11.1, SD=4.7) significantly decreased after 2 months (M=9.2, SD=4.4), $t(186.0) = 2.88$, $p < .01$. SF-36 Physical functioning score at baseline (M=34.0, SD=27.2) significantly increased after 2 months (M=43.9, SD=31.0), $t(170.3) = -2.26$, $p < .05$. See Table for secondary outcomes. **Conclusions:** Early evidence of FTP indicates promising results to increase financial and physical well-being, and in reducing anxiety among lower SES cancer patients. FTP showed improvements in COST scores and reduced non-medical cost concerns. However, COST scores reported in this study are still lower compared to other studies. A planned future study involving monthly guaranteed income payments will be carried out to examine if financial well-being and treatment adherence can be achieved. Supported by: One Family Foundation/Social Impact Fund Secondary outcomes. Research Sponsor: One Family Foundation/Social Impact Fund.

	Baseline	Follow-up	χ^2
Patient/Caregiver/family concerned about non-medical costs related to treatment	71.4%	45.3%	32.1*
1 or more utilities at risk of shutting off	34.7%	29.5%	45.1**
Missed/rescheduled a cancer related appointment in the past month	16.3%	19.8%	37.2*
Skipped/taken smaller doses of a prescribed medication to make it last longer in the last 3 months	4.1%	6.5%	49.3**

Evaluation of a mobile behavior change program for weight loss in breast cancer survivors: A prospective single-arm pilot study. *First Author: Sherry Shen, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Post-diagnosis weight gain is common among women with early-stage breast cancer and is associated with increased risk of recurrence, breast cancer death, and all-cause mortality. Intentional weight loss following diagnosis is difficult to maintain. Targeted lifestyle interventions focusing on behavioral changes and education that can be implemented long-term are needed. **Methods:** This was a prospective single-arm pilot study in patients with history of early-stage breast cancer (NCT04753268). Key eligibility criteria included body mass index (BMI) ≥ 27.5 kg/m², stage I-III breast cancer, and completion of active cancer treatment ≥ 6 months prior to study enrollment. Patients were recruited at the Dempsey Center in Lewiston, ME and via social media. Participants were given access to the Noom mobile application, which utilizes cognitive behavioral therapy, motivational interviewing, and self-determination theory to induce behavior change using an educational curriculum of daily articles, virtual health coaching, social networking, food records, and physical activity logs. The primary endpoint was change in self-reported weight from baseline to 26 weeks. Secondary endpoints included change in physical activity measured using step count and the Global Physical Activity Questionnaire (GPAQ), change in diet patterns analyzed using the Nutrition Data System for Research, patient-reported outcome (PRO) measures, and metrics for engagement with the mobile application. **Results:** 31 patients were enrolled; 24 at the Dempsey Center and 7 via social media. Mean age was 56.8 and mean baseline BMI was 33.5 kg/m². Mean weight change was -4.8 kg (range +0.6 to -19.9 kg, $p < 0.001$) and mean percent weight change was -5.6%; 11/31 patients (35.5%) lost $\geq 5\%$ of their initial weight. Average daily step count increased by 54.7% ($p = 0.004$). Mean GPAQ score for physical activity increased from 990 to 1773 ($p = 0.01$), and the proportion of patients who met physical activity guidelines increased from 45.1% to 74.2%. Mean energy intake did not change significantly over 26 weeks ($p = 0.779$). Improvements were observed in PROMIS-Physical Functioning T-scores and Body Image Scale scores ($p = 0.04$, $p < 0.001$ respectively). Metrics of engagement with Noom that were predictive of weight loss $\geq 5\%$ included total articles read ($p = 0.012$), total weights logged ($p = 0.006$), total food records logged ($p = 0.001$), messages sent to coach ($p = 0.001$), and number of times the application was opened ($p = 0.014$). **Conclusions:** In this pilot study, breast cancer survivors lost weight and became more physically active using a commercially-available mobile application. This digital weight loss program is a scalable intervention, and these findings support future studies investigating impact on breast cancer outcomes. Clinical trial information: NCT04753268. Research Sponsor: Noom, Inc.

Nutritional program among patients with prostate cancer receiving androgen deprivation therapy (ADT). *First Author: Dr. Paulo Sergio Lages, Oncoclinicas, Brasília, Brazil*

Background: Treatment with ADT can lead to changes in body composition, including an increase in body fat and a decrease in muscle mass. To minimize the nutritional risks associated with ADT, a nutritional program was developed. Thus, this study sought to determine the benefit of this program among patients with prostate cancer receiving ADT. **Methods:** Patients were recruited in a cancer center located in Brasília, Brazil. Patients were eligible if they were diagnosed with prostate cancer, and about to initiate treatment with ADT. They were assessed before starting ADT and at follow-up assessment (3 months). Based on their risk, patients were instructed to follow either a normocaloric (20-25 kcal/kg) or a hypocaloric (18-20 kcal/kg) diet, and both groups were required to consume a hyperprotein diet (1-1.2 g/kg), including the use of whey protein supplementation as needed. Outcomes measures included nutritional risk (Patient-Generated Subjective Global Assessment; PG-SGA), body composition (Medical software Lookin'Body120), and muscle strength (Jamar Hydraulic Hand Dynamometer). Descriptive statistics were generated, and paired T-test, Wilcoxon signed rank on paired samples and ANOVA-RM were used to evaluate changes in variables over time. **Results:** A total of 62 patients were included in this program. Participants had a median age of 75 years (range from 41-97) and were predominantly married (87%). A great proportion of patients (65%) were diagnosed with a stage IV disease. Notably, 23% were diagnosed with moderate to severe nutritional risk at baseline; 47% were overweight, 13% were obese and 14% were with sarcopenia. The nutritional program resulted in maintenance of total body weight (median 74.1 vs 75.6 kg, $P=0.12$), lean body weight (median 29.1 vs 29.4 kg, $P=0.11$), and muscle strength (median 30 vs 30 kg, $P=0.62$), while a statistically significant loss of body fat weight (median 22.0 vs 20 kg, $P=0.003$) was found over the 12-week period. Despite no change in the PG-SGA scores were noted overtime, the rate of sarcopenia has decreased (15% vs 13%, $P=0.03$) and the proportion of eutrophic patients has increased (18% vs 27%, $P=0.001$), as seen in the contingency table below. **Conclusions:** These findings suggest that this program may improve body composition and maintain muscle strength in men receiving treatment with ADT after only three months of intervention. Future studies should validate the benefit of this program in randomized trial with a longer follow-up assessment (6 and 12 months after treatment initiation). Research Sponsor: None.

Dietary and lifestyle profiles between patients with and without cancer in the national health interview survey. *First Author: Emma Gong, New York Medical College, Valhalla, NY*

Background: Although poor diet and lifestyle has been associated with cancer development and progression, it is unclear how the diagnosis of cancer impacts diet and lifestyle. We examined the dietary patterns and overall nutrition of adults diagnosed with cancer versus those never diagnosed with cancer in the 2015 National Health Interview Survey (NHIS). **Methods:** NHIS adults who reported having cancer (n=2,853) and not having cancer (n=27,002) were identified. A dietary/lifestyle score was developed based on World Cancer Research Fund and American Institute for Cancer Research Cancer Prevention Recommendations (Table). Participants were given a score for each recommendation which was then summed as an overall score, with seven meeting all requirements fully and zero meeting none of the requirements. **Results:** The mean composite score for the cancer population was 4.28 ± 0.88 and for the noncancer population was 4.30 ± 0.90 ($p = 0.18$). Compared to patients without cancer, those with a cancer diagnosis had higher rates of adherence to recommendations for fruit/vegetable consumption (0.08 vs. 0.07 , $p < 0.001$) and limitation of sugar-sweetened beverages (0.77 vs. 0.74 , $p < 0.001$), but had lower rates of the recommended physical activity (0.43 vs. 0.49 , $p < 0.001$). **Conclusions:** Patients with and without diagnosis of cancer had mediocre adherence (4.3 out of 7) to lifestyle recommendations, although those with diagnosis of cancer had a higher consumption of fruits/vegetables, lower consumption of sugary beverages, and lower level of physical activity than those without cancer. The data suggests a cancer diagnosis may prompt change in people's diet, but may limit their ability to exercise. The magnitude of lifestyle change that one can make after a cancer diagnosis may also be influenced by age or social connections. There is great opportunity for integrating healthy lifestyle interventions into routine cancer care. Research Sponsor: None.

Survivorship care and breast and cervical cancer screening. *First Author: Marco Santos Teles, Rutgers New Jersey Medical School, Newark, NJ*

Background: Studies suggest that despite their history, cancer survivors may be equally or less likely to be screened for various cancers. The impact of the components of survivorship care on post-treatment screening is unknown. We aim to gauge the association of receipt of treatment summaries, follow-up care instructions (including where to obtain "routine cancer check-ups"), and type of doctor providing survivorship care on breast cancer screening (BCS) and cervical cancer screening (CCS) in female cancer survivors. **Methods:** A cross-sectional, retrospective analysis using Behavioral Risk Factor Surveillance System (BRFSS) survey data from 2016 and 2018 was conducted. BCS-eligible women were aged 40-74; CCS-eligible women were 30-64. BCS completion was defined as a mammogram within 2 years and CCS completion as a pap smear within 3 years or an HPV test within 5 years. Univariate analysis was conducted using chi-square. Multivariate logistic regression was used to determine which survivorship care factors were associated with BCS and CCS. **Results:** 4,533 BCS and 2,566 CCS-eligible survivors were identified. In the BCS-eligible group, 85.9% were aged ≥ 50 , 89.7% were white, 62.5% had a degree beyond high school, 48.7% earned $\leq \$50,000$, and 96.1% were insured. In the CCS-eligible group, 68.1% were aged ≥ 50 , 87.9% were white, 63.7% had a degree beyond high school, 45.0% earned $\leq \$50,000$, and 93.3% were insured. 82.0% were up-to-date (UTD) with BCS; 92.6% were UTD with CCS. BCS and CCS were higher for insured survivors (82.2% vs. 66.2%, $p = 0.009$; 93.8% vs. 83.3%, $p = 0.013$, respectively). 48.7% of BCS-eligible and 50.5% of CCS-eligible survivors received a treatment summary. 75% of BCS-eligible and 77% of CCS-eligible survivors received follow-up instructions. Among BCS-eligible survivors, recipients of treatment summaries and follow-up instructions were significantly more UTD with BCS than non-recipients (84.9% vs. 78.5% and 84.5% vs. 74.3%, respectively, $p < 0.001$). Among CCS-eligible survivors, recipients of follow-up instructions were significantly more UTD with CCS (94.5% vs. 88.9%, $p = .021$); there was no significant difference for recipients of treatment summaries ($p = .201$). In both groups, there was no significant difference in BCS or CCS based on the type of physician providing survivorship care ($p = .732$ and $p = .098$, respectively). On multivariate analysis, receipt of follow-up instructions was the only factor significantly associated with BCS (OR 1.46; 95% CI: 1.05-2.03) and CCS (OR 2.57; 95% CI: 1.19-5.55). **Conclusions:** Follow-up instructions, which are part of the survivorship plan, have the greatest association with BCS and CCS among cancer survivors. Despite this, about 25% of BCS and CCS-eligible cancer survivors did not receive them. Additional research should focus on improving the practice of survivorship care, particularly follow-up instructions, as a method to increase uptake of BCS and CCS among cancer survivors. Associations between body mass index with cancer recurrence and all-cause mortality among survivors of breast cancer. *First Author: Po-Hua Chen, Northwestern Medicine McHenry Hospital, McHenry, IL*

Background: It is widely recognized that obesity is associated with increased breast cancer incidence. While body mass index (BMI) does not capture measures of body composition, it is routinely collected during clinical care. However, we do not know whether BMI at breast cancer diagnosis affects cancer recurrence or all-cause mortality. This study aims to investigate the associations between clinical categories of BMI, cancer recurrence, and all-cause mortality in this population. **Methods:** All breast cancer survivors treated at Northwestern Medicine on or after 1/1/2005 were included. We applied the WHO classification of BMI (kg/m²): underweight (< 18.5), normal (18.5-24.9), overweight (25-29.9), class I obesity (30-34.9), class II obesity (35-39.9), and class III obesity (≥ 40). Cox proportional hazards models were used to determine the associations between BMI category at baseline and cancer recurrence plus all-cause mortality for breast cancer survivors. Models were adjusted for potential confounders including age, gender, race, ethnicity, histological grade, clinical stage, chemotherapy use, smoking, alcohol use, history of coronary artery disease, and history of Diabetes Mellitus. **Results:** Among all the 20,322 breast cancer survivors, 1,371 all-cause deaths and 1,183 cancer recurrences were observed. For patients aged 55 and above at diagnosis, there were 964 deaths and 632 cancer among 11,818 cases. When compared with a normal BMI (18.5-24.9), a BMI of 40 and above is associated with a higher risk of all-cause mortality among stage 1 breast cancer survivors (HR 1.90, 95% CI 1.17-3.09), whereas a BMI of lower than 18.5 is associated with a higher risk of all-cause mortality among stage 4 breast cancer patients (HR 3.21, 95% CI 1.24-8.30). For cancer recurrence, when compared with a normal BMI (18.5-24.9), a BMI of 40 and above is associated with a higher risk of cancer recurrence among stage 0 breast cancer survivors (HR 3.78, 95% CI 1.21-11.81) and a BMI of 35 to 39.9 is associated with a higher risk of cancer recurrence among stage 3 breast cancer patients (HR 1.91, 95% CI 1.01-3.61). We did not observe effect modification for either association by age at diagnosis using a cut-point of 55 years, which is considered as reaching postmenopausal status. **Conclusions:** Higher levels of obesity are associated with a higher mortality risk among early-stage breast cancer survivors whereas underweight is associated with a higher mortality risk for terminal-stage breast cancer. The associations between high-class obesity and increased risk of cancer recurrence were observed among stage 0 and stage 3 breast cancer survivors. These findings emphasize the importance of BMI as a tool for monitoring the health of breast cancer survivors. However, further study is needed to better understand the impact of BMI, and more importantly body composition, on the health and longevity of breast cancer survivors. Phase 3 randomized placebo-controlled trial of donepezil for cancer-related cognitive impairment among breast cancer survivors: Results on patient-reported cognitive function from the wake forest nCI community oncology research program (NCORP) research base REMEMBER trial (WF97116). *First Author: Alayna E Ernster, Wake Forest University School of Medicine, Winston-Salem, NC*

Background: Cancer-related cognitive impairment (CRCI) is prevalent and persistent among breast cancer survivors (BCS). The REMEMBER prospective, randomized, double-blind, placebo-controlled trial compared the efficacy of donepezil, an acetylcholine esterase inhibitor, versus placebo to reduce late CRCI among BCS. (Clinical Trials #: NCT02822573). **Methods:** Women ≥ 18 years of age, with a history of breast cancer who completed ≥ 4 cycles of cytotoxic chemotherapy 1 to 5 years prior to enrollment, self-reported CRCI, with evidence of a memory deficit on the Hopkins Verbal Learning Test were eligible. Women were randomized to a 24-week course of daily donepezil (5mg) or placebo. If tolerated, the donepezil/placebo oral daily dose was increased to two tablets (donepezil 10mg) Weeks 7-24. The Functional Assessment of Cancer Therapy-Cognitive Function (FACT-Cog) Version 3 patient-reported outcomes (PRO) measure was administered at Baseline and weeks 12, 24, and 36. Mixed effects repeated measures analysis of covariance (RMANCOVA) models were used to assess treatment differences in FACT-Cog subscale scores with model covariates of treatment, time, time by treatment interaction, baseline outcome level, age stratification and an unstructured covariance matrix to account for within participant correlation over time. **Results:** A total of 276 patients from 87 NCORP sites (mean age = 57.1 yr., SD = 10.5) an average of 29.6 months post-chemotherapy completion were randomized to donepezil ($n = 140$) or placebo ($n = 136$). Participants in both arms experienced an improvement in all FACT-Cog subscale scores from baseline to week 12 (e.g., FACT-Cog Perceived Cognitive Impairment change: Donepezil = 14.8, SD = 14.6; Placebo = 13.9, SD = 15.7), with a slight improvement in week 24 (Donepezil = 3.6, SD = 11.4; Placebo = 3.1, SD = 11.4) and slight decrease in week 36 (Donepezil = -1.7, SD = 12.4; Placebo = -1.2, SD = 12.2). The magnitude of change was comparable across treatments at all timepoints (week 12 $p = 0.64$; week 24 $p = 0.75$; week 36 $p = 0.76$). There were no statistically significant differences across treatments at 12, 24 and 36 weeks on any FACT-Cog subscale. Exploratory analyses adjusting for education, baseline fatigue and depression as well as independent analyses considering treatment interaction with endocrine therapy and menopausal status also did not result in group differences for any outcome. **Conclusions:** There were no differences in PRO-assessed cognitive function domains between donepezil or placebo. The magnitude of improvement in patient-rated cognitive function was comparable across treatment arms. These results underscore the importance of placebo controls for CRCI intervention trials. Funding: NIH/NCI 2UG1CA189824. Clinical trial information: NCT02822573. Research Sponsor: U.S. National Institutes of Health.

Impact of exercise on chemotherapy-induced peripheral neuropathy (CIPN) in survivors with post-treatment primary breast cancer. *First Author: Kirin Saint, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common and debilitating side effect of neurotoxic chemotherapy with limited treatment options. We examined the association between exercise and CIPN symptoms in patients with post-treatment primary breast cancer.

Methods: Using a retrospective design, patients completing a standardized survey assessing exercise exposure, neuropathy symptoms, and pain in a tertiary cancer center survivorship clinic were included. Exercise was assessed using a standardized questionnaire quantified in standardized metabolic equivalent tasks (MET-h/wk). Chi-square tests, Mann-Whitney U-tests, Kendall's rank correlations, and multivariable logistic regressions adjusting for important clinical covariates examined the relationship between exercise and CIPN and whether this differed as a function of chemotherapy regimen (taxane vs. non-taxane based therapy). **Results:** A total of 5,444 patients with primary breast cancer previously treated with adjuvant chemotherapy (median age 62 years (IQR: 55, 71); median of 4.7 years post chemotherapy completion (IQR: 3.3, 7.6)) were identified. The overall prevalence of CIPN was 34% (95% CI: 33%, 36%); 33% (95% CI: 31%, 34%) for non-taxane and 37% (95% CI: 35%, 39%) for taxane based chemotherapy. The prevalence of CIPN was 28% (95% CI: 26%, 30%) among exercisers (≥ 5 days of moderate or ≥ 3 days of strenuous exercise per week) and 38% (95% CI: 37%, 40%) among non-exercisers (difference 11%; 95% CI: 8%, 13%; $p < 0.001$). Associations appeared dose-dependent. CIPN prevalence was 42% for < 6 MET-h/wk, 33% for 6-20.24 MET-h/wk and 29% for > 20.25 MET-h/wk (p -value < 0.001). Exercise was associated with reduced prevalence of all individual CIPN symptoms (numbness and tingling, pain, interference in daily living). Higher exercise was associated with lower CIPN regardless of chemotherapy regimen. **Conclusions:** CIPN is persistent several years following chemotherapy cessation in patients with breast cancer but significantly reduced by exercise in a dose-dependent manner. Pharmacological cardioprotective strategy for non-metastatic patients affected by breast cancer receiving an anthracycline-based chemotherapy: Final results of the phase 3 SAFE trial. *First Author: Lorenzo Livi, Department of Experimental and Clinical Biomedical Sciences "M. Serio", University of Florence, Florence, Italy*

Background: Several studies have evaluated cardioprotective strategies to prevent myocardial dysfunction in patients receiving cardiotoxic therapies. However, the optimal approach still represents a controversial issue. We aim to determine whether pharmacological cardiac prevention could reduce subclinical heart damage in breast cancer (BC) patients treated with anthracycline-based chemotherapy. **Methods:** The SAFE trial is a four-arm, randomised, phase 3, double-blind, placebo-controlled study. Patients were eligible for trial inclusion if they had indication to primary or postoperative systemic therapy using an anthracycline-based regimen. Patients with prior diagnosis of cardiovascular disease were excluded. Cardioprotective therapy (bisoprolol (B), ramipril (R), or both drugs (B+R), as compared to placebo) was administered for 1 year from the initiation of chemotherapy or until the end of trastuzumab therapy in case of HER2 positive patients. Doses for all groups were systematically up-titrated, up to the daily target dose of B (5 mg, once daily), R (5 mg, once daily), and placebo, if tolerated. The primary endpoint was defined as detection of any subclinical impairment (worsening $\geq 10\%$) in myocardial function and deformation measured with standard and 3-dimensional (3D) echocardiography, left ventricular ejection fraction (LVEF) and global longitudinal strain (GLS). **Results:** 262 women (median 48 years; range 24-75 years) were enrolled and treated in the study. We analysed patients who had completed the pre-planned cardiologic assessment at 24 months. All patients received an anthracycline-based chemotherapy, 215 patients received at least 3 cycles of anthracyclines (range 1-6) and 128 patients had postoperative radiation therapy. At Univariate logistic analysis to evaluate the risk of GLS worsening $> 10\%$ at 24 months, Odds ratios (OR) for improvement were 0.055, 0.083 and 0.060 for B, R and B+R, respectively ($P < 0.0001$), if compared to placebo arm. At Univariate logistic analysis to evaluate the risk of 3DLVEF worsening $> 10\%$ at 24 months, OR for improvement were 0.019, 0.048 and 0.054 for B, R and B+R, respectively ($P < 0.0001$), if compared to placebo arm. Study drugs were well tolerated with no serious adverse events, the ramipril plus bisoprolol arm showed significantly more toxic effects and had a significantly higher rate of allocated treatment discontinuation as compared to the other arms. **Conclusions:** Cardioprotective pharmacological strategies in patients affected by BC receiving an anthracycline-based chemotherapy are well tolerated and seem to protect against cancer therapy-related LVEF decline and heart remodelling. Clinical trial information: NCT2236806. Research Sponsor: None.

Cardiac dysfunction (CD) among breast cancer survivors (BCS): Role of cardiotoxic therapy and cardiovascular risk factors. *First Author: Geoffrey S. Bostany, University of Alabama at Birmingham School of Medicine, Birmingham, AL*

Background: CD is the leading cause of mortality in BCS. Limited information regarding the long-term risk of CD after exposure to cardiotoxic agents (anthracyclines, trastuzumab/pertuzumab and left breast/chest wall radiation) and additional factors that place BCS at highest risk has precluded development of surveillance guidelines for early detection of CD in BCS. **Methods:** Patients, who survived ≥ 1 y after BC and received potentially cardiotoxic therapy, underwent q2y echocardiographic (echo) screening at a single center. All echos from BC diagnosis to CD or last follow-up were processed in Python via automated text analysis. New-onset CD was defined as left ventricular ejection fraction (LVEF) $< 50\%$ or fractional shortening (FS) $< 28\%$. Treatment exposures, demographics and cardiovascular risk factors (CVRFs: diabetes, hypertension, dyslipidemia, obesity, smoking) were abstracted from medical records. Cumulative incidence of CD described the magnitude of risk in the entire cohort and among those who received anthracyclines ($\pm$ radiation), trastuzumab/pertuzumab ($\pm$ radiation), and radiation alone (without anthracyclines/trastuzumab/pertuzumab). Cox proportional hazards models estimated hazard ratios (HRs) and 95% CIs of associations between CD and treatment, adjusting for CVRFs (time varying) and demographics. Longitudinal echocardiographic analyses (adjusted for covariates) estimated trends in cardiac function prior to CD. **Results:** We evaluated 2,540 echos in 847 BCS exposed to potentially cardiotoxic therapy (median age at BC: 54.4y; median follow-up: 7.6y). Overall, 39% of BCS received anthracyclines, 17% received trastuzumab/pertuzumab, 5% received anthracyclines + trastuzumab/pertuzumab, and 39% received radiation alone. The cumulative incidence of CD in the entire cohort was 12.3% at 2y, increasing to 29.7% by 10y after BC. Multivariable analysis revealed the following to be independently associated with CD: treatment (anthracyclines: HR=2.72, 95% CI=1.9-3.9; trastuzumab/pertuzumab: HR=1.92, 95% CI=1.1-3.2; ref: radiation alone), presence of CVRFs before CD diagnosis (hypertension: HR=1.77, 95% CI=1.3-2.4; obesity: HR=1.82, 95% CI=1.4-2.4; and dyslipidemia: HR=1.63, 95% CI=1.3-2.1). Adjusted longitudinal echo analyses revealed a statistically significant decline in SF over 20y from BC diagnosis (but prior to CD onset) for the entire cohort ($p=0.0007$), trastuzumab/pertuzumab ($p=0.006$), anthracyclines ($p=0.037$), and radiation alone ($p=0.01$). **Conclusions:** In this large cohort of BCS followed longitudinally for an extended period, exposure to potentially cardiotoxic therapy results in a substantial burden of CD; the risk increases over time, and with CVRFs. These results provide evidence for close surveillance of BC survivors at increased risk of CD for extended periods, and aggressive management of CVRFs before, during and after BC. Serum cytokines and autoantibodies to GM-CSF and immune-related colitis in ipilimumab-treated patients with cancer. *First Author: Edgar Gonzalez-Kozlova, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Despite the demonstrated efficacy of immune checkpoint inhibitors (ICI) including CTLA-4 and PD-(L)1 blockade, serious immune related adverse events including immune-related colitis (irColitis) often limit their use. Understanding the mechanisms that drive irColitis as well as predictive biomarkers is critical to informing the benefit-toxicity ratio of these medications. **Methods:** We tested serial blood specimens from 63 patients enrolled in six ipilimumab-containing clinical trials to evaluate changes in circulating cytokines and autoantibodies (auAb) to GM-CSF with irColitis occurrence. Retrospective blood specimens were analyzed from 31 patients who developed irColitis and 32 age and sex matched controls. irColitis was defined as either: 1) histologically confirmed colitis or 2) clinically significant diarrhea prompting initiation of corticosteroid therapy. Over a 24-week period, serum samples were collected at baseline, week 6, symptom onset, and post-symptom resolution. Serum proteins were assessed using the Immuno-Oncology and Inflammatory Olink panels. Anti-GM-CSF auAb were measured by enzyme-linked immunosorbent assay. Unsupervised clustering and mixed linear models were used to evaluate the changes associated with irColitis. Demographics, treatments, and technical variables were modeled for controlling artifacts. Significance was defined as $\text{Log2FC} > 0.5$, $P < 0.05$ and FDR < 0.05 (false discovery rate adjusted p-values) denoted with * and **, respectively. **Results:** While 69 proteins were significantly dysregulated with ICI treatment, patients who developed irColitis compared to those who did not showed higher levels of CD8A*, CXCL10* at baseline and prior to colitis onset at week 6, and then higher MMP10**, IL17A*-C*, CCL20**, OSM**, among others, at time of colitis and resolution. Further, patients who experienced irColitis showed an increase in anti-GM-CSF IgA** and IgG** Ab titers at Week 6 and at colitis onset compared with baseline, with higher IgA* after irColitis resolution compared to no colitis, while no significant differences were identified at baseline. **Conclusions:** Indicators of clinical outcomes can be obtained easily and minimally invasively by measuring circulating soluble proteins. Here, we identified differentially expressed cytokines associated with irColitis from retrospective cohorts. These potential biomarkers point to transient dysregulation of gut homeostasis that could help to stratify patients developing irColitis and to consider targeted mitigation strategies. These observations are currently being prospectively investigated. Long-term longitudinal patterns of patient-reported quality of life (QOL) after breast cancer (BC) to inform the implementation of personalized pathways of care. *First Author: Maria Alice B Franzi, Cancer Survivorship Group, INSERM Unit 981, Gustave Roussy, Villejuif, France*

Background: There is substantial inter individual variability in long-term trajectories of patient-reported quality of life (QOL) after early BC. Previous work focused on a selected group of patients (pts) treated with chemotherapy (CT) identified a cluster of pts with upfront poor QOL but also pts with severe, persistent post-chemotherapy QOL deterioration. We aimed to expand this work to a non-selected group of pts with early BC to identify latent clusters of pts at risk for QOL deterioration, and to assess the relationship of actionable host factors and health behaviors with trajectory group membership. **Methods:** We performed a detailed longitudinal analysis of QOL using a large ongoing national prospective clinical cohort (CANcer Toxicity, NCT01993498) of pts with stage I-III BC treated from 2012-2018. QOL (EORTC QLQ-C30 summary score) was assessed at diagnosis (dx, baseline) and year 1, 2, 4 and 6 post-dx. Baseline clinical, sociodemographic, behavioral, tumor-related, and treatment-related characteristics were available. Trajectories of QOL and group membership associations were identified by iterative estimations of group-based trajectory models and multi-variable multinomial logistic regression, respectively, among the whole cohort. **Results:** Among 10,792 pts, 5,695 received adjuvant CT and 8,805 received adjuvant endocrine therapy (ET). Four QOL trajectory groups were identified: excellent (N = 4,934, 45.8%), very good (N = 3,596, 33.3%), deteriorating (N = 1,745, 16.1%), and poor (N = 517, 4.8%). The deteriorating trajectory group reported fairly good baseline QOL (73.3 [95% CI], [72.4 to 74.2]), which significantly worsened at year-1 (63.0 [62.1 to 63.9]) and never recovered to pretreatment values through year-6 (64.7 [63.3 to 66.0]) post diagnosis. Factors associated with membership to the deteriorating group included younger age (aOR, 10-years decrement 1.10 [95% CI, 1.05 to 1.16]), overweight or obesity (aOR v lean, 1.90 [95% CI, 1.60 to 2.25]; 1.25 [95% CI, 1.07 to 1.46], respectively), physical inactivity (aOR v active, 1.13 [95% CI, 1.04 to 1.35]), former smoking behavior (aOR v never, 2.14 [95% CI, 1.80 to 2.54]), Charlson comorbidity score ≥ 1 (aOR v 0, 1.56 [95% CI, 1.33 to 1.83]), lower household income (< 3000 EU/month) (aOR v ≥ 3000 , 1.50 [95% CI, 1.30 to 1.72]), receipt of adjuvant CT (aOR v no, 1.35 [95% CI, 1.14 to 1.59]) and receipt of adjuvant ET (aOR v no, 1.46 [95% CI, 1.22 to 1.75]). **Conclusions:** This study will help identify latent clusters of pts who are at risk of persistent QOL deterioration after BC, independently of receipt of CT. Trajectory clustering can help facilitate the creation of personalized pathways that may include early addressal of actionable factors, including referral to social work and healthy lifestyle interventions. Cardiac safety of reduced surveillance for cancer therapy related cardiac dysfunction in patients with breast cancer treated with HER2-targeted therapy. *First Author: Anthony Francis Yu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Non-anthracycline-based therapy is a treatment option for patients (pts) with HER2-positive breast cancer (BC) and is associated with lower risk of cancer therapy related cardiac dysfunction (CTCRD) compared to anthracycline-based treatment. Given the reduced CTCRD risk with non-anthracycline HER2-targeted therapies, updates to practice guidelines that recommend surveillance echocardiograms (TTE) every 3 months are needed. We evaluated the cardiac safety of reduced CTCRD surveillance in pts receiving non-anthracycline HER2-targeted therapies. **Methods:** Pts with BC treated with non-anthracycline HER2-targeted therapy were enrolled in this single-arm prospective study. Pts with previous anthracycline exposure, uncontrolled hypertension (systolic blood pressure ≥ 160 mmHg), or significant cardiovascular disease were excluded. TTEs were performed at baseline, 6 months, and 12 months during HER2-targeted treatment. The primary endpoint was a cardiac event, defined by clinical heart failure (New York Heart Association Class III/IV) or cardiovascular death, with a prespecified non-inferiority margin of 2.9% relative to a cardiac event rate of 1.1% based upon prior studies. Secondary endpoints were CTCRD, defined by decline of left ventricular ejection fraction (LVEF) $\geq 10\%$ to $< 53\%$, and interruption of HER2-targeted treatment secondary to CTCRD. **Results:** Between May 2019 and January 2022, 190 pts (age 52 ± 11 y) with HER2-positive BC were enrolled: 143 (75%) had stage I disease, 8 (4%) had diabetes, 38 (20%) had hypertension, and baseline LVEF was $64 \pm 5\%$ (Table). Additional TTEs outside the prespecified 6- and 12-month timepoints were performed for 35 (18%) pts, of which 20 were to assess for possible cardiac symptoms. After 1-year follow-up, there were 0 (0%; 95% CI 0-1.9%) cardiac events. Two (1.1%) pts developed CTCRD and 1 (0.5%) pt had a temporary CTCRD-related treatment interruption. **Conclusions:** Reduced CTCRD surveillance every 6 months is feasible and safe for selected pts with HER2-positive BC receiving non-anthracycline HER2-targeted therapy. Our findings support the need to update cardiology practice guidelines and allow for less frequent surveillance TTEs among pts at low-risk for CTCRD. Clinical trial information: NCT03983382. Estimating burden of cardiovascular disease among survivors of breast, colorectal, lung, and prostate cancer in the detroit research on cancer survivors (ROCS) cohort. *First Author: Vidhya Nair, Ascension Providence Hospital/Michigan State University, Southfield, MI*

Background: With new advances in cancer treatment, cancer-specific mortality has decreased by 31% over the past 3 decades. The growing number of cancer survivors has led to increased risk of other chronic conditions including cardiovascular disease (CVD), which has become an important competing cause of mortality. This study evaluates the incidence of CVD, including heart failure (HF), myocardial infarction (MI), coronary artery disease (CAD), atrial fibrillation (AF) and stroke after cancer in the Detroit ROCS cohort. **Methods:** ROCS is an African American cancer survivorship cohort that enrolled participants residing in the tri-county Detroit Metropolitan area. This study included survivors of breast, colorectal, lung, and prostate cancer who provided socio-demographic and clinic information on self-administered questionnaires. We calculated incidence as percentages and rates per 1,000 person-years of HF, MI, CAD, AF, and stroke after cancer. Multivariate logistic regression analysis was used to evaluate the relationship between socio-demographic and clinical predictors of CVD by using factors with p-value < 0.1 . **Results:** After excluding patients with pre-existing CVD or lack of data on comorbidities, the study cohort consisted of 2,865 participants. The mean (SD) age at cancer diagnosis was 60.3 (9.4) years with median follow up of 3.0 (1.0-9.3) years. The incidence rate for any CVD was 23.3 per 1,000 person-years. In the study sample, stroke was the leading CVD, followed by HF, AF, CAD and MI. Lung cancer survivors had the highest incidence of CVD followed by prostate, breast, and colorectal cancer. Age at cancer diagnosis, household income, insurance, aspirin, smoking, body mass index, hypertension, diabetes, and high cholesterol were included in the final model. In the multivariate analysis, decreased household income [OR 1.26 (95% CI 1.05-1.52)], prior aspirin use [OR 1.83 (95% CI 1.34-2.49)], and history of hypertension [OR 1.71 (95% CI 1.20-2.44)] were associated with higher odds of CVD. **Conclusions:** CVD is a relatively common outcome within years after cancer diagnosis in an African American survivorship cohort. Intervention should focus on the possible impact of socioeconomic variables and control of hypertension in reducing the risk of CVD after cancer. Research Sponsor: Epidemiology Research Core and Service Incentive Program by the Karmanos Cancer Institute.

Social determinants of health and neurocognitive and psychosocial outcomes in adult childhood cancer survivors: A report from the childhood cancer survivor study (CCSS). *First Author: Jinbing Bai, Nell Hodgson Woodruff School of Nursing, Emory University, Atlanta, GA*

Background: Limited data exist on the impact of social determinants of health on neurocognitive, psychological, and quality of life (QOL) outcomes in adult childhood cancer survivors. **Methods:** We examined patient-reported outcomes (PROs) of neurocognitive function, psychological symptoms, and QOL in association with the Area Deprivation Index (ADI) and neighborhood ambient air quality in 5,131 survivors (52.1% female, mean [SD] age 29.9 [7.1], mean [SD] age at diagnosis 7.9 [6.2], 81.5% White, and 42.3% leukemia) from the Childhood Cancer Survivor Study. The ADI, which reflects neighborhood socioeconomic deprivation, was coded using survivors' residential 9-digit ZIP codes; neighborhood ambient air quality was coded by the NASA Satellite-based pollution measures PM_{2.5} and NO₂ by ZIP codes. Impairment on PROs was identified from scores on the Neurocognitive Questionnaire ($\leq 10^{\text{th}}$ %ile), the Brief Symptoms Inventory (BSI; $\geq 90^{\text{th}}$ %ile), the pain survey (yes vs. no), and the Medical Outcomes Study Short Form-36 ($< 16^{\text{th}}$ %ile). Multivariable logistic regression assessed associations between social determinants and PROs with odds ratios (OR) and 95% confidence intervals (CI), adjusting for demographic and treatment (chemotherapy and radiation) factors. **Results:** Among survivors, impaired neurocognitive function was reported in 26.5% for task efficiency, 25.4% memory, 15.4% emotional regulation, and 11.6% organization. For the BSI and pain survey, 56.7%, 11.3%, 8.3%, and 7.3% reported total pain, depression, somatization, and anxiety, respectively. Poor physical and mental domains of QOL were reported by 10.9% and 17.0% of survivors, respectively. Survivors with an ADI in the top deprived 20% neighborhoods (compared to the bottom 80% neighborhoods) reported worse neurocognitive function (task efficiency, OR 1.89, 95% CI 1.45-2.46; emotional regulation, OR 1.74, 95% CI 1.30-2.34; and memory, OR 1.67, 95% CI 1.29-2.17), more severe symptoms (pain, OR 1.34, 95% CI 1.05-1.70; somatization, OR 1.55, 95% CI 1.05-2.28; and depression, OR 1.70, 95% CI 1.19-2.44), and poorer QOL (physical, OR 1.75, 95% CI 1.28-2.38; mental, OR 1.79, 95% CI 1.35-2.36), controlling for treatment factors. Survivors from the 20% most deprived neighborhoods showed worse task efficiency (OR 1.50, 95% CI 1.03-2.17), adjusting for all confounders. PM_{2.5} and NO₂ levels were not associated with impairment on PROs, adjusting for all confounders. **Conclusions:** Social determinants, particularly living in the top deprived neighborhoods, are adversely associated with neurocognitive, psychological, and QOL outcomes in adult childhood cancer survivors. These findings indicate the critical need of evaluating childhood cancer survivors' area-level deprivation and tailoring support and interventions for survivors based on their social and structural contexts. A prospective study evaluating the association of patient-reported outcomes with activity level and sleep patterns in sarcoma survivors. *First Author: Elizabeth J. Davis, Vanderbilt University Medical Center, Nashville, TN*

Background: Sarcomas are a rare heterogeneous malignancy group affecting both sexes and all ages. Treatment is often intensive, resulting in long-term toxicities. Given the rarity of sarcoma, there is a paucity of data defining physical and emotional outcomes. The Cohort to Augment the Understanding of Sarcoma Survivorship Across the Lifespan (CAUSAL) was constructed at Vanderbilt University Medical Center (VUMC) to evaluate health-related outcomes. **Methods:** Sarcoma patients treated at VUMC from 2012 – present are enrolled into CAUSAL. Patient demographics, tumor and treatment data are abstracted from the electronic medical record. Participants complete surveys including PROMIS-57 consisting of seven domains including physical function, sleep disturbance, fatigue, and satisfaction with participation in social roles, which are reported here. Participants who have completed treatment are given a FitBit to track activity level and sleep over 12 weeks. Data are synced to an online platform, Fitabase. Body mass index (BMI) is assessed at study entry. For each participant, FitBit data were summarized using medians. To estimate the association between PROMIS-57 scores and activity and sleep data (FitBit), linear regression models were fit controlling for age, sex, and BMI of participants. **Results:** Of 306 CAUSAL participants who completed the PROMIS-57, 193 were post completion of sarcoma therapy. Of these, 76 also had FitBit data and are included in this analysis. Median step count was 5826 (quartiles: 3668, 7967), which was lower than average Fit Bit step count data for the US population (8170). Median daily active minutes was 252 minutes (quartiles: 174, 307). Median duration of sleep was 447 minutes (quartiles:381, 474) which was greater than the average reported by FitBit for the general US population (436 min). Step count was correlated with higher physical function score ($p < 0.001$). A 10-point increase in physical function led to an average increase of 1291 (95% CI: 609,1973) steps when adjusting for age and sex. Compared with participants receiving treatment within 30 days prior to CAUSAL enrollment, participants not receiving treatment had 4.50 (95% CI: 1.53, 7.47) higher physical function score and 6.26 (95% CI: 1.87, 10.65) higher satisfaction in their social roles. There was no correlation between minutes of sleep recorded by FitBit and PROMIS responses. **Conclusions:** Using PROMIS-57, and FitBits, we demonstrated an association between higher step counts and self-reported higher physical function but did not find a correlation between FitBit recorded activity level/sleep and self-reported sleep disturbance or fatigue scores. Further, our data suggests patients with sarcoma sleep more and walk less than the general US population. As enrollment continues in CAUSAL, we will focus on PROMIS scores over time and their association with activity level and sleep. Research Sponsor: U.S. National Institutes of Health.

A genome-wide association study for doxorubicin-induced cardiomyopathy in childhood cancer survivors from the St. Jude lifetime cohort (SJLIFE) and the childhood cancer survivor (CCSS) studies. *First Author: Kateryna Petryk, St Jude Childrens Research Hospital, Memphis, TN*

Background: Treatment of childhood cancer using doxorubicin is associated with a well-established dose-related risk of cardiomyopathy, which can lead to heart failure and affects ~7-10% of exposed children and adolescents. Here, we identified a genetic variant associated with risk of doxorubicin-induced cardiomyopathy (diCM) in survivors of childhood cancer. **Methods:** A genome-wide association study using common variants ($MAF \geq 5\%$; whole-genome sequencing data) was performed among 993 SJLIFE survivors of European ancestry (median age, 36.6 years; range, 8.7-62.2 years) treated with doxorubicin only (210 with diCM; defined as CTCAE grade ≥ 2 clinically assessed cardiomyopathy). Replication analyses were performed separately among 1,430 CCSS survivors of European ancestry (median age, 35.4 years; range, 15.8-60.7 years) and 159 SJLIFE survivors of African ancestry (median age, 32.6 years; range, 8.9-61.1 years) exposed to doxorubicin only. Analyses were adjusted for age at primary cancer diagnosis, sex, doxorubicin dose, age at last contact and top five principal components. **Results:** We identified a genome-wide significant association between a novel locus near *HS3ST4* and diCM risk in SJLIFE survivors of European ancestry ($rs112474856$; $OR = 2.78$; $P = 3.3 \times 10^{-8}$). This association replicated in CCSS survivors of European ancestry ($OR = 1.74$, $P = 0.036$) but had an opposite effect among SJLIFE survivors of African ancestry ($OR = 0.34$, $P = 0.028$). SNP $rs112474856$ did not show significant association with diCM risk in two independent datasets including survivors of European ancestry in SJLIFE ($OR = 1.20$; $P = 0.71$) and CCSS ($OR = 1.02$; $P = 0.98$) who were not exposed to doxorubicin but were treated with daunorubicin or chest radiotherapy, suggesting doxorubicin specificity. No association was observed between $rs112474856$ and risks of cardiomyopathy ($OR = 1.00$; $P = 0.88$) or heart failure ($OR = 1.00$; $P = 0.59$) in 361,194 UK Biobank participants from the general population. *HS3ST4* was significantly upregulated ($P = 4.7 \times 10^{-6}$) in response to doxorubicin treatment in human induced pluripotent stem-cell-derived cardiomyocytes from patients with diCM. *HS3ST4* encodes heparan sulfate, the latter was recently linked to immune activation, cardiac fibrosis, and heart failure. **Conclusions:** Leveraging the two largest cohorts of childhood cancer survivors in North America, we identified and replicated a novel locus for diCM which was associated with increased risk in survivors of European ancestry but decreased in their African counterpart. Training and validation of a model predicting clusters of long-term cancer-related behavioral symptoms (CRBS) after breast cancer (BC). *First Author: Martina Pagliuca, INSERM Unit 981, Gustave Roussy, Villejuif, France*

Background: Fatigue, cognitive impairment, emotional distress, and sleep disturbance are prevalent and challenging symptoms among patients (pts) with BC. These symptoms often tend to cluster, they are usually responsive to similar behavioral interventions (e.g., exercise, psychosocial), and can be collectively defined as CRBS. We aimed to generate a model to predict clusters of long-term CRBS. **Methods:** CANcer Toxicity (CANTO; NCT01993498) is a prospective cohort of pts with stage I-III BC collecting longitudinal data at diagnosis (dx) and yearly post-dx. Our outcome was the proportion of pts reporting a cluster of ≥ 3 severe CRBS (EORTC QLQ-C30/HADS) 4 years post-dx. Clinical, behavioral, treatment (tx)-related predictors, and the baseline Behavioral Symptoms Score (BSS; based on the number of severe CRBS as proxy of symptom burden at dx) were tested in a training cohort (Mar 2012 - Feb 2015) with a multivariable logistic regression model implementing bootstrapped Augmented Backwards Elimination and 10-fold internal cross-validation. Performance was externally validated in pts from a subsequent enrolment period (Mar 2015 - Apr 2018). **Results:** In the training cohort (N=3555), 92.1% of pts had stage I-II BC, 52.6% received chemo, and 81.9% endocrine tx. At dx, 22.0% pts had severe fatigue (C30 $\geq 40/100$), 29.7% severe cognitive impairment (C30 $< 75/100$), 33.9% and 6.5% clinically suggestive anxiety and depression (HADS $\geq 11/21$), respectively, and 35.2% severe insomnia (C30 $> 50/100$). 19.0% of pts reported a severe CRBS cluster at dx, then 21.0% did so 4 years post-dx. Younger age, previous psychiatric disorders, and higher baseline BSS were predictors of CRBS clusters (Table:AUC 0.73 [95%CI 0.71-0.75]). Results were confirmed in the validation cohort (N=1533). **Conclusions:** 1 in 5 pts reports a cluster of severe CRBS 4 years post-dx of BC. Younger pts with previous psychiatric disturbance and a higher symptom burden at dx have greater risk of long-term CRBS. Systematic clinical implementation of predictive tools at dx of BC can aid a more thorough screening and referrals to targeted behavioral interventions. Clinical trial information: NCT01993498. Research Sponsor: National Research Agency (ANR), Grant No. ANR-10-COHO-0004; Conquer Cancer Foundation of the American Society of Clinical Oncology; Rising Tide Foundation for Clinical Cancer Research.

Burden of chronic health conditions (CHCs) among people with HIV (PWH) and non-AIDS defining cancers (NADC): A report from the center for AIDS research (CFAR) network of integrated clinical systems (CNICS). *First Author: Gaurav Goyal, University of Alabama at Birmingham, Birmingham, AL*

Background: Advances in anti-retroviral therapy (ART) have led to improved life expectancy of PWH and a growing population of PWH who are at an increased risk of NADC. While the risk of CHCs in HIV uninfected cancer survivors is well known, the burden of morbidity (CHCs) borne by PWH-NADC remains understudied and can adversely influence long-term survival. **Methods:** We utilized CNICS data for PWH ≥ 18 y from 1995- 2018. CNICS data are harmonized across 8 academic sites, comprising patient-level clinical, morbidity, and outcomes data in the ART era. We included individuals with the five most common NADCs: anal squamous cell cancer, non-small cell lung cancer (NSCLC), prostate cancer, classic Hodgkin lymphoma (cHL), and hepatocellular cancer (HCC). For controls, we conducted a 1:2 matching (age at CNICS entry, year of CNICS entry, sex) for each NADC subgroup to select PWH and no NADC at last follow-up. Comorbidities diagnosed after cohort entry are validated in CNICS and were graded using the Common Terminology Criteria for Adverse Events into grade 1 (mild) through grade 4 (severe/life-threatening). **Results:** We included 693 PWH-NADC and 1,345 non-cancer PWH controls in this study. The NADC distribution was anal cancer (n = 195, 28%), NSCLC (n = 155, 22%), prostate cancer (n = 144, 21%), cHL (n = 124, 18%), and HCC (n = 75, 11%). Mean age at CNICS entry was 45y for cases and controls (SD: 10.4). At a median follow-up of 12.5y for cases and 9.5y for controls, the prevalence of all-grade and grade ≥ 3 CHCs was higher in PWH-NADC compared with controls (94% vs. 88%, and 25% vs. 14%, respectively [$p < 0.01$]). PWH-NADC had a higher prevalence of all-grade HTN (87% vs. 80%), CKD (49% vs. 46%), hyperlipidemia (56% vs. 50%), DM (26% vs. 18%), VTE (4% vs. 1%), MI (12% vs. 5%), and CHF (7% vs. 3%) compared with controls (p-value for all < 0.01). In Cox regression including type of NADC, age at CNICS cohort entry, ART use, race/ethnicity, NADCs were associated with increased risk of new-onset grade 3 or 4 CHCs (HR 2.94, $p < 0.01$). When examining specific CHCs, all NADCs were associated with increased risk of new-onset grade 3 DM (anal cancer HR 2.34, HCC HR 5.02, NSCLC HR 3.89, cHL HR 2.77, and prostate cancer HR 1.88), p-value for all < 0.01). Additionally, NSCLC was associated with increased risk of G3-4 MI (HR 2.79, $p = 0.04$), and prostate cancer with G3-4 CHF (HR 6.19, $p < 0.01$). **Conclusions:** In this large multi-institutional study, 25% of PWH-NADC had developed severe/life-threatening CHCs at last follow up. Occurrence of NADC among PWH was associated with increased hazards of developing grade ≥ 3 morbidities. The specific types of CHCs observed in PWH with NADC subtypes could be used to inform risk-based anticipatory surveillance and risk reduction strategies. Polygenic risk of anthracycline-related cardiomyopathy in childhood cancer survivors: Report from children's oncology group and childhood cancer survivor study. *First Author: Noha Sharafeldin, Department of Hematology & Oncology, School of Medicine, University of Alabama at Birmingham, Birmingham, AL*

Background: Considerable inter-patient variability in anthracycline-related cardiomyopathy (aCM) risk exists among childhood cancer survivors (CCS). A polygenic risk score (PRS) that accounts for combined effects of multiple genetic variants is established in other clinical situations, but remains understudied in anthracycline-exposed CCS. **Methods:** For discovery, a case-control set of 278 anthracycline-exposed non-Hispanic White (NHW) CCS (129 aCM cases; 149 controls) matched on primary cancer diagnosis, year of diagnosis and duration of follow-up was included from a Children's Oncology Group study (COG-ALTEO3N1). Genomic DNA underwent whole exome sequencing (100X depth). We searched Medline and Embase databases between 2005 and 2022 to curate evidence for published single nucleotide polymorphisms (SNPs) associated with CM. We identified 1,156 SNPs on 343 genes with minor allele frequency [MAF] ≥ 0.05 in white populations. We constructed a weighted PRS using sequenced SNPs that were linkage disequilibrium pruned, yielding a final list of 279 independent SNPs. Conditional logistic regression models adjusted for anthracycline dose, age at diagnosis, sex, chest radiation and cardiovascular risk factors (CVRFs; diabetes, hypertension, dyslipidemia) were used to estimate PRS-aCM associations. An independent population of 475 anthracycline-exposed NHW CCS from the Childhood Cancer Survivor Study (CCSS: 96 cases; 379 matched controls) was used to replicate the PRS-aCM association. Area under the receiver operating characteristic curve (AUC) was used to evaluate the performance of a model including the PRS. **Results:** Median age at primary cancer diagnosis was 7y for cases and controls in the Discovery and 11y in the Replication set. Mean anthracycline dose was higher for cases (Discovery: 312 $\pm$ 186 mg/m²; Replication: 333 $\pm$ 289 mg/m²). Cases were more likely to have received chest radiation (Discovery: 35.7% ν 24.8%; Replication: 34.3% ν 23.2%); and were more likely to have a CVRF (Discovery: 37.2% ν 8.7%; Replication: 55.2% ν 31.9%). PRS_{continuous} was significantly associated with aCM (aOR = 2.09, 95%CI: 1.1-4.0, p = 0.024) in the Discovery set. Compared to a model with clinical variables only, a model including the PRS had significant predictive performance: AUC_{clin} = 0.72, 95% CI: 0.65-0.79. ν AUC_{clin+PRS} = 0.91, 95% CI: 0.87-0.95, p < 0.001. In the Replication set, the top PRS quartile (top 25%) was significantly associated with aCM (aOR = 2.14, 95%CI: 1.05-4.37, p = 0.036; reference: lowest PRS quartile). **Conclusions:** The significant association between this comprehensively curated PRS and aCM in CCS could serve as an important tool to identify survivors at increased risk for CM and inform targeted interventions. The impact of population pharmacogenomics and risk allele frequencies on cisplatin-induced peripheral sensory neuropathy (PSN). *First Author: Swetha Nakshatri, University of Chicago, Chicago, IL*

Background: Taxane-treated breast cancer patients with genetically African ancestry have worse PSN than other groups. However, no study has examined the association between ancestry and PSN after cisplatin-based chemotherapy. Increased risk could be partially explained by differing risk allele frequencies across populations for alleles increasing the general vulnerability to PSN or altering drug metabolism. **Methods:** The Platinum Study enrolled cisplatin-treated testicular cancer survivors (TCS) who completed clinical exams and surveys. A PSN score was derived from the mean of 8 sensory items (using EORTC-CIPN20), assigning severity on a 0-2 scale. Multidimensional scaling scores for each TCS were calculated, plotted and anchored by data from the 1000 Genomes Reference population to determine genetic ancestry. Multinomial logistic regression assessed the association between genetic ancestry and PSN. To determine risk alleles for PSN and allele frequencies across populations, risk allele panels were created, including ancestry-informative markers (AIMs) determined by the AncestrySNPMiner tool. Allele frequencies were calculated in each group; SNPs with frequency differences > 0.3 in the African (AFRAFR) population vs. others were included. For filtering the AIMs, GTEx data was used to identify expression quantitative trait loci (eQTL) or splicing quantitative trait loci (sQTL) in nerve/brain tissue. Multinomial logistic regression assessed associations between SNP genotype and PSN phenotype for SNPs with differing allele frequencies across populations. **Results:** Despite small numbers of non-Europeans, TCS with African ancestry had increased incidence and severity of PSN vs. TCS with European ancestry. In a subset analysis of EUR (n = 681) and AFRAFR (n = 13) patients who received 400-450 mg/m² of cisplatin, the relative risk ratio (RRR) in the AFRAFR vs. EUR TCS of severe neuropathy vs. none was 7.96 (P = 0.074) and the RRR for any neuropathy vs. none was 7.79 (P = 0.049). There were 394 independent AIMs with significant (> 0.3) allele frequency differences between the AFRAFR and other populations that were eQTLs and/or sQTLs in nerve/brain tissue. Using multinomial logistic regression between genotype and phenotype for all TCS (n = 1513) with covariates for age at survey and 10 genetic principal components: 16 SNPs had P-values < 0.05 for severe PSN vs. none and/or any PSN vs. none. Although not statistically significant with multiple testing corrections, these suggestively significant SNPs could be potentially validated in additional populations. **Conclusions:** These results are preliminary evidence for the potential importance of differing risk allele frequencies across populations in explaining some disparities in cisplatin-related PSN. If confirmed, genotyping for risk variants could impact treatment decisions and enable monitoring to mitigate PSN. Research Sponsor: U.S. National Institutes of Health.

Long-term prospective data on correlation between overall mortality and HADS (Hospital Anxiety and Depression Scale) assessed psychological distress in prostate cancer patients (11 year follow-up data). *First Author: Santhanam Sundar, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom*

Background: We prospectively assessed whether Psychological factors such as anxiety and depression can have a detrimental effect on long term overall survival of prostate cancer patients (pts). **Methods:** Prostate cancer pts participating in an ethics Committee approved, Prospective study evaluating an Andropause rating scale. All pts had radical radiotherapy with androgen deprivation therapy. Pts completed a baseline HADS questionnaire before any treatment was initiated & at 3mths & after completion of hormone therapy. Patient characteristics: Median age: 69 yrs (50 to 78 yrs). Charlson Comorbidity Index (CCI) prevalence at baseline as follows CCI-I 6.1%; CCI-II: 33.8%; CCI-III: 37.2%; CCI-IV: 14.2%; CCI-V: 6.1% and CCI-VI: 2.7%; At the survival update in Feb 2023, 49.3% of patients have died [n = 148]; Gleason grade was Low risk in 7.2%; Intermediate in 53.4% and high risk in 39.2%; Baseline PSA was < 10 ug/L in 45.3%; 10-20 ug/L in 33.1% and > 20 ug/L in 21.6%; Tumour stage was T1 in 8.1%; T2 in 63.5% and T3 in 28.4%. Baseline Median serum testosterone was 11.9 nmol/l (min 2.6 and max 26.7). Hormone duration was < 3 mths in 22.3%; 3-6mths in 35.8%; 6 to < 36mths in 19.6% and > 36mths in 22.3%. Cox regression models estimated hazard ratios (HR) and 95% confidence intervals (CI) of overall mortality, while controlling for the following covariates (Age, T stage, Gleason risk category, PSA Category, Baseline Serum Testosterone, ADT duration category and Charlson Comorbidity index). **Results:** Higher anxiety at time of diagnosis had a statistically significant adverse effect on overall survival (table); Higher depression symptoms at baseline did not affect survival but depressive symptoms after completing cancer treatment did affect all-cause mortality in this mature dataset with a median follow up of more than 11 years. **Conclusions:** Higher anxiety and depression symptoms in prostate cancer patients are associated with significantly higher long-term all-cause mortality. Racial and ethnic disparities in survival among persons with subsequent primary cancer. *First Author: Hyuna Sung, American Cancer Society, Atlanta, GA*

Background: Racial and ethnic disparities in survival after first primary cancer diagnoses have been well documented. Yet comprehensive data for disparities after subsequent primary cancer (SPC) are lacking despite the growing burden of SPCs. **Methods:** This study included 230,370 persons diagnosed with one of the 13 common SPCs at ages ≥ 20 years during 2000-2013 in 18 Surveillance, Epidemiology, and End Results registries. Cause-specific proportional hazards models were used to estimate HR (hazard ratio), overall and stratified by SPC types, comparing the risk of cancer or cardiovascular death in Hispanic, non-Hispanic Asian or Pacific Islander (API), or non-Hispanic Black (Black) persons to that in non-Hispanic White (White) persons. HRs were adjusted for sex, first primary cancer type and stage, age and year of SPC diagnosis (base model); and additionally household income, urbanicity, SPC stage, subtype, and treatment receipt (surgery, radiotherapy, chemotherapy) (final model). **Results:** During 54 months of median follow-up, 109,757 cancer deaths and 18,283 cardiovascular deaths occurred among persons with SPCs. Overall, HRs for cancer death were higher among Black (HR = 1.21, 95% CI = 1.18-1.23) and Hispanic (HR = 1.10, 95% CI = 1.07-1.13) persons compared with White persons, but lower among API persons (HR = 0.93, 95% CI = 0.90-0.96) in the base model. When stratified by SPC types, the increased HRs were evident for 10 of 13 cancers among Black persons with the greatest HR among those with uterine corpus cancer (HR = 1.87, 95% CI = 1.63-2.15) and for 7 of 13 cancers among Hispanic persons with the highest HR among those with melanoma (HR = 1.46, 95% CI = 1.21-1.76). For cardiovascular death, compared with White persons, the overall HR was higher among Black (HR = 1.42, 95% CI = 1.35-1.49) persons but lower among API (HR = 0.75, 95% CI = 0.69-0.81) and Hispanic (HR = 0.90, 95% CI = 0.84-0.96) persons. The risk of cardiovascular death was higher for 11 of 13 cancers among Black persons with the greatest HR among those with pancreatic (HR = 1.80, 95% CI = 1.17-2.75), thyroid (HR = 1.70, 95% CI = 1.12-2.57), and kidney (HR = 1.63, 95% CI = 1.38-1.93) cancers. Additional adjustments in the final model reduced the elevated HRs substantially especially for cancer death among Black or Hispanic persons, although the associations remained statistically significant for most cancers. **Conclusions:** Among persons with SPCs, Black persons had a higher risk of death from both cancer and cardiovascular disease, whereas Hispanic persons had a higher risk of death from cancer. Adjusting for differences in potentially modifiable factors attenuated the associations substantially, highlighting opportunities for interventions toward health equities among cancer survivors. Sexual dysfunction in patients with cancer: Results from the CLARIFY project. *First Author: Aylene Vanessa Ospina Serrano, Instituto de Investigación Sanitaria Puerta de Hierro - Segovia de Arana. Hospital Universitario Puerta de Hierro, Majadahonda, Madrid, Spain*

Background: Survivors patients with cancer may suffer long-term consequences related to antineoplastic treatments and tumor itself, leading to deterioration of quality of life and resulting in disturbances including sexual dysfunction (SD). We aimed to identify and characterize SD in a cohort of Spanish patients. **Methods:** Analytical observational study in patients included in the CLARIFY H2020 project at the Hospital Universitario Puerta de Hierro. From October 2020 to May 2022, clinical and demographic variables were collected as well as measures of sexual function using a validated Spanish-language, gender-targeted separately questionnaire. A descriptive domain on frequency of sexual activity during the last four weeks (DFS) and multiple domains assessing phases of sexual response (DESR), according to DSM IV and DSM V parameters including desire, arousal, lubrication, orgasm, satisfaction with sexual performance, global sexual satisfaction, anticipatory anxiety and sexual initiative were evaluated. Descriptive, trend associations and logistic regression analyses were performed. **Results:** 383 patients were included, cancer type distribution was breast cancer 68.14% (261), lung cancer 26.37% (101) and lymphomas 5.50% (21). The average age was 56.5 years (range 33-88). 19.58% (75) of patients were men and 80.42% (308) woman. 69% of men and 31% of women reported they were sexually active. The absolute frequency of Global sexual dissatisfaction (GSD) was 76% in women and 24% in men, according to neoplasia; GSD was 36% in patients with early breast cancer, 14% in men with lymphoma, and 9% in men with lung cancer. Women with metastatic breast cancer presented the highest tendency to have severe disorders of DESR. In multinomial logistic regression, significant associations were found in women with metastatic breast cancer and severe disorders of: arousal (p 0.000), lubrication (p 0.002) orgasm (p 0.000), as well as dissatisfaction with sexual performance (p 0.000) and global sexual dissatisfaction (p 0.000). On the other hand, in women with lung cancer, severe arousal disorder (p 0.016) and global sexual dissatisfaction (p 0.044) were observed. **Table. Conclusions:** In our study, cancer survivors have high prevalence of SD related with oncological treatment and clinical characteristics of malignancy, being women the most affected population. Efforts should be made to support SD during follow-up to improve the quality of life of this growing oncologic population. Research Sponsor: European Commission, H2020 programme.

Propensity score matched analysis of major adverse cardiac events in patients with localized prostate cancer receiving short term vs long term ADT. *First Author: Ye Yuan, Atropos Health, Palo Alto, CA*

Background: ADT is often used with radiation for dose-intensification in intermediate-risk prostate cancer (PrCa). ADT includes gonadotropin-releasing hormone (GnRH) agonists, often started with antiandrogens to prevent the initial surge in serum testosterone as well as GnRH antagonists. Studies have reported associations of ADT with increased risks of cardiovascular events. This is thought to be related to atherosclerosis, dyslipidemia and insulin resistance. Therefore, there is an opportunity to individualize ADT use to balance risk of PrCa specific outcomes with risk of MACE. To address this, we assessed whether there is a difference in major adverse cardiac events (MACE) between ST-ADT (< 6 months) or LT-ADT (> 6 months) in patients with localized PrCa. **Methods:** A nationally representative EHR-derived dataset was queried for patients with at least 90 days of longitudinal records and 90 days of continuous follow up. The inclusion criteria was a diagnosis of PrCa based on standardized diagnoses codes (ICD9 and ICD10). Patients who had a history of MACE (defined as combination of diagnosis and procedure codes associated with CAD, MI, unstable angina, CABG, PCI, catheterization) metastases, PSA above 10ng/mL, imaging for metastatic PrCa, or having received abiraterone or docetaxel within 3 months of inclusion were excluded. Patients were defined as receiving ADT if they received leuprolide, goserelin, bicalutamide, triptorelin, degarelix, flutamide, or nilutamide. The primary outcome of risk of any new MACE was compared between arms with Cox proportional hazards regression. Secondary outcomes including 10 year rates of new diagnoses of CAD, metastases, and new heart procedures were compared between arms with the Chi-square test. Significance was set at a two sided p-value of 0.05. All analyses were performed without matching, with age and gender matching, and high dimensional propensity-score matching (hdPS) using R version 4.05. **Results:** We identified 1209 patients with local PrCa and no prior MACE or use of abiraterone or docetaxel within 3 months of diagnosis. 385 patients received ST-ADT and 824 received LT-ADT. Baseline characteristics were comparable between the two arms with similar ages, and comorbidity scores. There was no significant difference in metastatic recurrence between arms in hdPS-matched analysis HR 0.95 [0.64-1.38] p = 0.8. There was also no significant difference in the composite endpoint of MACE HR 1.42 [0.86-2.36] p = 0.173. More patients in the LT-ADT arm had new CAD, which was significant after hdPS-matched analysis OR 1.84 [1.07-3.14], p = 0.024. **Conclusions:** In a national dataset analysis of patients with local PrCa and no history of MACE or abiraterone or docetaxel within 3 months of diagnosis LT-ADT was associated with increased odds of CAD but there was no difference in the composite endpoint of MACE or metastatic recurrence. Associations among anesthesia-induced brain biomarkers during surgery, preoperative exposure to cancer therapeutics, and clinical outcomes. *First Author: Tom A.D. Stone, Massachusetts General Hospital, Boston, MA*

Background: Cognitive impairment represents a key concern in oncology, as issues with memory and concentration can be a debilitating side effect of cancer and its treatment. Prior work demonstrates that the power of the alpha wave, a pattern of electroencephalographic (EEG) signals in the brain in patients under general anesthesia, correlates with cognitive function. In this study, we sought to investigate the associations among anesthesia-induced alpha power, preoperative exposure to cancer therapeutics, and clinical outcomes in a large cohort of patients undergoing surgery. **Methods:** We analyzed intra-operative EEG recordings of a retrospective cohort of patients with and without cancer who underwent surgery with general anesthesia at a single institution between 4/2016 - 12/2019. We used multivariable regression models (adjusted for age, sex, history of dementia) to determine associations of cancer-related covariates with patients' alpha power (measured in decibels [dB]), and to determine associations of alpha power with clinical outcomes, such as hospital length of stay, discharge location, hospital readmission, and survival. **Results:** Among 1,084 total patients included in this study, 377 (35%) had a preoperative diagnosis of cancer. The most common cancer diagnoses were breast (87, 23% of those with cancer), gastrointestinal (85, 23%), genitourinary (73, 19%), and lung (47, 12%). We found that a cancer diagnosis alone was not associated with alpha power (-0.015 dB, p = 0.95). However, among patients with cancer, receiving chemotherapy within 3 months before surgery was associated with a 1.6dB drop in alpha power (p < 0.001). By comparison, having a preoperative diagnosis of dementia was associated with a drop of 2.86dB (p < 0.001). Decreased alpha power was associated with longer hospital stays (1.03 times longer per dB drop, p < 0.001), higher rates of discharge to a rehab facility (odds ratio [OR] = 1.22 per dB drop, p < 0.001), and higher mortality (hazard ratio = 1.085 per dB drop, p < 0.001). We found no association between alpha power and 30-day readmission (OR = 1.04, p = 0.24). **Conclusions:** In this large cohort of patients undergoing surgery, we found that alpha power correlated with several important clinical outcomes, and that recent receipt of chemotherapy was associated with a decrease in alpha power. Of note, the observed drop of 1.6 dB among those with recent chemotherapy is roughly equivalent to aging 10-15 years, while a diagnosis of dementia was associated with a nearly 3dB drop in alpha power. As evidence suggests that alpha power corresponds with patients' cognitive function, our findings highlight the need to prospectively monitor and track longitudinal alpha power in patients receiving cancer treatment to determine if early detection of changes in alpha power may predict for future treatment-related cognitive decline. Associations of employment disruptions and financial hardship among individuals diagnosed with cancer in the US. *First Author: Michael T. Halpern, National Cancer Institute, Bethesda, MD*

Background: Financial hardship is experienced by approximately half of working-age individuals diagnosed with cancer. Many working individuals diagnosed with cancer also experience disruptions with their employment. This study examines whether employment disruptions are associated with financial hardship among individuals diagnosed with cancer in the US. **Methods:** We utilized data from the 2016/2017 Medical Expenditure Panel Survey (MEPS) Experiences with Cancer self-administered questionnaires and identified individuals diagnosed with cancer at age >18 who worked for pay at the time of or following their cancer diagnosis. Employment disruption was defined as taking extended paid time off work; switching to a part time or less demanding job or to a flexible work schedule; and/or retiring early due to cancer, cancer treatment, or late effects. Financial hardship was defined in 3 domains: material (borrowing money, financial sacrifices, or being unable to cover medical costs); psychological (worrying about medical bills, financial stability, keeping job/income, or future earnings); and behavioral (delaying/forgoing medical care because of cost). Multivariable logistic regression analyses adjusting for the MEPS survey design were used to determine associations of employment disruption due to cancer with any financial hardship and with financial hardship intensity while controlling for patient demographic, health insurance, and clinical characteristics. **Results:** Among 732 individuals with a cancer history, 47.4% experienced employment disruptions and 55.9% experienced any financial hardship. Financial hardship was significantly more common among cancer survivors with employment disruptions than without disruptions (68.7% vs. 44.5%; p-value of difference < 0.0001). Findings were consistent across multiple hardship measures/domains and across years since last cancer treatment. In multivariable logistic regression analyses, cancer survivors with employment disruptions were significantly more likely to have greater (OR = 2.8; 95% CI 2.0, 3.9) financial hardship intensity. Individuals of race/ethnicity other than non-Hispanic White; who had Medicare (vs. private) insurance and were age < 65 years old at diagnosis; or had breast, colon, or prostate cancer (vs. melanoma reference group) were also more likely to experience financial hardship. Older individuals and those who were married were less likely to experience financial hardship. **Conclusions:** Employment disruptions are common and significantly associated with multiple types of financial hardship among cancer survivors. Employer workplace accommodation and other policies to minimize disruptions among individuals diagnosed with cancer may reduce financial hardship in this vulnerable population. Patient-reported symptom monitoring linked to an alert algorithm: Effects on progression-free and overall survival in the SYMPRO-Lung trial. *First Author: Nicole Erica Billings, Amsterdam UMC, Amsterdam, Netherlands*

Background: Physician-initiated (active) monitoring of patient-reported outcomes (PROs) improves health-related quality of life (HRQOL) and overall survival (OS) in comparison to care as usual. We recently reported data from the SYMPRO-Lung trial showing for the first time that patient-initiated (reactive) PRO monitoring is equally effective as physician-initiated (active) monitoring in improving HRQOL. Here we investigate whether online PRO symptom monitoring via the active and reactive approach is also associated with improvements in 1-year progression-free survival (PFS) and OS compared to care as usual in lung cancer patients. **Methods:** SYMPRO-Lung is a Dutch multicenter randomized trial using a stepped wedge design. Inclusion criteria were (non-)small cell lung cancer stage I-IV, starting treatment. Patients in the intervention groups reported PRO symptoms weekly up to 1 year follow-up using the PRO-CTCAE lung cancer subset. If symptoms exceeded a pre-determined threshold, an alert was sent to a physician/nurse (active intervention group) or to the patient themselves (reactive intervention group). Survival was defined as time from start of treatment until progression (PFS), death (OS) or loss to follow-up. Follow-up time of all groups was calculated using the reverse Kaplan-Meier method. Cox proportional hazard analyses were performed to estimate the effect of PRO symptom monitoring on PFS and OS, adjusting for potential confounding (i.e. clinical characteristics and baseline EORTC QLQ-C30 domain scores). **Results:** 515 patients were included in the study (266 control, 249 intervention). The most pronounced uneven distribution in baseline characteristics was that the active intervention group had significantly more stage IV patients compared to the control group and the reactive intervention group (63% vs. 44% vs. 44%, $p=0.001$). The median follow-up duration was 12 months for all groups. Age, sex, cancer staging, ECOG performance status and some baseline EORTC domain scores affected the association and were included as covariates in the analyses. Although not significant, we observed a tendency towards a PFS benefit for the active intervention group compared to care as usual (HR .78, 95%CI: .58 – 1.04) and an OS benefit for both of the intervention groups compared to care as usual (active: HR .80, 95% CI: .55 – 1.15; reactive: HR .69, 95% CI: .42 – 1.15). **Conclusions:** Although not significant, weekly PRO symptom monitoring linked to an alert algorithm showed a tendency towards a small 1-year survival benefit in lung cancer patients. Since we did not power the trial to demonstrate a survival benefit, the non-significant association might be due to a limited sample size. However, the positive results of symptom monitoring in improving HRQOL within our trial still provide sufficient evidence for implementation of PROMs in standard (lung) cancer care. Patient- versus clinician-reported symptoms in the POLARIX study. *First Author: Carrie A. Thompson, Mayo Clinic College of Medicine, Rochester, MN*

Background: The safety profiles of novel agents are mainly based on clinician-reported adverse events (AEs) from clinical trials. Patient-reported outcomes (PROs) may better represent the treatment burden experienced by patients (pts) compared with clinician-reported AEs. Using data from POLARIX, a double-blind, placebo-controlled, randomized Phase 3 international study (NCT03274492), we previously presented PRO and clinician-reported data showing similar rates of neuropathy (Trnėný et al. 2022). Here, we evaluate the reporting of other common symptoms using PRO and clinician-reported data in POLARIX. **Methods:** POLARIX methods were previously described (Tilly et al. 2022); this analysis included all pts with PRO data. PRO and clinician-reported data described the incidence and severity of fatigue, constipation, diarrhea, nausea, and vomiting. Clinician-reported severity grading was based on the NCI Common Terminology Criteria for Adverse Events (NCI-CTCAE) v4.0. PROs were collected using the European Organisation Research and Treatment of Cancer Quality of Life-Core 30 questionnaire (EORTC QLQ-C30), which was administered to pts at clinic visits on Day 1 of Cycles 1 (baseline), 2, 3, and 5, and end of treatment (EOT). PRO severity scores included 'A little', 'Quite a bit', and 'Very much'. **Results:** Overall, 825 pts were evaluable. From baseline to EOT, PROs showed a higher incidence of symptoms compared with clinicians for fatigue (98% vs 27%), constipation (68% vs 29%), diarrhea (56% vs 26%), nausea (58% vs 40%), and vomiting (24% vs 15%). PRO severity scores of 'Quite a bit' or 'Very much' were reported in 33% of pts for fatigue, 29% for constipation, 17% for diarrhea, 19% for nausea, and 7% for vomiting. Clinicians reported Grade ≥ 2 symptoms in 11% of pts for fatigue, 11% for constipation, 11% for diarrhea, 14% for nausea, and 6% for vomiting. **Conclusions:** In POLARIX, pts reported a higher incidence and severity of symptoms compared with clinicians. Although distinct scales were used, the differences in symptom rates reported by pts and clinicians were clinically meaningful. These data may have implications for symptom management, including physician evaluation and communication of symptom expectations for pts. Reporting of symptoms by PROs should be incorporated into clinical trials as an adjunct to standard AE reporting to better characterize the patient experience. Clinical trial information: NCT03274492. Research Sponsor: The POLARIX study (NCT03274492) was sponsored by F. Hoffmann-La Roche Ltd and Genentech, Inc. Third-party editorial assistance was provided by Leen Al-Mohammad, BSc, of Ashfield MedComms, an Inizio company, and was funded by F. Hoffmann-La Roche Ltd.

Symptom,* n (%)	Clinician-reported severity, Grade ≥ 2	Patient-reported severity, 'A little'	Patient-reported severity, 'Quite a bit'	Patient-reported severity, 'Very much'
Fatigue	88 (10.7)	532 (64.6)	245 (29.7)	28 (3.4)
Constipation	93 (11.3)	330 (40.2)	143 (17.4)	91 (11.1)
Diarrhea	87 (10.5)	316 (38.4)	90 (10.9)	52 (6.3)
Nausea	119 (14.4)	317 (38.5)	112 (13.6)	46 (5.6)
Vomiting	46 (5.6)	143 (17.4)	33 (4.0)	25 (3.0)

PRO-evaluable population: n=825. *From baseline to EOT; [†]Based on NCI-CTCAE v4.0; [‡]Based on EORTC QLQ-C30.

Acupuncture versus massage for pain in patients living with advanced cancer: The IMPACT randomized clinical trial. *First Author: Jun J. Mao, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pain represents a challenging symptom for patients living with advanced cancer and is often associated with fatigue and insomnia. While American Society for Clinical Oncology clinical guidelines recommend acupuncture and massage for oncological pain management, the long-term comparative effectiveness between these two therapies is unknown, particularly among those living with advanced cancer. **Methods:** We conducted a pragmatic randomized clinical trial to compare acupuncture and massage for musculoskeletal pain among patients living with advanced cancer who experienced at least moderate pain and had a life expectancy of at least six months. Patients received weekly acupuncture or massage treatments for ten weeks, followed by monthly booster sessions up to 26 weeks. The primary endpoint was the change in worst pain intensity score measured by the Brief Pain Inventory (BPI) from baseline to 26 weeks. The secondary outcomes included pain-related interference (BPI), pain medication usage, patient-reported fatigue, insomnia, and quality of life. Analyses were performed using linear mixed models adhering to intent to treat. **Results:** Among 298 participants (mean age [SD] 58.7 [14.1] years, baseline worst pain 6.6 [1.5], 67.1% women, 25.9% non-white, 15.4% Hispanic, cancer types [21.5% hematologic, 19.8% breast, 14.4% gynecological, and 11.7% gastrointestinal, 9.7% lung, and 9.7% prostate]), 242 (81.2%) completed the primary endpoint. From baseline to week 26, acupuncture reduced worst pain by 2.53 points (95% CI 2.15-2.92) while massage reduced worst pain by 3.01 points (95% CI 2.63-3.38); the between-group difference was not significant (0.48, 95% CI -0.03-0.98, $p=0.066$). Both treatments reduced pain-related interference and pain medication usage and improved comorbid fatigue, insomnia, and quality of life to a similar degree without between-group differences. Adverse events were mild: bruising was reported by 9 (6.5%) acupuncture patients, and transient soreness was reported by 21 (15.1%) massage patients and 8 (5.8%) acupuncture patients. Despite receiving close in-person treatment, no known COVID-19 transmission was reported between patients and providers. **Conclusions:** Among patients living with advanced cancer, acupuncture and massage produced similar clinically meaningful improvements in pain and comorbid fatigue and insomnia, decreased use of pain medications, and improved quality of life. Integrating these non-pharmacological therapies into comprehensive cancer care can improve symptom management and quality of life for the ever-growing number of patients living with advanced cancer as a chronic illness. Clinical trial information: NCT04095234. Research Sponsor: Patient-Centered Outcomes Research Institute (PCORI); U.S. National Institutes of Health.

Early palliative care for patients with metastatic upper gastrointestinal cancers: A survival analysis of the EPIC randomized trial. *First Author: Antoine Adenis, Institut du Cancer de Montpellier, Montpellier, France*

Background: In 2010, Temel et al. reported that early palliative care (PC) (EPC) led to significant improvements in quality of life and, surprisingly, on overall survival (OS) over standard oncologic care (SOC) for patients (pts) with metastatic lung cancer. The American Society of Clinical Oncology then recommended “combined standard oncologic care and PC earlier in the course of the illness for any patient with metastatic cancer”. The median OS of unselected pts with metastatic upper gastrointestinal cancers (mUGIC) does not exceed 11 m. Whether EPC benefits also apply to pts with mUGIC was unknown. **Methods:** EPIC (NCT02853474) is a randomized 1:1, open-label, multicenter, phase 3 trial aiming to evaluate the OS benefit of EPC compared to SOC in pts with mUGIC (esophageal, HER2 negative esogastric junctional and gastric, pancreatic, and biliary tract cancers), with ECOG PS ≤ 2 , to be treated by first-line chemotherapy (CT). EPC included 5 PC visits scheduled every month, starting within 3 weeks of randomization. Pts allocated to SOC could access to PC visits upon request in case of worsening of health status. The primary endpoint was OS. Other endpoints included quality of life, and depression and anxiety assessment. A total of 381 deaths was required (1 year OS 40% vs. 50.3%, HR = 0.75, 2-sided alpha 5%, 80% power). Randomization was balanced on center, ECOG-PS and tumor site. **Results:** 473 pts were randomized from 10/2016 to 12/2021 in 19 French centers. Modified intention-to-treat population was 470. Median age = 67.5 (range, 24-90); 273 males; tumor site: esophagus 39, esogastric 48, pancreas 297, biliary tract 86; ECOG PS 0/1/2: 104/278/88. 74/233 pts (32%) in EPC arm had less than the planned EPC visits (major deviation): 3 related to treatment, 17 due to pt decision, 45 due to the clinical team decision, 2 other reasons, 7 unknown. 57/237 pts in the SOC arm got at least 1 PC visit, including 3 major deviation (performed < 6 months of treatment and set for a reason other than worsening of the health condition). Median follow-up was 46 m, and 35/470 pts were still alive. We did not observe any OS difference between arms (EPC, median OS: 7.0 m [95%CI: 6.1-8.8 m] and 1-year OS: 33%; SOC, median OS: 8.6 m [6.8-9.8 m] and 1-year OS: 32%; stratified HR = 1.04 [0.86-1.26], p = 0.68). Results were similar on the per-protocol dataset (excluding major violations). Results were homogeneous across the different tumor locations, and ECOG-PS groups. **Conclusions:** OS was lower than expected in both arms, which may reflect the difference between pharma-sponsored and academic trials with less stringent exclusion criteria. Also, only 68% of the pts got the planned number of PC visits in the experimental arm. EPC was not found to prolong OS over SOC in pts with mUGIC in this EPIC trial. Clinical trial information: NCT02853474. Research Sponsor: Ligue contre le cancer, France; National Cancer Institute, France; Région Nord-Pas de Calais, France.

A risk prediction model for cisplatin-induced acute kidney injury in patients with head and neck cancer who receive chemoradiotherapy: A supplement analysis of a phase II/III trial of JCOG1008. *First Author: Yoshinori Imamura, Kobe University Hospital, Kobe, Hyogo, Japan*

Background: Cisplatin-induced acute kidney injury (C-AKI) is a common reason for treatment interruption in head and neck cancer patients who receive chemoradiotherapy (CRT). We developed a risk prediction model for C-AKI in patients from a randomized phase II/III trial of JCOG1008, which demonstrated that CRT with weekly cisplatin at 40 mg/m² (weekly arm) was noninferior to 3-weekly cisplatin at 100 mg/m² (3-weekly arm) in terms of overall survival for postoperative high-risk head and neck cancer (*J Clin Oncol* 2022; 40: 1980-90). **Methods:** Two hundred fifty-one patients received RT with a total of 66 Gy/33 fr concurrently with 3-weekly or weekly cisplatin. AKI was defined using the AKI Network classification/staging system as an increase in serum creatinine of ≥ 0.3 mg/dL or a 1.5-fold or greater increase from baseline ($\geq$ stage I) by 30 days after the completion of CRT. AKI risk prediction models were developed by combining explanatory variables which were expected to contribute, including age, sex, ECOG performance status, primary site, pathological stage, diabetes mellitus, hypertension, main nutritional method, treatment arm, serum albumin, serum magnesium, and creatinine clearance (CCr) at registration. A logistic regression model with the Akaike information criterion was used to explore the optimal model. **Results:** Ninety-four of 251 (37.5%) patients developed C-AKI in this study. The optimal C-AKI risk prediction model was composed of four factors, including a primary site (hypopharynx/larynx or oral cavity/oropharynx, odds ratio [OR] 1.92 [95% CI, 1.10 to 3.30]), treatment arm (3-weekly arm or weekly arm, OR 1.75 [95% CI, 1.02 to 3.00]), serum albumin (≤ 3.5 g/dL or > 3.5 g/dL, OR 2.06 [95% CI, 1.11 to 3.87]) and CCr (< 90 mL/min or ≥ 90 mL/min, OR 1.85 [95% CI, 1.05 to 3.26]). The incidence of C-AKI increased in accordance with a total count of the four factors (Table): with a total count of 0-1, 2 and 3-4, the incidence of clinically relevant stage II/III C-AKI was 2.9%, 11.5%, and 22.6%, respectively. When total count was ≤ 1 , the positive and negative predictive values for stage II/III C-AKI development were 16.1% and 97.0%, respectively. **Conclusions:** We developed a risk prediction model for C-AKI in head and neck cancer patients who receive CRT using primary site, cisplatin administration method, serum albumin, and CCr. The high negative predictive value of this prediction model may help rule out the development of moderate to severe C-AKI. Clinical trial information: JRCTs031180135. Prospective evaluation of factors associated with acceptance of feeding tube (FT) placement and clinical outcomes during radiation therapy (RT) or radiochemotherapy (RTCT) for head and neck squamous cell carcinoma (HNSCC). *First Author: Florian Clatot, Department of Medical Oncology, Centre Henri Becquerel, Rouen, France*

Background: RT/RTCT during HNSCC treatment is associated with a high rate of severe dysphagia requiring the use of a FT. Randomized trials have failed to show a benefit of a prophylactic enteral nutrition in case of RTCT. Even when indicated, numerous patients refuse the placement of a FT. We assessed the factors associated with FT acceptance and outcomes between patients that had a FT, or not. **Methods:** The monocentric NutriNeck study (NCT02900963) recruited all HNSCC patients between 2014 and 2018 treated by RT/RTCT for curative intent. Patients fed by enteral nutrition before RT initiation were excluded. A daily monitoring of the weight and a weekly clinical evaluation during RT/RTCT were performed, as well as a quality-of-life (QoL) assessment using QLQ-C30 and HN 35 at baseline, 3 and 9 months after the end of treatment. A nutritional intervention by FT was systematically proposed in case of 2 kg weight loss under treatment or severe dysphagia. Patients were considered into 3 groups: FT indication and acceptance, FT indication but refusal, no FT indication. A p value < 0.05 was considered significant. **Results:** Among the 250 HNSCC patients included, 119 (48%) were treated by RT and 131 (52%) by RTCT. Overall, 114 patients (46%) accepted FT, 48 (19%) refused an indicated FT and 88 (35%) had no FT indication. In multivariable analysis, the only factor associated with an indication of a FT tube was having a RTCT vs a RT (p < 0.0001). Among the 162 patients (65%) with FT indication, in multivariate analysis factors associated with FT placement acceptance were having a RTCT (p = 0.01), being treated by exclusive RT+/-CT instead of adjuvant RT/CT (p = 0.05), having a tumor of the oral cavity (p = 0.02), having at baseline a decreased role functioning score (p = 0.04). When using linear mixed models for QoL analyses, over time role functioning, social functioning and pain were the only categories significantly different between patients that accepted FT and patients that refused or had no FT indication. At the end of treatment, median weight loss was significantly more important among patients with FT indication, compared to patients without FT indication (-4% vs -1%, respectively, p < 0.0001). This difference remained significant 3 and 9 months after the end of treatment. Among patients with FT indication, there was no difference in case of FT placement acceptance or refusal regarding grade 3 toxicities during treatment or weight loss at the end of treatment, after 3 and 9 months of follow-up. **Conclusions:** One third of the patients with an indicated FT have refused the FT placement, and did as well as those that accepted. Using baseline QoL items such as decreased role or social functioning, or increased pain may help identifying a subgroup of patients for which an earlier FT placement should be considered. Out-of-pocket costs burden for cancer treatment toxicities and symptoms management in Italy: A prospective, multicenter pilot study. *First Author: Giusti Raffaele, Medical Oncology, St. Andrea Hospital, Rome, Rome, Italy*

Background: Financial Toxicity (FT) refers to the financial burden and stress experienced by cancer patients as a result of the high costs associated with their treatment and care. This burden can significantly impact patients and families, affecting not only their financial well-being but also their physical and mental health. With the increasing cost of cancer care, FT has become a primary concern for those affected by the disease. Although there have been plenty of studies on the cost of cancer drugs and policy issues relating to curbing these increasing costs, studies on addressing FT in individual patients for drug-related toxicity and symptom management are still lacking. **Methods:** From January to October 2022, we conducted a cross-sectional, descriptive study to identify patient-administered drugs used to manage cancer treatment toxicities or cancer-associated symptoms. We recognize six common symptoms (anorexia/cachexia, fatigue, nausea and vomiting, pain, constipation, and diarrhea). All social and demographic data, including information on gender, age, performance status, education, and income, have been gathered and recorded. We collected information about the type of cancer disease and active treatment (on/off). Symptom assessment and financial distress were analyzed by administering the PERSONS and COST questionnaires, respectively, at the time of enrollment. **Results:** A total of 211 patients were enrolled and completed the questionnaires. 28/211 patients (13%) do not take any medications to control symptoms. Of the remaining 183 taking at least one prescription for managing these symptoms, 90% (165) pay for at least part of these drugs. Most frequently, patients assumed medicines for controlling pain (45%) and constipation (28%). Unlike all the other drug categories, these medicines correlate with financial distress (p > 0.0001 and p > 0.001). None of the following variables (age, type of tumor, and work situation) significantly interacted with COST and PERSONS at the univariate analyses. In contrast, a lower level of education significantly associates with the worst COST and PERSONS scores (p > 0.0001). As expected, patients in palliative home care have a higher mean score for symptom burden than those without home care and, surprisingly, a higher financial distress score. **Conclusions:** Our results identify cancer pain and constipation as the most incident and challenging problems associated with cancer diagnosis and treatment. Moreover, they ultimately lead to a higher financial hardship due to patient self-prescribing and out-of-pocket purchases of over-the-counter drugs to control them. In our population, a lower education level is an independent risk factor for developing financial distress. Research Sponsor: None.

Quality of pain management in patients with cancer in the outpatient setting.

First Author: Biplov Adhikari, MedStar Union Memorial Hospital, Baltimore, MD

Background: Pain represents a common health issue among patients with cancer. Uncontrolled pain significantly impairs the quality of life, resulting in increased healthcare utilization and costs. We examined the patterns of pain medication prescriptions among patients with cancer pain in the outpatient setting. **Methods:** We used the National Ambulatory Medical Care Survey (NAMCS), an annually administered survey designed to collect data regarding the use of ambulatory medical services from office-based physicians in the United States. We analyzed NAMCS data from 2005 to 2019 for all types of cancer visits. The primary outcome was prescription of pain medications among patients with cancer pain. We performed multivariate logistic regression to identify factors associated with opioid and non-opioid prescription among patients with cancer pain. **Results:** We captured a total of 520.8 million outpatient visits from 2005-2019. Breast cancer (18.7%) followed by cancer of the male genital tract (11.0%) represented the highest proportion of patient visits. 4.8% of cancer patients reported pain. Majority (60%) complaining of pain did not receive any pain medications. 14.9% received opioids and 25.1% received nonsteroidal anti-inflammatory drugs, acetaminophen, or adjuvant pain medications. The odds of receiving opioids were 3.4 times higher among 45-65 years vs patients over 75 years. African-Americans had 84% higher odds of receiving opioid prescription compared to white patients. The odds of receiving opioids were 61% lower for privately insured vs patients on Medicare. Patients visiting oncologic care had 2.1 times higher odds of receiving opioids compared to primary care (Table). **Conclusions:** This is one of the largest drug utilization studies among patients with cancer in outpatient setting, covering half a billion patient visits. A significant proportion of outpatients with cancer who reported pain did not receive a prescription for analgesics suggesting a possibility of undertreatment of pain. Within the limitation of this dataset, undertreatment of pain in outpatients with cancer remains a major unmet patient need. Research Sponsor: None.

Factors associated with pain medication prescription among cancer patients with pain in settings.

Efficacy of paxman scalp cooling system at lower temperatures for prevention of anthracycline associated chemotherapy induced alopecia.

First Author: Shari Beth Goldfarb, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Chemotherapy induced alopecia (CIA) significantly impairs QoL. Scalp cooling devices typically used at -5°C decrease CIA. However, there is still room to improve efficacy with anthracycline therapy. This prospective study was performed to evaluate the safety, tolerability, and efficacy of the Paxman Scalp Cooling System (PSCS) when used at cooler temperatures of -7.5°C and -10°C. **Methods:** Patients with stage I-III breast cancer receiving anthracycline chemotherapy at Memorial Sloan Kettering Cancer Center from 12/23/2019 – 10/12/2022 were enrolled on this IRB-approved study. They were evaluated for hair loss at baseline, weeks 4, 8 (primary endpoint), end of treatment, and 24 weeks post treatment using clinical photography and trichoscopy, which measures hair width and count. Degree of hair loss was graded using the Common Terminology Criteria for Adverse Events (CTCAE) v4. Successful hair preservation is indicated by alopecia grades 0 and 1. **Results:** 34 patients (mean age 44) used the PSCS at cooler temperatures with no DLTs. 7 patients received scalp cooling at -7.5°C and 27 patients at -10°C. 19 women (55.9%) were included in the final analysis; 7 patients withdrew or were taken off study prior to the primary endpoint and 8 patients did not successfully complete photographic or trichoscopic follow-up assessments. At the baseline visit, 95% of patients had grade 0 alopecia (n = 18) and 5.3% had grade 1 alopecia (n = 1). At week 8 (primary endpoint) 53% of patients had grade 1 alopecia and 47% had grade 2 alopecia. At completion of therapy, 7% of patients had grade 0 alopecia, 36% had grade 1 alopecia, 7% are pending and 50% had grade 2 alopecia. At 24 weeks post treatment completion, 23% of patients had grade 0 alopecia (n = 3), 31% had grade 1 alopecia (n = 4), and 46% of patients are pending results (n = 6). At baseline, the average hair count was 149.0 per cm² (n = 19) and the average hair width was 68.9µm (n = 19). At week 4 and 8, there was a -27% and -8.9% change in hair count and -8.6% and -9.3 percent change in hair width (n = 18) respectively. By end of treatment, percent change was -37.8 and -11.6 for hair count and hair width, respectively (n = 14). At 24 weeks post treatment completion, both the average hair count and hair width for patients were higher compared to their baseline (hair count = 242 per cm² and hair width = 70.7µm (n = 13; 6 patients pending). **Conclusions:** Overall, use of the PSCS for successful hair preservation is effective, safe, and tolerable at lower temperatures for patients being treated with anthracycline chemotherapy. 43% of patients had hair preservation at the completion of the study. At 24 weeks post treatment, the average hair count and width was higher than the values at baseline indicating thicker, full hair regrowth. None of the patients displayed grade 2 alopecia at 24 weeks post treatment, allowing patients to avoid the use of a wig to hide resulting CIA. Clinical trial information: NCT04180579. Research Sponsor: Paxman Coolers LTD.

The efficacy of hydrocolloid dressing as a prophylactic use for hand-foot skin reaction induced by multitargeted kinase inhibitors: A phase 3 randomized self-controlled study, J-SUPPORT 1701 APRON trial.

First Author: Atsuo Takashima, Gastrointestinal Medical Oncology Division, National Cancer Center Hospital, Tokyo, Japan

Background: Hand-foot skin reaction (HFS) is a well-known adverse event that affects the quality of life in patients (pts) who receive multitargeted kinase inhibitors (TKIs). To prevent HFS, prophylactic depressurization is considered to be one of the important strategies. However, the evidence of depressurization as a prophylactic use for HFS is limited. Therefore, we conducted a phase 3 trial to evaluate the efficacy of depressurization using hydrocolloid dressing, which was usually used for wounds such as decubitus ulcers. **Methods:** This is a phase 3 randomized self-controlled study to evaluate the efficacy of hydrocolloid dressing by comparing whether or not to add hydrocolloid dressing to prophylactic moisturizing for HFS. The eligible pts were to have unresectable colorectal cancer (CRC), gastrointestinal tumor (GIST), or hepatocellular carcinoma (HCC) and planned to receive either regorafenib or sorafenib. From the start of regorafenib or sorafenib, standard supportive care with moisturizing care alone was performed on one sole of the foot. Moisturizing care plus hydrocolloid dressing was applied to the other side soles of the foot. The primary endpoint was an incidence of grade 2 or more severe HFS (soles of the feet only) assessed by NCI CTCAE v.4.0. Grading of HFS was done according to pre-determined criteria, which consists of blinded central review of photographs of the foot, pain intensity (numerical rating scale) and interference score assessed by pts. The ethical approval was obtained from National Cancer Center Hospital. This study was registered with UMIN Clinical Trial Registry (UMIN000034853). **Results:** Between Jan 2019 and May 2021, 50 pts were enrolled. The median age was 62.5 years old, and cancer types were CRC in 78%, GIST in 12%, and HCC in 10% of the patients. 48 pts received regorafenib, and 2 pts received sorafenib. The table shows the summary of HFS in each arm. The primary endpoint of the incidence of grade 2 or more severe HFS was significantly lower in the hydrocolloid dressing arm than in the control arm (20% vs. 50%, p < 0.0001). Time to grade 2 or more severe HFS was significantly longer in the hydrocolloid dressing arm (hazard ratio 0.32, p = 0.0017). The incidence of moderate, severe, or very severe in patient-reported HFS using PRO-CTCAE was also lower in the hydrocolloid dressing arm (10% vs. 32%, p = 0.0002). **Conclusions:** Our study showed the efficacy of the prophylactic use of hydrocolloid dressing for HFS induced by multitargeted kinase inhibitors. Prophylactic moisturizing plus depressurization is the standard of care for this population. Multidisciplinary care plays an important role in the success of treatment with TKIs. Clinical trial information: UMIN000034853. Research Sponsor: Kimura foundation for nursing education.

HFS	Hydrocolloid dressing (n = 50)	Standard supportive care (n = 50)	
Grade1	29 (58%)	8 (16%)	
Grade2	10 (20%)	21 (42%)	
Grade3	0 (0%)	4 (8%)

Patient-reported hope, prognostic understanding, quality of life, symptom burden, coping mechanisms, and financial wellbeing in early phase clinical trial participants.

First Author: Debra Lundquist, Massachusetts General Hospital, Boston, MA

Background: Early phase clinical trials (EP-CTs) investigate novel treatment options in oncology, with recent advances in personalized therapy leading to improved outcomes and offering hope to patients with cancer. However, little research has sought to understand hope in EP-CT participants, thus we sought to study associations of patient-reported hope with prognostic understanding, quality of life (QOL), symptom burden, coping mechanisms, and financial wellbeing in EP-CT participants. **Methods:** We prospectively enrolled consecutive adults with cancer participating in EP-CTs at Massachusetts General Hospital from 04/2021-01/2023. Participants completed baseline surveys prior to treatment initiation that assessed hope (Herth Hope Index [HHI]), higher scores indicate greater hope), prognostic awareness (Prognosis and Treatment Perceptions Questionnaire [PTPQ]), QOL (Functional Assessment of Cancer Therapy-General), symptom burden (physical: Edmonton Symptom Assessment System [ESAS]; psychological: Patient Health Questionnaire-4 [PHQ4]), coping mechanisms (Brief COPE), and financial wellbeing (Comprehensive Score for Financial Toxicity [COST]). We used descriptive statistics and regression models to explore associations of hope with patient characteristics as well as patient-reported prognostic awareness, QOL, symptom burden, coping, and financial wellbeing. **Results:** Of 221 eligible patients, we enrolled 204 (enrollment rate 92.3%, median age = 63.4 years [range 54.8-70.5]; 56.9% female, and 94.0% metastatic cancer). Most common cancer types were gastrointestinal (34.8%), breast (19.6%), and head and neck (10.3%). Patients had a mean HHI score of 27.2 (range 12.0-36.0), with 27.1% reporting their cancer is curable (mean hope scores were higher for those reporting curable vs incurable on the PTPQ: 28.8 vs 26.7, p = 0.016). Higher hope scores were associated with better QOL (B = 0.21, p < 0.001), lower symptom burden (ESAS-physical: B = -0.10, p < 0.001; PHQ4-depression: B = -2.10 p = < 0.001; PHQ4-anxiety: B = -0.99, p < 0.001), more adaptive coping strategies (self-blame [B = -1.34, p < 0.001]; acceptance [B = 1.30, p < 0.001], denial [B = -1.31, p < 0.001], support [B = 1.03, p < 0.001], active [B = 0.97, p < 0.001], disengage [B = -2.69, p < 0.001], religion [B = 0.63, p < 0.001]), and greater financial wellbeing (B = 0.10, p = 0.013). **Conclusions:** In this prospective cohort study, we found novel associations of higher hope scores with prognostic understanding, better QOL, lower symptom burden, more adaptive coping mechanisms, and greater financial wellbeing. Future studies should measure patient-reported hope and explore its role as a potential moderator of other outcomes in EP-CT participants. Self-reported overall wellbeing and physical function among chemotherapy and surgery patients completing symptom questionnaires across six health systems. *First Author: Michael J. Hassett, Dana-Farber Cancer Institute, Boston, MA*

Background: Health systems have begun using electronic patient reported outcomes (ePROs) to evaluate and ideally mitigate patients' symptom burden following treatment for cancer and other conditions. However, the optimal number of symptoms and approach to capturing this information is unknown. We hypothesized that self-reported overall wellbeing (OWB) and physical function (PFN) would provide distinctive information, beyond that described by a multi-item symptom questionnaire, and augment the clinical utility of an ePRO system. **Methods:** eSyM, an EHR-integrated symptom management program, was deployed across six health systems for patients receiving chemotherapy or surgery for a suspected or confirmed thoracic, gastrointestinal, or gynecologic malignancy. eSyM prompts patients to complete a 12-item symptom questionnaire 2-3 times per week. This questionnaire also includes two pictogram questions that assess OWB and PFN – each scored using a four-point scale from 0 (best) to 3 (worst). We sought to identify patient characteristics associated with the lowest OWB and PFN (i.e., score = 3), to describe Spearman correlations between OWB and PFN, and to elucidate the relationships between symptom scores and OWB/PFN. Ordinal logistic regression models were used to adjust for potential confounding. **Results:** From September 2019-December 2022, 9753 patients submitted 75,166 questionnaires. There were 3846 chemotherapy patients (median age 66, 58% female, 17% non-white) and 5907 surgery patients (median age 61, 73% female, 7% non-white). The plurality of responses indicated mild impairment for OWB and PFN (Table). OWB and PFN scores were moderately correlated with each other (chemotherapy 0.62; surgery 0.59); with the sum of all symptom scores for chemotherapy (OWB 0.48, PFN 0.45) and surgery (OWB 0.51, PFN 0.45) patients; and with pain, fatigue, and anorexia (correlation coefficients 0.40-0.61). No individual symptoms were strongly correlated (coefficient > 0.7) with OWB or PFN. After controlling for other factors, OWB and PFN scores varied significantly by health system. Patients with disability were more likely to report low OWB and PFN (ORs 1.99-3.26; $p < 0.05$) versus other employment statuses. **Conclusions:** In a large cohort of chemotherapy and surgery patients from six community-based cancer centers, self-reported OWB and PFN scores were moderately correlated with common symptoms. These items offer discriminant and face validity and provide distinctive information that supplements a multi-item symptom questionnaire. Routine use of OWB and PFN can guide management strategies for symptomatic cancer patients. Clinical trial information: NCT03850912. Research Sponsor: U.S. National Institutes of Health.

	Score (impairment)	Chemotherapy (% of 3846 pts)	Surgery (% of 5907 pts)

Phase 3 RCT of dexamethasone versus placebo for chemotherapy induced fatigue in patients with advanced solid malignancies. *First Author: Venkattraman Radhakrishnan, Cancer Institute (WIA), Chennai, India*

Background: Short-term steroids (<2 weeks) have been used to alleviate fatigue in patients with advanced cancer. However, the efficacy and safety of long-term steroids (12 weeks) in patients with advanced cancer receiving palliative chemotherapy have not been studied. **Methods:** The study was an open-label, placebo-controlled, phase 3 RCT to evaluate the efficacy and safety of low dose dexamethasone (DEX) in reducing chemotherapy and cancer associated fatigue. Patients aged 18-60 years with performance status ≤ 2 , undergoing palliative chemotherapy for advanced solid malignancies were randomized 1:1 to receive either DEX (4mg/day) or a placebo for 12 weeks. Fatigue was measured using the Symbolic Assessment of Fatigue Extent (SAFE) scale and EORTC FA12 scale, and quality of life (QOL) was assessed using the EORTC QLQ c30 at baseline, 6 weeks, and 12 weeks. The primary endpoint was to compare fatigue between the study arms at 6 weeks. Secondary endpoints were to compare fatigue at 12 weeks, QOL and toxicities. With a power of 80%, α of 5% (2-sided), 126 patients (including 25% drop-outs) were required to show the superiority of DEX in reducing SAFE fatigue extent score by 50% at 6 weeks. **Results:** A total of 126 patients were randomized (64 in the placebo arm and 62 in the DEX arm) between Oct 2018-Sep 2022. The median age was 46.5 years and 67% were females. Metastatic breast (28%) and lung (16%) cancer were the common diagnosis. Twelve and 23 patients in the placebo arm and 13 and 22 patients in the DEX arm did not undergo week 6 and 12 assessment respectively due to disease progression. The results showed no significant differences in mean SAFE scores, FA12 scores, or QOL between the study arms at 6 and 12 weeks, except for higher FA12 social sequelae in the DEX arm at 12 weeks ($P=0.048$) (Table). There were no significant differences in toxicities between the arms. **Conclusions:** The results of this study suggest that low-dose DEX is not effective in reducing chemotherapy associated fatigue or improving QOL in patients with advanced cancer. Clinical trial information: CTRI/2018/08/015222. Research Sponsor: Cancer Institute (WIA).

Effects of yoga vs placebo on inflammation among cancer survivors: A nationwide multicenter phase III randomized controlled trial (RCT). *First Author: Po-Ju Lin, Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY*

Background: Inflammation, both acute and chronic, is universally associated with primary and secondary cancer development and progression, as well as a myriad of toxicities that negatively affect cancer treatment adherence and survival. The effectiveness of targeting inflammation with non-pharmaceutical therapies such as yoga is not known. As part of a nationwide, multicenter, phase III RCT with cancer survivors, we compared the effects of yoga (Yoga for Cancer Survivors; YOCAS) to a behavioral placebo (survivorship health education) on inflammation (i.e. pro-inflammatory, anti-inflammatory, and overall inflammatory status). **Methods:** Participants were recruited via the URCC NCORP Research Base in partnership with 23 community oncology practices across the United States. Eligible participants were cancer survivors with insomnia 2-60 months post-treatment. They were randomized to receive YOCAS (gentle Hatha and Restorative yoga, 75-min./session, 2x/week, 4 weeks) or placebo (ASCO survivorship recommendation-based health education, 75-min./session, 2x/week, 4 weeks). Serum samples were collected at baseline and post-intervention to assess inflammation (i.e., pro-inflammatory markers IL-1 β , IL-6, TNF- α , IFN- γ and anti-inflammatory markers IL-4, IL-8, IL-10, sTNFRI), via Luminex multiplex assays. Analysis of covariance (ANCOVA) and structural equation modeling (SEM) were used to access yoga's effects on inflammation. **Results:** 502 survivors (94% female, mean age 56 $\pm$ 11 years, 74% breast cancer) were enrolled. ANCOVAs revealed significantly lower levels of pro-inflammatory markers in YOCAS participants compared to placebo participants (IL-1 β : -0.07 $\pm$ 0.03, $p = 0.01$; TNF- α : -0.04 $\pm$ 0.02, $p = 0.08$; IFN- γ : -0.07 $\pm$ 0.03, $p = 0.02$) where YOCAS participants exhibited stable pro-inflammatory responses (all $p > 0.05$) and placebo participants exhibited significant increases in pro-inflammatory responses (all $p \leq 0.05$) from baseline to post-intervention. ANCOVAs also revealed a statistical trend toward lower levels of anti-inflammatory markers in YOCAS participants compared to placebo participants (IL-4: -0.06 $\pm$ 0.04, $p = 0.10$; IL-10: -0.06 $\pm$ 0.04, $p = 0.09$; sTNFRI: -0.06 $\pm$ 0.04, $p = 0.09$). SEM also demonstrated significantly lower pro-inflammatory status (-0.16 $\pm$ 0.03, $p < 0.01$), significantly lower anti-inflammatory status (-0.14 $\pm$ 0.03, $p = 0.03$), and significantly lower overall inflammatory status (-0.15 $\pm$ 0.03, $p = 0.01$) in YOCAS participants compared to placebo participants. **Conclusions:** Our data suggest that YOCAS yoga significantly reduces inflammation among cancer survivors. Clinicians should consider prescribing yoga for survivors experiencing inflammation, which may lead to a high chronic toxicity burden and increased risk of progression, recurrence, and second cancers. Apixaban versus rivaroxaban for treatment of acute deep venous thrombosis in patients with cancer. *First Author: Brittany Miles, Department of Biochemistry and Molecular Biology, University of Texas Medical Branch, League City, TX*

Background: Direct oral anticoagulants (DOAC) such as Apixaban and Rivaroxaban are increasingly used for the treatment of acute venous thromboembolism (VTE) over traditional vitamin K antagonists. Malignant neoplasms predispose to acute VTE and clinical management necessitates anticoagulation to prevent further complications. We compare Apixaban to Rivaroxaban for the treatment of acute VTE in the setting of malignancy with the endpoint of chronic deep venous thrombosis (DVT) development after 2 years. **Methods:** The TriNetX Research network was used for this study. TriNetX provides access to anonymized medical record information on more than 107 million patients in 76 large healthcare organizations. Two cohorts were created for this study using the International Classification of Disease-10 (ICD-10) codes. All patients were required to have a diagnosis of breast (C50), lung (C34), colon (C18), or prostate cancer (C61). All were diagnosed with acute deep venous thrombosis (DVT) of the lower extremities (I82.409). One cohort was treated with rivaroxaban while the other was treated with apixaban within 3 days of DVT diagnosis. Each cohort was excluded from being treated with the other anticoagulant. The cohorts were balanced for age, race, gender, and ethnicity, then evaluated for the development of chronic DVT (I82.509) within the subsequent twelve months. **Results:** The development of chronic DVT was significantly more common in the apixaban cohort, with a risk ratio of 1.36 (95% CI (1.12,1.65), p -value 0.0015). See table. **Conclusions:** Patients with acute VTE in the setting of malignancy were at a significantly higher risk of developing chronic DVT following treatment with Apixaban compared to those who received Rivaroxaban at 2 years post-treatment. These results may contribute to increased discussion between physicians and patients when deciding between these two direct oral anticoagulants for the management of acute VTE. Diagnosis of chronic DVT in cancer patients treated with apixaban and rivaroxaban. Research Sponsor: None.

Cohort	Cohort Size	Events	Risk
Apixaban	4,971	237	4.77%
Rivaroxaban	4,971	174	3.50%

Rose geranium in sesame oil nasal spray to improve symptoms of nasal vestibulitis: A phase III double blinded randomized controlled trial. *First Author: Elizabeth Jane Cathcart-Rake, Department of Medical Oncology, Mayo Clinic, Rochester, MN*

Background: A retrospective study suggested a potential benefit from rose geranium in sesame oil nasal spray for alleviating nasal vestibulitis symptoms in patients (pts) undergoing chemotherapy. **Methods:** Pts undergoing active chemotherapy who reported moderate or worse nasal symptoms were randomized 1:1 to receive a rose geranium in sesame oil nasal spray (RG) or an isotonic saline nasal spray (IS), administered twice daily for two weeks. Consenting pts completed nasal symptom questionnaires at baseline and then weekly while on treatment. The number and percentage of pts experiencing improvements in their nasal symptoms 2 weeks after initiating the nasal spray, defined as symptoms moderately (2) or very much (3) better on a 7-point global impression of change score (ranging from scores of -3: very much worse, to 3: very much better), was estimated within and then between each randomized arm, using Fisher's exact test (5% significance level). The estimated odds ratio was determined (95% confidence interval). After 2 weeks, pts initially randomized to IS were allowed to cross-over to RG and completed weekly surveys. **Results:** 106 pts consented to this study; 43 pts in the RG arm and 41 in the IS arm were evaluable for the primary endpoint. Pts had a mean age of 57.8 (SD 13.9). Demographic characteristics and baseline nasal symptoms were similar between arms. The most prominent baseline nasal symptoms were dryness (36%) and bleeding (35%). Of the 43 evaluable pts who received RG, 67.4% reported improved nasal symptoms, compared with 36.6% of the 41 pts who received IS ($p=0.009$; Table). On the global impression of change score, pts who received RG had a mean score of 1.93 (SD 1.16), compared to a mean score of 0.98 (SD 1.41) among pts who received IS. Adjusting for potential confounding factors, pts who received RG had a 4.56 odds of responding to the nasal spray, compared with those who received IS ($p=0.005$). There were no significant differences between pt responses based upon type of nasal symptoms, age, allergies, or gender. Adverse events were sparse and did not differ between arms. 34 pts crossed over to RG after week 2. Among the 29 pts who completed final surveys, 37% reported a response on IS, 79% reported a response on RG. **Conclusions:** Rose geranium in sesame oil nasal spray significantly improves nasal vestibulitis symptoms among patients undergoing chemotherapy. Clinical trial information: NCT04620369. Research Sponsor: Breast Cancer Research Foundation (BCRF) and the Minnesota Cancer Clinical Trials Network (MNCCTN).

		Rose Geranium in Sesame Oil (N=43) N (%)	Isotonic Saline (N=41) N (%)

Nationwide phase II randomized controlled trial of low-dose ibuprofen vs placebo for cancer-related cognitive impairment (CRCI). *First Author: Michelle Christine Janelins, University of Rochester Medical Center, Wilmot Cancer Institute, Rochester, NY*

Background: CRCI is an important clinical problem encompassing difficulties in attention, memory, and executive function. Interventions for CRCI during chemotherapy have not been established. Inflammation is associated with CRCI and thus targeting inflammation may alleviate CRCI. In a nationwide study, we investigated a low-dose of ibuprofen for alleviating CRCI in patients self-reporting cognitive problems during chemotherapy or after recent completion of chemotherapy. **Methods:** Participants with cancer currently on or recently completed chemotherapy and who self-reported cognitive problems were recruited via the NCI Community Oncology Research Program (URCC NCORP) and 11 affiliates. Participants completed pre-intervention assessments and were stratified by disease type (breast cancer; gastrointestinal cancer; other) and randomized to one of 2 groups for 6 weeks: ibuprofen (200 mg BID) or blinded placebo equivalent. At pre-intervention and post-intervention, participants completed a perceived cognitive function measure (FACT-Cog Perceived Cognitive Impairment (PCI)) and cognitive assessments including Rapid Visual Processing (RVP) latency, Delayed Match to Sample (DMS) visual memory, and Verbal Recognition Memory (VRM) word recall. ANCOVA was used to assess between group differences pre- to post-intervention adjusting for baseline cognitive test score. **Results:** In total, 87 participants were randomized; 45 were randomized to ibuprofen and 42 randomized to placebo (mean age = 55; 85% female; 47% breast cancer, 29% colon/colorectal cancer; 24% other diagnoses). Most participants were fully compliant and completed post-intervention assessments (86% in Ibuprofen arm, 87% in placebo arm). There were no gastrointestinal bleeding events of any grade in the ibuprofen arm and serious adverse events were rare in both arms occurring in only 4% and 7% of patients in the ibuprofen and placebo arms, respectively. For PCI, both groups significantly reported less impairment from pre- to post-intervention; there were no difference between groups. Patients randomized to ibuprofen had a significant improvement on RVP latency time compared to placebo (110.63 milliseconds; $p < 0.005$). On the DMS, patients receiving ibuprofen had a trend toward improved function compared to placebo (7.39%; $p = 0.08$). However, patients in placebo performed better in word recall compared to ibuprofen from pre- to post-intervention (1.64 words; $p < 0.05$). **Conclusions:** Low-dose, short duration ibuprofen was safe with minimal adverse events in patients with cancer receiving chemotherapy or recently completed chemotherapy. Ibuprofen showed improvements in processing speed time and visual memory in patients with cancer as hypothesized, but not verbal memory. These novel Phase II findings need to be replicated in a Phase III RCT. Funding: R21CA187500, UG1CA189961. Clinical trial information: NCT03186638. Research Sponsor: U.S. National Institutes of Health.

Feasibility and acceptability of implementing electronic patient reported outcomes (ePRO) collection in Zambia: Findings from a patient needs assessment. *First Author: Susan K. Peterson, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Studies in high-income countries have shown that systematic, remote and electronic collection of patient-reported outcomes (ePROs) during chemotherapy, with provider intervention if symptoms worsen, is associated with fewer symptoms, better quality of life (QOL), and improved survival. It is unknown whether similar ePRO interventions, often using electronic medical record patient portals or mobile devices, can improve outcomes for cancer patients in low- and middle-income countries (LMICs). In sub-Saharan Africa (SSA), cervical cancer (CC) is the second most common cancer and most common cause of cancer deaths in women. As most patients are diagnosed with locally advanced disease, chemoradiotherapy is standard care; many have severe comorbidities such as HIV. Due to patients' increased risk for high symptom burden, remote monitoring of ePROs during CC treatment may improve outcomes. We evaluated the feasibility and acceptability of ePRO collection in CC patients from SSA. **Methods:** Patients were recruited from a prospective cohort study of women with newly diagnosed CC at the Cancer Diseases Hospital in Lusaka, Zambia from June 2022 through January 2023. Patients completed an in-person interview regarding mobile technology usage comprising questions adapted from the 2019 Pew Report on Mobile Connectivity in Emerging Economies and the 2019 Global System for Mobile Communication Association Mobile Gender Gap Report. Questions were translated into 4 primary Zambian languages (Tonga, Nyanga, Lozi and Bemba). **Results:** Respondents' (n = 100) mean age was 49.6 years (range, 29-75, SD 9.2), 55% were diagnosed with stage III-IV disease and 59% were HIV+. Most (70%) completed only primary school or no school, 29% reported not being able to read at all and 29% could read only parts of a sentence. Most personally owned a mobile phone (90%) and 8% reported using a phone that belonged to another person. Most used phones to make or receive calls (98%), for banking/mobile money (92%), and text messaging (67%). Of the 26% who owned a smartphone, only half connected to the internet by phone more than once weekly. Nearly all indicated willingness to use a phone to self-report CC-related symptoms if compensated for costs (98%), with 97% preferring to do so via a phone call and fewer via text message (43%) or mobile app (17%). Most (71%) were able to charge phones at home using electricity or solar power and 18% traveled more than 30 minutes to charge phones. **Conclusions:** Nearly all patients owned or had access to mobile phones and expressed willingness to self-report CC symptoms via phone. Findings support the feasibility and acceptability of ePRO collection and provide contextual data to guide implementation in LMICs, including consideration of telecommunications infrastructure and literacy, low internet use, and ePRO reporting preferences (i.e., calls vs text). Baseline symptom, health status, and health utilities in patients in early-phase clinical trials combining immune checkpoint blockade with other anticancer therapies. *First Author: Goldy C George, Department of Symptom Research, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The overall goal of our prospective and longitudinal study (NCT01CA242565) is to examine the use of patient report to evaluate symptomatic adverse events associated with combination treatment including at least one immune checkpoint inhibitor in early-stage clinical trials. We present here the baseline symptom, health status and utilities in patients prior to trial start, and their association with clinical factors. **Methods:** Patients scheduled to start an early-phase trial of combination treatment with at least one immune checkpoint inhibitor and who had not received clinical trial-related treatment completed the validated MD Anderson Symptom Inventory - Immunotherapy (0-10, higher scores = worse severity) and the validated EuroQoL-5 dimensions questionnaire including a visual analog scale (EQ5D VAS) (0-100, higher scores = better health status) and health utility items (e.g., self-care, mobility). Clinical data were extracted from the EMR. Statistical tests included Spearman's correlation coefficients. **Results:** At baseline prior to start of trial-related treatment, 38% of patients (N = 164; median age = 60 y; 52% male; 85% White; 17% ECOG PS 0, 89% ECOG PS 1, 3% ECOG PS 2) experienced at least 1 severe symptom (≥ 7 on 0-10 scale). The most frequent severe baseline symptoms were pain (21% of patients), fatigue (17%), disturbed sleep (15%), drowsiness (12%), lack of appetite (10%), distress (10%), and pain in the abdomen (10%). Less than 2% of pts experienced severe immunotherapy-specific symptoms of rash, fever/chills and swelling of the hands and feet at baseline. Moderate-severe symptom-related interference (≥ 4 on 0-10 scale) was worst for activity (40% of patients), work (38%), and enjoyment of life (30%). For the EQ5D health utility dimensions, patients reported the most problems with pain or discomfort (75%) and fewest problems with self-care (10%). Worse composite symptom severity ($P = 0.013$) and worse problems with activity ($P = 0.001$) and pain ($P = 0.012$) were associated with worse and higher ECOG PS. Worse symptom severity (-0.54 , $P < 0.001$), symptom interference with activity (-0.57 , $P < 0.001$) and mood (-0.42 , $P < 0.001$) related functioning were associated inversely with superior health status. Worse symptom interference with activity-related functioning was linked with lower concurrent lymphocyte counts ($P = 0.01$), hemoglobin ($P = 0.01$) and serum albumin ($P = 0.004$) levels and higher platelet ($P = 0.02$) counts. **Conclusions:** Patients in early-phase trials that combine immunotherapy with other anti-cancer therapies may experience severe symptom burden and symptom interference with functioning, even at baseline prior to treatment start. Thus, it is important to baseline symptoms to fully understand the impact of combination treatments including checkpoint inhibitors in early-stage clinical trials. Experiences with pain management for survivors of complex cancers: Focus on opioids and cannabis. *First Author: Talya Salz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Survivors of complex cancers often experience pain. Clinical practice guidelines for pain management in cancer survivors cautiously recommend opioids and cannabis for subgroups with certain pain phenotypes, despite limited evidence regarding benefits and harms in survivor populations. We aimed to better understand pain management for these survivors, focusing on attitudes toward, and experiences with, opioids and cannabis. **Methods:** We conducted 7 90-minute focus groups with 26 disease-free survivors of head and neck and lung cancer who still experience cancer-related pain. Multiple coders conducted thematic analyses to identify themes regarding 1) experiences with post-treatment pain and pain management and 2) utilization, benefits, and harms of post-treatment cannabis and opioids. **Results:** Survivors (7-35 months from treatment completion) experienced post-treatment physical and psychological pain that affected multiple aspects of their daily life. Since treatment completion, 69% used opioids previously and 8% currently using. Fifty-four percent had used any cannabis product since treatment completion, and 35% currently use cannabis. While some survivors experienced no pain management challenges, others enumerated various difficulties, including fears of addiction to opioids or cannabis, perceived stigma around both products, and access challenges around provider attitudes, cost and insurance coverage, and legality. Survivors reported that providers did not know how to advise about cannabis; for example: "When I talked [to providers] about marijuana they didn't want to talk about it. They couldn't recommend it because there's no clinical data." Opioids were often perceived as critical to pain management but came with unpleasant side effects. Cannabis was effective at reducing both pain and anxiety for many, but not all, survivors. For some, cannabis reduced anxiety, which in turn reduced pain: "It just keeps my mind occupied enough where I'm not thinking of pain." Reducing anxiety also helped some survivors eat: "I have a lot of anxiety around eating because I have a fear of choking, so sometimes it helps that." Survivors described a balance of benefits and harms of opioids and cannabis; for example: "Where [the doctor has] me now...if I go down any lower, it's not going to work. If I go up any higher, I'm going to be not able to function." **Conclusions:** Post-treatment survivors of complex cancers continue to experience cancer-related pain, both psychological and physical, for which both opioids and cannabis present a complex set of harms and benefits that vary across survivors. Providers who care for cancer survivors should be aware of the interplay between psychological and physical pain, patient concerns and stigma around opioids and cannabis, and nuances of the harms, benefits, and access issues regarding these treatments. Unveiling inequities in palliative care and clinical trial participation among patients with metastatic breast cancer in the state of Florida. *First Author: Oluwadamilola Temilade Oladeru, Department of Radiation Oncology, University of Florida College of Medicine, Gainesville, FL*

Background: Persistent inequities in the care for patients with metastatic breast cancer (mBC) were recognized by ASCO and, in partnership with Pfizer, awarded our team a grant to understand and address them in people of color. Florida has a higher age-adjusted percentage of breast cancer in females and a higher mortality rate in those under the age of 65 compared to the United States. The racial disparity in mortality is further magnified among female patients with mBC. Therefore, we sought to characterize the prevalence and trends of palliative care utilization and clinical trial participation (CTP) among Floridians with mBC and quantify the associated factors. **Methods:** Using the OneFlorida+ Data Trust, a repository of patient-level electronic health records of ~17 million Floridians seen in public and private health care systems, including those enrolled in Medicaid, we obtained demographics of mBC patients, including sex, age, race, and ethnicity, insurance type, zip-code based socioeconomic status, Charlson comorbidity index (CCI) and rural/urban residence. CPT codes were obtained for palliative care services between the date of mBC diagnosis and death, including pain management, psychology, psychiatry, nutrition, and advanced care planning. Our analysis included the Cochran-Armitage trend test and bivariate analysis to correlate patient characteristics to palliative care receipt and CTP. **Results:** In Florida, 25,225 individuals (1.5% men and 98.5% women) were diagnosed with mBC between 2012 and 2021; 49.3% were under age 60. 19.5% of this cohort received palliative care at a median time of 10.1 months (IQR 2.1 – 27.1) from the initial diagnosis of mBC. The median survival was 13.6 months (IQR 3.4 – 31.6). On multivariable analysis, significant variables ($p < 0.001$) associated with increased palliative care utilization were Non-Hispanic Black, self-pay/uninsured and Medicaid insured, and a CCI of 5+. Only 3% of the study cohort had advanced care planning. There was a declining trend in CTP among patients with mBC, from 13.9% in 2012 to 7.9% in 2021. Among those participating in clinical trials, 80.2% did not receive palliative care. Variables associated with higher CTP ($p < 0.001$) were younger age (18-49), Asian and Hispanic race/ethnicity, the highest quartile of median household income and education level, private insurance, metropolitan residence, and CCI of 0. Further, there was a trend towards more prolonged survival among those enrolled in clinical trials. **Conclusions:** This robust statewide assessment highlights that less than 20% of patients with mBC receive palliative care, and its receipt is exclusive of CTP. We identified significant racial and socioeconomic disparities in CTP. Educational interventions with palliative care trained navigators, partnerships with providers on palliative care benefits, and state policy support are needed. Opioid use, gabapentinoid use, and pain-related emergency department visits for patients living with advanced cancer. *First Author: Vikram Jairam, Department of Therapeutic Radiology, Yale School of Medicine, New Haven, CT*

Background: Regulatory efforts in response to the United States opioid epidemic have resulted in a decrease in opioid prescribing among oncologists and non-oncologists. Understanding how decreased opioid prescribing affects cancer-related pain can provide key insights into the downstream effects of these efforts. In this study, we explored temporal trends in opioid use, gabapentinoid use, and pain-related emergency department (ED) visits in older adult patients with advanced cancer and those without cancer. **Methods:** We queried the Surveillance, Epidemiology, and End Results (SEER)-Medicare database from 1/1/2012 to 12/31/2017 to identify patients aged 66 years or older diagnosed with advanced solid tumor cancer (defined as stage IV and/or metastatic disease). A cohort of patients without a cancer diagnosis was identified using the Medicare 5% random sample. The three dependent outcomes assessed were opioid use, gabapentinoid use, and pain-related ED visits. Multivariable logistic regression was used to identify predictors of these outcomes and to calculate the predicted probability of each outcome for patients with and without cancer. We determined the absolute change in the predicted probability of each outcome from 2012 to 2017. **Results:** A total of 294,113 patients were included in the cohort: 45,899 (15.6%) with cancer and 248,214 (84.4%) without cancer. Between 2012 and 2017, the absolute change in predicted probability of opioid use declined less in the cancer [-6.1%; 68.6% to 62.5%] compared to the non-cancer cohort [-8.2%; 35.8% to 27.6%] ($p < .001$ for difference). Gabapentinoid use increased more in the cancer [3.9%; 10.8% to 14.7%] than non-cancer [1.8%; 10.5% to 12.3%] cohort ($p < .001$ for difference). There was no statistically significant change in pain-related ED visits in patients with cancer [0.6%; 12.4% to 13.0%] and a decrease in patients without cancer [-0.5%; 2.6% to 2.1%] ($p = 0.005$ for difference). **Conclusions:** Our findings showed that opioid use decreased to a lesser degree among older patients with advanced cancer compared to patients without cancer, whereas gabapentinoid use increased to a greater degree among patients with cancer. There was no corresponding rise in pain-related ED visits, suggesting that these shifts in medication use may not have adversely affected this important outcome. Research Sponsor: American Cancer Society.

Outcome	Cancer Status	Predicted Probability (95% CI) of outcome in:		Absolute Change (95% CI)
		2012	2017	
Receiving opioids	Non-cancer	35.8 (35.4, 36.3)	27.6 (27.3, 28.0)	-8.2 (-8.8, -7.6)*
	Cancer	68.6 (67.9, 69.3)	62.5 (61.8, 63.2)	-6.1 (-6.9, -5.3)*
Receiving gabapentinoids	Non-cancer	10.5 (10.2, 10.8)	12.3 (12.1, 12.6)	1.8 (1.4, 2.2)*
	Cancer	10.8 (10.4, 11.2)	14.7 (14.2, 15.1)	3.9 (3.3, 4.4)*
Pain-related ED visits	Non-cancer	2.6 (2.5, 2.8)	2.1 (2.0, 2.3)	-0.5 (-0.7, -0.3)*
	Cancer	12.4 (11.7, 13.1)	13.0 (12.3, 13.6)	0.6 (-0.3, 1.5)

End-of-life outcomes after implementation of an embedded, criteria-based palliative care consultation service in inpatient oncology. *First Author: Kathryn Norman, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Specialty palliative care (PC) improves outcomes for patients with advanced cancer, including quality of life and end-of-life (EOL) care utilization. In 2017, the American Society of Clinical Oncology recommended that patients with advanced cancer see specialty PC within 8 weeks of diagnosis. Despite this, inpatient PC referrals exceed outpatient referrals nationwide. Recognizing the importance of earlier PC access, our cancer center implemented a criteria-based PC consultation service in the inpatient oncology setting. We now report pre/post EOL outcomes from this novel care model. Care model: Our center embedded a "Palliative Oncology" consult team on the oncology floor consisting of 1 physician, 1 nurse practitioner (NP), 2 social workers, and 2 spiritual care providers, all with PC specialization. Admitted patients were screened by a floor nurse or PC NP for 2 referral criteria: 1) advanced/metastatic solid cancer, or 2) moderate/severe symptoms. The inpatient oncology team was informed of patients meeting criteria through daily prompting supported by ongoing education. Referrals remained at discretion of the oncology team rather than triggering automatically. **Methods:** We identified all cancer center decedents with advanced solid cancers who experienced an admission to the oncology floor before (10/1/19-6/30/20) or after (7/1/20-9/30/21) the new model. Six trained abstractors performed chart review. We compared outcomes between patients who died pre- and post-implementation using a t-test (continuous variables) and χ^2 test (categorical variables). **Results:** Of 820 decedents, 186 died pre-intervention and 634 died post-intervention. During the post-intervention period, more decedents saw inpatient PC (72% vs. 59%, $p < .001$) and outpatient PC (34% vs. 23%, $p < .01$). Post-intervention decedents had more inpatient PC visits (mean: 11.1 vs. 8.9, $p < .05$) and had their first PC visit sooner before death (mean: 159 vs. 76 days, $p < .001$). During the post-intervention period, fewer decedents had ED (41% vs. 52%, $p < 0.05$), hospital (57% vs. 71%, $p < .001$), or ICU encounters (17% vs. 25%, $p < .01$) in the last 30 days of life. For post-intervention decedents, the proportion referred to hospice remained stable (67% vs. 60%, $p = .09$), but mean hospice length-of-stay increased (36 vs. 22 days, $p < .05$), as did the proportion who died at home (50% vs. 41%, $p < .05$). Fewer post-intervention decedents received systemic cancer therapy in the last 14 days of life (5% vs. 9%, $p < .05$). There were no between-group differences in age at cancer diagnosis, age at death, gender, race/ethnicity, insurance, or primary cancer. **Conclusions:** A criteria-based "Palliative Oncology" inpatient consult service was associated with earlier, more intense PC and improved EOL quality outcomes, representing a successful effort to enhance PC integration in the inpatient oncology setting. A supervised remote exercising program for patients receiving immunotherapy alone or in combination with chemotherapy in Brazil: ExIO. *First Author: Paulo Gustavo Bergerot, Centro de Cancer de Brasília, Instituto Unity de Ensino e Pesquisa, Grupo Oncoclinicas, Brasília, Brazil*

Background: Exercise has been shown to ameliorate the side effects of cancer therapy, improve quality of life, and may even enhance treatment response. Since immunotherapy is widely used and approved for over 18 indications, studies are needed to determine the effect of exercise on immunotherapy outcomes. Additionally, there is a crucial need for understanding how to make such interventions cost-effective and accessible in low- and middle-income countries. We aimed to explore the feasibility and efficacy of a remote exercise program for patients receiving immunotherapy alone or in combination with chemotherapy in Brazil. **Methods:** This is a 12-week prospective study of a supervised remote exercise program. Patients diagnosed with any solid cancer receiving immunotherapy alone or in combination are eligible. The program is supervised using the WhatsApp and Vedio platforms and consists of resistance and aerobic exercises for 3 to 5 hours per week (4 to 6 days a week). Outcome measures include treatment-related symptoms (FACT-IT, scale 0-100), fatigue (BFI, scale 0-90), and overall quality of life (FACT-G, scale 0-108). Descriptive statistics were generated, and RM-ANOVA were used to evaluate changes in outcome measures over time. **Results:** A total of 40 patients have been enrolled to date, with 87.8% of complete adherence. Participants had a mean age of 59 years (SD = 12.2) and were predominantly female (53.7%), white (68.3%), married (68.3%), and had a college degree or higher education (56.0%). Patients were mostly diagnosed with breast (24.4%) or kidney (22.0%) cancers; 63.4% of patients had stage IV disease. Notably, significant improvements in treatment-related symptoms ($M_1 = 86.5$, $M_2 = 96.0$, $p = 0.001$), fatigue ($M_1 = 21.4$, $M_2 = 9.6$, $p = 0.001$) and quality of life ($M_1 = 87.5$, $M_2 = 98.6$, $p = 0.001$) have been observed. **Conclusions:** To our knowledge, this is the first study to examine the feasibility and efficacy of a supervised remote exercise program among patients with cancer receiving immunotherapy in Latin America. Our findings suggest that this remote program has high adherence and may improve treatment-related symptoms, fatigue, and overall quality of life while providing a practical and easily accessible alternative to patients. This study will be validated in an upcoming randomized clinical trial. Research Sponsor: None.

Patient-controlled subcutaneous analgesia with hydromorphone versus oral oxycodone for opioid titration of cancer pain: A prospective multicenter randomized trial. *First Author: Xiaoguang Xiao, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Background: Studies have shown that oral oxycodone sustained-release (SR) tablets can be used for opioid titration. The European Society for Medical Oncology (ESMO) guidelines for adult cancer pain recommend opioid titration through the parenteral route, usually the intravenous or subcutaneous route. Patient-controlled subcutaneous analgesia (PCSA) with hydromorphone needs further evaluation for opioid titration. This prospective multicenter study was designed to compare the efficacy and safety of hydromorphone PCSA with oral oxycodone SR tablets for opioid titration of cancer pain. **Methods:** Eligible patients with cancer pain were randomly assigned in a 1:1 ratio to the PCSA group or the oxycodone group for dose titration. Different titration methods were given in both groups depending on whether the patient had an opioid tolerance. The primary endpoint of this study was time to successful titration (TST). **Results:** A total of 256 patients completed this study. The PCSA group had a significantly lower TST compared with the oxycodone group [median [95% confidence interval (CI)], 5.5 [95%CI: 2.5-11.5] hours vs. 16.0 [95%CI: 11.5-22.5] hours; $p < 0.001$]. PCSA reduced the frequency of breakthrough pain (Btp), especially in patients with opioid tolerance. The number of Btp was 121 ± 28 times and 186 ± 31 times in the PCSA and oxycodone groups, respectively ($p < 0.001$). The 12-hour numeric rating scale (NRS) score was significantly lower in the PCSA group than that in the oxycodone group [median [95%CI], 2.5 [95%CI: 1.4-2.9] vs. 4.4 [95%CI: 3.2-5.8] ($p < 0.001$)]. Similar equivalent morphine consumption and significantly improved quality of life were observed in the two groups. No between-group difference in the incidence of opioid-related adverse effects was observed. **Conclusions:** Compared with oral oxycodone SR tablet, the use of PCSA with hydromorphone achieved faster pain relief and a shorter titration duration for patients with cancer pain without increasing adverse events. Risk of severe toxicity from topical fluoropyrimidine treatment in patients carrying DPYD variant alleles. *First Author: Javier Granados, University of Michigan, Ann Arbor, MI*

Background: Patients carrying variant alleles of *DPYD* that reduce activity of dihydropyrimidine dehydrogenase have unacceptably high risk of severe toxicity from systemic fluoropyrimidine chemotherapy. *DPYD* testing prior to systemic fluoropyrimidine treatment is standard of care across Europe and is increasingly used in USA. There is a published case report of fatal toxicity from topical fluoropyrimidine chemotherapy in a *DPYD* variant carrier, but the risk of severe toxicity in these patients is unknown. This information is critical to determine whether patients receiving topical fluoropyrimidine treatment should also undergo *DPYD* genetic testing. The objective of this retrospective cohort study was to determine whether patients carrying *DPYD* variant alleles have increased risk of severe toxicity from topical fluoropyrimidine treatment. **Methods:** Individuals who received topical fluoropyrimidine treatment at Michigan Medicine and had available *DPYD* genotype data, due to participation in the Michigan Genomics Initiative institutional genetic data repository, were eligible for this analysis. Clinical data for the first cycle of topical fluoropyrimidine treatment was abstracted from the electronic medical record by an investigator blinded to genetic data. Toxicities were graded based on the Common Terminology Criteria for Adverse Events (CTCAE) version 5.0. The primary endpoint was grade 3+ toxicity. The secondary endpoint was grade 1+ toxicity. Genotypes for five validated decreased- or null-activity *DPYD* variant alleles were included: *DPYD**2A (rs3918290), *DPYD**13 (rs55886062), *DPYD* p.D949V (rs67376798) *DPYD* HapB3 (rs56038477) and *DPYD* p.Y186C (rs115232898). Toxicity rates in *DPYD* variant carriers vs. wild-type were compared using Fisher's Exact tests. **Results:** 201 patients receiving topical fluoropyrimidine therapy who had available *DPYD* genotype data were included in the analysis. Most patients were self-reported white (97%), male (71%), and received topical fluoropyrimidine for a diagnosis of actinic keratosis (79%). As expected in a US patient cohort, 7.0% (14/201) of patients carried a *DPYD* variant. No patients experienced grade 3+ toxicity. Patients carrying a *DPYD* variant allele had nominally higher risk of grade 1+ toxicity (21.4% vs. 10.2%, odds ratio = 2.40 [95% Confidence Interval: 0.10-2.53], $p = 0.19$). **Conclusions:** Patients carrying *DPYD* variant alleles may have increased risk of non-severe toxicity from topical fluoropyrimidines, but the risk of severe toxicity is minimal regardless of genotype. *DPYD* genetic testing to prevent severe and fatal fluoropyrimidine toxicity should be reserved for patients receiving systemic treatment and need not include patients receiving topical treatment, in whom risk of severe toxicity is minimal. Research Sponsor: None.

Concurrent hospice healthcare utilization in the hematology/oncology patient population at veterans affairs. *First Author: Anshu Hemrajani, Loyola University Medical Center, Maywood, IL*

Background: The benefits of early hospice enrollment include improved quality of life and overall survival (Kumar, 2017). Yet, most oncology patients continue to receive aggressive treatments including chemotherapy, radiation therapy, and hospitalizations until close to death (Ersek, 2017). Veterans have the unique opportunity to receive concurrent hospice which allows patients enrolled in hospice to receive disease modifying treatments and other interventions not typically provided under the traditional Medicare hospice benefit. **Methods:** A single institution retrospective review of 72 hematology and oncology patients who enrolled in the concurrent care program at the Hines VA between 12/28/2018-4/3/2021 was conducted. Patients were eligible for the concurrent care program if they (1) had a life-limiting illness with a prognosis of less than six months (2) were willing to enroll in hospice (3) had an oncologist willing to administer cancer-directed therapy. Data were summarized with descriptive statistics including medians and percentages. **Results:** Patients in the concurrent care hospice program were predominantly White (69.4%) and older than 70 years of age (63.9%). Most patients were diagnosed with primary gastrointestinal (29.2%), thoracic (22.2%), or genitourinary (19.4%) malignancies. While enrolled in concurrent care hospice, 15.3% of patients visited the emergency department and 45.8% had at least one hospitalization. Few patients received cytotoxic chemotherapy (27.8%), immunotherapy (20.8%), palliative radiation (20.8%), or pain procedures (4.2%) while enrolled in concurrent care hospice. Of the 19 patients who received chemotherapy, only one patient received treatment within 7 days prior to death. The minority of patients (11.1%) received a blood product and of those patients that did, 8.3% required one to three transfusions and 2.8% required three or more transfusions. Most (91.7%) patients died while in concurrent care hospice; 21.2% died within 30 days of enrollment and 56.1% died within 31 to 180 days of enrollment. Patients were more likely to die at home (63.6%) or in inpatient hospice (13.6%) as opposed to the hospital (3%). **Conclusions:** Enrollment in concurrent hospice care prevents patients from having to choose between comfort care and cancer-directed treatments, which is often a barrier to early hospice enrollment (Salz, 2009). At Hines VA, most patients receiving concurrent hospice care rarely or never utilized cancer directed treatments, pain procedures, blood products, or emergency room visits/hospitalizations despite having access to these resources. Furthermore, the majority of patients died with hospice-style care at home or in inpatient hospice rather than in the hospital. This observational study demonstrates that when offered the choice to pursue cancer-directed treatments, most patients opt instead to focus on comfort care at end of life. Research Sponsor: None.

Denosumab biosimilar (LY01011) in the treatment of bone metastases in patients with solid tumors: A multicenter, randomized, double-blind, active comparator-controlled phase 3 study. *First Author: Mingchuan Zhao, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: The study was to evaluate the equivalence of LY01011 to the reference product denosumab in terms of reduction of bone metabolism markers. **Methods:** Eligible patients were randomized at 1:1 ratio to receive 120 mg LY01011 injection or 120 mg denosumab every four weeks subcutaneously. Following the completion of three doses of 120 mg LY01011 or denosumab in a 12-week double-blind treatment period (DBTP), all enrolled patients would continue to receive LY01011 administration until the week 53 of follow-up period. The primary end point was the natural logarithm change at week 13 from baseline in urinary cross-linked N terminal telopeptide of type I collagen, corrected for urine creatinine (uNTX/uCr). The equivalence between LY01011 and denosumab would be concluded if the 90% CI was completely inside the pre-defined equivalence boundary between -0.135 and 0.135. A formal blinded sample-size re-estimation (BSSR) was planned to take place once 60% of the planned participants had completed the Week 13 assessments. After BSSR, the sample size increased from 560 to 850 according to prespecified procedure based on pooled standard deviation from the blinded data, which was set as a cap to ensure a feasible sample size for the study and no need to do any multiplicity adjustment. **Results:** All eligible 850 patients, included in the full analysis set, were randomized into the LY01011 group (n = 424) and denosumab group (n = 426). The samples from the 12-week DBTP were collected for analysis in both groups. The least square mean (LSM) (SE) of the natural logarithm change of uNTX/uCr at week 13 from baseline was -1.740 (0.0420) in the LY01011 group and -1.745 (0.0421) in denosumab group. The LSM difference was 0.005 between LY01011 and denosumab groups with 90% CI of [-0.088, 0.097] (p > 0.05). Skeletal related events occurring in the LY01011 and denosumab groups were 3.5% and 2.8%, respectively. The mean (SD) percentage changes of serum bone-specific alkaline phosphatase (s-BALP) from baseline to week 13 were -31.154% (39.6790) and -33.021% (37.3826) in the LY01011 and denosumab groups, respectively. The median was -36.866% and -37.457% (p > 0.05). The incidence of treatment-emergent adverse events (TEAEs) of any grade was 91.7% and 90.8% in LY01011 and denosumab groups (p > 0.05). Both groups had 38.4% of Grade ≥3 TEAEs, of which 5.4% (LY01011) and 4.5% (denosumab) were judged to be related to the study drug. Immunogenicity analysis showed that no participant (0/399) had a positive ADA test in denosumab group and only one participant (0.2%, 1/401) was tested ADA positive in LY01011 group. **Conclusions:** The study demonstrated the equivalent efficacy of LY01011 in the reduction of bone metabolism biomarker NTX to reference product, denosumab, which met the primary endpoint. It had a good safety profile with no unexpected adverse reactions in the study. Clinical trial information: NCT04859569. Research Sponsor: Shandong Boan Biotechnology Co, LTD.

Utilization of early integrated palliative medicine among patients with metastatic solid tumor cancers: Findings from a safety net medical center treating a majority African American population. *First Author: Aneasha Ananthula, Louisiana State University Health Sciences Center, New Orleans, LA*

Background: Early interdisciplinary Palliative Medicine (PM) involvement is known to provide significant benefits when added to usual oncology care, however a study by Ferrari et al looking at oncologic patients between 2001 to 2016 found that only 36% of patients with cancers with a very poor prognosis received Palliative Medicine services. In 2016 ASCO provided a practice guideline recommending specialty PM services to begin within 8 weeks of diagnosis. Our study aimed to assess the integration of the above recommendation in a newly built academic, safety net hospital serving as a regional tertiary healthcare facility with a newly built PM service that included a free-standing outpatient clinic. **Methods:** This is a retrospective cohort study of all patients on the tumor registry with de novo stage IV cancer diagnosed in a four-year period from 2018 to 2021. Patient data was collected from the electronic medical record (EMR) and included demographics, health history, PM utilization, and advance care planning documentation. Logistic regression was used to analyze key predictors of PM utilization and advance care planning. **Results:** The majority of patients (N = 510) were African American (race: Black [56.5%], White [35.7%], all other racial groups [7.8%]; mean age = 59.8 [range from 18 or over 90]; sex: 60.6% male). Diagnoses included gastrointestinal (38.2%), thoracic (27.8%), genitourinary (26.3%), and other (7.7%) cancers. Out of the group, 60.5% of the patients received PM services and 55% of those had a visit within the ASCO recommendations of 8 weeks. A surprising 32.7% of those referred to PM had a first visit within the first 2 weeks via an urgent referral system, most often for symptom management. About 40.0% of initial visits were outpatient rather than inpatient and there were no racial or other demographic differences in the setting of the first visit. Patients receiving cancer care in more recent years (P < .001), who were younger (P = .025), and with non-genitourinary cancers (P = .005) were more likely to receive PM services. Also, patients who received PM were more likely to have a medical power of attorney (P < .001) and living will (P < .001) documented in the EMR. **Conclusions:** This study demonstrates that in centers with a robust PM team including an outpatient clinic, patients with advanced cancer are receiving early Palliative Medicine evaluation in accordance with the 2016 ASCO guidelines. In contrast to a previous study by Johnson et al our study shows that African-Americans were also equally referred and established with PM services. Our study is limited by the presence of a free-standing PM clinic rather than embedding into a cancer center which may assist with even earlier integration. Research Sponsor: None.

A phase III, double-blind, non-inferiority, randomized controlled trial of antiemetic prophylaxis for highly emetogenic chemotherapy without dexamethasone: CINV POD study. *First Author: Venkatraman Radhakrishnan, Cancer Institute (WIA), Chennai, India*

Background: Chemotherapy-induced nausea and vomiting (CINV) is a common side effect of highly emetogenic chemotherapy (HEC). Current guidelines recommend the use of dexamethasone (DEX) for prophylaxis, but the effectiveness and safety of a DEX-free regimen for CINV prophylaxis in HEC is not known. **Methods:** This was an investigator-initiated, double-blind, phase 3 RCT designed to show the non-inferiority of a DEX-free regimen (olanzapine, palonosetron, and fosaprepitant; OPF) compared to the NCCN recommended DEX-containing regimen (olanzapine, palonosetron, and dexamethasone; OPD). Chemotherapy-naïve patients aged 18-80 years receiving single-day HEC were randomized 1:1 to receive either the OPD regimen (olanzapine 5 mg once a day on days 1-4, palonosetron 0.25 mg on day 1, and DEX 12 mg on day 1) or the OPF regimen (olanzapine and palonosetron as above, and fosaprepitant 150 mg on day 1). The primary endpoint was to compare complete response (CR) rates for vomiting (no vomiting and no rescue medication) during the overall phase (start of chemotherapy to 120 h). The secondary endpoints were CR for nausea (ESAS), toxicities (CTCAE), and patient reported outcome measures (PROM) using MDASI. Assuming CR for vomiting for the overall phase of 77% (power = 90%, 2-sided alpha = 5%, and non-inferiority margin [NI] = 15%), 175 patients in each arm were required (including 5% dropout). **Results:** Between May 2022-Dec 2022, 350 patients were randomized and 346 received the study interventions (OPD arm n = 174 and OPF arm n = 172). The most common chemotherapy used was adriamycin/cyclophosphamide (66%) followed by cisplatin (27%). CR rates for vomiting for the overall phase were 48.8% in the OPD arm and 79.6% in the OPF arm (P < 0.001), with an absolute difference of -30.8% and 2-sided 95% CI = (-40.31, -21.24) which was within the pre-defined NI margin of 15% and also showed superiority. The DEX-free arm also had significantly higher CR rates for nausea and total control (vomiting and nausea combined) (Table). There were no significant differences in any grade CTCAE toxicities. PROM for fatigue (P = 0.009) and drowsiness (P = 0.002) were more in the OPF arm in the acute phase, and insomnia (P < 0.001) in the OPD arm in the delayed phase. **Conclusions:** This study shows that a DEX-free OPF regimen is superior to the DEX-based OPD regimen and should be considered a standard option for CINV prophylaxis for HEC. Clinical trial information: CTRI/2022/03/040906. Research Sponsor: Cancer Institute (WIA).

Phase		OPD (n = 174) % of patients	OPF (n = 172) % of patients	Absolute difference % (95% CI)	P (Chi-square)
CR for Vomiting	Acute (0-24 h)	85.6	94.7	-9.1 (-15.3, -2.9)	0.004
	Delayed (24-120 h)	50.5	81.9	-31.4 (-40.8, -22)	< 0.001
	Overall (0-120 h)	48.8	79.6	-30.8 (-40.3, -21.2)	< 0.001

Palliative care in hematopoietic stem cell transplant recipients and impact on survival: A nationwide analysis. *First Author: Naveen Premnath, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Palliative care benefits have been widely studied in solid tumors with early palliative care demonstrating prolonged survival in several malignancies including lung and esophageal cancer. There are limited data and guidelines for use of palliative care in hematopoietic stem cell transplants (HSCT). **Methods:** We used the National cancer database (NCDB) to identify HSCT recipients between 2004 to 2017 and retrospectively examined the outcomes based on receipt of palliative care. Chi-square and Wilcoxon tests were used to compare categorical and continuous variables respectively. Kaplan Meier analysis and a Cox multivariable proportional hazards model were used for survival analysis using R software. The NCDB is available as de-identified data. Hence, this study was exempt from a full IRB review. **Results:** We identified 17,464 eligible patients with hematologic malignancies who underwent HSCT during 2004-2017. The table below shows differences in baseline characteristics in patients who received palliative care vs no palliative care and shows an improved median survival in those receiving vs those not receiving (43.5 vs 31.6 months) (p = 0.0003). Patients with median household income in the lowest quartile as per 2016 survey data were taken as low-income group. A multivariable cox regression analysis that adjusted for age, sex, Charlson-Deyo Comorbidity Index, insurance status, income and Hispanic ethnicity found that integration of palliative care was associated with improved survival outcomes (HR 0.85, CI 0.77- 0.93, p = 0.0002). **Conclusions:** To our knowledge, this is the largest study demonstrating improved outcomes in HSCT recipients when palliative care was incorporated despite there being more economically challenged patients in the group that received palliative care. Although these data are retrospective and correlational, it underscores how palliative care should be incorporated as part of national society guidelines for HSCT recipients. Research Sponsor: None.

Key components of goals of care conversations on determining end-of-life care for advanced cancer patients. *First Author: Amy An, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Early goals of care (GOC) conversations appear to improve end of life (EOL) care in patients with advanced cancer. However, interventions to facilitate GOC conversations may be unsuccessful in changing EOL outcomes due to incomplete understanding of the components of such conversations essential to impacting EOL care. This study seeks to identify the specific components of GOC conversations between patients and oncologists that are associated with less aggressive EOL care. **Methods:** This was a secondary, sequential mixed-methods analysis of data collected as part of the Values and Options in Cancer Care (VOICE) study, an RCT to improve communication between patients and oncologists. We used qualitative methods to describe and quantify components of GOC conversations occurring in recorded oncology office visits. We then conducted logistic regression analyses to examine the associations between key components identified with less aggressive EOL care. **Results:** 107 patients who died within 1 year of the recorded visit were included for analysis. Content related to GOC conversations could be found in 80.4% of visits. Most commonly discussed content was related to treatment (72.9%), followed by prognosis (43.9%), EOL care (17.8%), and patient values and preferences (16.8%). In adjusted analyses, discussion of treatment expectation, offer of an alternative to cancer-directed treatment, and mention of hospice were significantly associated with less aggressive EOL care, OR 4.66 ($p = 0.047$), OR 6.09 ($p = 0.008$), and OR 7.60 ($p = 0.046$) respectively. We did not find significant association between discussion of life expectancy and EOL care. **Conclusions:** GOC conversations may be more effective at impacting EOL care when it includes discussion regarding treatment expectations and offer of an alternative option to cancer-directed therapy, such as hospice. Facilitating the transition to posttreatment survivorship for adolescent and young adults: A randomized waitlist control trial of a virtual mind-body intervention. *First Author: Giselle Katiria Perez, Massachusetts General Hospital, Boston, MA*

Background: Adolescent and young adults (AYAs) with cancer experience chronic stress and poor quality of life, particularly in early posttreatment as AYAs grapple with a "new normal." Mind-body programs introduced early posttreatment hold promise for providing AYAs with skills to mitigate the adverse psychosocial and physiological effects of stress. **Methods:** We adapted and piloted an 8-session virtual, mind-body stress management and resilience group program for AYAs (3RP-AYA) to support the posttreatment transition. AYAs were randomized to receive the 3RP-AYA immediately (intervention group; IG) or after 3 months (waitlist control; WC). Data were collected at baseline (T0), 3 (T1) and 6 months (T2). We assessed feasibility by examining 3RP-AYA participation and survey completion rates. Paired-samples t-tests evaluated within-group effects of the 3RP-AYA on coping, distress (worry, depression, uncertainty intolerance), and resilience from T0-T1 (intervention period for IG, waitlist period for WC). Independent-samples t-tests of T0-T1 change scores for each group tested between-group differences in strength of change. Cohen's d characterized strength of within- and between- group differences. Acceptability (i.e., content satisfaction and perceived helpfulness) was assessed at program end (T1 for IG, T2 for WC). **Results:** From 05/19-09/20, 72 AYAs (77% participation rate; $Mage = 23.8$; 73.6% female; mean 18-months posttreatment; 59.7% non-Hispanic white; 20.8% Hispanic; 25% international) were randomized to IG ($n = 35$) or WC ($n = 37$); 85.9% completed 6/8 sessions (median = 7), and 87.5% completed the T1 survey. At enrollment, AYAs presented with elevated worry ($M = 52.5$, $SD = 12.2$) and uncertainty intolerance ($M = 33.8$, $SD = 8.7$), resembling patients with generalized anxiety. From T0-T1, the IG demonstrated moderate-to-large improvements in coping ($d = 0.78$, $p < .001$), worry ($d = 0.45$, $p = .04$), depression ($d = .31$, $p = .11$), tolerance of uncertainty ($d = .37$, $p = .06$) and resilience ($d = .34$, $p = .09$). When examining between-group differences, the IG showed significantly greater improvement in coping ($d = 0.72$, $p = .01$), with non-significantly greater change in worry, depression, tolerance of uncertainty, and resilience ($ds = 0.27-0.49$, $ps > .09$) relative to WC. Notably, 96.6% of participants reported overall content satisfaction, and 91.7% reported the 3RP-AYA was helpful. **Conclusions:** A virtual mind-body program is feasible, acceptable and shows promising efficacy in improving coping and distress among posttreatment AYAs. Findings offer a paradigm shift in the way survivorship care is delivered, suggesting that integrating a mind-body program into early posttreatment survivorship care can facilitate adjustment to life after treatment. This can have downstream effects on the long-term emotional and physical health of AYAs. Clinical trial information: NCT03768336. Research Sponsor: U.S. National Institutes of Health.

Adjuvant endocrine therapy adherence changes among patients after a virtual behavioral intervention. *First Author: Jamie M. Jacobs, Massachusetts General Hospital, Boston, MA*

Background: Adjuvant endocrine therapy (AET) reduces risk of breast cancer (BC) recurrence; however, adherence is suboptimal and interventions are needed. We conducted a randomized controlled trial of a novel telehealth intervention (STRIDE), which led to improvements in symptom distress, coping, quality of life, and mood. Here we examine which patients had improved adherence following STRIDE by exploring characteristics that may moderate intervention effects. **Methods:** Women ($n = 100$) with nonmetastatic BC who reported AET-related distress were randomized to receive STRIDE or a medication monitoring control (MM) between 10/2019-6/2021. STRIDE consisted of six weekly, small-group cognitive behavioral telehealth sessions to enhance symptom management and adherence. All patients stored their AET in electronic MEMS Caps bottles to measure objective adherence. We collected patient characteristics (i.e., months on AET, education) and self-report measures at baseline. Patients completed the Medication Adherence Report Scale (MARS-5) and Cancer Therapy Satisfaction Questionnaire to report adherence behaviors (e.g., "I alter the dose") and AET perceptions (e.g., convenience, expectations, satisfaction), respectively. We conducted hierarchical linear modeling to test moderators of intervention effects on adherence rates (MEMS Caps) across months 1-3, controlling for ovarian suppression receipt and baseline distress due to group differences/stratification. We report the 'time X group X moderator' effects here. **Results:** Among participants reporting greater difficulty (lower MARS-5) with their AET regimen at baseline, STRIDE participants had greater improvement in adherence over time compared to MM participants ($b = -13.80$, $SE = 4.56$, $p < .01$). Greater expectations of therapeutic benefit predicted improvements in adherence for STRIDE versus MM participants ($b = 0.25$ $SE = 0.10$, $p = .01$). Additionally, among participants who reported greater convenience of taking AET ($b = 0.33$ $SE = 0.17$, $p = .06$), had lower education levels ($b = -4.02$, $SE = 2.12$, $p = .06$), and had been taking AET for fewer months ($b = -0.43$ $SE = 0.25$, $p = .09$), STRIDE participants showed adherence increases that approached significance. Other moderators were not significant. **Conclusions:** STRIDE demonstrated effects of a behavioral intervention on AET adherence. Participants reporting greater difficulty adhering to their AET regimen and who expected more benefit showed improved adherence following STRIDE. Gains in adherence from STRIDE were also more pronounced among those who reported that AET was convenient, started the medication more recently, and had lower levels of education. Patient-level and socioeconomic factors influence response to AET adherence interventions. Clinicians may play a key role in addressing modifiable targets at AET initiation (e.g., logistical barriers, perceived benefit) to enhance adherence. Clinical trial information: NCT03837496. Will we have a match? Observations from decision making conversations between hematologists and White and Black patients considering allogeneic stem cell transplant. *First Author: Thorunn Halldora Thordardottir, University of Wisconsin, Madison, WI*

Background: Allogeneic stem cell transplant (alloSCT) is the only treatment associated with cure for high-risk myelodysplastic syndrome (MDS), but carries substantial risks. One routinely mentioned concern is donor source. While white patients have an 80% chance of finding an unrelated fully matched donor, Black patients have among the lowest chance at 30%. The aim of this secondary analysis, from a telemedicine study assessing how hematologists engage in shared decision making with patients considering alloSCT, is to analyze how hematologists navigate discussions about donor concerns related to the apparent race of the patient. **Methods:** This is a qualitative analysis of transcribed video-recorded virtual encounters. We recruited US hematologists who perform alloSCT and randomized them to meet with a patient actor of Black or white race. The hematologists conducted a new patient encounter with the actors who were trained to portray the same 67 year old man with newly diagnosed high-risk MDS referred for specialty consultation to discuss treatment options. The patient character had multiple healthy siblings and children. **Results:** Transcripts from a total of 33 hematologists were available at the time of analysis (61% male, 30% non-white, mean age 46 +/- 11 years). Hematologists spent varying amounts of time discussing the concept of transplant donation. While some used complex language to describe matching and HLA tissue markers, others used simplified terms of finding a donor with "an immune system that's similar to your own," to eradicate foreign MDS cells and avoid attack on healthy cells. The majority emphasized searching for a donor among siblings, given the highest likelihood of matching. Conversations with the white actor included reassurance of finding a fully matched donor, whether through family or the international registry. Hematologists frequently disclosed the highest chance of success for people of European ancestry. While hematologists mentioned the registry in conversations with the Black actor, they rarely disclosed the lower chance of finding a fully matched unrelated donor. Instead they reassured that with better technology haploidentical match could be an option through donation from their child, "with as favorable outcomes." Some gave the Black actor an overestimation of finding a fully matched donor through the registry. Non-white hematologists more frequently acknowledged the concept of race in stem cell donation. **Conclusions:** Hematologists use multiple strategies to help patients understand the donor process. They reveal to white patients the high likelihood of finding a fully matched donor while appearing to avoid discussing the lower odds for a Black patient. Associations between psychosocial risk factors and immune checkpoint inhibitor outcomes. *First Author: Heather Derry-Vick, Center for Discovery and Innovation, Hackensack Meridian Health, Nutley, NJ*

Background: Psychosocial risk factors such as anxiety and depression can affect immune responses and cancer-related outcomes. Accordingly, we investigated whether an existing anxiety or depression diagnosis influenced immune checkpoint inhibitor (ICI) safety or efficacy. **Methods:** In our multicenter retrospective study across all cancers, we identified 913 patients who began anti-PD-1 or anti-PD-L1 monotherapy [PD(L)-1] between 2011-2018 with follow up until January 2021. Depression and anxiety disorder diagnosis at the time of treatment initiation were abstracted from medical charts. Immune-related adverse events (irAEs) were graded according to CTCAE v4.03. Overall survival (OS) and time to treatment failure (TTF) were recorded. Multivariable logistic regression models and proportional hazard models were used to test relationships between anxiety (or depression) diagnosis and irAEs (any grade vs. none), OS, and TTF, respectively, while adjusting for race, gender, age, and other relevant clinical variables associated with each outcome ($p < 0.1$) in the univariate analysis (e.g., performance status, autoimmune disease, and number of metastatic sites). **Results:** At the time of treatment initiation, 11% ($n = 102$), 12% ($n = 106$), and 4% ($n = 41$) of patients in the overall PD(L)-1 ICI cohort had an anxiety diagnosis, depression diagnosis, or both, respectively. The overall incidence of any grade irAEs was 32% ($n = 295$), including 44% ($n = 45$) and 37% ($n = 39$) among those with anxiety and depression history, respectively. Patients with an anxiety diagnosis had a greater likelihood of experiencing an irAE [Odds ratio (OR) = 1.80; 95% CI = 1.16 to 2.80, $p = 0.009$]. There was not a statistically-significant relationship between depression diagnosis and irAEs (univariable OR = 1.25; 95% CI = 0.82 to 1.91, $p = 0.295$). In the subset of patients with lung cancer ($n = 443$) receiving PD(L)-1 ICI, the rates of any grade irAEs, anxiety, and depression diagnosis were 32% ($n = 143$), 10% ($n = 44$), and 12% ($n = 52$), respectively. In multivariable analysis, anxiety diagnosis was associated with better OS (HR = 0.61; 95% CI = 0.39 to 0.97; $p = 0.038$) and TTF (HR = 0.68; 95% CI = 0.47 to 0.98; $p = 0.038$). The link between anxiety diagnosis and irAEs was weaker in this subsample (OR = 1.46; 95% CI = 0.74 to 2.87, $p = 0.274$). No significant associations between depression diagnosis and any grade irAEs (OR = 0.83; 95% CI = 0.44 to 1.57, $p = 0.573$), OS (HR = 1.06; 95% CI = 0.73 to 1.55, $p = 0.755$), or TTF (HR = 1.13; 95% CI = 0.83 to 1.54, $p = 0.433$) were observed. **Conclusions:** Our results suggest that baseline psychosocial risk factors, especially anxiety disorders, may influence ICI efficacy and safety. Prospective studies are warranted to better understand the relationship between psychosocial risk factors and ICI outcomes. The study also suggests a possible role for targeted supportive care in influencing cancer-related outcomes for those with psychosocial risk factors. Analysis of delivery of cancer survivorship education to community health-care professionals. *First Author: Ashley Pariser, Division of Medical Oncology, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: There are currently 18.1 million cancer survivors in the United States; anticipated to reach 26.0 million survivors by 2040. Educational opportunities for healthcare providers in survivorship care is needed to insure capacity for this rapidly growing population particularly in the community setting. This pilot study implemented a cancer survivorship Project ECHO model in two community hospitals within a larger community health system. **Methods:** Providers affiliated with the Mercy Health System were enrolled in one of two cohorts. Eligible participants included physicians, advanced practice providers, nurses, social workers, and dietitians. Six one-hour sessions were developed from a needs assessment and delivered over a 12-week period. Participants were invited to complete pre and post session surveys to evaluate the following 3 domains: professional improvement (PI), self-efficacy (SE), and knowledge (KN). A Likert scale was used with each survey item rated 1-5, where 1 represents lowest and 5 highest (agreement/confidence/knowledge). The average score for survey items within each domain was utilized to compare pre- and post-survey results. **Results:** Fourteen multidisciplinary providers were enrolled in both Cohort 1 and Cohort 2. Twenty-six completed the baseline survey and 22 completed the post-study survey. The mean change of each domain (PI, SE, KN) and mean overall change are summarized in the table. For cohort 1, the overall score significantly increased 0.94 (0.45,1.42) ($P=0.0023$). While the SE and KN domain scores increased significantly (1.1 (0.5,1.7), 1.03 (0.45,1.62) and $p = 0.003$, 0.0036, respectively), the PI did not change -0.09($p=0.726$). For cohort 2, the overall score significantly increased 0.617 (0.042,1.193) ($P=0.0378$). While the SE and KN domain increased significantly (0.728(0.048,1.407), 0.665 (0.041,1.289) and $p = 0.0379$, 0.0387, respectively), the PI did not change ($p=> 0.999$). **Conclusions:** The Cancer Survivorship ECHO model may serve as a scalable strategy for building cancer survivorship care capacity in community-based oncology practices through equipping multidisciplinary teams to meet the needs of cancer survivors within their community. Further research is needed to assess implementation of this model into novel settings and evaluate its impact on patient outcomes. Research Sponsor: U.S. National Institutes of Health.

Comparing the time toxicity of cancer treatments in the CCTG LY.12 trial. *First Author: Arjun Gupta, University of Minnesota Masonic Cancer Center, Minneapolis, MN*

Background: When different cancer treatments have similar oncologic outcomes, their respective time-related burdens can aid patient-oncologist decision-making regarding which treatment approach to pursue. We have previously developed a pragmatic and patient-centered metric of these time burdens— which we term “time toxicity”— as any day with physical healthcare system contact. This includes outpatient (e.g., bloodwork, scans, clinician, etc.) and emergency room visits, and overnight stays in a healthcare facility. Herein we sought to assess time toxicity in a completed RCT. **Methods:** We conducted a secondary analysis of the Canadian Cancer Trials Group LY.12 RCT that evaluated 2-3 outpatient cycles of gemcitabine, dexamethasone, and cisplatin (GDP) vs. dexamethasone, cytarabine, and cisplatin (DHAP) in 619 patients with relapsed/refractory lymphoma prior to stem cell transplant. Primary analyses reported similar response rates, transplantation rates, event-free-survival, and overall survival across arms. We calculated patient-level time toxicity by analyzing RCT forms. The study period was the date of assignment to the date of progression or the day before stem cell transplant. We considered days without healthcare contact as “home days”. We compared time measures across arms. **Results:** The median study duration was longer in the GDP arm (50, vs. 47 days in the DHAP arms, $p=0.007$). Median time toxic days were comparable in both arms (18 vs 19 days, $p=0.79$), but median home days were higher in the GDP arm (33 vs 28 days, $p<0.001$). The proportion of time toxic days (time toxic days divided by study duration) was lower in the GDP arm (34%, vs. 38%, $p=0.009$). The GDP arm experienced more time toxicity related to planned outpatient chemotherapy (median, 10 vs. 8 days), but the DHAP arm experienced many more hospitalization days (median, 11 vs. 0 days) (Table). **Conclusions:** This study demonstrates that measures of time toxicity can be extracted from RCTs. These measures can add clinical insight into patient burdens. In LY.12, despite broadly comparable short- and long-term oncologic outcomes, the GDP arm experienced less time toxicity. Such information can guide decision-making for patients with aggressive hematologic cancers, who already spend a significant portion of time with healthcare contact. Clinical trial information: NCT00078949. Research Sponsor: Canadian Cancer Society Research Institute; Roche Canada and Eli Lilly Canada.

Time toxicity measures in LY.12.			
Time toxicity measure, median (interquartile range)	GDP N=306	DHAP N=304	p-value

The FARGO study: Frailty assessment for risk prediction in gynecologic oncology. *First Author: Julie My Van Nguyen, Division of Gynecologic Oncology, Department of Obstetrics and Gynecology, McMaster University, Hamilton, ON, Canada*

Background: Little is known about how to best predict postoperative outcomes and chemotherapy tolerance in an increasingly aging and complex gynecologic oncology (GO) population. Frailty is a multidimensional age-related and disease-related state of vulnerability to stressors due to reduced capacity of different physiological systems. Resource limitations are a barrier to routine adoption of frailty assessments through comprehensive clinical evaluations in daily practice. This highlights the relevance of studying potential biomarkers of frailty, which could complement or replace clinical assessments. Frailty has been associated with worse perioperative and oncologic outcomes in many subspecialties, however the literature in patients with gynecologic malignancies is very limited. **Methods:** The FARGO study is a multi-centre prospective cohort study of 280 patients aged ≥ 55 years-old undergoing surgery, with or without chemotherapy for a suspected or confirmed gynecologic malignancy. Patient recruitment will occur over 13 months. The over-arching goal is to evaluate the predictive value of frailty assessments in predicting surgical and chemotherapy outcomes. The two primary objectives are: 1) To evaluate the predictive value of preoperative frailty assessment based on the Frailty Phenotype (FP), compared to a perioperative cardiovascular risk assessment, in predicting the composite of all-cause death or new disability at 6 months after surgery 2) To create of a biobank to explore possible biomarkers of frailty, including mitochondrial DNA levels. Secondary objectives include to evaluate the predictive value of clinical and biomarker frailty assessment for 30-day postoperative complications, for chemotherapy tolerance and 1-year recurrence-free survival. Patients will undergo frailty and cardiovascular risk assessment prior to surgery and/or neoadjuvant chemotherapy. A trained clinical research assistant will measure frailty based on the clinical frailty scale (CFS) and the FP. The cardiovascular risk calculation will be based on the preoperative Revised Cardiac Risk Index, age, and occurrence of myocardial injury after non-cardiac surgery (MINS). Research personnel blinded to the frailty and cardiovascular risk assessment will evaluate study outcomes including death, disability, and clinical events at 30 days, 6 months, and 12 months after surgery. Disability will be measured with the WHODAS 2.0 (World Health Organization Disability Assessment Schedule), a validated patient-reported outcome measure. Pre-specified blood biomarkers will be measured. Our study emphasizes patient-centered outcomes (i.e. loss of independence, short and long-term disability) and system-level outcomes. Our findings may have important implications to assist in risk stratification and planning for oncologic treatments and perioperative care needs. Comprehensive geriatric assessment based multidisciplinary team intervention for hospitalized frail patients in oncology: COMPASS-ONCO/KCSG AL21-13. *First Author: Yun-Gyoo Lee, Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: Comprehensive geriatric assessment (CGA) is a multidimensional, interdisciplinary assessment for evaluating older patients' medical, psychological, physical functions and social status. CGA-based multidimensional intervention is the gold standard in geriatric oncology to identify patients at high risk of adverse outcomes and optimize cancer and overall management. Numerous studies have demonstrated that CGA could modify oncologic treatment decision. However, little is known about the treatment outcomes of a multidisciplinary team intervention based on CGA. **Methods:** The COMPASS study is the first pragmatic multicentre trial within a cohort comprising three randomized controlled trials focusing on focusing on CGA and multidisciplinary intervention for hospitalised elderly patients in various healthcare settings of Korea. COMPASS-ONCO compares the effect of an oncologist-led multidisciplinary team intervention based on the CGA to that of conventional treatment for older cancer patients without the involvement of geriatricians. The patients will be randomised into the intervention or control groups in a 1:1 ratio. The inclusion criteria are as follows: (1) 65 years of age or older, (2) prefrail or frail status assessed by Korean version of the Fatigue, Resistance, Ambulation, Illnesses and Loss of Weight scale questionnaire, (3) having two or more of the following diseases: hypertension, diabetes, ischaemic heart disease, chronic lung disease, arthritis, stroke, depression, chronic kidney disease and dementia. (4) living at home for more than 3 months before hospitalization, (5) subject to palliative chemotherapy and (6) histologically confirmed gastric, colorectal, lung, pancreatic or biliary tract carcinoma. The intervention includes CGA and CGA-based multidisciplinary interventions by oncologists, nurses, nutritionists and pharmacists. The multidisciplinary intervention includes nutritional support, medication review and adjustment, rehabilitation, early discharge planning and prevention of geriatric syndromes (falls, delirium, pressure sore and urinary retention). The analysis will be based on an intention-to-treat principle. The primary outcome is overall treatment utility which is a clinical outcome incorporating objective and subjective measures of anticancer efficacy, tolerability and acceptability. Additionally, recognition of advance directives, changes in body composition and validity of anticancer drug toxicity prediction model will also be assessed. Approximately 1040 patients will be required for COMPASS study, and 260 will be enrolled in the COMPASS-ONCO substudy at five hospitals in Korea. Participants have been recruited from 2 November 2021, and recruitment will continue until December 2024. Clinical trial information: KCT0006270. Research Sponsor: Patient-Centered Clinical Research Coordinating Center (PACEN) funded by the Ministry of Health & Welfare, Republic of Korea (Grant number: HC20C0086).

Evaluating the impact of exercise in women living with indolent metastatic breast cancer: The EMBODY trial. *First Author: Martha Cancilla, IU School of Medicine, Indianapolis, IN*

Background: Exercise is associated with improved survival, physical function, treatment tolerability, and quality of life in early-stage breast cancer. Prospective trials support the positive impact of exercise on cardiorespiratory fitness (CRF), physical function, and muscle mass. These same endpoints matter in metastatic breast cancer (MBC). CRF is a predictor of worse cancer-specific survival, and there is a high prevalence of physical impairment and sarcopenia in patients with MBC, both associated with worse quality of life and survival. Two previous exercise trials in those with MBC have found exercise to be not feasible or of limited benefit. These findings may be due to a heterogeneous participant population that is primarily receiving cytotoxic chemotherapy. Patients with MBC have variable disease trajectories and supportive care needs; those with indolent MBC have longer life expectancy, lower symptom burden and distinct priorities, and are well-positioned to participate in and benefit from an exercise program. The EMBODY trial is focused on enrolling a homogeneous patient population with indolent, stable MBC and improving endpoints known to correlate with survival outcomes in this population. Here, we evaluate the impact of a multimodal exercise intervention on CRF, physical function, body composition, and PROs. This study will be a step toward redefining "survivorship" to extend to those living with MBC. **Methods:** In this prospective phase II trial (NCT05468034), 100 patients with MBC are randomized 1:1 to exercise intervention or wait-list control, stratified by baseline function. Eligible patients have no evidence of disease progression in the prior 12 months and may be receiving endocrine, targeted, immuno-, or antibody drug conjugate therapy. Patients receiving cytotoxic chemotherapy are not eligible as this subgroup did not benefit in prior trials. Target enrollment is 3-4 participants per month over 2.5 years, beginning January 2023. The virtually-delivered exercise intervention arm achieves moderate intensity exercise with oncology-certified exercise physiologists 3 days/week for 16 weeks. The 60-minute sessions include aerobic, resistance, balance and stretching exercises. The exercise arm receives informational sessions on the role of exercise in cancer and principles of habit and self-efficacy. The primary endpoint is 16 week change in CRF on a ramp treadmill test between the exercise and control arms. Secondary endpoints include change in a physical function battery, muscle mass assessed by CT scans, and PROs of fatigue and quality of life. Exploratory analysis includes behavioral modifiers of exercise adherence and effectiveness and serologic measures of inflammatory, metabolic, and immune pathway biomarkers, as well as changes in circulating tumor cells. Patients will be followed post-intervention for sustained behavior change and survival trajectory. Clinical trial information: NCT05468034. Research Sponsor: Susan G Komen Career Catalyst Research Grant.

Digital voice analysis as a measure of frailty and distress: A feasibility study (DIVAN). *First Author: Marcus Vetter, Cancer Center Baselland, Liestal, Switzerland*

Background: Assessing of frailty is essential not only in older patients with cancer, because frailty changes management of cancer therapy. Same is true for the routine assessment of distress to identify patient suffering and initiate adequate symptom control or psychosocial interventions. Here we present new potential method of frailty and distress assessment with digital voice analysis as a proof of concept trial. (NCT requested pending, DIVAN-1). **Methods:** Adult patients with the diagnosis of active incurable cancer can be enrolled into this study. Every participant will describe two to four images presented to him or her on a tablet computer in up to four sessions, and the patient's voice will be recorded digitally. Baseline characteristics including cancer type, stage, therapy, G8 questionnaire and distress questionnaire (ESAS) will be collected at every session. Acoustic features like mean fundamental frequency (F0) and first few formants (F1, F2, etc.), jitter (variation in F0 from cycle to cycle), shimmer (variation in peak-to-peak amplitude), etc. will be explored digitally along with for example and voice strength (volume). Additionally, a vowel test will conducted and explored. Depending on the distribution of the data, the Pearson R correlation test or the Spearman's R correlation test will be applied for each variable. The primary research question of this feasibility study is to identify quantitative parameters out of the audio signal to describe the changes in patient's state in relation to frailty and distress. Trial enrolment has begun in December 2022 and 11 out of 100 patients have been included. Clinical trial information: NCT05783401. Research Sponsor: Research Funding by FHNW, PZH, KSBL, Switzerland.

Comprehensive Outcomes for After Cancer Health: COACH. *First Author: Robin Mary Lally, University of Nebraska Medical Center, Omaha, NE*

Background: The landscape for cancer survivors continues to evolve as individuals live longer following primary therapy. For some, treatment is complete; for others, active surveillance or maintenance therapy may be indicated. Individual survivorship needs are diverse, influenced by tumor and treatment type, as well as social determinants of health. Digital interventions may support survivors in achieving personalized health goals throughout survivorship. The Comprehensive Outcomes for After Cancer Health (COACH) Study (NCT05349227) explores the feasibility of a digital health coaching (DHC) program for individuals enrolled with diverse tumor types and geographic regions. **Methods:** COACH is a multi-center, randomized, wait-list control trial enrolling 550 individuals ≥ 18 years old who are within 1-year of completion of primary cancer therapy at enrollment. Up to 100 participants, will be recruited at each of 6 study sites, of which 3 are currently enrolling. Consented individuals are randomized to 6 months of DHC or 6 months of data collection only, then cross-over for follow-up to 12-months. Both groups wear an activity tracker; complete patient reported outcome measures; and provide fecal specimens. The DHC program includes weekly Health Advisor calls and supplemental delivery of evidenced-based content via text, email or mobile platform. Topics fall in health domains of physical, mental/emotional, financial, social, and sexual, and emphasize nutrition, physical activity, sleep, and screening for recurrent or de novo cancer. Feasibility for this study is defined as a retention rate greater than or equal to 70%, and acceptability will be defined as less than or equal to 20% scoring "not at all helpful." Trends over time will be assessed using linear mixed models using time as a fixed effect, as well as any covariates and interactions of interest. Descriptive statistics will be used to evaluate exploratory endpoints. A cross-cohort end-point related to physical function as measured by the PROMIS Physical Function 10a, will also be evaluated. To date, 72 individuals have enrolled, with Nebraska as the lead site, including 71 women, with a mean age of 61.78 (Range 33-74), from the U.S. Midwest (n = 57) and Northeast (n = 15). 4 identify as African American/Black, 68 as White. 50 have a breast, 13 ovarian, 8 endometrial, 1 gastric diagnosis. Nine have completed the first 6 months of the study. The study is novel in the breadth of data collected and potential to understand variability in patient experiences and provide insights into the feasibility, acceptability, and efficacy of a DHC intervention supporting individuals after primary cancer treatment. Clinical trial information: NCT05349227. Research Sponsor: Daiichi-Sankyo; Gilead Sciences; GSK; Ohio State University; University of Florida.

The CROWN study (CaRdiac outcomes with near complete estrogen deprivation): A multicenter, prospective cohort study of cardiovascular outcomes in premenopausal women with hormone receptor positive breast cancer treated with ovarian suppression and an aromatase inhibitor. *First Author: Emily H. Douglas, Wake Forest University School of Medicine, Winston-Salem, NC*

Background: Treatment for premenopausal women with high or intermediate risk hormone receptor (HR)+ breast cancer (BC) now includes the concurrent use of ovarian function suppression (OFS) and an aromatase inhibitor (AI) to induce near complete estrogen deprivation (NCED). The long-term cardiovascular (CV) sequela for women treated with NCED is unknown. Premature menopause in non-cancer populations is associated with CV disease. Taken together with the CV morbidity associated with other aspects of BC treatment and the future life-years of these women, the CV impact of NCED warrants further study. The CROWN study will use sophisticated imaging assessments of cardiac dysfunction to understand the evolution of CV injury, as well as biomarker and demographic correlates, with the goal of developing tools to assess and mitigate CV risk. **Methods:** This is a NIH funded prospective cohort study conducted at 3 regional NCI-supported Cancer Centers (Atrium Health Wake Forest Baptist, Virginia Commonwealth and Duke) that will include premenopausal women, age $\leq$ 55, with Stage I-III BC following completion of planned chemotherapy, surgery and radiation with an ECOG 0-1. HR+ BC patients will receive an AI and OFS. Women with HR- BC are included as comparators. CV imaging and biomarkers will be obtained at baseline, 1 year and 2 years (Table 1). These assessments will include serial cardiac magnetic resonance (CMR) and coronary computed tomography angiography (CCTA) imaging as well as laboratory measurements, including exploratory biomarkers. The primary objective is to determine the 24-month difference in stress myocardial blood flow as measured by adenosine CMR imaging in both groups. We will correlate CMR imaging with CCTA to provide complementary detail of coronary plaque changes. The study will also assess the relevance of pre-existing risk factors on study outcomes, including an emphasis on racial disparities, and dynamic change in modifiable and treatment related risk factors. We plan to enroll 90 women, 67 in the NCED group and 23 in the HR-group, allowing for a 10% drop out rate. There are two primary types of statistical analyses. The first includes testing hypotheses between group (NCED vs HR-) and within group (longitudinal changes within the NCED group). The second analyses, involve developing predictive equations utilizing a stepwise linear regression approach to determine if patient demographics, clinical parameters and serum biomarkers are associated with cardiovascular changes over time. Present accrual is 4. Clinical trial information: NCT05309655. Research Sponsor: U.S. National Institutes of Health; Williams Family Chair in Breast Oncology.

A randomized phase III clinical trial of acupuncture for chemotherapy-induced peripheral neuropathy in survivors of cancer. *First Author: Ivana Lopez-Nieves, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common and debilitating side effect in cancer survivors that can last long after completion of neurotoxic chemotherapy. Patients with CIPN often experience neuropathy symptoms such as pain, tingling, numbness, paresthesia, and dysesthesia, which can lead to significant functional decline and diminished quality of life. This outcome highlights the importance of developing effective CIPN treatments to improve quality of life for this population. Identifying nonpharmacological approaches to reduce CIPN symptoms and improve cancer survivors' outcomes is urgently needed. Acupuncture is a widely used, minimally invasive Traditional Chinese Medicine technique that has shown promising evidence as an effective and safe treatment for CIPN. We hypothesize that acupuncture may reduce CIPN pain and improve overall CIPN symptoms in cancer survivors. **Methods:** We are conducting a two-arm, parallel randomized clinical trial comparing electro-acupuncture (EA) versus sham acupuncture (SA) in cancer survivors. The EA arm includes ten sessions of EA over eight weeks using a standardized, semi-fixed protocol developed by our group. The SA arm includes a sham technique that uses a combination of non-acupuncture points and a non-insertion procedure in ten sessions over eight weeks. The primary outcome of this study is the Brief Pain Inventory-Short Form average pain item. The secondary outcomes are quantitative sensory testing measures and patient-reported outcomes that include the Neuropathic Pain Scale, Functional Assessment of Cancer Therapy/Gynecologic Oncology Group-Neurotoxicity, CIPN-20, PROMIS Global Health Scale, and Patients' Global Impression of Change. The primary end point is week 12 and the secondary end point is week 24; treatment effects are assessed at baseline and at weeks 4, 8, 12, 18, and 24. The eligibility criteria includes: 1) Patients must be have no evidence of disease or have stable disease; 2) CIPN diagnosis with moderate-to-severe CIPN pain, defined by a score of 4 or greater on a scale 0-10 numerical scale rating; 3) completed neurotoxic chemotherapy at least three months prior; and 4) no changes in anti-neuropathy medications within three months of enrollment. As of February 2023, we have accrued 89 participants, with a total accrual target of 250 participants. Accrual completion is anticipated by December 2024. The demographic breakdown of our participants is as following: 71% white, 15% black or African American, 10% Asian, 3% more than one race, and 1% Native Hawaiian or Pacific Islander. 89% of the participants are non-Hispanic or Latino, 10% are Hispanic or Latino, and 1% are unknown. 71% of the participants are female and 29% are male. Clinical trial information: NCT04917796. Research Sponsor: U.S. National Institutes of Health.

Poster Session

A randomized phase III clinical trial of yoga for chemotherapy-induced peripheral neuropathy treatment. *First Author: Kirin Saint, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common, painful, and debilitating side effect of many standard chemotherapy regimens. CIPN symptoms include pain, paresthesia, and muscle weakness, and patients may exhibit functional decline and lower quality of life. Our prior study showed more than half of breast cancer survivors experience persistent CIPN up to a mean duration of 5.6 years, which is associated with a doubled fall risk. Identifying non-pharmacological approaches to reduce CIPN symptoms and improve cancer survivors' outcomes is urgently needed. Yoga is a meditative movement therapy that includes stretching, and flexibility and balance training. Our pilot study (NCT03292328) demonstrated that yoga reduced CIPN-related symptoms, and improved quality of life and functional reach scores compared to waitlist control. We hypothesize that yoga can reduce CIPN symptoms, improve function, and reduce the risk of falls. **Methods:** We are conducting a three-arm randomized education and usual care-controlled trial in cancer survivors with chronic CIPN pain at Memorial Sloan Kettering Cancer Center (MSK), New York, NY. Participants in the intervention arm will receive twice-weekly one-hour Hatha yoga classes taught virtually by MSK instructors and practice yoga at home daily for eight weeks. Participants in the education control arm will receive one-hour virtual education classes twice per week taught by an MSK instructor for eight weeks. Participants in the usual care arm will continue their usual care for CIPN for eight weeks. The primary endpoint is the Brief Pain Inventory-Short Form average pain item at weeks 8 and 24. Secondary outcomes include the Neuropathic Pain Scale, Functional Assessment of Cancer Therapy/Gynecologic Oncology Group-Neurotoxicity, Patient-Reported Outcomes Measurement Information System Global Health, Brief Fatigue Inventory, Insomnia Severity Index, Hospital Anxiety and Depression Scale, Quality of Life Questionnaire of CIPN twenty-item scale, functional assessments, and quantitative sensory testing at weeks 0, 4, 8, 12, 18, and 24. Eligibility criteria include: 1) Moderate-to-severe CIPN pain, defined by a score of 4 or greater on a 0-10 numerical rating scale; 2) completion of neurotoxic chemotherapy at least three months prior; 3) no changes in anti-neuropathy medications within three months of enrollment; and 4) changes in balance and functionality. As of February 2023, we have accrued 64 of our total target of 268 participants. We anticipate completing accrual in March 2025. We have 35 participants in the yoga intervention, 15 participants in education control, and 14 participants in usual care control. The majority (89%) of participants are female and 11% are male. 78% of our participants are white, 16% are black or African American, 1% are Asian, and 5% identify as more than one race. Clinical trial information: NCT05121558. Research Sponsor: U.S. National Institutes of Health.

Objective assessment of fatigue, sleep and insomnia in breast cancer survivors on estrogen deprivation therapy. *First Author: Lauren A. Fowler, University of South Carolina School of Medicine, Greenville, Greenville, SC*

Background: Fatigue, insomnia and sleep problems are common among breast cancer survivors (BCS). These symptoms remain underassessed, underreported and undertreated. Validated and objective measures of sleep metrics have yet to be widely incorporated into BCS studies to help examine the role that these play on patient patient reported fatigue and insomnia. While more than 50% of BCS experience fatigue and insomnia, most research on BCS fatigue is limited to short-term, self-report data that does not objectively assess sleep metrics. Estrogen Deprivation Therapy (EDT) has been shown to exacerbate sleep problems and contribute to perceptions of fatigue and insomnia, yet there is a paucity of research examining the specific effects of EDT on sleep metrics over time, especially objective measures. Wrist actigraphy is a non-invasive, objective measure of rest/activity cycles and sleep via a wrist-worn device. This study utilizes a novel instrument, called Readwatch (Fatigue Sciences). It is widely validated in the military and in industry but has not been used in patient studies. The Readwatch assesses fatigue and estimates cognitive performance, based on the Sleep Activity and Task Effectiveness (SAFTE) model developed in conjunction with the Department of Defense in 2004. The Readwatch syncs with the Fatigue Avoidance Scheduling Tool (FAST) app on the participant's smartphone to provide a score, called Readscore, based on previous sleep and activity. It has been shown to have greater than 92% accuracy with lab polysomnography results. The Readscore also serves as a "cognition" measure that represents the person's cognitive capacity based on sleep metrics. This novel, objective feedback to the BCS could be very accessible and useful in community medical practice. **Methods:** This single-center, pilot study of BCS, receiving endocrine therapy, possessing a smartphone and Scoring >8 on the Insomnia Severity Index (ISI), has enrolled 25 of 50 planned participants. Participants wear the Readwatch for two months to objectively assess their sleep metrics. Patient reported levels of fatigue and insomnia will be assessed prior to, midway, and following the two-month period. Participants document their self-reported experiences through surveys and track their own sleep and fatigue metrics using their smartphone app. At the conclusion of the study participants are provided with personalized feedback about their sleep metrics, along with detailed information related to sleep hygiene. Data analysis will model the effect of actigraphy fatigue measures on reported pain, anxiety, depression, and cognitive impairment and will also examine sleep metrics, perceptions of fatigue and insomnia scores in relation to type of EDT the patient is currently undergoing to determine if there are specific types of adjuvant therapy that are associated with fewer fatigue and insomnia problems. Research Sponsor: University of South Carolina School of Medicine Greenville seed grant.

Phase III, international, multicentre, double-blind, dose increment, parallel-arm, randomised controlled trial of duloxetine versus pregabalin for opioid-unresponsive neuropathic cancer pain. *First Author: Hiromichi Matsuoka, National Cancer Center Japan, Tokyo, Japan*

Background: Management of neuropathic cancer pain (NCP) refractory to regular opioids remains an important challenge. The efficacy of pregabalin for NCP except chemotherapy-induced peripheral neuropathy has already been confirmed in two randomised controlled trials (RCTs) compared with placebo. Duloxetine offers the potential of analgesia in opioid refractory NCP. However, there are no RCT of duloxetine for the management of opioid-refractory NCP as a first line treatment. Both classes of drugs have the potential to reduce NCP, but there has been no head-to-head comparison for the efficacy and safety, especially given differing side effect profiles.

Methods: An international, multicentre, double-blind, dose increment, parallel-arm, RCT. Eligibility criteria include: adult cancer patients experiencing NCP refractory to opioids; Brief Pain Inventory (BPI)-item 3 (worst pain) ≥ 4 ; Neuropathic Pain on the Leeds Assessment of Neuropathic Symptoms and Signs Pain Scale ≥ 12 despite of an adequate trial of regular opioid medication (≥ 60 mg/day oral morphine equivalent dose). The study will recruit inpatients and outpatients in Japan and Australia. Participants will be randomised (1:1 allocation ratio) to duloxetine or pregabalin. Dose escalation is to day 14 and from day 14 to 21 is a dose de-escalation period to avoid withdrawal effects. Dose escalation schedule in each-arm is shown in Table 1. The primary endpoint is the mean difference in BPI item 3 over the previous 24 hours on day 14 between groups. Null hypothesis is there is no difference in BPI item 3 in the previous 24 hours on day 14 between both groups for patients with opioid refractory NCP. Comparison of the BPI item 3 on day 14 between duloxetine groups and pregabalin groups will be conducted using a two-sided Student's t-test at a significance level of 5% according to the intention-to-treat principle. Point estimates and 95% CIs for the difference between two groups will be calculated. A sample size of 160 participants is required with 67 subjects enrolled to date. The DSMC last reviewed the trial in December 2022 and case accumulation expected to be completed by the end of 2024. Table 1 : Dose escalation schedule in each-arm. Duloxetine Arm Stage 1 (Day 1-3): Duloxetine (30 mg) 1 capsule (morning) and Placebo 1 capsule (bedtime) Stage 2 (Day 4-7): Same as Stage 1 Stage 3 (Day 8-14): Duloxetine (30 mg) 1 capsule twice a day (morning and bedtime). Pregabalin Arm Stage 1 (Day 1-3): Pregabalin (25 mg) 1 capsule twice a day (morning and bedtime). Stage 2 (Day 4-7): Pregabalin (75 mg) 1 capsule twice a day (morning and bedtime). Stage 3 (Day 8-14): Pregabalin (75 mg) 2 capsules (150 mg) twice a day (morning and bedtime). Clinical trial information: ACTRN12620000656932, jRCTs051190087. Research Sponsor: The Australian Government National Health and Medical Research Council; Japan Agency for Medical Research and Development (AMED), Grant-in-Aid for Scientific Research.

Prospective observational study to evaluate lemborexant utility in insomnia among women with breast cancer (WJOG14921B, LUNAR study). *First Author: Yukinori Ozaki, Breast Medical Oncology Department, The Cancer Institute Hospital of JFCR, Tokyo, Japan*

Background: Insomnia occurs in approximately 60% of cancer patients. The importance of early intervention to treat insomnia has been advocated because insomnia may be associated with poor prognosis, early discontinuation of treatment and decreased quality of life. It has been reported that breast cancer patients receiving endocrine therapy have the highest rate of insomnia among all cancer patients due to vasomotor symptoms (ie, hot flashes) and comorbid symptoms associated with fatigue and depression. Insomnia has also been found to occur in patients with metastatic/recurrent breast cancer. Lemborexant (LEM) is a dual orexin receptor antagonist, which has been shown to be effective for insomnia patients without malignancies. In clinical practice, while LEM has been administered to cancer patients with insomnia, there are no prospective data. The aim of this study is to evaluate prospectively whether LEM improves insomnia in patients with breast cancer receiving endocrine therapy.

Methods: This is an open-label, prospective, multicenter, observational study to evaluate efficacy and safety of LEM to treat insomnia in patients with breast cancer receiving endocrine therapy [UMIN000047718]. The primary endpoint is change from baseline of total Insomnia Severity Index (ISI) score at 1 month. Secondary endpoints include change from baseline of cancer fatigue scale scores, EORTC QLQ C-30 and BR23 score, and Patient Health Questionnaire-9 score after 1 month and 3 months, change from baseline in total sleep time and sleep efficiency using an electronic sleep diary after 2 weeks, 1 month and 3 months, and safety profile. Exploratory endpoints include biomarker analysis including evaluation of cytokines and orexin A levels, and evaluation of sleep parameters using Oura ring, which is a ring-type wearable device. The primary endpoint will be assessed by the Wilcoxon signed-rank test. Total sample size will be 70 patients (adjuvant cohort: 50 patients, recurrent and/or metastatic cohort: 20 patients). Patients ≥ 20 , meeting Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition for Insomnia Disorder and ISI score ≥ 10 will be eligible. LEM 5mg will be administered orally every night. Dosage of LEM will follow clinical practice and the Japanese LEM label. Enrollment began in September 2022; 14 patients have been recruited in adjuvant cohort as of January 2023. Clinical trial information: UMIN000047718. Research Sponsor: Eisai.

Phase 2 study to assess the efficacy, safety, and tolerability of the GDF-15 inhibitor ponesegromab in patients with cancer cachexia. *First Author: Jeffrey Crawford, Duke Cancer Institute, Durham, NC*

Background: Cancer cachexia is a multifactorial metabolic syndrome of wasting characterized by anorexia, unintended weight loss, and decreased skeletal muscle mass, leading to progressive functional impairment, fatigue, diminished quality of life, poor response to anticancer therapy, and reduced survival. One of the biomarkers associated with cancer cachexia is cytokine growth differentiation factor 15 (GDF-15), which is secreted by tumor cells. Preliminary phase 1 data suggest that suppression of GDF-15 may lead to improvement in cachexia-related symptom burden. Ponesegromab is a potent and selective humanized monoclonal antibody that inhibits GDF-15-mediated signaling. The primary objective of this study (NCT05546476) is to assess the effect of ponesegromab on body weight in patients with cancer, cachexia, and elevated circulating GDF-15 concentrations. Secondary objectives include assessing physical activity, gait, anorexia/appetite, nausea and vomiting, fatigue, and safety. Exploratory objectives include evaluating pharmacokinetics, pharmacodynamics, and immunogenicity. **Methods:** This phase 2 study will enroll approximately 168 adults with non-small cell lung, pancreatic, or colorectal cancers who have cachexia and elevated GDF-15 concentrations. The study will be conducted in 2 parts. The initial 12-week treatment period will be a randomized, double-blind, placebo-controlled study wherein participants who meet eligibility criteria will be randomized 1:1:1 to one of 3 dose groups of ponesegromab (administered subcutaneously [SC] every 4 weeks [Q4W]) or placebo. The double-blind period will be followed by optional open-label treatment (OLT) with ponesegromab Q4W SC for up to 1 year. Upon completion of the optional OLT period, there will be a follow-up visit at Week 72. Participants who do not proceed with the optional OLT period will complete the Week 12 visit and a follow-up visit at Week 16. The primary endpoint is the mean change from baseline in body weight at Week 12. A mixed model for repeated measures followed by a Bayesian E_{max} model will be used for the primary analysis. Secondary endpoints include physical activity and gait measured by remote digital sensors; patient-reported appetite-related symptoms assessed by Functional Assessment of Anorexia-Cachexia Therapy scores; anorexia/appetite, nausea, vomiting, and fatigue evaluated according to questions from the Cancer-related Cachexia Symptom Diary; and incidence of adverse events, safety laboratory tests, vital signs, and electrocardiogram abnormalities. © 2023 American Association for Cancer Research®. Study for the prevention of oral mucositis. *First Author: Artem Oganessian, Hematology Center after R. Yeolyan, Yerevan, Armenia*

Background: Oral mucositis (OM) is a serious complication of cancer treatments characterized by erythema and ulcerations of the mouth. Consequences of OM include pain, diminished functionality, and infections leading to decreased quality of life and discontinuity in therapy. About 20-40% of patients receiving chemotherapy develop OM within 7 days of treatment initiation. Current clinical guidelines recommend prophylactic oral care, cryotherapy, KGF-1, palifermin, and photobiomodulation to prevent OM in specific patient groups. Benzydamine is approved for the prevention of OM in head and neck cancer patients receiving radiotherapy or radio-chemotherapy but has not been well studied for chemotherapy alone. The effectiveness of oral topical treatments is limited by dilution in the saliva and swallowing shortening the duration of their action. Bocaliner is a novel medical device that is hypothesized to enhance the effects of treatments by prolonging the oral retention of topical therapies within the oral cavity.

Methods: The Study for the Prevention of Oral Mucositis (SPOM) is a randomized controlled Phase I/II trial that aims to evaluate the efficacy of two different tools (benzydamine mouthwash and Bocaliner) in reducing the incidence and severity of OM in patients undergoing systemic chemotherapy (NCT05338398). A total of 100 adult patients with hematologic malignancies undergoing chemotherapy in a centralized hematology center in Armenia will be randomized into two different treatment groups: saline mouthwash and benzydamine mouthwash (0.15%, 120mL) 3-5 times a day for a total of two weeks. Half of the patients within each group will also randomly receive Bocaliner, which will be placed inside of their mouth immediately after the application of the mouthwash for 20 minutes. Block randomization will be applied with 4 patients per block with 1:1 randomization based on gender, Bocaliner use, and mouthwash type. The primary endpoint is the difference in OM incidence measured by the WHO Oral Toxicity Scale. The secondary endpoints are differences in OM symptoms evaluated using a modified version of the PROMS questionnaire. Safety and tolerability of the medical device will be determined for the Phase I component of the study based on responses to standardized tryout (Day 0) and follow-up questionnaires (Day 14). Other outcomes include the duration and severity of OM. Statistical analysis will explore further clinically meaningful associations between patient data, received therapies, and outcomes. Forty-two patients have already completed the study, while the enrollment of other participants continues and is planned to be completed by the end of 2023. Clinical trial information: NCT05338398. Research Sponsor: E2Bio Life Sciences.

Effects of virtual reality on pain and anxiety in patients with cancer undergoing bone marrow biopsy. *First Author: Jacek K. Pinski, USC/Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Patients with cancer endure numerous procedures over their diagnosis and treatment course, many of which are invasive, causing significant distress beyond the emotional hardship of living with cancer. The utility of virtual reality (VR) as a companion to bone marrow biopsy will be evaluated in terms of its psychological and biological impacts, through patient reported pain scores, anxiety surveys and through assessment of serum biomarkers correlated with pain and anxiety. VR is the immersive simulation of a realistic, three-dimensional environment, generated via interactive software and hardware. The objectives of this study are to determine the feasibility of VR in patients undergoing a bone marrow biopsy and to estimate differences between the two arms in terms of pain and anxiety. In addition, we plan to explore the use of biomarkers associated with stress as a tool to reflect the impact of this intervention. We hypothesize a decrease in pain, anxiety and stress levels peri- and post-procedure in the VR arm compared to the non-VR arm (standard of care).

Methods: Patients with hematologic malignancies at USC/Norris Cancer Hospital or Keck Medical Center of USC are being randomized 1:1 to either arm 1 (experimental: VR) or arm 2 (control: no VR). Eight out of 30 planned patients have been enrolled. The VR content is standardized for every subject. It consists of relaxing techniques through visual and auditory input which can last up to one hour. We are using visual analogue scale for both pain (VAS-P) and anxiety (VAS-A) that utilizes numbers and graphic representations between 0 and 10, 0 representing no pain/anxiety at all, to 10 being the worst possible pain/anxiety. Both scales are being measured at 3 defined time points before, during and after the procedure. Usage of pain medications and anesthetics are being recorded for both arms. In addition, we are obtaining baseline levels of the following biomarkers: serum cortisol, highly sensitive C-reactive protein, and fibrinogen. Repeat levels are being collected at specified time intervals to determine if there is a correlation between biomarker levels and perceived pain or anxiety using patient assessed scales. This is a descriptive, feasibility trial that will determine the impact of VR on pain, anxiety, and stress biomarkers during a bone marrow biopsy. Feasibility (i.e. proportion of patients with a successful procedure) will be estimated for each arm separately. The standard error associated difference in success proportions will have a standard error that is less than 0.18. With 30 patients (15 assigned to VR and 15 to standard of care), we will be able to estimate the mean levels of pain and anxiety and biomarkers, as well as changes and differences between the arms with reasonable precision. The implementation of VR in the healthcare setting may serve as a cost-effective, non-pharmacological agent to alleviate pain, anxiety, and stress. Clinical trial information: NCT03568292. Research Sponsor: Tower Foundation.

Exploratory study investigating the efficacy and safety of olanzapine prophylaxis for opioid-induced nausea and vomiting (JORTC-PAL20). *First Author: Eriko Satomi, Department of Palliative medicine, National Cancer Center Hospital/Department of Palliative medicine, Juntendo University Graduate school of Medicine, Tokyo, Japan*

Background: In opioid therapy for cancer pain, it is essential to manage opioid-related adverse effects. Opioid-induced nausea and vomiting (OINV) is common, occurring in 20–40% of patients during initial opioid treatment or after opioid doses are increased. Tolerance to OINV develops within a few days to a week. In patients with cancer, OINV results in decreased quality of life as well as failure to relieve pain due to poor opioid adherence, thus increasing the psychological barriers to opioid use. Therefore, antiemetics are used for OINV prophylaxis, but their efficacy and safety in this context have not yet been fully elucidated. Olanzapine is a promising antiemetic for prophylaxis against nausea and vomiting induced by highly emetogenic chemotherapy, and it is less likely to cause extrapyramidal symptoms than haloperidol and prochlorperazine. We are conducting this exploratory study to evaluate the efficacy and safety of olanzapine prophylaxis against OINV. **Methods:** This single-arm, single-center exploratory study will evaluate the prophylactic antiemetic efficacy and safety of olanzapine (5 mg PO once a day for 5 days) in patients with cancer pain reserving initial regular opioid therapy. Thirty-five patients will be enrolled. This study was designed to provide preliminary efficacy data, with a primary objective of assessing the proportion of patients who achieved complete control (CC) of OINV during 120 hours of opioid treatment. CC was defined as the absence of emetic episodes, the lack of a need for rescue medication to treat nausea, and minimal or no nausea (3 or less on an 11-point categorical scale). Secondary endpoints include the following: the complete response (CR) rate, defined as the percentage of patients with no emetic episodes and no rescue medication use; the total control (TC) rate, defined as the percentage of patients with no emetic episodes, no rescue medication use, and no nausea during the 120 hours of opioid treatment; the time from opioid initiation to the first emetic episode; the time from opioid initiation to the first administration of a rescue antiemetic; the time to treatment failure, defined as the time from opioid initiation to the first emetic episode or to the administration of a rescue antiemetic; the number of emetic episodes; the levels of nausea, anorexia, sleepiness, pain, and fatigue, all determined using a numerical rating scale (0–10); the impact of antiemetic therapy on daily life severity and patient satisfaction, determined using a 7-grade categorical scale; and adverse events graded by PRO-CTCAE ver.1.0 and CTCAE ver. 5.0. The study is currently open, and 25 patients have been enrolled at time of abstract submission. Clinical trial information: jRCTs031220008. Research Sponsor: Japanese Society of Palliative Medicine.

Empathic communication skills training: Randomized controlled trial to reduce lung cancer stigma in lung cancer care. *First Author: Jamie S. Ostroff, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Stigma is commonly experienced by people diagnosed with lung cancer and is often triggered during clinical encounters with their oncology care provider (OCP), particularly associated with routine assessment of smoking history. Lung cancer stigma is associated with gaps in quality of care as well as poorer psychological and physical health-related outcomes for patients. The overall objective of this multi-site national clinical trial is to test whether an OCP-facing training intervention in empathic communication skills (ECS) reduces stigma and distress and promotes patient engagement. Our prior pilot work has demonstrated that the ECS intervention is both feasible and efficacious to reduce stigma during clinical encounters. **Methods:** This NCI-funded multi-site national trial employs a cluster randomized design comparing usual care (waitlist control) with ECS training (intervention). With outreach and site recruitment support provided by G02 for Lung Cancer and the American Cancer Society, community oncology sites (n = 16) nationwide will be randomized 1:1 to each arm. 9-11 OCPs will be recruited per site with 6 unique patients per OCP enrolled (total 54-66 patients/site). Statistical analysis will evaluate the effect of ECS training on primary OCP outcomes (e.g., empathic skill uptake) and secondary patient-reported outcomes (e.g., psychological distress). The 2.5 hour ECS training is delivered live using a videoconference platform. The didactic content covers knowledge and consequences of stigma on patients with lung cancer and in-depth review of specific ECS strategies. Participants then engage in experiential small-group role-play sessions with trained patient actors, where they are given tailored feedback by trained facilitators and their peers. Eligible sites must have at least 15 OCPs and clinic volume of at least 20 new patients with lung cancer per month. Eligible OCPs (physicians, NPs and PAs) must currently be treating and conducting outpatient clinic consultations with at least 1 patient with lung cancer per week. Eligible patients must be receiving treatment for lung cancer, English and/or Spanish speaking, currently or formerly smoking, and have had no more than 5 prior visits with the participating OCP. Currently, this trial is open to accrual and has 5 sites across the nation completing paperwork for activation. Clinical trial information: NCT05456841. Research Sponsor: U.S. National Institutes of Health.
