Background: Intra-patient inter-metastatic heterogeneity (IIH) has been demonstrated in metastatic castration resistant prostate cancer (mCRPC) patients based on genomic and imaging studies, most often after several lines of therapies. IIH is of utmost importance for PSMA radioligand therapy (RLT) eligibility, biopsy-based precision medicine and/or treatment intensification decision-making. The Triple-Tracer strategy against Metastatic Prostate cancer (3TMPO) study (NCT04000776) is a prospective multicenter PET imaging study that was designed to determine the prevalence of IIH in mCRPC patients and to determine candidacy for RLT. **Methods:** 3TMPO is a PET-imaging trial including mCRPC patients showing at least 3 metastases on conventional imaging with evidence of biochemical or radiographic progression, at least 3 months after initiation of the last systemic therapy. ⁶⁸Ga-PSMA-617 and ¹⁸F-FDG PET/CT scans were performed within 10 days and analyzed quantitatively. A third scan with ⁶⁸Ga-Octreotate was done when a PSMA-/FDG+ lesion was found. For all tracers, positivity of a lesion was defined as its SUV_{peak} being 1.5 times higher than the SUV_{mean} of the liver. Lesions smaller than 1 cc and likely benign foci of uptake were excluded. IIH prevalence was the primary outcome, defined as the percentage of patients having at least two lesions with discordant features on PET imaging. **Results:** We included 98 patients in the final analysis. Patients had a mean age of 69 years and a median PSA of 51.1 ng/mL. Number of metastases were <5 in 46.9% and ≥10 in 33.7% of patients and 10.2, 20.4, 18.4 and 51.0% had received 0, 1, 2 or >2 lines of systemic therapies for mCRPC, respectively. Prevalence of IIH was 83.7% based on pre-specified PET criteria. Overall, seven different combinations of lesion phenotypes were found among patients based on FDG and PSMA PETs, and at least one PSMA-/FDG+ lesion was found in 46 patients (46.9%). Of the 44 patients who underwent Octreotate PET, six (13.6%) had at least one Octreotate-positive lesion. In this FDG/PSMA/Octreotate-imaged subgroup, 11 different combinations of phenotypes were observed between metastases of individual patients. Overall, 52.0% (IC95: 41.7-62.2) of patients were found to be candidate for PSMA RLT, but none for Octreotate RLT. **Conclusions:** The majority of mCRPC patients showed IIH. Based on a multi-tracer approach, up to 11 lesion phenotype combinations were found amongst patients. Correlation of these imaging phenotypes with genomics and treatment response will be highly relevant for optimized precision medicine, especially with respect to PSMA-RLT. Clinical trial information: NCT04000776. Research Sponsor: Fonds de recherche du Québec - Santé, ONCOPOL (co-funding); Merck; Cancer Research Society.

Genetic ancestry associations with somatic mutations in a real-world cohort of over 3,000 patients with prostate cancer. *First Author: Francisco M De La Vega, Tempus Labs, Inc., Chicago, IL*

Background: Disparities in incidence and outcomes of prostate cancer among racial groups have been reported. Black men have a higher incidence of prostate cancer compared to White men and are more likely to be diagnosed at a later stage, resulting in poorer outcomes. These differences are likely due to a combination of genetic, socio-economic, and healthcare access factors. Furthermore, evidence has revealed racial differences in molecular profiles of prostate cancer, such as a higher incidence of *ERF* mutations and increased transcriptional activation of the androgen receptor signaling and inflammatory pathways in tumors derived from Black men compared to White men, suggesting that underlying biology may contribute to these disparities. Here, we aimed to identify differences in the mutational profiles of prostate cancers by race and genetic ancestry in a de-identified real-world cohort of 3,804 patients that underwent the Tempus xT 648-gene NGS tumor profiling test. **Methods:** We used 654 ancestry-informative markers to estimate continental ancestry likelihoods for five regions: Africa (AFR), Americas (AMR), East Asia (EAS), Europe (EUR), and South Asia (SAS). We imputed Asian (ASN, n=122), Hispanic/Latino/Native American (HLN, n=300), Non-Hispanic Black (NHB, n=619) and Non-Hispanic White (NHW, n=2,679) categories using genetic ancestry thresholds based on literature and validated with available metadata. Associations between either race/ethnicity categories or continental ancestry proportions and somatic variants (copy number alterations (CNAs), small nonsynonymous, OncoKB L1/2 & R1, and predicted driver somatic mutations) were assessed for 109 prostate cancer-related genes using logistic regression models. Likelihood ratio tests were used to compare models with and without race/ethnicity or ancestry terms, and the Benjamini-Hochberg method was used to adjust p-values and control the FDR at 5%. **Results:** NHB and ASN men had lower odds of having a *PTEN* CNA compared to NHW men (OR=0.58 and 0.40, p=0.0001 and 0.009, respectively). Confirming this finding was a positive association between EUR ancestry and *PTEN* CNAs (OR=1.07 per doubling of EUR ancestry proportion, p=0.0007). NHB men were also less likely to have actionable OncoKB somatic mutations in the *PIK3CA* gene when compared to NHW men (OR=0.48, p=0.03). Increased AFR ancestry was associated with the presence of nonsynonymous predicted driver mutations in *SPOP* (OR=1.04, p=0.04), while both EAS and SAS ancestries were associated with fewer such mutations in *TP53* (OR=0.95 in both cases, p=0.02 and 0.003). **Conclusions:** Analysis of a large real-world cohort leveraging genetic ancestry inferred from NGS data confirms previously known associations between the presence of somatic alterations in prostate cancer genes and race/ethnicity, and identifies novel associations of potential precision therapeutic relevance. HERCULES: A prostate cancer (PC) sequencing panel for parallel analysis of circulating tumor DNA (ctDNA) and circulating tumor cells (CTCs). *First Author: Daniel Bsteh, Division of Medical Oncology, Department of Medicine, Keck School of Medicine and Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA*

Background: In metastatic PC, tracking genomic alterations over time and with treatment can predict disease outcomes, guide treatment, and identify novel therapeutic targets. Analysis of peripheral blood ctDNA offers a non-invasive liquid biopsy for genomic profiling, but ctDNA often comprises a small portion of total cell-free DNA (cfDNA) in the blood, requiring high depth of sequencing which may still miss PC-relevant variants. We and others have shown that single CTCs captured from the same blood sample yield additional PC-relevant genomic data when combined with ctDNA profiling, but currently there is no assay that can be applied uniformly to both analytes. Here, we present a new amplicon-based sequencing panel capable of detecting PC-relevant variants in both cfDNA and single CTCs. **Methods:** PC-relevant genes were curated by overlapping reviews of cBioPortal for cancer genomics, the catalogue of somatic mutations in cancer (COSMIC), and PC-relevant genomic literature. HERCULES targets 36 genes with 258 amplicons covering PC-associated mutations and copy number variations. AmpliSeq HD targeted sequencing technology was applied for analysis of both cfDNA and CTCs. Analytical validation was performed sequentially, first using AcroMatrix and Seracare DNA control samples, then single and pooled LNCap and PC3 PC cells and cfDNA, then 8 patient peripheral blood samples of matched plasma cfDNA and single CTCs captured using the RareCyt platform from participants in SWOG S1802, an ongoing CTEP/CIRB-approved phase 3 trial for men with metastatic PC. **Results:** In DNA control samples with allele frequencies of 1%, 0.25%, and 0.1%, HERCULES displayed sensitivity of 100%, 75%, and 50%, respectively. In matched single cells and cfDNA from cell lines, HERCULES detected 100% of database-annotated somatic variants in cfDNA and in pools of 2 or more cells, and it identified >90% of variants in single cells. In 16 matched patient samples of cfDNA and single CTCs, with read coverage depths of >50,000x for 20ng cfDNA and >1,500x for single CTCs, HERCULES detected shared variants (mean N per sample = 6.1) as well as unique somatic variants (mean of 1.1 CTC variants not called in the cfDNA, and 4.1 cfDNA variants not called in the CTCs). **Conclusions:** HERCULES is, to our knowledge, the first PC-specific targeted sequencing panel capable of parallel genomic profiling of both ctDNA and CTCs. In our preliminary analytical validation, it detected somatic variants with high sensitivity in matched cfDNA and CTC samples. With additional validation, HERCULES has the potential to augment conventional ctDNA profiling by illuminating both cell-free and cellular genomic evolution during PC treatment and progression. Digital histopathology-based multimodal artificial intelligence scores predict risk of progression in a randomized phase III trial in patients with nonmetastatic castration-resistant prostate cancer. *First Author: Felix Y Feng, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: The addition of apalutamide (APA) to androgen deprivation therapy (ADT) improved metastasis-free survival (MFS) and second progression-free survival (PFS2) among patients (pts) with nonmetastatic castration-resistant prostate cancer (nmCRPC) [1]. We applied a previously-reported digital histopathology-based multimodal AI (MMAI) algorithm developed based on 5 phase III randomized trials, validated, and accepted to NCCN guidelines for localized prostate cancer, to evaluate whether MMAI could define risk of progression among nmCRPC pts treated with APA or placebo in the SPARTAN trial. **Methods:** Pts enrolled in the SPARTAN trial with available H&E-stained biopsy slides from their primary diagnosis were included. H&E slides were digitized. Baseline clinical parameters to generate MMAI scores were Gleason score, age, T stage, and PSA. MMAI scores for distant metastasis (DM) were generated, ranging from 0 to 1. Pts were further categorized into MMAI non-high-risk and high-risk groups using a previously established score cutoff. Kaplan Meier estimates were calculated for PFS2 and MFS; comparisons were performed using log-rank test and Cox proportional-hazards regression for treatment arms and MMAI risk groups. Two-way ANOVA was used to evaluate the interaction between treatment arms and risk groups. **Results:** The study included 471 pts with 1051 biopsy pathology slides: 311 pts treated with APA, and 156 with placebo. 55 pts were excluded due to missing treatment (n=4) or clinical data (n=49) and inadequate H&E images (n=2), resulting in 273 evaluable APA-treated and 147 placebo-treated pts. 63% of pts were MMAI high risk and 37% MMAI non-high risk. MMAI high risk pts demonstrated significant improvement in MFS with APA (HR 0.19 (95% CI: 0.12-0.29, p<0.005)), but not in PFS2 (HR 0.76 (95% CI: 0.45-1.28, p=0.30)). There was a significant interaction between MMAI risk group and treatment for MFS (p=0.02). Among the placebo-treated cohort, MMAI high risk status was associated with shorter MFS (HR 2.98 (95% CI: 1.72-5.18, p<0.005)) and PFS2 (HR 1.83 (95% CI: 1.09-3.09, p=0.02)). For APA-treated pts, MMAI risk group was not associated with MFS and PFS2. **Conclusions:** These findings suggest that MMAI may provide prognostic risk stratification for nmCRPC pts and that MMAI high-risk pts may benefit most from treatment with APA. The current results represent the first evaluation of this MMAI classifier in the nmCRPC setting. Prospective validation is warranted. Association of plant-based diet index with quality of life in patients with prostate cancer. *First Author: Stacy Loeb, New York University and Manhattan Veterans Affairs, New York, NY*

Background: Plant-based diets have many health benefits including a lower risk of fatal prostate cancer. Less is known about the relationship between diet and functional outcomes among prostate cancer survivors. We hypothesized that greater consumption of plant-based food after prostate cancer diagnosis is associated with improved quality of life (QOL). **Methods:** This prospective cohort study included 3,505 participants in the Health Professionals Follow-up Study with non-metastatic prostate cancer (1986-2016). Overall and healthful Plant-based Diet Indices were calculated from food frequency questionnaires with cumulative updating. QOL scores were calculated using the Expanded Prostate Cancer Index Composite. Generalized estimating equations were used to examine associations between Plant-based Diet Indices and 5 QOL domains, adjusted for clinical and demographic factors. **Results:** Higher Plant-Based Diet Index was associated with improved scores for sexual function, urinary irritation/obstruction, and urinary incontinence among men with prostate cancer. Consuming more healthful plant-based foods was also associated with better scores for bowel function and hormonal/vitality in the age-adjusted models. Results were similar in sensitivity analyses excluding patients with pre-existing erectile dysfunction or lower urinary tract symptoms, and adjusting for use of sexual or urinary medications. A limitation is that no participants followed a strict vegan diet. **Conclusions:** This prospective study suggests that greater consumption of healthful plant-based foods is associated with modest improvements in QOL domains among patients with prostate cancer. Research Sponsor: New York State Department of Health; NYU Perlmutter Cancer Center.

The impact of household income on prostate cancer diagnosis, treatment, and outcomes. *First Author: John Panzone, SUNY Upstate Medical University, Syracuse, NY*

Background: Financial difficulties can lead to cancer patients delaying or deferring necessary care, resulting in later presentation with more advanced disease and worse clinical outcomes. **Methods:** A cross-sectional study was conducted assessing 488,853 prostate cancer patients from the Surveillance, Epidemiology, and End Results (SEER) Program between the years of 2010 and 2018. The association between annual household income (HHI) and diagnosis and outcomes of prostate cancer were examined using ANOVA and Chi-square analyses comparing clinical measures based on categorical HHI groupings. **Results:** Sociodemographic data and univariate analyses are displayed. The average age across all HHI classifications was 66.63 years. ANOVA analysis demonstrated that patients with a lower HHI had higher PSA levels upon diagnosis (12.10 vs. 10.90, 10.61, and 10.37 for $\leq 35k$, 35-55k, 55-75k, and $\geq 75k$, respectively, $p < 0.001$). Patients with lower HHI also demonstrated lower rates of undergoing surgical treatment (31.9%, 36.9%, 37.6%, and 35.1% for $\leq 35k$, 35-55k, 55-75k, and $\geq 75k$, respectively, $p < 0.001$) and the highest rate of disease metastasis to bone upon diagnosis (6.3%, 5.6%, 5.7%, and 5.8% for $\leq 35k$, 35-55k, 55-75k, and $\geq 75k$, respectively, $p < 0.001$). Lastly, patients with lower HHI demonstrated progressively higher rates of cancer-specific mortality (8.4%, 6.8%, 6.5% and 5.1% for $\leq 35k$, 35-55k, 55-75k, and $\geq 75k$, respectively, $p < 0.001$), as well as higher overall mortality (21.2%, 18.0%, 15.0%, and 11.9% for $\leq 35k$, 35-55k, 55-75k, and $\geq 75k$, respectively, $p < 0.001$). **Conclusions:** In conclusion, these data suggest that prostate cancer patients with lower household income are diagnosed with more aggressive disease, tend to undergo surgery at lower rates, develop more advanced disease, and endure worse clinical outcomes than those in higher income brackets. Healthcare providers should be made aware of the clear associations between lower income and more aggressive disease at diagnosis, lower rates of surgical treatment and worse cancer-specific and overall mortality. Research Sponsor: None.

A single-arm, phase II study of durvalumab (D) and tremelimumab (T) for relapsed/refractory germ cell tumors (GCT). *First Author: Samuel A Funt, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients (pts) with GCT and progressive disease (PD) after salvage high-dose chemotherapy (HDCT) have dismal outcomes with median progression free survival (PFS) and overall survival (OS) of 1.0 and 4.7 months (mo), respectively (Feldman et al. Cancer 2012). Immune checkpoint blockade (ICB) has resulted in durable benefit in multiple tumor types. We tested D (anti-PD-L1) + T (anti-CTLA-4) for pts with relapsed/refractory GCTs in a phase II trial (NCT03158064). **Methods:** Eligible pts were ≥ 18 years old with GCT of any primary site who had PD after first-line chemotherapy and HDCT or were not candidates for HDCT or other curative options. Pts received D (1500 mg) and T (75 mg) every 4 weeks (wks) for 4 cycles followed by D (1500 mg) every 4 wks for up to 1 year (schedule 1). The study was later amended to one cycle of D (1500 mg) and T (300 mg) followed by D (1500 mg) every 4 wks for up to 1 year (schedule 2). The primary endpoint was initially overall response rate (ORR) in a Simon's two-stage design with null and alternate rates of 5% and 20%, respectively. The study was then amended to use a primary endpoint of 16-wk PFS in a new Simon's two-stage design with null and alternate rates of 5% and 25%. The regimen would be considered promising if 16-wk PFS was achieved in ≥ 3 of 20 pts. Secondary endpoints included PFS, OS, safety, and association of PD-L1 staining with outcome. **Results:** Between July 2017 and Jan 2022, 29 pts were treated, the last 7 (24%) on schedule 2. Median age was 37 (range, 21-70). Histology was non-seminoma in 25 pts (86%), and primary sites were testis in 20 (69%), mediastinum in 7 (24%), ovary in 1 (3%), and unknown in 1 (3%). Six (21%) pts had late relapse and 21 (72%) received prior HDCT. Median AFP was 310 ng/mL (range, 1-18,087) and HCG 471 mIU/mL (range, 3.3-62,302). Ten pts were treated with the ORR primary endpoint with no responses in stage 1, but 2 pts had tumor reductions of 20% and 22% with PFS of 9.9 and 10.4 mo, respectively, and 1 patient with elevated AFP but no RECIST measurable disease had a PFS of 5.7 mo. Of 19 pts treated with the 16-wk PFS primary endpoint, one had an ongoing partial response (59% tumor reduction) with 33 months follow-up; all others had PD in < 16 wks (17 with PD and 1 with stable disease). Thus, the study did not meet its primary endpoint. Among 29 treated pts, the 16-wk PFS was 13.8% (range, 4.3-28.6), and median PFS and OS were 1.4 (95% CI: 4.1, 7.1) and 7.3 mo (95% CI: 3.2, 10.9), respectively. PD-L1 expression data was available for 20/29 pts - 3/13 (23%) with low/negative and 1/7 (14%) with high expression achieved PFS > 16 wks. Six (21%) pts had grade 3-4 treatment-related adverse events, 3 (10%) of whom required high-dose steroids. **Conclusions:** D+T had limited antitumor activity in pts with relapsed/refractory GCT, failing to meet protocol-defined success. However, some pts did appear to benefit, including one exceptional responder. Additional correlative studies are ongoing. Clinical trial information: NCT03158064. Research Sponsor: AstraZeneca.

^{64}Cu -SAR-bisPSMA (PROPELLER) positron emission tomography (PET) imaging in patients with confirmed prostate cancer. *First Author: Eva Lengyelova, Clarity Pharmaceuticals, Eveleigh, NSW, Australia*

Background: Prostate cancer (PC) is the second most frequent malignancy in men globally. Prostate-specific membrane antigen (PSMA) is a type II transmembrane glycoprotein that is overexpressed in PC. Recently, several new ^{68}Ga - and ^{18}F -based PSMA-targeted PET agents have been approved by the FDA to detect PC, which offer improved sensitivity and specificity compared to traditional imaging. **Methods:** PROPELLER (NCT04839367) investigated ^{64}Cu -SAR-bisPSMA in 30 men with untreated, histopathologically proven, primary PC with intermediate- to high-risk features. At screening, patients completed ^{68}Ga -PSMA-11 PET/CT at 1h post dose. Following enrollment, patients received either 100MBq, 150MBq or 200MBq of ^{64}Cu -SAR-bisPSMA, followed by PET/CT at 2-4h post dose. Safety was evaluated before and after ^{64}Cu -SAR-bisPSMA dosing. The ^{68}Ga -PSMA-11 and ^{64}Cu -SAR-bisPSMA PET/CT scans were evaluated by 2 independent, blinded central readers for image quality, PC detection, and intensity of tracer uptake in lesions (SUVmax and Tumor-to-Background Ratio [TBR]). **Results:** A single, Grade 1 ^{64}Cu -SAR-bisPSMA-related AE was reported in the 200MBq cohort. Both readers scored 200MBq of ^{64}Cu -SAR-bisPSMA as the dose providing the highest image quality. In this cohort, ^{64}Cu -SAR-bisPSMA and ^{68}Ga -PSMA-11 was able to detect primary PC in 100% and 77.8% of patients for Reader 1 and 85.7% and 83.3% of patients for Reader 2, respectively. In the 200MBq cohort, Reader 1 identified 41 lesions with ^{64}Cu -SAR-bisPSMA vs 36 lesions with ^{68}Ga -PSMA-11, while Reader 2 identified 31 lesions with ^{64}Cu -SAR-bisPSMA vs 22 lesions with ^{68}Ga -PSMA-11. In the 200MBq cohort, ^{64}Cu -SAR-bisPSMA consistently showed higher uptake compared to ^{68}Ga -PSMA-11 (SUVmax: Reader 1 median [IQR]: 31.40 [27.45] vs 10.08 [13.92], $p < 0.001$, Reader 2 median [IQR]: 41.00 [46.09] vs 14.58 [14.98], $p < 0.001$); TBR: Reader 1 median [IQR]: 49.07 [67.69] vs 21.91 [35.71], $p = 0.0015$, Reader 2 median [IQR]: 76.34 [66.37] vs 23.90 [33.05], $p < 0.001$). **Conclusions:** ^{64}Cu -SAR-bisPSMA was safe and effective for detecting PSMA-expressing lesions. 200 MBq of ^{64}Cu -SAR-bisPSMA was determined as the optimal dose for future trials. ^{64}Cu -SAR-bisPSMA PET/CT showed a greater number of lesions and lesions exhibited significantly higher uptake when compared to ^{68}Ga -PSMA-11 in men being with intermediate- to high-risk PC. Further studies to evaluate ^{64}Cu -SAR-bisPSMA as an imaging agent in patients with biochemical recurrence of PC are underway. Clinical trial information: NCT04839367. Research Sponsor: Clarity Pharmaceuticals.

Prognostic factors for relapse in patients with clinical stage I testicular seminoma: A nationwide, population-based cohort study. *First Author: Thomas Wagner, Department of Oncology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark*

Background: Approximately 20% of patients with clinical stage I testicular seminoma will relapse after orchiectomy. No robust prognostic factors for relapse exist which challenges risk assessment and counselling for patients. Previous studies have been hampered by selection bias and variable pathology reporting that limit interpretation and generalization of results. We therefore assessed prognostic factors for relapse in a large unselected nationwide population-based setting with centralized pathology review. **Methods:** Patients with clinical stage I seminoma diagnosed in Denmark between 2013 and 2018 were identified in the prospective Danish Testicular Cancer database. By linkage to the Danish National Pathology Registry, microscopic slides from the orchiectomy specimens were retrieved and reviewed blinded to the clinical outcome. Clinical data were obtained from medical records with follow-up until July 2022. The association between prespecified clinical and histopathological prognostic factors and relapse were assessed by use of Cox regression analysis. Potential prognostic factors included age, pre-orchiectomy values of β -human chorionic gonadotropin (β -hCG) and lactate dehydrogenase (LDH), tumor size, tumor multifocality, tumor necrosis, lymphovascular invasion, pagetoid rete involvement, and invasion of rete testis, hilar soft tissue, epididymis, spermatic cord, tunica albuginea, and tunica vaginalis. **Results:** In total, 924 patients were included. During a median follow-up of 6.3 years, 148 (16%) patients relapsed. Invasion of the testicular hilum (rete testis and hilar soft tissue), lymphovascular invasion, and elevated pre-orchiectomy levels of β -hCG and LDH were independent predictors of relapse. The estimated 5-year risk of relapse ranged from 6% in patients with no risk factors, to 64% in patients with all four risk factors with tumor extension into the hilar soft tissue of the testicular hilum. After internal model validation, the model had an overall concordance statistic of 0.70. **Conclusions:** The provided prognostic factors allow a long-awaited opportunity to make more informed treatment decisions about post-orchiectomy management in patients with clinical stage I seminoma. These should replace current risk factors in guidelines and be used in future studies investigating risk-adapted follow-up and treatment strategies. Research Sponsor: The Danish Cancer Society, The Danish Cancer Research Foundation, The Preben and Anna Simonsen's Foundation, and The Valdemar Beck's Foundation.

Hospital Anxiety and Depression Scale (HADS) score trends among testicular cancer survivors: A longitudinal study. *First Author: Khalid Y. Alkhatib, University of Pennsylvania, Philadelphia, PA*

Background: The rarity of testicular germ cell tumors, in conjunction with the young age of its patients, makes it challenging to study its long-term adverse effects. We sought to investigate the changes in Hospital Anxiety and Depression Scale (HADS) scores over time in our institutional cohort of testicular cancer (TC) survivors, hypothesizing that anxiety and depression indices will improve over time, and specifically after treatment completion. **Methods:** A longitudinal analysis of TC survivors at the University of Pennsylvania between 2013 and 2020, quality of life metrics were measured annually during routine clinic visits. A validated HADS score was utilized to calculate indices of anxiety and depression. Multivariable linear mixed-effects regression models adjusted for pathology type, stage, treatment type, age, marital status, education, income, insurance, employment status, living situation, and time from diagnosis to first survey administration were used to calculate the mean predicted HADS, HADS-Anxiety, and HADS-Depression scores. ANOVA was used to test for parallelism and changes between survey scores. Each item is rated on a 4-point scale (ranging from 0 = no not at all, to 3 = yes definitely), for a total score ranging from 0-21 for each sub-scale with a cut-off point of 8/21 for anxiety or depression. **Results:** A total of 353 patients were included in the study. Baseline mean scores were 7.3, 4.9, and 2.4 for HADS overall, HADS-Anxiety, and HADS-Depression, respectively. Mean scores did not change over time, ANOVA testing of $p=0.84$, $p=0.78$, and $p=0.0.65$ for overall HADS, HADS-Anxiety, and HADS-Depression, respectively. Stratification by pathology, stage, or treatment did not show any significant interaction. **Conclusions:** Our data demonstrates that there was no significant change over time in HADS scores, thus considering the risks associated with depression and anxiety, such as suicide, it is essential to consider early referrals to psychiatric services. Our results are from a single institution, limited by a small sample size, and data lacks granularity, including mental health history. Nonetheless, our findings serve as a framework for future prospective studies of TC survivors. Research Sponsor: None.

Penile squamous cell carcinoma (PSCC) with elevated tumor mutational burden (TMB): A genomic landscape study. *First Author: Rebecca A Sager, SUNY Upstate Medical University, Syracuse, NY*

Background: TMB has emerged as a novel biomarker of immune checkpoint inhibitor (ICPI) response in a wide variety of malignancies, but not yet in PSCC. **Methods:** 397 clinically advanced PSCC underwent hybrid capture based comprehensive genomic profiling (CGP) to evaluate all classes of genomic alterations (GA). TMB was determined on up to 1.1 Mb of sequenced DNA and categorized into three groups: <10 mutations/Megabase [mut/Mb] (low), 10-19 muts/Mb (high), and >20 muts/Mb (very high). MSI was determined on 114 loci. Genome-wide loss of heterozygosity (gLOH) was determined using validated pipelines and PD-L1 expression by IHC (TPS and Dako 22C3). Statistical comparisons utilized the Bonferroni correction method. **Results:** There were 339 (85.4%) TMB low, 40 (10.1%) TMB 10-19 and 18 (4.5%) TMB very high PSCC cases. The mean age of PSCC with very high TMB at 70.1 yrs was older than TMB low at 63.4 yrs ($p=.08$). The GA per tumor frequencies ranged from 5.4 to 5.5 in the 3 groups. There were no significant differences in genomic ancestry among the 3 groups. The TMB 10-19 and TMB very high tended to feature an APOBEC genomic mutational signature more than the TMB low PSCC cases (74 and 76% vs 44%). MSI high status was absent in the TMB low PSCC, but was present in 7.5% in the TMB 10-19 and 11.8% in the TMB very high cases. gLOH levels above 16% were similar in all 3 groups and ranged from 6.2 to 9.4%. GA associated with differences in TMB status in the PSCC cases included higher *PIK3CA* GA in TMB 10-19 (40.0%) vs TMB low (18.3%; $p=.035$) and TMB very high (66.7%) vs low ($p=.0002$). *CDKN2A* GA were higher in TMB low (45.7%) than the combined TMB 10-19 + very high (25.9%; $p=.049$). GA in *KMT2D* were higher in the combined TMB 10-19 + very high (29.3%) than TMB low (7.7%; $p=.0002$). *FGFR3* GA were similar in all 3 groups. In total, 6.5% of all GA were predicted to be of germline nature. The highest proportions of germline GA were seen for HRR genes *ATM* and *CHEK2* (both 40%) and *BRCA2* (37.5%) and *PMS2* (40%) linked to Lynch syndrome. PD-L1 expression was not significantly different among the 3 groups with TMB low (78.3%), TMB 10-19 (64.2%) and TMB very high (54.5%). HPV identification was more frequent as TMB increased: 28.3% for TMB low, 50.0% for TMB high and 58.8% for TMB very high groups. **Conclusions:** The evaluation of PSCC by CGP based on TMB levels reveals significant differences in biomarkers for the near 15% of cases that have TMB ≥ 10 muts/Mb. TMB and MSI status can also serve as biomarkers of response to SOC anti-PD1 based on the current FDA indications. These data may be useful to provide rationale for inclusion of PSCC in basket or umbrella trials testing novel monotherapies or combination therapies. Research Sponsor: None.

Phase II study of the efficacy of retifanlimab (Rf) (INCMGA00012) in penile squamous cell carcinoma (PSqCC): ORPHEUS final analysis. *First Author: Xavier Garcia del Muro, Medical Oncology. Institut Català d'Oncologia (ICO) L'Hospitalet del Llobregat, Barcelona, Spain*

Background: PSqCC is a rare tumor with poor prognosis. The standard of care for advanced disease (AD) has been palliative platinum-based chemotherapy (CT). Most PSqCC patients (pts) have high levels of programmed death-ligand 1 (PD-L1). ORPHEUS has evaluated the efficacy and safety of Rf—a PD-1 antagonist—in pts with unresectable locally advanced or metastatic PSqCC. **Methods:** ORPHEUS (NCT04231981) is an international, multicenter, open-label, single-arm phase II trial. The study enrolled pts aged ≥ 18 years with locally advanced or metastatic PSqCC who had not received any previous treatment with PD-1 or PD-L1/2 agents. Pts received Rf 500 mg intravenously on day 1 of each 28-day cycle until progressive disease, unacceptable toxicity, discontinuation or death. The primary endpoint was investigator-assessed objective response rate (ORR) as per RECIST v.1.1. Secondary endpoints included clinical benefit rate, progression-free survival (PFS), duration of response (DoR), time to response (TTR), disease control rate (DCR), overall survival (OS) and safety evaluated as per NCI-CTCAE 5.0. The design was planned to attain an 80% power at 5% one-sided α level (H0: ORR $\leq 5\%$; H1: ORR $\geq 25\%$). **Results:** Between Jul 7, 2020, and Aug 26, 2021, 18 men were enrolled at 8 sites from Italy and Spain. Median age was 64.2 years (range 42-81), 13 (72.2%) pts had an AD at first diagnosis, 15 (83.3%) had a previous surgical procedure for penile cancer (lymphadenectomy in 7 pts), 10 (55.6%) had previously received platinum-based CT (TPF/TIP in 8 pts) and 7 (38.9%) were naïve to AD treatment. At data cutoff (Aug 26, 2022), with a median follow-up of 7.2 months, no pts remained on therapy. ORR (3 partial responses) was 16.7% (95% CI 5.8%-39.2%) with a median DoR and TTR of 3.3 (range 1.8-8.5) and 1.9 (range 1.7-2.4) months, respectively. DCR was (33.3%) (1 stable disease ≥ 6 months). Median PFS was 2.0 months (95% CI 1.6-3.3) and median OS with 17 events was 7.2 months (95% CI 3.0-9.8). Most common non-hematological treatment emergent adverse events (TEAEs) of any grade (G) were fatigue (27.8%; 5.6% G ≥ 3), cellulitis, groin infection and Pseudomonas infection (11.1%; 5.6% G ≥ 3), respectively. Treatment related (TR) TEAEs were fatigue (22.2%; 5.6% G ≥ 3), rash (5.6%; 0% G ≥ 3) and decreased appetite (5.6% G ≥ 3). Anemia (11.1%; 0% G ≥ 3) was the most frequent hematological TEAE. Serious unrelated TEAEs occurred in 5 pts (27.8%). Two (11.1%) pts discontinued treatment due to unrelated non-hematological TEAEs; 1 case of infected lymphocele (G3) and 1 case of skin neoplasm bleeding (G3). No TR deaths were reported. **Conclusions:** Rf in monotherapy showed signals of clinical activity in advanced or metastatic PSqCC pts. Safety profile was consistent with previous data. These results along with identification of suitable biomarkers could help to develop novel immunotherapy combination strategies in this orphan genitourinary tumor. Effects of [¹⁷⁷Lu] Lu-PSMA-617 on overall survival in TheraP versus VISION randomized trials: An exploratory analysis. *First Author: Yu Yang Soon, NHMRC Clinical Trials Centre, The University of Sydney, Australia; Department of Radiation Oncology, National University Cancer Institute, Singapore, Singapore*

Background: Observed effects on overall survival (OS) differed in the first two randomized trials (RCTs) of [¹⁷⁷Lu] Lu-PSMA-617 (LuPSMA) in metastatic, castration-resistant prostate cancer. TheraP randomized participants to LuPSMA or Cabazitaxel (CBZ). In TheraP, the CBZ group (n = 101) included 20 participants who crossed over to LuPSMA, and the LuPSMA group (n = 99) included 32 who crossed over to CBZ. VISION randomized participants to treatment with or without LuPSMA, plus physicians' choice among protocol-defined treatments, excluding CBZ. Thirty-eight percent of control group participants in VISION had received CBZ prior to randomization. This study investigated explanations for differences in these RCTs in the observed effects of LuPSMA on OS. **Methods:** Individual participant data (IPD) on survival time from VISION was extracted from published survival curves for comparison with IPD from TheraP. Rank-preserving structural failure time (RPSFT) and inverse probability of censoring weighting (IPCW) were used in TheraP to estimate treatment effects on OS in counterfactual analyses assuming crossover had not occurred in either group, or in both groups. **Results:** OS was longer in the comparator group of TheraP than the comparator group of VISION (HR: 0.57, 95% CI 0.43 - 0.75) while OS was similar in the LuPSMA groups of VISION and TheraP (HR: 0.92, 95% CI 0.70 - 1.19). No significant differences in OS between the LuPSMA and CBZ groups of TheraP were apparent using counterfactual analyses assuming crossovers had not occurred (No crossover from CBZ: RPSFT HR 0.97, 95% CI 0.62 -1.52, IPCW HR 0.92, 95% CI 0.65-1.32; No crossover from LuPSMA: RPSFT HR 0.97, 95% CI 0.60-1.58, IPCW HR 0.82, 95% CI 0.55-1.24; No crossover from LuPSMA or CBZ: RPSFT HR 0.97, 95% CI 0.53-1.74, IPCW HR 0.82, 95% CI 0.53-1.27). **Conclusions:** The difference in observed effects of LuPSMA on overall survival in TheraP and VISION are better explained by the use of different comparator treatments in their control groups than by crossovers in TheraP from Cabazitaxel to LuPSMA, or LuPSMA to Cabazitaxel. Clinical trial information: NCT03392428, NCT03511664. Research Sponsor: None.

Tumor dosimetry of [¹⁷⁷Lu]-Lu-PSMA-617 for the treatment of metastatic castration-resistant prostate cancer: Results from the VISION trial sub-study. *First Author: Bernd J. Krause, Rostock University Medical Center, Rostock, Germany*

Background: In VISION, lutetium (¹⁷⁷Lu) vipivotide tetraxetan ([¹⁷⁷Lu]-Lu-PSMA-617; ¹⁷⁷Lu-PSMA-617) plus protocol-permitted standard of care (SoC) significantly improved overall survival and radiographic progression-free survival compared with SoC alone, in patients with prostate-specific membrane antigen (PSMA)-positive metastatic castration-resistant prostate cancer. In a VISION dosimetry sub-study, ¹⁷⁷Lu-PSMA-617 had a good safety profile with low radiotoxicity in at-risk organs. Here, we estimated the dosimetry of tumors after administration of ¹⁷⁷Lu-PSMA-617. **Methods:** The VISION sub-study was performed in a separate cohort of 29 non-randomized participants at four sites in Germany. Eligible patients received ¹⁷⁷Lu-PSMA-617 (7.4 GBq every 6 weeks, ≤ 6 cycles) plus SoC. Patients underwent single-photon emission computed tomography/computed tomography (SPECT/CT) scans at approximately 2, 24, 48 and 168 hours after the first administration of ¹⁷⁷Lu-PSMA-617 (Cycle 1). Up to five tumors in each patient were selected according to tumor size and relative activity uptake. Tumor delineation, volume and morphology were determined using positron emission tomography (PET)/CT images. Kinetic (time-activity) data was determined using SPECT images and the application of phantom derived recovery coefficients. Tumor dosimetry was estimated using the standard Medical Internal Radiation Dose/Radiation Dose Assessment Resource (MIRD/RADAR) method for internal dosimetry. S-values were determined using CT-derived tumor volumes and tissue type as input to the Internal Dose Assessed by Computer (IDAC-Dose) 2.1 program. Tumor dosimetry estimates were reported as absorbed dose per unit activity (Gy/GBq) and cumulative estimated absorbed dose (Gy) over all 6 cycles (44.4 GBq cumulative activity). **Results:** In total, 104 tumors were analyzed after administration of ¹⁷⁷Lu-PSMA-617 in Cycle 1. Tumor sites included bone (n = 84), lymphatic tissue (n = 18), lung tissue (n = 1) and soft tissue (n = 1). Mean tumor mass by site was 14.6 (standard deviation [SD], 29.8; range, 0.49–224) g for bone and 12.5 (15.9; 0.68–60.7) g for lymphatic tissue. The mean radiation-absorbed dose for all tumors was 6.5 (SD, 8.4; range, 0.13–55) Gy/GBq, and the median absorbed dose was 4.4 Gy/GBq. The mean radiation-absorbed dose by tumor site was 5.4 (SD, 6.0; range, 0.13–45) Gy/GBq for bone and 9.7 (12; 0.99–55) Gy/GBq for lymphatic tissue. The 6-cycle cumulative estimated absorbed dose for all tumors was 287 (SD, 373; range, 5.7–2432) Gy. The 6-cycle cumulative estimated absorbed dose by tumor site was 240 (SD, 268; range, 5.7–2010) Gy for bone and 429 (549; 44–2432) Gy for lymphatic tissue. **Conclusions:** Tumor dosimetry estimates after administration of ¹⁷⁷Lu-PSMA-617 in the VISION sub-study patient population were consistent with previously published estimates. Clinical trial information: NCT03511664. Research Sponsor: Advanced Accelerator Applications, a Novartis Company.

Bone biomarkers and subsequent survival in men with bone-metastatic hormone sensitive prostate cancer (HSPC): Results from the phase III SWOG S1216 trial of androgen deprivation +/- orteronel. *First Author: Primo N Lara, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: We previously reported that circulating serum biomarkers of bone metabolism were significantly associated with overall survival (OS) in men with advanced prostate cancer, either in the hormone sensitive (Lara, et al. ASCO 2022) or castration resistant state (Lara, et al. JNCI 2016). In S1216, we showed that elevated bone biomarkers were significantly associated with an increased risk of death in HSPC regardless of bone metastases (mets). We also identified three risk groups (low, intermediate, and poor) with differential OS outcomes (median OS: 8.2, 5.1, and 2.1 years, respectively) based on combinations of bone biomarkers in these patients. Here we report the association of bone biomarkers with OS in men with HSPC and documented skeletal mets as part of a planned analysis of S1216. **Methods:** Bone resorption [C-telopeptide (CTX) and Pyridinoline (PYD)] and bone formation markers [C-terminal collagen propeptide (CICP) and bone alkaline phosphatase (BAP)] were assessed from patient sera. Patients were randomly divided into training (n=238) and validation (n=475) sets. In the training set, recursive partitioning that maximizes discrimination of OS was used to identify the dichotomous cut-point for each biomarker and for a combination of biomarker split points to define prognostic groups. In the validation set, Cox proportional hazards models were used to assess the impact of biomarkers on OS, adjusted for patient and tumor characteristics. **Results:** Of 1,279 men in S1216, 713 had both baseline bone mets and evaluable bone biomarkers. Patient characteristics were similar between the overall population and the subset with bone mets. Elevated levels of CICP, CTX, and PYD were strongly prognostic for OS, but not for BAP. Hazard ratios (95% CI) for OS adjusted for treatment arm and baseline clinical variables were: BAP – 1.31 (0.93, 1.84), p=0.12; CICP – 1.58 (1.09, 2.29), p<0.02; CTX – 1.55 (1.12, 2.15), p=0.008; and PYD – 1.66 (1.27, 2.217), p=0.0002. There was no evidence of interaction between elevated biomarkers and treatment (all p>0.2). Recursive partitioning algorithms identified four groups of patients with differential OS outcomes based on bone biomarkers, adjusted for baseline clinical variables, with median OS ranging from 2.3 years (highest risk group) to 7.5 years (lowest risk group). **Conclusions:** In this subset analysis of men with HSPC and bone mets in S1216, elevated serum markers of bone metabolism were significantly associated with worse OS. Bone biomarker levels alone and in combination with patient and tumor characteristics identify unique subsets of men with differential OS outcomes. Clinical trial information: NCT01809691. Research Sponsor: U.S. National Institutes of Health; Millennium/Takeda; Jerry and Susan Knapp.

Concurrent chemo-hormonal therapy of enzalutamide (ENZ) and cabazitaxel (CAB) in patients (Pts) with metastatic castration-resistant prostate cancer (mCRPC): Final analysis of objective response rate (ORR), radiographic progression-free survival (rPFS), and overall survival (OS). *First Author: Alexandra Sokolova, OHSU Knight Cancer Institute, Portland, OR*

Background: We previously reported the PSA response rate and toxicity data of a phase 1/2 single-arm, multi-institutional trial to examine the efficacy and safety of co-administration of ENZ + CAB in mCRPC without prior chemotherapy given in the mCRPC setting. We found that full doses of ENZ (160 mg daily) and CAB (25 mg/m²) were tolerable and that 80% of pts had PSA decline ≥50%. Here, we report the final analysis of ORR, rPFS and OS. **Methods:** We calculated the ORR (CR/PR) and 95% confidence intervals using the Clopper-Pearson Exact Method. We determined response according to RECIST 1.1 for measurable disease and Prostate Cancer Working Group 2 criteria for non-measurable (bone) disease. We estimated median rPFS (time from the study entry to the time of confirmed progression (radiographic or clinical) or death) and OS (time from the study entry to death) with 95% confidence intervals using the Kaplan-Meier method; data cutoff was 6/1/22. Statistical analysis was performed using R: A language and environment for statistical computing. **Results:** 37 pts consented and 35 were included in the efficacy analyses (1 withdrew consent, 1 was lost to follow up before efficacy assessment); 7/35 (20%) had prior exposure to chemotherapy given for mHSPC and 9/35 (25%) had prior exposure to abiraterone (ABI), including 2/35 (25.7%) with prior exposure to chemotherapy and ABI. 28 pts had at least one on-study trial imaging study and were evaluable for ORR. After a median follow-up of 23.7 (range: 4.9 to 62.4) months (mo), median OS was 25.1 mo (95%CI 19.4 - 37.6 mo). Median PSA PFS was 11.9 mo (95%CI 9.2 - 15.4), and median rPFS was 22.2 mo (95%CI 13.6 - 25.2). PK assessments revealed that ENZ decreased CAB levels: CAB (monotherapy) Cmax 178.9ng* h/ml vs CAB (in the presence of ENZ) Cmax 85.5 ng* h/ml (p<0.05). **Conclusions:** The combination of ENZ+CAB in this heterogeneous mCRPC population, which included about a quarter of pts with prior chemotherapy and ABI exposure, resulted in an OS of 22.5 mo comparing favorably with the OS of 25.2 mo seen in the FIRSTANA trial of single agent CAB in docetaxel naïve men, 15.1 mo post chemotherapy in the TROPIC trial, and 13.6 mo in the post-docetaxel, post-ABI in the CARD trial. Of note, the rPFS in this trial was 22.2 months compared to 5.1 months in FIRSTANA suggesting improved efficacy; however cross-trial comparisons are discouraged due to several confounders. Chemo-hormonal therapies and prognostic/predictive biomarkers warrant further study in mCRPC. Clinical trial information: NCT02522715. Research Sponsor: PCF YIA; SPORE, DoD; SPORE.

Radiographic Best Response (n=28)	Pts N (%)	Lower 95%CI	Upper 95%CI
Complete response	3 (10.7%)	2.3%	28.2%
Partial response	11 (39.3%)	21.5%	59.4%
Stable disease	12 (42.9%)	24.5%	62.8%
Progressive disease	2 (7.1%)	0.9%	23.5%
ORR	14 (50%)	30.6%	69.4%

Impact of synchronous (sync) vs metachronous (meta) metastasis at the presentation on survival in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) treated with androgen receptor signaling inhibitors (ARSI). *First Author: Georges Gebrael, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Pts with sync metastatic castration-sensitive prostate cancer (mCSPC) appear to have worse survival outcomes and earlier time to developing castration resistance than pts with meta mCSPC (PMID: 33914595). However, the impact of the initial timing of metastasis on survival in the mCRPC setting is less clear. Herein, our objective was to assess the correlation between the sync/meta metastatic disease presentation and survival in real-world newly diagnosed mCRPC pts. **Methods:** In this IRB-approved study, patient-level data were collected retrospectively. Eligibility: confirmed diagnosis of mCRPC, treatment with ARSI (abiraterone or enzalutamide) as first-line (1L) therapy for mCRPC, and no prior exposure to ARSI in the mCSPC or localized states. The disease was considered sync if distant metastasis was diagnosed within 90 days of the initial prostate cancer diagnosis. Study endpoints: progression-free survival (PFS) was defined from the start of therapy for 1L mCRPC to progression (per PCWG-2) or death from any cause. Overall survival (OS) was defined from the start of therapy for 1L mCRPC to the date of death from any cause or censored at the last follow-up. A multivariate analysis using the Cox proportional hazards model was used, adjusting for potential confounders. **Results:** 323 pts (144 sync and 179 meta) were eligible and included in the analysis. Sync and meta pts had respectively similar baseline characteristics: median PSA (19.6 vs 20.8 ng/ml), liver metastasis (9 vs 12.3%), median alkaline phosphatase (97 vs 95 IU/L), and ECOG performance > 1 (9 vs 3.9%). The difference in median PFS was not statistically significant (8.2 vs. 10.7 months, HR 1.13, 95% CI 0.85-1.49, p=0.4 for sync and meta, respectively). Median OS was significantly shorter in pts with sync compared to meta (26 vs. 38.7 months, HR 1.51, 95% CI 1.11-2.08, p=0.01). In the multivariate analysis, the initial timing of metastasis remained an independent prognostic factor. **Conclusions:** For the first time, we report the impact of the initial timing of metastasis on mCRPC prognosis in a real-world patient population with sync disease being associated with having a poor prognosis. Initial timing of metastasis may be worth accounting for in future mCRPC clinical trials to explore its prognostic value further. These hypothesis-generating data need external validation. Research Sponsor: None.

Variable	PFS	OS
	HR (95% CI, P-value)	HR (95% CI, P-value)
Sync vs Meta	1.13 (0.85 – 1.49, p = 0.4)	1.51 (1.11 – 2.08, p = 0.01)
Baseline Log PSA	1.15 (1.07 – 1.23, p < 0.001)	1.12 (1.04 – 1.21, p = 0.005)
Liver Metastasis (yes vs no)	1.86 (0.87 – 3.99, p = 0.11)	1.88 (0.82 – 4.29, p = 0.14)
ECOG (≤1 vs >1)	0.86 (0.51 – 1.47, p = 0.59)	1.35 (0.73 – 2.34, p = 0.34)
Alkaline Phosphatase (continuous)	1.00 (1.00 – 1.00, p = 0.002)	1.00 (1.00 – 1.00, p = 0.08)

Real-world safety and effectiveness of radium-223 (²²³Ra) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) treated in the US: The non-interventional REASSURE study. *First Author: Daniel Y. Song, Department of Radiation Oncology and Molecular Radiation Sciences, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: ²²³Ra improved overall survival (OS) and quality of life and demonstrated a favorable safety profile in pts with mCRPC in the phase 3 ALSYMPCA trial. REASSURE (NCT02141438) is a global, prospective, single-arm, observational study of ²²³Ra use in pts with mCRPC and bone metastases in routine clinical practice. Here, we present clinical outcomes from the second planned interim analysis of REASSURE for pts treated in the US. **Methods:** This analysis included pts with confirmed mCRPC with bone metastases scheduled to receive ²²³Ra in the US. All pts received ≥1 dose of ²²³Ra. Primary endpoints are short- and long-term safety, including incidence of bone marrow suppression and second primary malignancies (SPM). Secondary endpoints included OS and pt-reported pain (Brief Pain Inventory – Short Form [BPI-SF] scores). A clinically meaningful pain response was defined as a decrease from baseline of ≥2 points in BPI-SF worst pain item. **Results:** Pts were enrolled from 2014–2017. Overall, 498 pts were included in this analysis. At the data cut-off (20 March 2019), the median duration of observation was 11.9 months (0.4–41.3). Most pts (81%) had bone metastases only; 69% of pts received 5–6 ²²³Ra injections. Overall, 77% of pts had received ≥1 prior life-prolonging therapies: abiraterone (45%), enzalutamide (48%), docetaxel (25%), cabazitaxel (6%), or sipuleucel-T (24%). Concomitant enzalutamide was received by 31% of pts, and 47% received concomitant bone health agents. After ²²³Ra, 31% of pts received ≥1 life prolonging therapies. During treatment, 208/358 (58%) pts with a baseline BPI-SF ≥2 had a clinically meaningful pain response. Any-grade and grade ≥3 drug-related treatment-emergent adverse events (TEAEs) occurred in 32% and 10% of pts, respectively. Drug-related TEAEs resulted in ²²³Ra discontinuation in 4% of pts. Treatment-emergent and drug-related serious AEs (SAEs) occurred in 21% and 6% of pts, respectively. The most common (>5% of pts) any-grade drug-related TEAEs were diarrhea (10%), fatigue (9%), anemia (8%) and nausea (7%). Overall, 4% of pts had fractures; 2% of pts developed bone disorders. Eleven SPMs occurred in 10 pts (2%). In total, 60% of pts died during study follow-up. Median OS was 17.8 months (95% CI 15.6–19.4). **Conclusions:** Within the current treatment landscape in routine clinical practice in the US, median OS after ²²³Ra treatment was close to 18 months. A majority of pts completed 5–6 ²²³Ra injections. The known safety profile of ²²³Ra was confirmed with no new safety signals. Over half of pts with pain at baseline had a clinically meaningful pain response during ²²³Ra treatment. Clinical trial information: NCT02141438. Research Sponsor: Bayer AG.

A novel abiraterone acetate oral suspension for patients with metastatic prostate cancer: An open-label, phase 3, randomized trial. *First Author: Imanol Martinez, Jiménez Díaz Foundation University Hospital, Madrid, Spain*

Background: Abiraterone acetate (AA) is a first-line oral hormone therapy for metastatic prostate cancer (mPC), but the licensed formulation is limited by large tablet size, requirement to take on an empty stomach, and pharmacokinetic variability. TAVT-45, a novel formulation of AA granules for oral suspension, offers improved oral bioavailability (allowing dose reduction), decreased food effect, and may provide an option for the ~20-30% of patients with dysphagia. This Phase 3, open-label global study (NCT04887506) aimed to establish therapeutic equivalence between TAVT-45 granules and reference AA tablets (R-AA). **Methods:** Patients with castrate-resistant or castrate-sensitive mPC (mCRPC or mCSPC) were randomized 1:1 to receive TAVT-45 (1 sachet of AA granules [250 mg] in water or juice, twice daily) or R-AA tablets (2 x 500 mg once daily ≥1 h before or ≥2 h after food), plus prednisone (5 mg once [mCSPC] or twice [mCRPC] daily) for 84 days. Efficacy (serum testosterone and prostate-specific antigen [PSA]) and safety were assessed. Average serum testosterone concentrations on Days 9 & 10 (primary endpoint, analyzed via analysis of covariance) were compared to show therapeutic equivalence. The key secondary endpoint was PSA-50 response (patients with ≥50% decrease in PSA from baseline at any time). mCRPC was the primary analysis population. Preliminary results are presented. **Results:** Of 107 randomized patients, 103 received TAVT-45 (n=54) or R-AA (n=49). The TAVT-45 and R-AA groups were well matched (mean [SD] age: 74.5 [8.45] and 74.9 [8.40] years; mCRPC: 61.1% and 61.2%). In mCRPC, serum testosterone concentrations fell rapidly from mean (SD) baseline of 9.7 (5.19) for TAVT-45 and 10.6 (7.32) ng/dL for R-AA, with all <1 ng/dL by Day 9. Therapeutic equivalence between TAVT-45 and R-AA at Days 9 & 10 was also shown in the full study population: Days 9 & 10 average rounded-up least-squares mean serum testosterone levels were comparable (TAVT-45 [n=52]: 1.004 ng/dL; R-AA [n=47]: 1.015 ng/dL), and the geometric mean ratio between groups was 0.990 (90% CI: 0.978-1.002), with the 90% CI falling within 80.0–125.0% equivalence limits. No statistical difference between TAVT-45 vs R-AA was demonstrated for PSA-50 (mCRPC 85% vs 70%; mCSPC 90% vs 95%). The frequency of treatment-emergent adverse events (TEAEs) was similar between groups; most were mild or moderate. Serious TEAEs occurred in 5 TAVT-45 and 3 R-AA patients. There were two deaths in treated patients due to cardiorespiratory arrest (TAVT-45) and prostate cancer (R-AA); neither was considered related to study drug. **Conclusions:** This Phase 3 study demonstrates that TAVT-45, a novel AA formulation with improved bioavailability, yields similar testosterone/PSA responses and a comparable safety profile to R-AA, and as an oral solution, may be suitable for mPC patients with dysphagia. Clinical trial information: NCT04887506. Research Sponsor: TAVANTA Therapeutics.

The effect of a reduced dose of enzalutamide on fatigue and cognition. *First Author: Joanneke Overbeek, Department of Pharmacy, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Enzalutamide (ENZA) is a highly effective treatment for patients (pts) with metastatic prostate cancer, but central nervous system (CNS)-associated side effects occur frequently and may hamper the quality of life. These side effects are addressed with dose reductions, while they potentially can be prevented by starting at a reduced dose, since androgen receptor saturation is already observed at dose levels above 60 mg once daily (OD) and ENZA plasma concentrations > 5 mg/L. We hypothesized that a lower starting dose of ENZA can reduce the risk of CNS side effects in frail pts while preserving efficacy. In this study (NCT03927391) the effect of a reduced dose of ENZA on fatigue and cognitive side effects is determined. **Methods:** This randomized multi-center trial compared the ENZA standard dose of 160 mg OD to the reduced dose of 120 mg OD in frail prostate cancer pts. At baseline, and 6, 12, and 24 weeks after start of ENZA, fatigue and cognitive side effects were measured by the Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-F) and Functional Assessment of Cancer Therapy–Cognition (FACT-Cog) questionnaires. A change in scores of 3.0 for the FACIT-F and 7.0 for the FACT-Cog was considered clinically relevant. Linear mixed effects models were used to study within and between-group differences in fatigue and cognitive side effects over time. Furthermore, ENZA plasma concentrations were measured after 6, 12, and 24 weeks of treatment and PSA response (>50% PSA decline) was compared between the two dosing regimens. **Results:** A total of 51 pts were included (25 reduced dose, 26 standard dose). Completion rates for the questionnaires were high throughout the study (>90%). Pts treated at the reduced dose showed no significant changes in FACIT-F and FACT-Cog scores over time. Pts treated at the standard dose showed increasingly worse FACIT-F and FACT-Cog scores. This resulted in clinically relevant and statistically significant better FACIT-F and FACT-Cog scores for pts treated at the reduced dose compared to pts treated at the standard dose after 24 weeks (table). All pts had therapeutic ENZA concentrations (>5 mg/L) throughout the study. PSA response did not differ between both groups (87% for 120mg OD vs 80% for 160mg OD, p=0.796). **Conclusions:** By starting with a reduced dose of ENZA of 120mg OD CNS side effects can be prevented, which might beneficially affect the quality of life of frail prostate cancer pts, without any indication of interference with efficacy endpoints. Clinical trial information: NCT03927391. Research Sponsor: Dutch health insurance company VGZ.

Difference in change from baseline between the reduced dose vs standard dose (95%CI).				
		6 weeks	12 weeks	24 weeks
FACIT-F score	Standard dose	Ref	Ref	Ref
	Reduced dose	2.0 (-2.8, 6.8)	3.0 (-2.0, 8.0)	6.4 (1.1, 12)*
FACT-Cog score	Standard dose	Ref	Ref	Ref
	Reduced dose	3.8 (-5.6, 13)	1.1 (-8.7, 11)	11 (0.24, 22)*

Higher scores represent less fatigue and cognitive side effects. * Significant p<0.05.

Talazoparib (TALA) plus enzalutamide (ENZA) in metastatic castration-resistant prostate cancer (mCRPC): Safety analyses from the randomized, placebo (PBO)-controlled, phase 3 TALAPRO-2 study. *First Author: Arun Azad, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: The phase 3 TALAPRO-2 study demonstrated a clinically meaningful and statistically significant improvement in radiographic progression-free survival for 1st-line TALA + ENZA versus PBO + ENZA in men with mCRPC, unselected for homologous recombination repair gene alterations (all-comers population). Here, we detail the safety profile of TALA + ENZA. **Methods:** In this double-blind, randomized, PBO-controlled trial, men received TALA 0.5 mg or PBO, plus ENZA 160 mg once daily (QD). Patient (pts) were ≥18 yrs of age, had Eastern Cooperative Oncology Group performance status ≤1, were receiving ongoing androgen deprivation therapy, and had no prior systemic therapy for mCRPC. Treatment-emergent adverse events (TEAEs) were evaluated: type, severity, timing, and associated dose modifications/discontinuations. **Results:** The all-comers safety population included 398 pts in the TALA + ENZA arm. Data cutoff was August 16, 2022. The median treatment duration of TALA was 19.8 months. All-cause any-grade TEAEs were observed in 98.5% of pts. Overall, 19.1% of pts discontinued TALA due to TEAEs. The 3 most common hematologic all-cause TEAEs and associated dose modifications are reported. To ensure optimal dosing of TALA at the individual level, the protocol did not require dose modification of TALA until anemia was grade (G) ≥3. Median time to onset of first G≥3 anemia was 3.3 months. At study entry, 49.0% had G1–2 anemia. 43.2% had anemia leading to dose reduction (with or without transfusion) and 8.3% discontinued TALA due to anemia. Despite dose reduction, the relative dose intensity of talazoparib remained >80% (approx. 0.4 mg/day). The 3 most common nonhematologic TEAEs were fatigue (33.7%; 4.0% G3), back pain (22.1%; 2.5% G3), and decreased appetite (21.6%; 1.3% G3). **Conclusions:** TALA 0.5 mg QD + ENZA 160 mg QD was generally manageable, with dose modifications of TALA and/or standard supportive care. Anemia was the most common TEAE and led to discontinuation of TALA in 8.3% of pts. G≥3 hematologic AEs typically occurred within 6 months of starting therapy and resolved in <1 month. A detailed understanding of the onset, duration, and severity of AEs, as well as the impact of dose adjustments in the TALAPRO-2 study, will optimize the management of pts receiving TALA + ENZA for mCRPC. Clinical trial information: NCT03395197. Research Sponsor: Pfizer Inc.; Astellas Pharma Inc. provided enzalutamide.

Final results of a pilot study of docetaxel and carboplatin for treatment of patients with mCRPC containing biallelic inactivation of genes in the homologous recombination DNA repair pathway. *First Author: Ruben Raychaudhuri, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Inactivating mutations in genes important in homologous recombination DNA repair (HRD) are present in the tumors of ~25% of patients with metastatic castration resistant prostate cancer (mCRPC). These alterations are associated with more aggressive disease but may also predict vulnerability to DNA damaging agents. We previously reported promising interim results from a single arm, Phase 1/2 trial studying the combination of the DNA damaging agent carboplatin with docetaxel for patients with mCRPC containing HRD mutations. Here we report final results after completing accrual and two additional years of follow up. **Methods:** We assessed response to the combination of docetaxel 60mg/m² and carboplatin AUC 5 IV q21 days in patients with mCRPC whose tumors had evidence of biallelic inactivation of genes involved in HRD and who had progressed on any prior treatment, including docetaxel and/or PARP inhibitor (PARPi). The primary endpoint was the proportion of patients who achieved ≥50% PSA decline from baseline (PSA₅₀). With H0 of PSA₅₀ of 26%, 14 patients provided 80% power to conclude H1 of PSA₅₀ of 60% based on Simon's 2-stage design with 1-sided α = 5%. The secondary endpoints included PSA₃₀, response duration, progression-free survival (PFS), and overall survival (OS). **Results:** The trial opened in Jan 2016 and completed in Sep 2021. A total of 16 patients were treated on study, including 6 who had previously received PARPi and 5 who had received docetaxel. 11/16 patients (69%) achieved PSA₅₀. 7/9 patients (78%) with biallelic inactivation of *BRCA2* (7), *BRCA1* (1), or *PALB2* (1) achieved PSA₅₀. Other biallelic inactivated HRD-related genes were *ATM* (1), *CHD1* (1), *CDK12* (3), *MRE11A* (1), and *NBN* (1). Of these patients, 4/7 (57%) achieved PSA₅₀. Notably, 3/6 patients (50%) previously treated with PARPi therapy achieved PSA₅₀. The median PFS was 8.4 months, and the median OS was 2 years. 6/16 patients (38%) had grade 3 AEs, most commonly thrombocytopenia (25%) and anemia (13%). One patient (6%) had a grade 4 AE (thrombocytopenia). **Conclusions:** The addition of carboplatin to docetaxel significantly improved response rates in patients with mCRPC with biallelic inactivation in genes involved in the HRD pathway. Responses were also seen in patients who had previously received PARPi. The combination was relatively safe and well-tolerated. The encouraging activity and favorable toxicity profile observed here merits further investigation. Additional work is ongoing to further refine biomarkers predictive of treatment response and resistance. Clinical trial information: NCT02598895. Use of circulating tumor DNA (ctDNA) to complement tumor tissue homologous recombination repair (HRR) gene alteration testing in TALAPRO-2, a phase 3 study of talazoparib (TALA) + enzalutamide (ENZA) versus placebo (PBO) + ENZA as first-line (1L) treatment in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Arun Azad, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: In TALAPRO-2 (NCT03395197), pts unselected for tumor genetic alterations in DNA damage repair pathways, directly or indirectly involved with HRR, received TALA + ENZA (n=402) or PBO + ENZA (n=403) as 1L treatment for mCRPC. HRR status was informed by tumor tissue for 804 pts (99.9%), by tumor tissue and ctDNA for 114 (14.2%), and by ctDNA only for 1 (0.1%). TALA + ENZA demonstrated statistically significant and clinically meaningful improvements in imaging-based progression-free survival over standard of care PBO + ENZA regardless of HRR gene alteration status (presented by Agarwal N at ASCO-GU 2023). Here we assessed the overall agreement of solid tissue vs ctDNA-based testing in assessing tumor HRR gene alteration status. **Methods:** HRR status for pts randomized in TALAPRO-2 was determined prospectively by testing for the presence of HRR gene alterations using FoundationOne CDx and/or FoundationOne Liquid CDx. Pts were considered HRR-deficient if they had ≥1 alteration in ≥1 of 12 HRR genes by either test. Plasma samples collected at screening were retrospectively tested using FoundationOne Liquid CDx to examine retrospective test performance and to support exploratory resolution of pts with unknown prospective HRR status. Results were reported as HRR-deficient, non-HRR-deficient, or unknown. **Results:** In prospective testing, high concordance in HRR status was observed between ctDNA and tumor tissue sample results: 95% agreement (90/95) between tests was observed in pts evaluable as either HRR-deficient or non-HRR-deficient by both tests. Retrospective ctDNA test results were reported for 739 pts (207 [28%] with a status of HRR-deficient, 480 [65%] non-HRR-deficient, and 52 [7%] unknown; 66 pts had samples not collected or reported). There was high concordance in pt-level alteration status between prospective molecular profiling (mainly based on solid tumor tissue per above) and retrospective ctDNA testing: the agreement was 84% (438/519) between tests for pts evaluable as HRR-deficient or non-HRR-deficient both prospectively and retrospectively (421/501 [84%] for prospective tumor tissue only vs retrospective ctDNA). **Conclusions:** Results show 95% agreement between prospective tissue and ctDNA-based HRR status using FoundationOne, consistent with tumor vs ctDNA results recently reported (Tukachinsky. *Clin Cancer Res.* 2021;27:3094–3105). The high agreement between prospective test results based primarily on tumor tissue and retrospectively assessed ctDNA collected at screening is supportive of exploratory retrospective testing of ctDNA to inform the HRR status of pts whose alteration status is unknown based on prospective testing. Clinical trial information: NCT03395197. Research Sponsor: Pfizer Inc.; Astellas Pharma Inc. provided enzalutamide.

PSMA expression and response to 177Lu-PSMA-617 (LuPSMA) in men with vs. without DNA damage repair (DDR) mutations. *First Author: Ruben Raychaudhuri, Fred Hutchinson Cancer Center, Seattle, WA*

Background: LuPSMA, a radioligand targeting the cell surface protein PSMA, is approved for men with PSMA-positive metastatic castration resistant prostate cancer (mCRPC) following an androgen receptor (AR)-signaling inhibitor (ARSI) and docetaxel. DNA damage repair gene (DDR) mutations are common in mCRPC, and given that ionizing radiation induces DNA damage, we hypothesized that the presence of these alterations could associate with improved clinical outcomes to LuPSMA. Data also suggests that the presence of DDR mutations may correlate with PSMA expression, providing further motivation to evaluate if DDR alterations are associated with the clinical activity of LuPSMA. **Methods:** We abstracted retrospective data from all patients at our center who received at least one cycle of LuPSMA per the FDA label and who had panel-based sequencing performed (e.g. UW-OncoPrint, Foundation One). Patients with somatic or germline alterations in a DDR gene were assigned to the DDR deficient cohort, while patients with somatic testing negative for a DDR gene mutation were assigned to the DDR intact cohort. Mutations in any DDR gene were considered for the purpose of stratifying between genomic subgroups. Differences in baseline PSMA SUVmean and PSA₅₀ responses (i.e. ≥50% decline in PSA) were compared between cohorts. **Results:** Of 91 patients who received ≥1 cycle of LuPSMA, 54 had genetic testing. 35 (64%) received ≥2 lines of prior ARSI therapy, 30 (56%) received ≥2 lines of prior chemotherapy and 15 (28%) received prior PARP inhibitor. 21 patients had alterations in a DDR gene and the remaining 33 patients had somatic testing without an identifiable DDR mutation. PSMA SUVmean was similar between groups: 8.04 (95% CI: 6.95 - 9.12) (DDR intact) vs. 7.32 (95% CI: 6.23 - 8.41) (DDR deficient), p = 0.37. 7/33 (21%) patients in the DDR intact group achieved PSA₅₀ response compared to 11/21 (52%) in the DDR group (p = 0.018). Survival data is immature but will be presented at the meeting. Rapid autopsy (RA) was performed in one subject with a *BRCA2* mutation (baseline PSMA SUVmean 5.6) and immunohistochemistry analysis revealed profound loss of PSMA following progression on LuPSMA. **Conclusions:** Mutations in DDR genes were associated with a higher PSA₅₀ response rate following LuPSMA compared to patients without a DDR mutation. There was no difference in baseline PSMA expression based on DDR mutational status, suggesting that higher response rates in the DDR cohort may have been mediated primarily by increased sensitivity to ionizing radiation. Evaluation for associations between DDR mutational status and survival endpoints is needed and will require a larger sample size and longer follow up. RA post-LuPSMA revealed loss of PSMA expression, suggesting that antigen loss may be a relevant resistance mechanism. Research Sponsor: U.S. National Institutes of Health.

DDR gene	N	PSA50 Response, n (%)

Tumor heterogeneity and treatment response assessment using next generation imaging and liquid biopsy in patients with metastatic castration resistant prostate cancer receiving abiraterone (ANGELA): A single-center prospective observational trial. *First Author: Yao Zhu, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Metastatic castration resistant prostate cancer (mCRPC) is a disease of intra-patient tumor heterogeneity which poses obstacles in treatment and response evaluation. With the development of next generation imaging (NGI) and liquid biopsy, precise assessment of heterogeneity has entered a new era. In this study, we used longitudinal NGI (⁶⁸Ga-PSMA and ¹⁸F-FDG PET/CT) and circulating tumor DNA (ctDNA) testing to assess tumor heterogeneity and treatment response in mCRPC patients receiving abiraterone. **Methods:** ANGELA is a single-center prospective observational trial (NCT05188911). We recruited mCRPC patients who received abiraterone as initial hormonal treatment. Eligible patients should have a life expectancy >12 months. CtDNA testing and NGI were performed at baseline and after 12 weeks of abiraterone (Week 13). Conventional imaging and PSA testing were performed at Week 1 and every 12 weeks. Primary end-point of this study is intra-patient lesion heterogeneity evaluated by 3 dimensions: (1) Imaging heterogeneity: defined as at least 1 lesion with FDG+/PSMA- phenotype at baseline and/or Week 13; (2) Genomic heterogeneity: quantified by ctDNA fraction increase and mutational changes per gene between baseline and Week 13; (3) Response heterogeneity: defined as at least 1 new tumoral lesion with either PSMA or FDG abnormal uptake at Week 13. Secondary end-points are correlations of heterogeneity with conventional-evaluated progression-free survival (PFS) and 2-year overall survival (OS). **Results:** Between May 20, 2020 and Feb 02, 2021, we included 33 eligible patients in our study. FDG+/PSMA- tumoral lesion was observed in 7/33 (21.2%) and 8/33 (24.2%) of patients at baseline and Week 13, respectively. Notably, 5 of 8 patients with imaging heterogeneity at Week 13 had no FDG+/PSMA- lesion at baseline. For genomic heterogeneity, we detected ctDNA fraction increase in 4/33 patients (12.1%). In addition, we found new gene mutations detected in Week 13 ctDNA testing in 5/33 patients (15.2%), 2 of 5 had ctDNA fraction increase. For response heterogeneity, we observed 15/33 patients (45.5%) patients developed at least 1 new tumoral lesion (FDG+ or PSMA+) at Week 13. We correlated heterogeneity factors with prognosis, and found that detection of new mutated genes (P=0.005 and P<0.001), new PSMA+ lesion (P<0.001 and P<0.001), and new FDG+ lesion (P=0.008 and P<0.0001) at Week 13 were significant predictors of shorter PFS and decreased 2-year OS. Detailed biomarker study for response analysis is still in process. **Conclusions:** Intra-patient tumor heterogeneity was common among mCRPC patients receiving abiraterone. Combining liquid biopsy with NGI can monitor changes in tumor heterogeneity and indicate early combination therapy. Clinical trial information: NCT05188911. Research Sponsor: None.

mFAST-SeqS based aneuploidy score in circulating cell-free DNA and role as early response marker in patients with metastatic prostate cancer treated with androgen receptor signaling inhibitor. *First Author: Khrrstany T. Isebia, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: Several treatment modalities in metastatic castration resistant prostate cancer (mCRPC) are available to prolong progression-free and overall survival. With the arrival of additional treatment modalities, the need for accurate monitoring of treatment response is becoming more eminent and research for biomarkers pivotal. Cell-free circulating tumor DNA (ctDNA) has emerged as a promising prognostic and predictive biomarker. Several techniques have been employed for the detection and characterization of ctDNA within the total pool of cell-free DNA (cfDNA), one of which is the modified Fast Aneuploidy Screening Test-Sequencing System (mFAST-SeqS). This affordable and robust assay enables the quantitation of a sample's ctDNA using a genome-wide aneuploidy score (GWA). Our aim was to investigate whether estimation of the GWA by mFAST-SeqS can be used to evaluate early response to treatment and predict response to treatment at baseline in patients with mCRPC. **Methods:** We prospectively enrolled mCRPC patients before start of treatment with androgen receptor signaling inhibitor (ARSI) abiraterone or enzalutamide. Blood samples were collected at baseline before start of treatment (BL, $n=134$) and at an early treatment time point during treatment (ET, $n=20$). We isolated cfDNA from plasma collected at both time points using the QiaSymphony or Maxwell system, and performed mFAST-SeqS on 1 ng cfDNA by amplifying and sequencing long interspaced nuclear elements (LINE-1) throughout the genome. The GWA-scores were calculated by taking the summed square of individual Z scores per chromosome arm relative to healthy controls. GWA-score was dichotomized in high (GWA^{high}) and low (GWA^{low}), based on the previously described cut-off of 5. Clinical outcome, defined as treatment duration with ARSI, was compared for patients with a GWA^{high} and GWA^{low} score at baseline and at an early time point. In addition, conversion of GWA score from baseline to early time point was explored. **Results:** Median age at start of treatment was 68.5 years (interquartile range (IQR): 63-73). Median time between start treatment and blood draw at BL and ET was 3 (IQR: 0-10 days before treatment) and 28 (IQR: 18-62 days during treatment) days, respectively. Median number of prior therapy lines was 1 (IQR: 0-10). Treatment duration was significantly shorter in the GWA^{high} group versus the GWA^{low} group both at BL and at ET in patients treated with ARSI (BL: $p<0.001$, log-rank test, median 221 and 82 days; ET: $p<0.01$, log-rank test, median 123 and 42 days). **Conclusions:** The genome-wide aneuploidy score, based on mFAST-SeqS of cfDNA, is a useful tool to predict response to ARSI in patients with mCRPC. The current dataset will be extended to 199 samples at baseline and 78 samples at early time point, and also include mCRPC patients treated with taxanes. Clinical trial information: NCT01855477, NTR732. Research Sponsor: KWF-CPCT alpe project (NKI2014-7080).

The impact of circulating tumor cell HOXB13 RNA detection in men with metastatic castrate-resistant prostate cancer (mCRPC) treated with abiraterone or enzalutamide. *First Author: Siyuan S Guo, Duke University, Durham, NC*

Background: It has been shown that HOXB13 is an important androgen receptor (AR) coregulator. The primary objective of this analysis was to correlate HOXB13 expression with clinical outcomes in men with mCRPC. **Methods:** We conducted a retrospective analysis of the multicenter prospective PROPHECY trial of mCRPC men ($n=118$) treated abiraterone (abi) or enzalutamide (enza). CTC detection and specific HOXB13 cDNA detection and expression was measured using a modified Adnatest using appropriate controls. CTC HOXB13 status was categorized into 3 groups: undetectable CTCs (CTC=0 based on CTC PSMA & PSA=0); CTC+ but HOXB13 CTC negative (<4 copies) or positive (≥ 4 copies) where the HOXB13 cutoff point was determined by the maximally selected rank statistic for prognostic associations. The association between HOXB13 and overall survival (OS) and radiographic progression-free survival (rPFS) were explored using the proportional hazards model. We also explored the association between the two endpoints and multigroup of HOXB13 at cutoff 0 and CellSearch CTC at cutoff 1 and 5. **Results:** 102 men who had sufficient CTC cDNA sample for HOXB13 detection. Of those men with detectable CTCs, 19% ($n=19$) had no detectable HOXB13, while the majority of men at 67% ($n=58$) had both CTC and HOXB13 detection. The proportion of patients with CTC=0, CTC+ HOXB13-, and CTC+ HOXB13+ using the optimal HOXB13 threshold were 25%, 31% and 44%, respectively. Men with HOXB13- CTCs were more likely to have low PSA (median 3 vs 79 copies), low CTC PSMA (0 vs 99 copies), low AR-FL (47 vs. 89 copies) and CTC AR-V7 (5.9 vs. 42 copies), and more likely to have liver/lung metastases (41% vs 25%). Median OS were 25.7, 25 and 12.1 months while the median rPFS of the three groups were 9.0, 7.2 and 4.7 months, respectively. Compared to CTC=0, men with HOXB13- CTCs did not have a worse hazard rate for OS (HR: 0.9, 95% CI: 0.4-1.9), while HOXB13+ CTC patients had a worse hazard for OS (HR: 2.0, 95% CI: 1.0-3.9), adjusting for prior abi/enza treatment and Halabi clinical risk score. The positive HOXB13 had also statistically significant increased hazard for progression/death (HR: 2.31, 95% CI: 1.24-4.30). Compared to the group with both HOXB13=0 and CellSearch CTC=0, men with HOXB13 >0 and CellSearch CTC ≥ 5 had increased hazard on both OS and rPFS (OS: HR:2.39, 95% CI: 1.06-5.4; rPFS: HR: 2.78, 95% CI: 1.38-5.59). **Conclusions:** Higher CTC HOXB13 expression is associated with AR dependent biomarkers in CTCs and is adversely prognostic in the context of potent AR inhibition in men with mCRPC, and this assay could be useful to select for patients appropriate for AR or future HOXB13 targeted therapies. Clinical trial information: NCT02269982. Research Sponsor: Pfizer; Astellas.

Characterizing the molecular landscape of early onset and average onset prostate cancer. *First Author: Ifeanyichukwu Ogbuoro, University of Miami Miller School of Medicine, Miami, FL*

Background: Prostate cancer (PC) has a median onset age of 66, however, recent evidence suggests an increase in incidence of PC diagnosis in males <55 years of age. Family history and increased mutational burden has been associated with early onset PC (EOPC), nonetheless, comprehensive molecular and immune signatures that cluster in EOPC and average onset PC (AOPC) is poorly understood. Here, we characterized EOPC and AOPC, and their association with molecular and immune signature. **Methods:** 5,305 PC samples (<55 yrs, $n=575$; ≥ 65 yrs, $n=4730$) were tested by NGS (592, NextSeq; WES, NovaSeq), WTS (NovaSeq) (Caris Life Sciences, Phoenix, AZ). PC Patients with age <55 and ≥ 65 was classified as EOPC and AOPC, respectively. Microsatellite-instability (MSI) was tested by IHC and NGS. Tumor mutational burden (TMB) totaled somatic mutations per tumor (high ≥ 10 mt/MB). Androgen receptor (AR) signature and Neuroendocrine Prostate Cancer (NEPC) score was calculated based on expression of a list of previously defined genes (Hieronimus *et al.* 2006, Beltran *et al.* 2016). Pathway enrichment determined by Gene Set Enrichment Analysis (Broad Inst). Immune cell fractions were calculated by deconvolution of WTS: Quantiseq. Statistical significance was determined using chi-square and Mann-Whitney U test ($p<0.05$) along with FDR-corrected p-values ($q<0.05$). **Results:** EOPC had higher frequency of *TPMRSS2* (35.8% vs 29.7%), *ETV1* (5.2% vs 2.8%), *ETV4* (3.4% vs 1.6%), and *BRAF* (1.9 vs 0.7%) fusions, but lower frequency of APC (4% vs 8%), CTNNB1 (2.4% vs 4.6%), RB1 (2.3% vs 4.7%) and AR (1% vs 4.9%) mutation, TMB high (2.1% vs 4.6%) and dMMR/MSI-H (2.1% vs 4%) compared to AOPC (all $p<0.05$). EOPC had pathway enrichment of myogenesis (NES: 1.5, $q<0.01$), but no difference in hedgehog signaling (NES:1.3, $q=0.09$) and epithelial mesenchymal transition (NES: 1.3, $q=0.09$) pathways compared to AOPC. EOPC had higher median NEPC score (0.359 vs 0.353, $q=0.04$), higher MAPK pathway activity score (MPAS) (3-fold, $q=0.02$) but no difference in median AR signature ($q=0.39$) compared to AOPC. In addition, EOPC had higher expression of PSA (1.2-fold, $q<0.01$) and immunomodulatory genes (*IL12A*, *CTLA4*, FC:1.2, $q<0.05$) with reduced AR expression (1.3-fold, $q<0.01$), however there was no difference in IHC-AR ($q=1$) and PD-L1 ($q=0.57$). Analysis of inferred immune cell infiltrates showed that EOPC had increased infiltration of NK cells (4.5% vs 4.1%, $q<0.01$) and dendritic cells (1.9% vs 1.8% $q<0.05$) compared to AOPC. **Conclusions:** Our data suggest that EOPC is enriched in fusion events including *TPMRSS2*, *ETV1*, *ETV4* and *BRAF*. Distinct transcriptomic features seen in EOPC included neuroendocrine differentiation, MAPK activations, immunomodulatory gene expression, and increased infiltration of NK cells and dendritic cells, suggesting inherent molecular differences and differential tumor immune microenvironment in EOPC and AOPC. Associations between androgen-directed treatments and AR mutational landscapes in the circulating tumor DNA of a real-world metastatic prostate cancer cohort. *First Author: Elisa M. Ledet, Tulane University, New Orleans, LA*

Background: AR alterations evolve under the selective pressure of testosterone suppression and AR targeted agents. In metastatic, castration-resistant prostate cancer (mCRPC) AR's mutational landscape and therapeutics targeting is still an unexplored area. Here we evaluate AR mutations in the circulating tumor DNA (ctDNA) of patients treated with AR targeted agents such as abiraterone (abi), enzalutamide (enza) and in combination (abi + enza) setting in a large Tempus real-world mCRPC cohort. **Methods:** De-identified records of patients with mPC who underwent Tempus xF next-generation sequencing (NGS) ≥ 6 months after treatment initiation of abi, enza, or abi + enza were selected for analysis. If patients had multiple NGS samples, the most recent sample was used. The assay is a targeted liquid biopsy panel that detects single-nucleotide variants and insertions and/or deletions in 105 genes, copy number variants in six genes, and chromosomal rearrangements in seven genes. **Results:** The cohort included 1,122 patients treated with abi only ($n=483$), enza only ($n=374$), or prior exposure to abi + enza ($n=265$). Pathogenic/likely pathogenic mutations were detected in 15% ($n=71$) of patients treated with abi, 15% ($n=56$) treated with enza, and 27% ($n=71$; $P<0.001$) treated with both. The most frequent AR alterations were *L702H* (18%, 32%, and 25%) and *T878A* (34%, 3.6%, and 21%) and *H875Y* (7%, 12%, and 8.5%) in abi, enza, and abi + enza, respectively (Table). *L702H* and *T878A* alterations were found in an additional 8.5%, 3.6% and 9.9% of patients treated with abi, enza, or abi + enza, respectively. Alterations in *L702A* and *H875T* were found in 2.8%, 8.9% and 9.9% of patients treated with abi, enza, and abi + enza respectively. Approximately 4.2%, 1.8% and 1.4% (abi, enza, abi + enza) of treated patients had alterations in *T878A* and *H875Y*. Other single-hit alterations included 6 patients with *W742C* and 4 patients with *F877L*. **Conclusions:** AR mutations have implications for clinical decision making and drug development in patients treated with abiraterone and/or enzalutamide. Research Sponsor: None.

Phase I trial of enzalutamide (Enz) plus the glucocorticoid receptor antagonist relacorilant (Rela) for patients with metastatic castration resistant prostate cancer. *First Author: Kunal Desai, University of Chicago Medical Center, Chicago, IL*

Background: Resistance to androgen receptor (AR) targeted therapies is common in mCRPC. Glucocorticoid receptor (GR) expression increases with AR inhibition in patients (pts) and blockade of GR signaling inhibits CRPC growth in preclinical models when combined with AR blockade. We thus conducted a phase I study of the combination of rela and enz in patients with mCRPC. **Methods:** The study used a 6+3 design to assess safety and pharmacokinetics (PK) of the 2-drug combination. The starting dose of rela 100mg/day was chosen based on current clinical studies indicating this dose was both safe for daily dosing and pharmacologically active and the starting dose for Enz was 120mg based on anticipated drug-drug interactions. Escalating doses of rela were combined with Enz 120 using pre-specified dose escalation profiles. An additional 12 patients were to be assessed at the MTD to refine safety and PK profiles. Primary endpoint was safety of the combination and to establish safe and pharmacologically active doses of both agents. Key secondary endpoints were tumor response per RECIST 1.1 criteria and progression-free survival (PFS; defined as either PSA progression, radiographic progression or death). PSA was measured after 12 weeks or at the last time at which PSA data was available, including times <12 weeks. **Results:** 35 pts were enrolled. Pts had a median age of 74 (range 62–85) and baseline PSA of 89.5 (range 7.3–2391). 100% had prior potent AR signaling inhibitor (abi or enz) with 89% receiving prior enz, 94% prior abi, 83% prior both. 69% of pts received prior docetaxel. Median PSA change was 0.1%. Enz 120mg + Rela 100mg and Enz 120mg+Rela 150 were found to be safe and tolerable and achieved desirable Enz PK. DLTs were noted in 3 pts at the 200mg Rela dose, which was deemed to have exceeded the MTD, which was thus defined as 150mg Rela+120mg Enz. Most common ≥ grade 3 treatment related adverse events (TRAEs) were fatigue (11% of pts), anemia (9%), abdominal pain (6%) and pericardial effusion (6%). Median PFS was 2.5 months for 21 of 35 evaluable pts. Best response per RECIST 1.1 were Not Evaluable (40%), SD (34%) & PD (26%). No CR or PR were noted. Most common reasons for discontinuation from trial included progressive disease/hospice (82%), AEs (12%), physician discretion (3%) & death (3%). 2 pts remain on trial as of data cutoff (12/31/22). **Conclusions:** The combination of enzalutamide and relacorilant was safe & largely well tolerated. The majority of pts were discontinued from trial due to progressive disease or hospice. Further analyses of secondary & correlative endpoints such as translational/endocrine biomarkers, GR target gene expression and circulating tumor cells are ongoing. Clinical trial information: NCT03674814. Research Sponsor: U.S. National Institutes of Health; University of Chicago.

Early changes of PSMA PET signal after initiation of androgen receptor signaling inhibitors in mCRPC: An international multicenter retrospective study. *First Author: Lena Unterrainer, Ahmanson Translational Therapeutics Division, Department of Molecular and Medical Pharmacology, David Geffen School of Medicine, UCLA, Los Angeles, CA*

Background: Androgen receptor signaling inhibitors (ARSi) play a relevant role in the treatment of prostate cancer. A potential influence of ARSi on PSMA expression has been described. We evaluated early changes of PSMA-expression by PET in mCRPC patients. **Methods:** This retrospective study included 5 international sites. Patients with mCRPC undergoing ⁶⁸Ga-PSMA-11 PET/CT prior to (PET1) and early after ARSi (PET2 within 29 days maximum) were included. Whole-body (WB) PSMA-positive tumor volume (PSMA-TV) was evaluated using a liver-specific semi-automatically threshold (Affinity 3.0.2, Hermes Medical Solutions). WB PSMA-TV, SUV_{mean} and SUV_{max} and their respective changes (%) were analyzed. PSA changes between PET1 and PET2 were evaluated. Median values and ranges are provided. **Results:** 54 patients were included in the analysis. ARSi was initiated 1 day (range 0–28) after PET1 while PET2 was performed 14 days (range 7–29) after ARSi initiation. PSA at PET1 and PET2 was 9.5 ng/ml (range 0.2–490.0) and 8.7 ng/ml (range 0.1–732.0), respectively (p = 0.035); -33.0% (range -98%–+496%). The WB PSMA-TV at PET1 and PET2 was 89.9 ml (0.0–3097.0) and 112.2 ml (0.0–3133.0) ml, respectively (p = 0.016; change of +6.0% (range -88%–+260%). WB PSMA SUV_{mean} and SUV_{max} at PET1 and PET2 was 9.0 (range 5.0–43.7) and 9.3 (range 0.0–42.5) and 26.5 (range 0.0–125.0) and 28.5 (range 0.0–212.0), respectively (p = 0.194 and p = 0.353); % change of +3 % (-85%–+71%) and 0% (-55%–+232%). Four of 7 patients with PSA increases at PET2 had an increasing PSMA-TV, 6/7 showed an increasing SUV_{mean} and 5/7 presented with an increased SUV_{max}. Decreasing WB-PSMA-TV in 18/54 (33%) patients was accompanied by decreasing SUVs in 10 of them (56%). Percent PSA change was unrelated to changes in PSMA-TV, SUV_{mean} and SUV_{max}. **Conclusions:** PSMA-PET performed early after ARSi revealed slight increases in the WB-PSMA-TV, stable WB-PSMA SUVs while serum PSA decreased in most of the patients. We conclude that ARSi does not have a strong effect on PSMA expression within 30 days after treatment initiation. Research Sponsor: None.

	PET1	PET2	Change in %	Significance (p-value)
PSA (ng/ml)	9.5 (0.2–490.0)	8.7 (0.1–732.0)	-33 (-98–496)	0.035*
PSMA-TV (ml)	89.9 (0.0–3097.0)	112.2 (0.0–3133.0)	+6 (-88–260)	0.016*
SUV _{mean}	9.0 (5.0–43.7)	9.3 (0.0–42.5)	+3 (-85–71)	0.194
SUV _{max}	26.5 (0.0–125.0)	28.5 (0.0–212.0)	0 (-55–232)	0.353

All values are displayed as median (range). * Statistically significant.

Circulating tumor cells (CTCs) in patients with metastatic castration resistant prostate cancer (mCRPC) treated with olaparib plus ¹⁷⁷lutetium-prostate specific membrane antigen-617 (¹⁷⁷Lu-PSMA-617) in the LuPARP trial. *First Author: Hamid, Department of Medical Oncology, Peter Mac-Callum Cancer Centre and University of Melbourne, Melbourne, Australia*

Background: LuPARP (NCT03874884) is evaluating the safety and efficacy of olaparib in combination with ¹⁷⁷Lu-PSMA-617 in patients (pts) with mCRPC who have progressed on an androgen receptor pathway inhibitors and docetaxel. We aim to identify potential prognostic and predictive biomarkers from serial CTC profiling. **Methods:** Twenty-six pts with high PSMA expression on PSMA-PET received 7.4 GBq of ¹⁷⁷Lu-PSMA-617 every 6 weeks (wk) together with an escalating dose-schedule of olaparib (50mg BD–300mg BD, days 2 to 14 or days -4 to 14) for up to 6 cycles. For CTC analysis, 10 mls of blood was collected at baseline, 12-weekly for 48 wk, and thereafter every 24 wk and at disease progression. CK+, CD45-, and DAPI+ CTCs were enumerated from 3 mls of blood and immunoassayed for PSMA expression using the Epic Sciences platform. Correlations between total and PSMA+ CTC counts and PSA50 response (PSA reduction of ≥ 50%) were evaluated. Low pass whole genome sequencing (lpWGS) was performed on baseline and longitudinal CTC samples to identify copy number alterations. **Results:** At baseline, 23 of 26 pts (88%) had detectable CTCs (median 2.9 CTC/ml, range 0–30), and of these 23 pts, 17 (74%) had detectable PSMA+ CTCs (median 0.9 CTC/ml, range 0.3–27), indicating heterogeneity of PSMA expression in CTCs. The CTC positivity rates (% of cases ≥ 1 CTC) at week (w) 12, w24, w36, w48 and at disease progression were 57%, 58%, 75%, 36% and 100%, and the PSMA positivity rates (% of cases ≥ 1 PSMA+ CTC) were 38%, 36%, 22%, 50% and 56%, respectively. Fifteen of 20 (75%) evaluable pts with paired baseline and w12 CTCs had a ≥ 50% decline in total CTC count, of which 9/15 (60%) pts also achieved a PSA50 response. Five of these 9 (56%) pts had 100% CTC clearance at w12. In terms of PSMA+ CTCs, 14/15 (93%) evaluable pts had ≥ 50% PSMA+ CTC decline with 13 pts (93%) achieving complete CTC clearance by w12. Six of the 13 pts with complete PSMA+ CTC clearance at w12 also achieved a PSA50 response. Beyond PSMA expression, genomic heterogeneity was evident in baseline and on-treatment CTCs, including recurrent loss of *PTEN*, *TP53*, *BRCA2*, *ATM*, and *RB1*, and gain of *AR* and *MYC*. lpWGS in 10 baseline samples identified 5 cases with *BRCA2* loss and 5 cases with *ATM* loss. Two pts with *BRCA2* loss and 3 pts with *ATM* loss had a PSA50 response by w12. **Conclusions:** We observed high rates of total and PSMA+ CTCs in PSMA-expressing mCRPC. Total and PSMA+ CTCs decline with combined olaparib and ¹⁷⁷Lu-PSMA-617 treatment. Early declines in total and PSMA+ CTCs including 12w CTC clearance paralleled PSA responses. Notably, total and PSMA+ CTCs rise again in the setting of disease progression. Serial CTC profiling may assist in tracking response to ¹⁷⁷Lu-PSMA-617 therapy. Clinical trial information: NCT03874884. Research Sponsor: Prostate Cancer Foundation.

Deutenzalutamide, an oral deuterated androgen receptor inhibitor, vs placebo for patients with mCRPC who have experienced treatment failure with abiraterone and docetaxel: Results of the HC-1119-04 phase 3 trial. *First Author: Ding-Wei Ye, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Deutenzalutamide (HC-1119) is a novel deuterated derivative of enzalutamide with a different metabolic profile while maintaining biologic activity at a lower dose. Abiraterone and docetaxel are widely used in mCRPC, however, resistance mechanisms eventually occur. **Methods:** The HC-1119-04 (NCT03851640), a multicenter, randomized, double-blind phase 3 trial in China enrolled patients with mCRPC who have failed abiraterone, or failed or were not eligible for docetaxel. Patients were randomized 2:1 to deutenzalutamide (80 mg orally daily) or placebo. Stratification factors included lesion site (visceral/non-visceral), prior docetaxel treatment (yes/no). The primary endpoint was investigator-assessed radiographic PFS. Secondary endpoints included: OS, independent radiologic review committee (IRC)-assessed rPFS, ORR, and PSA response. The hazard ratio (HR) and its 95% confidence interval (CI) between the two groups were calculated using a stratified Cox proportional hazards model. **Results:** The HC-1119-04 study enrolled 417 subjects between April 2019–Nov 2021, with 276 randomized to deutenzalutamide and 141 to placebo. Demographics and disease characteristics were well-balanced across treatment arms. All subjects were previously treated with abiraterone. Most of the subjects received docetaxel (68.8% vs. 68.1%); visceral lesions accounted for 27.9% in the deutenzalutamide and 27.7% in the placebo group. The study met its primary endpoint with a 42% reduction in the risk of progression or death in the deutenzalutamide arm (HR = 0.58 [95% CI: 0.439, 0.770]; P = 0.001. The median rPFS (95% CI) was 5.55 (4.830, 7.360) months for deutenzalutamide vs 3.71 (2.860, 5.490) months for placebo. Results in the pre-specified subgroups, including visceral metastases, and prior docetaxel were consistent with the overall outcome. The median OS (95% CI) was 14.98 (9.560, -) months and 11.24 (9.890, 15.510) months in the deutenzalutamide and placebo group, respectively, with an HR (95% CI) of 0.88 (0.577, 1.331). Common treatment-related adverse events (TEAE) (> 10%) with deutenzalutamide vs placebo included: weight decreased (23.4% vs 18.6%), platelet count decreased (12.8% vs 10.7%), lymphocyte count decreased (10.2% vs 7.9%), and hypercholesterolemia (10.9% vs 4.3%), mostly grade 1/2. The overall incidence of ≥ Grade 3 study drug related TEAEs in the deutenzalutamide group was not significantly different from placebo, except anemia (6.6% vs 2.9%) and hypertension (2.2% vs 0.7%). **Conclusions:** Deutenzalutamide demonstrated a statistically significant improvement of PFS vs placebo in a randomized phase 3 study in patients with mCRPC who have failed abiraterone, and who failed or were intolerant to docetaxel. Deutenzalutamide was well tolerated and has the potential as additional treatment option. Clinical trial information: NCT03851640. Research Sponsor: Hirona Pharma.

Enzalutamide vs abiraterone in patients with prostate cancer with and without type 2 diabetes mellitus. *First Author: Amy L Shaver, Department of Medical Oncology, Thomas Jefferson University, Philadelphia, PA*

Background: Estimations are that 8-18% of newly diagnosed cancer patients have Type 2 Diabetes Mellitus (T2DM). Current guidelines offer no clarification on the choice of therapy for prostate cancer (PCa) patients with T2DM. Since the comorbid PCa—T2DM population is increasing and these patients face unique challenges from adverse events requiring acute care utilization (ACU) it is important to ascertain which medication poses less of a threat of adverse events. The objective of this study was to describe the SEER-Medicare T2DM-PCa population in terms of those with and without complications and determine if T2DM influences ACU and PCa medication choice. **Methods:** We identified men with primary PCa treated with abiraterone (ABI, 2011) or enzalutamide (ENZ, 2012) with comorbid T2DM using the Surveillance, Epidemiology, and End Results (SEER)-Medicare database (1999-2019). Patients with a missing date of diagnosis, those diagnosed at death, having HMO or no continuous A and B coverage 12 months before diagnosis and 6 months continuous part D coverage before starting treatment as well as 6 months following treatment or until death were excluded. T2DM was identified using ICD-9 and ICD-10 codes. ACU was calculated utilizing the CMS Research Data Assistance Center definition focusing on emergency room visits resulting in in-patient hospitalization during the 6 months following treatment initiation. Differences in emergency room in-patient visits were evaluated using negative binomial models adjusted for age, race, SEER region, marital status, state-buyin, education, income, and modified Charlson Comorbidity Index (excluding T2DM). **Results:** The sample of 11,163 men included 61.8% treated with ABI and 38.2% with ENZ. We identified 3,044 (27.3%) men with T2DM, of which, 59.1% were treated with ABI and 40.8% with ENZ. Compared to those without T2DM those with T2DM had more ACU, regardless of medication, with a higher rate in the ABI than ENZ group, see table. Among diabetics, those with complications related to T2DM compared to those without also experienced a higher rate of ACU. The rate of ACU was 43% higher among those treated with ABI compared to ENZ (IRR 1.43; 95% CI 1.28, 1.61). Overall mortality (15.7% vs 10.1%, $p<0.01$) and PCa-specific mortality (8.2% vs 5.3%, $p<0.01$) were worse in those with T2DM treated with ABI compared to ENZ. **Conclusions:** Outcomes for PCA patients with T2DM are worse than for those without. ACU is higher in men treated with ABI compared to ENZ regardless of T2DM status. Given the worse outcomes for comorbid T2DM patients, further study to evaluate comorbidity management in this population is warranted. Research Sponsor: U.S. National Institutes of Health; PA CURE: 4100088563.

Genomic alterations and self-reported Agent Orange exposure in United States veterans with metastatic prostate cancer. *First Author: JJ Haijing Zhang, David Geffen School of Medicine at University of California Los Angeles (UCLA), Department of Urology, Los Angeles, CA*

Background: Agent Orange has been posited as an environmental risk factor for prostate cancer among United States Veterans. Prior studies have shown that Veterans with Agent Orange exposure are diagnosed at a younger age and at more advanced clinical stages. It is unknown if there are differences in somatic alterations among Veterans exposed to Agent Orange. **Methods:** Genomic alterations were identified from clinical tumor testing conducted from 2019 – 2022 in a large cohort of Veterans with metastatic prostate cancer diagnosed from 2001 – 2022. Primary prostate and metastatic carcinoma tissue specimens were submitted for Foundation Medicine tumor-only sequencing. Baseline demographics, clinical, and genomic alterations data were stratified by Veteran self-reported exposure to Agent Orange in accordance with an institutional review board approved protocol. **Results:** Of the 2673 Veterans with metastatic prostate cancer who underwent tumor-only genomic testing, 629 reported exposure to Agent Orange and 2044 were not exposed. After verification of military service records of Veterans with self-reported Agent Orange exposure to include only Veterans who served in the Vietnam War between 1962 – 1975 and Korean War between 1967 – 1971, 603 patients with self-reported Agent Orange exposure (22.8%) and 2044 without exposure (77.2%) were included in the analysis. On univariate analysis, *TPMRSS2-ERG* fusions were significantly more frequent in men who reported exposure to Agent Orange (35.3% vs 28.8%, $p<0.01$) after multiple hypothesis testing with Benjamini-Hochberg. Agent Orange exposure also correlated to higher rates of androgen receptor (*AR*) alterations (12.4% vs 9.5%, $p=0.04$) and *FGFR1/2/3/4* alterations (3.2% vs 1.7%, $p=0.02$). There were no significant differences in alterations in Agent Orange exposure in *TP53*, *CDK12*, *ERBB2*, *EGFR*, *BRCA*, and genes implicated in the DNA damage response and repair (*DDR*), mismatch repair (*MMR*), and *PTEN/PI3K/AKT* pathways. On multivariable analysis controlling for race, age at diagnosis, smoking, secondary malignancies, and environment, only alterations in *AR* (OR 1.43, $p=0.02$) remained more frequent in Veterans exposed to Agent Orange. As expected, age at diagnosis (OR 0.98, $p<0.001$) and Black/African-American race (OR 0.33, $p<0.001$) were associated with decreased odds of *TPMRSS2-ERG* alterations. **Conclusions:** Agent Orange exposure may contribute to tumor somatic alterations in Veterans with prostate cancer. These findings hold potential prognostic and therapeutic implications for U.S. Veterans with metastatic prostate cancer. Research Sponsor: None.

Determinants of widespread metastases and of metastatic tropism in patients with prostate cancer: A genomic analysis of primary and metastatic tumors. *First Author: Edward Christopher Dee, Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: A growing body of evidence suggests that metastatic cancer is better described as a spectrum of disease rather than a binarily defined state, ranging from oligometastatic cancer to widespread metastases. Widespread metastases represent the most common cause of cancer-related death among patients with prostate cancer. Therefore, a greater understanding of the genomic features that determine the extent and location of metastatic spread may inform risk stratification, treatment, and monitoring. We identify genomic alterations from primary prostate tumors that are predictive of widespread metastatic potential. **Methods:** Genomic and clinical data for 1,312 patients with primary prostate adenocarcinomas were extracted from the MSK-MET cohort through cBioPortal. Metastatic site counts and overall survival (OS) data were publicly available for all patients. All samples from primary tumors were profiled using the MSK-IMPACT targeted sequencing platform. Our study focused on 58 genes frequently altered in prostate cancer. Cox proportional hazard analyses defined hazard ratios (HRs) and 95% confidence intervals (CIs) for overall mortality in patients with different metastatic outcomes. Patterns of genomic alterations of the primary tumor associated with metastatic extent and location were compared. **Results:** Out of 1,312 patients, 939 (71%) developed metastases, and 113 (8.6%) had metastases to 5 or more distinct anatomical sites (defining wide-spread metastases, WSM). Bone was the most common site of metastasis (36%), and 80% of patients with liver metastases had 4 or more additional sites of metastasis. Among patients with metastases, increasing number of metastatic sites was associated with increased risk of death (HR:1.8, 95% CI:1.63-1.99, $p<0.001$). To define genomic determinants of WSM, we characterized genomic alterations in 58 prostate cancer related genes. Alterations in the following genes were enriched in tumors from patients with WSM vs others: TP53 mutation (40% vs 20%, $p<0.0001$), FOXA1-amplification (8% vs 3%, $p=0.02$), AR-amplification (4.4% vs 1%, $p=0.01$), RB1-deletion (5.3% vs 0.7%, $p=0.001$), and BRCA2-deletion (4.4% vs 0.7%, $p=0.01$). In a univariable survival analysis, all these alterations were predictive of OS ($p<0.05$). However, on multivariable analysis, only TP53 mutations, and FOXA1 and AR amplifications were independent prognostic factors. Amplifications of FOXA1 ($n=37$) and AR ($n=13$) were mutually exclusive (0 overlap), and we found that patients who have either AR or FOXA1 amplifications experienced very poor OS (HR:3.57, 95%CI:2.26-5.6, $p<0.001$). **Conclusions:** We identified genomic alterations (TP53 mutations, FOXA1 and AR amplification, RB1 and BRCA2 deletions) from primary prostate tumors that are predictive of wide-spread metastases and poor outcomes. Association of dynamic changes in serological markers with survival in de novo metastatic hormone-sensitive prostate cancer. *First Author: Soumyajit Roy, Rush University Medical Center, Chicago, IL*

Background: Prognostic association of serological markers of systemic inflammatory response have been demonstrated in metastatic castrate resistant prostate cancer. However, it remains unknown whether dynamic changes in these markers over time are prognostic earlier in the disease process, namely in metastatic hormone sensitive prostate cancer (mHSPC). We performed a secondary analysis of LATITUDE trial to determine if dynamic changes in hemoglobin (Hb), neutrophil to lymphocyte ratio (NLR), platelet to lymphocyte ratio (PLR), and lymphocyte to monocyte ratio (LMR) are predictive of prostate cancer-specific survival (PCSS), and overall survival (OS). **Methods:** We used a joint model approach to determine the association of the dynamic change in the marker levels with PCSS, and OS. For the time-to-event submodel, a multivariable Cox regression model was constructed with treatment arm, skeletal lesion number, liver or lung metastasis, ECOG performance status, and age. For the longitudinal submodel, a linear mixed-effects model was built with an interaction term for treatment arm and time of evaluation in addition to treatment arm, time of evaluation, and baseline value of the serological markers. The two submodels were linked through a shared random effect. **Results:** Overall 1172 patients were eligible - 580 from the abiraterone plus ADT arm and 592 from the ADT alone group. Median follow-up for surviving patients was 52 months (IQR 47-57). Median number of post-baseline assessments was 16 (IQR 10-28). On univariate joint models, every 10 g/L dynamic increase in Hb was associated with superior PCSS (HR 0.71 [0.67-0.75]) and OS (HR 0.74 [0.68-0.79]) while every 5 points dynamic increase in LMR was associated with a superior PCSS (HR 0.38 [0.26-0.53]) and OS (HR 0.41 [0.29-0.56]). In contrast, dynamic increase in NLR was associated with inferior PCSS (HR 1.29 [1.22-1.36]) and OS (HR 1.29 [1.23-1.36]) while every 10-point dynamic increase in PLR was associated with a small but significant deterioration in PCSS (HR 1.05 [1.04-1.06]) and OS (HR 1.05 [1.04-1.06]), respectively. On multivariate joint modeling, dynamic increase in Hb was also associated with superior PCSS (HR per 10g/L increase 0.74 [0.69-0.79]) and OS (HR per 10g/L rise 0.75 [0.71-0.80]). When dynamic changes in Hb, LMR, NLR, and PLR were included in the same multivariate model with dynamic change in PSA, dynamic increase in Hb continued to show association with significantly superior PCSS (HR per 10g/L rise 0.80 [0.75-0.86]), and OS (HR per 10g/L rise 0.81 [0.75-0.86]), respectively. **Conclusions:** Our findings suggest that dynamic increase in hemoglobin can predict for superior PCSS, and OS in men with de novo mHSPC treated with ADT with or without abiraterone. These findings need additional validation before implementing routine use of hemoglobin as a prognostic biomarker in de novo mHSPC. Research Sponsor: None.

Assessing PSA levels as prognostic of overall survival (OS) in men with metastatic hormone-sensitive prostate cancer (mHSPC). *First Author: Susan Halabi, Duke University Medical Center, Durham, NC*

Background: Prior data have shown that prostate specific antigen (PSA) ≤ 0.2 ng/dL at 6-7 months with androgen deprivation therapy (ADT) with testosterone suppression (TS) alone is prognostic of OS. We hypothesized that PSA ≤ 0.1 ng/dL at 7 months would be a stronger prognostic for OS in men with mHSPC treated with TS alone. This hypothesis was investigated by the STOPCAP M1 collaborators. **Methods:** Individual patient data from 13 eligible randomized trials comparing treatment regimens (TS or TS + docetaxel in the control or research arms in mHSPC trials) were utilized. Landmark survival analyses were performed at 7 months after ADT initiation. Overall survival was computed as the time from 7 months after start of initial TS to death or date of last follow for patients who started TS prior to randomization or 7 months after randomization to death or date last follow-up for patients who started TS after randomization. PSA measurements between 4-7 months after ADT were selected and cut off-points of PSA ≤ 0.2 , 0.2-4, and >4 ng/dL or PSA ≤ 0.1 , 0.1-0.2, 0.2-4, and >4 ng/dL were considered. The proportional hazards model was utilized to explore the prognostic significance of PSA levels in predicting OS adjusting for treatment in all patients and patients who were enrolled on docetaxel trials. **Results:** IPD from 5,438 patients randomized 1994-2012 from 13 trials were pooled. At 7 months, the proportion of patients who had PSA ≤ 0.1 and PSA ≤ 0.2 were 18.1% and 26.1%. The median OS in patients who experienced PSA ≤ 0.1 and PSA ≤ 0.2 and in patients enrolled on docetaxel trials are presented in the table below. The hazard ratios (HR) for death for PSA ≤ 0.1 and PSA ≤ 0.2 vs. those PSA >4 at 4-7 months were 0.26 and 0.27, respectively. In patients enrolled on docetaxel, HRs for death for PSA ≤ 0.1 and PSA ≤ 0.2 vs. those PSA >4 at 7 months were 0.35 and 0.34, respectively. **Conclusions:** PSA ≤ 0.1 and PSA ≤ 0.2 at 7 months have similar prognostic value of OS in men with mHSPC treated with weak ADT (TS alone) without and with docetaxel. Clinical trial information: NCT00309985; NCT00268476; NCT00104715; NCT00079001; NCT00002651; NCT00685646. Research Sponsor: Prostate Cancer Foundation; U.S. National Institutes of Health.

Early results from CASCARA: A phase 2 study of cabazitaxel/carboplatin plus abiraterone in high-volume metastatic castrate-sensitive prostate cancer (mCSPC). *First Author: Charles J. Ryan, Prostate Cancer Foundation, Santa Monica, CA*

Background: Best treatment of mCSPC involves doublet therapy (ADT + novel hormonal agent) or triplet therapy (ADT + novel hormone + docetaxel); however, opportunity remains for further improvement. Studies show that homologous recombination repair (HRR) gene mutations are enriched in metastatic prostate cancer, and may portend resistance to docetaxel. CASCARA tested quadruplet therapy (ADT + cabazitaxel/carboplatin + abiraterone) in high-volume mCSPC, aiming to enhance PSA responses and decrease progression at 1 year. **Methods:** This phase 2 study enrolled 61 mCSPC patients with high-volume disease who received ADT plus cabazitaxel (20 mg/m² q21d x 6) and carboplatin (AUC=4 q21d x 6) followed by abiraterone (1000 mg, plus prednisone 5 mg). Primary endpoint was freedom from PSA/radiographic progression at 1 year. Other endpoints included PSA₅₀ response, freedom from PSA progression, and safety. Archival biopsies were retrospectively evaluated for HRR (*BRCA1/2*, *ATM*, *CHEK2*, *CDK12*, *BRIP1*, *RAD51B*) mutations at a CLIA-certified lab. A sample size of 61 was determined using a Simon two-stage design (stage 1: 32 men, stage 2: 29 men) with a null hypothesis of a 1-year PSA/radiographic progression-free rate of 0.80 against a one-sided alternative of 0.92. **Results:** From 11/2019 to 06/2022, 61 men enrolled at 7 sites. Median age was 64 (range, 45–76) years; 21% were African American. Median baseline PSA was 8.9 (range, 0.1–1021) ng/mL. 44% of men had ECOG=1. 91% had Gleason sum 8–10. Prevalence of DNA alterations (50 evaluable pts) was 18% for HRR mutations, 38% for *TP53* muts, 22% for *ERG* fusions, 10% for *SPOP* muts. Freedom from PSA/radiographic progression at 1 year was 77% (95% CI, 63–87%), and freedom from PSA progression at 1 year was 81% (95% CI, 67–90%). The PSA₅₀ rate response was 97%. PSA ≤ 0.2 ng/mL at month-7, a surrogate for survival in other mCSPC studies, was 61%; PSA ≤ 4 ng/mL at month-7 was 82%. Outcomes according to mutation status are shown. AEs included 7% grade (Gr)-3/4 myelosuppression, 8% Gr-3/4 infections, 10% Gr-3 GI disorders, and 3% Gr-3 fatigue. There were 4 treatment-related discontinuations. **Conclusions:** Quadruplet therapy with ADT + cabazitaxel/carboplatin + abiraterone was well tolerated. At 1 year, 77% of pts were progression-free. PSA ≤ 0.2 ng/mL at month-7 was 61%, exceeding the historical month-7 PSA ≤ 0.2 ng/mL rate of 45% in CHAARTED-docetaxel arm. Further exploration of this quadruplet strategy in randomized phase III studies is warranted. Clinical trial information: NCT03934840. Research Sponsor: Sanofi-Genzyme.

Enzalutamide, docetaxel and androgen deprivation (ENZADA trial) for metastatic castrate sensitive prostate cancer (mCSPC). *First Author: Earle F Burgess, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: The use of contemporary androgen receptor signaling inhibitors (ARSI) in combination with docetaxel (Doc) and androgen deprivation therapy (ADT) has shown improved outcomes in recent trials. Prostate specific antigen (PSA) serologic complete response (CR) has correlated with improved overall survival (OS) in prior studies. In the E3805 study, the 12-month PSA CR rate was 28% for the ADT + Doc arm. In this study, we hypothesized the combination of androgen deprivation therapy with Doc and enzalutamide (Enz) would improve the 52-week PSA CR rate compared to the historical control with ADT + Doc in newly diagnosed patients with mCSPC. **Methods:** The ENZADA trial is a single institution phase II study in patients with mCSPC. Patients received ADT, Doc 75 mg/m² IV every 3 weeks for up to 6 cycles and Enz 160mg daily until radiographic progression. The primary endpoint was 52-week PSA CR. Secondary endpoints included safety/toxicity, best PSA response, time to castration resistance (TTCR) and overall survival (OS). Patients were stratified by radiographic volume of disease by E3805 criteria. The study was designed with 90% power and 1-sided alpha 0.1 to show an improvement in the 52-week PSA CR from 25% to 45%, with rejection of the null hypothesis if 14 of 39 evaluable subjects achieved a 52-week PSA CR. **Results:** Between Sep 2017 and Aug 2021, 40 subjects were enrolled, and 36 were evaluable for the primary endpoint. At the data cut-off of 9/2/22, median follow up was 42.6 months. Thirty subjects (75%) had high volume disease, and 32 (80%) subjects presented with de novo metastatic disease. Median age was 64.5 years; 65% (N=26) were identified as White and 35% (N=14) were identified as Black or African American (AA). Median pretreatment PSA was 129.5 ng/mL. 67.5% (27/40) of subjects received six cycles of Doc. 10% (4/40) of subjects had Enz dose modifications. 52-week PSA CR occurred in 22/36 (61.1%) patients (P<0.001). 13/23 (56.5%) White subjects and 9/13 (69.2%) Black or African American subjects experienced 52-week PSA CR (P=.50). Median TTCR was not reached; castrate resistance at 2 and 4 years was 62.4% and 53.5%, respectively. Eleven deaths occurred (3/14 Black or AA and 8/26 White); median OS was not reached. OS at 2 and 4 years was 83.2% and 63.1%, respectively. OS at 2 and 4 years was 85.7% and 78.6%, respectively, in Black or AA subjects and 82.4% and 50.9%, respectively, in White subjects (P=.26). Treatment-related Grade 3-5 adverse events occurred in 17/40 (42.5%) patients, including 3 episodes of febrile neutropenia. **Conclusions:** ADT+Doc+Enz improved 52-week PSA CR compared to historical control with ADT+Doc. These results are consistent with the recent ARASENS and PEACE1 studies and support the use of triplicate regimens combining ADT+Doc+ARSI in newly diagnosed mCSPC patients. No detectable difference in outcome by race has been observed to date in the study cohort. Clinical trial information: NCT03246347. The relationship between a priori defined prognostic risk groups and overall survival (OS) in men with metastatic hormone sensitive prostate cancer (mHSPC). *First Author: Susan Halabi, Duke University Medical Center, Durham, NC*

Background: Prior analyses have shown that men who present with high volume (HV) disease and *de novo* metastases have shorter OS compared with other mHSPC subgroups. The objective of this analysis was to determine the prognostic relationship between *a-priori* defined 4-prognostic groups and OS in men with mHSPC and in a subset of trials in patients treated with androgen deprivation therapy (ADT) + docetaxel. This hypothesis was investigated by the STOPCAP M1 collaborators. **Methods:** We obtained individual patient data (IPD) from 13 randomized trials comparing treatment regimens (ADT or ADT + docetaxel in the control or research arms) in mHSPC. OS was defined as the time between date of randomization and date of death/or last follow-up. Patients (pts) were classified into 4 mutually exclusive groups. Poor prognostic risk-group was defined as HV (presence of visceral metastases, and/or >4 bone metastases) or presence of bone metastases beyond pelvic or vertebral bones) plus synchronous diagnosis (SYN); whereas intermediate risk groups were patients with HV and metachronous (MET; intermediate A) or low volume plus SYN (intermediate B); and lastly good risk group had LV plus MET. The proportional hazards model was used to estimate the hazard ratio (HR) and assess the prognostic significance of risk groups in predicting OS adjusting for treatment. **Results:** Of 6041 pts included in this analysis, 60% (3622 pts) had died. Median follow-up time=5-years. Overall 11%, 8%, 47% and 34% were in the good, intermediate A, intermediate B and poor risk groups, respectively and for trials including docetaxel (n=2627 pts) 9%, 5%, 39% and 47% respectively. HRs for risk groups are shown in the table. **Conclusions:** Differences in OS across the risk groups were observed. Further work is needed to investigate if more precise prognostic groups can be defined such as better characterization of patients' groupings of extent of bone metastases and visceral metastases. Clinical trial information: NCT00309985; NCT00268476; NCT00104715; NCT00079001; NCT00002651; NCT00685646. Research Sponsor: Prostate Cancer Foundation.

Prostate-specific antigen value at 3 & 7 months (PSA-3mo, PSA-7mo) and overall survival (OS) in metastatic hormone-sensitive prostate cancer (mHSPC) treated with androgen deprivation (ADT) with or without orteronel (SWOG S1216). *First Author: Mamta Parikh, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Analysis of phase 3 studies of patients (pts) with mHSPC in the era of ADT, including in combination with docetaxel and/or androgen receptor axis targeted therapies have established PSA-7mo as a key prognostic marker. Our objective was to evaluate the association between PSA-3mo, PSA 7-mo and OS measured in the phase 3 S1216 trial in mHSPC comparing ADT + orteronel (treatment arm) vs ADT + bicalutamide (control arm) [NCT01809691]. **Methods:** Pts enrolled in the S1216 trial with available PSA-3mo & PSA-7mo were included in this analysis. PSA responses were defined as complete response (CR) if PSA $\leq$ 0.2 ng/mL, partial response (PR) for PSA $>$ 0.2 and $\leq$ 4ng/mL, and no response (NR) as PSA $>$ 4 ng/mL at month 3 or 7. Landmark OS was measured and Cox regression model applied adjusting for stratification (performance status, extent of disease, early vs late start of treatment, treatment arm). **Results:** 1251 pts were alive and evaluable for PSA-3mo and 1231 pts were evaluable at 7 mo, out of a total of 1279 pts. The median age was 67 (range: 43-92), 10% of patients were black, 96% had a Zubrod performance status of 0-1. Median PSA at baseline was 29 ng/ml (range: 2-6710). Of pts on treatment vs control arm, PSA-3mo CR, PR, and NR occurred in 52% vs 35%; 31% vs 42%, and 17% vs 23%, respectively. Of pts on treatment vs control arm, PSA-7mo CR, PR, and NR occurred in 61% vs 46%, 20% vs 26%, and 19% vs 29%, respectively. CR or PR at either timepoint led to significantly better outcomes than those with NR. No interaction between treatment arm and PSA response was observed in terms of OS. **Conclusions:** PSA-3mo and PSA-7mo are strong prognostic markers for pts with mHSPC. More pts on ADT with orteronel achieved CR at 3 and 7 mo. In addition to its use in counseling patients in the clinic, PSA-3mo and PSA-7mo may be used as parameters for designing future trials in pts with mHSPC, utilizing the next generation of intensification or de-intensification treatment regimens. Clinical trial information: NCT01809691. Research Sponsor: U.S. National Institutes of Health; Millenium Pharmaceuticals (Takeda Oncology Company).

Comparing the efficacy of abiraterone and enzalutamide in United States veterans with metastatic castration-sensitive prostate cancer (mCSPC) by estimating rates of tumor growth (g-rate). *First Author: Harshraj Leuva, University of Nebraska Medical Center, Omaha, NE*

Background: The choice of 1st line novel hormonal therapy in mCSPC is often based on comorbidities/physician preference due to the lack of data comparing abiraterone (Abi) and enzalutamide (Enza) in clinical trials and in real-world settings; especially in Black American (BA) patients. We have developed a novel method to estimate rates of tumor growth (g-rate) and have shown that the g-rate is a robust biomarker of drug efficacy and overall survival in prostate cancer (Wilkerson, 2017; Leuva, 2019). We performed a 1:1 matched analysis to compare Abi and Enza outcomes in 1st line mCSPC, using g-rate and median overall survival (mOS) estimates. **Methods:** All patients with mCSPC diagnosis in national VA Corporate Data Warehouse were eligible for comparison. The cohort date range was from 7/2017 to 6/2022. Drug efficacy was established by estimating g-rates using PSA values while on therapy via the TUMGr package for R. For the matched analyses, we created 1:1 comparison cohorts for Abi and Enza, matched on age ($\pm$ 10 years), race, total number of therapies received ($1\geq 2$), drug start year ($<2020\geq 2020$), PSA at diagnosis ($<20\geq 20$), Gleason score (GS) ($<8\geq 8$), Charlson comorbidity index excluding cancer diagnosis ($<5\geq 5$) and therapy setting (urban/rural). **Results:** We identified a total of 1712 and 464 Veterans with mCSPC who received Abi and Enza as 1st line, with median follow-ups of 19 and 12 mo, respectively. Fewer Veterans and shorter duration of follow up with Enza than Abi reflect Abi's earlier approval in mCSPC. The Abi and Enza cohorts had similar median g-rates 0.000114/d and 0.000110/d, respectively (p=0.76). The mOS was 43 mo for Abi versus not reached (NR) for Enza (p=0.33). Our cohort had 425(25%) and 119(26%) BA veterans who received Abi and Enza, respectively. Compared to Caucasians, mOS was similar with Abi (42.7 vs 41.9 mo, HR=0.96, p=0.6) and Enza (NR, HR=0.85, p=0.4) for BA. In 1:1 matched analysis, the Abi and Enza arms had 391 patients and both had median follow-ups of 13 mo. We did not observe a statistically significant difference in median g-rate and mOS for either the whole matched cohort or BA subgroup when comparing Abi to Enza. The matched cohort had 203 (52%) with GS $\geq$ 8 and 228 (58%) Veterans with PSA $\geq$ 20 at diagnosis; there was no significant mOS difference in these subgroups. **Conclusions:** Real-world data from 2176 Veterans show comparable efficacy for Abi and Enza as 1st line for mCSPC, with similar g-rates and mOS, even when matched on various factors, including comorbidities, and in aggressive/high volume matched cohorts. BA patients also had similar g-rates and mOS. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Differential tumor gene expression profiling of obese and non-obese patients (pts) with prostatic adenocarcinoma (PC). *First Author: Vinay Mathew Thomas, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Increased baseline body mass index (BMI) has been linked to poorer prostate cancer outcomes, including recurrence, reduced quality of life, and mortality (PMID: 21325564, 17211863). Herein, we sought to interrogate and validate the corresponding differences in tumor gene expression profiles of obese (Ob) vs. non-obese (N-Ob) pts with PC. **Methods:** In this IRB-approved retrospective study, eligibility criteria included histologically confirmed PC and available RNA sequencing results from treatment naïve primary prostate tissue from a CLIA-certified lab (either Tempus or Caris Life Sciences). Tempus cohort was used for interrogation and Caris for validation. Pts in each cohort were categorized into two groups: obese (BMI $\geq$ 30) and non-obese (BMI $<$ 30). BMI at the time of diagnosis of PC was used for analysis. The DESeq2 pipeline was used to analyze differentially expressed genes between the groups. The data included the Log2 fold change, Wald-Test p-values, and Benjamini-Hochberg adjusted p-values for each differentially expressed gene. These results were subjected to Gene Set Enrichment software analysis (GSEA) to identify pathways enriched in each cohort. All bioinformatic analysis was undertaken using R v4.2. **Results:** Tempus cohort: n=60 (Ob =22, N-Ob=38); Caris cohort: n=50 (Ob=17, N-Ob=33). Both Tempus and Caris showed that Ob pts had an increased expression of the heme metabolism, androgen response, protein secretion, fatty acid, and bile metabolism pathways. N-Ob pts had a significantly higher expression of genes involved in the inflammation pathways (interferon-alpha & TNF alpha pathways). Normalized enrichment scores are reported in the table. Differential gene set expression analysis in Ob vs. N-Ob pts with PC. **Conclusions:** Our study showed an upregulation of distinct genomic pathways in Ob pts with prostate cancer. For example, Ob pts with PC have tumors that depend more on androgen signaling, and N-Ob pts' tumors express increased inflammatory pathway genes that promote PC growth, invasiveness, and metastasis. After external validation, these hypothesis-generating data may provide the rationale for personalized therapy in men with PC. Research Sponsor: None.

Depth of PSA nadir and subsequent PSA progression-free survival in patients (pts) with high-risk biochemically relapsed prostate cancer: Results from the phase 3 PRESTO study (AFT-19). *First Author: Rahul Raj Aggarwal, University of California, San Francisco, San Francisco, CA*

Background: In the phase 3 PRESTO study, intensified androgen deprivation therapy (ADT) with apalutamide (Apa) with or without abiraterone acetate plus prednisone (AAP), administered for a finite treatment period of 52 weeks, prolonged prostate-specific antigen progression-free survival (PSA PFS) in pts with high-risk biochemically relapsed prostate cancer (BRPC). We evaluated the association between PSA nadir within 3 months of treatment initiation with subsequent PSA PFS in this study. **Methods:** PRESTO is a randomized phase 3, open-label trial in pts with BRPC following radical prostatectomy (RP) and PSA doubling time (PSADT) $\leq$ 9 months, without distant metastases on conventional imaging (NCT03009981). Pts were randomized 1:1:1 to receive a finite 52-week treatment course with ADT, ADT + Apa, or ADT + Apa + AAP, stratified by PSADT ($<$ 3 vs 3–9 months), with post-treatment follow-up. The association between PSA nadir within the first three months on treatment with subsequent PSA PFS was analyzed in a post hoc fashion. **Results:** 504 pts were randomized to ADT alone (N = 167), ADT + Apa (N = 168) or ADT + Apa + AAP (N = 169). 463 pts were evaluable for PSA nadir at 3 months. Across the three treatment arms, a PSA nadir of less than 0.1, between 0.1 – 0.2, and $\geq$ 0.2 ng/mL within the first three months of treatment was observed in 86.3%, 4.4%, and 9.3% of patients, respectively. A PSA nadir of $<$ 0.2 ng/mL was reached within 3 months of treatment initiation in 79.8%, 96.9%, and 95.0% of pts randomized to the ADT, ADT + Apa, and ADT + Apa + AAP arms, respectively. The association between time to PSA nadir and subsequent PSA PFS was -0.30 (standard error = 0.03, Kendall's tau modified for bivariate censoring), and median time to PSA nadir was 2.0 months (interquartile range 1.12 – 4.76 months). Failure to reach a PSA nadir $<$ 0.2 ng/mL within the first three months of treatment was associated with a significantly shorter PSA PFS compared to pts with a PSA nadir $\leq$ 0.1 ng/mL (median PSA PFS of 13.9 vs. 22.8 months from 3 months post-treatment initiation; hazard ratio = 5.60, 95% CI: 3.58 – 8.75, p $<$ 0.0001). There was also a significant difference in PSA PFS in those with a three-month PSA nadir between 0.1 – 0.2 vs $\leq$ 0.1 ng/mL (median PSA PFS 17.4 vs 22.8 months, HR = 2.63, 95% CI: 1.49 – 4.63, p = 0.0008). **Conclusions:** Using a landmark analysis at 3 months, a failure to reach PSA nadir less than 0.1 ng/mL within three months following initiation of ADT in BRPC is associated with shorter time to subsequent progression following treatment discontinuation. Follow-up is ongoing to integrate genomic profiling of primary prostate cancer tissues and whole blood RNA in pts with suboptimal PSA nadir to identify potential markers of relative androgen pathway inhibitor resistance. Clinical trial information: NCT03009981. Research Sponsor: Janssen.

Assessing racial differences in time to treatment escalation following androgen-deprivation therapy among veterans with prostate cancer. *First Author: Nadine Adriana Friedrich, Department of Urology, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles*

Background: Androgen deprivation therapy (ADT) is standard care first-line (1L) systemic treatment for advanced and metastatic prostate cancer (PC). Currently, there are no population-level studies assessing the duration of 1L ADT and time to treatment escalation (chemotherapy [CT], novel hormonal therapy [NHT], or non-steroidal antiandrogen [NSAA]). **Methods:** We performed a retrospective population-level analysis to assess the association between race and time to treatment escalation after ADT in the Veterans Affairs Health Care System. From 2001-2021, 164,477 patients (pt) diagnosed with PC and treated with ADT alone were identified. Baseline demographic and clinical characteristics were sorted by race: Non-Hispanic White (NHW), Non-Hispanic Black (NHB), Hispanic, Other and compared among groups using chi square tests for categorical variables and Kruskal-Wallis tests for continuous variables. The primary outcome was time from ADT to treatment escalation, defined as receipt of NHT, NSAA, or CT. Men with no evidence of treatment escalation were censored at time of death or most recent visit. We estimated 5-year event rates by race using Kaplan-Meier (KM) analyses. Univariable and multivariable Cox proportional hazards models were used to test the association between race and time to treatment escalation with time of ADT as time zero. Multivariable models were adjusted for age, year, time from PC diagnosis to ADT, Charlson Comorbidity Index and BMI at ADT start along with PSA, testosterone level, and receipt of radiation therapy (RT) prior to ADT. **Results:** NHB were youngest ($p < 0.001$), started ADT in more recent years ($p < 0.001$), had the highest pre-ADT PSA ($p < 0.001$) and testosterone levels ($p < 0.001$), the most comorbidities ($p < 0.001$), and the highest rate of RT prior to ADT ($p < 0.001$) relative to other groups. During a median (Q1, Q3) follow-up of 55.2 (25.0, 102.4) months, 31,288 pt (19%) had treatment escalation, of which 12,093 (39%) were NHTs, 14,842 (47%) were NSAAs, 3,895 (12%) were CT and 458 (2%) were other 2nd line therapies. Compared to NHW, NHB had significantly lower rate of treatment escalation in univariable (HR=0.89, 95% CI=0.87-0.92) and multivariable analysis (HR=0.82, 95% CI=0.80-0.84). KM estimates at 5-year for the percent free from escalation was 80.5 (80.2-80.8%) in NHW vs. 83.0 (82.6-83.4%) in NHB. Rate of treatment escalation was similar for Hispanics and other races compared to NHW, with 5-year KM estimates of 81.0 (80.3-81.7%) and 81.0 (80.0-82.0%) for Hispanics and other races, respectively. **Conclusions:** This study assessing racial differences in time to treatment escalation of men receiving 1L ADT found that NHB had a significantly lower rate of treatment escalation. Whether this decreased rate of treatment escalation among NHB men represents improved outcomes (i.e. lower risk of progression) or undertreatment requires further study. Baseline circulating tumor cell (CTC) count as a prognostic marker of overall survival (OS) in metastatic hormone sensitive prostate cancer (mHSPC): Results from SWOG S1216, a phase III randomized trial of androgen deprivation plus orteronel (cyp17 inhibitor) or bicalutamide. *First Author: Amir Goldkorn, Division of Medical Oncology, Department of Medicine, Keck School of Medicine and Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA*

Background: Biomarkers are needed to predict clinical outcomes in mHSPC. We previously reported that baseline CTC counts in S1216 were prognostic of PSA response and disease progression (ASCO 2020; CCR 2021). However, the trial's primary overall survival (OS) endpoint was not yet mature at that time. Here we present the final results of S1216 using all available samples to assess the prognostic value of CTC counts for response, progression, OS, and treatment arm interactions. **Methods:** In S1216, peripheral blood was drawn with informed consent at registration (baseline) and at progression to metastatic castrate resistant prostate cancer (mCRPC). CTCs were enumerated on the FDA-cleared CellSearch platform (Menarini). CTC counts were evaluated for associations with 3 pre-specified trial endpoints: 7-month PSA (7mPSA) ≤ 0.2 ng/ml vs. 0.2-4.0 vs. > 4.0 using a generalized logit model; and progression-free survival (PFS) and OS using Cox regression. **Results:** From 2014 to 2021, 503 evaluable samples were collected at baseline and 93 at progression. Baseline CTC count was ≥ 5 in 11.9% of samples, 1-4 in 19.3%, and 0 in 66.8%. Comparing men with 0 vs. ≥ 5 CTCs at baseline, those with 0 CTCs were significantly more likely to attain a complete PSA response and had significantly lower risk of a PFS event and death after adjusting for clinical covariates (disease burden, bone metastases, age, race, alkaline phosphatase, hemoglobin, PSA, treatment arm). These associations were not modified by treatment arm. Progression CTCs < 5 vs. ≥ 5 also were prognostic of OS (logrank $p = 0.001$), consistent with prior findings in mCRPC. Same-patient CTC counts in matched baseline-progression pairs ($n = 61$) were highly correlated (Spearman $p < 0.001$). **Conclusions:** CTC count at the start of treatment for mHSPC was highly prognostic of PSA response, PFS, and OS; associations that held in both treatment arms. Moreover, baseline CTC count strongly correlated with progression count, suggesting that mild vs. aggressive disease phenotypes may persist from mHSPC to mCRPC. This evidence from a large prospective phase 3 trial suggests that baseline CTC count is a valuable prognostic marker in men initiating therapy for mHSPC, discriminating those likely to experience favorable vs. unfavorable response and OS. Research Sponsor: U.S. National Institutes of Health; Millennium Pharmaceuticals (Takeda Oncology Company).

	Baseline CTCs 0 vs. ≥ 5
Likelihood of 7mPSA ≤ 0.2	OR = 3.85 (95% CI 1.85, 8.33; $p < 0.001$)
Risk of progression	HR = 0.41 (95% CI 0.29, 0.57; $p < 0.0001$)
Risk of death	HR = 0.31 (95% CI 0.21, 0.45; $p < 0.0001$)

Treatment and survival of de novo metastatic hormone sensitive prostate cancer among African American US Veterans. *First Author: Rigoberto De Jesus Pizarro, Washington University School of Medicine, St. Louis, MO*

Background: Combinations of androgen deprivation therapy (ADT) plus docetaxel (DOC) or androgen signaling inhibitors (ASIs: abiraterone, enzalutamide, etc.) have revolutionized treatment of metastatic hormone sensitive prostate cancer (mHSPC), particularly for high volume disease. However, little is known about the use of and outcomes of combination therapy in African Americans (AA) with de novo mHSPC, due to their lack of representation in clinical studies. This study evaluates the patient characteristics, treatment, and survival in a cohort of US veterans with mHSPC with equal access to treatment under the Veterans Affairs Health System (VA). **Methods:** Veterans with mHSPC were identified from 2014-2022 in the VA using the initial pathological diagnosis of prostate cancer with SEER stage 'distant' and first ADT initiated within 1 month prior and 3 months after diagnosis. Therapies including DOC or ASIs were collected if initiated from 1 month prior to 4 months after ADT. Additional information at the time of diagnosis was collected including Prostate Specific Antigen (PSA), race from VA enrollment, and Charlson Comorbidity Index (CCI). Median survival was obtained for each group and stratified by PSA level > 100 ng/mL. Chi-square and ANOVA testing were used to assess differences in survival (OS) were assessed by log-rank testing. **Results:** 4,248 veterans with de novo mHSPC were identified, 1,138 (26.8%) were AA and 3,110 (73.2%) white. Black veterans were younger (70.8 vs. 74.8, $p < 0.001$) and had higher median PSA (183 vs. 86.3, $p < 0.001$) with similar mean CCI (4.4 vs. 4.4, $p = 0.78$). AA veterans were likely to have a PSA > 100 ng/mL at diagnosis (61.6% vs. 46.1%, $p < 0.001$) and to receive combination therapy than white veterans (36.8% vs. 32.7%, $p = 0.01$). The median OS among AA and white veterans was similar (32.5 months vs. 32.1, $p = 0.75$). In 1,210 veterans with PSA > 100 ng/mL (a surrogate for higher volume disease), AA veterans were more likely to receive combination therapy (39.5% vs. 32.9%, $p = 0.003$) without differences in survival in AA veterans compared to white (31.0 vs. 26.9 months, $p = 0.18$). **Conclusions:** In an equal access health care system, AA veterans had similar survival to white veterans despite having double the PSA levels, reflecting higher risk disease. AA presented 4 years younger and are likely treated with doublet therapy. The differences in the age of onset and burden of disease highlight persistent differences in populations with mHSPC. Further investigations to understand environmental, social, and tumor factors are warranted to explain these disparities. Research Sponsor: Department of Defense grant W81XWH-22-1-0602 and a Prostate Cancer Foundation Young Investigator Award.

	2014-2021		2014-2021 PSA > 100 ng/mL

Cost-effectiveness analysis (CEA) of seven treatment regimens in metastatic hormone-sensitive prostate cancer (mHSPC): A public payer perspective using network meta-analysis. *First Author: Manish Kohli, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Recently several new drug treatment regimens have been approved in mHSPC state, building on using androgen deprivation therapy (ADT) alone. These include docetaxel + ADT (DA), Abiraterone Acetate + Prednisone + ADT (AAP), Apalutamide + ADT (AAT), Enzalutamide + ADT (ET), Darolutamide + Docetaxel + ADT (DAD) and AAP + ADT + Docetaxel (AAD). At present, there are no predictive biomarkers for choosing a specific drug regimen over the other. The goal of this study was to conduct an economic evaluation of FDA-approved standard of care drug regimens in the current management of mHSPC state to determine a cost-effective optimal treatment from the US public sector (Veterans Affairs-VA) perspective with a 10-year time horizon. **Methods:** We developed a partitioned survival model in which mHSPC patients (pts) transitioned between three health states (progression free, progressive disease to castrate resistance state, and death) at monthly intervals based on Weibull survival model estimated from published Kaplan-Meier curves using a network meta-analysis. A Bayesian network meta-analysis of seven randomized clinical trials included 7,208 mHSPC pts. The effectiveness outcome in our model was quality-adjusted life-years (QALYs) with utility values obtained from published literature. Costs in our model included those associated with treatment regimens, subsequent therapies, terminal care, and for managing grade 3-4 drug related adverse events. Costs were obtained from the Federal Supply Schedule and published literature. Incremental cost-effectiveness ratios (ICERs) were calculated for nondominated treatments. **Results:** Average 10-year costs ranged from \$32,697 (ADT) to \$649,622 (DAD). Mean QALYs ranged from 3.25 (ADT) to 4.57 (ET). Treatment with DAT, EAD, and DAD were eliminated due to dominance (i.e. they were more costly and less effective than other treatments). AAT was the most cost-effective strategy at a willingness-to-pay threshold of \$100,000/QALY (ICER = \$70,150/QALY). Results from our analysis for all regimens are shown. **Conclusions:** Our CEA simulation model found AAT is an optimal cost-effective first-line treatment strategy in mHSPC state from a public (VA) payer perspective. Research Sponsor: None.

Results from cost-effectiveness analysis of treatment regimens for mHSPC.			
Treatment strategy	Cost (\$)	Effectiveness (QALYs)	ICER(\$/QALY)
Androgen Deprivation Therapy (ADT)	\$32,697	3.25	
Abiraterone Acetate-Prednisone + ADT (AAP)	\$45,512	3.83	\$22,299
Apalutamide + ADT (AAT)	\$68,503	4.16	\$70,150
Enzalutamide + ADT (ET)	\$488,061	4.57	\$1,017,538
Docetaxel + ADT (DA)	\$51,093	3.79	Dominated
Enzalutamide + ADT + Docetaxel (EAD)	\$396,809	3.99	Dominated
Darolutamide + ADT + Docetaxel (DAD)	\$649,622	4.29	Dominated

Landscape and impact of germline pathogenic variants (PVs) in metastatic hormone sensitive prostate cancer (mHSPC): Ancillary study of E3805 CHAARTED. *First Author: Anis Hamid, University of Melbourne, Parkville, Australia*

Background: Enrichment of germline PVs in metastatic castration resistant prostate cancer (mCRPC), compared to localized disease, has directly informed genetic testing guidelines. The prevalence and prognostic/predictive associations of such variants are not well characterized in the mHSPC state, in particular the effect of susceptibility mutations related to DNA damage and repair (DDR) pathways. **Methods:** We performed whole exome sequencing of germline DNA derived from whole blood available from patients (pts) in the phase III CHAARTED trial (NCT00309985) of androgen deprivation therapy (ADT) versus ADT plus docetaxel (ADT+D). After filtering for low coverage, variant annotation and effect prediction, PVs from a curated list of 588 prostate cancer-associated genes were reviewed. The prognostic effect of PVs was evaluated within each treatment arm. Endpoints of time to CRPC (ttCRPC), time to clinical progression (ttClinPD), and overall survival (OS) were estimated by Kaplan-Meier method. Hazard ratios (HRs) and 95% confidence intervals (95% CIs) were estimated by Cox models evaluating association of endpoints with biomarkers/arm. Multivariable analysis adjusted for metastatic timing and volume. **Results:** Of 137 pts, 135 had unique germline exomes that passed downstream analysis. Most pts had synchronous (66.7%) and high-volume (62.2%) disease. This biomarker cohort showed benefit of adding docetaxel to ADT (ttCRPC: HR 0.55, 95% CI 0.37-0.82; OS: HR 0.68, 95% CI 0.44-1.07). In total, 61 PVs were detected; 49 pts (36.3%) harbored at least 1 PV in 41 different genes. The most frequently-mutated gene was *BRCA2* (6.67%). In addition, PVs were found in DDR-associated genes including *PALB2* (1.48%), *CHEK2* (1.48%), *BRCA1* (0.74%) and *PMS2* (0.74%) for an overall prevalence of 11.1% (15/135). Pts with *BRCA2* PV on ADT alone had shorter ttCRPC compared with men without the PV (UVA: HR 2.67, 95% CI 0.93-7.63, log rank p=0.057; MVA: HR 2.59, 95% CI 0.91-7.39, p=0.074). There was no evidence of a difference in the ADT+D arm (UVA: HR 1.00, 95% CI 0.31-3.25, log rank p=0.1). Supportive data was observed for ttClinPD in ADT arm (HR 2.85, 95% CI 1.01-8.08, log rank p=0.04). Metastatic volume and timing were not significantly associated with germline *BRCA1/2* or DDR PVs. **Conclusions:** The prevalence of germline *BRCA1/2* and DDR PVs in mHSPC is similar to mCRPC and *BRCA2* PV may confer worse outcomes on ADT alone. This supports the need for genetic testing at diagnosis of mHSPC. Research Sponsor: U.S. National Institutes of Health.

CABIOS trial: A phase Ib study of cabozantinib and nivolumab in combination with abiraterone in patients (pts) with metastatic hormone sensitive prostate cancer (mHSPC). *First Author: Jesse Meir Zaretsky, Washington University School of Medicine, Department of Medicine, Division of Oncology, St. Louis, MO*

Background: Androgen deprivation therapy (ADT) combined with novel hormonal agents +/- docetaxel is a standard of care treatment for mHSPC. The combination of tyrosine kinase inhibitors (TKI) and immune checkpoint blockade (ICB) is FDA approved in renal cell carcinoma, and shows promising efficacy in preclinical models of prostate cancer by favorably altering the tumor immune microenvironment. There are currently ongoing trials of TKI + ICB in metastatic castration resistant prostate cancer. Here we present interim safety results from an ongoing phase Ib single-arm trial of cabozantinib + nivolumab + abiraterone/prednisone (cabo, nivo, abi/pred) in pts with newly diagnosed mHSPC (NCT04477512). **Methods:** Eligible pts had de-novo or recurrent mHSPC with up to 12 weeks ADT prior to enrollment, ECOG 0-1, and adequate organ function. Prior abi and docetaxel were excluded. Pts received cabo 20 mg or 40 mg daily (3+3 dose escalation in 2 cohorts) combined with nivo 480mg IV q4 weeks, and abi/pred 1,000mg/5mg daily until progression or unacceptable toxicity. The primary endpoint is safety and tolerability. Secondary endpoints include overall response rate (ORR) by RECIST 1.1, overall survival (OS), progression free survival (PFS), and PSA response. Exploratory analyses include CyTOF of peripheral blood and serum cytokine ELISA. **Results:** As of 19DEC2022, 17 pts were enrolled, 3 at 20mg and 14 at 40mg cabo with no dose-limiting toxicity (DLTs) observed. Median age was 65 yrs, 4/17 pts are Black, 11 had de-novo and 6 recurrent disease, with median baseline PSA 78ng/mL. Most had bone (n=16), lymph node (6), or lung (1) mets, and 11 (64.7%) had high-volume disease. With median follow-up 12.8 months, 9 pts (53%) remain on study. 1 withdrew, 3 discontinued due to disease progression (with 1 death), and 4 stopped due to toxicity. Grade $\geq$ 3 adverse events (AEs) include encephalitis (n=1, grade 4 likely nivo-related after 1yr on therapy), diarrhea (n=2), elevated AST/ALT (n=4), wound infection/dehiscence, adrenal insufficiency, hypertension, elevated lipase, and proteinuria (grade 3, n=1 each). No other AEs were reported outside the current safety labels for the study agents. Of 15 response evaluable pts, 7 had RECIST-measurable lesions; 4 had partial response and 3 had stable disease as best response at data cutoff. 9/14 (64.3%) evaluable had PSA <0.2ng/mL at 7 months. Immune correlative studies are ongoing. **Conclusions:** Here we present the initial safety and preliminary efficacy results of the first trial of cabo + nivo in mHSPC patients receiving SOC ADT + abi. To date, the combination has a safety profile consistent with known AEs for these agents, no DLTs, and evidence of clinical benefit. Further follow up will be required to fully assess clinical safety, efficacy and immune responses. Future, larger studies could compare this combination to SOC ADT + abi. Clinical trial information: NCT04477512. Research Sponsor: Exelixis, Bristol-Myers Squibb.

Development and independent validation of a predictive gene expression signature based on RB1, PTEN, and TP53 in patients with metastatic hormone-sensitive metastatic prostate cancer (mHSPC). *First Author: Oscar Reig Torras, Department of Medical Oncology, Hospital Clinic of Barcelona, Barcelona, Spain*

Background: Alterations on the tumor suppressor genes (TSG) RB1, PTEN and TP53 are associated with treatment resistance and aggressive clinical evolution of prostate cancer patients (pts). Here, we developed and validated a TSG gene expression signature in mHSPC pts. **Methods:** This is a multicenter retrospective biomarker study in mHSPC pts. Mutations on TSG were assessed by targeted sequencing, mRNA expression by nCounter platform and protein by IHC in FFPE tumor samples. Expression data of the training cohort were used to establish the cut-off applied to the other cohorts. TSGlow was considered when $\geq$ 2 out of 3 TSG presented low expression and TSGwt in the remaining cases. CHAARTED trial pts with microarray data (Hamid, Ann Oncol, 2021) were analyzed as an independent validation cohort. TSG signature was correlated with castration resistance-free survival (CRPC-FS) (primary endpoint) and overall survival (OS) by Kaplan Meier and multivariate Cox analysis. **Results:** 218 pts were included: 125 treated with ADT + docetaxel (ADT+D) and 93 with ADT. 160 pts from the CHAARTED dataset were analyzed (84 with ADT+D and 76 with ADT). ADT+D pts with available TSG gene expression and targeted sequencing were considered as the training cohort (n=54). Pts with low *PTEN* and *RB1* gene expression had lower IHC expression (p<0.01). Low *PTEN* pts had a higher frequency of *PTEN* mutations (p<0.05). TSGlow (25.9%) pts had a worse CRPC-FS (14.3 vs 21.7 months (m); HR 2.2 (95% CI, 1.1 – 4.4) p=0.022). In the internal validation cohort of ADT+D-treated pts (n=71), TSGlow (9.9%) correlated with a worse CRPC-FS (11.7 vs 20 m, p=0.027) and OS (27.6 vs 58.1 m, p=0.012). TSGlow was independently associated with CRPC-FS (HR 2.7 (95% CI, 1.2 – 6.1) p=0.02) and OS (HR 3.7 (95% CI, 1.3 – 10.1) p=0.012). In the ADT cohort (TSGlow 21.5%), no differences in either CRPC-FS or OS were observed. When analyzed together the ADT+D and ADT cohorts, we observed that TSGwt pts treated with ADT+D had the largest CRPC-FS (21.6 m; p=0.014) and OS (58.1 m; p=0.029), while TSGlow pts receiving ADT+D had a CRPC-FS and OS similar to ADT-treated pts. Similarly, in the CHAARTED dataset, TSGlow (20.2%) pts treated with ADT+D had a worse CRPC-FS (14.8 vs 29.4 m, HR 2.2 (95% CI, 1.1 – 4.3) p=0.023) and OS (32.9 vs 57.4 m, HR 2.2 (95% CI, 1 – 4.5) p=0.04). TSGlow (35.5%) was not predictive of either CRPC-FS or OS in ADT-treated pts. Analyzing together ADT+D and ADT pts, TSGwt pts treated with ADT+D had the best CRPC-FS and OS (p<0.01). **Conclusions:** Our results suggest that a TSGlow expression may predict the lack of benefit to taxanes in mHSPC pts, which may be useful to personalize the treatment. An analysis to inform the timing of docetaxel use leveraging data from the United States Veterans Administration on patients with metastatic castration-sensitive prostate cancer (mCSPC). *First Author: Mengxi Zhou, Columbia University Medical Center, New York, NY*

Background: Every oncologist caring for patients(pts) with a diagnosis of mCSPC at some point finds themselves deciding whether to use docetaxel (DOCE) in 1st line or later, a difficult selection often based on perceived tolerability. In 1st line mCSPC, both novel hormonal therapies (NHTs) and DOCE have been shown effective, with direct comparisons lacking. We conducted the present analysis to help address this issue. **Methods:** All pts with mCSPC diagnosis in the VA Corporate Data Warehouse (CDW) who received either DOCE or NHT (abiraterone or enzalutamide) in the mCSPC setting and the converse after disease progression to castrate-resistant prostate cancer (mCRPC) were eligible for comparison. The cohort date range was from 7/2015 to 6/2022. We then created two arms — DOCE 1st and DOCE later — matched 1:1 exactly for age, race, total lines of therapy received, PSA at diagnosis, Gleason score (GS), Charlson comorbidity index (CI) excluding cancer diagnosis, and rurality. **Results:** 580 pts met study eligibility, with two 147 patient cohorts identified for matched analysis. Median age was 69 (64-73) and 70 (65-73) for the DOCE 1st and DOCE later cohorts, respectively. In both cohorts, 66%/31% were white/black. Starting PSA was <20/ $\geq$ 20 in 36%/64%. 60% had GS $\geq$ 8. CI was <5/ $\geq$ 5 in 80%/20%. 2/ $\geq$ 3 total lines of therapy had been given to 32%/68%. Urban/rural distribution was 74%/26%. Median follow up of 30.2/23.7 months for DOCE 1st/DOCE later, reflects DOCE approval in mCSPC two years before approval of NHTs. Median OS were 37.9/31.6 months for DOCE 1st/DOCE later, [HR 0.65 (0.48-0.89), p=0.012], with HRs when comparing those from each cohort with GS $\geq$ 8 or with starting PSA $\geq$ 20, of 0.7 (0.47-1.05), p=0.018 for GS $\geq$ 8, and 0.48 (0.32-0.73) p=0.001 for starting PSA $\geq$ 20, both in favor of DOCE 1st. Duration of abiraterone treatment was greater in DOCE later with values of 284 (160-460) and 153 (90-286) days, p<0.0001 for DOCE later and DOCE 1st, respectively. Durations of DOCE treatment was statistically insignificant between cohorts at 135 (94-141) and 93 (51-177) days, p=0.35 for DOCE 1st and DOCE later, respectively. Surprisingly, time to mCRPC, defined as time from diagnosis to 1st mCRPC therapy, was longer but not statistically significant for DOCE later than for DOCE 1st, with durations of 23.7 and 20.3 months, respectively, p=0.23. **Conclusions:** Our data in US Veterans suggest the strategy of using DOCE upfront in those with mCSPC followed by a NHT on progression results in superior OS compared with DOCE later in mCRPC, especially in men with PSA $\geq$ 20 as a surrogate for high volume disease. Concordant with data from CHAARTED and STAMPEDE arm C where single agent ADT was the reference and ADT + DOCE emerged as the SOC for high volume or high-risk disease, the 6.3-month survival difference between strategies in this analysis argues for consideration of a prospective comparative study. Androgen-deprivation therapy and risk of dementia in patients with prostate cancer: Clinical outcomes from real-world data. *First Author: Dina Elantably, MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH*

Background: Androgen deprivation therapy (ADT) is the cornerstone for the treatment advanced prostate cancer. However, there has been growing concerns regarding increased risk of dementia with ADT. Previous studies of dementia risk following ADT were controversial and inconclusive. **Methods:** Data was collected from an electronic health record database (TriNetX LLC., Cambridge, MA) which includes over 89 million patients from 56 healthcare systems in the United States. We identified males over the age 50 years who were diagnosed with any stage of prostate cancer between 2005 and 2022. Patients receiving ADT were 1:1 propensity score-matched with non-exposed controls for demographics and risk factors for dementia; diabetes mellitus, hypertension, hyperlipidemia, obesity, depression, cerebrovascular disease, tobacco use, alcohol dependence and benzodiazepine use. Patients with prior dementia, stroke, or TIA were excluded. **Results:** In a cohort of 627,025 men with prostate cancer, 73,933 patients (mean age of 70.8 years) received ADT and 57,005 patients (mean age of 70.4 years) did not. ADT exposure was associated with a diagnosis of dementia (Alzheimer's disease, vascular dementia, or unspecified dementia); HR 1.6; 95% CI (1.49, 1.73). Subgroup analysis by dementia subtype is highlighted in (table). Compared to non-ADT group, exposure to ADT was associated with a statistically higher risk of dementia among whites (78.6% vs. 77.7%, $P < 0.001$), whereas there was no significant difference among African Americans. The risk of dementia with different ADT regimens is shown. **Conclusions:** This is the largest real-world study describing the association between ADT and the risk of dementia, including over 600 thousand prostate cancer patients. The risk of dementia was significantly higher in patients on ADT, with a 60% increased risk. The highest risk was witnessed with GnRH antagonists (degarelix), with a 92% increased risk. Interestingly, the increased risk of dementia in ADT groups was observed only among whites but not in African Americans. Possible causes of this discrepancy include socioeconomic disparities, bias that resulted in underdiagnosis, or biological differences. Research Sponsor: None.

Association between androgen deprivation therapy and the risk of dementia.

The role of volume of disease for treatment selection in patients with metastatic castration sensitive prostate cancer (mCSPC): A living meta-analysis. *First Author: Syed Arsalan Ahmed Naqvi, Mayo Clinic, Phoenix, AZ*

Background: Previous evidence suggests that there may be no additional benefit of triplet therapy in low volume disease based on limited data. Therefore, we investigated the efficacy of triplet therapy as compared to docetaxel (D) and androgen pathway inhibitor (API) doublets by volume of disease using the most up to date results from the ARASENS trial. **Methods:** Phase III randomized controlled trials (RCTs) assessing treatment intensification with API, and/or D in patients with mCSPC were included. Precomputed hazard ratios (HR) with 95% confidence intervals (CI) for OS were pooled using an inverse-variance approach. A DerSimonian-Laird random-effects meta-analysis was conducted to assess the efficacy of triplet therapy compared to D doublet therapy. P-value of interaction was computed to assess difference between high (HV) and low volume (LV) disease subgroups ($P_{int} < 0.1$ - statistical significance). Additionally mixed treatment comparisons were computed using network meta-analysis (NMA) to assess the comparative effectiveness of triplet therapy compared to API doublets by volume of disease. **Results:** Pairwise meta-analysis included a total of 3 RCTs (ARASENS, PEACE-1, ENZAMET) with 2518 patients (HV: 1820; LV: 698) as shown. In patients with HV disease, 385 (43%) and 484 (53%) deaths were observed with triplet therapy, and D doublet, respectively. Triplet therapy significantly improved OS as compared to D doublet in HV (HR: 0.73; 95% CI: 0.64-0.84). In patients with LV disease, 73 (20%) and 94 (28%) deaths were observed with triplet therapy, and D doublet, respectively. Triplet therapy significantly improved OS as compared to D doublet in LV (HR: 0.71; 95% CI: 0.52-0.97). There was no statistically significant interaction by volume of disease for triplet therapy vs. D doublet (P_{int} : 0.86). NMA including 10 clinical trials and over 11500 patients updated as of 13th Feb 2023 showed that in HV mCSPC, triplet therapy was ranked as potentially the most efficacious treatment option and may improve OS compared to API doublet therapy (HR: 0.83; 95% CI: 0.66-1.03). In LV mCSPC, API doublet therapy was ranked as potentially the most efficacious treatment followed by triplet therapy. There was no significant difference between triplet therapy and API doublet therapy (HR: 1.12; 95% CI: 0.74-1.12). **Conclusions:** These results underscore that triplet therapy may be preferred in mCSPC patients with HV disease whereas API doublet therapy may be preferred in LV disease. Research Sponsor: None.

Subgroup	Overall Survival		Anticipated absolute effects	
	Participants (trials)	Hazard ratio (95% CI)	Risk of death with D doublet	Risk difference with triplet therapy
Volume of disease				
High volume	1820 (3 trials)	0.73 (0.64 to 0.84)	530 deaths per 1,000	106 fewer per 1,000; (147 fewer to 60 fewer)
Low volume	698 (3 trials)	0.71 (0.52 to 0.97)	280 deaths per 1,000	72 fewer per 1,000; (123 fewer to 7 fewer)

Phase 2 study of olaparib (without ADT) in men with biochemically recurrent prostate cancer (BCR) after prostatectomy. *First Author: Catherine Handy Marshall, Johns Hopkins University, Baltimore, MD*

Background: The natural history of BCR after prostatectomy is variable and current treatment approaches include observation, salvage radiation, or androgen deprivation therapy (ADT), although many men wish to defer such therapy. We hypothesized that olaparib, now approved for use in certain men with metastatic castration resistant prostate cancer, might be an alternative option for men with high-risk BCR. **Methods:** This was a single arm, phase 2 trial (NCT03047135) conducted at 4 US sites. Subjects with biochemically recurrent (MO) prostate cancer, post prostatectomy, with a PSA doubling time of ≤ 6 months and an absolute PSA of ≥ 1.0 ng/mL were eligible. Patients were NOT selected based on the presence of homologous recombination repair (HRR) mutations. 51 patients were treated with olaparib 300mg twice per day, until radiographic or symptomatic progression, PSA doubling from baseline value, or drug-related toxicity. The primary endpoint was PSA50 response (50% PSA decline from baseline). Secondary endpoint was PSA progression free survival (PFS). Patients were required to undergo tissue-based next generation sequencing on the radical prostatectomy specimen to determine the presence of mutations in HRR genes (*ATM*, *BARD1*, *BRCA1/2*, *BRIP1*, *CDK12*, *CHEK1/2*, *FANCA/E/L*, *PALB2*, *AD51B/C/D*). A prespecified endpoint was to assess PSA responses in HRR[+] and HRR[-] cohorts separately. **Results:** Mean age was 64 years (SD 7), and 92% (47/51) of patients were White. Mean baseline PSA doubling time was 2.9 (SD 1.5) months. 55% (28/51) of pts had Gleason 6-7, 14% (7/51) had Gleason 8, and 31% (16/51) had Gleason 9-10. 86% (44/51) of patients had previously received salvage radiation. 27 patients harbored HRR mutations, the most common of which were *BRCA2* (n=11), *CHEK2* (n=6), and *ATM* (n=6). The overall PSA50 response rate was 24% (12 of 51) (95% CI 0.13, 0.38), with no responses in the HRR[-] group and 44% (12/27) PSA50 responses in the HRR[+] group (95%CI 0.26, 0.65). All 11 of the participants with a *BRCA2* mutation achieved a PSA50 response. The median PSA PFS was 22 months in the HRR[+] group and 13 months in the HRR[-] group (HR 0.71; 95% CI 0.31, 1.63). Most AEs were low grade. The most common all-grade AEs were fatigue, nausea, leukopenia, anemia, and dysgeusia. Grade-3 AEs were leukopenia (9.8%), ALT/AST increase (3.9%), and anemia (2.0%). There were no grade 4-5 AEs. **Conclusions:** Olaparib, in the absence of ADT, can be safely administered and demonstrated activity in men with BCR prostate cancer and HRR mutations, especially for *BRCA2* mutations. Additional studies to further evaluate olaparib in these patients are indicated. Clinical trial information: NCT03047135. Research Sponsor: Astra Zeneca; U.S. National Institutes of Health.

Early findings from the GARUDA trial: The impact of a genetic signature of late radiation toxicity on prostate cancer treatment decision making. *First Author: Joanne B. Weidhaas, UCLA Radiation Oncology, Los Angeles, CA*

Background: GARUDA (Germline DNA-Based Radiosensitivity Biomarker Influence on Toxicity Following Prostate Radiotherapy) was a single center phase II prospective study evaluating the impact of sharing results from a germline genetic signature (PROSTOX) characterizing patients as having a low or high risk of developing late > 2 genitourinary (GU) toxicity from stereotactic body radiation therapy (SBRT) on decision making and toxicity. The goal of this early analysis was first to see if this information changed treatment choice, and second to see if patients categorized as genetically "low-risk" would have less late GU toxicity than those categorized as genetically "high-risk." **Methods:** PROSTOX is a test of germline mutations run in the MiradX CLIA-certified laboratory. Results were reported to the ordering physician and their patient for joint decision-making before proceeding with treatment selection. To be enrolled on the study patients could choose SBRT or moderately hypofractionated radiation therapy (MHFRT) for treatment of their prostate cancer. 279 men were screened for the GARUDA study between November 2020 and May of 2022. 71 withdrew for a variety of reasons, primarily choosing another location for treatment or form of treatment. 208 patients remained on the protocol and are included in this exploratory analysis. Statistical comparisons of stratified proportions are based on Gaussian approximations to Binomial probabilities. **Results:** The average age for the cohort was 72.12 with the majority being non-Hispanic and Caucasian. Overall, 85.15% (177) of patients were classified as low-risk and 14.9% of patients (31) were classified as high-risk for late grade > 2 GU toxicity by PROSTOX. There was not a significant difference in predicted toxicity risk by age (72.45 vs 70.2), ethnicity or race. Regarding treatment choice based on toxicity score, in patients determined to be low-risk, 1.2% chose MHFRT, and 98.8% chose MRI- or CT-guided SBRT. In patients who were classified as high-risk, 44.8% chose MHFRT, and 55.2% chose MRI- or CT-guided SBRT. The difference in treatment choice was significant ($p < 0.001$). In an early analysis of physician scored late > 2 GU toxicity in patients with > 18 months of follow-up (n = 57), 8.8% of patients had toxicity - 4.8% of those predicted to be low-risk, and 27.3% of those predicted to be high-risk ($p = 0.015$). **Conclusions:** In this exploratory analysis, predicting toxicity risk with PROSTOX significantly impacted patient and physician radiation treatment choice in localized prostate cancer. Early results also suggest that these changed treatment decisions lowered overall toxicity, which remained significantly different between patients classified as low-risk and high-risk. Analysis is ongoing to include patient reported outcomes and toxicity rates depending on treatment choice for those identified as high-risk. Clinical trial information: NCT04624256. Research Sponsor: U.S. National Institutes of Health.

Pre-surgical ⁶⁸Ga-PSMA-11 PET for biochemical recurrence risk assessment: A surrogate of pelvic lymph node dissection? Follow-up analysis of a multicenter prospective phase 3 imaging trial. *First Author: Loic Djaïleb, UCLA Ahmanson Translational Therapeutics Division, LOS Angeles, CA*

Background: To compare the prognostic value of presurgical PSMA-PET and pelvic lymph nodes invasion (pN1) for biochemical recurrence (BCR) free-survival (FS) in patients with intermediate-risk to high-risk prostate cancer (PCa) treated with radical prostatectomy (RP) and pelvic lymph node dissection. **Methods:** This is a follow-up study of the surgery cohort included in the multicenter prospective phase 3 imaging trial (n=277; NCT03368547, NCT02611882, NCT02919111). Each ⁶⁸Ga-PSMA-11-PET scan was read by three blinded independent readers. Local histopathology risk score (CAPRA-S (Cancer of the Prostate Risk Assessment) score without pN data), PSMA-PET extra-prostatic disease (N1/M1), and pN were used to assess risk of BCR. Patients were followed up after RP by the local investigators using electronic medical records. BCR was defined by a prostate-specific antigen (PSA) level ≥ 0.2 ng/ml after RP or an initiation of PCa specific secondary treatment (>6 months after surgery). Univariate, multivariate Cox model, and c-statistic index were performed to assess the prognostic value of PSMA-PET, LNI and its added value to Local histopathology risk score. **Results:** From December 2015 to December 2019, 277 patients underwent surgery after PSMA-PET. Clinical follow-up was obtained in 240/277(87%) patients. Median follow-up from surgery was 32.4 (IQR 23.3-42.9) months. Ninety-one/240 BCR events (38%) were observed. PSMA-PET N1/M1 and pN1 were found in 41/240 (17%) and 67/240 (28%) patients respectively. Local histopathology risk score, PSMA-PET and pN were significant univariate predictors of BCR. Only Local histopathology risk score and PSMA-PET were significant in multivariate analysis (HR [95% CI] 1.4 (1.2-1.5) $p < 0.0001$ and (1.7 (1-2.9) $p = 0.03$). Prognostic value of model combining local histopathology and PSMA-PET was not significantly different than model combining local histopathology and pN (c-statistic 0.74 (0.69-0.79) vs 0.73 (0.68-0.78); $p = 0.69$). In patient group with low-risk Local histopathology score and PSMA-PET NO-M0 only 4/109 (5%) were pN1. In patients with high-risk local histopathology score, a PSMA-PET N1/M1 was associated with a significant lower BCR-FS than a PSMA-PET NO-M0 (median survival (95% CI) 32.7 (14.9-NR) vs 8 (3.2-15.5) $p = 0.001$). pN1 was found in respectively 25/34 (74%) and 34/90 (38%). **Conclusions:** Combination of pre-surgical PSMA-PET and Local histopathology was not statistically different than the reference standard, i.e. local histopathology and pN to predict BCR-FS. Interestingly rate of discrepancy with pN was low among patient with low histopathology risk and PSMA-PET (NO-M0) and patient with high histopathology risk and PSMA-PET (N1/M1). Clinical trial information: NCT03368547. Research Sponsor: None.

Socio-demographic, clinical, and genetic predictors of low versus high Gleason score among men with prostate cancer in the Detroit Research on Cancer Survivorship (ROCS) cohort. *First Author: Samantha Goodenow, Wayne State University School of Medicine, Detroit, MI*

Background: Black men with prostate cancer typically present with a higher Gleason Score (GS) and more aggressive disease than White men. The purpose of this project is to describe the relationship between socio-demographic, clinical and genomic variability with GS categories among 599 men with prostate cancer in the Detroit Research on Cancer Survivorship (ROCS) cohort. **Methods:** Detroit ROCS is a cohort of Black cancer survivors based in the Detroit Metropolitan area. Patient data was obtained from a self-administered questionnaire, cancer registry and biologic samples were collected through at home phlebotomy or mailed saliva kits. The primary analysis focused on clinical and genetic differences between men with GS ≤ 6 vs. ≥ 7 . Germline data was compiled into the multi-ethnic genotyping array (MEGA) data panel and 21 genes were chosen for analysis (2,393 SNPs) based on their clinical applicability. Eight tools were used in ANNOtate VARIation (ANNOVAR) to determine whether a genetic variant was pathogenic. The determination of pathogenicity was defined by at least seven of the tools indicating variant pathogenicity. We assessed the rate of pathogenic variants for each GS category. Multivariable models of predictors of GS categories were conducted using logistic regression. **Results:** The categories across GS in the ROCS cohort included: ≤ 6 (21.2%), 3+4 (40.4%), 4+3 (20.2%) and ≥ 8 (18.2%). Variables associated with increased GS (≥ 7 vs. ≤ 6) included age (for each 10-year increase the OR was 1.71, 95% CI 1.26-2.34) and body mass index (for each 5 unit increase the OR was 1.27, 95% CI 1.06-1.54). Higher vs. lower education (some college education or higher vs less than or equal to a high school education) was associated with lower GS, OR 0.58, 95% CI 0.37-0.96. Out of a total of 2,393 SNPs analyzed, 880 (36.8%) were polymorphic, of which 684 had a minor allele frequency (MAF) >0.001 , and 282 had a MAF >0.05 . Overall, 16.2% of the men were carriers of a pathogenic variant, the most common of which were *ATR* (9.3%), *FANCL* (3.5%), and *ATM* (1.7). Men with GS 6 had a lower rate of pathogenic variants (8.7%), than those with GS 3+4 (18.2%), GS 4+3 (16.5%), and GS 8 (20.2%). Men with a pathogenic variant in *ATR* were 2.87 (95% CI 1.08- 7.65) times more likely to have GS ≥ 7 vs. ≤ 6 . Higher GS was specifically associated with SNP rs33972295 in the *ATR* gene. **Conclusions:** The relationship between older age, higher BMI, and less educational background suggests that socio-demographic risk factors should be accounted for when assessing risk for higher grade prostate cancer. Identification of genomic differences associated with aggressive prostate cancer may provide insight into new targeted therapy options. Research Sponsor: None.

PSMA PET findings in an “EMBARC-like” cohort of patients with high-risk non-metastatic hormone-sensitive prostate cancer: A single center post-hoc retrospective analysis. *First Author: Wesley Robert Armstrong, UCLA-Caltech Medical Scientist Training Program, Los Angeles*

Background: The EMBARK trial is a phase 3, randomized, study evaluating use of enzalutamide with or without concomitant leuprolide in non-metastatic castrate sensitive prostate cancer patients. Eligibility status for the trial relied upon conventional imaging which under detects metastatic disease in comparison to PSMA-PET imaging. The aim of this post-hoc retrospective analysis was to describe the PSMA-PET findings in a patient population representative of the EMBARK trial. **Methods:** This was a post-hoc, retrospective analysis of 5 prospective studies of PSMA PET conducted at UCLA from 2016 to 2021 that included patients with recurrent PCa following RP, RT or SRT. Patients were included if they met eligibility for enrollment in the EMBARK trial at the time of their PSMA scan defined as the following: Rising PSA at a level above 1.0ng/mL (post RP and SRT) or 2.0ng/mL $>$ nadir (post-RT), PSA doubling time ≤ 9 months, Serum testosterone ≥ 150 ng/dL. Exclusion criteria constituted: distant metastatic disease as assessed by radiographic imaging, prior hormonal therapy or systemic therapy for prostate cancer. PSMA PET findings (PROMISE mITNM stage, number of lesions) were collected from the clinical imaging reports. Descriptive statistics were used (median, range). **Results:** From 2002 patients screened, 146 patients were included in the analysis. Median time from primary therapy to PSMA PET was 39 (2.1-261) months. Median pre-scan PSA levels and PSA doubling time in patients who underwent RP (n=85), dRT (n=22), post-RP SRT (n=39) and overall (n=146) were 2.4 ng/mL (1-72.1), 8.3 ng/mL (2.37-202), 2.58 ng/mL (1.1-32.3), 2.7 ng/mL (1-202), and 3.5 months (1-9), 3.3 months (1-9), 4.4 months (1-9), 3.7 (1-9) months, respectively. PSMA-PET was positive in 80%, 41%, 85%, 83% of the RP, dRT, RP + SRT and overall populations, respectively. Poly-metastatic disease (≥ 5 lesions) was found in 19%, 32%, 21% and 21% of cases, respectively. PSMA-PET detected disease only localized to the prostate fossa (miT+NOMO) in 7%, 32%, 0% and 9% respectively. PSMA-PET detected pelvic nodal disease (miTxN1M0) in 40% 18% 28% and 34% respectively. PSMA PET detected any distant metastatic disease (miTxNxM1) in 33%, 41% 56% and 40% respectively. PSMA-PET detected metastatic nodal only disease (N1 and/or M1a) in 58% 32% 74% and 39% and osseous disease (M1b) in 19% 23% 31% and 23% cases respectively. **Conclusions:** In this “EMBARC-like” cohort of patients with high-risk nmCS PCa and PSA DT < 9 months, PSMA PET was positive in 83% of patients, detected M1 disease in 40% of patients and over one-fifth of cases presented with 5 or more lesions. PSMA-PET provides novel additional risk stratification for patients with high-risk nmCS PCa without distant metastasis based on conventional imaging. Further studies are needed to assess its independent prognostic value and use for treatment guidance. Clinical trial information: NCT03582774. Research Sponsor: None.

Racial differences in the utilization of MRI-guided biopsy before prostate cancer diagnosis. *First Author: Grace L. Lu-Yao, Division of Population Science, Department of Medical Oncology, Sidney Kimmel Medical College, Sidney Kimmel Cancer Center at Jefferson Health, Philadelphia, PA*

Background: Most low-risk prostate cancer (PCa) patients undergo active surveillance (AS). Compared with Whites, Blacks are more likely to opt for AS and suffer a higher risk of cancer progression while on AS. A primary concern of AS is the likelihood of missing clinically significant cancer. Transrectal ultrasound-guided biopsy is the most common method for diagnosing and grading PCa; however, this method often misses anterior PCa. Magnetic resonance imaging (MRI) allows clinicians to identify better and detect PCa; however, current guidelines on MRI-guided biopsy (MRI-GB) are inconsistent. This population-based study aimed to examine the utilization of MRI-GB 6 months before PCA diagnosis over time by race in the US. **Methods:** We used SEER-Medicare data to identify men diagnosed with PCa between January 1, 2012, to December 31, 2017, and excluded patients missing the date of diagnosis, being diagnosed at death, enrolled in HMO, or having no continuous A and B coverage six months before diagnosis. We used the CPT codes to identify prostate biopsy and MRI use. Multivariable logistic regression was used to evaluate racial disparity in MRI use six months before PCa. The model included covariates age, race, SEER region, marital status, state buy-in for Medicare (a poverty indicator), education, income, Charlson comorbidity index, and procedure (MRI) year. **Results:** Among 38,612 eligible men, MRI use six months before PCa diagnosis increased from 2012 to 2017 (3.2% to 24.3% among Whites, 1.8% to 14.2% among Blacks). Compared with Whites, Blacks were 38% less likely to receive pre-diagnosis MRI (OR=0.62, 95% CI 0.52-0.74). Besides race, having state buy-in for Medicare (OR=0.44; 95% CI 0.30-0.65) and geographic regions (Central vs. West OR=0.40; 95% CI 0.34-0.45) were strong predictors of lower utilization of MRI. **Conclusions:** The gap in the utilization of MRI may exacerbate racial disparities in PCa. Future studies are needed to identify potential barriers to adopting MRI for PCa workups. Research Sponsor: U.S. National Institutes of Health; Pennsylvania Department of Health.

Basal-luminal subtyping of localized high-risk prostate cancer and benefit of adding docetaxel to definitive radiotherapy with androgen suppression in the NRG Oncology/RTOG 0521 phase III trial. *First Author: Ryan Phillips, Mayo Clinic, Rochester, MN*

Background: In prior studies, basal vs. luminal differentiation portends differential response to a) androgen suppression (AS) duration for high-risk prostate cancer (PCa) (NRG-GU-TS006) and b) docetaxel chemotherapy (CT) and AS for metastatic hormone-sensitive disease (CHAARTED). In NRG-GU-TS006, basal tumors appeared to benefit the most from longer duration of AS while those with luminal subtype did not whereas, in CHAARTED, luminal subtype had greater benefit from addition of CT. Herein, we examined basal-luminal subtyping to predict differential response to the addition of CT in the setting of high-risk PCa treated with AS and definitive radiotherapy (AS + RT) in NRG/RTOG 0521. **Methods:** Per pre-specified and approved NCI analysis plan (Navigator #1061), we obtained available NRG biobank biopsy specimens from patients enrolled on the NRG/RTOG 0521 phase III trial, which randomized patients to AS + RT +/- CT. The highest-grade tumors were profiled on clinical-grade whole-transcriptome arrays (Veracyte, San Diego, CA). Basal-luminal subtypes were generated using a 215-gene PCa subtyping classifier (PSC), a second generation PAM50 basal-luminal model. Treatment effects in Luminal Proliferating (LP) and non-LP subtypes were examined with Cox (for overall survival, OS, and metastasis-free survival, MFS) and Fine & Gray (for distant metastasis, DM) multivariable (MVA) models adjusted for age and trial risk stratification, as well as with restricted mean survival times (RMST). **Results:** Of 183 samples available for analysis (91 from control and 92 from the CT arm), 52 (28%) were classified as LP subtype. Median follow-up for OS was 9.9 years. No significant differences in clinical or pathological variables were observed between LP and non-LP subtypes. In MVA, we did not detect any significant LP subtype-by-CT treatment interaction but observed evidence of non-proportional hazards (Grambsch-Therneau test, $p < 0.05$). In unselected patients, 5- and 10-year RMST difference between the arms was 0.9 (95% CI [-1.5, 3.4], $p = 0.46$) and 5.7 (95% CI [-2.5, 13.9], $p = 0.17$) months of OS. Stratifying by tumor subtype, at 5 years the RMST difference in months was 3.8 (95% CI [0.3, 7.2], $p = 0.03$) for LP and -0.2 ([-3.4, 2.9], $p = 0.89$) for non-LP. The RMST difference in months at 10-years was 13.7 (95% CI [-0.2, 27.5], $p = 0.053$) for LP and 2.5 ([-7.6, 12.5], $p = 0.63$) for non-LP. **Conclusions:** In pre-treatment biopsy samples from a Phase 3 trial cohort of localized high-risk men, luminal-basal subtyping of tumors demonstrated differential response to docetaxel CT. Similar to results from the CHAARTED trial of metastatic disease, LP tumors may derive greater benefit from addition of CT. Validation of these findings may enable effective earlier use of CT in men with PCa. Research Sponsor: U.S. National Institutes of Health; Sanofi.

Poster Session

Post radical prostatectomy (RP) PSA outcomes following 6 vs 18 months of perioperative androgen deprivation therapy (ADT) in men with localized high risk prostate cancer (LHRPC): Results of Part 2 of a randomized phase 2 trial. *First Author: Rana R. McKay, University of California San Diego, La Jolla, CA*

Background: Patients with LHRPC have an increased risk of relapse following RP. We previously reported on Part 1 of a phase 2 trial testing neoadjuvant apalutamide, leuprolide, and abiraterone acetate plus prednisone (ALAAP) or leuprolide and abiraterone plus prednisone (LAP) for 6 months followed by RP (McKay, J Urol, 2021). We demonstrated favorable pathologic responses (tumor < 5 mm) at RP in 20.3% of patients ($n = 24/118$). Herein, we report the results of Part 2 testing adjuvant ALAAP (NCT02903368). **Methods:** Eligible patients had a Gleason score $\geq 4+3$, PSA > 20 ng/mL, or T3 disease (by DRE or MRI) and lymph nodes < 20 mm. At Part 2, patients were randomized 1:1 to ALAAP for 12 months (Arm 2A) or observation (Arm 2B), stratified by neoadjuvant therapy and pathologic T stage ($< y pT3$ or $\geq y pT3$). The primary endpoint was biochemical progression-free survival (bPFS) at 3 years post-RP. bPFS was defined as the time from randomization to progression (PSA ≥ 0.2 ng/mL, local/distant disease on CT/MRI or bone scan, or receipt of post-RP therapy or radiation for rising PSA) or death. The Kaplan-Meier estimate of bPFS at 3 years was compared between arms using a Chi-square test (Klein, Stat Med, 2007). Secondary endpoints included safety and time to testosterone recovery (> 200 ng/dL). **Results:** Overall, 82/118 (69%) of patients enrolled to Part 1 were randomized to Part 2. Median follow-up was 47 months post-RP. Patient preference was the main reason for non-randomization in Part 2. In the intent-to-treat analysis, the 3-year bPFS estimate was 80% (95% CI: 65-90%) for Arm 2A and 72% (95% CI: 56-84%) for Arm 2B, which was not statistically significant (2-sided $p = 0.39$). Patients who achieved pathologic responses ($n = 14$) had longer bPFS than non-responders (log-rank test 2-sided $p = 0.03$; 3-year bPFS 100% vs 72%). In per-protocol population, of 36 patients receiving Arm 2A treatment with available data, 83% had testosterone recovery and median time to recovery from therapy end was 8.7 months. For patients on observation ($n = 42$), 95% had testosterone recovery, and median time to recovery from RP was 4.0 months. No new safety signals were observed. **Conclusions:** Neoadjuvant ADT in LHRPC resulted in favorable pathologic responses and 3-year bPFS in a subset of patients. As 30% of patients declined an additional 12 months of adjuvant treatment, the study was underpowered to detect a difference between 6 months vs. 18 months of treatment. Subsequent analyses will evaluate predictors of improved bPFS. Clinical trial information: NCT02903368. Research Sponsor: Investigator initiated study funded by Janssen.; Prostate Cancer Foundation.

Testosterone recovery following androgen suppression and prostate radiotherapy (TRANSPORT): Updated individual patient data meta-analyses from the MARCAP consortium. *First Author: Wee Loon Ong, Odette Cancer Centre, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada*

Background: Time to testosterone recovery (TR) following androgen deprivation therapy (ADT) and radiotherapy for prostate cancer varies following cessation of ADT. We aimed to quantify the association between time to TR and duration of ADT and patient age. **Methods:** We identified prospective randomized trials of prostate radiotherapy and ADT in the Meta-Analysis of Randomized trials in Cancer of the Prostate (MARCAP) consortium for which prospectively collected serial testosterone values were available. The time to non-castrate TR (NCTR) (> 1.7 ng/mL), non-hypogonadal TR (NHTR) (> 8.0 ng/mL) and full TR (FTR) (> 10.5 ng/mL) were estimated from the end date of prescribed ADT using the Kaplan Meier method. Cox regression was used to evaluate the differences in time to TR for men aged < 65 years and ≥ 65 years for each duration of ADT. Interaction effects between ADT duration and patient age on TR were evaluated. **Results:** 2628 men from 5 trials (TROG 9601, TROG 0304, PCSIII, PCSIV, and Ottawa-01) met the inclusion criteria for analysis. Of these, 236, 1485, 731, and 176 men had 3-, 6-, 18-, and 36-months of ADT respectively. 1502 (57%) men had baseline (pre-ADT) testosterone data available, of which 99% (1494/1502) had non-castrate testosterone (> 1.7 ng/mL), and 78% (1178/1502) had normal testosterone (> 10.5 ng/mL) at baseline. At last follow-up, there were 96% (2522/2628), 77% (2035/2628) and 65% (1700/2628) of men who had NCTR, NHTR and FTR respectively. The median time (range) to NCTR was 1.9 (0.2-60), 6.2 (0.0-92), 6.3 (0.0-92), and 15.7 (0.1-75) months for men who had 3-, 6-, 18- and 36-months of ADT, respectively. The median time (range) to NHTR was 2.5 (0.4-73), 11.2 (0.1-93), 17.7 (0.2-92), and 53.4 (5.3-76) months for men who had 3-, 6-, 18- and 36-months of ADT, respectively. The median time (range) to FTR was 5.8 (0.4-72), 16.7 (0.3-95), and 26.0 (0.2-90) for men who had 3-, 6-, and 18-months of ADT, respectively, while the median time to FTR was not reached in men who had 36-months of ADT. In men who had 6-months of ADT, men aged ≥ 65 years were 35% (95% CI=26-43%) less likely to have FTR compared to men aged < 65 years, while for those who had 18-months of ADT, men aged ≥ 65 years were 52% (95% CI=41-60%) less likely to have FTR compared to men aged < 65 years. There was no statistically significant interaction between the effect of ADT duration and age on the time to FTR (interaction $P = 0.07$ for the entire cohort). **Conclusions:** In this updated individual patient-data meta-analysis of prospectively collected serial testosterone data from 5 randomized trials, substantial delay in FTR in men who had longer duration of ADT was observed, consistent with prior analyses. Approximately 1-in-3 men did not have FTR, which may have life-long impacts on their quality of life. Research Sponsor: RANZCR-TROG Research Grant.

Comparative real-world (RW) evidence on darolutamide (Daro), enzalutamide (Enza), and apalutamide (Apa) for patients (Pts) with nonmetastatic castration-resistant prostate cancer (nmCRPC) in the United States: DEAR. *First Author: Alicia K. Morgans, Dana-Farber Cancer Institute, Boston, MA*

Background: Novel androgen receptor inhibitors (ARIs) are recommended for pts with nmCRPC. Daro has a distinct structure with low blood-brain barrier penetration which may lead to a lower risk of central nervous system-related adverse events (AEs) and minimal risk of AEs commonly associated with ARIs. DEAR is the first study comparing RW utilization, outcomes, and AEs between daro and enza/apa in nmCRPC pts. **Methods:** This retrospective chart review cohort study uses electronic medical records from the PPS network of US urology practices. Eligible pts had nmCRPC, no prior novel hormonal therapy, and initiated first ARI treatment (index date) between 8/2019-3/2022. We describe the % of pts who discontinued initial ARI treatment (DISC), % who progressed to metastasis (PROG), and % with AEs. A comparative analysis was performed between daro and enza/apa using Cox proportional hazards models for time to DISC/time to PROG, adjusting for observed baseline (BL) factors. **Results:** 870 pts were included (daro/enza/apa, $n = 362/382/126$). Median age (80/79/80 y), median BL prostate-specific antigen (PSA) doubling time (6.8/6.4/7.4 mo), other BL characteristics, and median follow-up (22.2/22.7/23.3 mo) were similar for daro/enza/apa. A lower % of pts had a DISC event on daro vs enza/apa (30.4 vs 40.8/46.0) or a PROG event (17.7 vs 28.3/27.8) during the study period. Multivariate analyses adjusting for BL factors showed that pts on daro had a lower risk of DISC and PROG over time vs enza/apa. A lower % of pts on daro had AEs vs enza/apa (24.9 vs 29.3/30.2). **Conclusions:** Overall, a lower % of pts discontinued initial ARI treatment, progressed to metastasis, or had AEs on daro vs enza/apa. In analyses adjusting for observed BL factors, pts on daro had considerably lower risk of DISC and PROG vs enza/apa. This study confirms daro's strong efficacy and favorable tolerability profile in a RW setting. The longer treatment duration seen with daro may be associated with a lower risk of progression to mCRPC vs enza/apa. Research Sponsor: Bayer AG.

Outcomes.

Adjusted Cox proportional hazards model, ^a HR (95% CI)	Daro (n=328) vs Enza (n=341)	Daro (n=328) vs Apa (n=122)
Time to DISC ^b	0.73 (0.56-0.94)	0.61 (0.44-0.85)
Time to PROG ^c	0.59 (0.43-0.82)	0.65 (0.42-0.99)

^aAdjusted for age at index, race, insurance coverage, index yr, BL PSA, BL PSA doubling time, time from CRPC to index date, and Gleason score. ^bDISC was defined as occurrence of any of the following: initial ARI treatment stop/switch to another ARI/death. ^cPROG was defined as evidence of bone, visceral/soft tissue, or distant nodal metastases, such as secondary neoplasm diagnosis codes or codes associated with a PC-related claim, manual data entry in patient charts, and/or initiation of mCRPC treatment (abiraterone, sipuleucel-T, docetaxel, cabazitaxel, mitoxantrone, or radium-223).

Whole-food plant-based diet (WFPBD) to control weight and metabo-inflammation in overweight/obese men with prostate cancer (PC) receiving androgen deprivation therapy (ADT): A multi-center randomized control trial.

First Author: Nicole Jacobs, Weill Cornell Medicine, New York, NY

Background: Obesity promotes a chronic inflammatory state that is associated with PC progression. ADT can cause significant side effects including weight gain, accumulation of body fat, insulin resistance, and an increased risk of diabetes and cardiovascular disease. A WFPBD has been shown to promote weight loss, decrease chronic inflammation, and shift gut microbial profiles to a microbiome that promotes insulin sensitivity. We hypothesize that a WFPBD and behavior intervention will promote weight loss and a reduction in adiposity in overweight/obese patients with PC on ADT and will decrease biomarkers of metabo-inflammation; and that a WFPBD, which is enriched in fiber, will modulate the fecal microbiota and metabolites, and alter study participants' serum metabolome. Correlative studies will offer insight into the impact of nutrition on metabolic pathways that are known to be affected by PC, ADT and/or excess body fat, including steroid metabolism, ketogenesis, and fatty acid metabolism. **Methods:** Key eligibility criteria include pts with PC with a BMI ≥ 27 receiving ADT with an LHRH/GnRH analogue for >24 weeks pre-study (+ androgen receptor pathway inhibitor for >3 mos) with anticipation of >26 more weeks of ADT. 60 patients randomized 1:1 between two cohorts. Cohort 1: pts receive 12 prepared meals (provided by *Plantable*) per weeks 1-4 and 6 meals weeks 5-8 plus *Plantable* coaching, nutritional counseling and education to assist in self-prepping plant-based meals (weeks 9-26); Cohort 2 (control): pts receive general nutritional counseling from a Registered Dietician weekly for 8 weeks, then monthly x 4. Collection of baseline and serial measurements (pre-intervention, weeks 4, 8 and 26) including weight, serum carotenoid levels (to monitor dietary compliance), dual energy x-ray absorptiometry (DXA) scans, MnSOD polymorphisms, and biomarkers of inflammation and metabolism. The primary comparison is weight loss at 4 weeks (with an 80% power to detect an effect size 0.74 standard deviations with a 2-sided significance level of 0.05 using a two-sample t-test). Secondary objectives will assess and compare changes in: a) biomarkers of metabolic disorders (Hemoglobin A1c, fasting insulin/glucose) and cardiovascular risk (LDL cholesterol, HDL cholesterol, triglycerides); b) pro-inflammatory markers (IL-6, hsCRP) and adipokines (leptin, adiponectin); c) fecal microbiota; and d) quality of life measurements. Exploratory objectives will assess the effects of a WFPBD on serum and fecal metabolomics and on clonal hematopoiesis. Trial is open at Weill Cornell Medicine (WCM), John Hopkins University and Columbia University. First pt enrolled at WCM September 2022. Funding support from the Prostate Cancer Foundation; PC Clinical Trials Consortium c22-301. Clinical trial information: NCT05471414. Research Sponsor: Prostate Cancer Foundation.

CLIMATE: Assessing the clinical utility of miR-371a-3p as a marker of residual disease in stage 1 testicular germ cell tumour (TGCT) following orchiectomy: ANZUP 1906. *First Author: Ciara Conduit, Personalised Oncology, Walter and Eliza Hall Institute of Medical Research, Parkville Victoria, Australia*

Background: There is impetus to identify biomarkers in TGCT to help select those at high-risk of relapse following orchiectomy and target interventions to prevent over-treatment. miR-371 has been shown to reliably predict presence of active malignancy with higher accuracy than currently available biomarkers. More clinical evidence is required to ascertain its clinical utility as a marker of microscopic disease to guide treatment recommendations in stage 1 TGCT and other settings. **Methods:** CLIMATE ANZUP1906 (ACTRN12622000247774) is a prospective, single-arm, non-interventional cohort study recruiting adults with clinical stage 1 TGCT entering active surveillance. Eligible participants are recruited within six weeks of orchiectomy and are willing to undergo active surveillance in accordance with the Australian and New Zealand Urogenital and Prostate (ANZUP) Cancer Trials Group Surveillance Recommendations (or similar), without adjuvant treatment. Participants with metastases, non-testicular primaries, or history of contralateral TGCT are ineligible. Serum, plasma, and buffy coat samples are collected at consent and every three months until 24 months (and at relapse, if applicable). miR-371 will be assessed using established protocols. Clinical data, including treatment(s), surveillance, and relapses are captured in Australia's national TGCT registry, iTestis. Archival tissue from diagnosis $\pm$ relapse is identified for future translational research. The primary endpoint for CLIMATE is 12-month relapse-free survival of miR-371 positive/negative groups. Key secondary endpoints include miR-371 during surveillance and at relapse, concordance between serum/plasma miR-371 and archival tissue, and health economic analyses. Prior studies suggest ~20% of post-orchidectomy miR-371 samples are positive. A sample size of 200 participants will result in 20 relapses, 160 non-relapses and 20 individuals lost to follow-up, and will permit description of the primary endpoint. Patient-level data from CLIMATE will contribute to a joint analysis of parallel trials evaluating miR-371 in this setting, COG AGCT1531 and SWOG1823. The first participant was recruited to CLIMATE in February 2022. 9/12 study sites in Australia and New Zealand have been activated and 47/200 (24%) have been enrolled. Recruitment is expected to take 36 months, followed by a further 24 months follow-up. Clinical trial information: ACTRN12622000247774. Research Sponsor: ANZUP.

GUIDE: A randomized non-comparative phase II trial of biomarker-driven intermittent docetaxel versus standard-of-care docetaxel in metastatic castration-resistant prostate cancer (ANZUP 1903). *First Author: Ciara Conduit, Australian & New Zealand Urogenital and Prostate (ANZUP) Cancer Trials Group, Camperdown, Australia*

Background: Docetaxel improves survival in people with metastatic castration resistant prostate cancer (CRPC) but is associated with toxicities which impact tolerability, particularly for patients who may be older and often with multiple comorbidities. Biomarker-driven de-escalation of docetaxel chemotherapy may allow improved balance of cancer control and quality of life against toxicity. In patients with metastatic CRPC receiving docetaxel, a reduction to undetectable levels in circulating promoter methylated glutathione S-transferase Pi-1 (*mGSTP1*) DNA after 2 cycles of chemotherapy is associated with improved overall survival¹. This study aims to determine the efficacy and safety of intermittent docetaxel chemotherapy guided by the presence or absence of circulating *mGSTP1* DNA in patients with metastatic CRPC. **Methods:** GUIDE (NCT04918810) is a randomized, two-arm, non-comparative phase 2 trial recruiting 120 patients at eight Australian centres. Patients with Prostate Cancer Working Group-3 defined metastatic CRPC who are commencing docetaxel 75mg/m² q3w will be pre-screened for detectable *mGSTP1* at baseline +/- following two cycles of treatment. Those with detectable plasma *mGSTP1* at baseline that becomes undetectable after two cycles of chemotherapy will be eligible for GUIDE. Prior to Cycle 4 of docetaxel, these patients are randomized 2:1 to one of two treatment arms: Arm A (cease docetaxel and reinstitute if *mGSTP1* becomes detectable) or Arm B (continue docetaxel 75mg/m² q3w in accordance with clinician's usual practice) (Figure 1). The primary endpoint is radiographic progression-free survival (rPFS). Secondary endpoints include time on treatment holidays, safety, patient-reported outcomes, overall survival, health resource use and cost associated with treatment. This study is powered to detect a rPFS curve with at least 50% rPFS at 12 months using a one-sided log-rank test with 2.5% alpha and 90% power. 3 of planned 120 patients have been enrolled. This novel study is the first to prospectively test the clinical utility of a circulating epigenetic biomarker (*mGSTP1*) in clinical decision-making in prostate cancer, building upon existing data supporting analytical and clinical validity. We anticipate that this novel biomarker will safely guide treatment de-escalation and improve the quality of survival for a group of patients with metastatic CRPC. Clinical trial information: NCT04918810. Research Sponsor: Chris O'Brien Lifehouse Philanthropic Fund; ANZUP Discretionary Funding Initiative and ANZUP Below the Belt Research Fund.

A study of prospective monitoring of patients with recurrent prostate cancer using serial PSMA imaging (18F-DCFPyL). *First Author: Mohammad O. Atiq, Genitourinary Malignancies Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: 18F-DCFPyL PSMA PET imaging is now FDA approved for patients with high-risk prostate cancer and those with biochemically recurrent prostate cancer (BCR). BCR has been traditionally defined as a rising PSA after definitive surgery and/or radiation have not been curative in patients without tumor findings on a CT or Tc99 bone scan. There are an estimated 25,000-50,000 new cases of BCR in the US annually. BCR patients are usually managed conservatively, often with surveillance since there is no data demonstrating interventions improve survival. Although 18F-DCFPyL will be able to detect disease at the micrometastatic/subclinical level, there is limited prospective data on how these patients should be managed. While great enthusiasm exists to utilize radiation or ADT-based regimens extrapolated from a more advanced disease state, the natural history of subclinical disease seen on 18F-DCFPyL remains unclear (Madan RA et al. J Clin Oncol 2022). **Methods:** The primary objective of this study is to monitor patients with recurrent prostate cancer to learn about the natural history of 18F-DCFPyL PET positive disease in this patient population. Eligible patients include those who have had prior definitive surgery or radiation, current PSA ≥ 0.50 ng/mL, testosterone > 100 ng/mL, no evidence of soft tissue disease on CT scan/MRI and no bone lesions on bone scan. Patients will undergo initial imaging with 18F-DCFPyL scans. Those with negative findings on the initial scan will have annual repeat 18F-DCFPyL scans. Patients with positive initial scans will be scanned every 6 months. All patients will have PSA testing every 3 months and will undergo annual CT and Tc99 bone scans. Up to 250 patients will be followed for 5 years or until off-study criteria is met (including new findings on CT/bone scans consistent with metastatic disease or continuous systemic prostate cancer therapy for more than 6 months). In addition to monitoring the imaging changes, we will evaluate patterns of progression on 18F-DCFPyL scans over time, analyze PSA doubling time in context of 18F-DCFPyL changes and evaluate circulating biomarkers. ClinicalTrials.gov Identifier: NCT05588128. Clinical trial information: NCT05588128. Research Sponsor: U.S. National Institutes of Health.

P3BEP (ANZUP 1302): An international randomized phase 3 trial of accelerated versus standard BEP chemotherapy for male and female adults and children with intermediate and poor-risk metastatic germ cell tumours (GCTs). *First Author: Danka Sinikovic Zebic, NHMRC Clinical Trials Centre, The University of Sydney, Camperdown, NSW, Australia*

Background: Bleomycin, etoposide, and cisplatin (BEP) given 3-weekly x 4 remains standard 1st line chemotherapy for intermediate or poor risk metastatic GCT. Accelerating standard regimens by shortening the cycle length to 2-weekly improved cure rates in other cancers. P3BEP will determine effects of accelerated versus standard BEP in this setting. This is the first international, randomized trial of chemotherapy for intermediate and poor-risk metastatic GCT to include adults and children of both sexes. **Methods:** This open label, randomized, phase 3 trial is conducted seamlessly in 2-stages. The primary endpoint for stage 1 (n = 150) was favourable response; and for stage 2 (n = 500) is progression free survival at 2 years (PFS2y). These sample sizes provide > 80% power with a 2-sided type I error rate of 5% to detect an absolute improvement of 21% in the favourable response rate (stage 1) and of 7% in the PFS2y (stage 2). The target population is males and females aged 11 to 45 with intermediate- or poor-risk metastatic GCT of the testis, ovary, retroperitoneum, or mediastinum. Participants are randomized (1:1) to 4 cycles of standard BEP (q3w) or accelerated-BEP (q2w) with cisplatin 20mg/m² D1-5, etoposide 100mg/m² D1-5, bleomycin 30 KIU weekly x 12, and pegylated G-CSF D6 or filgrastim daily (Figure 1). Study assessments occur at 30 days after completing chemotherapy, 6 months from randomisation, and after completion of all post-chemotherapy treatments (e.g. surgery). Tumour and blood samples are collected for translational substudies. Progress - As of Jan 2023, 241 participants have been recruited from 22 ANZ sites, 16 UK sites (led by Cambridge Clinical Trials Unit), and 55 USA sites (led by Children's Oncology Group). The first planned interim analysis for safety (n = 76) identified no safety concerns. The stage 1 analysis of safety and activity (response rate) for the 1st 150 patients was reviewed by the IDSMC, which recommended continuation of the trial as per protocol. Clinical trial information: NCT02582697. Research Sponsor: Cancer Australia; Clinical Trials Awards and Advisory Committee (UK) and National Cancer Institute (USA).

SWOG S1823/CCTG GCC1: Translational observational investigational study of the liquid biomarker microRNA 371a-3p in newly diagnosed germ cell tumours—Real-world trial design, rapid accrual, and robust secondary use of data opportunities. *First Author: Antoine Morin Coulombe, BCCancer, Vancouver, BC, Canada*

Background: With the discovery of the very promising, germ cell malignancy (GCM) specific, liquid biomarker microRNA 371a-3p (miR371), the investigative trajectory has markedly accelerated. With its outstanding, previously-reported specificity and positive predictive value, miR371 likely will become a powerful tool for clinical decision-making. The primary objective of SWOG S1823/CCTG GCC1 [NCT03067181] is to define the operating characteristics of plasma miR371 expression at the time of clinical relapse for low/moderate risk non-seminoma GCM patients on active surveillance. **Methods:** S1823 is a prospective, observational, adult GCM translational trial which is actively accruing. Broad eligibility includes all newly diagnosed adult GCM patients. Patients are assigned to low (<25% risk of relapse), moderate (25-90% risk of relapse) or high (≥90% risk of harboring active GCM) risk groups. Pragmatic logistics include using Streck tubes and centralized processing for miR371 sample processing and analytics. Research samples were drawn at the time of routine blood draws minimizing patient burden. Source documents are submitted along with case report forms. This data-gathering model gives an important data quality-control check. S1823 began in July 2020 and has since accelerated its accrual to consistently predicted new enrollments of 20-30 cases/month. As of January 2023, the study enrolled 389 low-risk, 114 moderate-risk and 146 high-risk patients (657 total). Interim analysis is planned at the time 40 non-seminoma GCM patients have relapsed and is anticipated in late 2023 to early 2024. 404 centers have opened S1823. 3 Canadian centers have enrolled >10 patients (range 11-51). 17 USA institutions have enrolled >10 patients (range 11-112). In North America, 9 of the 12-storied GCM clinical research programs have had robust participation. The leading accruing organization was the Kaiser Permanente system where 112 patients have been enrolled. In Canada, all population centers contributed proportionally. In the USA, the dominant enrollment comes from the west coast and mid-west. Proportional enrollments have been seen in Hispanic and Asian populations. The entire study provides rich opportunities for a variety of secondary use and patterns of care projects that will begin to roll out over the next year. Clinical trial information: NCT03067181. Research Sponsor: Hope Foundation for Clinical Research.

AGCT1531: Evaluating the utility of circulating microRNA in the management of children, adolescents, and adults with malignant germ cell tumors. *First Author: Furqan Shaikh, Division of Haematology/Oncology, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Conventional serum tumor markers for malignant germ cell tumors (MGCTs) have limited performance characteristics, especially in non-secreting histologies such as embryonal carcinoma or seminoma. Growing evidence has shown circulating microRNAs (miRNA), particularly miR-371a-3p, to be a more sensitive biomarker, elevated across all MGCT subtypes except teratoma. However, studies to date have been retrospective or non-randomized. If confirmed in prospective clinical trials, circulating miRNA may have the potential to become a universal MGCT biomarker, aiding in diagnosis, prognostication, relapse detection, and prediction of viable disease after chemotherapy. One of the key objectives of AGCT1531 is to test the performance characteristics of circulating miRNA in children, adolescents, and young adults (AYAs) with low-risk and standard-risk MGCTs. AGCT1531 is unique among MGCT trials for including patients across all ages, genders, sites, histologies, and treatments. **Methods:** AGCT1531 is a prospective clinical trial sponsored by the Children's Oncology Group (COG), co-designed with United Kingdom, Japan, and India, and supported by all NCTN groups. It has three strata for low-risk tumors, defined as stage I tumors treated with surgery followed by active surveillance: non-seminomatous tumors of any site; testis seminomas; and ovarian immature teratomas. Patients of any age are eligible. Target accruals are 432, 277, and 212 patients, respectively. Key endpoints include overall and event-free survival and longitudinal measurements of circulating miRNA. Serum is collected at intervals aligned with NCCN follow-up guidelines to minimize testing burden. For patients over 11 years old with stage I non-seminomatous tumors, serum is collected at enrollment, months 4, 8, 12, 18, and 24; and (if applicable) at relapse. The trial also has two strata for standard-risk MGCTs: SR1 for children under age 11 years and SR2 for AYAs age 11-25 years. Target accruals are 518 and 595 patients, respectively. Both strata are randomized trials of cisplatin-based versus carboplatin-based regimens, with carboplatin used at doses higher than those previously tested in adult MGCTs. Serum collection is recommended at enrollment, months 6, 12, 18, 24, and (if applicable) at relapse. AGCT1531 was activated in August 2017. The low-risk seminoma stratum was added on November 2021. The trial is currently open at 466 sites across seven countries. For adults with testicular GCTs, data from AGCT1531 can contribute to joint analyses of parallel trials evaluating circulating miR-371a-3p in this population: SWOG1823, ANZUP1906 (CLIMATE), and ANZUP P3BEP. Together, this suite of trials will help validate the utility of circulating miRNA and set the stage for future investigations where miRNA is used to influence real-time management decisions for patients with MGCTs. Clinical trial information: NCT03067181. Research Sponsor: U.S. National Institutes of Health.

Poster Session

A phase (Ph) I/II trial of abiraterone acetate in combination with tildrakizumab (anti-IL23 monoclonal antibody) in patients with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Christina Guo, Institute of Cancer Research, London, United Kingdom*

Background: Tumor-infiltrating inflammatory myeloid cells promote prostate cancer (PC) growth and therapeutic resistance. Myeloid inflammatory cells release interleukin-23 (IL-23) to fuel tumor growth via JAK2-STAT3 signalling and facilitate tumor-promoting T helper 17 (T_H17) differentiation in PC models *in vivo*. IL-23 blockade reverses resistance to AR-targeting *in vivo*; we hypothesise that targeting IL-23 can be an effective therapeutic strategy for CRPC. Tildrakizumab, an anti-IL-23 (p19) monoclonal antibody, is FDA/EMA approved for treating moderate-severe psoriasis. In progress is the first clinical trial to combining IL-23 and AR signalling blockade in humans. **Methods:** This is an open-label, single-arm, Ph I/2, dose-escalation and expansion study evaluating safety and tolerability of tildrakizumab and abiraterone acetate combination therapy in patients with mCRPC. Eligible patients must have progressed on androgen deprivation therapy, plus abiraterone and/or enzalutamide. The Ph 1 trial will adopt a one-stage Bayesian Continual Reassessment Method design exploring escalating doses of 4-weekly, IV tildrakizumab (100 mg, 300 mg, and 600 mg), in combination with standard fixed doses of abiraterone acetate and methylprednisolone, with the aim of determining the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D). Depending on the number of responses observed, tolerable dose levels may be expanded up to 10 patients after review by the Safety Review Committee (SRC). The RP2D and MTD determination will be based on the rate of toxicity and efficacy, reviewed by the SRC. Once RP2D is determined, the Ph 2 study will enrol up to 25 response-evaluable patients using a Simon's two-stage design. Primary endpoint of the Ph 2 trial is overall response rate. Adverse events are assessed according to CTCAE v5. Tumor response is determined according to RECIST v1.1, confirmed PSA decline of at least 50%, and/or CTC conversion. PK analyses is being performed for both drugs to identify potential drug-drug interactions. PD analyses is being performed on archival and serial tumour biopsies and blood samples to investigate putative predictive biomarkers and confirm on-target and downstream effector modulation. The trial began enrolling in January 2021 in the United Kingdom and Switzerland. As of January 22th 2023, 12 patients were included in the study. Clinical trial information: NCT04458311. Research Sponsor: Prostate Cancer Foundation; Sun Pharmaceuticals; Prostate Cancer UK, CRUK, National Institute of Health and Research (NIHR) Biomedical Research Centre.

Poster Session

The Maverick trial: A phase 2 study of abivertinib in patients (pts) with metastatic castration resistant prostate cancer (mCRPC). *First Author: Rana R. McKay, University of California San Diego, La Jolla, CA*

Background: Abivertinib is a potent, small molecule third-generation tyrosine kinase inhibitor (TKI) of epidermal growth factor receptor (EGFR), Bruton tyrosine kinase (BTK) receptor, and bone marrow tyrosine kinase gene on chromosome X (BMX). Abivertinib irreversibly binds to the BTK receptor, preventing the phosphorylation of the receptor, and also BMX. The adrenal-permissive HSD3B1(1245C) allele, which is present in upwards of 50% of men with prostate cancer, encodes a 3 β HSD1 enzyme missense that up-regulates the rate-limiting step of androgen biosynthesis from androgen precursor steroids and promotes poor clinical outcomes. 3 β HSD1 must be phosphorylated by BMX for androgen biosynthesis. Preclinical studies suggest BMX inhibition blocks 3 β HSD1, androgen biosynthesis and CRPC in xenograft models. These provide the rationale for use of the combination of abivertinib and abiraterone to block residual androgen synthesis that escapes abiraterone inhibition. **Methods:** The Maverick Trial is a multicenter, open-label phase 2 study within the US Dept of Defense Prostate Cancer Clinical Trials Consortium (DOD PCCTC) of abivertinib with abiraterone in pts with mCRPC harboring the adrenal-permissive HSD3B1(1245C) allele (germline heterozygous or homozygous). HSD3B1 status will be confirmed centrally prior to enrollment via CLIA testing at the Cleveland Clinic. The study includes two cohorts: abiraterone-naïve and abiraterone-progressing. There will be cap of 50% of accrual in each cohort for pts heterozygous for the HSD3B1(1245C) allele. An interim futility analysis is embedded in each cohort, and toxicity rates will be continuously monitored for early stoppage according to predefined rules. Pts receive continuous treatment with abivertinib 200 mg BID with abiraterone 1000 mg QD + prednisone 5 mg BID until radiographic progression, unacceptable toxicity, intercurrent illness, or other reason, such as subject withdrawal. The primary endpoint is 6-month rPFS defined as percent of subjects alive and without progression by RECIST version 1.1 for measurable disease and PCWG3 criteria for bone metastases. Secondary and exploratory endpoints include objective response rate, duration of response, PSA progression, pharmacokinetics, pharmacodynamic tissue changes, and mechanisms of response and resistance to therapy via sequential tissue and blood sampling. The study is currently open at 1 site and will activate at 9 additional sites. It is sponsored by Sorrento Therapeutics, Inc, and managed by the Prostate Cancer Clinical Trials Consortium. Trial Registration: NCT05361915 Funding Source: Sorrento Therapeutics, Inc, the trial's sponsor who is funding the trial. Clinical trial information: NCT05361915. Research Sponsor: Sorrento Therapeutics, Inc.

HB-300, a novel arenavirus-based cancer immunotherapy in patients with metastatic castration-resistant prostate cancer. *First Author: David D. Chism, Thompson Cancer Survival Center, Knoxville, TN*

Background: Prostate cancer is the most frequent type of malignant neoplasia in men. Immunotherapy targeting self-antigens in prostate cancer is evolving and requires overcoming multiple mechanisms that mediate immune tolerance. Sipuleucel-T, a cell-based therapy recognizing prostatic acid phosphatase (PAP) protein, is approved for treatment of patients with metastatic castration-resistant prostate cancer (mCRPC) and induced PAP-specific T cell responses correlating with overall survival (OS). Poxvirus vectors encoding prostate-specific antigen (PSA) increased PSA-specific T cell levels and were associated with OS benefit, although not confirmed in a Phase 3 study. Arenaviral vectors used in preclinical tumor models could overcome self-tolerance by inducing strong self-antigen specific CD8 T cell responses. In humans, arenaviral vectors encoding HPV16 E7E6 fusion protein (HB-200) induced unprecedented E6E7-specific CD8 T cell levels in patients with recurrent/metastatic HPV16+ cancers. Preliminary clinical activity and favorable safety and tolerability were observed in these heavily pre-treated, checkpoint inhibitor-resistant patients (ref: Fu et al. ASCO 2022; NCT04180215). It is therefore hypothesized that HB-300, a live-attenuated arenaviral vector therapy encoding the self-antigens PAP and PSA, will induce substantially stronger T cell responses in prostate cancer patients than previously tested active immunization approaches. **Methods:** This is a Phase 1/2 open-label clinical study of HB-300 in ~ 70 patients with advanced mCRPC. A 3+3 Dose Escalation will be followed by a dose-expansion to confirm the recommended Phase 2 dose (RP2D). HB-300 consists of HB-302 (Pichinde virus based) alternating with HB-301 (LCMV based) vectors, administered IV every 3 weeks (Q3W) for 5 doses then Q6W. The program's entry into the clinic with a mini dose-escalation was supported by the submission of a data master file along with the HB-300 Investigational New Drug application, based on arenavirus vector platform data collected in the HB-200 program. Trial inclusion criteria include male participants age $\geq$ 18; documented mCRPC (adenocarcinoma without neuroendocrine or small cell features); receipt of at least 1 androgen deprivation therapy and no prior chemotherapy regimens (docetaxel in the castration-sensitive setting is allowed); $\geq$ 1 measurable lesion; ECOG PS 0-1. Exclusions are uncontrolled pain or symptoms; active auto-immune disease; immunosuppression; active central nervous system or liver metastasis; and active infection. Phase 1 primary objectives include safety/tolerability and determination of RP2D, secondary objectives include preliminary efficacy, and exploratory assessments include antigen-specific T cell response and circulating tumor cell analysis. Clinical trial# NCT05553639. Clinical trial information: NCT05553639. Research Sponsor: Hookipa Pharma Inc.

Poster Session

A randomized phase II study of apalutamide with or without carotuximab (ant-CD105) in metastatic, castration-resistant prostate cancer. *First Author: Edwin Melencio Posadas, Cedars-Sinai Cancer, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: CD105 (endoglin) is a co-receptor for the transforming growth factor-beta (TGF- β) receptor family. TGF- β signaling is activated in response to castration and is a determinant of PCa epithelial cell death in response to castration. In prostate cancer, silencing of TGF- β receptor type 2 (Tgfr2) in cancer-associated fibroblasts (CAF) potentiates tumor progression and castrate resistance primarily by paracrine signaling mechanisms mediated by the bone morphogenic protein (BMP)-SMAD axis. Upregulation of CD105 is observed in the face of progression through AR suppression and can drive pro-survival, pro-metastatic pathways BMP-SMAD signaling. This is accompanied with an increase in neural differentiation and the generation of AR-splice variants. In model systems, suppression of CD105-mediated signaling reversed these behaviors and resorted sensitivity to AR suppression. Carotuximab is a humanized monoclonal antibody that potentially inhibits CD105-mediated signaling. It was originally developed for clinical use as an anti-angiogenic agent and was found to have an acceptable toxicity profile. Given our previous work, we hypothesized that use of CD105 will restore sensitivity to AR inhibition in men who have developed early resistance to an AR signaling inhibitor (ARSI) that would result in a synthetic lethality from combination treatment that will manifest as an extension of progression free survival when compared to ARSI therapy alone. **Methods:** This study (NCT05534646) is open to men with metastatic, castration-resistant prostate cancer who have progressed on previous ARSI therapy. Patients with recent thrombotic and/or cardiovascular events are excluded. Patients are allowed to have had prior docetaxel only in the setting of castration sensitive disease. The study includes a safety lead-in of 10 patients on combination therapy based on our previous work with carotuximab with other ARSI in NCT03418324. This will ensure that the probability of starting the phase 2 dose with a safe dose is sufficiently high. The study then proceeds to a (1:1) randomized study of apalutamide with or without carotuximab (n = 90). Patients randomized to apalutamide alone are permitted to cross over to combination therapy at the time of radiographic progression. The primary endpoint of the study is radiographic progression free survival (rPFS) and is designed to detect a 45% difference in rPFS in the two arms with 81% power and two-sided alpha of 0.10. This study also includes extensive correlative studies focusing on circulating tumor cells and extracellular vesicles which will be enriched and studies using novel nanotechnology enabled methodologies from our group as well as cell free DNA studies which will be used identify those patients with the greatest benefits from this form of therapy to expedite the development of this therapeutic approach. Clinical trial information: NCT05534646. Research Sponsor: Enviro Therapeutics, Inc.

Poster Session

First-in-class oral innate immune activator BXCL701 combined with pembrolizumab, in patients with metastatic castration-resistant prostate cancer (mCRPC) of small cell neuroendocrine (SCNC) variant: Randomized phase 2b trial. *First Author: Rahul Raj Aggarwal, University of California, San Francisco, San Francisco, CA*

Background: BXCL701 (talabostat), oral small molecule inhibitor of dipeptidyl peptidases (DPP)—primarily DPP8/9 & DPP4—triggers inflammasome to alert and prime immune cells, leading to induction of IL-18 & IL-1 β , bridging innate & adaptive immunity. BXCL701 + pembrolizumab evaluated in a Phase 2 study, in mCRPC patients with SCNC. SCNC is highly proliferative and aggressive with limited duration of response to platinum-based chemotherapy. Final results of Phase 2a presented at ASCO GU 2023 (abstract #176) after enrollment of 28 evaluable SCNC patients. 7 (25%) patients achieved a composite response, primary endpoint of trial. In patients with measurable disease (n = 25), RECIST 1.1-defined partial response (PR) observed in 5 (20%) patients (4 confirmed PR + 1 uPR). Disease control rate (complete response + PR + stable disease) was 48% (12 patients). Median duration of response for both composite responses and RECIST-defined PRs was 6+ months as of data cutoff on 19-DEC-22. 6 / 34 patients (18%) in safety population experienced serious adverse events (SAEs) possibly related to BXCL701 or pembrolizumab, and 6 (18%) patients discontinued any drug due to an AE. No evidence found that BXCL701 potentiates immune-related AEs related to immune checkpoint inhibitors. DPP9 overexpression was identified as a potential predictive biomarker for BXCL701 response; biomarker evaluation is ongoing and additional findings will be presented at an upcoming medical meeting. Since SCNC cohort showed encouraging efficacy in Phase 2a, the Phase 2b portion of study was initiated to evaluate SCNC variant in a potential registration randomized study. **Methods:** Patients with any SCNC histopathological features, either *de novo* or treatment-emergent including mixed SCNC, are randomized 2:1 to receive BXCL701 + pembrolizumab (n = 40) or BXCL701 monotherapy (n = 20). Patients are required to have progression by PCWG3 on $\geq$ 1 prior line of cytotoxic chemotherapy (patients who either have refused chemotherapy or are considered unsuitable for chemotherapy also permitted entry with prior approval by sponsor). Patients receive pembrolizumab (200 mg IV q3week Day 1) + BXCL701 or BXCL701 alone (0.2 mg BID Days 1-7 with step-up to 0.3 mg BID Days 8-14, and 0.3 mg BID Days 1-14 of subsequent 21-day cycles). Primary endpoint is response rate defined by RECIST 1.1 criteria. Secondary objectives are $\geq$ 50% decline in PSA from baseline, OS, duration of response, rPFS, and PSA PFS. Exploratory biomarkers and changes in relevant immune effector cells are also evaluated. Phase 2a activity threshold for accrual was met. ClinicalTrials.gov Identifier: NCT03910660. Clinical trial information: NCT03910660. Research Sponsor: BioXcel Therapeutics, Inc.

A phase 1/2 study of combination olaparib and radium-223 in men with metastatic castration-resistant prostate cancer with bone metastases (COM-RADE): A trial in progress. *First Author: Chinmay Jani, Mount Auburn Hospital, Harvard Medical School, Cambridge, MA*

Background: Radium-223, an α -emitting radioisotope inducing DNA double-stranded breaks leading to cell death has demonstrated improvement in overall survival (OS) in men with metastatic castration-resistant prostate cancer (mCRPC) with bone metastases. PARP inhibitors prevent the repair of DNA single-stranded breaks and have demonstrated clinical efficacy as monotherapy in mCRPC patients harboring alterations in the homologous recombination repair (HRR) pathway and in combination with androgen receptor signaling inhibitors irrespective of DNA repair mutation status. In preclinical models, PARP inhibitors have shown efficacy as radio sensitizing agents. We designed a phase 1/2 trial to identify the recommended phase 2 dose (RPD2) of olaparib and radium-223 and test the hypothesis that radium-223 + olaparib will demonstrate anti-tumor activity in mCRPC irrespective of homologous recombination repair deficiency (HRD) status (NCT03317392). **Methods:** This open-label, multi-center, phase 1/2 study evaluates the dosing, safety and efficacy of olaparib with radium-223 in men with mCRPC with bone metastases. The phase 1 component used a 3+3 dose escalation design to determine the olaparib recommended phase 2 dose (RP2D) + fixed dose radium-223 (55 kBq/kg IV every 4 weeks x 6). The phase 1 portion has completed accrual (n = 12) and demonstrated that the RP2D of olaparib is 200 mg by mouth twice daily when combined with standard dose radium-223. The phase 2 component of the study which was activated in 1/2021 is an open-label, randomized trial (1:1) evaluating olaparib + radium-223 compared to radium-223 alone. The inclusion criteria include patients with mCRPC with any number of prior therapy lines for mCRPC and ≥ 2 bone metastases by imaging and at least 1 lesion which has not been treated with prior radiation. Patients with visceral metastases or malignant lymphadenopathy (> 4 cm in short diameter) are excluded. The primary endpoint for phase 2 is radiographic progression-free survival (rPFS) per PCWG3 guidelines for bone metastases and RECIST v1.1 for non-bone disease. The integrated biomarker is Oncopanel assay to determine HRR status. A key secondary endpoint will evaluate rPFS in biomarker positive and negative patients. Other secondary endpoints include time to PSA progression, PSA response, time to subsequent therapy, time to first skeletal event, and OS. Exploratory endpoints include WES/WTS of baseline biopsy tissue, assessment of RAD51 IHC and correlation with outcomes, ctDNA assessment and correlation with responses, evaluation of changes in the tumor immune microenvironment, and quality of life assessment. Target accrual is 133 patients. Clinical trial information: NCT03317392. Research Sponsor: U.S. National Institutes of Health.

Open-label study of darolutamide plus androgen-deprivation therapy (ADT) vs ADT in metastatic hormone-sensitive prostate cancer using an external control arm (ARASEC). *First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC*

Background: Darolutamide (DARO) is a structurally distinct and highly potent androgen receptor inhibitor. In the phase 3 ARASENS study (NCT02799602) in patients (pts) with metastatic hormone-sensitive prostate cancer (mHSPC), DARO + ADT + docetaxel significantly reduced the risk of death by 32.5% vs ADT + docetaxel (hazard ratio 0.68; 95% confidence interval 0.57–0.80), with a favorable tolerability and safety profile. In the global (excluding US), phase 3 ARANOTE study (NCT04736199), DARO + ADT vs ADT alone is being evaluated in pts with mHSPC. ARASEC (NCT05059236) will complement ARANOTE by assessing DARO + ADT in US pts. As ADT alone is no longer an acceptable comparator in the US, the external control arm will be derived from the historical US CHAARTED study (NCT00309985). A real-world analysis of electronic health record data from pts with mHSPC (TIMES) indicated that there was minimal risk of historical time bias associated with the use of the external ADT alone arm from CHAARTED as a comparator for ARASEC (Shore N, et al. *J Clin Oncol* 2022;40(28 Suppl):Abstract 403). **Methods:** ARASEC is a phase 2, open-label, single-arm study enrolling pts with confirmed mHSPC and no prior systemic therapy. Pts will receive DARO 600 mg orally twice daily + ADT (luteinizing hormone-releasing hormone agonist/antagonist or orchiectomy). The external control arm will be derived from 394 pts with mHSPC treated with ADT alone in CHAARTED. To remove biases in evaluating outcomes that could arise due to differences in baseline profiles between arms, pts will be matched 1:1 using a propensity score (PS) summarizing baseline characteristics relevant to disease outcomes. Baseline variables will include age (< 70 vs ≥ 70 years), Eastern Cooperative Oncology Group performance status (0–1 vs 2), CHAARTED-defined extent of disease (low vs high volume + bone metastases only vs high volume + visceral metastases $\pm$ bone metastases), and prior therapy (yes vs no; as a proxy for recurrent vs *de novo* disease). Matching patients with scores within a narrow window across the cohorts will ensure that pts in CHAARTED are representative of pts in the DARO + ADT arm. The primary endpoint is progression-free survival (PFS), as defined in CHAARTED. Secondary endpoints include overall survival, radiographic PFS, time to CRPC, undetectable prostate-specific antigen response rate (< 0.2 ng/mL) at 6 months, and safety. Target enrollment for the DARO + ADT arm is 200 pts at 30 sites. The study will continue until either the event count threshold triggering the primary endpoint analysis has been met (161 PFS events) or all pts have been followed for ≥ 2 years, whichever occurs later. As of January 2023, 121 pts have been enrolled. A per-protocol, predefined matching exercise on the first 100 pts enrolled will be conducted to ensure that the planned sample size is adequate. Clinical trial information: NCT05059236. Research Sponsor: Bayer and Orion Corporation.

A phase 2, randomized, open-label study comparing the effects of darolutamide versus enzalutamide monotherapy on serum testosterone levels in patients with hormone-naïve prostate cancer: ARAMON study. *First Author: Xin Gao, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

Background: Darolutamide is a structurally distinct and highly potent androgen receptor inhibitor with low blood–brain barrier penetration. In the phase 3 ARAMIS study (NCT02200614) of patients with nonmetastatic castration-resistant prostate cancer, treatment with darolutamide significantly improved metastasis-free survival and overall survival versus placebo, with a favorable safety profile. The incidences of central nervous system adverse events (AEs; e.g. falls, memory impairment, and depression) showed a $\leq 2\%$ difference between the darolutamide and placebo groups. Fatigue was the only AE with an incidence of $> 10\%$ for darolutamide (13.2% vs 8.3% for placebo). In a separate neuroimaging study of healthy volunteers, cerebral blood flow was not altered in patients treated with darolutamide but was significantly reduced in brain areas related to cognition in patients treated with enzalutamide. Furthermore, it is postulated that the low blood–brain barrier penetration of darolutamide may result in lower serum testosterone elevations than those seen with enzalutamide, with the potential of leading to fewer associated feminizing AEs. The objective of ARAMON (NCT05526248) is to compare the effect of darolutamide and enzalutamide monotherapy on post-treatment testosterone levels in patients with hormone-naïve prostate cancer experiencing biochemical recurrence after definitive treatment for localized disease. **Methods:** ARAMON is a two-stage, open-label, phase 2 study of patients with histologically or cytologically confirmed adenocarcinoma of the prostate who have biochemical recurrence after radical primary prostatectomy or radiation therapy, with a prostate-specific antigen (PSA) doubling time of ≤ 20 months, baseline serum testosterone > 150 ng/dL, and Eastern Cooperative Oncology Group performance status 0/1. During a 52-week lead-in phase, 25 patients will receive darolutamide 600 mg twice daily. If criteria based on serum testosterone increase from baseline to Week 12 are met, the study will proceed to a 52-week randomized phase in which the effects of darolutamide (600 mg twice daily, n = 20) will be compared with the effects of enzalutamide (160 mg once daily, n = 20). The primary endpoint of both phases is the change in serum testosterone level from baseline to Week 12. Secondary endpoints of the randomized phase include the change in serum testosterone levels from baseline to Weeks 24 and 52; PSA at Weeks 4, 12, 24, 36, and 52; changes in blood levels of markers for glucose, lipid metabolism, and endocrine function related to sex hormones; safety; and quality of life. Safety will be assessed through AE monitoring. The first of the 25 planned patients in the lead-in phase was enrolled on January 13, 2023. Clinical trial information: NCT05526248. Research Sponsor: Bayer and Orion Corporation.

A feasibility study of ^{177}Lu -PSMA radioligand therapy alternated with radium-223 in patients with bone-metastatic, oligo-metastatic, hormone-sensitive prostate cancer after curative therapy: The DUET study. *First Author: André Vis, Amsterdam UMC, location VUMC, Amsterdam, Netherlands*

Background: Previous randomized clinical trials have shown an improvement in overall survival in patients with metastatic castration resistant prostate cancer (mCRPC), who have already failed other therapies, treated with ^{177}Lu -PSMA radioligand therapy (RLT). Although ^{177}Lu -PSMA RLT has shown exciting treatment responses in men with mCRPC and suggests a low toxicity profile, it has not been widely investigated in patients with metastatic hormone-sensitive prostate cancer (HSPCa). As of today, treatment with systemic drugs is proof of concept in advanced or metastatic HSPCa, as well as in other cancer types, and leads to improved oncological outcome, potentially by eradicating micro-metastatic disease. As a bone-seeking calcium mimetic, Radium-223 (Ra-223) is incorporated into new bone stroma, predominantly within sclerotic metastatic deposits. The high-energy of the alpha-particle radiation generates double-stranded DNA breaks, offering a potent and highly localized cytotoxic effect in the target areas. In a phase 3, randomized, double-blind, placebo-controlled study, Ra-223 has proven to significantly improve overall survival (by a treatment comprising 1 injection per month, at a dose of 50 kBq per kilogram of body weight intravenously), as compared with placebo. The optimal therapy in patients with oligometastatic bone HSPCa after previous curative treatment has not yet been defined. **Methods:** This is a single center, interventional, one-arm phase I-II study that prospectively investigates if a treatment strategy in which two types of cytotoxic RLT, i.e., an alpha-emitter and a beta-emitter, alternatively offered to patients with oligometastatic HSPCa, is feasible and safe. Eight patients with low volume, PSMA expressing, radiological progressive HSPCa (minimal 2 bone metastases, maximal 5, and at 0 to 3 lymph node metastases) will be recruited. In these patients, loco-regional radiotherapy or surgery is not an option anymore. The PSA doubling time in participating patients should be less than 6 months. **Primary endpoint:** To assess the feasibility and safety in patients with bone metastatic, oligometastatic HSPCa, treated by Ra-223 RLT alternated with ^{177}Lu -PSMA RLT. **Secondary endpoints:** Toxicity and (serious) adverse events will be monitored and reported in concordance with the NCI CTCAE v5.0; Assessment of the xerostomia inventory; Prostate-specific antigen (PSA) levels on follow-up at 3, 6 and 12-months; **Investigative Treatment:** Patients enrolled in the trial will receive three intravenous applications of Radium-223, in a dose of 5.5 kBq/kg body weight at t = 0 weeks, t = 4 weeks and t = 8 weeks (± 1), and two intravenous applications of 7.4 GBq ^{177}Lu -PSMA RLT at t = 6 weeks and t = 12 weeks (± 1). Clinical trial information: NL81658.029.22. Research Sponsor: Bayer B.V.

ProSperA: Phase I study to evaluate safety, tolerability and preliminary efficacy of a bispecific PSMAxCD3 antibody in men with biochemical recurrence of prostate cancer. *First Author: Christopher Hackenbruch, University Hospital Tübingen, German Cancer Consortium (DKTK), Department of Internal Medicine, Clinical Collaboration Unit Translational Immunology, Tübingen, Germany*

Background: Bispecific antibodies (bsAbs), like CAR T cells, are not yet successful in solid tumors. Recently we developed a PSMAxCD3 bsAb termed CC-1 in an IgG-based format mediating fully target cell-restricted T cell activation and potent antitumor activity (Zekri *et al*, EMBO Mol Med, 2020). In prostate cancer (PC), PSMA is not only expressed on the malignant cells themselves, but also on tumor vessels. Targeting the latter improves accessibility of the tumor site for immune effector cells, a critical prerequisite for success. CC-1 is under evaluation in a First in Human trial enrolling patients with castration resistant prostate carcinoma (NCT04104607) and, in combination with checkpoint inhibition, in a phase I trial enrolling patients with squamous cell carcinoma of the lung (NCT04104607). On the basis of the meanwhile available very favorable safety and preliminary efficacy data, CC-1 is now being evaluated as first line treatment in patients with biochemical recurrence (BCR) of PC (NCT05646550), where tumor burden is low and accordingly further reduced side effects and sustained efficacy are expected. **Methods:** This is an ongoing open label, single center phase I clinical trial evaluating CC-1 without androgen deprivation therapy as first line treatment in men with BCR of PC. Key eligibility criteria include low risk of disease progression (PSA-Doubling time > 1 year after prostatectomy or interval to BCR > 18 months after radiation; ISUP grade < 4; PSA ≥ 0.2 ng/ml and < 5 ng/ml) and no androgen deprivation therapy except in a neoadjuvant/adjuvant setting. The clinical trial consists of (i) a dose escalation part (24-42 patients) using a 3+3 design to determine overall safety, tolerability as well as maximum tolerated dose (MTD) and (ii) a dose expansion part, in which 14 patients are treated at the MTD. CC-1 is applied twice-weekly over 21 days as three-hour infusion in up to six 28-day cycles. In the first cycle, step dosing (day 1: 10µg, day 2: 28µg, day 3 and thereafter: target dose) is performed, and 7 patient cohorts receiving dose levels from 78µg to 600µg are evaluated. Premedication includes acetaminophen, dimetindene and cortisone to minimize the risk of infusion reactions and cytokine release syndrome (CRS). The primary objectives are definition of MTD and recommended phase II dose. Assessment of safety is based on the frequency of adverse events according to CTCAE v5.0. Dose limiting toxicities are defined as ≥ 3° adverse drug reactions (e.g. CRS) with predefined exceptions (e.g. temporary laboratory abnormalities). Efficacy is determined by serial PSA-measurements (PSA-response: ≥50% decrease compared to baseline). Furthermore, percentage of patients with no clinical relapse, no salvage and no subsequent antineoplastic therapy will be assessed. Clinical trial information: NCT05646550. Research Sponsor: AKF program of the University Tübingen; Else-Kröner Fresenius Stiftung.

PSMAAddition: A phase 3 trial to compare treatment with ¹⁷⁷Lu-PSMA-617 plus standard of care (SoC) and SoC alone in patients with metastatic hormone-sensitive prostate cancer. *First Author: Scott T. Tagawa, Weill Cornell Medicine, New York, NY*

Background: Lutetium (¹⁷⁷Lu) vipivotide tetraxetan (¹⁷⁷Lu-PSMA-617) plus protocol-permitted standard of care (SoC) significantly improved radiographic progression-free survival (rPFS) and overall survival (OS) in patients with prostate-specific membrane antigen (PSMA)-positive metastatic castration-resistant prostate cancer, previously treated with at least one androgen receptor pathway inhibitor (ARPI) and one or two taxanes. Androgen deprivation therapy (ADT) and ARPIs may alter PSMA expression and radiosensitivity. PSMAAddition will assess the efficacy and safety of ¹⁷⁷Lu-PSMA-617 plus SoC versus SoC alone in adults with metastatic hormone-sensitive prostate cancer (mHSPC). **Methods:** PSMAAddition (NCT04720157) is an international, prospective, open-label, randomized, phase 3 trial, with crossover, in adults with mHSPC. Eligible patients are treatment-naïve or minimally treated candidates for hormonal therapy, with PSMA-positive disease (determined by ⁶⁸Ga-PSMA-11 PET/CT), ECOG performance status of 0 to 2 and adequate major organ function. Patients are excluded if they have rapidly progressing tumors that require chemotherapy. Approximately 1126 patients will be randomized 1:1 to receive ¹⁷⁷Lu-PSMA-617 (7.4 GBq every 6 weeks for a maximum of 6 cycles) plus SoC or SoC alone (an ARPI and ADT). Stratification factors are tumor volume (high/low), age (≥ 70 / < 70 years), and previous/planned prostatectomy or radiation treatment of the primary prostate tumor (yes/no). Recruitment for a China extension cohort (40–60 patients) will follow after completion of main study recruitment. The primary endpoint is rPFS, as assessed by blinded independent centralized review. Upon centrally confirmed radiographic progression, participants in the SoC-only arm can cross over to the ¹⁷⁷Lu-PSMA-617 arm. The planned sample size provides 95% power to detect a hazard ratio of 0.7 for rPFS after 418 events with an overall one-sided significance level of 0.025. The key secondary endpoint is OS, others include the proportion of patients with a prostate-specific antigen (PSA) decline of ≥ 90% from baseline, time to development of metastatic castration-resistant prostate cancer, composite PFS (radiographic, clinical or PSA progression), safety and tolerability, and health-related quality of life. Imaging and biospecimen (tissue and blood) collection is embedded for correlative analysis. Participants who have received ¹⁷⁷Lu-PSMA-617 will have the option to enroll in a separate long-term safety follow-up study. Updated from previous presentation at the 2021 European Society for Medical Oncology Congress, FPN 3035, with permission. Clinical trial information: NCT04720157. Research Sponsor: Novartis.

APPROACH trial: Multimodal approach in patients with mHSPC: A pragmatic, randomized, phase 3 trial of androgen-deprivation therapy (ADT) plus apalutamide (APA) versus ADT plus apalutamide (APA) and local treatment—Meet-URO 29 study. *First Author: Valentina Guadalupi, Department of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: it is reasonable to offer radiotherapy (RT) to improve outcomes for patients with newly diagnosed M1 prostate cancer with < 5 bone metastases (HRRAD) or low volume disease (STAMPEDE) (Burdett, S *et al.*, Eur. Urol. 2019). Data from clinical randomized trials evaluating feasibility and overall benefit of cytoreductive radical prostatectomy (cRP) in oligo-metastatic hormone sensitive patients are not available. The rationale for performing cytoreductive radical prostatectomy is to eliminate lethal clones of castration-resistant intraprostatic PCa, which can favor the process of metastasis (A Heidenreich *et al.* Current Opinion in Urology 2020), in order to improve OS and PFS and to prevent local progression and correlated events. **Methods:** APPROACH is an Italian multicenter study, which is enrolling ~566 pts with oligometastatic hormone sensitive prostate cancer who are candidates to receive treatment with apalutamide. After 6 months from the start of treatment, patients will be randomized 1:1 to receive local treatment or not in addition to apalutamide (investigator's choice between primary radiotherapy and cytoreductive prostatectomy). Primary end point: To determine whether treatment with apalutamide plus ADT for 6 months followed by locoregional treatment with radiotherapy or radical prostatectomy has better efficacy than treatment with apalutamide plus ADT alone in terms of radiographic progression-free survival (rPFS). Secondary end points: To evaluate tumor shrinkage after locoregional approach and to evaluate short and long-term side effects after locoregional surgery or RT, time to PSA progression, time to castration resistance, cancer specific survival, overall survival and quality of life according to EPIC-26 and EQ-5D-5L questionnaires. Clinical trial information: NCT05649943. Research Sponsor: Janssen.

Phase 1/2a study of PRL-02, a long-acting intramuscular (IM) depot injection of abiraterone decanoate, in patients (pts) with advanced prostate cancer. *First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC*

Background: PRL-02 is a long-acting IM depot injection of abiraterone decanoate, a novel prodrug of abiraterone delivered through the lymphatic system. PRL-02 potentially blocks androgen production with minimal increases in mineralocorticoids or decreases in glucocorticoids through preferential inhibition of Cytochrome P450 (CYP)17 lyase versus CYP17 hydroxylase. Phase 1 is a standard 3+3 design intended to identify a recommended Phase 2 dose (RP2D). PRL-02 is administered every 84 days (1 cycle). As of 9/8/22, 17 pts (6 mCRPC, 11 mCSPC) were treated across 5 dose cohorts (180, 360, 720, 1260, 1800mg). At 720mg and above, 9 of 11 had a 90% reduction in testosterone (T), including 2 pts with T ≤ Lower Limit of Quantitation (LLOQ) of 0.1ng/dL. A PSA decline of ≥50% from baseline (PSA50) was observed in 8 of 10pts. PRL-02 was very well tolerated. Only minimal and transient changes in 'upstream' steroids (e.g., progesterone) were observed at doses of 1260 mg (the RP2D) and lower. **Methods:** Phase 2a is an A'Hern single-stage design. Group 1 includes pts with mCSPC divided into 2 groups (1A: previously untreated high-volume disease and 1B: previously untreated, low-volume disease). Group 2 includes pts with mCRPC. Enrollment of 66 pts is planned across 30 sites in the U.S. (Clinical Trial information: NCT04729114). Patient populations, interventions and study design are described below. Clinical trial information: NCT04729114. Research Sponsor: U.S. National Institutes of Health; Propella Therapeutics, Inc.

Patient population, primary endpoints, hypothesis testing and rationale.			
Group	1A	1B	2
Patient Population	mCSPC, previously untreated high-volume disease	mCSPC, previously untreated, low-volume disease	Chemotherapy-naïve, mCRPC
Treatment	PRL-02 + dexamethasone (Dex) + docetaxel + Androgen Deprivation Therapy (ADT)	PRL02 + Dex + ADT	PRL02 + Dex + ADT
Primary Endpoint	Undetectable PSA (≤0.2ng/mL) at 8 months	Undetectable PSA (≤0.2ng/mL) at any time	PSA50 confirmed by a second consecutive PSA at least 3 weeks later
HO and Ha Rationale/Precedent	0.51, 0.70 PEACE-1 trial (NCT01957436) (Mescam 2022; Klaassen 2022), which showed a strong correlation between undetectable PSA at 8 months and clinical benefit. (overall survival and Radiographic progression-free survival) The combination of abiraterone + prednisone + docetaxel + ADT had a 51% rate of undetectable PSA at months	0.51, 0.70 Null hypothesis based on the LATITUDE study (NCT01715285) (Fizazi 2019; Tran 2019) in which the undetectable PSA rate at any time was 0.55	0.50, 0.75 Null hypothesis based on the activity of the ACIS study control arm abiraterone + prednisone (NCT02257736) (Saad 2021)

Phase III study of local or systemic therapy intensification directed by PET in prostate cancer patients with post-prostatectomy biochemical recurrence (INDICATE): ECOG-ACRIN EA8191. *First Author: Neha Vapiwala, Abramson Cancer Center, Philadelphia, PA*

Background: Salvage radiation therapy (sRT) to the prostate bed and pelvic nodes with short-term androgen deprivation therapy (STAD) is considered a standard of care (SOC) salvage therapy (ST) paradigm for prostate cancer (PC) patients (pts) with post-prostatectomy (RP) biochemical recurrence (BCR). PET imaging with recently FDA-approved agents in this setting (18F-Fluciclovine, 18F-DCFPyL and 68Ga-PSMA-11), have shown improved accuracy for detection of metastases not identified with conventional imaging (CIM). Given the greater sensitivity and specificity of PET, its findings are being increasingly but variably applied to justify modification or omission of SOC therapies without high-level evidence of clinical benefit. PET may help identify candidates for different treatment intensification approaches. In metastatic prostate cancer, metastasis-directed RT (MDT) has been used to avoid or delay systemic therapy in men with oligometastatic disease. Apalutamide (Apa) is an androgen receptor signaling inhibitor that has been shown to improve outcomes when added to ADT in mCSPC. This study will evaluate whether patients with PET-detected lesions outside the pelvis will benefit from addition of MDT to treatment intensification with STAD/Apa, and whether patients with no PET-detected lesions outside the pelvis will benefit from addition of Apa to standard sRT/STAD. **Methods:** PC pts with post-RP BCR (PSA > 0.5ng/mL; > 0.2ng/mL if first detectable within 12 mos of RP) and no extrapelvic metastases on CIM who are candidates for SOC ST (sRT to prostate bed and pelvic nodes with STAD) are eligible. Pts will undergo SOC baseline PET using a FDA-approved tracer. Based on institutional clinical interpretation of the SOC PET, pts will be placed in Cohort 1 (PET-negative) or 2 (PET-positive for extra-pelvic metastases). Cohort 1 will be randomized to SOC ST +/- Apa for 6 months and Cohort 2 will be randomized to SOC ST and Apa +/- MDT to PET-positive lesions. The primary endpoint is PFS, defined as time from randomization to radiographic progression on CIM, symptomatic disease or death, whichever occurs first. Primary objectives are to evaluate whether addition of Apa to SOC ST and addition of MDT to SOC ST and Apa could prolong PFS in Cohorts 1 and 2, respectively. For Cohort 1, 480 pts will be randomized with 85% power to distinguish a 5-year PFS rate of 90% (Apa arm) vs. 80% (SOC arm) using one-sided stratified logrank test with type I error of 0.025. For Cohort 2, 324 pts will be randomized with 85% power to distinguish a 5-year PFS rate of 76.5% in the experimental arm from 61.5% in the control arm. Secondary endpoints include overall and event-free survival, toxicity, PET progression and quality of life. Clinical trial registry number: NCT04423211. Clinical trial information: NCT04423211. Research Sponsor: U.S. National Institutes of Health; Janssen.

Exercise to enhance cardiovascular health among Black patients with prostate cancer with androgen deprivation therapy: The POWER trial. *First Author: Dong-Woo Kang, Dana-Farber Cancer Institute, Boston, MA*

Background: Large racial disparities persist in prostate cancer (PCa) incidence and mortality in the US. Among all races, Black men have the highest rates of PCa incidence and mortality, where they are 1.7 and 2.1 times more likely to develop and die of PCa compared to non-Hispanic White men, respectively. Androgen deprivation therapy (ADT) is one of the most recommended treatments for intermediate and advanced PCa. However, men receiving ADT have a higher risk of developing cardiovascular disease (CVD) by 65% compared to patients not receiving ADT, which is likely linked to ADT-induced cardiovascular and metabolic toxicity. Moreover, Black men with PCa receiving ADT have a higher risk of CVD-related death and a higher prevalence of comorbid conditions. Therefore, prevention and management of CVD risk factors in this population is an important unmet clinical need. Exercise is an effective way to lower CVD risk factors in many clinical settings; however, Black men with cancer are underrepresented in exercise oncology research, and no studies to date have focused on Black men with PCa on ADT. We designed a randomized controlled trial, entitled "Exercise to Enhance Cardiovascular Health among Black Prostate Cancer Patients with Androgen Deprivation Therapy: POWER Trial." The objective of the POWER Trial is to examine the effects of a tailored exercise intervention on CVD risk factors in Black men with PCa undergoing ADT. **Methods:** The POWER trial is a two-arm, multi-center, randomized controlled trial, recruiting 62 Black men with localized or metastatic PCa who are receiving ADT at Dana-Farber Cancer Institute or Beth Israel Deaconess Medical Center, Boston, MA. Participants are randomly assigned to either exercise training or usual care at a 1:1 ratio. Participants in the intervention group are asked to complete a culturally tailored, home-based, virtually supervised exercise training program thrice weekly for 16 weeks. Aerobic exercise is high-intensity interval training and performed on a stationary bike, alternating 1-min high-intensity (75-95% of VO_{2peak}) and 1-min recovery (40% of VO_{2peak}) intervals. Resistance exercises are performed on large muscle groups using dumbbells with 2-3 sets of 15-20 repetitions at 60-75% of the 1-repetition maximum. Participants in the usual care group are asked not to change their baseline exercise behavior and then may cross over to the exercise program after the initial 16 weeks. The primary outcome is the CVD risk assessed by the Framingham Risk Score (i.e., age, sex, blood cholesterol, blood pressure, and smoking). The secondary and exploratory outcomes include cardiorespiratory fitness, muscular strength, body composition, patient-reported outcomes, and treatment-related symptoms. To date, five out of the planned 62 patients have been enrolled. This trial is registered in clinicaltrials.gov (NCT05327465). Clinical trial information: NCT05327465. Research Sponsor: CDMRP.

Prime-boost immunotherapeutic trial in men with biochemical recurrence after definitive local therapy for prostate cancer. *First Author: Mark N. Stein, Department of Medicine and Division of Hematology/Oncology, Columbia University Medical Center, New York, NY*

Background: VTP-850 is a heterologous prime-boost immunotherapeutic consisting of 2 nonreplicating viral-vectored components: ChAdOx1-PCAQ, based on an adenoviral vector, and MVA-PCAQ, based on a modified vaccinia virus Ankara (MVA) vector. Both components encode the same 4 prostate cancer antigens: prostate-specific antigen (PSA), prostatic acid phosphatase (PAP), six transmembrane epithelial antigen of prostate 1 (STEAP1), and 5T4, an oncofetal antigen. Preclinical studies in inbred, outbred, and HLA-A2 transgenic mice show that VTP-850 is highly immunogenic. Immune responses were measured in splenocytes using IFN- γ ELISpot assay, multiparameter flow cytometry, and targeted in vivo killing assays. The results indicate that VTP-850 can elicit T cell responses to each of the 4 encoded antigens, with the responses to PSA of greatest magnitude in all mouse strains studied. Intravenous administration of the boost resulted in a 6-fold increase in the magnitude of antigen-specific T cells induced and increased in vivo killing relative to the intramuscular boosting route. **Methods:** This is a first-in-human multicenter Phase 1/2 trial to evaluate safety, PSA response rate and duration, and immunogenicity of VTP-850 in men with biochemical recurrence of prostate cancer after definitive local therapy. Phase 1 (15-18 participants) will follow a 3+3 design to determine the recommended phase 2 regimen; dose level of both ChAdOx1-PCAQ and MVA-PCAQ, and route of administration of MVA-PCAQ (IM or IV). Phase 2 will consist of 2 stages. In Stage 1, 19 additional participants will be enrolled at the chosen Phase 2 regimen. If 4 or more of the 25 participants (including the 6 Phase 1 participants who received the same regimen) have a PSA response (defined as $\geq 50\%$ reduction in serum PSA compared to baseline at any time, measured twice consecutively, at least 2 weeks apart), Stage 2 will enroll 100 additional participants. Participants will be followed for 6 months or until start of new therapy (e.g. ADT) or until development of metastatic disease. Participants who have a PSA response during the 6 months follow up will be followed for up to an additional 18 months. Patients who have undergone primary therapy for prostate cancer and have biochemical recurrence are eligible. Patients must have nonmetastatic (M0) disease; serum PSA of > 0.3 ng/mL for participants with prior radical prostatectomy or serum PSA of 2 ng/mL above nadir for participants with prior external beam radiation or brachytherapy; PSA doubling time ≤ 12 months; and testosterone > 75 ng/dL. They cannot have received ADT within 6 months prior to Day 1 and cannot have received prior chemotherapy, immunotherapy or experimental agent for prostate cancer. The trial is open in the USA, with sites in Spain and Italy planned to open later in 2023. 1. Vardeu A et al 2022. Clinical trial information: NCT05617040. Research Sponsor: Vaccitech.

A multi-center natural history study of precision-based genomics in prostate cancer (PC). *First Author: Himisha Beltran, Dana-Farber Cancer Institute, Boston, MA*

Background: With genomic-based therapies approved for advanced PC, there has been a substantial rise in the clinical use of genomic sequencing. In addition to identifying actionable targets, there is a long list of less common 'tail' alterations in metastatic PC with unclear prognostic or predictive significance. We hypothesize that integrative clinico-genomic studies of uncommon subgroups of PC, defined based on a molecular biomarker of low-prevalence or based on an exceptional clinical outcome to therapy, can lead to the identification of new predictive and resistance biomarkers and will accelerate the development of precision medicine strategies for patients with PC. **Methods:** This is a multi-institutional prospective observational study for longitudinal collection of clinical and genomic data from participants (prts) with distinct molecular alterations of interest and/or exceptional phenotypes. The primary objectives are: 1) to define the natural history of men with select molecular alterations and/or exceptional clinical responses, 2) to establish a biospecimen repository for extensive molecular analyses to study the biology of PC and mediators of therapeutic response and resistance. Exploratory objectives include: 1) understanding the impact of co-occurring genomics alterations and other molecular alterations on the natural history of PC in these defined subsets, 2) identifying biologic mechanisms of exceptional response, primary and secondary resistance, and tracking evolutionary patterns that occur during acquired resistance. Eligible prts have a diagnosis of PC with known germline and/or somatic variants in *PIK3A*, *PIK3CB*, and/or *AKT*, *PALB2*, *BRIP1*, *RAD50*, *RAD51*, *RAD54*, *RB1*, *SPOP*, Wnt/B-catenin pathway, MMR genes (*MLH1*, *MSH2*, *MSH6*, *PMS2*), *EPCAM* and/or TMB-high (as defined by TMB ≥ 10 mut/Mb). Any platform for genomic testing is acceptable and data is collected centrally. Prts deemed exceptional responders (with or without mutational aberrations) are defined as those with a complete response or a confirmed partial response of any duration of time to systemic therapies or any response of exceptional duration (particularly with therapies targeting PARP, the androgen receptor, and/or immunotherapies). Data including demographic, disease characteristics, treatment outcomes including response to therapies, and survival are collected along with other pathologic, radiographic, and molecular/genomic data. Correlative sample collection includes archival primary and metastatic biopsy specimens and prospective collection of blood for future analyses. This study will provide insights into the significance of individual and co-occurring alterations and will help establish a path forward for the expansion of drug indications for PC patients with rare variants. 37 prts have been accrued with an accrual ceiling of 2000 prts. Clinical trial information: NCT04706663. Research Sponsor: U.S. National Institutes of Health.

KEYNOTE-826: Final overall survival results from a randomized, double-blind, phase 3 study of pembrolizumab + chemotherapy vs placebo + chemotherapy for first-line treatment of persistent, recurrent, or metastatic cervical cancer. *First Author: Bradley J. Monk, Division of Gynecological Oncology, HonorHealth Research Institute, University of Arizona College of Medicine, Phoenix and Creighton University School of Medicine, Phoenix, AZ*

Background: The first interim analysis of KEYNOTE-826 (NCT03635567) showed that first-line pembrolizumab (pembro) + chemotherapy (chemo) provided statistically significant and clinically meaningful improvements in OS and PFS vs placebo (pbo) + chemo in patients (pts) with recurrent, persistent, or metastatic cervical cancer across all prespecified populations (PD-L1 combined positive score [CPS] ≥ 1 , all-comer, and CPS ≥ 10). Here, we present the protocol-specified final OS analysis results of KEYNOTE-826. **Methods:** Eligible adults with persistent, recurrent, or metastatic cervical cancer not previously treated with systemic chemo (prior radiosensitizing chemo allowed) and not amenable to curative treatment (surgery or radiation) were randomized 1:1 to pembro 200 mg or placebo Q3W for up to 35 cycles + chemo (paclitaxel 175 mg/m² + cisplatin 50 mg/m² or carboplatin AUC 5), $\pm$ bev 15 mg/kg. Pts were stratified by metastatic status at diagnosis (yes/no), planned bev use (yes/no), and PD-L1 CPS (< 1 , 1 to < 10 , or ≥ 10). Dual primary end points were OS and PFS per RECIST v1.1 assessed by investigator review, each tested sequentially in the PD-L1 CPS ≥ 1 , all-comer, and CPS ≥ 10 populations. **Results:** From Nov 2018 to Jan 2020, 617 patients were randomized (pembro + chemo, n = 308 [63.6% with bev]; pbo + chemo, n = 309 [62.5% with bev]); 548 (88.8%) pts had PD-L1 CPS ≥ 1 and 317 (51.4%) had CPS ≥ 10 . At the Oct 3, 2022 data cutoff, median follow-up was 39.1 mo. Pembro + chemo significantly improved OS and PFS in the CPS ≥ 1 , all-comer, and CPS ≥ 10 populations (Table). The pembro + chemo benefit was seen regardless of bev use. Grade ≥ 3 AE incidence was 82.4% in the pembro + chemo arm and 75.4% in the placebo + chemo arm. The most common grade ≥ 3 AEs were anemia (30.3% vs 27.8%), neutropenia (12.4% vs 9.7%), and hypertension (10.4% vs 11.7%). **Conclusions:** The addition of pembro to chemo $\pm$ bev significantly reduced the risk of death by 40% in the PD-L1 CPS ≥ 1 population, by 37% in the all-comer population, and by 42% in the CPS ≥ 10 population, and had a manageable safety profile. These data are consistent with the earlier results and provide further support for pembro + chemo $\pm$ bev as a new standard of care for first-line treatment of persistent, recurrent, or metastatic cervical cancer. Clinical trial information: NCT03635567. Research Sponsor: Merck & Co., Inc.

Oral Abstract Session

Incorporation of triapine (T) with cisplatin chemoradiation (CRT) for locally advanced cervical and vaginal cancer: Results from NRG-GY006, a phase III randomized trial. *First Author: Charles A. Leath, O'Neal Comprehensive Cancer Center at the University of Alabama at Birmingham School of Medicine, Birmingham, AL*

Background: Definitive cisplatin-based chemoradiation (CRT) plus brachytherapy for locally advanced cervical cancer (FIGO IB3-IVA) results in sustained survival for 60-70% of patients. Recent studies integrating anti-PD-1 checkpoint immunotherapy (CALLA, NCT03830866) or consolidation chemotherapy (OUTBACK, ACTRN12610000732088) have not demonstrated a survival benefit over CRT. Intrinsic overexpression of ribonucleotide reductase may enhance DNA damage repair due to CRT. We report on the efficacy and tolerability of adding the ribonucleotide reductase inhibitor, triapine, to CRT. **Methods:** NRG GY006 is a randomized, open-label phase III clinical trial. Eligible patients had FIGO 2009 locally advanced cervical (stages IB2, II, IIIB or IVA without radiographic evidence of para-aortic nodal involvement) or stages II-IV vaginal cancer. Patients were randomly assigned to receive cisplatin (40 mg/m² weekly) with RT 45 Gy + lymph node boost alone (CRT) or CRT in combination with 15 total infusions of triapine (25 mg/m² IV) Mon/Wed/Fri (CRT + T). Both image guided IMRT or 3D RT were allowed but needed to be specified and pass a rigorous credentialing process. All RT plans had a pre-treatment review with expert planning feedback to the sites. The primary endpoint was overall survival (OS); secondary endpoint was progression-free survival. Exploratory endpoints included rate of complete metabolic response on post treatment PET/CT imaging at 3 months and knowledge-based planning for image guided IMRT. The target sample was 450 with 127 OS events. The design was to provide 80% power to detect a 10% improvement in OS at 3 years over the control (or HR = 0.6) at 2.5% significance level including one interim futility analysis at 50% information time. **Results:** Between 1/15/16 and 9/22/22 448 eligible patients were randomized to CRT (n=224) or CRT+T (n=224). The database was locked on 10/18/22 with 69 deaths. Median age was 47 years (range 23-85 years). The majority had cervical cancer (93.3%) and squamous cell carcinoma (82%). 52% had FIGO stage II disease. Racial/ethnic distribution included non-Hispanic white (53.8%), Hispanic/Latina (22.5%), and black (15.2%). IMRT was used in (74.3%) and HDR brachytherapy (98.2%) of cases. No differences in Grade 3-5 toxicities were observed: CRT =52% and CRT +T= 49% with Two G5 toxicities (cardiac arrest and acidosis) in the CRT+T arm. 343 patients have completed all protocol directed therapy. With a median follow-up of 28 months (IQR 15-45 months), the median PFS and OS for both arms were not reached yet. HR for death was 1.018 (95% CI 0.634-1.635), the conditional power was 15% to detect a HR = 0.6 at 100% information time. **Conclusions:** The addition of triapine to CRT did not improve OS. Clinical trial information: NCT02466971. Research Sponsor: U.S. National Institutes of Health.

Oral Abstract Session

In situ immune impact of nivolumab + ipilimumab combination before standard chemoradiation therapy (RTCT) for FIGO IB3-IVA in patients (pts) with cervical squamous carcinoma: COLIBRI trial, a GINECO study. *First Author: Isabelle Laure Ray-Coquard, Centre Léon Bérard, University Claude Bernard Lyon 1, Lyon, France*

Background: We report the results of a window-of-opportunity phase 2 trial using neoadjuvant nivolumab + ipilimumab followed by standard chemoradiation therapy (RTCT) in cervical squamous cell carcinoma pts using the CD8⁺/FOXP3⁺ ratio as a surrogate marker of immune checkpoint blockade (ICB) *in situ* effect. Association with better clinical outcome after neoadjuvant chemotherapy and higher CD8⁺/FOXP3⁺ ratio was described in cervical cancer pts. However, immune modulation after ICB and correlation with treatment response needs to be characterized. **Methods:** The primary objective was to explore the changes in the ratio of CD8⁺/FOXP3⁺ in tumor biopsies performed before and after ICB (prior to standard RTCT) by multiplex-immunofluorescence (mIF) analyzing densities of CD8 effector T cells (CD8⁺: CD3⁺CD8⁺FOXP3⁻) and CD4 regulatory T cells (FOXP3⁺: CD3⁺CD8⁻FOXP3⁺). To normalize the distribution of the values, mIF data were log-transformed (log10). Targeted gene expression profiling of 2,549 genes using HTG technology allowed us to evaluate the 27-gene based 'HOT' score reported to be associated with immunologically active tumors (Foy J-P. *et al.*, 2022, Eur J Can). **Results:** Pts received 1 cycle of nivolumab 3 mg/kg (D1D15) + ipilimumab 1 mg/kg (D1) before starting RTCT + brachytherapy. After RTCT, pts could continue nivolumab in maintenance 480 mg total dose every 28 days for 6 months. Forty pts were treated (including 50% FIGO III-IV). There were no new or unexpected toxicity. Grade ≥ 3 AEs related to ICB occurred in 3 pts. mIF data of the 28 evaluable pts revealed an increase of total CD8⁺ cells (Wilcoxon, p=0.009), proliferating CD8⁺ cells (p=0.002) and CD8⁺/FOXP3⁺ ratio (p=0.03) between baseline and before RTCT. In the 37 pts evaluable by HTG, a significant increase of expression of the *CD8A* gene (paired t-test, p=2.2e-05) and the 'HOT' score (paired t-test, p=3.1e-06) was observed after ICB. The Objective Response Rate on primary tumor before, after, at the end of treatment (EOT) is reported in table. Correlation between CD8⁺/FOXP3⁺ ratio, the 'HOT' score and response to treatment will be presented. **Conclusions:** These data indicate that neoadjuvant nivolumab + ipilimumab is safe and orchestrates *de novo* immune responses in cervical squamous cell carcinoma. The 82.5% CR rate on primary tumor 6 months post RTCT suggests favorable clinical outcomes. Clinical trial information: NCT04256213. Research Sponsor: Bristol-Myers Squibb.

Oral Abstract Session

Dostarlimab for primary advanced or recurrent (A/R) endometrial cancer (EC): Outcomes by blinded independent central review (BICR) of the RUBY trial (ENGOT-EN6-NSGO/GOG-3031/RUBY). *First Author: Matthew A. Powell, National Cancer Institute sponsored NRG Oncology, Washington University School of Medicine, St Louis, MO*

Background: RUBY (NCT03981796) evaluated the efficacy and safety of the anti-programmed death 1 (PD-1) dostarlimab + standard of care (SOC) carboplatin paclitaxel (CP) versus CP alone in A/R EC. The primary endpoint of PFS by investigator assessment (INV) per RECIST v1.1 was significantly longer with dostarlimab+CP than placebo (PBO)+CP in the mismatch repair deficient/microsatellite instability-high (dMMR/MSI-H; HR 0.28; 95% CI 0.162-0.495) and overall populations (HR 0.64, 95% CI 0.507-0.800). Here we present secondary efficacy endpoints by BICR. **Methods:** RUBY is a phase 3, global, randomized, double-blind, multicenter, PBO-controlled study. Patients (pts) with primary advanced stage III or IV or first recurrent EC were randomized 1:1 to receive dostarlimab 500 mg, or PBO, plus carboplatin AUC 5 and paclitaxel 175 mg/m² Q3W (6 cycles), followed by dostarlimab 1000 mg, or PBO, monotherapy Q6W for up to 3 y. Secondary endpoints by BICR assessment per RECIST v1.1 were PFS, ORR, DOR, and DCR in the overall and dMMR/MSI-H populations. **Results:** 494 pts were randomized (245:dostarlimab+CP; 249:PBO+CP); 47.8% had recurrent disease, 18.6% and 33.6% had primary stage III and IV disease, respectively. PFS by BICR was longer with dostarlimab+CP than PBO+CP in the dMMR/MSI-H (HR 0.29; 95% CI 0.158-0.543) and overall populations (HR 0.66; 95% CI 0.517-0.853; Table). Consistent benefits were seen with dostarlimab+CP for ORR, DCR, and DOR by BICR in the dMMR/MSI-H and overall populations (Table). Safety was previously reported. **Conclusions:** Dostarlimab+CP showed clinically meaningful improvement in BICR-assessed PFS in the dMMR/MSI-H and overall populations compared with CP alone. The HRs for PFS per BICR and per INV were consistent, which supports the reliability of PFS by INV in EC trials. Benefits were seen in all BICR-assessed endpoints, which were consistent with INV. Dostarlimab+CP represents a new SOC for pts with primary A/R EC. Clinical trial information: NCT03981796. Research Sponsor: GSK.

Oral Abstract Session

Patient-reported outcomes (PROs) in primary advanced or recurrent endometrial cancer (pA/REC) for patients (pts) treated with dostarlimab plus carboplatin/paclitaxel (CP) as compared to CP in the ENGOT-EN6/GOG3031/RUBY trial. *First Author: Mansoor Raza Mirza, Rigshospitalet, Copenhagen University Hospital, Nordic Society of Gynaecological Oncology—Clinical Trial Unit, Copenhagen, Denmark*

Background: In RUBY, a phase 3, global, randomized, double-blind, placebo (PBO)-controlled trial, dostarlimab+carboplatin/paclitaxel demonstrated significant and clinically meaningful improvement in PFS compared with PBO+CP in pts with pA/REC. PROs are reported here. **Methods:** 494 pts with pA/REC were randomized 1:1 to dostarlimab (D)+CP or PBO+CP Q3W for 6 cycles followed by D or PBO monotherapy Q6W $\leq$ 3 yrs or to disease progression. EORTC QLQ-C30 and EN24 were prespecified secondary endpoints. PROs were administered on Day 1 of each treatment (tx) cycle (C), end of tx (EOT), and at safety and survival follow-ups and reported here for C7, the end of chemotherapy (chemo) and C13, and the end of 1 yr of study. Change (chg) from baseline (BL) to C7/C13 was calculated for all scales assessed. Mixed model for repeated measures analysis was conducted to generate least-squares means (LSM), adjusting for correlations across multiple time point assessments within a pt and controlling for the BL value for the global, pain, fatigue, and physical function (PF) scores. **Results:** PRO outcomes were similar for D+CP and PBO+CP through the chemo period (C7). The table shows selected scores at C7 and C13 for mean (SD) and chg from BL. Further, no differences across the 3 yr period between the 2 arms were reported; LSM (standard error) for global QoL was 0.5 (1.42; $P=0.72$), PF was -0.7 (1.39; $P=0.63$), fatigue was 0.2 (1.75; $P=0.91$) and pain was -1.0 (1.99; $P=0.62$). Mean chg from BL to EOT showed improvement in back/pelvic pain for D+CP and deterioration in global QoL/GHS, social functioning, body image, and chg in taste for pts on PBO+CP. **Conclusions:** Dostarlimab + CP significantly improved PFS while maintaining HRQoL, further supporting its use as a standard of care in pA/REC. Clinical trial information: NCT03981796. Research Sponsor: GSK.

Oral Abstract Session

Randomized controlled phase III trial of weekly paclitaxel $\pm$ ofranergene obadenovex (VB-111) for platinum-resistant ovarian cancer (OVAL Study/GOG 3018). *First Author: Rebecca Christian Arend, University of Alabama at Birmingham, Birmingham, AL*

Background: Ofranergene obadenovex (ofra-vec, VB-111) is a nonreplicating adenoviral vector with a murine pro-endothelin 1 (PPE-1-3X) promoter and pro-apoptotic Fas-tumor necrosis factor receptor 1 (TNFR1) chimeric transgene thought to have a dual mechanism of action: vascular disruption and immune activation. **Methods:** This is a randomized, placebo-controlled, double-blind, multi-center randomized phase III trial (ClinicalTrials.gov identifier: NCT03398655) of ofranergene obadenovex combined with paclitaxel vs paclitaxel with placebo for the treatment of patients with recurrent platinum resistant ovarian cancer (PROC). Patients were randomly assigned 1:1 to receive IV VB-111 1×10^{13} viral particles (VPs) every 8 weeks with weekly IV paclitaxel 80 mg/m² or placebo with paclitaxel until disease progression. The dual primary endpoints were overall survival (OS) and progression free survival (PFS) as assessed by Blinded Independent Central Review (BICR). **Results:** Between December 2017 and March 2022, 409 patients were randomized at 86 clinical sites in US, Israel, Spain, Poland and Japan. The median PFS was 5.29 months in the VB-111 arm and 5.36 months in the control arm; hazard ratio (HR) 1.03 (CI: 0.83-1.29, $p = 0.7823$), and median OS with was 13.37 months vs. 13.14 months HR 0.97 (CI: 0.75-1.27 $p = 0.8440$). Objective response rates (ORR) were similar in both arms: RECIST 1.1 ORR was 28.9% with VB-111 vs. 29.6% with control (CA-125 ORR 41.1% vs 49.4%). In both treatment arms response to CA-125 was a substantial prognostic factor for both PFS and OS. In the VB-111 arm, the HR in CA-125 responders compared to non-responders was for PFS HR 0.2428 (CI: 0.1642-0.3588), and for OS HR 0.3343 (CI: 0.2134-0.5238). Safety profile was consistent with the known safety profile of ofra-vec and was characterized by common transient flu like symptoms such as fever and chills. **Conclusions:** The addition of ofranergene obadenovex to paclitaxel did not improve PFS or OS. Clinical trial information: NCT03398655. Research Sponsor: VBL Therapeutics.

Oral Abstract Session

Luveltamab tazevivulin (STRO-002), an anti-folate receptor alpha (FolR α) antibody drug conjugate (ADC), safety and efficacy in a broad distribution of FolR α expression in patients with recurrent epithelial ovarian cancer (OC): Update of STRO-002-GM1 phase 1 dose expansion cohort. *First Author: Ana Oaknin, Vall d'Hebron Institute of Oncology (VHIO), Vall d'Hebron University Hospital, Barcelona, Spain*

Background: Luveltamab tazevivulin (luvelta) is a novel FolR α -targeting ADC with a stable cleavable linker and a 3-aminophenyl hemiasterlin warhead (DAR of 4) that induces cytotoxic and immunologic cell death. Using site-specific conjugation technology, luvelta is designed to target a broad range of FolR α expressing OC. STRO-002-GM1 is a global phase 1 study evaluating luvelta in patients with relapsed OC. We provide updated data from the initial ovarian expansion cohort. **Methods:** The study enrolled advanced OC pts who had progressive platinum resistant (PROC) after 1-3 prior lines or platinum sensitive disease after 2-3 prior lines of platinum chemotherapy. Pts were randomized 1:1 to received luveltamab at 4.3 or 5.2 mg/kg given IV every 3 weeks until disease progression. Prophylactic corticosteroid eyedrops were not required/administered. FolR α expression was not required for study entry but was analyzed retrospectively in archival tissue using the FOLR1 IHC assay (Ventana Medical Systems). The scoring paradigm assessed percentage of cells with any intensity expression (TPS). TPS $>25\%$ was selected for further analysis. **Results:** 44 pts were enrolled (23 pts at 4.3 mg/kg and 21 pts at 5.2 mg/kg). For pts with a TPS $>25\%$ ($n=35$), the median prior lines of therapy was 2.5 (range 1-3), 69% had prior bevacizumab treatment, and 83% prior PARP inhibitor treatment. Investigator assessed efficacy data for pts with a TPS $>25\%$ are presented in the table. The most common grade ≥ 3 treatment emergent adverse events (TEAEs) included neutropenia (70.5%), arthralgia (18.2%), and anemia (13.6%). G3/4 neutropenia had a higher incidence at 5.2 mg/kg than 4.3 mg/kg (76% vs 65%); most notable for G4 neutropenia (52% vs 22%). 1 pt at each dose level had febrile neutropenia. TEAEs led to dose delay in 80% of pts with a higher incidence at 5.2 mg/kg (95% vs. 65%). TEAEs led to dose reduction in 61% of pts with a higher incidence at 5.2 mg/kg (76% vs. 48%). 1 pt had a G5 sepsis with G4 neutropenia. Neutropenia, arthralgia and anemia were managed with standard medical treatment and dose reductions. **Conclusions:** These dose expansion data confirm activity of luvelta at starting doses ranging from 4.3-5.2 mg/kg in recurrent OC with FolR α expression as low as TPS $>25\%$ and supports further clinical study in this population. The global phase 2/3 REFRAme registration study will evaluate luvelta in PROC pts with TPS $>25\%$. Clinical trial information: NCT03748186. Research Sponsor: Sutro Biopharma, Inc.

Clinical Science Symposium

Final survival analysis of the phase III OVHIPEC-1 trial of hyperthermic intraperitoneal chemotherapy in ovarian cancer after ten year follow-up. *First Author: Lot Aronson, The Netherlands Cancer Institute - Antoni van Leeuwenhoek, Amsterdam, Netherlands*

Background: The randomized, phase 3 OVHIPEC-1 trial (NCT00426257) investigated the addition of hyperthermic intraperitoneal chemotherapy (HIPEC) to interval cytoreductive surgery in patients with stage III epithelial ovarian cancer who were ineligible for primary cytoreduction. OVHIPEC-1 previously demonstrated improved recurrence-free and overall survival after 4.7 years of follow-up. Here, we report the final survival outcomes after ten years of follow-up. In addition, we report new data on the subsequent anti-cancer treatments given after disease progression. **Methods:** Patients were randomized to receive interval cytoreductive surgery with or without HIPEC, after receiving three cycles of neo-adjuvant carboplatin and paclitaxel. Randomization was performed at the time of surgery when either complete (no visible disease) or optimal cytoreduction (residual tumor measuring <10mm in diameter) was anticipated. All patients received an additional three cycles of adjuvant systemic chemotherapy. We analyzed survival according to the intention-to-treat principle using stratified log-rank tests and Kaplan-Meier methods. Subsequent lines of therapy were compared between arms. **Results:** At a median follow-up of 10.1 years, 114 of 123 patients (92.7%) who underwent surgery alone and 109 of 122 patients (89.3%) who had surgery-plus-HIPEC experienced recurrence, progression, or death from any cause. Median recurrence-free survival was 10.7 months in the surgery group compared to 14.3 months in the surgery-plus-HIPEC group (HR, 0.63; 95% confidence interval [CI], 0.48-0.83; stratified P<0.001). One hundred and eight patients (87.8%) in the surgery group have died as compared to 100 patients (82.0%) in the surgery-plus-HIPEC group. Median overall survival was 33.3 versus 44.9 months (HR, 0.70; 95% CI, 0.53-0.92; stratified P=0.011), respectively. Subsequent anti-cancer therapies, including chemotherapy (platinum and non-platinum based), secondary surgery, poly (ADP-ribose) polymerase (PARP) inhibitors and bevacizumab, were received by 104 patients (84.6%) in the surgery group and 100 patients (82.0%) in the surgery-plus-HIPEC group. The median number of subsequent systemic treatment lines was 2 (IQR 1-3) in both arms. **Conclusions:** This study provides the first long-term survival analysis of HIPEC in ovarian cancer and confirms the benefit of HIPEC in patients with primary stage III epithelial ovarian cancer undergoing interval cytoreductive surgery. No imbalance in subsequent therapy after disease recurrence was found that could explain the improved overall survival after HIPEC. Clinical trial information: NCT00426257. Research Sponsor: Dutch Cancer Society (NKI 2006-4176).

Clinical Science Symposium

Hyperthermic intraperitoneal chemotherapy in platinum-sensitive relapsed epithelial ovarian cancer: The CHIPOR randomized phase III trial. *First Author: Jean-Marc Classe, Institut de Cancérologie Ouest, Nantes, France*

Background: Standard treatment for patients with first platinum-sensitive relapse of epithelial ovarian cancer (EOC) is based on surgery and second-line systemic chemotherapy (CT). The role of hyperthermic intra-peritoneal chemotherapy (HIPEC) remains uncertain. **Methods:** The CHIPOR multicentric randomized phase III trial (NCT01376752), conducted in 31 institutions, enrolled patients with a first platinum-sensitive relapse (platinum-free interval of ≥6 months) of EOC. Patients were treated with 6 cycles of platinum and taxane based CT ± bevacizumab, and those amenable to a complete cytoreductive surgery at the end of CT were enrolled and randomly assigned to receive HIPEC (cisplatin 75 mg/m² at 41°C for 60 min) or not. Randomization was performed during complete cytoreductive surgery, stratified by center, surgical outcome (no residual disease vs residual <0.25 cm), chemotherapy-free interval before relapse, and PARP inhibitor use (yes vs no). The primary endpoint was overall survival (OS). The target sample size was 404 evaluable patients, providing 80% power at 5% alpha after 268 deaths. Secondary endpoints included progression-free survival (PFS), peritoneal PFS, patient-reported outcomes, safety, and postoperative morbidity and mortality (≤60 days after surgery). **Results:** Between May 11, 2011, and May 14, 2021, 415 patients were randomized. Baseline characteristics were balanced between treatment arms. At the data cutoff (Jan 8, 2023), with a median follow-up of 6.2 years, 268 patients (65%) had died. Efficacy results are summarized below. **Conclusions:** HIPEC significantly improves OS and peritoneal PFS of women with first platinum-sensitive relapse of EOC treated with second-line platinum-based CT followed by secondary complete cytoreductive surgery. Ongoing analyses, including patient reported outcome, BRCA status, bevacizumab exposure, and subsequent therapy, will be presented. Clinical trial information: NCT01376752. Research Sponsor: The trial was supported by R&D UNICANCER, by a Clinical Research Hospital Program grant from the French Ministry of Health/Institut National du Cancer and by French national Ligue against cancer.

Poster Discussion Session

Randomized phase 2 study of gemcitabine with or without ATR inhibitor berzosertib in platinum-resistant ovarian cancer: Final overall survival (OS) and biomarker analyses. *First Author: Panagiotis A. Konstantinopoulos, Dana-Farber Cancer Institute, Boston, MA*

Background: The multicenter, open-label, randomized phase 2 NCI-9944 study (NCT02595892) demonstrated that addition of ATR inhibitor (ATRi) berzosertib to gemcitabine increased progression-free survival (PFS) compared to gemcitabine alone (HR = 0.57, one-sided log-rank p = 0.044, which met the one-sided significance level of 0.1 used for sample size calculation). Final overall survival (OS) and corresponding biomarker analyses are reported here. **Methods:** Patients (pts) with platinum-resistant high-grade serous ovarian cancer and unlimited previous lines of cytotoxic therapy in the platinum-sensitive setting but no more than one line of cytotoxic therapy in the platinum-resistant setting, were randomized 1:1 to gemcitabine/berzosertib versus gemcitabine alone. Randomization was stratified based on platinum free interval (PFI), PFI ≤3 months versus > 3 months. Crossover from gemcitabine to gemcitabine/berzosertib was allowed upon disease progression by RECIST 1.1. OS was a secondary endpoint while preplanned exploratory correlative studies included assessment of DNA repair pathways and replication stress (RS) alterations by targeted gene sequencing and/or immunohistochemistry (IHC). **Results:** Seventy pts were randomly assigned to treatment with gemcitabine/berzosertib (34 pts) or gemcitabine alone (36 pts); 15 pts crossed over from gemcitabine to gemcitabine/berzosertib. At the final OS analysis (92.9% maturity), median follow-up was 53.2 weeks in the gemcitabine/berzosertib and 43 weeks in the gemcitabine alone groups. Median OS in the intent-to-treat (ITT) population was 59.4 weeks in the gemcitabine/berzosertib group versus 43.0 weeks in the gemcitabine alone group (HR 0.79, 90% CI 0.52-1.2, one-sided p = 0.18). However, when patients who crossed over to gemcitabine/berzosertib were excluded from analysis, a significant OS benefit was observed with gemcitabine/berzosertib (HR 0.60, 90%CI 0.37–0.97); HR was 0.26 (90% CI 0.1–0.7) in pts with PFI ≤3 months and 0.89 (90%CI 0.50–1.59) in pts with PFI > 3 months. Furthermore, significant OS benefit was observed in pts with RS-low tumors (HR 0.39, 90%CI 0.17–0.91, defined as tumors harboring no genomic RS alterations related to loss of RB pathway regulation and/or oncogene-induced RS) but not in pts with RS-high tumors (HR 0.74, 90%CI 0.35–1.56). Additional targeted gene sequencing and IHC analyses as well as analyses adjusting for patient crossover will be reported at the meeting. **Conclusions:** In the ITT population, gemcitabine/berzosertib did not significantly improve OS versus gemcitabine alone. Pts with PFI ≤3 months and pts with RS-low tumors may derive a survival advantage from addition of berzosertib to gemcitabine in the platinum-resistant setting. Clinical trial information: NCT02595892. Research Sponsor: U.S. National Institutes of Health.

Poster Discussion Session

Correlation of cyclin E1 expression and clinical outcomes in a phase 1b dose-escalation study of azenosertib (ZN-c3), a WEE1 inhibitor, in combination with chemotherapy (CT) in patients (pts) with platinum-resistant or refractory (R/R) epithelial ovarian, peritoneal, or fallopian tube cancer (EOC). *First Author: Joyce F. Liu, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Azenosertib (ZN-c3) is a novel, selective, and orally bioavailable WEE1 inhibitor demonstrating single-agent antitumor activity. Azenosertib may inhibit CT-induced DNA damage repair and provide benefit in pts with platinum R/R EOC. Cyclin E1 amplification/overexpression is present in $\geq 35\%$ of metastatic ovarian cancer. High expression/amplification of Cyclin E1 is a poor prognostic marker and predictive of lack of response to platinum-based CT. Ovarian models overexpressing Cyclin E1 have exquisite sensitivity to azenosertib *in vitro* and *in vivo*; forced Cyclin E1 overexpression sensitizes cell lines with low endogenous Cyclin E1 to azenosertib. **Methods:** This open-label, multicenter study (NCT04516447) assessed azenosertib + paclitaxel (PAC), carboplatin (Carbo), gemcitabine (GEM), or pegylated liposomal doxorubicin (PLD) in pts with metastatic high-grade serous EOC after ≤ 2 lines of CT including platinum CT. Primary endpoint is safety and identification of RP2D of each combination. Secondary endpoints include clinical activity. Azenosertib was given continuously or intermittently QD in 21 or 28D cycles until PD or unacceptable toxicity. **Results:** 103 pts were enrolled; at data cut-off, 94 were efficacy evaluable. 26.6% had a partial response (PR) and median progression free survival (PFS) = 9.03 mo (95%CI: 5.52-11.01). Azenosertib + PAC demonstrated the highest ORR [9/18 (50%)], followed by Carbo [9/27 (33.3%)]; ORR for azenosertib + PLD or + GEM was 14.3% (5/35, 2/14 respectively). 80 pts had available Cyclin E1 expression data by IHC; higher Cyclin E1 (H-score > 50) correlated with higher ORR and longer PFS (ORR = 31.3% vs 7.7%; PFS = 10.35 vs 3.25 mo, HR=0.3; Table). Frequent Grade ≥ 3 TEAEs (%) were neutropenia (44.4), thrombocytopenia (30.3), anemia (12.1), leukopenia (11.1), fatigue (10.1), diarrhea (6.1), nausea (5.1), and vomiting (5.1). **Conclusions:** Azenosertib + CT is well tolerated and has encouraging clinical activity, with durable responses in pts with platinum R/R EOC. Pts with Cyclin E1 overexpressing tumors, a subgroup with suboptimal benefits from CT, demonstrated significant improvements in ORR and PFS vs pts with tumors having low expression. These data support a planned trial of azenosertib + CT vs CT alone in Cyclin E1 overexpressing platinum R/R EOC. Clinical trial information: NCT04516447. Research Sponsor: Zentalis Pharmaceuticals.

Poster Discussion Session

A phase II trial of palbociclib combined to letrozole after progression on second-line chemotherapy for women with ER/PR-positive high-grade serous or endometrioid ovarian, fallopian tube, or peritoneal cancer: LACOG 1018. *First Author: Fernanda Bronzon Damian, Hospital São Lucas da PUCRS, Porto Alegre, Brazil; Hospital Fêmima - Grupo Hospitalar Conceição, Porto Alegre, Brazil; Brazilian Gynecologic Oncology Group (EVA), Brazil; Latin American Cooperative Oncology Group (LACOG), Porto Alegre, Brazil*

Background: Treatment options for patients with high-grade ovarian serous (HGSC) or endometrioid carcinoma (HGEC) who progress after receiving chemotherapy for recurrence are limited. **Methods:** LACOG 1018, a phase II, single-arm, multicenter trial evaluated the efficacy of letrozole 2.5mg/day po continuously plus palbociclib 125mg/day po for 21 days in 28-day cycles in patients with histologically proven ovarian HGSC or HGEC, fallopian tube or peritoneal cancer who had progressed on prior chemotherapy for locoregional recurrence or metastatic disease (at least one platinum-based regimen). Patients had centrally confirmed ER and/or PR positivity ($> 10\%$ by immunohistochemistry) and ECOG PS 0-2. The primary endpoint was progression-free survival (PFS) at 12 weeks by RECIST 1.1. Secondary endpoints were overall survival (OS), overall response rate (ORR), clinical benefit rate (CBR) and safety. Tumor evaluations were performed every 6 weeks until week 24. Sample size was calculated as 31 patients for the primary endpoint (90% power to detect a two-sided significance level of 5%, 45% PFS at 12 weeks) and 39 patients for secondary endpoints considering 10% drop-out. NCT03936270. **Results:** A total of 41 eligible patients were included in five Brazilian centers between Feb2020-Jan2022 (table). The PFS-week12 rate was 63.4% (95%CI 46.8 – 76.1). At the time of analysis (cut-off date Jan 18th, 2023) median follow-up was 18.1 months (95%CI 12.9 – 24.3), and 37 PFS events had occurred. Median PFS was 4.2 months (95%CI 2.7 – 5.5) and median OS was 13.4 months (95%CI 10.4 – 20.1). The ORR was 7.7% (N=3 PR) and the CBR was 71.8%. Treatment-related adverse event rates of any grade and grade 3-4 were 95.1% and 51.2%, respectively. Grade 3-4 neutropenia was reported in 17 (41.5%) patients, and febrile neutropenia in 1 (2.4%). Only one patient (2.4%) discontinued the treatment due to toxicity. At the cut-off date, three patients remained on treatment. **Conclusions:** Palbociclib combined to letrozole demonstrated a significant efficacy in terms of PFS rate at 12 weeks (63.4%) and CBR (71.8%), with no new safety concerns in women with recurrent advanced and metastatic hormone receptor-positive ovarian cancer. These results warrant further investigation of palbociclib plus letrozole in high-grade ovarian cancer. Clinical trial information: NCT03936270. Research Sponsor: Pfizer.

Poster Discussion Session

Initial efficacy and safety results from ENGOT-ov60/GOG-3052/RAMP 201: A phase 2 study of avutometinib (VS-6766) $\pm$ defactinib in recurrent low-grade serous ovarian cancer (LGSOC). *First Author: Susana N. Banerjee, The Royal Marsden NHS Foundation Trust and Institute of Cancer Research, National Cancer Research Institute (NCRI), London, United Kingdom*

Background: LGSOC is a RAS/MAPK pathway driven cancer that constitutes $\leq 10\%$ of ovarian cancer. There are no FDA approved treatments specifically for LGSOC. Avutometinib is a novel small molecule RAF/MEK clamp. Focal adhesion kinase (FAK) activation is a resistance mechanism to RAF/MEK inhibition, and defactinib, a small molecule inhibitor of FAK, has shown synergistic antitumor activity with avutometinib in preclinical models. The combination of avutometinib and defactinib has demonstrated a high rate of confirmed and durable responses (overall response rate [ORR] = 46%) in recurrent LGSOC (Banerjee S, ESMO 2021). **Methods:** A registration-directed phase 2, adaptive, multicenter, randomized study was initiated to evaluate avutometinib $\pm$ defactinib in patients with *KRAS* mutant (mt) and *KRAS* wild-type (wt) recurrent LGSOC to identify the optimal regimen based on confirmed ORR by blinded independent central review (Part A) and determine the efficacy of the optimal regimen (Part B) (NCT04625270). Pts were randomized to avutometinib 4 mg orally (PO), twice weekly, 3 weeks on, 1 week off (mono) or avutometinib 3.2 mg PO twice weekly + defactinib 200 mg PO BID 3 weeks on, 1 week off (combo). Key inclusion criteria include histologically confirmed recurrent LGSOC, known *KRAS* status and prior systemic therapy with platinum chemotherapy. Unlimited additional prior lines, including prior MEK inhibitor, were permitted. Here we present efficacy results from Part A (evaluable patients, N=59) and safety data from all pts enrolled (N=121). **Results:** In Part A, the median number of prior systemic regimens was 3 for mono, and 4 for combo. In evaluable patients, a confirmed ORR of 7% (2/30) was observed for mono (13% *KRAS* mt, 0% *KRAS* wt), and an ORR of 28% (8/29) was observed for combo (27% *KRAS* mt, 29% *KRAS* wt). Two of 4 patients previously treated with a MEK inhibitor showed a confirmed partial response (PR) on the combination arm. A high disease control rate (PR or SD ≥ 8 weeks) was observed for both mono (90%) and combo (93%). The majority of treatment related adverse events (AEs, any grade) for combo (N=57) were mild to moderate. The most common Grade ≥ 3 AEs for combo were blood CPK increase (15.8%), fatigue (5.3%), diarrhea (3.5%), dermatitis acneiform (1.8%), and rash (1.8%). A similar AE profile was observed for mono (N=64). Most AEs were manageable/reversible. On the combo arm, 90.6% ($\pm 20\%$) of planned doses were given and 9% (n=5) of pts discontinued due to AEs (asymptomatic elevated blood CPK (n=3) and fatigue (n=2)). **Conclusions:** The interim data support avutometinib + defactinib as an active go-forward regimen in heavily-pretreated recurrent LGSOC, regardless of *KRAS* status. No new safety signals were observed, and most AEs were mild to moderate. Enrollment continues in Part B for the combination of avutometinib and defactinib. Clinical trial information: NCT04625270. Research Sponsor: Verastem Oncology.

Oral Abstract Session

Camrelizumab plus apatinib in patients with advanced or recurrent endometrial cancer after failure of at least one prior systemic therapy: A single-arm phase II trial. *First Author: Huaying Wang, Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China*

Background: The first stage results of a Simon's two-stage single-arm phase II trial showed promising antitumor activity and manageable safety of camrelizumab (a humanized anti-PD-1 monoclonal antibody) plus apatinib (a highly selective VEGFR2 inhibitor) in patients with advanced or recurrent endometrial cancer after failure of prior systemic therapy. Here, we report the primary results of this trial. **Methods:** This open-label, single-arm, phase II trial used a minimax Simon's two-stage design. Patients with advanced or recurrent endometrial cancer that had progressed after at least one prior systemic therapy were treated with camrelizumab (200 mg, intravenously, every two weeks) and apatinib (250 mg, orally, daily) on a four-week cycle until disease progression or intolerable toxicity. The primary endpoint was the objective response rate per Response Evaluation Criteria In Solid Tumors (RECIST) version 1.1. Other assessed endpoints were disease control rate, time to response, duration of response, time to treatment failure, progression-free survival, overall survival, and treatment-related adverse events. **Results:** Between January 20, 2020 and October 14, 2022, 36 patients (median age: 60 [range: 29, 76] years; 17 [47.2%] had Eastern Cooperative Oncology Group [ECOG] performance status 1; 15 [41.7%] had received at least two prior systemic therapies) were enrolled. At the date of data cutoff (December 31, 2022), the median follow-up time was 13.9 (interquartile range: 5.8-23.2) months. All 36 patients were evaluable for efficacy, the confirmed objective response rate was 44.4% (95% CI: 27.9%, 61.9%) and the confirmed disease control rate was 88.9% (95% CI: 73.9%, 96.9%), with two complete response, 14 partial response, and 16 stable disease. The median progression-free survival was 6.4 (95% CI: 5.2, 13.0) months. The treatment-related adverse events of grade 3 or greater occurred in 19 (52.8%) patients, with increased gamma-glutamyltransferase (8 [22.2%]), hyperglycemia (4 [11.1%]), hypertension (4 [11.1%]) and increased direct bilirubin (4 [11.1%]) being most common. Reactive cutaneous capillary endothelial proliferation occurred in 6 (16.7%) patients and all were grade 1 or 2. No treatment-related death occurred. **Conclusions:** Camrelizumab plus apatinib show promising antitumor activity and manageable toxicity in patients with advanced or recurrent endometrial cancer after failure of prior systemic therapy and warrant further investigation. Clinical trial information: ChiCTR2000031932. Research Sponsor: National Natural Science Foundation of China (No. 82002758).

Poster Discussion Session

A phase II basket trial of dual anti-CTLA-4 and anti-PD-1 blockade in rare tumors (DART) SWOG S1609: The vulvar cancers. *First Author: Young Kwang Chae, Northwestern University, Chicago, IL*

Background: Dual checkpoint inhibition with Anti-PD-1 and anti-CTLA4 checkpoint inhibitors have proven to be effective in several malignancies but their potential role in various rare solid cancers is yet to be established. The efficacy of immunotherapy in vulvar cancer patients has not been explored. This study presents the first results of ipilimumab and nivolumab in vulvar cancers (cohort 35) of the SWOG S1609 Dual Anti-CTLA-4 & Anti-PD-1 blockade in Rare Tumors (DART) trial. **Methods:** DART is a prospective, open-label, multicenter/multi-cohort phase 2 clinical trial of ipilimumab (1mg/kg intravenously every 6 weeks) plus nivolumab (240mg intravenously every 2 weeks). The primary endpoint was objective response rate (ORR) (RECIST v1.1) (confirmed complete (CR) and partial responses (PR)); progression-free survival (PFS), overall survival (OS), stable disease (SD) > 6 months, and toxicity are secondary endpoints. **Results:** Sixteen evaluable patients (median age, 55.5 years) were analyzed. 14 cases were of squamous cell carcinoma histology and 2 were of poorly differentiated carcinoma. ORR was 18.8% (3/16, 25% when including one unconfirmed PR). There was 1 CR (SCC; PFS of 465 days) and 2 PR (both SCC; one with 57% regression with PFS of 1022 days, another with 53% regression with PFS of 501 days). Of note, there was one SCC patient with unconfirmed PR that showed 69% regression with PFS of 209 days. Overall clinical benefit rate (CBR; no progression > 6months) was 31.3% (5/16). The median PFS was 2.2 months, 6-month PFS 33%, 1-year PFS 20%. The median OS was 7.6 months, 6-month OS 62%, 1-year OS 44%. The most common adverse events were diarrhea, fatigue, pruritus, anorexia, and nausea (25%, n = 4 each). Grade 3-4 adverse events occurred in 25% of patients (n = 4). There was 1 grade 3-4 adverse event (6.7%) that led to discontinuation, and 1 (6.7%) grade 5 death adverse event. **Conclusions:** Ipilimumab plus nivolumab in vulvar cancers resulted in an ORR of 18.8% and CBR of 31.3%, with durable responses seen. Correlative studies to determine response and resistance markers are ongoing. Expanded prospective studies exploring the role of immunotherapy in vulvar cancers are warranted. Clinical trial information: NCT02834013. Research Sponsor: U.S. National Institutes of Health; Bristol-Myers Squibb.

Neoadjuvant camrelizumab plus chemotherapy for locally advanced cervical cancer (NACI study): A prospective, single-arm, phase II trial. *First Author: Jing Chen, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Background: First-line treatments for locally advanced cervical cancer (LACC) have limited efficacy and neoadjuvant chemotherapy (NACT) is an emerging approach, however, two-thirds of patients (pts) respond to it and pts without response benefit little. PD-1 inhibitors have shown promising role in recurrent or metastatic cervical cancer. This study aims to evaluate the efficacy and safety of preoperative PD-1 inhibitor camrelizumab combined neoadjuvant therapy for LACC. **Methods:** The study is designed as a multicenter, open-label, single-arm, prospective phase II study. Pts are enrolled if they had previously untreated LACC (2018 FIGO staged IB3, IIA2 and IIB/IIIC1r (tumor size > 4cm). Eligible pts will receive neoadjuvant chemo-immunotherapy (NACIT), defined as one cycle of cisplatin (75-80 mg/m², iv) plus nab-paclitaxel (260 mg/m², iv) NACT and subsequent two cycles of camrelizumab (200mg, iv) combined NACT. Either surgery or concurrent chemoradiotherapy are conducted according to the response as per the Response Evaluation Criteria In Solid Tumors (RECIST) version 1.1. The primary endpoint was objective response rate (ORR), and the secondary endpoints were pathological complete remission (pCR) rate, rate of postoperative adjuvant treatment, event-free survival, overall survival and safety. **Results:** From Dec 1, 2020 to Feb 1, 2023, 83 pts were enrolled, and 78 pts were evaluated for response. The ORR was 100% (95%CI, 95.38 to 100), with 14 (17.95%) complete response (CR) and 64 (82.05%) partial response. Regarding the pathological findings of 76 pts who underwent radical surgery, 30 (39.47% (95%CI, 28.44 to 51.35)) pts achieved pCR, while 17 (22.37%) needed postoperative adjuvant treatment as indicated in NCCN guideline, of who 14 had positive pelvic nodes, positive surgical margin, and/or positive parametrium and the other three met Sedlis criteria. RECIST CR was significantly associated with pCR (P = 0.016). Pre-treatment PD-L1 expression (Combined Positive Score) was a predictive biomarker for RECIST CR (P = 0.036) but not for pCR (P = 0.078) in these evaluated patients. Grade 3 or 4 treatment-related adverse events occurred in 35 (44.87%) pts during NACIT; the most common were lymphocytopenia (25.64%), neutropenia (12.82%) and leucopenia (8.97%). **Conclusions:** NACIT for LACC demonstrated extremely high ORR and pCR rate with manageable toxicity profile, and greatly reduced the need of postoperative adjuvant therapy. Clinical trial information: NCT04516616. Research Sponsor: Jiangsu Hengrui Medicine, Lianyungang, China; Chinese Clinical Medical Research Center for Obstetrical and Gynecological Diseases.

Poster Discussion Session

Efficacy and final safety analysis of pre- and co-administration of nivolumab (Nivo) with concurrent chemoradiation (CCRT) followed by Nivo maintenance therapy in patients (pts) with locally advanced cervical carcinoma (LACvCa): Results from the phase I trial, GOTIC-018. *First Author: Kazuto Nakamura, Department of Gynecology, Gunma Prefectural Cancer Center, Ota, Japan*

Background: LACvCa is associated with a poor prognosis, and CCRT is the standard treatment for LACvCa pts. Anti-PD1 monoclonal antibodies are associated with increased survival in recurrent or persistent CVCa pts; thus, Nivo may enhance antitumor immune responses. We previously reported that the addition of pre- and co-administration of Nivo was safe and feasible in the acute phase in pts with LACvCa who were treated with CCRT (GOTIC-018; JMA-IA00425). Herein, we report the efficacy and final safety of GOTIC-018. **Methods:** The GOTIC-018 study was a multicenter, multi-cohort phase I study of Nivo plus CCRT in pts with LACvCa. The treatment plan in cohort A was co-administration of Nivo (240 mg/body once every 2 weeks) with CCRT followed by Nivo maintenance therapy for 52 weeks. The treatment plan in cohort B was pre-CCRT (two doses of Nivo before CCRT) followed by co-administration of Nivo with CCRT followed by Nivo maintenance therapy. Efficacy was evaluated using the RECIST v1.1. Tumor biopsies were obtained before treatment in each cohort and after two doses of Nivo in cohort B. **Results:** 30 pts (15 in each cohort) were enrolled between May 2019 and June 2021. There were one stage IVA, 11 stage IIIB, 16 stage II, and two stage IB2 tumors based on FIGO 2008. 28 squamous cell and 2 adenocarcinomas were included. 27 of the 30 tumors were positive for high-risk HPV, 14 were positive for PD-L1 TPS, and all tumors were microsatellite stable. The median follow-up was 15.2 months. The median number of Nivo cycles was 30 and 32 for cohorts A and B, respectively. 26 pts completed the study protocol, two discontinued Nivo due to AEs, and two withdrew their consent during the maintenance phase. Ten and eight pts in cohorts A and B, respectively, required Nivo interruption. The best overall response rates were 100% and 93.3% in cohorts A and B, respectively. A total of 73.3% of the pts achieved a complete response in each cohort. The 12-months progression-free survival rate was 100% of the evaluable 29 pts for each cohort. The most common grade ≥ 3 AEs were neutropenia (60.0 and 26.7% in cohorts A and B, respectively), followed by diarrhea (13.3 and 26.7%, respectively), and anemia (13.3 and 16.7%, respectively). Grade ≥ 3 irAEs were observed in two (13.3%) and one (6.7%) pts in cohorts A and B, respectively. The most common grade ≥ 3 irAEs were increased serum lipase levels in two pts. In addition, 6 of the 12 tumors that were PD-L1 TPS negative turned positive after two doses of Nivo in cohort B. **Conclusions:** The addition of pre- and co-administration of Nivo followed by Nivo maintenance therapy appears safe and shows encouraging efficacy in pts with LACvCa treated with CCRT. Pre-CCRT administration of Nivo may affect the tumor microenvironment. Clinical trial information: JMA-IA00425. Research Sponsor: Ono.

Poster Discussion Session

Toxicity profile and discordance between patients/physicians regarding niraparib maintenance in recurrent ovarian cancer (ROC) patients: Lessons from the NIQOLE real-life study—GINECO study. *First Author: Florence Joly, Department of Medical Oncology, Centre François Baclesse, Caen, France*

Background: Niraparib (NI) maintenance is a standard of care in platinum-sensitive ROC. Based on pivotal randomized trials, toxicity profile appears manageable through adapted drug dosing. However, data on tolerance and feasibility for unselected patients (pts) are missing, especially regarding pts' reported adverse events (AE). **Methods:** NIQOLE study is a real-life longitudinal multicenter, phase IV study in ROC pts treated with NI maintenance. NI starting dose was adapted to pts' weight and platelet count. The primary endpoint was to describe physicians' reported AE (NCI-CTC-AE, grading from 0 to 5) leading to treatment modifications (TM), defined by dose reduction or treatment interruption/discontinuation from baseline to month 3 and delay of first TM. Secondary endpoints included duration of treatment and pts' reported AE. Progression rates were exploratory endpoints. Owing to a digital device, pts provided remoted weekly AE (NCI PRO-CTC-AE, grading from 0 to 3) which were accessible to investigators. Concordance between the main symptomatic AEs reported by pts and those reported by physicians was analyzed. **Results:** 139 pts were treated: median age 70 [44-88], high-grade serous histology 91%, BRCA mutation 5%, first relapse 72%, prior bevacizumab 71%. The median delay from platinum-based regimen and NI was 49 days [15-109]. NI starting dose was 200 mg in 80% of pts and the median treatment duration was 5.6 months [0.2-21]. Progression rates at 3 and 6 months were 19 and 45%, respectively. At 3 months, 60% (n=84%) of pts had at least one TM, of whom 47% (n=66) were treatment-related AEs: dose reduction in 17/66 (26%), interruption in 53/66 (80%) and discontinuation in 11/66 (17%). The first AE inducing TM occurred at 22 days (median) [2 -91]. Thrombocytopenia was the main AE leading to TM (70% of cases). 24% of AEs were grade 3-4. Remoted PRO-CTC-AEs were acknowledged by physicians in 59% of cases of whom 31% led to adaptation of pts' care. During the 3 months, 98% of pts reported symptomatic AEs (including nausea, constipation, fatigue, dry mouth and insomnia), of which 66% were grade 3. There was a very poor correlation (<0.20) between symptomatic AEs reported by the pts vs by the physicians (table). **Conclusions:** In real life, despite initial individual dosing, NI maintenance requires frequent TM during the first 3 months of treatment. There is a strong discrepancy between symptomatic AEs regularly captured by pts and those reported by physicians during clinics. Next generation of clinical trials should integrate pts' perspective to better assess toxicity and manage treatment course. Clinical trial information: NCT03752216. Research Sponsor: GSK.

Main symptomatic Aes	Patients (%)		Physicians (%)	
	All	Severe*	All	Severe**
Fatigue	93	32	43	2

Poster Discussion Session

The Normal Risk Ovarian Screening Study (NROSS): Twenty-one year update. *First Author: Chae Young Han, The UT MD Anderson Cancer Center, Houston, TX*

Background: The Normal Risk Ovarian Screening Study (NROSS) tested a two-stage screening strategy in post-menopausal women at conventional hereditary risk where significantly rising CA125 prompted transvaginal sonography (TVS) and abnormal TVS prompted surgery to detect ovarian cancer. **Methods:** A total of 7,856 healthy postmenopausal women were screened annually for a total of 50,596 women-years in a single arm study (NCT00539162). Serum CA125 was analyzed with the Risk of Ovarian Cancer Algorithm (ROCA) each year. If risk was normal ($< 1:2000$), women returned in a year. If risk was elevated ($> 1:500$), TVS was undertaken immediately and if risk was intermediate, CA125 was repeated in 3 months, risk recalculated, and the participant re-triaged. An average of 2% of participants were referred to TVS annually. **Results:** Thirty-four patients were referred for operations detecting 15 ovarian cancers and 2 borderline tumors with 12 in early stage (I-II). In addition, 7 endometrial cancers were detected with 6 in early stage. Thus, the positive predictive value (PPV) of the NROSS trial was 50% (17/34) for detecting ovarian cancer and 74% (25/34) for any cancer, far exceeding the minimum acceptable study endpoint of 10% PPV. As 4 ovarian cancers and 2 borderline tumors were diagnosed within a year of each participant's last normal risk, the sensitivity for detecting ovarian and borderline cancer was 74% (17/23) and 70% of ROCA-detected cases (12/17) were in stage I-II. NROSS screening reduced incidence of late stage (III-IV) disease by 34% compared to the United Kingdom Collaborative Trial of Ovarian Cancer Screening (UKCTOCS) control arm and by 30% compared to US SEER values. Results of our NROSS trial contrast dramatically with those of the recently reported UKCTOCS that showed only a modest 14% early-stage shift, underlying a lack of reduction in mortality. Across multiple randomized trials of mammography, those trials that demonstrated at least a 20% late-stage incidence reduction had a significant mortality reduction, whereas those with less of a stage shift did not. **Conclusions:** An elevated ROCA, characterized by a significantly rising CA125, prompted referral of 2% of participants to TVS each year and required only 2 operations to detect each case of ovarian cancer, indicating that CA125 used in this way is adequately specific for effective screening. While the NROSS trial was not powered to detect reduced mortality, the high specificity, PPV and marked stage shift support further development of this strategy. Clinical trial information: NCT00539162. Active bone marrow-sparing to reduce the incidence of grade 3+ acute hematologic toxicity in patients with locally advanced cervical cancer who receive chemoradiotherapy: A single-center prospective randomized controlled trial. *First Author: ShanBing Wang, Department of Oncology, the Second People's Hospital of Yibin City, Yibin, Sichuan, China*

Background: Acute hematologic toxicity is the most common side effect of chemoradiotherapy in patients with locally advanced cervical cancer. We aim to test the efficacy of single-photon emission computed tomography-defined active bone marrow-sparing volumetric-modulated arc therapy in reducing grade 3+ acute hematologic toxicity (HT) in locally advanced cervical cancer patients treated with chemoradiotherapy. **Methods:** This was a prospective, single-center, open label, randomized clinical trial that enrolled locally advanced cervical cancer patients. Participants were randomized to the ^{99m}Tc sulfur colloid SPECT-defined ABMS VMAT (ABMS group) or control group, who received weekly cisplatin concurrently with volumetric-modulated arc therapy followed by high-dose-rate intracavitary brachytherapy. The ABMS group additionally received SPECT-defined ABM dose constraints. The primary endpoint was the incidence of grade 3+ acute hematologic toxicity. Secondary objectives included acute gastrointestinal toxicity, planning Target Volume (PTV) coverage, dosimetric parameters of organs at risk (OARs), progression-free survival (PFS), overall survival (OS). **Results:** A total of 192 FIGO stage IB-IIIB patients were randomized treated (96 each in the ABMS control groups). The median follow-up was 24.0 months. The incidence of grade 3+ acute hematologic toxicity in the ABMS group was significantly lower than that in the control group (32.3% vs 53.1%, $p < 0.01$). The number of patients completing five cycles of cisplatin was 88.5% in the ABMS group and 75% in the control group, and the difference was significant ($p = 0.02$). There were no significant differences in the mean dose to 95%, 97% and 99% of the PTV between the ABMS group (45.1 Gy, 44.6 Gy, and 43.3 Gy, respectively) and the control group (45.4 Gy, 44.8 Gy, and 43.6 Gy). There were no differences in dosimetric parameters of OARs, acute gastrointestinal toxicity, 2-year PFS or 2-year OS between the two groups. Patients in the control group had nonsignificantly worse 2-year distant metastasis than patients in the ABMS group (17.8% vs. 11.1%, $p = 0.19$). **Conclusions:** ABMS VMAT significantly reduced grade 3+ acute HT and improved chemotherapy delivery compared with the control treatment. We found weak evidence of the effect of ABMS VMAT on distant metastasis. Clinical trial information: ChiCTR-IOR-16010214. Research Sponsor: This study was supported by the Sichuan Medical Association youth innovation project (NO. Q16082.NO.Q21022) and the health commission of Yibin City (NO.2019yw029).

The effects of the Covid-19 pandemic on practice patterns and outcomes in patients diagnosed with gynecologic malignancies in the United States. *First Author: Adrian Kohut, City of Hope National Comprehensive Cancer Center, Duarte, CA*

Background: The Covid-19 pandemic caused historic disruptions in the United States healthcare system due to many factors, including a lack of medical equipment and pharmaceutical availability, over-capacitated hospital censuses, and limited essential workers. The short- and long-term effects on patients diagnosed with gynecologic malignancies during this time have yet to be delineated. **Methods:** The National Cancer Database (NCDB) was queried for patients diagnosed with ovarian, uterine, and cervical malignancies from 2019 (pre-covid) to 2020 (covid). Descriptive statistics of practice patterns and outcomes were performed and compared using IBM SPSS Statistics (version 29.0). **Results:** Within the NCDB, 10,261 patients were diagnosed with ovarian cancer in 2019 compared to 8,501 in 2020. A significantly higher proportion of ovarian cancer patients were diagnosed with stage IV disease at diagnosis in 2020 (32.7%) compared to 2019 (30.9%), $p = 0.007$. Patients were less likely to undergo primary debulking surgery during covid (37.7%) compared to pre-covid (40.5%), $p < 0.001$. There was no significant difference in time from diagnosis to initiation of treatment (median: 9 vs. 9 days), nor was there a difference in the proportion of patients undergoing cytoreductive surgery to no gross residual disease (54.3 vs. 54.3%). 42,828 patients were diagnosed with uterine cancer in 2019 compared to 37,431 in 2020. A significantly higher proportion of uterine cancer patients were diagnosed with stage IV disease at diagnosis in 2020 (8.7%) compared to 2019 (8.2%), $p = 0.016$. The median time from diagnosis to initiation of treatment was 28 days in 2020 compared to 30 days in 2019, $p < 0.001$. The proportion of uterine cancer patients receiving primary radiation was higher during covid (1.7% vs. 0.5%), $p < 0.001$. Additionally, the proportion of uterine cancer patients receiving primary hormonal management was also higher during covid (2.5% vs. 2.1%, $p < 0.001$). 9,289 patients were diagnosed with cervical cancer in 2019 compared to 7,661 in 2020. A significantly higher proportion of cervical cancer patients were diagnosed with stage IV disease at diagnosis in 2020 (16.6%) compared to 2019 (14.9%), $p = 0.0021$. The median time from diagnosis to initiation of treatment was 31 days in 2020 compared to 32 days in 2019, $p = 0.005$. **Conclusions:** We identified significant variations in practice patterns and outcomes in patients diagnosed with gynecologic malignancies in the United States in 2020 (covid) compared to immediately before covid (2019). Notably, we found a significantly higher proportion of patients presenting with advanced disease stages in all queried ovarian, uterine, and cervical cancer patients. Long-term follow-up and survival outcomes are currently pending. Research Sponsor: None.

Neoplastic and blood-based biomarkers of response in patients with advanced endometrial cancer: Results from NRG GY012. *First Author: Helen Mackay, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: NRG GY012 is a randomized, 3-arm phase II study, comparing olaparib (O) and the combination of cediranib and olaparib (CO) to the reference arm cediranib (C) for metastatic pre-treated, endometrial cancer (EC). The trial found a trend towards benefit for CO and no benefit for O compared to C. Archival tumor and prospective blood samples were collected for biomarker analysis. **Methods:** Targeted next-generation sequencing (BROCA-GO) was used to detect pathogenic variants (PV) and loss of heterozygosity (LOH) in DNA from paired blood and archival cancers. The LOH cut-off was identified at 11% for HRD based on testing ovarian cancers with known HRD. Plasma samples collected at baseline, cycle 2 day 1, and end-of-treatment were analyzed via multiplex ELISA for 25 angiogenic and inflammatory circulating protein biomarkers (Angiome); IL6 was of specific interest. Prognostic associations with PFS and OS were analyzed using proportional hazards models (PhM) stratified by histology and adjusted for treatment assignment. Predictive associations (PFS and OS) were analyzed using PhM stratified by histology and including main effects for both treatment assignment and biomarker group plus an interaction term. **Results:** In 97 patients (pts) with evaluable tumor, BROCA-GO identified 370 somatic PV; TP53 (61%) was the most commonly mutated gene. PV in homologous recombination repair (HRR) genes were identified in 5 cases (5%). Somatic PVs were identified in BRCA2, RAD51B and PALB2. 1 pt had a germline BRCA1 PV. 2 cases had somatic PV that might restore HRR: 1 case with a somatic BRCA2 PV had somatic PVs in CHD4 and TP53BP1; the TP53BP1 frameshift PV was present only in the recurrent and not primary cancer. LOH was available for 45 cases. LOH high occurred in 16 (35.6%) cases and was exclusive to EC with TP53 mutations ($p = 0.0003$). LOH was not associated with outcome in any of the arms. For the circulating biomarker analysis (N=96), median IL-6 was 4pg/ml. IL-6 levels $> 4\text{pg/ml}$ were associated with increased risk of progression (HR: 1.59; 95% CI: (1.04-2.42); $p\text{-value} = 0.032$). In predictive analyses, pts with IL-6 $> 4\text{pg/ml}$ receiving C or C+O had increased PFS (3.8 mo vs 1.9 mo) and OS (11.9 mo vs 5.7 mo) compared to pts receiving O, the interaction p value did not reach statistical significance. **Conclusions:** LOH high status was not associated with outcome to O. There were too few cases with HRR PVs to determine their relationship to PARPi response. The restriction of LOH high to cancers with TP53 mutation may suggest that genomic LOH in ECs correlates better with aneuploidy than with HRR function indicating that at least some biomarkers of PARPi response vary between tumor types. IL-6 levels were prognostic of PFS but were not predictive of either OS or PFS for pts receiving C compared to pts receiving O in this small study. Further analysis of the complete Angiome and integration with the BROCA-GO dataset are ongoing. Clinical trial information: NCT03660826. Research Sponsor: U.S. National Institutes of Health.

Molecular tumor profiling and therapy selection in advanced gynecological cancers: A retrospective cohort analysis from the Australian Molecular Screening and Therapeutics (MoST) Program. *First Author: Damien Kee, Austin Health and Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Gynecological (gyne) cancers are highly diverse with distinct sites of origin and histological subtypes that can limit development of evidence-based therapies. Comprehensive genomic profiling (CGP) has an increasing role in characterizing clinically relevant molecular subsets and in identifying actionable biomarkers with potential to guide therapy selection. **Methods:** MoST (ACTRN12616000908437) is an Australia-wide precision oncology program for adult patients (pts) with advanced cancers and limited treatment options. Tumor specimens are analysed by CGP and genomic results tiered by the level of evidence supporting matched therapies (https://topograph.info). Pts are followed for subsequent treatment and survival. Here, we present data for the MoST gyne cancer cohort. **Results:** Between Sept 2016 and Oct 2022, 533 gyne tumors were sequenced, with included pts having a minimum 4 months (mo) follow-up. Key histotypes included: ovarian serous (n=162) and non-serous (n=46) epithelial tumors; uterine carcinomas (n=99) and sarcomas (n=108); cervical carcinomas (n=51); germ cell and sex-cord stromal tumors (n=18); carcinosarcomas (n=33); and vulva/vaginal tumors (n=16). The median number of reported variants was 3 (IQR 2-5) and tumor mutational burden 3.1 mut/Mb (IQR 1.3–5.5, Range 0–284); 9 (2%) tumors were microsatellite unstable; and 22 (4%) had high level loss-of-heterozygosity (confirmed on validated genome-wide assays). The most common pathways involved in this pan-gyne cohort were: p53 (n=287, 54%), PI3K/AKT (n=227, 43%), cell cycle (n=182, 34%), and mitogen-activated protein kinase (n=91, 17%). Pathogenic mutations in *BRCA1/2* were identified in 29 tumors (5%; 18 in ovarian serous cancers), whereas 81 tumors (15%) had alterations in other homologous recombination genes, most commonly uterine sarcomas (n=32, 30%). Actionable genomic biomarkers matched to a clinically active treatment (TOPOGRAPH tier 1-3) were identified in 207 (39%) tumors. In 19 pts (3.5%) who received Tier 1-3 matched therapy after CGP, a trend towards longer survival was observed (median OS 22.3 mo, 95% CI 17.3 to not reached) compared to those receiving unmatched therapy (n=65, median OS 14.9 mo, 10.2 to 22.1, p=0.052) following CGP. No OS difference was seen in pts who received matched investigational therapy (Tier 3B/4, n=31, median OS 17.0 mo, 8.1 to NR) versus only unmatched therapy (n=118, median OS 14.0 mo, 11.3 to 22.5; HR 0.97, 0.57 to 1.64; p=0.91). **Conclusions:** CGP identified actionable genomic results in nearly half of advanced gyne cancers, with enrichment in particular histotypes that supports testing above current standard of care. Trends in prolonged OS with subsequent matched therapies may be better realized with earlier testing and improved drug/clinical trial access. Research Sponsor: Australian Government.

Poster Discussion Session

Advanced cervical cancer therapy: Comparison of contemporary expert and healthcare professional recommendations from an online treatment decision tool. *First Author: Lauren S. Prescott, Vanderbilt University Medical Center, Nashville, TN*

Background: Practice patterns for the management of advanced cervical cancer are rapidly evolving given the emergence of novel treatment options. We developed an online Interactive Decision Support Tool (IDST) for advanced cervical cancer to provide expert guidance to healthcare professionals (HCPs). **Methods:** With input from 5 experts, an IDST was developed for patient scenarios with newly diagnosed (ND) and recurrent/second-line (2L) advanced cervical cancer. The IDST included expert insights on 352 scenarios based on criteria such as adenopathy, disseminated disease status, previous therapy, and actionable biomarkers (PD-L1, MMR/MSI, TMB). Users were asked to enter specific patient criteria and their intended management approach. The IDST then showed the 5 expert recommendations for that specific scenario and HCPs were asked to indicate whether the recommendations changed their intended treatment plan. Expert recommendations vs user-selected therapy for different scenarios were analyzed. We present self-reported practice patterns in this disease setting and the impact of expert recommendations on treatment choice. **Results:** At this interim analysis, 141 unique learners used the IDST, entering 232 unique patient scenarios. Data from the IDST also showed areas of consensus and controversy in treating patients with advanced cervical cancer. For locally advanced, ND, no adenopathy and no metastases, all experts recommended pelvic chemoradiation with or without brachytherapy vs only 61% of HCPs; 16% and 3% of those entering cases for the locally advanced ND setting indicated expert recommendation changed their treatment choice and that barriers impeded the recommendations, respectively. For advanced ND, with adenopathy, metastatic, PD-L1–positive cervical cancers, all experts vs 50% of HCPs chose an immunotherapy-containing platinum-based chemotherapy regimen with/without bevacizumab; 9% of those indicated barriers to implementing expert recommendations. In 2L recurrent disease, all experts chose either single-agent immunotherapy (if PD-L1 positive) or tisotumab vedotin (if PD-L1 negative) vs 45% and 40% of HCPs, respectively; 19% of those selecting 2L therapy in the recurrent setting said the expert recommendations had changed their intended choice. **Conclusions:** Analysis from this IDST indicates differences in practice patterns between experts and HCPs for various case scenarios of advanced cervical cancer. Online decision support tools may increase the number of HCPs making optimal treatment decisions for advanced cervical cancer, particularly when new data, indications, and guideline updates must be considered. Updated and detailed analyses from the IDST will be presented. Research Sponsor: Clinical Care Options.

Association of HRD ovarian cancer by RAD51 with hot immune microenvironment: Translational analyses of MITO 16A/MaNGO-OV2 trial. *First Author: Benedetta Pellegrino, University of Parma, Parma, Italy*

Background: Homologous recombination repair (HRR)-deficient Ovarian Cancer (OvC) is sensitive to PARP inhibitors and platinum salts. Genomic HRR-deficiency (HRD) tests (i.e. Myriad MyChoice) are currently used to guide treatment selection in the maintenance setting. However, they are showing a limited predictive value, they are expensive and static, i.e. unable to capture the restoration of the HRR functionality, as a mechanism of drug resistance. **Methods:** We performed the functional and dynamic RAD51 test on 164 patients with high-grade serious OvC, enrolled in the MITO16A/MANGO OV2 trial and treated with first-line therapy containing carboplatin, paclitaxel, and bevacizumab. The RAD51 assay included the immunofluorescence of gH2AX (as a marker of Double Strand Breaks DNA damage), BRCA1 and RAD51 nuclear foci. Stromal Tumor Infiltrating Lymphocytes (TIL) by Immunohistochemistry, and gene expression profile were performed on the same samples. **Results:** RAD51 assay was informative on 70% (115/164) of the samples. On evaluable samples, median gH2AX score was 57%. BRCA1 foci by immunofluorescence were detected on 55% (49/112) of the samples; 45% (63/112) of the tumors did not show BRCA1 foci likely due to germline or somatic BRCA1 mutations, or BRCA1 promoter hypermethylation. RAD51 identified 69% (79/115) of all tumors as HRD, with a median RAD51 score of 8.8%. HRD tumors presented a statistically significantly higher TIL content than HRR-proficient ones (p = 0.03). **Conclusions:** Our preliminary results confirmed the feasibility of the RAD51 functional assay on primary untreated OvC. The association between HRD by RAD51 and TIL content encouraged to investigate the efficacy, in clinical trials, of the combination of PARPi and immune-checkpoint inhibitors on selected patients (i.e. HRD by RAD51 and TIL high). Gene expression profile and comparison of the HRD status by RAD51 and genomic HRD (both Myriad MyChoice and academic) and correlations with clinical outcomes will be available for the meeting. Research Sponsor: Associazione Italiano Ricerca sul Cancro (AIRC).

SHR-1701 in combination with platinum-based chemotherapy and BP102 (a bevacizumab biosimilar) for persistent, recurrent, or metastatic cervical cancer: Data from a phase 1b/3 study. *First Author: Jihong Liu, Department of Gynecologic Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Platinum-based chemotherapy (chemo) ± bevacizumab is the standard first-line therapy for cervical cancer, regardless of PD-L1 expression. SHR-1701 is a novel bifunctional fusion protein targeting PD-L1 and TGF-βRII, and shows promising efficacy and controllable safety in pretreated patients (pts) with cervical cancer. This ongoing phase 1b/3 study aims to assess the addition of SHR-1701 to standard first-line therapy. **Methods:** In the phase 1b part, eligible pts had persistent, recurrent, or metastatic squamous-cell carcinoma, adenocarcinoma, or adenosquamous cell carcinoma of the cervix not previously treated with systemic chemo for recurrence or metastasis and not amenable to curative treatment. Prior chemoradiotherapy was permitted for recurrence, if mono-chemo was used as sensitizer. Pts were given SHR-1701 (30 mg/kg), paclitaxel (175 mg/m²), cisplatin (50 mg/m²) / carboplatin (AUC 5), and BP102 (15 mg/kg) every 3 weeks. The primary endpoints were safety and ORR. **Results:** From Feb 26 to Aug 12, 2022, 31 pts were enrolled. Median age was 55 years (range, 27-71). 24 (77.4%) had squamous-cell carcinoma, and 7 (22.6%) had adenocarcinoma. 20 (64.5%) had metastatic disease, 7 (22.6%) had recurrent cervical cancer, and 4 (12.9%) had persistent cervical cancer. Grade ≥3 treatment-related adverse events (TRAEs) were reported in 25 (80.6%) pts, with the most common being decreased neutrophil count (n=16, 51.6%), decreased white blood cell count (n=12, 38.7%), and anemia (n=8, 25.8%). TRAEs led to discontinuation of any study agent in 8 (25.8%) pts; of note, only 2 (6.5%) pts discontinued SHR-1701 due to TRAEs (grade 3 infusion reaction and grade 3 immune-mediated rash). No treatment-related deaths occurred. Efficacy outcomes are summarized in Table. ORR was 77.4%, with 4 CRs and 20 PRs; responses were ongoing in all 24 responders. DCR was 93.5%. Shrinkage in target lesions was observed in 30 (96.8%) pts. PFS rate at 6 months reached 93.5%. **Conclusions:** SHR-1701 plus platinum-based doublet chemo and BP102 provided a manageable safety profile and potent antitumor activity in pts with persistent, recurrent, or metastatic cervical cancer, supporting the subsequent randomized, double-blind, placebo-controlled phase 3 part. Clinical trial information: NCT05179239. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Efficacy and safety of combining PD-1 blockage and human papillomavirus vaccine for patients with relapsed/refractory advanced cervical cancer. *First Author: Bu hai Wang, Cancer Institute of Northern Jiangsu People's Hospital, Yangzhou, China*

Background: The prognosis for patients with relapsed/refractory advanced cervical cancer is dismal with a 5-year survival rate of 17%. Limited treatment options were available including platin based therapy, antiangiogenic therapy and immune therapy. Immune checkpoint blockage with anti-programmed cell death 1 (PD-1) antibodies had an overall response rate of 17% among a minority of patients. Recently a phase II study showed human papillomavirus (HPV) 16 vaccination amplified PD-1 antibodies in incurable HPV16 positive cancer with an ORR of 33%. But the study enrolled majority were oropharyngeal cancer patients (92%). Here, we designed and conducted phase II clinical trial to assess the efficacy and safety of combining anti-PD-1 antibody and HPV vaccination for patients with relapsed/refract cervical cancer. **Methods:** In this single-arm, single-center phase II clinical trial, patients with relapsed/refract cervical cancer were registered (NCT04096911) and enrolled from Dec, 2019 to Dec, 2022 in Department of Oncology, Northern Jiangsu People's Hospital, Yangzhou, China. All patients received prior radiation therapy and had at least one or more lines of therapies. Duration of follow up for censored patients was 36 months. The recombinant human papillomavirus quadrivalent vaccine (0.5ml) was given subcutaneously on day 0, third month, and 6th month. Anti-PD-1 antibody, 200mg was given intravenously every 3 weeks starting on day 1 for up to 2 years. **Results:** As of Dec 21, 2022, thirteen patients were enrolled in the trial. The median age was 55 years (range, 52 to 83 years). The overall response rate was 69.2%. Disease control rate was 84.9%. Median duration of response was 7.07 months (95%CI, 1.94 to 15.8 month). Six patients achieved complete response. Median overall survival was 13.96 month. No grade 3 and 4 toxicity occurred. **Conclusions:** Our study was the first clinical trial using HPV vaccine as therapeutic agent in advance cervical cancer treatment. Up to date, immunotherapy along in cervical cancer had limited response rate less than 20% and the combination therapies was less than 40%. In our study, the overall response of 69.2%, disease control rate of 84.9% and median overall survival of 13.96 months were significantly higher compared with anti-PD-1 antibody alone or any current available regimen combinations in relapsed/refract advance cervical cancer patients. We also found synergistic effect of T cell and B cell plays an important role in our study. It appears neoantigen associated with tumor was easier to initiate immune response in cervical cancer patients. This is the first time to show employing combined immune therapeutic agents only is a novel effective clinical strategy in relapsed/refract advance cervical cancer. Clinical trial information: NCT04096911. Research Sponsor: None.

A confirmatory trial of modified radical hysterectomy for patients with FIGO stage IB1 cervical cancer with tumor diameter preoperatively estimated at 2 cm or less: Japan Clinical Oncology Group study, JCOG1101. *First Author: Takahide Arimoto, Toranomon Hospital, Tokyo, Japan*

Background: The standard surgery for Stage IB1 uterine cervical cancer is radical hysterectomy (RH, Piver class III hysterectomy). However, RH is highly invasive, and there is a need to establish less invasive techniques. We conducted a single-arm confirmatory trial (JCOG1101) to evaluate the efficacy and safety of modified radical hysterectomy (MRH) in patients with tumor diameter $\leq$ 2 cm Stage IB1 cervical cancer (jRCT: jRCTs031180167). **Methods:** From January 2013 to August 2017, 240 patients were enrolled from 40 institutions in Japan. Eligibility criteria included: (1) FIGO 2008 Stage IB1 cervical cancer; (2) histologically proven squamous cell carcinoma, adenocarcinoma (mucinous or endometrioid) or adenosquamous carcinoma; (3) tumor diameter $\leq$ 2 cm (measured by MRI or conization specimen); and (4) neither distant LN metastasis nor distant metastasis in CT. In case that the cancer could be microinvasive, conization was required to exclude Stage IA cases. The protocol surgery involved cutting the anterior layer of the vesicouterine ligament of the uterus and dissecting regional lymph nodes. Only laparotomy was permitted; laparoscopy and robotic surgery were not allowed. Postoperative irradiation was administered in cases where pelvic LN or parametrial invasion was positive, depth in the cervical wall invasion was $\geq$ 2/3, or surgical margin was $<$ 1 cm by pathological findings. The primary endpoint was 5-year overall survival (OS). We set the expected 5-year OS of MRH at 95.8% (5-year OS of RH in JCOG0806A, retrospective observational study) and the threshold 5-year OS at 90.8%. **Results:** Among 225 eligible patients, 193 (85.8%) were pT1b1 (UICC 7th), and 184 (81.8%) had pathological maximal tumor diameter $\leq$ 2 cm. Parametrial involvement, lymph node metastasis, $\geq$ 2/3 stromal invasion and $<$ 1 cm surgical margin were observed in 3 (1.3%), 16 (7.1%), 30 (13.3%) and 11 (4.9%) patients, respectively. Thirty-nine patients (17.3%) underwent adjuvant (chemo)radiation. Median follow-up was 77.7 months. Five patients (2.2%) died, and 5-year OS was 98.2% (90% CI: 96.0-99.2, $>$ 90.8%). Thirteen patients (5.8%) relapsed (8 local recurrence and 5 distant recurrence), and 5-year relapse-free survival was 94.7% (95% CI: 90.8-96.9%). Self-urination was observed in all patients, and residual urine disappearance up to 56 days after urethral catheter removal was observed in 213 patients (94.7%). Median time to disappearance of residual urine after urethral catheter removal was 1 day. There was no treatment-related death. Grade 3/4 non-hematological adverse events were observed in 17 patients (7.6%), including 8 infection and 4 hemorrhage. **Conclusions:** In this study, MRH was as effective as RH and less invasive. MRH can be considered a standard surgery for tumor diameter $\leq$ 2 cm Stage IB1 uterine cervical cancer. Clinical trial information: UMIN000009726, jRCTs031180167. The efficacy and safety of tislelizumab plus bevacizumab and chemotherapy as first line therapy in patients with persistent, recurrent, or metastatic cervical cancer: A multicenter, phase II study. *First Author: Jianqing Zhu, Cancer Hospital of the University of Chinese Academy of Sciences (Zhejiang Cancer Hospital), Hangzhou, China*

Background: Patients (pts) with persistent, recurrent, or metastatic cervical cancer are at high risk of progression after first line standard treatment with platinum-doublet chemotherapy $\pm$ bevacizumab. The addition of programmed death-1 (PD-1) inhibitor to this standard treatment has shown improved survival profiles in pts with PD-L1 positive. This study aims to investigate the efficacy and safety of PD-1 inhibitor (tislelizumab) plus bevacizumab and platinum-doublet chemotherapy as the first line therapy in pts regardless of the PD-L1 expression status. **Methods:** Pts with persistent, recurrent, or metastatic cervical cancer were enrolled and received tislelizumab 200 mg + bevacizumab 7.5 mg/kg + cisplatin 50 mg/m² or carboplatin AUC5 + paclitaxel 175 mg/m² IV D1 Q3W. This study comprised two parts: safety run-in (Part 1) and cohort expansion (Part 2). In Part 1, a total of 6 pts were enrolled and underwent safety assessment during the first treatment cycle (21 days). If no more than 2 of 6 pts were observed with dose-limiting toxicity (DLT), pts will be allowed to continue treatment and additional 43 pts will be enrolled (Part 2). The primary endpoint was progression-free survival. A one-sample log-rank test with a total sample size of 49 pts with one sided alpha of 5%, achieved 85% power to detect a difference in PFS between the investigated treatment and historical control. The secondary endpoints were objective response rate (ORR), disease control rate (DCR), duration of response (DOR) and safety and tolerability. **Results:** We report the preliminary results of this study. No DLT was observed among the first 6 pts in Part 1 stage and the study proceeded to the Part 2. Until Oct 28, 2022, a total of 24 pts were enrolled with the median age of 56.0 years. 6 (25.0%) pts were diagnosed with stage IV disease at the study entry and 21 (87.5%) were with squamous cell carcinoma. At the data cutoff time of Nov 30, 2022, among the 19 efficacy evaluable pts, the unconfirmed ORR was 73.7% (14/19, 95% CI: 48.8%-90.8%), and the DCR was 100% (19/19, 95% CI: 82.3%-100.0%). With the median follow up time of 3.8 months, DOR was not reached. The incidence of treatment related adverse events (TRAEs) of any grade was 79.2% (19/24), and grade $\geq$ 3 TRAEs occurred in 45.8% (11/24) pts. Most common TRAEs ($\geq$ 20%) of any grade were anemia (58.3%, 14/24), decreased platelet count (37.5%, 9/24), alopecia (29.2%, 7/24), decreased white blood cell count (25.0%, 6/24), and weight decreased (20.8%, 5/24). Immune related adverse events were all grade 1-2 (16.7%, 4/24). Severe adverse events were reported in 4 (16.7%) pts. **Conclusions:** Tislelizumab plus bevacizumab and chemotherapy showed preliminary promising efficacy and was well-tolerated as the first line therapy in pts with persistent, recurrent, or metastatic cervical cancer. Clinical trial information: NCT05247619. Research Sponsor: BeiGene (Beijing) Co., Ltd.

Patient-reported outcomes during pelvic radiation therapy: A secondary analysis on sexual function from NRG-RT0G 1203. *First Author: Kelsey L Corrigan, Department of Radiation Oncology, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: NRG-RT0G 1203 reported that intensity-modulated radiation therapy (IMRT) reduced patient-reported GI and GU toxicities in cervical/endometrial cancer patients receiving adjuvant RT, as compared to standard whole field pelvic RT (WPRT). We conducted a secondary analysis of patient-reported sexual function (PR-SF) to compare this endpoint among treatment groups and identify factors associated with sexual dysfunction. **Methods:** Patients on NRG-RT0G 1203 were randomly assigned to WPRT vs. IMRT and completed the PRO-CTCAE for GI toxicity and the cervical cancer FACT-Cx at baseline, week 5 of RT, and at 4-6 weeks, 1-year, and 3-years post-RT. Patient responses to FACT-Cx sexual function questions were analyzed. The between arm frequency and severity of responses were tested using chi-square. PR-SF was compared with PRO-CTCAE GI toxicity using chi-square. A repeated measures logistic regression model was used to determine the impact of clinical/treatment factors on sexual function by dichotomizing the responses. **Results:** Of the 279 patients included for primary analysis, 236 (85%) completed PR-SF questions; 125 (53%) in the WPRT arm and 111 (47%) IMRT. There were no significant differences in PR-SF between treatment groups ($p > 0.05$). PR-SF improved for both groups post-RT, except responses to "my vagina feels too narrow or short" worsened (Table). Women without abdominal pain interference at 4-6 weeks post-RT were less likely to fear sex (74.2% vs. 25.8%, $P = 0.03$) and more likely to like their body appearance at 1 year (95.7% vs. 4.3%, $P < 0.01$) compared to women with interference. Women liked the appearance of their body less during RT vs. at baseline (OR 1.95, 95% CI 1.04-3.64, $P = 0.04$). Women were less interested in sex during RT in both arms (WPRT: OR 3.61, 95% CI 1.40-9.34; IMRT: OR 3.96, 95% CI 1.02-15.34) and at 4-6 weeks post-RT for IMRT (OR 3.16, 95% CI 1.14-8.72) vs. at baseline. **Conclusions:** PR-SF was similar between treatment groups. PR-SF during and post-RT was not significantly reduced compared to baseline with the exception of patients with abdominal pain interference, who had significantly worse PR-SF at 4-6 weeks and 1-year post-RT. Clinical trial information: NCT01672892. Research Sponsor: U.S. National Institutes of Health.

Longitudinal change in the percent of women reporting "very much" or "quite a bit"

	Baseline	During RT	4-6 Weeks Post-RT	1-Year Post-RT	3-Years Post-RT
"I am bothered by discharge/bleeding from my vagina"	(n=201) 3.1%	(n=203) 1.5%	(n=201) 0.5%	(n=179) 1.1%	(n=49) 0%
"I am afraid to have sex"	(n=192) 14.9%	(n=184) 19%	(n=192) 12.5%	(n=174) 12.6%	(n=48) 6.3%
"My vagina feels too narrow/short"	(n=190) 6%	(n=183) 8.2%	(n=190) 8.9%	(n=171) 11.1%	(n=47) 10.6%

A peptide-based human papillomavirus therapeutic vaccine, PepCan, or *Candida* adjuvant alone in treatment of cervical intraepithelial neoplasia 2/3 (CIN2/3). First Author: Mayumi Nakagawa, University of Arkansas for Medical Sciences, Little Rock, AR

Background: A non-surgical alternative for treating CIN2/3 would be desirable for women of childbearing age due to a risk of cervical incompetency in subsequent pregnancies following surgical treatments. PepCan consists of four current good manufacturing-grade HPV 16 E6 peptides and a *Candida* skin testing reagent (Candin, Nielsen Biosciences), because of *Candida*'s ability to regress common warts in humans, and to promote T cell proliferation and interleukin-12 secretion *in vitro*. **Methods:** In this single-center, randomized, double-blind Phase II study (NCT02481414), women with biopsy-confirmed CIN2/3 were treated with PepCan or *Candida* (1:1). Four intradermal injections were given 3 weeks apart which were followed with two visits 6 months apart. Histological responses (primary endpoint) were assessed using quadrant biopsies, and those whose lesions regressed to no CIN were considered to be responders. Regression rate of each treatment group was compared to that of a historical placebo group following the same treatment schedule. A sample size of 35 per arm had 93% power to test the null hypothesis that $\pi = 0.29$ (historical control placebo rate) and detect a difference of 0.31 with a two-sided type I error of 5%. Adverse events (AEs) were assessed using Common Terminology Criteria for Adverse Events Version 4. **Results:** Of 99 subjects screened, 81 (81.8%) qualified for vaccination, and 80 received at least one vaccination. No dose-limiting toxicity was observed. With the intention-to-treat analysis, PepCan showed 30.8% efficacy (12 of 39, $p=0.16$) while *Candida* demonstrated 47.6% efficacy (20 of 42, $p=0.0004$). Likewise, with the per-protocol analysis, PepCan showed 45.8% efficacy (11 of 24, $p=0.06$) and *Candida* showed 62.1% efficacy (18 of 29, $p=0.0002$). There was no difference between efficacy of PepCan and *Candida*. **Conclusions:** PepCan and *Candida* treatments are safe. Only *Candida* was effective in inducing histological regression in the intention-to-treat and per-protocol analyses. *Candida* could become a new treatment for CIN2/3 by eliciting general immune stimulation similar to checkpoint inhibitors. Clinical trial information: NCT02481414. Research Sponsor: U.S. National Institutes of Health; University.

Surgical resection based on ontogenetic cancer field theory for cervical cancer: 10-year updated results of the MMR study. First Author: Laura Weydandt, University of Leipzig Medical Center, Department of Gynecology, Leipzig, Germany

Background: Previously published findings from our center suggest that carcinoma of the cervix propagates within ontogenetic cancer fields, tissue compartments defined by staged morphogenesis. In the MMR study we aimed to determine whether surgical treatment that accounts for stage-associated, ontogenetic cancer fields and their associated lymphoid tissues results in locoregional tumor control without the need for adjuvant radiotherapy. **Methods:** The Leipzig School Mesometrial Resection Study (MMR study) is an ongoing, prospective, single-center, observational cohort study including patients with primary cervical cancer. All study participants undergo either total or extended mesometrial resection (TMMR or EMMR) and therapeutic lymph node dissection. Because this treatment strategy enables surgical removal of all locoregional at-risk tissues, no adjuvant radiotherapy is necessary, even in the presence of established risk factors. The trial is registered at the German Clinical Trials Register, number DRKS00015171. For this updated analysis, we identified patients in our institutional study database with primary cervical cancer staged IB1 – IIA2 according to the 2009 International Federation of Gynecology and Obstetrics staging system. Using the Kaplan-Meier estimator, we calculated recurrence free and overall survival. **Results:** Between October 16, 1999, and December 16, 2020, 420 patients were treated per protocol and followed up for a median of 136 months (IQR 77–190). The median age was 42 years (IQR 36–51). 329 patients (78.3%) had stage IB1, 58 (13.8%) stage IB2, 24 (5.7%) stage IIA1 and 9 (2.1%) stage IIA2 disease. Patients had either squamous cell ($n = 297$, 70.7%), adenocarcinoma ($n = 104$, 24.8%), adenosquamous ($n = 18$, 4.3%) or other ($n = 1$, 0.24%) histology. The nodal status was pN0 in 349 (83.1%) patients and pN1 in 71 (16.9%) of the cases. Clinically occult parametrial involvement was present in 47 (11.2%) patients. 10-year overall survival was 90.2% (95% confidence interval [CI] 87.1–93.4) and recurrence-free survival was 90.6% (95% CI 87.8–93.6). Stratified for lymph node status 10-year overall survival was 91.7% (95% confidence interval [CI] 88.5–95) for pN0 and 83.2% (95% confidence interval [CI] 74.6–92.9) for pN1. Recurrence-free survival was 93.8% (95% CI 91.2–96.5) for pN0 and 75.4% (95% CI 65.9–86.3) for pN1. **Conclusions:** Despite dispense of adjuvant radiotherapy, patients treated with total or extended mesometrial resection with therapeutic lymph node dissection have excellent survival outcomes. Additional multicenter studies are needed to further investigate and confirm our results. Clinical trial information: DRKS00015171. Research Sponsor: None.

Association between serum folate and vitamin B12 and cervical high-risk human papillomavirus (HPV) infection. First Author: Josephine Peitz, University of Maryland School of Medicine, Baltimore, MD

Background: Serum concentration of folate (vitamin B9) and vitamin B12 were inversely associated with cervical intraepithelial neoplasia and cervical cancer in some studies. The association between folate and vitamin B12, and human papillomavirus (HPV) infection has not been well elucidated. We evaluated whether low serum level of folate and vitamin B12 was associated with high-risk HPV (hrHPV) infection. **Methods:** The study population was 6,452 women, aged 18–59 years old, enrolled in the National Health and Nutrition Examination Survey (NHANES), from 2003 to 2016, in the United States. In this cross-sectional study, odds ratios (ORs) of hrHPV were calculated, by quintiles of low folate and vitamin B12 combined, using logistic regression models. **Results:** The mean age (standard deviation) of the women was 36.98 (12.19) years. Women in the lowest quintile had less than 20.6 nmol/L of folate and less than 248 pmol/L of vitamin B12. Some of the women, 23% (1,509/6,452), were hrHPV positive. In age-adjusted models, low folate and vitamin B12 was significantly associated with hrHPV infection. The ORs and 95% confidence intervals (CI) was (OR: 0.704, 95% CI: 0.509 - 0.975, $p = 0.034$) for the second, (OR: 0.671, 95% CI: 0.479 - 0.940, $p = 0.020$) third, (OR: 0.534, 95% CI: 0.370 - 0.770, $p = 0.0008$) fourth and (OR: 0.476, 95% CI: 0.33 - 0.679, $p < 0.0001$) fifth quintiles, compared to women in the lowest quintile. The association remained statistically significant after the models were further adjusted for smoking status and income level; women in the highest quintile were less likely to have hrHPV infection compared to those in the lowest quintile (OR: 0.541, 95% CI: 0.343 - 0.855, $p = 0.008$). **Conclusions:** This study supports an association between low serum levels of folate and vitamin B12, and hrHPV infection, among women in the United States. Efficacy and safety of camrelizumab in combination with radiation and chemotherapy for recurrent or metastatic cervical cancer. First Author: Zhongjie Chen, Tianjin Medical University Cancer Hospital & Institute, Tianjin, China

Background: Cisplatin-based concurrent chemoradiation regimens have been suggested to be beneficial in recurrent or metastatic cervical cancer. Immunotherapy has also shown good therapeutic efficacy in recurrent or metastatic cervical cancer. Among them, Pembrolizumab in combination with chemotherapy has been used for first-line treatment of advanced PD-L1-positive cervical cancer. Meanwhile, Camrelizumab has shown good anti-tumor activity and manageable toxicity in patients with locally advanced cervical cancer. The primary objective of this study is to evaluate the efficacy and safety of Camrelizumab in combination with concurrent chemoradiation in patients with recurrent or metastatic cervical cancer. **Methods:** Patients diagnosed with recurrent or metastatic cervical cancer received Camrelizumab combined with concurrent chemoradiotherapy, radiotherapy: External beam radiotherapy (EBRT) 1.8–2.15 Gy/f, a total of 28 fractions; Brachytherapy: high-risk CTV using image guidance 28 Gy in 4 fractions (18 Gy in 3 fractions for posthysterectomy recurrent patients); chemotherapy regimen used TP regimen (paclitaxel: 175 mg/m², cisplatin: 75 mg/m², Q3W 6 cycles); Camrelizumab 200 mg Q3W 6 cycles. The primary endpoint of this trial was objective response rate (ORR), and secondary endpoints were progression-free survival (PFS), overall survival (OS), disease control rate (DCR), and incidence of adverse reactions. **Results:** From September 16, 2020 to September 30, 2022, a total of 29 patients were recruited. 27 of these patients completed 6 cycles of planned treatment. 27 patients had a median age of 53 years (33–73 years), ECOG PS 0 ($n = 8$), ECOG PS 1 ($n = 14$), ECOG PS 2 ($n = 1$). The ORR rate was 96.30% (26/27), including 17 patients with CR, 9 patients with PR, and 1 patient with SD. Treatment-related AEs were mainly lymphocyte count decreased, anemia, and white blood cell count decreased, with overall safety manageable and no treatment-related deaths. **Conclusions:** Camrelizumab combined with concurrent chemoradiation in patients with recurrent or metastatic cervical cancer has good efficacy, low side effects and acceptable toxicity. Clinical trial information: NCT04884906. Research Sponsor: None.

The spectrum of homologous recombination deficiency in cervical cancer: Is it also a cervical issue? *First Author: Muhammad Danyal Ahsan, Weill Cornell Medicine - Qatar, Doha, Qatar*

Background: Tumors deficient in homologous recombination DNA damage repair (HR-DDR) demonstrate sensitivity to therapeutic agents targeting the HR-DDR pathway, such as poly-ADP ribose phosphate (PARP) inhibitors. The landscape of homologous recombination deficiency (HRD) is not well-characterized for cervical cancer; thus, we sought to analyze the prevalence of somatic pathogenic gene variants (PGVs) in HRD genes in cervical cancers. **Methods:** The American Association for Cancer Research's (AACR) Project Genomics Evidence Neoplasia Information Exchange (GENIE) database version 13.0 was queried for all cervical cancer tumors via cBioPortal (<http://genie.cbioportal.org>). This is a publicly available, multi-institutional database of next-generation sequencing (NGS) genomic profiles of multiple tumors. PGV frequencies of 27 genes involved in HR-DDR were descriptively reported for cervical cancer tumors, with histologic stratification: *ATM*, *ARID1A*, *ATRX*, *BRCA1*, *BRCA2*, *BARD1*, *BRIPI*, *BLM*, *BAP1*, *CHEK1*, *CHEK2*, *FANCA*, *FANCC*, *FANCD2*, *FANCE*, *FANCF*, *FANCG*, *FANCL*, *MRE11*, *NBN*, *PALB2*, *RAD50*, *RAD51*, *RAD51B*, *RAD51C*, *RAD51D*, *WRN*. **Results:** A total of 857 cervical tumors from 817 patients were included for analysis. At least one somatic PGV in an HRD gene was found in 16.5% of all tumors (141/857). When stratified by histological subtypes with at least 25 tumors sequenced, highest frequencies of ≥ 1 PGV in HRD genes were observed in mucinous cervical cancer (13/66, 19.7%), cervical adenocarcinoma (48/262, 18.3%), squamous cell cervical cancer (53/349, 15.2%), adenosquamous cervical cancer (6/43, 14.0%) and neuroendocrine cervical cancers (5/42, 11.9%). Substantial rates of PGVs in HRD genes were also observed in histological subtypes with fewer than 25 sequenced tumors. Across all tumors, HRD genes with the highest frequencies of PGVs were *ARID1A* (9%), *BAP1* (3%), *ATM* (1.6%) and *BRCA1* (1.6%). **Conclusions:** NGS data demonstrate a substantial rate of somatic PGVs in HRD genes in cervical cancers, including among HPV related subtypes. These data suggest the need to expand routine functional HRD status assessment to cervical cancers in order to further characterize the landscape of HRD in these tumors. Furthermore, genetically driven clinical trials are warranted to evaluate the efficacy of HRD-targeted therapies such as PARP inhibitors, ataxia telangiectasia, and Rad-3 related kinase (ATR) inhibitors. Research Sponsor: None.

Correlating expression of NaPi2b and FRa in high grade serous ovarian cancer (HGSOC). *First Author: Debra L. Richardson, Stephenson Cancer Center/University of Oklahoma Health Sciences Center and Sarah Cannon Research Institute, Oklahoma City, OK*

Background: Biomarker driven therapies are increasingly being used for gynecologic cancers, with mirvetuximab soravtansine, a Folate Receptor alpha (FRa) targeting antibody drug conjugate (ADC) being a recent FDA approved agent for patients with FRa positive PROC. Uptifitambic rilosodotin (UpRi) is a late-stage, first in class NaPi2b-targeting ADC with a novel scaffold-linker-payload that enables high drug to antibody ratio and a controlled bystander effect. Approximately 29% of HGSOC patients have FRa positive tumors (Roche VENTANA FOLR1 (FOLR-2.1) Rx Dx Assay, USPI 2022); ~59% have NaPi2b positive tumors (Okeke et al, USCAP 2022). With the high unmet medical need in PROC and the evolving landscape of available treatments, understanding biomarker expression and correlation between FRa and NaPi2b is critical. Here we evaluate NaPi2b and FRa RNA expression correlation in HGSOC. **Methods:** Tumor samples (N=84) from the Ph1b UpRi expansion (EXP) cohort were analyzed via Nanostring (770 immune-focus genes from IO 360 panel + 30 customized ADC-related genes) to evaluate the association between NaPi2b and FRa expression. The cutoff for NaPi2b RNA positive or negative was based on approximately 60% of HGSOC patients having NaPi2b positive tumors (top 60% of samples based on expression deemed NaPi2b positive; bottom 40% NaPi2b negative) and FRa RNA cutoff assumed that ~30% of samples were FRa positive. To correlate the NaPi2b expression level between RNA and IHC, the N=84 samples with known expression levels via IHC were analyzed via Nanostring. **Results:** When evaluating NaPi2b and FRa RNA expression correlation, 21% (N=18) of samples had both NaPi2b positive and FRa positive expression. 38% (N=32) samples were NaPi2b positive and FRa negative. No statistically significant association was observed (Chi-squared test, p=0.129). NaPi2b RNA and IHC expression was evaluated; a statistically significant association was observed (Kappa statistic, p=0.001). Results are in the Table below. **Conclusions:** Based on this analysis of a limited sample size, there does not appear to be an association between FRa and NaPi2b expression, with the majority of NaPi2b positive samples not being FRa positive. Additionally, general NaPi2b prevalence and the correlation of expression between RNA and IHC suggest that NaPi2b may be a rational biomarker to integrate in RNA tumor panel testing. This research underscores the importance of early, comprehensive testing of all relevant biomarkers to guide therapy selection, and suggests that additional research is needed to evaluate the potential association between FRa and NaPi2b expression via IHC. Research Sponsor: Mersana Therapeutics.

N (% of total)	NaPi2b RNA	
	Positive (upper 60%)	Negative (lower 40%)
FRa RNA	Positive (upper 30%) Negative (lower 70%)	18 (21.4%) 32 (38.1%)
N (% of total)	Positive (upper 60%)	7 (8.3%) 27 (31.2%)

Phase 1 dose escalation study of SL-172154 (SIRP α -Fc-CD40L) in platinum-resistant ovarian cancer. *First Author: Nehal J. Lakhani, START Midwest, Grand Rapids, MI*

Background: SIRP α -Fc-CD40L is a hexameric, bi-functional fusion protein consisting of SIRP α linked to CD40L via an inert Fc linker. This molecule competitively inhibits CD47 to enhance tumor cell phagocytosis and activates CD40 to increase antigen processing and cross-presentation by antigen presenting cells (APCs) to CD8 T cells, thus bridging innate and adaptive immunity. **Methods:** This first-in-human, Phase 1 dose escalation study evaluated SL-172154 in patients (pts) with advanced platinum resistant ovarian, fallopian tube and primary peritoneal cancers (PROC). SL-172154 was administered intravenously across 5 dose levels (0.1, 0.3, 1.0, 3.0, 10mg/kg). Dose escalation followed a modified toxicity probability interval 2 design. Objectives included evaluation of safety, dose-limiting toxicity (DLT), recommended phase 2 dose, pharmacokinetic and pharmacodynamic (PD) parameters, and antitumor activity per RECIST 1.1. **Results:** As of 3 Jan 2023, 27 pts (median age 66 years [range 33-85]; median of 4 prior systemic therapies [range 2-9]) with ovarian (70%), fallopian tube (15%) or primary peritoneal (15%) cancer were dosed. Treatment-emergent AEs (>15% regardless of grade (G) included infusion related reaction (IRR) (67%), fatigue (44%), nausea (33%), back pain (26%), constipation, diarrhea (both 22%), decreased appetite and pruritus (both 19%). There was one DLT of G3 ALT increased at 10mg/kg requiring dose interruption for resolution. A maximum tolerated dose was not reached. G3/4 treatment-related AEs (>1pt) were AST increased (G3) and lymphopenia (G4), each in 2 pts (7%); all were fully resolved with no dose modifications. There were no fatal AEs, no AEs that led to drug discontinuation and no events of cytokine release syndrome. The frequency of IRR events increased with increasing dose, and slowing the rate of infusion was utilized for mitigation. SL-172154 Cmax and AUC increased with dose with greater than proportional exposure noted at 3 and 10mg/kg potentially due to target saturation. These findings were supported by dose-dependent target engagement of CD47 and CD40 on CD4 T cells and B cells respectively, approaching 100% by 3 mg/kg. Rapid dose-dependent egress of CD40+ B cells was maximal at ≥ 3 mg/kg. SL-172154 induced dose-dependent responses in IL-12, CXCL-8, CXCL-10, IL-10, CCL2, CCL20, and CCL22, which also approached a plateau at ≥ 3 mg/kg. Analysis of peripheral and tumor immunophenotypes and anti-drug antibodies in response to SL-172154 is ongoing and will be presented. Best response was stable disease in 6/27 response evaluable (22%) pts. **Conclusions:** SL-172154 is well tolerated in heavily pretreated PROC pts. IRRs were readily manageable. Maximal CD47 and CD40 target engagement and CD40-dependent PD effects were observed with ≥ 3 mg/kg SL-172154. 3mg/kg is a safe, tolerable, and pharmacologically active dose for evaluation in combination studies in pts with PROC. Clinical trial information: NCT04406623. Research Sponsor: Shattuck labs.

Systematic high-throughput combination drug screen to enhance poly (ADP-ribose) polymerase (PARP) inhibitor efficacy in ovarian cancer. *First Author: Katherine Foster, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PARP inhibitors currently offer the greatest benefit to patients with loss-of-function *BRCA1* or 2 mutations or other causes of homologous recombination deficiency (HRD). We hypothesized that combination therapy, possibly by augmenting or inducing an HRD phenotype, would enhance the efficacy of PARP inhibition in epithelial ovarian cancer. **Methods:** We performed a high-throughput screen of an informer set containing FDA-approved drugs, clinical candidates, and small-molecule probes to identify synergistic partners with olaparib in representative HRD and non-HRD human epithelial ovarian cancer cells. Single agent activity was described by area under the curve of the Hafner growth rate index (AUC_GRI) and synergy was ranked by cumulative difference from Bliss (Δ_{Bliss}). Analysis of the drug screen was performed using algorithms developed by the Gulf Coast Consortia's Combinatorial Drug Discovery Program at the Texas A&M Institute of Bioscience and Technology. MTT assays were then independently performed to verify and characterize synergy between CT7439, an agent selected following the drug screen, and olaparib. MTT data were analyzed using the SynergyFinder Plus web application. **Results:** In an initial single agent screen, we identified 62 compounds with a mean AUC_GRI <0.75, indicating inhibitory activity. Prioritizing more potent agents and those of mechanistic interest, we selected 40 hits to validate and advance to a combination screen. Diverse mechanisms of action were represented among the hits, including many small molecule inhibitors of various cell cycle pathways. Following a combination screen with olaparib, the compounds selected for final validation were: AZD 7762 (CHK1/2 inhibitor), dinaciclib (pan-CDK inhibitor), onalespib (HSP90 inhibitor), and SN-38 (topoisomerase 1 inhibitor). The Δ_{Bliss} for these agents are presented in the table. Due to mechanistic rationale and concern for overlapping toxicities among the other candidates, we focused further study on CDK inhibitors. In MTT assays, we identified robust synergy between olaparib and CT7439, a next-generation oral CDK12/13 inhibitor, with a mean Bliss synergy score of 1.31 and scores as high as 22.03 at certain concentrations in the non-HRD model OVCAR-5. These findings were recapitulated in the HRD cell lines OVCAR-4 (mean Bliss synergy score 1.56) and OVCAR-8 (mean Bliss synergy score 5.69). Results from an *in vivo* model will be presented as well. **Conclusions:** Pairing a PARP inhibitor and CDK inhibitor, a strategy identified by a high-throughput drug screen and known to impair homologous recombination, resulted in robust synergy in both HRD and non-HRD ovarian cancer models. Clinical translation of this combination may enhance the efficacy of PARP inhibitors in patients with ovarian cancer. Research Sponsor: MD Anderson Ovarian Cancer Moon Shot; CPRIT Grant #RP200668.

Compound	Mean Δ_{Bliss}

The impact of adjuvant platinum-based chemotherapy in early adult granulosa cell tumor of the ovaries: A meta-analysis of comparative studies. *First Author: Dinesh Keerty, LSUHSC-S, Feist-Weiller Cancer Center, Shreveport, LA*

Background: Adult granulosa cell tumors (AGCT) are the most common type of malignant ovarian sex chord stromal tumors but only comprise 2 to 5 percent of all malignant ovarian neoplasms. Most granulosa cell tumors have an indolent growth pattern, and prognosis depends on the disease stage at diagnosis and the presence of residual disease after surgery. Though these tumors have metastatic potential, their tendency for late relapses is well documented. Despite the lack of supporting data, the National Cancer Centers Network recommends platinum-based adjuvant chemotherapy (AC) for Stage I with intermediate and high-risk features. Most studies have failed to show any benefit of AC with disease-free or overall survival. However, several of these studies were small, and some had short median follow-ups. Others included advanced stages and the juvenile variant of the disease. Therefore, we conducted this meta-analysis to evaluate the impact of AC on disease recurrence in a stage I enriched AGCT. **Methods:** A review of the medical literature was conducted using online databases. Inclusion criteria consisted of English language, diagnosis of AGCT, studies with a preponderance of stage I, comparative studies of AC versus none, and studies that reported recurrence rates. Studies that had a preponderance of advanced stages or juvenile variants were excluded. A meta-analysis using the fixed effects and random effects models was conducted. **Results:** Seven retrospective comparative studies with a total of 500 patients were included. The average median age was 47 years, and the average median follow-up was 58 months. Approximately 79% of the sample were stage I, and 79% of stage I were IC. Most AC regimens used were BEP and EP, though it varied among the regions. Platinum-based AC in early-stage AGCT failed to impact recurrence rates compared to clinical observation (HR=1.39, 95%CI 0.86-2.25, $I^2=48\%$, $p=0.18$). **Conclusions:** This is the first meta-analysis to show that adding platinum-based adjuvant chemotherapy to surgery does not improve the recurrence rate in early AGCT. Therefore, in the absence of evidence supporting any benefit of AC in this disease, recommendations to use AC should be re-evaluated, especially since the risk of platinum-based AC with or without Bleomycin is well-documented and carry potentially serious side effects. Utility of surgically documented minimal residual disease as a therapeutic target and early surrogate of frontline treatment outcomes in ovarian cancer. *First Author: Anne Knisely, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Cure rates for patients with advanced stage ovarian cancer have not changed over the last four decades likely due to inability to eradicate residual cancer cells after frontline therapy. Identifying clinically undetectable minimal residual disease (MRD) after frontline therapy by second look laparoscopy (SLL) has potential to a) uncover mechanisms of chemoresistance, b) identify MRD-specific therapeutic targets, and c) allow for earlier intervention with investigational therapies. The objective of this study is to describe the initial safety and feasibility of SLL and illustrate clinical pathologic correlates. **Methods:** This IRB-approved observational, single-center study includes patients with epithelial high-grade ovarian cancer with complete CA-125 and radiologic response after frontline treatment who underwent SLL from 4/2017-12/2022. Patients were subsequently offered standard of care or investigational maintenance therapy options based on homologous recombination deficiency (HRD) and MRD status. Summary statistics described the study population, chi-square tests compared categorical variables, and progression free survival (PFS) based on MRD status was estimated using Kaplan-Meier method and compared using log rank test. **Results:** 64 patients underwent SLL with a median of 8 biopsies (range 1-16). The majority of patients had stage III-IV disease (89%), and high-grade serous histology (89%). Approximately half (52%) of patients underwent neoadjuvant chemotherapy (NACT) with interval tumor reductive surgery (TRS). MRD was present in 28 patients (44%), and the presence of MRD was associated with a worse PFS (HR 3.1, 95% CI 1.5-6.3; 9.2 vs 24.6 months; $P=0.002$). MRD was more frequent among NACT recipients compared to those who underwent primary TRS (61% vs 26%, $P=0.005$), those with HRD negative tumors (63% vs 22%, $P=0.003$), and those with R1 versus R0 resections (71% vs 35%, $P=0.012$). Of patients with MRD, 20 patients (71%) received bevacizumab until progression as part of a clinical trial (NCT02884648), 3 (11%) received bevacizumab off trial, 4 (14%) received a PARP inhibitor (all HRD positive) and 1 received other therapy. There was one (1.6%) intraoperative complication requiring conversion to laparotomy. **Conclusions:** SLL is feasible, overall safe, and detected MRD in 44% of ovarian cancer patients who were in radiologic and CA-125 remission after frontline therapy. MRD rates were higher in patients who received NACT and HRD negative patients, and PFS was significantly longer in patients without residual disease. MRD rate by SLL may have utility as an early surrogate for efficacy in trials evaluating novel frontline investigational therapies. Knowledge of MRD status in this patient population enables interventional, observational, and translational investigations, as well as personalized prognostic counseling. Nivolumab plus ipilimumab (N+I) in patients (pts) with ovarian cancer (OC) with BRCA1/2 mutation (mut): Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) study. *First Author: Charles Drescher, Swedish Cancer Institute, Seattle, WA*

Background: TAPUR is a phase II basket study evaluating antitumor activity of commercially available targeted agents in pts with advanced cancers with genomic alterations. Results in a cohort of pts with OC with *BRCA1/2* mut treated with N+I are reported. **Methods:** Eligible pts had advanced OC, measurable disease, ECOG performance status (PS) 0-2, adequate organ function, and no standard treatment (tx) options. Genomic testing was done in CLIA-certified, CAP-accredited labs. PD-L1 status was not routinely reported. Pts received I at 3 mg/kg every 3 wks for 4 doses with N at 1 mg/kg IV every 3 weeks (wks) for 4 doses. N alone was then continued at 240 mg every 2 wks or 480 mg every 4 wks until disease progression. Primary endpoint was disease control (DC) per investigator defined as complete or partial (PR) response per RECIST v. 1.1, or stable disease of at least 16+ wks duration (SD16+). CA-125 levels were not routinely reported. Simon 2-stage design tested the null DC rate of 15% vs. 35% (power = 0.85; $\alpha = 0.10$). If ≥ 2 of 10 pts in stage 1 have DC, 18 more pts are enrolled; otherwise, the cohort is closed. If ≥ 7 of 28 pts have DC, the null DC rate is rejected. P-value calculated based on 2-stage design. Secondary endpoints were progression-free survival (PFS), overall survival (OS), and safety. **Results:** 33 pts with OC and *BRCA1* (n=20), *BRCA2* (n=10), or both mut (n=3) were enrolled from Sept 2017 to Oct 2019. 6 pts were not evaluable for efficacy analysis; 1 pt was found to be ineligible after enrolling, 5 pts discontinued tx before the post-baseline tumor evaluation due to an adverse or serious adverse event (SAE). Table shows demographics and efficacy outcomes. 6 pts with PR were observed for an OR rate of 22% (95% CI: 9% to 42%) and a DC rate of 27% (90% CI: 13% to 36%); the null hypothesis of a 15% DC rate was not rejected ($p=0.17$). 3 pts with PR had *BRCA1* mut only, 2 pts had *BRCA2* mut only and 1 pt had both *BRCA1* and *BRCA2* mut. Of the 6 pts with PR, 4 had microsatellite (MS) stable (MSS) tumors and MS status was not reported in 2. Of the 4 with MSS, 3 had a tumor mutational burden (TMB) ≤ 10 mutations per megabase and 1 had TMB of 11. 11 pts had at least 1 tx-related SAE, including acute kidney injury, ALT/AST increase, colitis, dehydration, diarrhea, E. coli, electrolyte disorder, fever, nausea/vomiting and pneumonitis. **Conclusions:** N+I did not meet prespecified criteria to declare a signal of activity in pts with OC and *BRCA1/2* mut. However, given 22% of pts had PR (2 with >1 year duration) in this heavily pretreated cohort, additional study may be warranted to further evaluate efficacy. Clinical trial information: NCT02693535. Efficacy of subsequent therapies in patients (pts) with advanced ovarian cancer (AOC) in the phase III PAOLA-1/ENGOT-ov25 trial according to whether disease progression occurred during or after the end of olaparib (ola) maintenance. *First Author: Philipp Harter, Kliniken Essen-Mitte, and AGO, Essen, Germany*

Background: In the PAOLA-1/ENGOT-ov25 trial (NCT02477644), maintenance ola (a PARP inhibitor) + bevacizumab (bev) led to prolonged progression-free and overall survival vs placebo (pbo) + bev in AOC pts, specifically those with homologous recombination-deficient (HRD+) tumors (Ray-Coquard et al. ESMO 2022, LBA29). Here, we explore the efficacy of subsequent chemotherapy (CT) in pts after progression on first-line (1L) treatment in PAOLA-1. **Methods:** The efficacy of subsequent CT was explored by analyzing the median time from first subsequent therapy (FST) to second subsequent therapy (SST). Efficacy was compared by FST type, HRD status, and timing of progression (during/after ola). A multivariate Cox model was used in ola + bev pts to identify prognostic factors influencing time from FST to SST, including HRD status, platinum-free interval (PFI), clinical risk based on disease stage and surgical status, timing of progression, and response to 1L CT. All P values are exploratory. **Results:** In total, 544/806 (67.5%) pts progressed and received subsequent CT: 338/537 (62.9%) ola + bev pts and 206/269 (76.6%) pbo + bev pts. In the overall population and in the subgroup who received platinum-based combination therapy (PBC), time from FST to SST was shortest in pts who progressed during ola (Table). Pts who progressed after ola had similar outcomes to pbo + bev pts (Table). Efficacy was broadly consistent regardless of HRD status (Table). The multivariate analysis confirmed that progression after (vs during) ola prolonged time from FST to SST (hazard ratio [HR] 0.65, 95% confidence interval [CI] 0.50-0.84; $P=0.0011$) independently of other known prognostic factors, such as PFI ≥ 12 vs <12 months (HR 0.38, 95% CI 0.29-0.51; $P<0.0001$) or lower vs higher clinical risk (0.58, 0.42-0.81; $P=0.0015$). **Conclusions:** In this post hoc exploratory analysis of PAOLA-1, the efficacy of subsequent CT at relapse appeared dependent on whether progression occurred during or after the end of ola treatment. Efficacy was reduced when relapse occurred during ola but was comparable between pts who progressed after ola vs pbo + bev pts. Clinical trial information: NCT02477644. Research Sponsor: This work was supported by ARCA Research, AstraZeneca, Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA, and F. Hoffmann-La Roche.

Real-world data from a multi-center study: Insights to the efficacy and safety in patients with ovarian cancer (OC) received niraparib as first-line (1st-L) maintenance therapy (MT). *First Author: Minmin Zhao, Department of Obstetrics and Gynecology, Zhongda Hospital Southeast University, Nanjing, China*

Background: Niraparib has significantly extended PFS as 1st-L MT OC in PRIMA/PRIME. Due to the more complex in treatment and status of the patients (pts) in clinical practice, more real-world data is needed to verify the efficacy and safety of Niraparib. Meanwhile, exploring the link between clinical characters and PFS, may to establish a clinical model to predict Niraparib benefits. **Methods:** This is a retrospective multicentric study recruiting OC pts received Niraparib as 1st-L MT from fourteen hospitals throughout China from Jan. 2019 to Dec. 2021. The database lock-time was on Dec. 31st, 2022. The pts' basic characters, especially biomarkers, KELIM scores, etc. were recorded. Survival analyses were conducted using the Kaplan-Meier method and log-rank test, and 95% CI were calculated. The primary endpoint was PFS, and secondary endpoints included time to treatment discontinuation (TTD), time to first subsequent therapy (TFST) and safety. The exploratory endpoint was to establish a clinical prediction model of Niraparib benefits. **Results:** 199 pts' data were analyzed. The median(m) follow-up at the time of the data cutoff was 14.93 months (mos) (12.17, 39.47). Baseline characteristics were shown in Table. MPFS was not reached (NR) (29.80 to not be estimated, NE), with maturity 29.64%, and PFS rate at 6, 12, 18, 24mos was 89.4%, 79.5%, 68.3%, 64.5% respectively, showing the efficacy of Niraparib. MPFS (95% CI) in subgroups were as follows: BRCAwt 23.83mos (23.83 to NE); HRD negative 15.63mos (12.6 to NE); KELIM < 1 NR (15.33 to NE); BRCA1/2m, HRD positive and KELIM≥1 subgroups all NR yet, due to the no longer enough follow-up time and low data maturity. Multivariate analysis found that pts with <65 years, BRCA1/2m, HRD positive, KELIM > 1, and R0 after primary cytoreductive surgery were likely to have longer PFS. The rate of grade ≥3 thrombocytopenia was 19.1%. Treatment discontinuation occurred in 11 (5.5%) pts due to TEAEs. The clinical prediction model for probability of progression was established from 149 pts (training dataset): Score = 0.612 Age_{> 65} + 0.3889 BMI_{≥ 23.90} + 0.097 FIGO_{IV} + 0.191Chronic_N + 1.398 Surgery result_{R1/R2} + 2.552 BRCA_{wt}. The probability of disease progression received Niraparib in 6, 12 and 18m can be obtained by mapping the score to the nomogram. **Conclusions:** The efficacy and safety of Niraparib in this study are consistent with the results in PRIME. The clinical predictive model established in this database needs more data to be matured and verified. Research Sponsor: Beijing Science & Technology Innovation Fund (KC2021-JX-0186-143).

Circulating tumor DNA (ctDNA) as a marker of residual disease and recurrence in resected stage I-IV epithelial ovarian cancer (EOC). *First Author: Sumitra Ananda, Peter MacCallum Cancer Centre, Epworth Healthcare, Western Health, Walter and Eliza Hall Institute, University of Melbourne, Melbourne, VIC, Australia*

Background: The management of EOC remains challenging, with a high risk of relapse despite surgery, chemotherapy and maintenance therapy. Detection of ctDNA after surgery and adjuvant chemotherapy (CT) may identify patients (pts) at highest risk of recurrence suitable for treatment escalation. Our primary aim was to investigate the use of ctDNA as a marker of residual disease following both surgery and adjuvant CT that might predict later recurrence. **Methods:** In this multi-centre observational study, we collected blood samples post-op and 6-8 weeks post-CT completion from pts with debulked stage I-IV EOC planned for adjuvant CT. Pre-cycle 1 CT and pre-op blood was also collected from some pts who received neoadjuvant CT. We used a tumor-informed approach for ctDNA analysis with whole exome sequencing of tumor tissue followed by detection of up to 50 variants in the plasma with the SaferSeqS assay. The primary outcome was recurrence-free survival (RFS), calculated using the Cox proportional-hazards model. **Results:** 81 pts who had post-op ctDNA results were included. 84% had high grade serous histology and 23% had BRCA mutations. Median number of tumor-informed variants analyzed in the plasma was 44 (range 3-60). Overall, post-operative ctDNA was detected in 63 of 81 (78%) of pts, 18 of 26 (69%) in Stage I-II and 45 of 55 (82%) in Stage III-IV. Pts who were ctDNA negative post-surgery had longer RFS versus who were ctDNA positive (HR 3.28, 95% CI 1.39 to 7.72, p = 0.007). Estimated RFS at 2 years was 78% among pts who were ctDNA negative post-surgery and 44% among the ctDNA positive group. Pts with BRCA mutations were less likely to have positive post op ctDNA (OR 0.12, 95% CI 0.036 to 0.39, p < 0.001). For post-CT ctDNA, estimated RFS at 2 years was 74% in the ctDNA negative pts versus 43% in the ctDNA positive group but this was not statistically significant (HR 1.64, 95% CI 0.84 to 3.18, p = 0.15). Pts with zero residual disease were more likely to be ctDNA negative post-surgery (OR 12.36, 95% CI 1.54 to 99.4, p = 0.018). Post-op ctDNA outperformed post-op CA-125 in predicting recurrence; pts with elevated CA-125 post-surgery had shorter RFS compared to those with normal CA-125 post-surgery (HR 1.99, 95% CI 1.15 to 3.42, p = 0.013). Of 18 pts who had neoadjuvant CT, pre-treatment ctDNA was detected in 17 (94%). Only two pts had clearance of ctDNA post neoadjuvant CT and both had zero residual disease at surgery. For the pts that maintained positive ctDNA results post-op, 7/15 (47%) pts had zero residual disease. **Conclusions:** ctDNA detection after ovarian cancer cytoreduction identifies pts at very high risk of recurrence. Pts with BRCA mutations were more likely to have negative ctDNA post-op. The role of ctDNA in guiding neoadjuvant and adjuvant therapy to improve outcomes, warrants further investigation. Venous thromboembolism prophylaxis during neoadjuvant chemotherapy for patients with ovarian cancer. *First Author: Hannah Dysinger McLaughlin, University of Michigan Hospital, Ann Arbor, MI*

Background: The primary objective was to assess the rate of venous thromboembolism (VTE) in patients with ovarian cancer who received neoadjuvant chemotherapy (NACT) following a quality improvement (QI) intervention of routine pharmacologic VTE prophylaxis compared to patients that did not receive prophylaxis. **Methods:** This is a retrospective cohort study of patients with pathologically confirmed ovarian cancer that received NACT between January 2009 to December 2021 from a single institution. Patients were excluded if VTE was diagnosed prior to initiating NACT. Routine pharmacologic VTE prophylaxis during NACT started in January 2017 following a QI initiative. VTE events were diagnosed by doppler scan of extremities or computed tomography of the chest ordered for symptomatic patients or diagnosed incidentally on routine treatment imaging. Patient factors and perioperative variates of interest were investigated for their association with VTE events through univariate and multivariate models. **Results:** A total of 290 patients with ovarian cancer received NACT and were included, with 106 of 290 patients (36.5%) receiving pharmacologic prophylaxis during NACT. Rate of VTE prophylaxis prior to the QI intervention was 3.68% (n=5) compared to 65.58% (n=101) after. The rate of VTE during NACT was 11.41% (n=21) without prophylaxis and 2.83% (n=3) with prophylaxis (p=0.013) (Table). The rate of any VTE event from the start of NACT through adjuvant chemotherapy was 20.11% (n=37) without prophylaxis and 4.72% (n=5) with prophylaxis (p<0.01). There was no difference in adverse bleeding events in those that received prophylaxis to those that did not (0% vs 1.32%, p=0.239). On univariate analysis, VTE prophylaxis was associated with a decreased risk of VTE during NACT (OR 0.23; 95% CI: 0.06-0.78) and any VTE during primary treatment (OR 0.19; 95% CI 0.07-0.52). On multivariate analysis, VTE prophylaxis remained significantly associated with reduced VTE rates during NACT and during primary treatment (p=0.02 and p=0.001, respectively). **Conclusions:** Routine administration of pharmacologic VTE prophylaxis during NACT for patients with ovarian cancer is associated with reduced risk of VTE during NACT and throughout primary treatment and is not associated with adverse bleeding events. Research Sponsor: None.

Safety and efficacy of PIPAC in patients with ovarian cancer with peritoneal metastases: A first-in-US phase I study. *First Author: Rosemary Senguttuvan, City of Hope National Medical Center, Duarte, CA*

Background: Epithelial ovarian cancer (EOC) is characterized by chemoresistant recurrences primarily confined to the intraperitoneal cavity, frequently leading to malignant small bowel obstructions. Intraperitoneal (IP) chemotherapy has been incorporated in EOC, but only in the first-line setting. Pressurized intraperitoneal aerosolized chemotherapy (PIPAC) is a novel IP drug delivery method that optimizes tissue penetration depth and drug distribution, to treat recurrent peritoneal malignancies. Recent trials outside the U.S. demonstrated partial to stable response following PIPAC in recurrent EOC. To date, no clinical trials have been completed investigating the role of PIPAC in EOC in the United States. **Methods:** We performed a multicenter prospective phase I trial using IP cisplatin 10.5 mg/m² and doxorubicin 2.1 mg/m² via PIPAC at 6-week intervals. Patients were eligible if they had recurrent disease with peritoneal metastasis; extraperitoneal metastasis was allowed. The primary endpoint was dose-limiting toxicity (DLT). Secondary endpoints included progression free survival, PCI scoring, RECIST measurements, and quality of life (QoL). The patients with gastric and uterine cancers' toxicity data were used but given inherent prognostic differences the treatment efficacy for these patients were not used in this analysis. Adverse event (AE) monitoring was graded using CTCAE spanning 18 weeks. Following completion of treatment (≥2 PIPACs) patients were followed up every 12 weeks. QoL was measured using patient-reported assessments at 0, 6, 12, and 18 weeks. Baseline demographics were summarized. Mean change in PCI was calculated between cycle (C) 1 and 2, and cycle 2 and 3. Toxicities attributed to the surgery or PIPAC were reported with highest grade for each patient. **Results:** Nine heavily pretreated, recurrent patients were enrolled in the trial: 7 with platinum-resistant recurrent EOC, 1 with uterine cancer, and 1 with gastric cancer. PIPAC completion rate was 71.4%. Median age of participants was 65 years. Median prior lines of chemotherapy were 4 (range 2 - 10). No surgical complications occurred in the cohort. Two patients came off study: one for G3 abdominal pain and the other for G3 anorexia. For the EOC cohort, the median PCI reduction was -1.4% (C1 to C2) and -2.8% (C1 to C3). One low-grade serous EOC patient demonstrated a partial response based on RECIST criteria and received 6 cycles. Two EOC patients showed an initial response based on PCI reduction, but progressed following Cycle 2. Overall, QoL was stable. **Conclusions:** PIPAC with cisplatin/doxorubicin in platinum-resistant ovarian cancer is well tolerated. Intraperitoneal responses were seen in a subset of low-grade serous ovarian cancer patients, which may warrant further study. Heavily pretreated, platinum-resistant high-grade EOC patients derived limited intraperitoneal control from PIPAC monotherapy. Clinical trial information: NCT04329494. Research Sponsor: Internal Funding.

Analyses of tumor microenvironment affecting the survival in patients with ovarian cancer receiving intraperitoneal chemotherapy: Translational research from the phase 3 trial of intraperitoneal therapy for ovarian cancer with carboplatin (TRiPocc). *First Author: Aiko Ogasawara, Aichi Cancer Center Research Institute, Nagoya, Japan*

Background: The iPocc trial is a randomized, global phase (P) 3 study of intraperitoneal (IP) versus intravenous (IV) carboplatin with dose-dense paclitaxel chemotherapy in epithelial ovarian cancer (EOC) patients that demonstrated an improved progression-free survival (PFS) but not overall survival (OS) in the former. IP chemotherapy induces an antitumor immune response and increases survival in a murine xenograft model. This study aimed to assess whether immunological background affected the clinical outcomes of patients receiving IP chemotherapy. **Methods:** Fresh frozen tumor samples at the time of primary surgery were obtained from 116 patients who joined the iPocc P3 trial for microarray analysis. Cell-type deconvolution was performed using MCP counter. Single sample Gene Set Enrichment Analysis was performed to evaluate the tumor immune microenvironment. Clinical data were obtained from the iPocc P3 trial. We stratified 116 patients according to the high or low values of each factor determined by the median values. The Kaplan-Meier method and log-rank test were used to analyze PFS and OS. **Results:** A total of 116 patients were assigned to either the IP (n=59) or IV (n=57) group. The most common histologic type was serous (58.6%), followed by endometrioid (17.2%) and clear cell (12.1%). The patients who received IP therapy had longer OS than those who received IV therapy in the group with a high infiltration of T cells, NK cells, or cytotoxic lymphocytes in the MCP counter (median OS: not reached (NR) vs 75.0 months, $P=0.041$, NR vs. 75.0 months, $P=0.042$, NR vs 65.2 months, $P=0.031$), but not in the group with a low infiltration. Similarly, the IP therapy improved OS in the patients with high expression of immune-related genes such as *CD8A*, *FOXP3* or *PDCD1* (median OS; NR vs 65.2 months, $P=0.035$, NR vs 65.2 months $P=0.030$, NR vs 53.1 months, $P=0.016$), but not in the patients with low expression of those genes. In addition, a multifaceted evaluation was conducted because of the limitations of evaluating the interaction between cancer and immunity using a single factor. When the patients were divided into two groups, "Immune Hot" and "Immune Cold" based on the hierarchical clustering analysis with 4 parameters representing "Innate immunity," "T cells," "Interferon gamma response" and "Inhibitory molecules," the IP therapy increased both PFS and OS compared to the IV therapy in the "Immune Hot" group (median PFS; 35.5 vs 23.4 months, $P=0.024$, median OS; NR vs 75.0 months, $P=0.040$), but not in the "Immune Cold" group. **Conclusions:** IP therapy may improve the survivals in EOC patients with a high immunological background. Further studies are warranted to validate this hypothesis and to clarify the impact of IP therapy on the tumor immune microenvironment. Clinical trial information: NCT01506856 / GOTIC-001/JGOG3019. The role of innate immune system in modulating CHK1 inhibitor (CHK1i) response in BRCA wild-type (BRCAwt), platinum-resistant high-grade serous ovarian cancer (PR-HGSOC): Exploratory analysis from a phase II study of CHK1i prexasertib. *First Author: Elena Giudice, Women's Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Immune checkpoint blockade, e.g., anti-PD-1/PD-L1, demonstrated limited efficacy in HGSOC despite high levels of tumor-infiltrating lymphocytes, suggesting the innate, rather than adaptive, immune system may play a prominent role in anticancer response. Preclinical studies suggest CHK1i modulates the innate immune milieu. We previously showed clinical activity of prexasertib in BRCAwt, PR-HGSOC patients (pts). Here, we investigated the association of innate immunogenic features with CHK1i response. **Methods:** Prexasertib was given at 105 mg/m² IV every 14 days in a 28-day cycle. Baseline (BL) fresh core biopsies were collected from pts enrolled in the biopsy (Bi) cohort for RNA sequencing. Computational immunogenomic analysis (CIBERSORT) was used for immune cell fractions quantification. Blood samples (BS) were obtained at BL and cycle 1 day 15 (C1D15) from pts enrolled in both Bi and non-Bi (nBi) cohorts for multiparametric flow cytometry (FC) analysis to evaluate dynamic changes in immune cell subsets. Mann-Whitney and Wilcoxon tests were used to compare unpaired and paired data, respectively. **Results:** 49 BRCAwt, PR-HGSOC pts were enrolled in the Bi cohort (n=25) and nBi cohort (n=24). 39 were evaluable per RECIST v1.1. 18/39 pts (46.2%) had a clinical benefit (CB), defined as progression-free survival ≥ 6 months. Transcriptomic profiles of BL biopsies (n=15) met the quality control and assurance (Gene Similarity Index, Principal Component Analysis) for further *in silico* analysis. CIBERSORT analysis did not exhibit any differences in the immune cell fractions between CB and non-CB (NCB) groups at BL. FC analysis on paired BS (BL and C1D15) showed an increase of immunosuppressive monocytic myeloid-derived suppressor cells (M-MDSCs, $p<0.001$) and classical monocytes (CM, $p=0.003$) in the NCB group (18 paired BS). In the CB group (19 paired BS), CD141+ and CD1c+ dendritic cells (DCs) express higher rates of CD83, a marker of maturity and functionality ($p<0.001$ and $p<0.001$, respectively), despite no increase in the absolute number of DCs. At C1D15, a higher rate of M-MDSCs (median 7.8% vs. 5.52%; $p=0.03$) and CM (median 40.7% vs. 31.7%; $p=0.03$) were found in the NCB group (n=18) compared to the CB group (n=19); also, CM showed lower expression of HLA-DR in the NCB group (median 19.25% vs. 27.8%; $p=0.02$). **Conclusions:** Collectively, our data suggest the possible involvement of innate immunity in modulating CHK1i response. Increasing peripheral immunosuppressive cells and lower immunocompetence of the innate immune system may contribute to CHK1i resistance, whereas the functionality of DCs may be involved in the response. Enhancing innate immunity may represent a strategy to increase CHK1i response in this hard-to-treat population. Clinical trial information: NCT02203513. Research Sponsor: U.S. National Institutes of Health.

Pegylated liposomal doxorubicin and carboplatin versus paclitaxel and carboplatin as first-line treatment for Chinese patients with ovarian cancer: A multi-center, randomized, open-label trial. *First Author: Yuanming Shen, Women's Hospital School of Medicine Zhejiang University, Hangzhou, Zhejiang, China*

Background: Paclitaxel combined with carboplatin is a standard first-line chemotherapy regimen for ovarian cancer. This study was designed to evaluate the efficacy and safety of pegylated liposomal doxorubicin (PLD) plus carboplatin (CD) compared with paclitaxel plus carboplatin (CP) as first-line treatment for epithelial ovarian cancer (EOC). **Methods:** Patients with stage IC to IV EOC, fallopian tube cancer, or primary peritoneal cancer were eligible for enrolment in this open-label, randomized controlled trial at 20 centers in China. Patients were randomly assigned 1:1 to CD group (carboplatin area under the curve [AUC] 5 plus PLD 30 mg/m²) or CP group (carboplatin AUC 5 plus paclitaxel 175 mg/m²) every 3 weeks for 3-6 cycles. The primary end point was progression free survival (PFS); secondary end points were overall survival (OS), objective response rate (ORR), disease control rate (DCR) and safety. **Results:** Between March, 2019 to December, 2021, 395 patients were enrolled, of whom 391 patients were analyzed (195 assigned to CD, 196 to CP). Baseline characteristics were balanced between the two treatment groups. The median follow-up was 21.6 months for the CD group and 22.5 months for the CP group. There was no significant difference in PFS between the two arms ($P=0.516$); the median PFS was 28.1 months and 30.1 months in the CD and CP arms, respectively. OS data were immature at data cutoff, with a total of 26 deaths in the two treatment groups. In patients with at least one measurable lesion at baseline, ORR was 65.5% in the CD arm and 66.2% in the CP arm ($P=0.941$); DCR was 74.1% and 73.8% in the CD and CP arms, respectively ($P=0.971$). Among patients who were evaluable by GCIG CA125 criteria, CA125 response was obtained in 86.0% and 88.5% of patients in the CD and CP arms, respectively ($P=0.560$). More frequent grade 1 to 3 alopecia (32.1% vs 12.3%) and neurotoxicity (20.4% vs 0%) were observed in the CP arm; more hand-foot syndrome (grade 1 to 3, 10.8% vs 2.6%), and oral mucositis (grade 1-3, 12.8% vs 5.1%) in the CD arm. **Conclusions:** The efficacy of CD regimen is comparable to that of CP, with less alopecia and neurotoxicity. CD may be an alternative first-line treatment for EOC. However, survival data are not yet mature, and longer follow-up is needed. Clinical trial information: NCT03794778. DNA methylation patterns between tissue and blood samples in ovarian cancer. *First Author: Hao Wen, Department of Gynecological Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Altered DNA methylation pattern, with functional consequences in the activity of key carcinogenic pathways, has been shown to be involved in the carcinogenesis of ovarian cancer. Tumor DNA is released into the blood via apoptosis or necrosis. Therefore, cell-free DNA (cfDNA) methylation alteration can also be detected in blood, which has shown promising performance in ovarian cancer early detection and prognostication. However, the difference of DNA methylation patterns between the tissue and blood samples of ovarian cancer is still unclear. **Methods:** PERCEIVE-I study (NCT04903665) is a prospective study aimed at the early detection of gynecological malignancies. Blood and paired tissue samples from this study were collected at the Fudan University Shanghai Cancer Center. Blood samples from age-matched non-cancer controls were also collected. All the blood and paired tissue samples were sequenced by a target methylation panel covering ~490,000 CpG sites. Finally, The ovarian cancer methylation patterns were analyzed based on 11 paired cancer-adjacent tissue samples and 170 blood samples (cancer, n=48; non-cancer control, n=122). **Results:** In total, 7,225 differentially methylated blocks (DMBs) were identified by comparing cancer and adjacent tissues, with 5,093 hypomethylated and 2,132 hypermethylated. By contrast, there were 5,853 hypomethylated and 8,685 hypermethylated DMBs in cancer blood samples compared with non-cancer controls. Among the 7,225 DMBs in tissues, 3,962 (54.8%) blocks were also observed to be altered in blood samples, including 2,354 hypomethylated blocks and 1,114 hypermethylated blocks. GO analysis revealed that these hypomethylated blocks were mainly associated with functions such as regulation of synaptic membrane and DNA-binding transcription activator activity, while the hypermethylated blocks were mainly enriched in the pattern specification process, transcription factor complex, and the DNA-binding transcription activator activity. The alteration of the above 3,962 DMBs in tissue were highly correlated with the alteration in blood (correlation coefficient of 0.71, 0.50, 0.73 and 0.73 for stage I-IV, respectively). Furthermore, in patients carrying germline *BRCA1/2* mutations (n=11), most of the above DMBs were not significantly different from those without germline *BRCA1/2* mutations (n=37). **Conclusions:** In this study, we demonstrated that blood DNA methylation alteration was highly consistent with tissue DNA methylation alteration in ovarian cancer, indicating the sustained release of DNA methylation signals from the primary cancer sites. These results suggest that cfDNA methylation can be used as reliable biomarkers for the early detection of ovarian cancer. Clinical trial information: NCT04903665. Research Sponsor: None.

BRCA1 and RAD51 methylation impact on outcome in patients with advanced ovarian cancer: A PAOLA-1 ancillary study. *First Author: Helene Blons, APHP, European Georges Pompidou Hospital, Department of Biochemistry, Pharmacogenetics and Molecular Oncology, Paris Cancer Institute CARPEM, Paris, France*

Background: The PAOLA-1/ENGOT-ov25 trial showed that adding olaparib (ola) to maintenance bevacizumab (bev) after first-line therapy led to a progression-free and overall survival benefit in advanced ovarian high-grade carcinoma (AOC) patients with homologous recombination deficiency (HRD) (Myriad MyChoice[®] Genomic Instability Score) or *BRCA1/2* mutations (*BRCAmut*). Here, we address the impact of *BRCA1* and *RAD51C* epimutations to improve our understanding of GIS beyond *BRCAmut*. **Methods:** *BRCA1* and *RAD51C* methylation analysis was assessed and quantified in pre-treatment biopsies (66%), after neo-adjuvant chemotherapy (NACT) (20%) or unknown (14%) from bisulfite converted DNAs using fluorescent methylation specific PCR and methylation specific droplet digital PCR (ddPCR). Methylation status was correlated to clinical data, *BRCA1/2* mutations, GIS and HRD scores, PFS (PFS1, PFS2) and OS. R (r-project.org) was used for statistical analysis. **Results:** Among the 537 patients randomized to maintenance ola + bev and 269 to placebo (pbo) + bev, 348 and 171 were available for methylation analysis. Their baseline molecular and clinical characteristics were well balanced with those of the entire cohort. Promoter methylation was identified in 67 (12.9%) samples for *BRCA1* and 25 (4.8%) for *RAD51C* (4 were methylated on both genes). Methylation and *BRCAmut* were mutually exclusive except for 3 samples. Mean GIS scores were 62.5 [59.6-65.5]; 59.4 [57.2-61.5]; 54.2 [50.5-57.8]; 23.4 [21.6-25.2] for *BRCA1* or *RAD51C* methylated (*met-tumors*), *BRCAmut*, *non-mut/non-met* HRD+ (*b-/m-HRD+*) and HRP (proficient) tumors respectively. Among *met-tumors* 92% (66/72) were GIS positive (>42). The mean GIS score of *Met-tumors* were significantly higher than that of *b-/m-HRD+* samples (p=0.009). Benefit of adding ola maintenance to bev was in a similar between patients with *met* AOC and those with *b-/m- HRD+* tumors (*table*). **Conclusions:** Methylated *BRCA1/RAD51C* tumors are HRD+ and provide to ovarian cancer patients a similar clinical benefit of ola+bev as patients with *b-/m- HRD+* tumors. Methylation assessment represents a rapid and cost effective tool; which coupled with *BRCA1-2* somatic testing allows the identification of the majority (81%) of HRD+ AOC. Clinical trial information: NCT02477644. Research Sponsor: Fondation ARC pour la recherche sur le cancer.

Cell-free DNA in plasma and ascites as a biomarker of bevacizumab response: A translational sub-study of the REZOLVE (ANZGOG-1101) clinical trial. *First Author: Bonnita Werner, UNSW, Sydney, Australia*

Background: The REZOLVE clinical trial investigated the effect of administering bevacizumab via the intraperitoneal route to reduce re-accumulation of ascites in patients with ovarian cancer who were not suitable for further chemotherapy. Plasma and ascites were collected throughout for translational research. Ascites contains cell-free DNA (cfDNA), a large proportion of which is tumour derived (ctDNA). There is increasing interest in cfDNA in plasma, yet little is known of it in ascites. Objectives: To compare cfDNA in ascites and plasma in terms of total concentration, tumour proportion and endothelial-cell derived (ec-cfDNA) proportion and investigate their association with clinical outcomes (paracetesis-free interval, overall survival) and CA125 level. **Methods:** Longitudinal plasma and ascites samples were collected from 20/24 participants and stored at -70°C for up to 8.5 years. cfDNA was extracted from 0.3-1 mL fluid using conventional protocols. Standard and methylation-specific PCR was used to measure total cfDNA, ctDNA and ec-cfDNA. Values were correlated with time to paracetesis pre- and post-bevacizumab treatment (the primary trial outcome) as well as overall survival, using log-rank tests. Relationships with clinical CA125 levels were tested by Pearson's correlation coefficient. Comparisons between plasma and ascites used non-parametric analyses. **Results:** cfDNA was detected in all samples, with higher yield in ascites (average 669 ng/mL) than plasma (average 75 ng/mL, p<0.0001). ctDNA was detected in 30/32 (94%) ascites samples and 37/56 (68%) plasma samples. ctDNA was detected in plasma and/or ascites from each patient at at least 1 time point. ctDNA proportion was higher in ascites than plasma (p<0.0001) and ec-cfDNA proportion was higher in plasma than ascites (p=0.002). High ctDNA (>75%) in ascites at baseline was associated with significantly shorter paracetesis-free interval (median interval 47.5 versus 84 days, hazard ratio (HR) 2.21, 95% confidence interval (CI) 0.85 to 5.73, p=0.039). ctDNA presence in plasma at baseline was unfavourable for survival (median survival 56 versus 242 days, HR 3.21, 95% CI 1.15 to 9.00, p=0.008). A significant positive correlation was observed between ctDNA proportion in plasma and CA125 level measured within 7 days (p=0.0006). No difference in total cfDNA, ctDNA nor ec-cfDNA was observed between participants who were bevacizumab responders and non-responders in the trial. **Conclusions:** Sufficient cfDNA was obtained from plasma and ascites to perform qPCR for three biomarkers. Ascites was found to contain proportionately more ctDNA, while plasma contained more ec-cfDNA. The early evidence presented here supports the potential value of cfDNA biomarkers in plasma and ascites, however incorporation of their collection in future clinical trials will allow further investigation. Randomized phase 2 trial of personal dendritic cell (DC)-autologous tumor antigen (ATA) vaccines in newly diagnosed advanced ovary cancer. *First Author: Bradley Corr, University of Colorado Cancer Center, Aurora, CO*

Background: Advanced ovarian cancer has a high recurrence rate and poor overall survival (OS). The addition of DC-ATA AV-OVA-1, a personal vaccine consisting of autologous DC pulsed with ATA, was investigated to pursue improving OS. **Methods:** A multi-center, 2:1 double-blind randomized phase 2 trial was designed for patients with newly diagnosed stage 3 or 4 epithelial ovary cancer to determine feasibility of manufacturing study product, and to compare safety and efficacy between DC-ATA and autologous monocytes (MC). Primary endpoint was OS from randomization. Following completion of debulking surgery and chemotherapy, about 6 to 7 months after initial tumor collection, patients were screened and eligible for randomization if a short-term cell line was established from resected tumor, sufficient numbers of MC were collected by leukapheresis, and ECOG status was 0 or 1. Intent was to enroll 99 patients stratified by whether they had residual cancer. MC were differentiated into DC by incubating with IL-4 and GM-CSF. DC-ATA was produced by incubating DC with an ATA lysate prepared from irradiated self-renewing tumor cells. Just prior to each treatment, DC-ATA or MC was admixed in 500 mg GM-CSF and injected s.c. at weeks 1, 2, 3, 8, 12, 16, 20 and 24 (up to 8 doses). Interferon-gamma elispot assays were performed on cryopreserved mononuclear cells obtained from heparinized blood collected prior to each of the first 3 injections. Patients were monitored for adverse events (AE), immune response, OS, and progression-free survival (PFS). Analysis was planned after 44 deaths. **Results:** During the SARS-CoV-2 pandemic the sponsor terminated accrual and long-term follow up. 70/72 tumors yielded a successful cell line. 20/70 patients did not proceed with leukapheresis. Sufficient MC were collected from 47/50 patients. 45 patients were randomized: 29 to DC-ATA, 16 to MC. Study arms did not differ in patient age, cancer stage, use of neoadjuvant therapy, ECOG status, or residual cancer. Injections were well-tolerated. No patient stopped therapy because of toxicity. Mean number of injections were 7.7 and 7.3. Study arms did not differ in type, proportion or severity of AE, which typically were mild to moderate, short-lived, and self-limited. Number of interferon-gamma elispots were unchanged after MC (p=0.256), but more than doubled after DC-ATA (p<0.0012). The 45 patients were followed for 1 to 31 months from randomization. Median PFS (24 events) was 16.9 months (95% CI 9.2 to 18.7); median OS was not reached (8 deaths). 1-yr OS was 91% (95% CI 78.9, 96.9), 2-yr was 80% (95% CI 49.7, 93.7). There was no difference between study arms in PFS (p=0.837) or OS (p=0.790). **Conclusions:** Manufacturing DC-ATA was feasible and treatment well-tolerated. There were no differences in AE, PFS or OS between study arms, but survival analyses were severely underpowered. An enhanced immune response was detected after DC-ATA. Clinical trial information: NCT02033616. Research Sponsor: AIVITA Biomedical Inc.

Efficacy and safety of niraparib maintenance therapy in patients with newly diagnosed advanced ovarian cancer who had measurable residual disease: A post-hoc subgroup analysis of the PRIME study. *First Author: Beihua Kong, Qilu Hospital of Shandong University, Jinan, China*

Background: Niraparib maintenance therapy significantly prolonged progression-free survival (PFS) versus placebo in patients with newly diagnosed advanced ovarian cancer (aOC), but its antitumor activity remains unclear in those with measurable residual disease (MRD) after first-line platinum-based chemotherapy (1LCT). This study aims to report the efficacy, including antitumor activity, and safety of niraparib maintenance therapy in patients with MRD after 1LCT from the phase 3 PRIME trial (NCT03709316). **Methods:** In PRIME, adults with newly diagnosed aOC who had received cytoreductive surgery and responded to 1LCT were randomized 2:1 to receive niraparib or placebo with stratification by receipt of neoadjuvant chemotherapy, response to 1LCT, status of germline *BRCA* mutations, and tumor homologous recombination deficiency status. Tumor assessment was conducted at baseline and every 12 weeks thereafter by blinded independent central review (BICR) according to RECIST, version 1.1. Between 29 June 2018 and 11 November 2019, 384 patients were randomized (255 niraparib, 129 placebo). The data cut-off date was 30 September 2021. This *post-hoc* analysis reports BICR-assessed objective response rate (ORR) and PFS in patients with MRD at baseline. An initial response was confirmed $\geq$ 4 weeks later. **Results:** In total, 73 (19.0%) patients (47 niraparib, 26 placebo) had MRD at baseline. Baseline characteristics were well balanced between the two MRD groups. Complete and partial responses, both confirmed, were observed in 12 (25.5%) and 15 (31.9%) niraparib-treated patients and 3 (11.5%) and 5 (19.2%) placebo-treated patients, respectively, leading to a confirmed ORR of 57.4% with niraparib and 30.8% with placebo (odds ratio, 3.20; 95% confidence interval [CI], 1.11–9.11). ORRs by biomarker status are provided in the table. Median PFS (95% CI) was 22.3 (8.7–not estimable) months with niraparib versus 8.3 (5.6–11.0) months with placebo (hazard ratio, 0.36; 95% CI, 0.19–0.71). Treatment-emergent adverse events (TEAEs) of grade $\geq$ 3 occurred in 28 (59.6%) niraparib-treated patients and 7 (26.9%) placebo-treated patients. TEAEs led to treatment discontinuation in three (6.4%) niraparib-treated patients and one (3.8%) placebo-treated patient. **Conclusions:** In patients with newly diagnosed aOC who had MRD after 1LCT, niraparib maintenance therapy tended to induce additional antitumor activity and led to a clinically meaningful increase in PFS versus placebo. Clinical trial information: NCT03709316. Research Sponsor: This study was funded by Zai Lab (Shanghai) Co., Ltd and partially supported by the National Major Scientific and Technological Special Project for Significant New Drugs Development in 2020, China [grant number 2020ZX09101-014].

Ex vivo tumor testing platform for predicting clinical response to platinum-based therapy in patients with high grade serous ovarian cancer. *First Author: P. B. Ottevanger, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Precision medicine for cancer patients has brought effective novel therapy options over the past decades. However, treatment for high-grade serous ovarian cancer (HGSOC) is still based on platinum-containing therapy. Around 30% (Morgan 2020) of primary disease patients do not respond to this treatment, and non-response rates in residual disease are higher still. We present an ex vivo 3D tumor testing platform that predicts patient-specific response to standard of care therapy using the CA125 half-life, the primary ovarian cancer marker (Charkhchi, 2020). **Methods:** Patients with HGSOC, eligible for platinum-based neoadjuvant chemotherapy (NACT), were included in the study between 2019 and 2022 in the Netherlands (IRB P18.032). Clinical data was collected including CA125 levels at baseline and after 2-4 courses of NACT. Tumor clusters enriched from ascites were embedded in hydrogel and exposed to first-line (carboplatin, paclitaxel) and second-line therapies (doxorubicin, gemcitabine, topotecan and olaparib). Screening plates were imaged in a high content screening 3D platform. Morphological features were extracted after image analysis and fitted as dose-response (Hill)-curves. A Bayesian linear regression model was trained on the AUCs of carboplatin and paclitaxel to predict the CA125 half-life. The result was classified according to clinical standards: insensitive (IN, progressive and stable disease), moderate response (MR), or strong response (SR). In addition, for each second-line treatment the top 25% strongest responding samples were classified as *sensitive* while the bottom 25% were classified as *resistant* samples. **Results:** The model was trained using 30 patients. The correlation coefficient between the predicted and actual CA125 half-life is 0.739 ($R^2 = 0.55$). This results in a classification accuracy of 87% (insensitive: 100% (n = 2), MR: 80% (n = 14), SR: 80% (n = 14)). The percentage of samples, per response class, responding to at least one of the alternative chemotherapies is as follows: SR: 58% (8/14), MR: 29% (4/14) and IN 50% (1/2). For olaparib the equivalent results are SR: 36% (5/14), MR: 21% (3/14) and IN: 0% (0/2). When sufficient tumor content is received, the assay has a technical success rate of 89%. Results are delivered in two weeks. **Conclusions:** The presented platform for ex vivo tumor testing predicts clinical response to platinum-based NACT in HGSOC patients. The same platform measured patient specific patterns of relative sensitivity to other chemotherapies. The platform enables better stratification of responders vs non-responders, and can support informed treatment decisions for first-line and second-line therapies. The value of integration of this predictive tool in the clinical routine will be assessed in an ongoing prospective trial for patients with suboptimal response and recurrent disease. Germline variants in non-*BRCA1/2* homologous recombination-related genes and ovarian cancer: Analysis of tumor phenotype and survival. *First Author: Ryan M. Kahn, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *BRCA1/2*-associated ovarian cancer (OC) exhibits homologous recombination (HR)-deficiency (HRD) and a better prognosis than *BRCA1/2*-wildtype (WT) OC. However, it is unclear if patients with germline pathogenic variants (gPV) in other HR-related genes have a similar tumor phenotype. We sought to define OC molecular features from patients with gPV in other HR genes and analyze survival compared to patients with *BRCA1/2* and WT OC. **Methods:** We identified patients with OC treated at our institution who underwent tumor-normal sequencing using MSK-IMPACT targeting 341-505 cancer-related genes with germline analysis of ≥ 76 genes from 7/2015-12/2020. Biallelic inactivation was inferred via assessments of loss of heterozygosity (LOH) at gPV in non-*BRCA1/2* HR-related genes (*ATM*, *BARD1*, *BRIP1*, *FANCA*, *FANCC*, *NBN*, *PALB2*, *RAD50*, *RAD51B*, *RAD51C*, and *RAD51D*). Clinical characteristics were compared to patients with *BRCA1/2*-associated and WT OC using non-parametric tests. Progression-free (PFS) and overall-survival (OS) were calculated from date of pathologic diagnosis using the Kaplan-Meier method. Left truncation at date of MSK-IMPACT consent was applied. Whole-exome sequencing (WES) was performed in a subset of OCs. **Results:** Of 882 patients with OC, 56 (6.3%) had gPV in non-*BRCA1/2* HR-related genes compared to 95 (10.8%) patients with *BRCA1*-associated OC (58 germline, 37 somatic) and 59 (6.7%) patients with *BRCA2*-associated OC (40 germline, 19 somatic). Patients with a deleterious genetic alteration were diagnosed with OC at younger age and more likely to have high-grade serous histology compared to the WT group ($p < 0.01$). High rates of biallelic alterations were observed amongst gPV in *BRIP1* (11/13), *PALB2* (3/4), *RAD51B* (3/4), *RAD51C* (3/4), and *RAD51D* (8/10), and WES was performed in a subset ($n = 27$) of tumors from these patients with adequate tumor purity ($>30\%$). We observed a higher tumor mutational burden (TMB), median 2.5 (1.1-6.0) vs. 1.2 (0.6-2.6) mut/Mb, and enrichment of HRD mutational signatures in tumors associated with *PALB2* and *RAD51B/C/D* compared with *BRIP1* ($p < 0.01$), although markers of telomeric-allelic imbalance (TAI), large-scale state transitions (LST) and fraction of genome altered (FGA) were similar. PFS and OS varied by gene group with best survival in *BRCA1/2*-associated OC, even after adjustment for clinical covariates in multivariable models ($p < 0.01$). Although we observed heterogeneity in PFS and OS for those with gPV in other HR-related genes by biallelic status and HRD phenotype, none had significantly better survival than those with WT OC. **Conclusions:** OCs associated with gPV in non-*BRCA1/2* HR-related genes represent a heterogeneous group. OCs in those with gPV in *PALB2* and *RAD51B/C/D* preferentially harbored biallelic alterations and displayed an HRD phenotype. Research Sponsor: U.S. National Institutes of Health; MSKCC.

Phase 2 trial of TRC102 (methoxyamine HCl) with temozolomide (TMZ) in patients with granulosa cell ovarian cancer. *First Author: Sarah Shin, Developmental Therapeutics Clinic/Early Clinical Trials Development Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD*

Background: TRC102 is a novel small molecule that binds to reactive aldehyde created in apurinic/apyrimidinic (AP) sites, inhibiting base excision repair (BER), which is implicated as a pathway of resistance to alkylating agents. In preclinical studies, TRC102 demonstrated synergistic anti-tumor activity when TRC102 was combined with the alkylating agent temozolomide (TMZ) and the phase 1 trial of this combination reported 4 patients with partial response, two of which were of granulosa cell ovarian cancer (GCOC) histology. Here we report the phase 2 results of the combination TRC102 and TMZ in the GCOC cohort (NCT01851369). **Methods:** We conducted an open-label, single center Simon 2-stage trial including patients (pts) with GCOC who received $\geq$ one line of therapy in the metastatic setting. TRC102 was dosed at 125 mg (100 mg for BSA < 1.6) and TMZ was dosed at 150 mg/m² orally on day (D) 1-5 in 28-day cycle (C). Restaging CT scans every 2 Cs were evaluated by RECIST v1.1. Mandatory paired biopsies (C1D1 pretreatment and C1D4 3-4 hours after drug administration) and optional blood samples for circulating tumor cells (CTC) were collected at set time points for pharmacodynamic analyses. **Results:** Nine pts with GCOC (7 adult, 2 juvenile histology) were enrolled as of 12/23/2022. Median age was 53 years (range 21-79) and median prior lines of therapy was 6 (range 3-9). Most common grade (G) 1 and G2 treatment-related adverse events (trAE) were fatigue, myelosuppression, nausea, and vomiting. One pt had G3 trAE of vomiting. No toxicity-related treatment discontinuations and no treatment-related deaths were reported. The median PFS for the 8 evaluable pts was 3.7 months. One pt exited the study after one C per pt's choice with no restaging available. Four pts had stable disease (SD) as their best response. Of those who had SD, one pt completed 26 Cs prior to progression, one pt completed 11 Cs as of data cut-off but continues on study, two pts completed 6 Cs (one pt went off study for PD and one by pt choice). MGMT analysis was performed for 3 pts, including the pt still on study after 11 Cs with SD. MGMT immunohistochemistry (IHC) of pretreatment biopsies were positive for protein expression, consistent with unmethylated MGMT status. No significant induction in the levels of the DNA damage response markers γ H2AX, pNbs1, and RAD51 was detected in 5 evaluable post-treatment biopsy samples as compared to the pre-treatment timepoint. **Conclusions:** TRC102 combined with TMZ was well-tolerated and demonstrated durable disease control in 4 pts, which is promising in this heavily pretreated GCOC cohort. MGMT analysis suggests that unmethylated MGMT status and protein expression does not preclude response to TRC102/TMZ combination therapy. Analysis of CTCs and biopsy samples are ongoing to further elucidate possible biomarkers of response. Funded by NCI Contract No. HHSN261201500003I. Clinical trial information: NCT01851369. Anastomotic leakage following bowel resection in radical cytoreductive surgery for ovarian cancer: A subgroup analysis of the prospective AGO-OVAR.OP3/LION. *First Author: Bastian Czogalla, Department of Obstetrics and Gynecology, University Hospital, Ludwig-Maximilians-Universität München, Munich, Germany*

Background: Anastomotic leakage (AL) is an important and severe complication following bowel resection in cytoreductive surgery (CRS) for ovarian cancer (OC). Identifying patients (pts) at risk for AL could improve clinical management and reduce frequency and severity of complications. **Methods:** AGO-OVAR.OP3/LION intraoperatively randomized 647 pts with advanced OC (FIGO IIB-IV) following complete cytoreduction with unsuspected lymph nodes to either undergo systematic pelvic and paraaortic lymphadenectomy (LNE) or not. All pts who underwent bowel resection were included in this analysis. Potential prognostic impact of AL was analyzed by Kaplan-Meier method and log-rank tests regarding progression-free (PFS) and overall survival (OS). Risk factors for AL in a subset of clinicopathological parameters were evaluated by calculating odds ratio (OR) with 95% confidence interval (CI) in univariate and multivariate logistic regression models. A stepwise variable selection algorithm using the Akaike Information Criteria (AIC) for identification of the final logistic regression model was applied. *P* values presented were two-tailed, and $P < 0.05$ was considered as statistically significant. **Results:** Among all 647 randomized pts, AL was noted in 24 (3.7 %) pts. The AL rate of the 336 pts with bowel surgery during CRS (median age 61.3 years; 316 large bowel, 94 small bowel resections) was 7.1% (24/336 pts). Pts following stoma formation had an AL rate of 5.5% (3/55 pts) compared to 7.5% (21/281 pts) in pts without stoma. Median PFS was 18 months in pts with AL versus 19 months in the no-AL-group (hazard ratio (HR) 0.86; 95% CI 0.5 to 1.4, $P=0.53$), median OS was 31 months in the AL group and 58 months in the no-AL-group (HR 0.69; 95% CI 0.4 to 1.2, $P=0.17$). The clinicopathological characteristics "volume of blood loss" (OR 1.05 per 100cc; 95% CI 1.01-1.10) and "LNE vs non-LNE" (OR 4.10; 95% CI 1.60-12.62) were identified as factors potentially predictive for AL in univariate analysis, and both factors (volume of blood loss [OR 1.04 per 100cc, 95% CI 1.0001-1.09], LNE vs non-LNE [OR 3.67, 95% CI 1.41-11.39]) remained a significant independent factor in multivariate analysis. **Conclusions:** Considering the high surgical complexity in this large prospective surgical trial, the overall rate of AL following bowel surgery was relatively low and had no significant impact on PFS or OS. While protective stoma formation was not identified as protective factor in this cohort, volume of blood loss and LNE procedure were clinical parameters associated with higher risk of AL. Being potential surrogates for extensive surgery, these factors should be considered in perioperative management in pts with advanced OC. Further specific factors predicting AL were not identified. Clinical trial information: NCT00712218. Research Sponsor: Deutsche Forschungsgemeinschaft; Austrian Science Fund.

Proactive assessment of patient reported outcomes in patients with ovarian cancer. *First Author: Ainhoa Madariaga, 12 de Octubre University Hospital, Madrid, Spain*

Background: Patient reported outcome (PRO) measures are key instruments to provide an evaluation of health outcomes from the patient's perspective. Assessment of PROs may help identify the nature, severity, and time course of symptoms of concern in patients with ovarian cancer. The ability to access this information in real-time, including changes over time, could improve patient safety and decision-making. **Methods:** This systematic review evaluated the proactive or real-time assessment of PROs in patients with ovarian cancer undergoing systemic therapy. Medline, Embase, and Cochrane databases were searched (up to February 2022), and prospective ovarian cancer studies (experimental or observational) that incorporated PROs (including quality of life) were included. Conference abstracts were excluded. Primary objective was to assess the frequency of studies incorporating proactive use of PROs. A secondary objective was to describe PRO reporting. Descriptive statistics were used. **Results:** 3,071 articles were screened, with 117 included in the final analysis. Studies were published between 1990-2022 and contained 35,735 patients (median 140 patients per study; inter-quartile range 58-415). Median time from patient enrollment initiation to study publication was 7 years (range 1-15). Most studies were experimental/clinical trials (n=93, 79%), followed by observational (n=23, 20%) and not reported (n=1; Table). Among experimental studies, 56% (52/93) were phase III, 35.5% (33/93) phase II, 6.5% (6/93) phase I or I/II trials and it was not reported in two. Therapeutic strategies were assessed in 98% (91/93) of experimental studies, being the most frequent one chemotherapy (n=53, 58%), followed by antiangiogenics and PARP inhibitors (n=8, 9%, each). Types of observational studies were descriptive 43.5% (10/23), cohort 26% (6/23), cross-sectional 22% (5/23), or other 9% (2/23). PROs were the primary objective in 7.5% (7/93) and 83% (19/23) of experimental and observational studies respectively. The table describes PRO reporting standards per type of study. PROs were assessed in real-time in 0.8% (1/117) of studies. **Conclusions:** Completion of PRO and quality of life questionnaires involve time and effort for patients with ovarian cancer. PRO questionnaire responses were only assessed in real-time in <1% of analyzed studies. Efforts should be made to incorporate proactive assessment of PROs to optimize patient care and safety. Research Sponsor: None.

Summary of PRO reporting information provided in the study publication.

CD47 expression in ovarian cancer: Dynamic correlation with lymphocyte and macrophage features as well as thrombospondin-1 (TSP-1) under neo-adjuvant chemotherapy. *First Author: Alexandra Leary, Gustave Roussy Cancer Center, INSERM U981, and Groupe d'Investigateurs Nationaux pour l'Etude des Cancers Ovariens (GINECO), Villejuif, France*

Background: To date, the results of immunotherapy strategies to treat ovarian cancer (OC) have been unfulfilling. A more comprehensive knowledge of the intricate immune tumor microenvironment (iTME) as well as the effects of chemotherapy on immune features may reveal novel immune targets. CD47 is overexpressed in OC and correlates with shorter survival and immune evasion via interaction with circulating ligands such as TSP-1. Little is known about how the CD47 receptor or its ligand TSP-1 changes under chemotherapy or their association with other features of iTME. In the randomized CHIVA trial, we therefore investigated CD47 expression in OC patients at diagnosis and after neoadjuvant chemotherapy (NACT) and assessed its relationship to other iTME features, including circulating level of thrombospondin-1 (TSP-1). **Methods:** Tumour samples were collected from 105 patients from the CHIVA trial, a GINECO-GINEGEPS study. CD47 expression was assessed by IHC in paired samples before and after NACT and scored by H-score: staining intensity (0, +1, +2, +3) x % cells positive (0-300). At baseline, we defined a CD47^{high} (highest quartile, score above 240) and CD47^{low} population (lowest quartile, score under 150). CD4⁺, CD8⁺, CD68⁺, CD163⁺, FoxP3⁺ cells were assessed by IF and scored as number of positive cells. The Pearson correlation coefficient (r) was used to determine the linear correlation between CD47 expression and other immune markers. Circulating TSP-1 was quantified by ELISA on paired plasma samples pre- and post-NACT. **Results:** While CD47^{high} does not correlate with CD4 and CD8 expression at baseline, a correlation with CD8 (r=0.59, p=0.02) and a trend with CD4 (r=0.49, p=0.05) is observed after NACT. These linear correlations do not exist in the CD47^{low} population. In addition, NACT induces a 2-fold decrease in FoxP3⁺ cells, but only within the CD47^{high} group (p=0.028). Thus, both the CD4⁺/FoxP3⁺ (p=0.001) and CD8⁺/FoxP3⁺ (p=0.005) ratios were increased by 2-fold under NACT, exclusively in OC patients with CD47^{high} expression. Interestingly, these correlations appear to be T-cell specific as no correlation exist when considering CD68 and CD163 before or after NACT, neither for CD47^{high} nor CD47^{low}. In parallel, we determined that the plasma level of TSP-1, a preferential CD47 agonist, was very high (>1500 ng/mL) in OC patients and decreased by about 2-fold after NACT. Interestingly, a pattern emerges in which the highest level of circulating TSP-1 is associated with the CD47^{low} population. **Conclusions:** Our data suggest that OC patients with the highest CD47 expression profile at baseline have greatest lymphocyte influx post-NACT and may be most likely to benefit from post-operative immunotherapy. Whether blocking the immune-suppressive CD47:TSP1 interaction in this subset would provide an alternative strategy merits investigation. Clinical trial information: NCT01583322. Research Sponsor: French National Cancer Institute (INCa).

The effect of maintenance hormone therapy on overall survival in advanced-stage low-grade serous ovarian carcinoma: A risk-set matched retrospective study. *First Author: Syem Barakzai, Massachusetts General Hospital, Boston, MA*

Background: Low-grade serous ovarian carcinoma (LGSOC) is a rare malignancy often treated similarly to high-grade serous ovarian carcinoma (HGSOC) despite differences in clinical behavior and carcinogenesis. Observational studies suggest that, among patient with advanced-stage LGSOC, maintenance hormonal therapy (HT) following primary treatment is associated with improved progression free survival. We conducted a multi-institutional observational study to investigate whether HT is associated with an overall survival advantage in this setting. **Methods:** We included patients with histologically confirmed stage III or IV LGSOC diagnosed between Jan 1, 2004, and Dec 31, 2019, treated in Commission on Cancer accredited cancer programs in the US. Patients who received HT within 6 months of diagnosis were matched to controls who did not initiate HT during this timeframe. The primary outcome was risk of death from any cause, within five-years of initiation of HT or observation. For each treated patient, we employed risk-set propensity score matching to identify a control in a manner that avoided the introduction of immortal-time-bias, and balanced groups with respect to year of diagnosis, upfront treatment strategy, age, stage, race/ethnicity, comorbidity index, insurance status, zip-code median income, and cancer program type. **Results:** There were 296 patients who initiated HT within 6 months of diagnosis, and 2,805 potential controls. Patients who received HT were more often treated in academic medical centers (55% vs 44%), diagnosed later in the study period (62% vs 23% diagnosed in 2018-2019), and received upfront chemotherapy less frequently (55% vs 83%). After risk set and propensity score matching, we identified 204 patients treated with HT and 204 untreated controls, who were otherwise similar with respect to measured covariates. In the matched cohort, maintenance HT was associated with a reduction in the risk of death (hazard ratio 0.61; 95% CI 0.37-0.99), corresponding to a 60-month survival of 71% compared with 61%, and an improvement in 5-year life expectancy of 3.6 months (95% CI 0.004-7.2). **Conclusions:** Maintenance hormone therapy following primary management of LGSOC is associated with an overall survival benefit compared with observation. Research Sponsor: None.

Trends in ovarian cancer incidence and incidence-based mortality: A 15-year population-based analysis. *First Author: Sahana Somasegar, Stanford University School of Medicine, Palo Alto, CA*

Background: The predicted incidence and incidence-based mortality (IBM) of ovarian cancer (OC) in 2023 is lower than prior years. OC encompasses a range of heterogeneous cancers with subtypes categorized on histology and site of origin. Given differences in survival and treatment paradigms, we aim to characterize trends in OC incidence and IBM based on histology and site of origin to determine what factors are responsible for the decline. **Methods:** Patients with OC from 2000-2019 were identified from the US Surveillance, Epidemiology, and End Results 17 registry database. Using ICD-O-3 codes, patients with epithelial, stromal, and germ cell cancers of the ovary, fallopian tube, and peritoneum were included. Incidence and IBM were reported as age-adjusted rates and stratified by cancer subtype. Using Joinpoint 4.9.1.0, we characterized piecewise log-linear time trends to identify inflection points in the rates' annual percentage change (APC). **Results:** The incidence of epithelial OC decreased significantly from 2004-2019 (APC -1.24%). When stratified by disease stage, this trend was seen in distant disease (APC -2.11%) and unknown/unstaged disease (APC -3.40%); however, there was a significant increase in incidence of local disease (APC +0.83%). There was no significant change in the incidence of germ cell and stromal OC from 2004-2019 in all stages. (APC -0.30% and +0.33%). Among all OC subtypes, there was a significant decline in incidence from 2000-2019 (APC -1.57%) with a sharper decline from 2015-2019 (APC -3.41%). Among all cancer subtypes, the incidence trended down from 2000-2019, with a significant decline from 2015-2019 (APC -2.37%). Similar trends are observed in IBM. Among all stages of epithelial OC, there was a significant decrease in IBM from 2006-2019 (APC -2.02%). When stratified by disease stage, there was a decline in IBM in local disease (APC -7.19%, 2014-2019) and distant disease (APC -2.44%, 2010-2019). There were no changes in IBM of germ cell and stromal OC from 2004-2019 (APC +0.78% and -0.20%). Among all cancers, IBM significantly decreased from 2006-2019 (APC -2.28%). When stratified by disease stage, there was no change among local disease and an increase in regional disease from 2006-2019 with the increase from 2006-2010 (APC +14.35%) compared to 2010-2019 (APC +1.45%). Conversely, there was a significant decrease in IBM for distant disease (APC -2.51% from 2010-2019) and unknown/unstaged disease (APC -3.27% from 2006-2019). **Conclusions:** There has been an overall decline in incidence and IBM of OC over a 15-year period, primarily driven by the epithelial histology. Over the past 20 years, OC has been increasingly diagnosed at earlier stages with a corresponding improvement in survival. While stage migration and improved survival may contribute to these trends, they do not entirely explain them. As new treatments become available, the incidence and IBM of OC may further decline. Mechanisms of resistance to bispecific T-cell engager therapy for ovarian cancer. *First Author: Syem Barakzai, Massachusetts General Hospital, Boston, MA*

Background: Patients with recurrent ovarian cancer (OC) invariably develop multidrug resistance and have poor prognoses. Bispecific T-cell engager (BiTE) immunotherapy represents an innovative therapeutic modality where cytotoxic T-cells are activated and recruited to tumor cells using a predefined tumor-associated antigen. Clinical trials evaluating BiTEs in OC are currently in progress with promising results, and exploration of potential mechanisms of resistance to BiTEs could provide meaningful insight into disease biology and combination strategies. **Methods:** After obtaining informed consent, experiments were performed on patient samples collected under an IRB-approved tissue-banking protocol. Samples were collected before patients started clinical trials and at disease progression. Serum, peripheral blood mononuclear cells (PBMCs), and malignant ascites were collected when available for translational analysis. Immune cell subsets were evaluated for activation and exhaustion via flow cytometry, and tumor cells were subjected to western blot analysis and IHC. Ex vivo cytotoxicity assays were performed using BiTEs, patient tumor samples, OC cell lines (immortalized), and patient-derived and healthy donor PBMCs. Patient serum samples were analyzed by multiplex ELISA to determine cytokine and chemokine signatures. **Results:** Serum and PBMC samples from 10 patients and ascites from 2 patients were used for these analyses. Cells derived from patient ascites after progression on BiTEs were primarily comprised of tumor cells and myeloid-derived suppressor cells (MDSCs). These tumor cells had lost expression of the target antigen recognized by the BiTE and upregulated markers as N-cadherin and vimentin with concordant down-regulation of E-cadherin consistent with epithelial to mesenchymal transition (EMT). Ascites immune subset analysis showed a predominance of CD11b+, CD163+, and PD-L1+ cells. Compared to PBMCs from healthy donors, patient PBMCs showed higher frequencies of CD4+ TIM3+ LAG3+ cells consistent with T-cell dysfunction. Compared with healthy donors, serum from patients revealed higher levels of myeloid recruiting and activating chemokines and cytokines (CCL3, CXCR3, CXCL10, and IL18) and low immunostimulatory cytokines (IL-7 and IFN- α). Coculture of patient tumor cells with BiTEs and T-cells ex vivo showed diminished cytotoxicity, consistent with the loss of target antigen expression. Patient PBMCs retained cytotoxicity against OC cell lines ex vivo, suggesting preserved cytotoxic capacity. Finally, T-cells cocultured in the presence of patient serum displayed suppressed cytotoxicity against OC cell lines. **Conclusions:** Resistance to BiTE therapy is multifactorial, primarily involving tumor-associated antigen loss, EMT, and an immunosuppressive tumor microenvironment. Combination treatment approaches to mitigate these factors might increase response rates. Impact of cytoreductive surgery on survival outcomes for recurrent adult-type granulosa cell tumors of the ovary. *First Author: Jeffrey How, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Adult-type granulosa cell tumor of the ovary (aGCT) is a rare tumor that often relapses and the optimal management strategy is not known. Cytoreductive surgery (CRS) offers an attractive option for disease confined to the abdomen/pelvis. However, few studies have evaluated the role of CRS compared to systemic therapy alone. Thus, the study objective was to determine the impact of secondary, tertiary, and quaternary CRS on survival outcomes for patients with relapsed aGCT. **Methods:** This was an IRB-approved retrospective cohort study that evaluated all patients with relapsed aGCT who were enrolled in the Rare Gynecologic Malignancy Registry at MD Anderson. Study inclusion criteria were patients who had histology-proven aGCT, were above 18 years of age, had at least one documented relapse, and had received treatment or treatment planning at MD Anderson. Progression-free survival (PFS) endpoints were the outcomes of interest and were defined as follows: PFS2 was defined from first recurrence to subsequent progression or death (PFS2), PFS3 was defined as second relapse/progression to third relapse/progression or death, and PFS4 was similarly defined. PFS2, PFS3, and PFS4 were estimated with methods of Kaplan and Meier and were modeled via cox proportional hazards regression. Analyses were performed among those with resectable disease at time of disease progression. **Results:** Among the 369 aGCT patients identified from January 1970 to October 2022, 162 met the study inclusion criteria for analysis. The mean age of diagnosis was 44.4 years old and the majority were initially diagnosed with stage 1 disease (72.8%). The median follow-up time for all patients was 5.86 years (range 0.09 – 34.27). At the first relapse, there were 151 patients who had resectable disease with 128 who underwent secondary CRS. PFS2 was significantly improved among those who underwent CRS compared to those who did not (HR 0.50, 95% CI 0.30 – 0.81; $p = 0.005$) with the median PFS2 difference being 18.24 months ($p = 0.006$). At the second relapse/progression, there were 120 patients with resectable disease with 52 who underwent tertiary CRS. PFS3 was significantly improved among those who underwent CRS compared to those who did not (HR 0.57, 95% CI 0.39 – 0.84; $p = 0.004$) with the median PFS3 difference being 6 months ($p = 0.01$). At the third relapse/progression, there were 96 patients with resectable disease with 46 who underwent quaternary CRS. There was a trend towards improved PFS3 among those who underwent CRS compared to those who did not (HR 0.69, 95% CI 0.45 – 1.06; $p = 0.09$). The use of systemic or hormonal therapy did not confer additional PFS benefit among those who underwent CRS. **Conclusions:** For relapsed, resectable aGCT, CRS may offer a beneficial impact on PFS. Future studies should evaluate the role of CRS on survival outcomes. Research Sponsor: None.

Patterns of ovarian cancer care in an elderly population in Australia: A prospective cohort study from the National Gynaecology Oncology Registry (NGOR). *First Author: Mahendra Naidoo, Monash University School of Public Health and Preventive Medicine - Cancer Research Program, Melbourne, VIC, Australia*

Background: Elderly women with ovarian cancer are often undertreated in comparison to best practice. The National Gynaecology Oncology Registry (NGOR) is Australia's first country-wide clinical quality registry (CQR) measuring compliance with optimal care defined by a set of clinical quality indicators (CQIs). **Objectives:** To assess compliance with a predefined set of CQIs for elderly women with newly diagnosed ovarian cancer aged > 75 compared to non-elderly women aged < 75 years of age from the NGOR sites. **Methods:** All women with newly diagnosed ovarian cancer from May 2017 – July 2022 were eligible for inclusion. Data were collected from medical records and relevant hospital linked databases by expert data managers. **Results:** A total of 1590 women were eligible for inclusion from 21 hospitals across 5 Australian states. The CQI data were subsequently aggregated and are summarised in the table. The proportion of elderly women receiving first-line chemotherapy with a platinum and taxane doublet was significantly lower compared to non-elderly (60% vs 89%, $p < 0.001$). The proportion of women with sub-optimally debulked or Stage IV cancer who received first-line chemotherapy with a platinum/taxane doublet and bevacizumab was significantly lower in elderly women compared to non-elderly (10% vs 30%, $p < 0.001$). Enrolment in clinical trials or translational research was significantly lower in elderly women compared to non-elderly (13% vs 21%, $p = 0.002$). The remaining CQIs showed no significant differences between the age groups. **Conclusions:** In this cohort, most measures of best practice were not significantly different between elderly and non-elderly women, with the exception of elderly women receiving less first line doublet chemotherapy, less doublet chemotherapy with bevacizumab in sub-optimally debulked or Stage IV cancer, and less likely to be enrolled in clinical trials or translational research. While these 3 CQIs represent a minority of the overall list of CQIs, such lack of compliance may result in significant differences in quality of life and overall survival for elderly women with ovarian cancer. Subsequent investigation is therefore warranted to confirm and explain these findings. Research Sponsor: MRFF.

Clinical Quality Indicators by age group.

CQI	Women aged < 75 (n = 1307)	Women aged > 75 (n = 283)	p-value
Presented at a multi-disciplinary team meeting	98 %	98 %	0.7
Histological or cytological diagnosis confirmed prior to receiving first-line neoadjuvant chemotherapy.	88 %	91 %	0.3
Primary surgery (no macroscopic residual disease)	57 %	50 %	0.4
Interval surgery (no macroscopic residual disease)	46 %	40 %	0.4
1st line chemotherapy with a platinum/taxane doublet	89 %	60 %	< 0.001
1st line chemotherapy with a platinum/taxane doublet and bevacizumab in sub-optimally debulked or Stage IV cancer	30 %	10 %	< 0.001
Enrolled in clinical trial/translational research	21 %	13 %	0.002

A phase 1 study of the SYK inhibitor fostamatinib and weekly paclitaxel for recurrent platinum-resistant ovarian cancer. *First Author: Stephanie Gailard, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: Response to chemotherapy in patients (pts) with recurrent platinum-resistant ovarian cancer (PROC) is generally $< 15\%$. Spleen tyrosine kinase (SYK) is overexpressed in PROC and is a key mediator of paclitaxel resistance in ovarian cancer cells. Fostamatinib (Fos), an orally available inhibitor of SYK, is currently FDA approved for the treatment of idiopathic thrombocytopenic purpura. The active form of Fos (R406) was shown to synergistically enhance taxane-mediated cytotoxicity in preclinical ovarian cancer models. This phase 1 study aimed to identify the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of Fos when combined with standard weekly paclitaxel (wPac) for pts with PROC. **Methods:** Pts with PROC, defined as progression ≤ 6 months of last platinum, were eligible. A modified toxicity probability interval (mTPI) dose escalation design was used to determine the MTD/RP2D and response was assessed using RECISTv1.1 criteria. All pts received paclitaxel (wPac) 80mg/m² intravenously on Days 1, 8, and 15, of a 28-day cycle. Fos was administered orally twice a day (BID) on a continuous schedule. Three dose levels (DL) were planned: DL1 - 100mg, DL2 - 150mg, and DL3 - 200mg. MTD was determined based on cycle 1 dose-limiting toxicities (DLTs) and responses were assessed every 2 cycles. A dose expansion cohort to further assess adverse events (AEs) and tolerability was performed. **Results:** 27 eligible pts, median age 62 years (range 35-79 years) with high-grade serous (n = 18), clear cell (n = 4), carcinosarcoma (n = 3), or other (n = 2) histology were treated at 3 centers. Twelve pts were treated in the dose escalation cohort (DL1 = 6, DL2 = 3, DL3 = 3). Common AEs at least possibly attributed to Fos, wPac, or both included diarrhea (70%), fatigue (52%), anemia (44%), neutropenia (33%), nausea (33%), hypertension (30%), and dysgeusia (30%). Treatment-emergent grade 3-4 AEs were neutropenia (37%), anemia (26%), and thromboembolic event (22%). During DL1, updated toxicity management guidelines not consistent with the original protocol were released and 2 of the 3 pts treated prior to the amendment were not considered evaluable for DLT. Thus 3 more pts were enrolled to DL1 after the amendment. Of the 10 pts evaluable for DLT in dose escalation, no DLTs were reported on any of the 3 DLs (DL1 = 4, DL2 = 3, DL3 = 3). DL3 was selected for dose expansion. One of 15 pts in the dose expansion cohort had a DLT (neutropenia) and one patient had a grade 5 infection. Of 18 pts treated at DL3, 7 (39%) had partial or complete response (95% CI: 17.3, 64.3%). Overall, 27 patients received a median of 3 cycles (range 0-10). Analysis of pharmacokinetic and correlative molecular studies of target expression are ongoing. **Conclusions:** The RP2D of Fos will be 200 mg orally BID when combined with wPac. AE profile of the combination was as expected and the combination demonstrated promising efficacy in pts with recurrent PROC. Clinical trial information: NCT03246074. Anlotinib combined with carboplatin/paclitaxel and maintenance anlotinib as front-line treatment for newly diagnosed advanced ovarian cancer: A phase II, single-arm, multicenter study (ALTER-GO-010). *First Author: Yi Jiang, Jiangsu Province Hospital, Nanjing, China*

Background: Several studies have shown that antiangiogenic drug combined with chemotherapy as first-line treatment, followed by antiangiogenic drug maintenance therapy significantly improve outcomes for patients with ovarian cancer. Anlotinib, a highly effective VEGFRs, FGFRs, PDGFRs and c-kit multi-target tyrosine kinase inhibitor, has been approved for multiple tumor types in China. The aim of this single arm, multicentric, phase II study is to investigate the efficacy and safety of using anlotinib combined with carboplatin/paclitaxel as front-line treatment for advanced ovarian cancer patients. **Methods:** Eligible patients with FIGO stage III–IV primary epithelial ovarian cancer, fallopian tube cancer, or primary peritoneal cancer and ECOG PS 0–1 undergo primary cytoreductive surgery or interval debulking surgery, will receive 6–8 cycles of chemotherapy (paclitaxel 175 mg/m² + carboplatin area under the curve [AUC] 5 q3w) and anlotinib (12 mg po qd, days 1–14, 21 days per cycle, anlotinib will be omitted from the first treatment cycle to prevent delayed wound healing). After chemotherapy finished, anlotinib continues as maintenance monotherapy until disease progression, unacceptable toxicity, or death. Patients with prior anti-angiogenic therapy or major surgical procedure within 28 days before starting anlotinib therapy will be excluded. The primary endpoint is progression free survival (PFS). Key secondary endpoints include overall response rate, disease control rate per RECIST1.1, overall survival, safety. **Results:** From 9 Sep 2021 to 30 Jan 2023, 30 pts were enrolled, including 96.7% (29/30) high-grade serous carcinoma (HGSC) and 3.33% (1/30) endometrioid carcinoma (EC). The median age was 56 years old, with 96.7% (29/30) patients in FIGO stage III and 3.33% (1/30) in stage IV. Median follow-up was 5.36 (95% CI: 3.68, - 7.98) months. PFS rates at 6 months and 9 months were both 100%. Twenty-nine patients (96.7%) experienced adverse events (AE) of any level. The most common AEs include white blood cell decreased, neutrophil count decreased, anemia, platelet count decreased, lymphocyte count decreased and hypertension. There was no treatment-related death during the study. **Conclusions:** Preliminary results of anlotinib combined with carboplatin/paclitaxel have shown favorable efficacy and tolerated safety profile in newly diagnosed advanced ovarian cancer patients. Clinical trial information: NCT04807166. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

First-in-human, phase I study of CBP-1008, a bi-specific ligand drug conjugate, in patients with advanced solid tumors. *First Author: Jifang Gong, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Gastrointestinal Oncology/Early Drug Development Center, Peking University Cancer Hospital & Institute, Beijing, Beijing, China*

Background: Folate receptor α (FR α) and vanilloid subfamily member 6 of transient receptor potential channels (TRPV6) are overexpressed in many solid tumors including ovarian cancer hence could be promising therapeutic targets. CBP-1008 is a first-in-class bi-specific ligand drug conjugate targeting FR α and TRPV6 carrying monomethyl auristatin E (MMAE) as payload. **Methods:** CBP-1008 was administered by intravenous infusion. Phase Ia study included a dose-escalation period initiated by accelerated titration (0.015, 0.03mg/kg d1,15; q28d) and then switched to 3–3 scheme (0.12, 0.15, 0.17, 0.18mg/kg d1,15; q28d) and a dose expansion period. Phase Ib clinical expansion study included 3 cohorts, platinum-resistant ovarian cancer (PROC), metastatic triple negative breast cancer (TNBC) and other solid tumors. The primary objective was to assess the safety and preliminary efficacy. **Results:** As of September 30, 2022, 178 patients received at least one dose of study drug were enrolled (phase Ia: n=35; phase Ib: n=143) and received median 3 prior regimens. Included tumor species were PROC (n=101), TNBC (n=25), ER+/Her2+ breast cancer (BC) (n=17), colorectal cancer (n=6), pancreatic cancer (n=12) and others (n=17). In phase Ia study, DLTs were observed in 3 patients (0.12, 0.15, 0.18mg/kg, n=1 each), including grade 4 hypophosphatemia, neutropenia, febrile neutropenia, and grade 3 hyperglycemia, alanine aminotransferase (ALT) elevation. MTD was not yet reached. Majority of adverse events were mild to moderate. Grade 3/4 treatment-emergent adverse events (TEAEs) occurred in $\geq 3\%$ subjects were neutropenia (n=85), decreased leukocyte count (n=49), anaemia (n=10), AST elevation (n=7), ALT elevation (n=7). Drug-related death was observed in 1 patient. A total of 82 PROC patients at dose of 0.15mg/kg or above were evaluable for efficacy assessment. There were 21 patients achieved partial response (PR) and 30 patients achieved stable disease (SD). The objective response rate (ORR) and the disease control rate (DCR) were 25.6% and 62.2%, respectively. The median progression-free survival (mPFS) was 3.7 months (95% CI: 2.7–5.1). In 34 PROC patients with FR α expression $\geq 25\%$ and ≤ 3 prior treatment regimens, ORR was 32.4% and mPFS was still 3.7 months (95% CI: 3.3–7.3). Given the small sample size, efficacy data of breast cancer and other solid tumors will be analyzed after recruiting more patients. **Conclusions:** The current result showed that CBP-1008 has manageable safety profile. Antitumor activity was observed in PROC patients at dose of 0.15mg/kg or above, especially in PROC patients with FR α expression $\geq 25\%$ and ≤ 3 prior treatment regimens. Jifang Gong, Jian zhang and Ning Li contributed equally to this work. Xichun Hu, Lin Shen and Lingying Wu are the corresponding authors. Clinical trial information: NCT04740398. Understanding differences in the rates of BRCA/HRD testing and treatment in 1st line maintenance in patients with ovarian cancer treated by gynecologic oncologists compared to other providers: A quality initiative by Integra Connect (IC) PrecisionQ. *First Author: Fred J. Kudrik, South Carolina Oncology Associates, West Columbia, SC*

Background: The role of PARPi in the treatment of advanced ovarian cancer (aOC) has expanded in recent years. In this context, South Carolina Oncology Associates (SCOA) partnered with Integra Connect (IC) on a quality initiative (QI) to evaluate the rate of BRCA and HRD testing in newly diagnosed OC patients and the use of maintenance therapy in the 1st line (1L) setting in aOC. Patients with aOC at SCOA are typically managed by gynecologic oncologists. **Methods:** Using the IC Precision Q real-world database of over 1 million cancer patients across 275 sites of care, we assessed newly diagnosed OC patients evaluated via medical chart curation from 1/1/2020 to 6/30/2022 for BRCA and HRD testing at SCOA (N = 81) and other oncology practices (N = 1,045). We also studied the use of maintenance therapy in patients with stage II–IV OC who completed platinum-based chemotherapy from 1/1/2020 to 6/30/2022 at SCOA (N = 75) and other oncology practices (N = 899). SCOA was compared to other oncology practices in terms of provider specialty treating the patient, rates of HRD and BRCA testing, and use of 1L maintenance treatment in patients with or without BRCA or HRD mutations. Descriptive analyses were used. Proportions were compared using a two tailed two sample z-test. **Results:** Among newly diagnosed patients at SCOA, 95% of patients with OC were primarily managed by a gynecologic oncologist compared to 5% at other practices. The rate of BRCA testing at SCOA was 81% (66 of 81) compared to 75% (788 of 1045) and HRD testing was 60% (49 of 81) compared to 39% (403 of 1045) at other oncology practices in the IC database. The difference in HRD testing was significant ($p < 0.01$). The use of 1L maintenance regardless of biomarker status was 64% (48 of 75) at SCOA compared to 50% (449 of 899) at other practices. The difference in 1L maintenance use was significant ($p < 0.05$). PARPi were used at SCOA for maintenance therapy in 82% (38 of 46) of patients compared to 74% (314 of 427) at other practices. The use of maintenance in BRCA or HRD positive patients was 84% (21 of 25) at SCOA compared to 75% (151 of 201) for other practices. **Conclusions:** In this real-world study, treatment by gynecologic oncologists was associated with higher rates of BRCA and HRD testing and higher use of 1L maintenance treatment in patients with aOC compared to other practices. These findings underscore the importance of gynecologic oncologists in the management of aOC to ensure optimal testing and adherence to treatment guidelines. Research Sponsor: None.

Response to subsequent platinum-based chemotherapy post PARP inhibitor in recurrent epithelial ovarian cancer. *First Author: Genevieve MacAulay Vacheresse, University of Ottawa, Ottawa, ON, Canada*

Background: Maintenance therapy with PARP inhibitors (PARPi) can increase progression free survival (PFS) for recurrent or metastatic platinum-sensitive epithelial ovarian cancer (EOC). Little is known about disease trajectory following treatment with these agents, though some evidence suggests a decreased response to subsequent platinum-based chemotherapy. This retrospective cohort study assessed real-world response rates to platinum-based chemotherapy for recurrent high grade EOC following treatment with a PARPi. **Methods:** All patients prescribed a PARPi as maintenance therapy for recurrent or metastatic EOC at the Ottawa Regional Cancer Center (ORCC) from September 2017 to May 2022 were included. PFS following penultimate therapy (line of therapy preceding PARPi initiation) as well as the PFS following subsequent platinum-based chemotherapy in patients with disease progression more than 6 months after penultimate therapy were calculated. Incidence of platinum resistance in patients with disease progression following PARPi therapy was determined. **Results:** 91 patients were included in the analysis including 54 patients on niraparib and 36 patients on olaparib. Follow-up after initiation of PARPi ranged from 4.6 months to 62.0 months with a median of 16.3 months. 54 (59.3%) of patients experienced disease progression after initiation of PARPi therapy, including 10 (11.0%) who progressed within 6 months of their penultimate therapy. Of the 44 patients who experienced disease progression more than 6 months following penultimate therapy, 32 (72.7%) were rechallenged with platinum-based chemotherapy. Of these, 16 (50.0%) experienced further disease progression with 14 (43.8%) progressing within 6 months of their platinum rechallenge. Median PFS following platinum rechallenge was 4.4 months (from 0.8 months to 34.9 months), significantly lower than previous reports. **Conclusions:** Patients who experienced disease progression following PARPi therapy showed a poor response to subsequent platinum-based chemotherapy, even when progression occurred more than 6 months after completion of their penultimate platinum-based chemotherapy. This supports the theory that PARPi resistance may be a surrogate for platinum resistance and raises concern for possible contribution of PARPi in the induction of platinum resistance in recurrent EOC. Research Sponsor: University of Ottawa Department of Obstetrics & Gynecology.

Molecular and immune profiling of TP53-mutated ovarian cancers with non-BRCA1/2 homologous recombination gene alterations. *First Author: Kyle C. Strickland, Labcorp Oncology; Duke University Medical Center, Duke Cancer Institute, Department of Pathology, Durham, NC*

Background: Molecular alterations in homologous recombination (HR) pathway genes lead to HR deficiency (HRD) in ~50% of high grade serous ovarian carcinomas (HGSOC). The immune microenvironment of BRCA1/2-mutated HGSOC has been extensively characterized, in contrast to tumors with mutations in other HR genes. We evaluated a cohort of epithelial ovarian cancers (EOC) enriched for HGSOC and compared molecular and immune signatures of tumors with BRCA1/2 mutations (BRCAm) to those with non-BRCA1/2 HR gene mutations (NBHRD). **Methods:** We characterized 173 EOC by comprehensive genomic and immune profiling (CGIP) using panel-based next-generation DNA (523 genes) and RNA sequencing (384 genes), respectively. We enriched for HGSOC by selecting for TP53 mutations and excluding tumors with non-serous histology or any mutation in POLE, MLH1, PMS2, MSH2, MSH6, or nucleotide excision repair genes. Tumors lacking BRCA1/2-mutations were classified as NBHRD if a reportable mutation was present in canonical HR genes. Mutational burden (TMB, mut/Mb) was estimated from detected SNV/indels. We calculated immune-related expression signatures, including tumor immunogenicity score (TIGS), cellular proliferation (CP), and cancer testis antigen burden (CTAB). PD-L1 expression was assessed by tumor proportion score (TPS) following 22C3 immunohistochemistry. Differences in TMB, TIGS, CP, CTAB, PD-L1 and gene expression rank were tested for using Wilcoxon rank-sum test. **Results:** Of 173 EOC, 84 cases had complete CGIP, including 11 (13%) BRCAm, 7 (8%) NBHRD (Table), and 66 (79%) lacking HR gene alterations. On average, NBHRD tumors harbored lower TMB (4.1±2.3 vs. 6.6±2.3 vs. p=0.03) and elevated TIGS (59.1±16.2 vs. 41.7±16.2 p=0.044) compared to BRCAm tumors. We found no difference in PD-L1 (p=0.21), CP (p=0.26), or CTAB (p=0.48). Expression changes were identified in 32 immune genes, of which 31 (97%) were substantially up-regulated (1.3-3.3 fold) in NBHRD compared to BRCAm tumors. **Conclusions:** Our findings showed our cohort of NBHRD tumors were more immunogenic but less mutagenic than BRCAm tumors, implying enhanced immunogenicity unrelated to neoantigen load. Given that immune checkpoint inhibitors have shown limited efficacy in ovarian cancer, our data suggest NBHRD tumors may have stronger and possibly distinct immune escape mechanisms compared to BRCAm tumors. Research Sponsor: Labcorp.

Trends in the use of neoadjuvant chemotherapy for low-grade serous ovarian cancer in the United States. *First Author: Jason Silberman, Massachusetts General Hospital, Boston, MA*

Background: Following the publication of randomized trials demonstrating its noninferiority, the use of neoadjuvant chemotherapy (NACT) for the treatment of advanced stage epithelial ovarian cancer has increased substantially in the United States. However, low-grade serous ovarian cancers (LGSOC) respond poorly to chemotherapy compared with high-grade serous carcinoma. For LGSOC, clinical guidelines favor surgical resection prior to adjuvant therapy. This study seeks to describe patterns and temporal trends in the use of NACT for LGSOC. **Methods:** This cohort study identified women treated for stage III or IV LGSOC in a Commission on Cancer accredited cancer program between January 1, 2004, to December 31, 2020. We fit Poisson regression models to evaluate temporal trends in the use of NACT and cytoreductive outcomes, and to identify factors associated with receipt of NACT. We considered age, race/ethnicity, Charlson Comorbidity Index, year of diagnosis, insurance status, income, facility type, census region, and stage as potentially associated with NACT. Due to the high rate of missingness in data describing cytoreductive outcomes after surgery, we undertook both multiply imputed and complete case analyses. **Results:** A total of 3,343 patients received treatment for LGSOC during the study period. The mean age at diagnosis was 54.8 year (SD 15.5) and most patients (82%) were white. The most commonly observed upfront treatment strategies were cytoreductive surgery followed by adjuvant chemotherapy (63.7%) and surgery without chemotherapy (19.2%). Treatment with NACT followed by interval cytoreductive surgery (13.0%) or chemotherapy alone (4.1%) were less common. The proportion of patients who received NACT increased from 9.5% in 2004 to 25.9% in 2020, corresponding to a statistically significant annual percent change (APC) of 7.2% (95% CI 5.6-8.9). Increasing decade of age (risk ratio [RR] 1.15; 95% CI 1.09-1.23), increasing calendar year of diagnosis (RR 1.07; 95% CI 1.05-1.08) and stage IV disease (RR 2.66; 95% CI 2.3-3.07) were associated with a higher probability of receiving NACT. Other variables were not associated with receipt of NACT. Among patients who underwent cytoreductive surgery, the proportion who achieved no gross residual disease remained stable over the course of the study period in both complete case (APC 0.5%; 95% CI -1.8 to 0.9) and multiply imputed (APC -0.1%; 95% CI -1.6 to 1.3) analyses. **Conclusions:** The use of NACT for patients with LGSOC increased substantially from 2004 to 2020. Despite increased utilization of NACT, the rate of complete cytoreduction has not improved over the study period, possibly calling into question the effectiveness of NACT in reducing tumor burden in this setting. Exploring the significance of PARP inhibitor therapy after first-line chemotherapy in patients with homologous recombination proficient ovarian cancer: An extracted individual patient data and trial-level meta-analysis. *First Author: Mateus Trinconi Cunha, Instituto do Câncer do Estado de São Paulo, University of São Paulo, São Paulo, SP, Brazil*

Background: The use of poly (ADP-ribose) polymerase inhibitors (PARPi) as maintenance therapy in advanced epithelial ovarian cancer (EOC) patients (pts) has shown to delay cancer progression among patients with mutated BRCA (mBRCA) or homologous recombination deficiency (HRD), with debatable and divergent benefit among the subgroup of patients with homologous recombination proficiency (HRP). We aimed to further clarify the efficacy of PARPi after first-line chemotherapy (1L CT) in patients with HRP EOC. **Methods:** A systematic literature search of PubMed, Embase, The Cochrane Library until February 9th was conducted to identify articles or presentations of phase III clinical trials (P3CT) evaluating PARPi maintenance therapy after 1L CT in ovarian cancer. Individual patient data was reconstructed from Kaplan-Meier plots of progression-free survival (PFS) among pts with mBRCA, HRD and HRP through WebPlotDigitizer and R package IPDfromKM and further combined. We also performed trial-level meta-analysis with a random effects model. Comparisons were made with Cox proportional hazards. Clinical benefit for each sub-group was accessed with the ESMO Magnitude of Clinical Benefit Formulary 2b (ESMO MBCS). **Results:** The literature search resulted in 513 items. After screening, 6 P3CT (SOLO1, PRIMA, VELIA, PAOLA, PRIME, and ATHENA-MONO) were selected, and the longer follow-up data of each trial was used. A total of 3205 pts were included in the analysis (2090 in PARPi arms, 1115 in control arms). HRP was associated with worse PFS regardless of the treatment arm (HRP vs mBRCA in PARPi arms: HR 1.92, 95% CI 1.62 - 2.21, P < 0.001). Compared to control treatment arm, PARPi therapy was associated with a improved PFS in all subgroups, although the magnitude of benefit decreased from mBRCA to HRD and HRP (Table). Trial-level meta-analysis yielded similar results. PARPi therapy summed 4 out of 4 possible points at ESMO MBCS for mBRCA and HRD, but only 2 points among HRP pts, confirming a lower clinical benefit in this subgroup. **Conclusions:** This meta-analysis included additional P3CT recently presented and new data of subgroup analysis of previous studies. Results confirm a statistically significant benefit of PARPi maintenance after 1L CT for HRP EOC. Nevertheless, the relative and absolute gain in PFS is modest (9% in 2 years), while mBRCA and HRD subgroups have a substantial benefit. The worse prognosis of HRP pts, in addition to the small clinical benefit of PARPi therapy, highlights the need for new treatment strategies for this subgroup. Research Sponsor: None.

	Median PFS (PARPi vs control)	2-year PFS (PARPi vs control)	HR	95% CI	P
mBRCA	45.5 vs 16.6 mo	69% vs 38%	0.41	0.35 - 0.49	< 0.001
HRD	23 vs 15.6 mo	49% vs 32%	0.62	0.51 - 0.75	< 0.001
HRP	13.9 vs 10 mo	28% vs 19%	0.80	0.69 - 0.92	0.002

Distinguishing primary mucinous ovarian tumors from metastases of non-gynecologic mucinous cancers: Can we leverage next-generation sequencing? *First Author: Muhammad Danyal Ahsan, Weill Cornell Medicine - Qatar, Doha, Qatar*

Background: Primary mucinous ovarian cancers (MOC) are histopathologically challenging to differentiate from ovarian metastases of non-gynecologic origin, with this distinction being critical for appropriate management and prognosis. We compared the somatic gene variant landscape of MOC to that of non-gynecologic mucinous tumors. **Methods:** Data were extracted from the American Association for Cancer Research's (AACR) Project Genomics Evidence Neoplasia Information Exchange (GENIE) database version 13.0 via cBioPortal. This publicly available, multi-institutional database provides next generation sequencing (NGS) genomic profiles of tumors. We queried this database for samples of MOC, mucinous colorectal cancer (MCRC), mucinous appendiceal cancer (MAC), mucinous breast cancer (MBC) and gastric type mucinous cancer (GMC). Frequencies of somatic gene variants including mutations, copy number alterations and structural variants were compared using Chi-squared or Fisher's exact tests, using the Benjamini-Hochberg method to control for multiple hypothesis testing with q-values reported. **Results:** A total of 883 tumors were included for analysis: 358 MCRC, 268 MAC, 157 MOC, 59 MBC and 41 GMC samples. Compared to MAC, MOC samples had higher variant frequencies of CDKN2A (33.3% vs 0.4%, q<0.001), CDKN2B (24.0% vs 0.0%, q<0.001), TP53 (64.3% vs 23.5%, q<0.001), ERBB2 (14.3% vs 1.1%, q<0.001) and CDK12 (13.2% vs 0.0%, q<0.001), whereas GNAS variants were more common in MAC (45.5% vs 5.7%, q<0.001). Compared to MCRC, MOC samples had higher variant frequencies of CDKN2A (33.3% vs 2.3%, q<0.001), CDKN2B (24.0% vs 3.7%, q<0.001), TP53 (64.3% vs 42.9%, q<0.001), KRAS (69.4% vs 51.1%, q<0.001) and ERBB2 (14.3% vs 5.3%, q<0.001), whereas MCRC had higher variant frequencies of 57 genes, with the largest differentials among APC (48.8% vs 2.6%, q<0.001), SMAD4 (25.2% vs 5.8%, q<0.001) and TCF7L2 (19.0% vs 0.0%, q<0.001). Samples of MOC had significantly higher rates of KRAS variants compared to GMC (69.4% vs 31.7%, q<0.001) and lower rates of STK11 variants (1.9% vs 22.0%, q<0.001). Compared to MBC, MOC samples had higher variant rates of CDKN2A (33.3% vs 3.4%, q<0.001), TP53 (64.3% vs 10.2%, q<0.001) and KRAS (69.4% vs 0.0%, q<0.001), whereas MBC samples had higher variant frequencies of 11 genes, with the largest differentials among GATA3 (32.1% vs 0.8%, q<0.001), FGF3 (30.4% vs 2.4%, q<0.05) and CCND1 (28.1% vs 1.6%, q<0.001). **Conclusions:** NGS demonstrates that MOCs carry a distinct genetic signature compared to mucinous tumors of non-gynecologic origin, most commonly with significantly higher variant frequencies of CDKN2A, CDKN2B and lower variant frequencies of GNAS, APC, STK11 and GATA3. This provides rationale for prospective studies evaluating genetic signatures as an adjunct to histopathology in the diagnosis of primary MOC. Research Sponsor: None.

Effectiveness of PARP inhibitor maintenance therapy (mPARPi) in advanced ovarian cancer (OC) by *BRCA1/2* and HRD signature in real-world practice. *First Author: Debra L. Richardson, Stephenson Cancer Center/University of Oklahoma Health Sciences Center and Sarah Cannon Research Institute, Oklahoma City, OK*

Background: mPARPi following surgery and platinum chemotherapy (PCT) is a standard of care treatment for newly diagnosed advanced OC. Clinical trials have demonstrated benefit of mPARPi for patients (pts) with and without *BRCA1/2* mutations (*BRCA*+/-). The degree of benefit of mPARPi for pts without homologous recombination deficiency (HRD) biomarkers detected remains in question. This study aimed to compare the effectiveness of mPARPi in real world practice defined by biomarker status (*BRCA*+/- mutation and a novel HRD signature [HRDsig]). **Methods:** This study included pts with advanced OC who received 1st-line PCT with real-world progression-free survival (rwPFS) of at least 10 months after treatment initiation and received either mPARPi (without bevacizumab) or no maintenance therapy (nm). Pt data was obtained by the US-based de-identified Flatiron Health-Foundation Medicine real-world OC clinico-genomic database, originating from ~280 US cancer clinics (~800 sites of care) between 01/2015 and 09/2022. rwPFS and real-world overall survival (rwOS) were compared between pts +/- biomarkers by Cox models, adjusted for propensity scores accounting for disease stage at diagnosis, ECOG, age, and *BRCA* status (for the HRDsig analysis). HRDsig+ (Foundation Medicine) status was determined using a pre-specified cutoff. **Results:** Of 604 included pts, 128 pts received mPARPi (25.8% *BRCA*+ and 48.4% HRDsig+) and 476 received nm (14.3% *BRCA*+ and 35.5% HRDsig+). *BRCA*+ pts receiving mPARPi vs. nm had more favorable rwPFS (HR 0.44, 95% CI 0.24-0.79, *p* = 0.006), as did *BRCA*- pts (HR 0.7, 95% CI 0.51-0.95, *p* = 0.021). More favorable rwOS was not observed for either group (*p* = 0.7112, *p* = 0.2066 respectively). HRDsig+ pts receiving mPARPi vs. nm had more favorable rwPFS (HR 0.31, 95% CI 0.20-0.48, *p* < 0.001) and rwOS (HR 0.35, 95% CI 0.12-1.05, *p* = 0.061), while no differences were observed for those HRDsig- (rwPFS HR 0.99 0.71-1.40, *p* = 0.976 / rwOS HR 0.86, 95% CI 0.5-1.47, *p* = 0.575). A treatment interaction was observed for HRDsig+ vs. HRDsig- (rwPFS *p* < 0.001 / rwOS *p* = 0.042) but not for *BRCA*+ vs. *BRCA*- (rwPFS *p* = 0.213 / rwOS *p* = 0.596). Among *BRCA*- pts, those HRDsig+ receiving mPARPi vs nm had favorable rwPFS (HR 0.27, 95% CI 0.15-0.49, *p* < 0.001) and rwOS (HR 0.40, 95% CI 0.08-1.98, *p* = 0.216), while no difference was observed for those HRDsig- (rwPFS HR 1.02, 95% CI 0.72-1.44, *p* = 0.923 / rwOS HR 0.86, 95% CI 0.49-1.49, *p* = 0.590), with a treatment interaction observed for rwPFS (*p* < 0.001), but not for rwOS (*p* = 0.120). **Conclusions:** In this analysis of real-world practice, we observed improved outcomes among biomarker positive pts treated with mPARPi. HRDsig+ pts had improved outcomes, even among those who were *BRCA*-, while HRDsig- pts showed no enrichment for benefit with mPARPi, suggesting that a novel HRDsig might be able to predict benefit from mPARPi regardless of *BRCA* status. The diagnostic landscape of HRD testing based on cross-sectional survey of physicians and molecular biologists conducting testing (INDICATOR ONE). *First Author: Robert L. Coleman, Texas Oncology, Texas, US & Sarah Cannon Research Institute (SCRI), Tennessee, US, Texas, TX*

Background: Homologous recombination deficiency (HRD) occurs in approximately 50% of epithelial ovarian cancer (OC) cases. As HRD-positive tumors are more sensitive to poly(ADP-ribose) polymerase inhibitors (PARPi), HRD testing (determined by BRCAm and genomic instability score) identifies advanced ovarian cancer (AOC) patients who will benefit most from PARPi treatment. The value of these tests is recognized by guidelines to inform PARPi maintenance treatment decisions following first-line chemotherapy. This study characterizes the current testing landscape. **Methods:** This non-interventional, cross-sectional, web-based survey will be repeated in three waves, 9-12 months apart. Reported results are from Survey Wave 1 open from July to November 2022 and conducted among physicians and clinical laboratory heads/molecular biologists in the US and Europe (UK, France, Germany, Austria). Participants were recruited from clinical sites/laboratories known to be conducting HRD testing and via a standing physician panel. **Results:** Responses were received from 287 eligible participants (representing invitees from ~9% sites and < 2% panelists), 265 of whom completed the full survey (Europe: 153, US: 112; 228 physicians, 37 clinical laboratory heads/molecular biologists). Physicians ordered HRD testing for 70% ± 27% (mean ± SD) of newly diagnosed AOC patients. Nearly all physicians ordered the test to inform treatment decisions (*n* = 222; 97%). Physicians were most likely to conduct testing at stage 3 or 4 of OC diagnosis (Europe: *n* = 89, 64%; US: *n* = 63, 71%), followed by OC diagnosis regardless of stage (Europe: *n* = 51, 37%; US: *n* = 51, 57%). When European participants selected all types of tests used MyChoice CDx, Myriad Genetics (*n* = 82, 54%) was most commonly selected, followed by FoundationOne CDx, Foundation Medicine (*n* = 38, 25%). US participants used FoundationOne CDx (*n* = 62, 55%), followed by MyChoice CDx (*n* = 49, 44%), and QIAGEN QIASeq HRD (*n* = 38, 34%). Test costs were often partially (Europe: *n* = 47; 27%; US: *n* = 125; 53%) or fully covered (Europe: *n* = 89; 51%; US: *n* = 48; 21%). Results were received within 10 ± 6 (mean ± SD) working days in the US and 16 ± 11 working days in Europe. Testing guided treatment decisions 'always/often' (Europe: *n* = 117, 84%; US: *n* = 65, 73%) or 'sometimes' (Europe: *n* = 21, 15%; US: *n* = 23, 26%). Most European (*n* = 108, 78%) and US (*n* = 71, 80%) institutions offered genetic counselling. **Conclusions:** Among physicians and molecular biologists known to be conducting HRD testing, most newly diagnosed AOC patients were tested for HRD, and results usually played a role in treatment decisions. Variations in testing between the US and Europe include test types, test cost coverage, and time to receive results. Differences indicate potential areas for improvement in HRD testing to further benefit patients. Triplet maintenance (olaparib, pembrolizumab, and bevacizumab) in *BRCA* non-mutated patients with platinum-sensitive recurrent ovarian cancer: A multi-center, single-arm phase II study (OPEB-01). *First Author: Yoo Na Kim, Department of Obstetrics and Gynecology, Yonsei University College of Medicine, Seoul, South Korea*

Background: The optimal treatment of *BRCA* 1/2 non-mutated patients with platinum-sensitive recurrent ovarian cancer remains unknown. In this study, we evaluated the efficacy and safety of triplet maintenance therapy in *BRCA* non-mutated patients with platinum-sensitive recurrent ovarian cancer. **Methods:** *BRCA* 1/2 non-mutated patients with platinum-sensitive recurrent epithelial ovarian cancer, showing a complete/partial response after second-line platinum-based chemotherapy, were eligible. Triplet maintenance therapy (olaparib, bevacizumab, and pembrolizumab) was administered until disease progression or unacceptable toxicity. The primary endpoint was the progression-free survival (PFS) rate at six months after therapy initiation. The secondary endpoints were PFS, overall survival, and safety. The translational objectives included biomarker evaluation with respect to survival outcomes. **Results:** Forty-four patients were enrolled (median age 61 years), majority with high-grade serous carcinoma (93.2%) and partial response (75.0%) to second-line chemotherapy. Overall, 54.6% were homologous recombination deficiency (HRD)-positive (genomic instability score ≥ 42) and 63.6% had PD-L1 positive tumors (combined positive score [CPS] ≥ 1). At 6 months, the PFS rate was 88.6% (95% confidence interval [CI] 75.4–96.2). The median PFS has not been reached. The most common ≥ grade 3 treatment-related adverse events (AEs) were anemia (20.5%) and neutropenia (6.8%), but there were no grade 4 AEs. Exploratory analysis demonstrated remarkable survival outcomes regardless of HRD status, whereas patients with PD-L1 CPS ≥ 1 showed improved PFS compared to those with PD-L1 CPS < 1 (*P* = 0.032). Analysis of molecular consensus subtype of the pre-treatment tissue samples showed that patients with mesenchymal subtype demonstrated poor PFS, compared to non-mesenchymal subtypes (*p* = 0.0023). **Conclusions:** This is the first report on triplet maintenance therapy in *BRCA* non-mutated platinum-sensitive recurrent ovarian cancer. The results show that the triplet maintenance therapy is efficacious with manageable toxicity, showing a particular promise for patients with molecular consensus subtype other than mesenchymal. Clinical trial information: NCT04361370. Research Sponsor: MSD supported the study drugs; Korean government.

Immune features of ovarian tumors with a good response to neo-adjuvant chemotherapy in combination with an anti-PD-L1 alone or with an anti-CTLA4: Data from the randomized IneOV trial (a GINECO study). *First Author: Alexandra Leary, Gustave-Roussy Cancer Campus, Villejuif, and GINECO, Paris, France*

Background: We have shown that chemotherapy may have immunomodulatory properties and prime the tumor microenvironment (TME) by recruiting cytotoxic immune cells. We previously reported that neoadjuvant chemotherapy (NACT) associated with Durvalumab (D) +/- Tremelimumab (T) resulted in encouraging complete resection (70%) and complete pathological response (18%) rates in patients with unresectable ovarian cancer. Here, we aimed to 1) characterize the immune TME at baseline of responders compared to non-responders and 2) describe changes in immune TME in paired tumor samples at diagnosis and after 3 cycles of NACT with D +/- T in the randomized IneOV trial. **Methods:** Tumor samples from IneOV trial (55 at diagnosis, 40 after treatment) were analyzed for CD3+, CD68+ and CD20+ by multiplexed immunohistochemistry. Stromal and intra-epithelial TILs were scored as percentage of positive surface. Patients were classified as good pathological responders (pR) (CRS3) or pathological non-responders (pNR) (CRS1 or 2). Intra-tumoral T cell infiltration was described as High or Low (intraepithelial (ie)CD3+ > median vs <, respectively). Non parametric statistical tests were used. We evaluated the correlation of the markers with each others (Spearman test) and with pathological response rate (Mann-Whitney test). **Results:** At diagnosis, in the intra-epithelial compartment of the TME, the most abundant cells were macrophages (median ieCD68+ = 3.4) compared to T (ieCD3+ = 1.1), B (ieCD20+ ND) ANOVA *p*-value = 0.002 and < 0.0001 respectively. In individual tumors, infiltration by the 3 different immune subsets was poorly correlated suggesting immune TME heterogeneity in OC. Pathological response was evaluable in 64 patients: 19 pR and 45 pNR. At diagnosis, CD3+ (*p* = 0.02) and CD68+ (*p* = 0.006) infiltration was significantly higher in pR tumors compared to pNR. Most of pR (76%) had high intra-tumoral CD3+ infiltration versus 39% in pNR (*p* = 0.011). After treatment, tumors with pR showed significantly greater CD3+ intra-epithelial infiltration compared to pNR (*p* = 0.047). **Conclusions:** Our results suggest that good pathological response to NACT +D+/-T is associated with high levels of both T cells and macrophages in iTME at baseline, and increased intratumoral T cell infiltration post-treatment. Work is ongoing to further characterize the iTME, especially in pNR to identify other strategies to enhance the anti-tumor immune response. Clinical trial information: NCT03249142. Ovarian cancer and bevacizumab: Real-world use across western countries and effect on survival in high-risk subgroups. *First Author: Kristina Lindemann, Department of gynecological oncology, Radiumhospital, Oslo University Hospital & Faculty of Medicine, University of Oslo, Oslo, Oslo, Norway*

Background: Bevacizumab (bev) may be part of first-line treatment for patients with "high-risk" epithelial ovarian cancer (OC) (GOG-Q218 and ICON7 trials). The prevalence of high-risk patient subgroups, including bev use and its effect on survival in a real-world setting is not well studied. **Methods:** The observational multi-country cohort study RESPONSE collected retrospectively medical record data on women with newly diagnosed advanced high-grade serous or endometrioid OC (DOI: 10.1002/cncr.34350). We analysed patients defined as 'high-risk' according to ICON7 definition as either 1) stage IV disease, 2) inoperable stage III disease or 3) sub-optimally debulked (>1 cm residual disease) stage III disease. Unadjusted Cox proportional hazards regression analysis was performed to estimate the association of bev with the risk of death. Follow up time was calculated from time between response assessment at the end of primary chemotherapy and death or 20 months follow-up, whichever occurred first. **Results:** Of 954 patients in total, we identified 386 high-risk patients (40%) treated with platinum-based chemotherapy. Of these, 132 (34%) received bev maintenance treatment. Baseline characteristics did not differ between patients receiving bev or no bev. Bev use was associated with a statistically significant reduction in risk of death with a HR of 0.49 (95%CI: 0.18-0.78, p=0.002) in the total group of high-risk patients. The effect on survival was most evident among inoperable stage III/IV patients (n=151) with a 63% reduction in risk of death (HR 0.37; 95% CI (0.18-0.78, p=0.009). Risk estimates for additional subgroups are given in the table. **Conclusions:** Forty percent of this real-world population are considered high-risk according to ICON7 and a majority of these patients did not receive bev during first-line treatment. In line with ICON 7, this analysis supports the beneficial effect of bev on overall survival in this high-risk population. Patients who do not receive surgery are underrepresented in clinical trials and this real-world study confirms the strong benefit of bev particularly in this subgroup. Any real-world study may be limited by the potential presence of selection bias of patients to receive bevacizumab or not. Research Sponsor: AstraZeneca, part of an alliance between AstraZeneca and Merck Sharp & Dohme Corp, a subsidiary of Merck & Co, Inc (Kenilworth, New Jersey).

Effect estimates on overall survival in patients receiving platinum-based chemotherapy with or without bev.

Analysis set	Chemotherapy with bevacizumab (no. of pts)	Chemotherapy without bevacizumab (no. of pts)	Events N	HR 95% CI	p-value
High-risk*	132	254	102	0.49 (0.31-0.77)	0.002
Inoperable (stage III/IV)	34	117	62	0.37 (0.18-0.78)	0.009
Stage IV	89	150	56	0.50 (0.28-0.91)	0.023
Stage III inoperable	15	68	28	0.33 (0.10-1.10)	0.069
Stage III >1cm residual	28	38	18	0.63 (0.25-1.6)	0.324

*High-risk patients included stage IV disease, inoperable stage III disease or sub-optimally debulked (>1 cm) stage III disease

Predictors of long-term progression-free survival (PFS) in niraparib-treated patients (pts) from the PRIMA/ENGOT-OV26/GOG-3012 study. *First Author: Whitney Graybill, Medical University of South Carolina, Charleston, SC*

Background: Niraparib was approved as maintenance therapy for pts with advanced ovarian cancer (OC) after complete or partial response (CR/PR) to first-line (1L) platinum-based chemotherapy (CT) based on results from the PRIMA study. In this post hoc analysis, we identified factors associated with long-term PFS. **Methods:** PRIMA is a phase 3, randomized study of pts with newly diagnosed advanced high-grade serous or endometrioid ovarian, primary peritoneal, or fallopian tube cancer at high risk for relapse with CR/PR after 1L platinum-based CT. Pts were randomized 2:1 to niraparib 200 or 300 mg or placebo QD, and stratified by best response to 1L CT (CR/PR), neoadjuvant CT (yes/no), and homologous recombination deficiency (HRD) status (deficient [HRD]/proficient or not determined [HRP/nd]). Investigator-assessed PFS was dichotomized in niraparib-treated pts with progressive disease (PD)/censoring <2 years vs PD/censoring ≥2 years after randomization (data cut, Nov 17, 2021). Logistic regression modeling using backward elimination (significance level=0.15) was used to identify baseline covariates associated with long-term PFS. **Results:** Of 487 niraparib-treated pts, 152 (31%) had PD/censoring ≥2 years after randomization. Odds ratios (OR) for PFS ≥2 years by baseline subgroup are shown (Table). The logistic regression model showed that BRCA mutation and HRD status, International Federation of Gynecology and Obstetrics (FIGO) stage, fallopian tube as the site of the primary tumor, and absence of baseline nontarget lesions were associated with longer PFS. Eastern Cooperative Oncology Group (ECOG) performance score, body mass index, age, time from CT to randomization, number of target lesions, best response after CT, number of CT cycles, type of debulking surgery, and residual disease were not associated with PFS ≥2 years. Safety has been reported previously (*Ann Oncol*. 2022;33 [suppl 7]:S789). **Conclusions:** Results suggest that long-term PFS in pts treated with niraparib may be associated with BRCA/HRD biomarker status, FIGO stage, primary tumor site, and number of baseline non-target lesions. These data are hypothesis generating. Clinical trial information: NCT02655016. Research Sponsor: GSK.

Variable	OR* (95% CI)	P Value
BRCA/HRD status	3.73 (2.191-6.335)	<0.0001
BRCA1/HRd, n=105	10.75 (5.158-22.407)	<0.0001
BRCA2/HRd, n=47	2.49 (1.422-4.372)	0.0014
BRCAwt + HRd, n=95	1.00	
FIGO stage		0.0412
III, n=318	1.62 (1.019-2.568)	
IV*, n=169	1.00	
Primary tumor site	0.53 (0.208-1.332)	0.1755
Primary peritoneal, n=34	0.54 (0.275-1.052)	0.0700
Fallopian tube, n=65	1.00	
Ovarian*, n=388		
Baseline nontarget lesions	4.67 (2.076-10.485)	0.0002
0, n=331	2.20 (0.857-5.649)	0.1010
1, n=90	1.00	
≥2, n=66		

*Reference variable. *Higher OR indicates more likely to remain progression free; eg, OR of 1.63 is 63% more likely to remain progression free for ≥2 years vs reference. wt, wild type.

Blinded-assessment of a solution to evaluate olaparib maintenance treatment efficacy in patients with ovarian cancer from the GINECO/ENGOT PAOLA-1 trial. *First Author: Adrien Buisson, Department of Biopathology, Centre Léon BÉRARD, Lyon, France*

Background: SOPHiA DDM Dx HRD Solution (SOPHiA GENETICS, SA) combines analysis of genomic instability with mutational status of HRR genes, including *BRCA1/2*, generated through a single genomic workflow in order to predict Homologous Recombination Deficiency (HRD) status in ovarian cancer (OvCa) samples. Previous evaluation of SOPHiA DDM Dx HRD Solution demonstrated its results to be highly concordant with a reference HRD method. As part of the ENGOT HRD initiative, we present updated clinical relevance results of SOPHiA DDM Dx HRD Solution. **Methods:** GINECO/ENGOT-Ov25 PAOLA-1 trial randomized (2:1) 804 patients (pts) to receive after the end of first-line platinum-based chemotherapy either maintenance olaparib+bevacizumab or placebo+bevacizumab for up to 2 years. DNA from a sub-cohort of 384 formalin-fixed paraffin-embedded (FFPE) OvCa pts samples included in the PAOLA-1 clinical trial were analyzed using SOPHiA DDM Dx HRD Solution(*). We combined SOPHiA DDM Dx HRD Solution genomic instability score, with *BRCA* mutational status obtained from a Clinical Decision Support module, and clinical interpretation of Variants of Unknown Significance to establish the pts HRD status and investigated differences in progression-free survival (PFS) in the olaparib+bevacizumab and placebo+bevacizumab arms between pts with HRD positive or HRD negative test. **Results:** We determined the HRD status of 98.4% of pts using SOPHiA DDM Dx HRD Solution. The median PFS time for pts with HRD positive tumors was 35.7 months longer in the olaparib+bevacizumab arm than in the placebo+bevacizumab arm (hazard ratio [HR], 0.36; 95% confidence interval [CI], 0.25-0.51, p< 0.001), confirming the findings of our previous interim analysis. No significant difference in PFS was observed between treatment arms in pts with HRD negative test (HR, 1.02; 95% CI, 0.71-1.48; p= 0.90). **Conclusions:** These clinical relevance results from the SOPHiA DDM Dx HRD Solution evaluation on the PAOLA-1 samples further support the value of combining low-pass whole genome and targeted sequencing in a unique workflow for reliable and cost-effective HRD testing and future patient stratification. (*) Comparison data generated using the CE-IVD pipeline with Clinical Decision Support module for *BRCA* status only available in EU, Switzerland, UK. Research Sponsor: None.

Phase 1/1b study of PRGN-3005 autologous UltraCAR-T cells manufactured overnight for infusion next day to advanced stage platinum resistant ovarian cancer patients. *First Author: John B. Liao, University of Washington Medical Center, Seattle, WA*

Background: Relapsed or refractory (r/r) ovarian cancer patients (pts) have limited treatment options. PRGN-3005 UltraCAR-T cells express a chimeric antigen receptor (CAR) targeting unshed MUC16, membrane bound IL-15 (mbIL15) and a kill switch with robust activity in preclinical models. UltraCAR-T investigational therapies are manufactured overnight using the proprietary UltraPorator electroporation system at the medical center and administered to patients one day after gene transfer. **Methods:** The Phase 1/1b study of PRGN-3005 evaluates the safety and recommended Phase 2 dose (RP2D) of PRGN-3005 in pts with r/r ovarian cancer (NCT03907527). In Phase 1, pts received PRGN-3005 without lymphodepletion (LD) via Intraperitoneal (IP) infusion (Cohort 1, C1) or Intravenous (IV) infusion (Cohort 2, C2) at Dose level 1-3. Dose level 3, IV infusion was further evaluated in pts treated with cyclophosphamide LD (60mg/kg/day on days -4 to -3 (IV LD)). As of the February 6, 2023 data cut-off, 25 evaluable pts have been treated in C1 (n = 12), C2 (n = 6), and IV LD (n = 7). Pts had a median age of 64 years (38-76) and were heavily pre-treated with a median of 8 prior regimens (4-11). Pts treated in C1 received 1 to 65.5 x 10⁵ cells/kg, pts treated in C2 received 0.1 to 50 x 10⁵ cells/kg and pts treated in IV LD received 0.1 to 39 x 10⁵ cells/kg. **Results:** PRGN-3005 was well tolerated at up to 65.5 x 10⁵ cells/kg. There have been no deaths, dose-limiting toxicities, neurotoxicity, grade ≥3 Cytokine Release Syndrome (CRS), or unexpected on-target/off-target toxicities related to PRGN-3005, and no use of the kill switch as of data cut-off. Grade 1 CRS occurred in 3/7 IV LD pts and one pt had transient grade 2 CRS, which resolved in < 24 hours. Plasma levels of IL-15 did not increase with treatment confirming mbIL15 is not shed. A dose dependent increase in PRGN-3005 was observed in peripheral blood of patients even in the absence of LD, and *in vivo* persistence of PRGN-3005 could be observed in some patients for up to 9 months post infusion. Response was evaluated per RECIST 1.1, and 20% of all subjects experienced a response in at least 1 target lesion. In the IV LD pts, the disease control rate (DCR) was 85.7% at first restaging, with a decreased target tumor burden in 4/7 (57%), and a 27.4% average decrease in CA125. One pt had a 28% decrease in target tumor burden after receiving a second infusion of PRGN-3005 after 12 months. **Conclusions:** PRGN-3005 UltraCAR-T targeting MUC16 has been well tolerated with minimal toxicity. PRGN-3005 demonstrated a dose-dependent expansion and persistence in blood with or without LD. Encouraging DCR rates and a reduction in overall tumor burden have been observed in heavily pretreated, ovarian cancer pts treated with LD. The study continues to enroll to the Phase 1b expansion phase and is treating pts at DL3 with LD with an option to receive a second dose. Clinical trial information: NCT03907527. Research Sponsor: Precigen, Inc.

The role of Chemotherapy Response Score (CRS) in the decision making process for patients with advanced high grade serous ovarian cancer undergoing neoadjuvant chemotherapy. *First Author: Claudia Marchetti, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy*

Background: The role of chemotherapy response score (CRS) in predicting PARP inhibitors (PARPi) response for high grade serous Advanced Ovarian Cancer (AOC) patients undergoing Neoadjuvant Chemotherapy (NACT) has never been investigated. Also, the correlation between CRS and Homologous Recombination status (HRs) is unclear. **Methods:** In this observational retrospective study, we collected data from patients with high grade serous AOC, FIGO stage III-IV, undergoing NACT and subsequent Interval Debulking Surgery (IDS) from 2017 to 2021. KELIM score, CRS and BRCA status were considered; additionally, HRs (Foundation test) was reported when available. Primary endpoint was Progression Free Survival (PFS) according to CRS (CRS 1/2 vs 3) in patients receiving PARPi. **Results:** We enrolled 309 patients; 102 had CRS3 and 193 had CRS1/2 (14 were undetermined). Patients with CRS3 and PARPi maintenance showed the best prognosis, compared to all other subgroups (median PFS Not Reached, $p=0.014$); additionally, in the BRCA wild type population, CRS3 was predictive of longer survival (median PFS for the CRS3+PARPi BRCAwt population 24 months compared with 15 months for the CRS1/2+PARPi BRCAwt patients, $p=0.041$). Furthermore, among the 44 patients with known HRs, 59.1% of HR Deficiency (HRD) positive patients had CRS3, conversely 22.7% of HRD negative ones had a CRS3 ($p=0.048$). Finally, we found out that a favorable KELIM was significantly associated with CRS3 in the all-comers patients ($p=0.007$) and in the BRCAwt ($p=0.04$), but it was not predictive of PARPi response. **Conclusions:** Our findings suggested that the higher the CRS at the interval cytoreduction, the better the subsequent PARPi response. CRS correlates with PARPi response, as the HRD test does in other clinical trials and it may be considered as a surrogate of HRD status. We have planned to retrospectively perform HR test on a total sample size of 77 patients who received PARPi to corroborate this hypothesis. Research Sponsor: Fondazione Policlinico Universitario Agostino Gemelli IRCCS.

	Patients (N)	Median PFS (months, CI 95%)	p value
All-Comers			
CRS 3 + PARPi	47	NR	-
CRS 1/2 + PARPi	106	26	0.014
CRS 3 - NO PARPi	23	18	<0.001
CRS 1/2- NO PARPi	61	13	<0.001
BRCA-wt population			
CRS 3 + PARPi	24	24	-
CRS 1/2 + PARPi	53	15	0.041

Gynecologic-cancer analysis of ARID1A alterations detected in tissue and liquid biopsies. *First Author: Natalie Danziger, Foundation Medicine, Inc., Cambridge, MA*

Background: The tumor suppressor gene *ARID1A* is an emerging target for new cancer treatment strategies including ATR inhibition. This study aimed to describe the landscape of *ARID1A* alterations (*ARID1A*mut) in gynecologic malignancies. **Methods:** Patients (pts) with a diagnosis of ovarian (OC) or uterine cancer (UC) of different histologies and comprehensive genomic profiling (CGP) by Foundation Medicine Inc. were included in this study. CGP of solid tissue biopsies (Tbx; FoundationOneCDx) included evaluation of genomic loss of heterozygosity (gLOH; gLOH-high as $\geq 16\%$ as validated in OC), microsatellite instability (MSI), and tumor mutational burden (TMB; high as ≥ 10 mutations/Megabase). CGP of peripheral whole-blood liquid biopsies (Lbx; FoundationOneLiquidCDx) included evaluation of MSI and tumor fraction (TF), a measure of the relative quantity of circulating tumor DNA (ctDNA). TF was calculated by measures of aneuploidy and allele frequency and binned as TF $< 1\%$, TF 1 to $< 10\%$, or TF $\geq 10\%$. **Results:** Tbx Cohort: 5,778/30,212 (19.1%) cases were *ARID1A*mut. Pts had a median age of 63 (range 21-89) years. *ARID1A*mut were observed across many subtypes and most frequently in endometrial endometrioid ($n = 3,052$, 57.7%) and ovarian clear cell ($n = 982$, 57.6%) but rarely in serous (OC, $n = 12,258$, 2.8%; UC, $n = 2,682$, 8.9%). Pts frequently harbored more than one *ARID1A*mut (2,360/5,778, 40.8%). Of the 8,484 observed *ARID1A*mut, 97.6% were short variants (SV), 0.5% were deletions, and 1.9% were inactivating rearrangements. SV were primarily frameshifts (68.5%) and nonsense mutations (27.6%). The most frequent alterations observed were frameshifts at the D1860 codon. SV were predicted to be homozygous in 11.9%, heterozygous in 65.3%, or unknown zygosity in 22.8%. Overall, 16.6% of *ARID1A*mut cases with SV had at least one homozygous alteration. 6.6% of pts with homozygous *ARID1A*mut were MSI-high (MSI-H), while 39.4% of pts with only heterozygous or unknown zygosity *ARID1A*mut were MSI-H ($p < 0.0001$). Overall, 1,905 (33.0%) of *ARID1A*mut cases were MSI-H, and 2,183 (37.8%) were TMB high. For *ARID1A*mut cases with evaluable gLOH ($n = 4745$), the median gLOH was 2.7%, and 5.9% pts were gLOH-high. The most frequently altered co-occurring genes were *PTEN* (62.2%), *PIK3CA* (54.2%), and *TP53* (27.6%). 8.7% of *ARID1A*mut also harbored a *BRCA* alteration. Lbx Cohort: 59/967 (6.1%) cases were *ARID1A*mut. 17 (28.8%) were MSI-H. Frequency of *ARID1A*mut increased as TF increased, with a detected frequency of 1.3%, 6.7%, and 14.0% among Lbx with TF $< 1\%$, TF 1 to $< 10\%$, or TF $\geq 10\%$ respectively. **Conclusions:** *ARID1A*mut are observed across a variety of Gynecological cancer subtypes but are enriched in clear cell and endometrioid histologies and detected in both tissue and liquid biopsies. *ARID1A*mut were not associated with elevated gLOH but were often MSI-H and TMB ≥ 10 mut/Mb. Clinical trials targeting *ARID1A* may wish to consider the context of co-occurring biomarkers. Research Sponsor: Foundation Medicine Inc.

Real-world overall survival in second-line maintenance niraparib monotherapy vs active surveillance in BRCA wild-type patients with recurrent ovarian cancer. *First Author: Robert L. Coleman, US Oncology Research/Sarah Cannon Research Institute and GOG-Foundation, The Woodlands, TX*

Background: The Phase 3NOVA trial assessed niraparib versus placebo as a maintenance treatment (tx) for patients (pts) with recurrent ovarian cancer (OC) who were platinum-sensitive after ≥ 2 regimens; progression-free survival was the primary endpoint and overall survival (OS) was a secondary endpoint (NCT01847274). The aim of this real-world study was to compare OS in a breast cancer gene wild-type (BRCAwt) population of pts with recurrent OC and who received second-line maintenance (2Lm) niraparib monotherapy or were under active surveillance (AS). **Methods:** This study used the US nationwide Flatiron Health de-identified electronic health record (EHR)-derived database. Pts diagnosed with epithelial OC between 1Jan2011–31May2021 who completed 2L therapy between 1Jan2017–2Mar2022 were eligible for inclusion. Pts were BRCAwt, had an ECOG PS score 0–1, epithelial histology, and platinum-sensitive disease with ≥ 6 months between end of first-line tx and start of 2L tx. Pts were assigned to 2Lm niraparib or AS cohorts based on their management following 2L non-maintenance therapy (≤ 120 days). Follow-up was measured from the index date (end of 2L non-maintenance therapy) until end of study (31May2022), last activity, or death, whichever came first. A target trial emulation cloned inverse probability of censoring weighting (IPCW) methodology was selected *a priori* to minimize bias. IPCW median OS and hazard ratios (HR) for 2Lm versus AS were estimated with Kaplan-Meier curves and Cox regression models. **Results:** Overall, 266 BRCAwt pts were included and received niraparib 2Lm ($N=123$) or were under AS ($N=143$). Across 2Lm and AS cohorts, prior to cloning and IPCW, 23.6% and 34.3% of pts were aged ≥ 75 years, and 26.0% and 16.8% had an EHR value for race as other than White, respectively. The majority of pts were from community practice (80.5% and 90.2%, respectively), had serous OC (79.7% and 81.1%) and had Stage III disease (53.7% and 60.8%). Homologous recombination deficiency status was unknown for 92.7% and 86.0% of pts in 2Lm and AS cohorts, respectively. Median follow-up for 2Lm and AS cohorts was 16.8 (Quartile [Q] 1, Q3: 10.4, 28.7) and 10.2 (Q1, Q3: 4.1, 23.7) months, respectively. IPCW median OS was 28.1 (95% confidence interval [CI]: 22.5, 43.2) and 21.5 (95% CI: 14.7, 27.0) months (HR: 0.63 [95% CI: 0.45, 0.88]) for niraparib 2Lm and AS cohorts, respectively and survival rates at 24 months were 58.2% (95% CI: 47.5, 67.6) and 46.1% (95% CI: 33.6, 57.7). **Conclusions:** This analysis provides real-world data on OS among pts with OC receiving niraparib 2Lm or under AS in the 2L setting following chemotherapy. Funding: GSK study (219306). Editorial support was provided by Fishawack Health, funded by GSK. Research Sponsor: GSK.

Healthcare access dimensions and uterine cancer survival: A National Cancer Database study. *First Author: Mary Katherine Anastasio, Duke Medical Center, Durham, NC*

Background: Racial disparities persist throughout the continuum of care for Black patients with uterine cancer. Few studies have evaluated how multiple dimensions of healthcare access (HCA) contribute to these disparities in patients who present at an advanced stage and meet criteria for adjuvant therapy. **Methods:** Patients with Stage III-IV uterine cancer between 2004-2015 who received adjuvant therapy with complete sociodemographic and other relevant covariate data were identified in the National Cancer Database (NCDB). Race and ethnicity were defined as non-Hispanic (NH)-Black, Hispanic, and NH-White. Healthcare access dimensions of affordability, availability and accessibility were measured using variables defined in the NCDB. Overall survival was analyzed using Kaplan-Meier curves, log-rank test, and multivariable Cox proportional hazard models. **Results:** The study cohort included 43,134 patients: 78.8% NH-White, 15.3% NH-Black, and 5.9% Hispanic. Compared to NH-White and Hispanic patients, NH-Black patients were more likely to have Type II (75.6% vs. 53.9% and 55.4%) and Stage IV disease (40.8% vs. 30.7% and 32.3%). NH-Black patients were more likely to receive chemotherapy alone (53.5% vs. 43.1% and 46.2%) compared to NH-White and Hispanic patients. NH-Black patients were the most likely to have government funded insurance (58.6% vs. 50.3% and 50.4%) and live in the lowest income quartile (46.4% vs. 14.2% and 29.9%) compared to NH-White and Hispanic patients. NH-Black patients had a significantly higher risk of death than NH-White patients when adjusting for demographic/clinical characteristics and all three healthcare access dimensions (HR 1.29; 95% CI 1.24, 1.34). **Conclusions:** Healthcare access affordability predicts survival but does not fully explain racial disparities in survival rates of patients with advanced stage uterine cancer. NH-Black patients are more likely to have aggressive disease, receive chemotherapy alone, and have worse survival than NH-White patients regardless of pathogenic subtype. Investigating additional healthcare access dimensions may be critical to addressing disparities in uterine cancer. Research Sponsor: None.

Preliminary antitumor activity of the combination of COM701 + BMS-986207 + nivolumab in patients with recurrent, metastatic MSS endometrial cancer. *First Author: Drew W. Rasco, START San Antonio, San Antonio, TX*

Background: There is a high unmet medical need for the treatment of patients [pts] with microsatellite stable [MSS], recurrent, metastatic, endometrial cancer [EC]. We reported encouraging preliminary antitumor activity with the triple combination of COM701 + BMS-986207 + nivolumab in patients with platinum resistant epithelial ovarian cancer [1]. COM701 is a novel, 1st-in-class immune checkpoint inhibitor [ICI] that binds to PVRIG, a DNAM-1 axis member, leading to activation of T-and NK-cells; BMS-986207 is an ICI of TIGIT. Nivolumab is an ICI of PD-1. We hypothesized that in pts with EC, the triple combination would demonstrate antitumor activity with a favorable safety and tolerability profile. We present encouraging preliminary results. **Methods:** As part of an expansion cohort, we enrolled 9 patients [pts] with EC. All pts received COM701 20 mg/kg + BMS-986207 480 mg + nivolumab 480 mg all IV Q4W. Primary objectives were safety/tolerability, with secondary objective of antitumor activity in pts with EC. Key inclusion criteria: Age $\geq$ 18 yrs, measurable disease, MSS by IHC or genomic testing, $\leq$ 2 prior systemic cytotoxic therapies, prior PD-1/PD-L1 permissible. Key exclusion criteria: prior receipt of anti-PVRIG, anti-TIGIT. Investigator assessed responses were per RECIST v1.1, safety per CTCAE v5.0. **Results:** Median age 71yrs, median of 2 prior lines of therapy, prior PD-1/PD-L1 3/9 [33%]. All pts received prior cytotoxic therapy. Objective response rate (ORR) 2/9 [22%] pts; 2 pts with SD. Disease control rate [CR + PR + SD] 4/9 [44%]. There were 2 pts with confirmed PR; 1 of these pts was refractory to prior receipt of lenvatinib + pembrolizumab [best response assessment of progressive disease]. Treatment related AEs were reported in 6/9 [67%] pts, the majority 4/6 [67%] were Grade 1 [1 pt each with chills, pyrexia, back pain and pruritus, lipase increased]. No new safety signals are reported. **Conclusions:** The combination of COM701 + BMS-986207 + nivolumab demonstrates encouraging preliminary signal of antitumor activity in pts with EC including in a pt refractory to prior exposure to lenvatinib + pembrolizumab. The triplet combination has a favorable safety/tolerability profile. Additional data analyses and pt follow up are ongoing and will be presented at the conference. Data extract 01/24/2023. 1. Moroney JW, Yeku O *et al.* Triple blockade of the DNAM-axis with COM701 + BMS-986207 + nivolumab demonstrates preliminary antitumor activity in patients with platinum resistant OVCA. *Annals of Oncology* (2022) 16 (suppl_1): 100104-100104. 10.1016/j.annonc.2022.100104. The effect of megestrol acetate $\pm$ pterostilbene in endometrial cancer: A prospective, randomized, window-of-opportunity clinical trial. *First Author: Rosemary Senguttuvan, City of Hope National Comprehensive Cancer Center, Duarte, CA*

Background: Pterostilbene (3,5-dimethoxy-40-hydroxystilbene) is a potent oral antioxidant found naturally at highest concentrations in blueberries. Its anti-tumor effects in preclinical studies of various solid tumors include carcinogenesis, inflammation, reactive oxygen species (ROS) formation, and antiproliferative effects. In endometrial cancer (EC), *in vitro* and *in vivo* studies demonstrated a synergistic antiproliferative effect of pterostilbene (PT) in combination with megestrol acetate (MA). No clinical trials testing the potential therapeutic benefit of pterostilbene in cancer have been completed. **Methods:** We performed a prospective, window-of-opportunity, randomized phase 2 clinical trial (NCT03671811) in patients with EC. Eligible patients had to be surgical candidates for treatment with hysterectomy and not have received prior therapy. The primary objective was to determine the effect of MA plus PT versus standard treatment of MA alone on tumor proliferation as measured by the Ki-67 index during the preoperative window. Patients were randomized 1:1 to one of two arms: MA+PT PO BID versus MA PO BID, for 3 weeks. The Ki-67 index was measured via hot-spot and H-score methodology in the preoperative tumor and hysterectomy specimen by two blinded pathologists whose measurements were averaged. The net change between pre- and post-operative specimens was calculated for each patient and expressed as a percentage. Toxicity was assessed using CTCAE grading. **Results:** A total of 44 patients with EC of all histologies were recruited to the study and included in the toxicity analysis. Median age was 61.9 years. Baseline demographics were comparable between both arms. Median treatment duration was 21 days (14-56), similar in both arms. One G3 hypertension was encountered in the MA arm; one G3 thromboembolic event in the MA+PT arm. Of 35 patients with sufficient treatment duration (>10 days) and available pre-and post-treatment specimens, 29 patients with endometrioid histology were evaluated for the Ki67 analysis: 14 in the MA arm and 15 in the MA+PT arm. The MA+PT group demonstrated a -41.1% change in Ki-67 index by Hot Spot Score compared to -27.5% in the MA-only group ($p=0.17$). A similar trend was observed for the Ki-67 index by H Score methodology (-41.6% vs -26.7%, MA+PT vs MA, $p=0.17$). **Conclusions:** The combination of MA + PT in preoperative treatment of endometrial adenocarcinoma is well tolerated. The addition of Pterostilbene demonstrates a trend towards decreased Ki-67 index in endometrioid EC patients. Molecular studies are pending to delineate biomarkers associated with response. Clinical trial information: NCT03671811. Research Sponsor: internal funding.

Pathogenic germline variants in patients with endometrial cancer across diverse ancestries. *First Author: Ying L. Liu, Gynecologic Medical Oncology Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Racial/ethnic disparities in outcomes exist in endometrial cancer (EC), particularly amongst self-reported Black compared to Non-Hispanic White (NH-White) patients. However, the contribution of differences in germline pathogenic variants (gPV) and genetics care to disparities is unknown. We seek to describe the spectrum of gPV in unselected patients with EC by ancestry to characterize variations and describe any differences in subsequent genetic counseling follow-up. **Methods:** Germline assessment of ≥ 76 cancer predisposition genes was performed in patients with EC undergoing clinical tumor-normal MSK-IMPACT sequencing from 1/1/15-6/30/21. Self-reported data on race/ethnicity and Ashkenazi Jewish (AJ) ancestry were used to classify patients into mutually exclusive ancestry groups: AJ, Asian, Black, Hispanic, NH-White, or Unknown. Genetic ancestry was inferred from MSK-IMPACT, and those with single population ancestral fraction >0.8 were assigned to African (AFR), European (EUR), East Asian (EAS), Native American (NAM), South Asian (SAS), and AJ (ASJ) ancestry populations or considered admixed (Mixed). Clinicopathologic variables were reported using summary statistics and compared by ancestry using non-parametric tests. **Results:** Among 1,625 patients with EC, self-reported ancestry [202 AJ (12.4%), 124 (7.6%) Asian, 171 Black (10.5%), 124 Hispanic (7.6%), 927 NH-White (57.1%), and 77 missing (4.7%)] correlated with genetic ancestry. In those identifying as Black, 122 (71%) had $>80\%$ African ancestry, 45 (26%) were considered Mixed, and 4 (3%) had missing data. We observed gPV in 216 (13.3%) patients (73 high, 36 moderate and 107 low/uncertain penetrance), with 15 patients having >1 gPV. Rates of gPV varied significantly by self-reported ancestry [AJ: 40 (19.8%), Asian: 15 (12.1%), Black: 12 (7.0%), Hispanic: 15 (12.1%), NH-White: 129 (13.9%), Missing: 5; $p=0.009$] and genetic ancestry [AFR: 9 (6.4%), AJ: 53 (19.3%), EAS: 9 (11.0%), EUR: 112 (13.3%), NAM: 2 (40%), SAS: 7(20%), Mixed: 17 (8.6%), Missing: 7; $p<0.001$]. Self-reported Black patients had the lowest rate with 13 gPV observed in 12 patients (7.0%); 5 gPV had biallelic inactivation within the tumor (2 *MSH2*, 1 *MSH6*, 1 *BRCA2* and 1 *FANCA*). Biallelic inactivation was observed in 70 (32%) patients overall with highest rates in Black (42%), Asian (40%), AFR (67%) and SAS (71%) populations. In those with new gPV ($n=114$), 102 (89%) overall were seen in genetics clinic for follow-up care, with the lowest rates in patients identifying as Black (75%) and of AFR ancestry (67%). **Conclusions:** Although rates of gPV varied by ancestry, they are drivers of disease in all populations, emphasizing the importance of germline assessment in EC. Differences in gPV and subsequent genetics care may contribute to racial/ethnic disparities in outcomes in EC by affecting treatment and cancer prevention and should be studied further. Overall survival and subsequent therapy from a phase II study of sintilimab and anlotinib in patients with advanced or recurrent endometrial cancer. *First Author: Zhen Zeng, Department of Gynecologic Oncology, State Key Laboratory of Oncology in South China, Sun Yat-sen University Cancer Center, Guangzhou 510060, P. R. China, Guangzhou, China*

Background: Although the combination of immunotherapy and antiangiogenic agents has been proved a promising strategy in endometrial cancer, studies in Chinese patients are limited. In the earlier phase II study (NCT04157491), Chinese patients with recurrent or advanced endometrial cancer treated with sintilimab + anlotinib had an objective response rate of 73.9% (95% confidence interval [CI]: 51.6% to 89.8%). Here we further updated overall survival (OS) and subsequent therapy for this study. **Methods:** Patients with endometrial carcinoma progressed after platinum-based chemotherapy were enrolled. Sintilimab 200 mg was supplied intravenously on day one, whereas anlotinib 12 mg was administered orally on day 1 - 14 every three days. **Results:** Twenty-three patients were enrolled in the study. 47.8% of patients received ≥ 2 lines of prior chemotherapy; microsatellite instability-high/mismatch repair deficiency (MSI-H/dMMR) and microsatellite instability stable/mismatch repair proficient (MSS/pMMR) accounted for 39.1% and 60.9% of patients, respectively. We observed a median OS of 17.8 months (95% CI, 9.4 to 26.3 months). Patients with microsatellite instability-high (MSI-H) had superior OS than their counterparts (not available vs. 13.3 months; HR 0.15, 95% CI, 0.33-0.70; $P=0.006$). All patients had dropped out of the cohort [56.5% progression disease (PD), 13.0% adverse events (AE)]. Notably, five patients with partial responses (PRs) obtained pathological or radiography complete responses (CRs) in the follow-up. Pathological CRs were confirmed in three patients with long-lasting PRs who underwent surgery, consistent with PET/CT scans. Two patients with PR continued to have tumor shrinkage following treatment cessation due to AE and achieved CR during follow-up. Three out of four patients with CR experienced recurrences. There were no new grade 3-4 AEs associated with therapy. **Conclusions:** In terms of OS, combining sintilimab and anlotinib had promising therapeutic effects. Pathological CR was observed in patients with long-lasting PR, thus exploratory surgery may be required in selected patients. Clinical trial information: NCT04157491. Research Sponsor: None.

Summary of subsequent therapies (N = 23).

Preliminary results of a phase II trial with sacituzumab govitecan-hzyi in patients with recurrent endometrial carcinoma overexpressing Trop-2. *First Author: Alessandro Santin, Department of Obstetrics, Gynecology, and Reproductive Sciences Yale University School of Medicine, New Haven, CT*

Background: Despite recent advances, there remains a significant need for targeted, efficacious treatments for advanced and recurrent endometrial carcinoma (EC). Trop-2 has been demonstrated to be overexpressed in several EC including grade 3 endometrioid adenocarcinoma (96%), and uterine serous carcinoma (65%). Trop-2 overexpression has been found to confer a worse prognosis and predicts disease recurrence. Sacituzumab govitecan-hzyi (SG) is an antibody-drug conjugate comprised of a humanized anti-Trop-2 antibody conjugated with the active metabolite of irinotecan, a topoisomerase-I inhibitor. SG is currently FDA-approved for use in metastatic urothelial cancer and metastatic triple-negative breast cancer. **Methods:** We report results from the stage 1 of an open-label non-randomized phase 2 trial (NCT04251416) established to evaluate the clinical activity of SG in patients with persistent or recurrent EC of epithelial origin with Trop-2 overexpression. Criteria for study participation included radiographically confirmed and measurable persistent or recurrent EC, progression after or during platinum-based chemotherapy, and at least 2+ staining of Trop-2. One target lesion by RECIST v1.1 and adequate bone marrow, renal, and hepatic function were required. Patients were at least two weeks beyond prior treatment, major surgery, or high dose systemic corticosteroid use. Patients were given 10mg/kg of SG administered as an intravenous infusion once weekly on days 1 and 8 of 21-day treatment cycles. This 3-week cycle was continued without rest until disease progression or unacceptable toxicity. **Results:** Twenty-one patients were enrolled into stage 1. Ten patients (48%) had uterine serous carcinoma, seven (33%) had endometrioid adenocarcinoma, three (14%) had carcinosarcoma, and one patient had mixed serous and clear cell histology. All patients received at least one prior line of chemotherapy, (median 3 lines, range 1-6). At the time of submission, 20 patients were response-evaluable (Table); seven (35%) achieved objective response (5 out of 7 confirmed). Eighteen patients were evaluable for durable disease control; 7 (39%) achieved it. Follow-up durations had a median (IQR) of 15.6 (5.7–22.5) months. Median OS was 22.5 months, and median PFS was 5.7 months. The treatment was well-tolerated with no new or unexpected safety signals reported. **Conclusions:** Sacituzumab govitecan shows remarkable clinical activity against some of the most historically challenging and chemotherapy-resistant endometrial pathologies and demonstrates a favorable safety profile. With these promising results, we will begin the stage 2 expansion of this phase 2 trial. Clinical trial information: NCT04251416. Research Sponsor: Gilead.

OATH trial: A phase II clinical trial evaluating the combination of onapristone with anastrozole for women with hormone receptor positive endometrial cancer—Preliminary results. *First Author: Russell J. Schilder, Thomas Jefferson University Hospital, Philadelphia, PA*

Background: Endometrial cancer is the most common gynecologic cancer and is primarily treated with chemotherapy. Many endometrial cancers though express hormone receptors and may respond to hormonal therapy, a potentially attractive non-chemotherapy alternative in such a population of women. The aim of OATH is to investigate the potential of dual hormonal blockade through the combination of antiprogesterone and anti-estrogen therapy via the administration of onapristone extended release (ONA) plus anastrozole (ANA), respectively. OATH is an open-label, multicenter, investigator-initiated, non-randomized, phase 2 study to evaluate the safety and efficacy of ONA + ANA in patients (pts) with endometrial cancer (EC). ClinicalTrials.gov Identifier: NCT04719273. **Methods:** Pts received ONA 50 mg twice daily plus ANA 1 mg once daily and were treated until progressive disease (PD) or unacceptable toxicity. Co-primary endpoints were 4-month progression-free survival (PFS) rate and overall response rate (ORR). A sample size of 25 pts will achieve 80% power to detect an improvement in 4-month PFS estimates from 25% (historical) to 52% and an improvement in response rate from 15% (historical) to 37%, using two-sided exact test at 5% significance level. Secondary endpoints include PFS, disease control rate (DCR), and safety. **Results:** As of January 20, 2023, 14 pts were enrolled. Median age was 67 years (44-80). ECOG performance status was 0 (36%), and 1 (64%). Number of prior chemotherapy regimens was 0 (1 pt, 7%), 1 (9 pts, 64%) and 2 (4 pts, 29%). Seven (50%) pts received radiotherapy and 3 (21%) pts received prior checkpoint inhibitor therapy. Median treatment duration was 4.2 (1.0-19.9) months, and 8 pts remain on treatment. Adverse events were mainly grade 1 and 2. The most common treatment-related adverse events (AEs) and abnormal laboratory values were hot flashes (36%), alanine transferase (ALT) increased (29%), aspartate aminotransferase (AST) increased (29%), nausea (29%), and diarrhea (21%). No treatment-related serious AE, deaths on treatment, or treatment-related drug discontinuations were reported. The 4-month PFS Kaplan-Meier rate was 63.5%. Among 13 pts who had at least one tumor assessment after baseline, the best overall response was: 1 complete response, 1 partial response (response rate: 15.4%), 9 (69%) stable disease, and 2 (15.4%) progressions. Updated results will be presented. **Conclusions:** Preliminary results of dual hormonal blockade using ONA and ANA in heavily pretreated pts with EC suggest that this combination ONA + ANA has promising activity and is well tolerated. Racial and ethnic disparities in quality of diagnostic evaluation for uterine cancer among Medicare patients. *First Author: Xiao Xu, Yale University, New Haven, CT*

Background: Uterine cancer is the most common gynecologic malignancy. As there is no routine screening for uterine cancer, appropriate evaluation of presenting symptoms is crucial for early diagnosis. We examined racial/ethnic disparities in the quality of diagnostic evaluation received by Medicare patients with uterine cancer. **Methods:** Using the Surveillance, Epidemiology and End Results (SEER)-Medicare database, we identified patients ≥ 65 years with uterine cancer diagnosed in 2008-2017 who presented with abnormal uterine bleeding (AUB, the most common symptom of uterine cancer). Patients with other cancer or unknown race/ethnicity were excluded. Race/ethnicity was categorized as White, Black, Hispanic, or Other (including American Indian/Alaska Native and Asian/Pacific Islander). Quality of diagnostic evaluation was measured by: 1) not receiving guideline-recommended diagnostic procedures (yes/no), and 2) number of days between AUB presentation and first diagnostic procedure. We compared these measures across racial/ethnic groups using multivariable regressions adjusting for patient sociodemographic characteristics, comorbid conditions, histology, and tumor grade. We further examined racial/ethnic differences in stage at diagnosis before vs. after accounting for these quality indicators. **Results:** The sample included 23,017 patients. Compared to White patients, Black, Hispanic, and Other patients were younger; more likely to reside in a metropolitan area, lack preventive care in the past year, or have comorbidities; and tended to have uterine cancer of non-endometrioid types and higher grade ($p < 0.001$ for all). A larger proportion of Black than White patients did not receive guideline-recommended diagnostic procedures (Black: 9.6% vs. White: 5.0%, $p < 0.001$; adjusted odds ratio [aOR] = 1.45, 95% CI: 1.20-1.74). Time from AUB presentation to first diagnostic procedure was longer for Black than White patients (90th percentile: 34 vs. 21 days, $p < 0.001$; adjusted mean ratio = 1.38, 95% CI: 1.21-1.57). Black patients were more likely than White patients to be diagnosed at regional (aOR = 1.18, 95% CI: 1.04-1.33) or distant stage (aOR = 1.27, 95% CI: 1.06-1.52), rather than localized stage, even after adjusting for other characteristics. Further adjusting for quality of diagnostic evaluation slightly reduced Black-White differences in stage at diagnosis (regional: aOR = 1.16, 95% CI: 1.03-1.32; distant: aOR = 1.23, 95% CI: 1.03-1.48). Hispanic and Other patients also experienced delay in time to first diagnostic procedure, but they did not differ from White patients in receipt of guideline-recommended diagnostic procedures or stage at diagnosis. **Conclusions:** There were racial/ethnic disparities in the quality of diagnostic evaluation received by Medicare patients with uterine cancer, which may partially explain Black-White differences in their stage at diagnosis. Correlation of cardiovascular disease with racial disparities in endometrial cancer outcomes. *First Author: Mitchell Depke, Medical College of Wisconsin, Milwaukee, WI*

Background: Survival for Black women with endometrial cancer (EC) is shorter than that for non-Hispanic White (NHW) women, with a rate ratio for mortality of 1.98 per the American Cancer Society. Cardiovascular risk factors and disease are also more prevalent in Black women than NHW women. In women with breast cancer, Black patients received less optimal management of comorbidities and experienced increased cardiovascular disease (CVD)-related mortality as compared to White women. Similar to breast cancer, we hypothesize that CVD contributes to EC mortality disparities for Black women. **Methods:** In this retrospective cohort study, SEER and institutional data were utilized to investigate the contribution of CVD to outcomes for Black EC patients. The primary outcome was the contribution of cardiovascular mortality to the overall survival of Black patients. Secondary outcomes included identifying rates of new cardiovascular diagnoses, renal dysfunction, and adequacy of blood pressure control. The SEER cohort was defined using SEER*Stat 8.4.0.1. Uterine cancer patients were identified from the 2020 SEER Research Data. Survival by cause of death and proportion of deaths by cause of death were analyzed. Raw and adjusted hazard ratios for cardiovascular mortality were calculated. Next, institutional data was used to investigate survival, CVD diagnoses, renal dysfunction, and HTN in EC patients. **Results:** The SEER cohort contained 192,465 patients. Of these, 153,878 (80.8%) were White and 19,906 (10.3%) were Black. Black race was associated with decreased survival among patients who died of cardiovascular causes (HR 1.51, 95% CI 1.4 - 1.63, $p < 2 \times 10^{-16}$). When adjusted for age, stage, and histology, the hazard for decreased survival remained elevated for Black patients who died of cardiovascular causes (adjusted HR 1.65, 95% CI 1.52-1.77, $p < 2 \times 10^{-16}$). Our institutional cohort included 1491 patients, 1263 (84.7%) White and 151 (10.0%) Black. Black patients had a relative risk of death of 1.92 (95% CI 1.38 - 2.61) compared with White patients. Among patients with CVD, the hazard for death was 2.02 (95% CI 1.39 - 2.80). Black patients had significantly higher blood pressure, creatinine, and eGFR measurements. **Conclusions:** Racial outcome disparities in EC are multifactorial. CVD management will become increasingly important with the use of targeted therapies including lenvatinib and trastuzumab. Our study highlights an additional area of disparity and suggests possible interventions. Research Sponsor: None.

Association of the Duffy-null allele and endometrial cancer characteristics: An effort to explore racial disparity in Black women with endometrial cancer.*First Author: Emily M. Webster, Weill Cornell Medicine, New York, NY*

Background: Efforts are needed to identify factors that account for the disparately high mortality in Black women with endometrial cancer. The Duffy antigen receptor for chemokines (DARC) is expressed on erythrocytes and endothelial cells and modulates levels of inflammatory chemokines in circulation and in tissues. The African ancestry-specific Duffy-null allele, in which erythrocyte expression and function of DARC is lost, is associated with worse breast cancer phenotypes and survival. Here, we characterize Duffy-null status and associated prognostic and clinical outcomes in patients with endometrial cancer. **Methods:** Patients with endometrial cancer were prospectively consented, and germline DNA was extracted from saliva or blood samples. Duffy-null genotype was determined using an allelic discrimination assay. Associations between Duffy-null genotype status and clinicopathologic characteristics were performed using Fisher's Exact analysis. **Results:** 33 patients were enrolled (Table); 17 (51.5%) were Duffy-null, 5 (15.2%) were Duffy-null allele carriers, and 11 (33.3%) were non-carriers. Compared with non-carriers, Duffy-null patients were more likely to be Black (100% v 9.1%, $p < 0.0001$) and have non-endometrioid histology (64.7% v 10%, $p = 0.0173$). There was a trend towards higher rates of grade 3 histology (70.6% v 36.6%), intact tumor mismatch repair (MMR) (86.7% v 54.6%), estrogen receptor (ER) negative tumor status (25% v 10%), advanced stage (37.5% v 18.2%), and positive lymph nodes (25% v 0%) (Table). Over a minimum of 12 months of follow up, only Duffy-null individuals died from disease (4 v 0, $p = 0.0006$). **Conclusions:** Duffy-null status was associated Black race, aggressive histologic subtypes, intact MMR mechanisms, and worse survival. Further investigation is needed to explore the underlying mechanism of the Duffy-null phenotype on endometrial cancer outcomes to better elucidate risk factors and underlying causes that may contribute to endometrial cancer disparities. Research Sponsor: U.S. National Institutes of Health.

Patient characteristics and Duffy-null status.

Laparoscopic versus open-surgery in FIGO stage II endometrioid endometrium cancers: Is there a prognostic effect?*First Author: Daniel Uwe Reimer, Innsbruck Medical University; Department of Obstetrics and Gynecology, Innsbruck, Austria*

Background: Based on two randomized trials (LACE and LAP2) minimal invasive surgery has turned into the surgical standard in early stage endometrial cancer including "high-risk" patients. However, these recommendations are predominantly based on "low-risk" cancers, which are mainly represented in both trial collectives. We herein provide a retrospective study, which focuses on potential differences in clinical outcome in early stage endometrioid endometrial cancers with distinct risk constellations treated by laparoscopy or open surgery. **Methods:** 420 early stage endometrial cancers were retrospectively dichotomized according to the surgical approach and correlated to the recurrence rate and clinical outcome. In addition, subgroup analyses were performed according relevant clinical risk parameters, namely FIGO stage, grading and LVSI. **Results:** The analyzed collective consisted of 73.8% stage IA, 19.5% stage IB, and 6.7% stage II cases. Twenty-three percent of patients exhibit G3 tumors and LVSI was detected in 12.4%. Minimal invasive surgery was performed in 54.5% of study patients. During a median follow-up of 5.0 years, recurrence or death were observed in 8.3% and 6.7%, respectively. Recurrences were predominately located in the vaginal cuff (n = 21; 60.0%), to a minor extent in loco-regional lymph nodes (n = 11; 31.4%), and in three patients (8.6%) in both sides. No distant metastases were detected at first recurrence. Also under consideration of the mentioned clinicopathologic parameters, the surgical approach in FIGO stage I did not influence the recurrence rate and patients' survival. However, in a subgroup analysis of stage II disease, the laparoscopic approach was clearly associated with a significant higher recurrence rate (85.7% vs. 14.3%; $p = 0.013$). All of the recurrences were located in the vaginal cuff, and in one case, additional relapse was found in loco-regional lymph nodes. Moreover, laparoscopic surgery in stage II disease was associated with impaired progression-free and overall survival (HR 8.86 (1.008 – 20.85) and HR 6.36 (1.102 – 28.61), respectively). **Conclusions:** We herein demonstrate that a minimal invasive surgical approach in stage II endometrial cancer is associated with higher recurrence rates and impaired clinical outcome. These data could be interpreted to be in line with the results of the LACC trial in cervical cancer. Although, grounded on a retrospective analysis, these hypothesis-generating results warrants a confirmatory trial, which is ongoing in a much larger collective of stage II endometrial cancer patients. The impact of cause of mismatch repair deficiency and other molecular markers on clinical outcomes with the use of durvalumab in advanced endometrial cancer in the phase 2 PHAEDRA trial (ANZGOG1601).*First Author: Daniel D. Buchanan, University of Melbourne, Parkville, VIC, Australia*

Background: In the single arm phase 2 PHAEDRA trial, MMR deficiency (dMMR) was predictive of response to durvalumab (1500mg IV Q4W), with an objective tumor response rate (OTR; defined by iRECIST) of 47% in dMMR compared with 3% in MMR-proficient (pMMR) advanced endometrial cancer (AEC). This substudy of the PHAEDRA trial investigates MMR molecular subtypes and other genomic tumor features and their correlation with treatment outcomes. **Methods:** Testing was performed to determine molecular subtypes of dMMR, including germline pathogenic variants in DNA MMR genes (Lynch syndrome), somatic biallelic MMR gene inactivation through somatic mutation and somatic hypermethylation of the *MLH1* gene promoter. DNA from formalin-fixed paraffin-embedded tumor tissue and matched peripheral blood was available from 41/71 (25 dMMR, 16 pMMR) participants for testing on a custom capture-based 298-gene targeted panel (2.005Mb) including the MMR genes and key somatic AEC driver genes. The derived tumor genomic features included microsatellite instability (MSI), tumor mutational burden (TMB), COSMIC v.3.2 tumor mutational signatures and insertion/deletion (Indel) somatic mutation count. **Results:** Of the 71 patients recruited, 35 were dMMR and 36 were pMMR. Median follow-up was 44 vs 52 months in dMMR vs pMMR participants, respectively. The dMMR molecular subtypes were 4 (11.4%) Lynch syndrome, 4 (11.4%) somatic MMR mutation, 25 (71.4%) *MLH1* methylated and 2 (5.7%) dMMR-uncategorized. The OTR rate was 100% (4/4; 95%CI 40-100%) for Lynch, 75% (3/4; 95%CI 22-99%) for somatic MMR mutations and 40% (10/25; 95%CI 22-61%) for *MLH1* methylated groups. The median TMB (assessed in 41/71) was higher in those with a confirmed radiological response (37, IQR:26-50) vs non-responders (16, IQR:9-25; $p < 0.001$). Within the *MLH1* methylated group, TMB was also higher in responders vs non-responders (40 v 21; $p = 0.03$). Somatic mutations in *KRAS*, *PTEN*, *PIK3CA*, *ARID1A* and *TP53* were not associated with OTR rate. **Conclusions:** dMMR-*MLH1* methylated AEC demonstrated greater heterogeneity in OTR to single agent durvalumab than the dMMR-Lynch and dMMR-somatic MMR mutation molecular subtypes. Higher TMB was seen in responders, and specifically within dMMR-*MLH1* methylated responders, compared to non-responders. Clinical trial information: ANZGOG1601. Impact of best practice advisory on genetic counseling referral patterns for patients with endometrial cancer.*First Author: Julia M. Nagle, University of Kentucky Medical Center, Lexington, KY*

Background: The National Comprehensive Cancer Network (NCCN) recommends that patients with endometrial cancer under age 50 undergo germline genetic testing. Despite this recommendation, completion rates are suboptimal for patients with gynecologic malignancies. The reasons for failure to complete testing are unknown, but oncology providers may not refer patients to genetic counselors, who frequently order this testing. Best practice advisories (BPAs) in electronic medical records can alert providers of patients who meet guideline-based treatments and testing criteria. It is unknown how oncology providers interact with a BPA indicating patients with endometrial cancer meet NCCN germline testing criteria. The objective of this study is to evaluate genetic counseling referral patterns after implementing a BPA. **Methods:** Our team developed a BPA to prompt oncology providers to order genetic counseling referrals for patients diagnosed with endometrial or uterine cancer under age 50. We reviewed all provider-BPA interactions between go-live (January 2022) and January 2023. Patient demographic, histopathologic, and cancer treatment data were collected. Provider actions, including BPA cancellation and order placement, were collected. The Chi-Square goodness of fit test was used to identify differences in referral rates by patient or disease characteristics. **Results:** The BPA displayed 1121 times for 103 patients. Attending physicians received 535 alerts, fellow physicians – 269, and advanced practice providers (APPs) – 317. The median number of alerts per patient was 7 (range 1-87). Of the 103 patients, 23 were excluded from analysis due to no diagnosis of endometrial cancer, patient declined referral, previously completed, or a lack of provider visits within the study period. Of the 80 eligible patients, 36 (45%) received referrals; 18 were placed by attending physicians, 17 by fellows, and one by an APP. Patients under age 40 versus age 40-49 were more likely to be referred (65% vs. 35%; $p = 0.011$). Patients with active disease were more likely to be referred than those in surveillance (65% vs. 18%; $p < 0.001$). There were no differences in referral rates by primary language, race, body mass index ≥ 40 , fertility-sparing versus definitive treatment, stage I versus stage II-IV disease, or grade 1-2 versus three tumors. **Conclusions:** Despite implementing a BPA, only 45% of eligible patients received indicated referrals. Attending and fellow physicians frequently manage patients with active disease and often order referrals; however, APPs frequently manage patients in surveillance and infrequently place referrals, highlighting an opportunity for education. In addition, patients aged 40-49 are less likely to be referred, suggesting a need for new strategies to improve referral rates. Further research is indicated to identify referral barriers for patients undergoing active treatment. Research Sponsor: None.

Impact of surgical weight loss treatments on care burden among obese endometrial cancer survivors. *First Author: Katia Noyes, University at Buffalo School of Public Health and Health Professions, Buffalo, NY*

Background: Among obesity-related cancers globally, 40% of disability adjusted life years loss are attributed to endometrial cancer (EC). EC patients are more likely to die of obesity-related complications rather than the cancer itself. Metabolic and bariatric surgery (MBS) is an effective weight loss treatment that has been shown to reduce prevalence and severity of many obesity-related chronic conditions. However, there is limited evidence on MBS on EC survivors. We examined the burden of patient healthcare utilization among EC survivors who did and did not undergo MBS. **Methods:** We utilized the SEER-Medicare database to identify 31,437 patients diagnosed with endometrial cancer between 2015 and 2017. We selected 9,229 (29.4%) patients with documented obesity (ICD codes) among whom 75 (0.8%) patients underwent MBS after completing EC treatment (2017-2019). EC survivors with and without a history of MBS were matched on age at EC diagnosis. We examined annualized Medicare inpatient and provider claims payments among EC-MBS (starting 3 months after the surgery, n=66) and EC-no MBS patients (2017-2019) and used Wilcoxon Rank-Sum tests to examine differences in payments in a 1:5 matched sample. **Results:** EC-MBS patients were younger (59.9 years) at the time of cancer diagnosis compared to EC-no MBS patients (68.2 years, $p<0.01$). In an age-matched sample, annualized median inpatient and provider claim payments among EC-MBS patients (\$1,824) were lower than that of EC-no MBS patients (\$2,920, $p<0.01$). **Conclusions:** Surgical weight loss achieves rapid and effective weight loss and has the potential to lower healthcare utilization among EC survivors but less than 1% of eligible patients receive the surgery. Further research is needed to better understand patient, provider, and access barriers to surgical weight loss in patients with obesity-related cancers. Research Sponsor: NYS DOH.

A multicenter, single-arm, phase 2 study of surufatinib plus toripalimab for patients with advanced endometrial cancer. *First Author: Guangwen Yuan, Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China*

Background: Several immunotherapy monotherapies, or combined with anti-angiogenic inhibitors, have shown antitumor efficacy in endometrial cancer (EMC) and been approved by FDA. However, therapeutic options for EMC after failure of first-line treatment remain scarce in China. The open-label, multi-cohort, single-arm phase 2 study was performed to evaluate the efficacy and safety of the combination of surufatinib (a small-molecule inhibitor of VEGFR 1-3, FGFR1 and CSF-1R) with toripalimab (an anti-PD-1 antibody) for Chinese patients (pts) with EMC after failure of one or more prior lines of systemic treatment. **Methods:** Pts with EMC who progressed or were intolerable after at least one prior line of systemic antitumor therapy were eligible and enrolled. They received 21-day cycles of surufatinib 250 mg orally, QD, plus toripalimab 240 mg IV, Q3W, until disease progression or reaching the maximum treatment duration with toripalimab of 24 months, or other protocol-specified criteria. The primary endpoint was objective response rate (ORR) per RECIST 1.1. **Results:** From August 2020 to March 2022, 28 pts were enrolled and received the combination treatment (median duration: 4.6 months). Median age was 58 years (range: 50-71), and 22 (78.6%) pts were endometrioid adenocarcinoma at diagnosis. 9 (32.1%) pts had received ≥ 2 prior lines of therapy. As of 28 Dec 2022, the median follow-up duration was 16.8 months. Microsatellite status was available in 25 pts. 20 with mismatch repair-proficient (pMMR) and 5 with mismatch repair-deficient (dMMR) were determined. All 28 pts were evaluable with at least one post-baseline tumor assessment. Efficacy results were: confirmed ORR, 28.6% (8 partial response [PRs]); DCR, 82.1%; mDoR, 5.7 months; mPFS (95%CI), 5.4 months (2.7, 8.3); 12-month OS rate, 71.0%. Among pts with pMMR, the confirmed ORR was 25.0%; DCR was 85.0%; mDoR was 4.2 months; mPFS (95%CI) was 4.0 months (2.7, 8.3); 12-month OS rate was 75.4%. All pts experienced at least one treatment-emergent adverse event (TEAE), and 19 (67.9%) of them reported grade ≥ 3 TEAEs. The most common ($\geq 5\%$ pts) grade ≥ 3 TEAEs were hypertension (28.6%), aspartate aminotransferase increased (14.3%), alanine aminotransferase increased (10.7%), proteinuria (7.1%), Gamma-glutamyltransferase increased (7.1%) and malignant neoplasm progression (7.1%). No new safety signals were observed. **Conclusions:** Surufatinib plus toripalimab had a promising antitumor activity and a manageable safety profile in pts with EMC after failure of one or more prior lines of systemic therapy. Clinical trial information: NCT04169672. Research Sponsor: HUTCHMED Limited.

Efficacy and safety of anlotinib in overall and disease-specific advanced gynecological cancer: A real-world study. *First Author: Xinyi Hong, Southeast University, Nanjing, China*

Background: Anlotinib is a novel oral small-molecule multi-target tyrosine kinase inhibitor that has been approved for treating non-small cell lung cancer. However, its efficacy and safety among patients with advanced gynecological cancer. We conducted this study to address this issue in the real-world setting. **Methods:** Data from patients treated with anlotinib for persistent, recurrent or metastatic gynecological cancer including cervical, endometrial, and ovarian cancer were collected from 17 centers from August 2018. The database lock-time was on March 2022. Anlotinib was administered orally on days 1-14 every 3 weeks until disease progression, severe toxicity occurred, or death. The outcomes included objective response rate (ORR), disease control rate (DCR), and progression-free survival (PFS). **Results:** A total of 249 patients were analyzed, with a median follow-up of 14.46 months. The overall ORR and DCR were 28.1% (95% CI 22.6% to 34.1%), and 80.7% (95% CI 75.3% to 85.4%), respectively. Specifically, the ORR varied from 19.7% to 34.4% and the DCR differed from 81.7% to 90.0% in disease-specific advanced gynecological cancer. The median PFS was 6.1 months and ranged from 5.6 to 10.0 months in the overall and disease-specific advanced gynecological cancer, respectively. Larger cumulative dosage of anlotinib (>700 mg) was in general associated with longer PFS in the overall and disease-specific advanced gynecological cancer. The most common adverse event related to anlotinib use was pain/arthritis (18.3%). **Conclusions:** In conclusion, anlotinib holds promise in treating patients with advanced gynecological cancer, such as cervical, endometrial, and ovarian cancer, with reasonable efficacy and tolerable safety. TROPiCS-03: A phase 2 basket study of sacituzumab govitecan (SG) in patients (pts) with metastatic solid tumors—Early analysis in pts with advanced/metastatic endometrial cancer (EC). *First Author: Alessandro Santin, Yale School of Medicine, New Haven, CT*

Background: Pts with advanced/metastatic EC who progressed on or after platinum (PT)-based and anti-PD-(L)1 therapies have a poor prognosis with limited treatment options. SG is a Trop-2-directed antibody-drug conjugate. In the open-label, phase 1/2 IMMU-132-01 basket study, SG monotherapy resulted in a 22% objective response rate (ORR) with a manageable safety profile in 18 pts with metastatic EC who had relapsed after or were refractory to ≥ 1 prior standard therapeutic regimen (Bardia et al. *Ann Oncol*. 2021). Here, we report early data in pts with advanced/ metastatic disease from the EC cohort of the TROPiCS-03 Ph2 study. **Methods:** TROPiCS-03 (NCT03964727) is a multicohort, open-label, Ph 2 basket study in pts with metastatic solid tumors. Adult pts in the EC cohort progressed after prior PT-based chemotherapy and anti-PD-(L)1 directed therapy [requirement for PD-(L)1 progression added in amendment], had ECOG PS 0-1 and creatinine clearance ≥ 30 mL/min. Pts received 10 mg/kg of SG on D1 and D8 of a 21-D cycle. The primary endpoint was ORR by investigator's assessment per RECIST 1.1. Secondary endpoints included duration of response (DOR), clinical benefit rate (CBR), and progression-free survival (PFS) per investigator's assessment, overall survival, and safety. The safety population included pts who received ≥ 1 dose of SG; the efficacy population included pts receiving ≥ 1 dose of SG and had ≥ 13 weeks of follow-up. **Results:** As of data extraction on October 11, 2022, 28 pts received ≥ 1 dose of SG. Median study follow-up was 5.3 mo (range, 0.4-13.1); median age 69 y (range, 44-83), 57% ECOG PS 1, 14% microsatellite instability high. Pts received a median of 3 prior therapies (range, 1-6); 100% received prior PT-based chemotherapy, 61% prior immunotherapy, 54% prior targeted agents, and 11% prior hormonal therapy. In 20 pts with ≥ 13 weeks of follow-up, ORR was 25% (95% CI, 8.7-49.1). Regarding best overall response, all responses were partial response (PR). In addition, stable disease (SD) was 40% and progressive disease was 15%; CBR (confirmed complete response + PR + SD ≥ 6 mo) was 35% (95% CI, 15.4-59.2). Median PFS was 5.6 mo (95% CI, 2.3 mo-not reached [NR]) and median DOR was NR (95% CI, 2.76 mo-NR; n = 5). Treatment was ongoing for 50% of pts. Grade ≥ 3 treatment-related adverse events (TRAEs) occurred in 64% of pts; most common grade ≥ 3 TRAEs were neutropenia (25%), febrile neutropenia (14%), and diarrhea (14%). Discontinuation rate due to TRAEs was 7%. While on treatment, two deaths occurred due to causes unrelated to SG. **Conclusions:** Preliminary findings showed encouraging efficacy of SG with a manageable toxicity profile in a pretreated population with advanced/metastatic EC. Safety signals were consistent with the known SG safety profile. This early analysis will be updated with the full dataset. Clinical trial information: NCT03964727. Clinical and genomic landscape of RAS pathway mutations in gynecologic cancers. *First Author: Ji Son, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We aimed to describe RAS mutations in gynecologic cancers as they relate to clinicopathologic features, subtypes, co-mutations, and implications for therapy. **Methods:** Patients with gynecologic cancers who had next-generation sequencing at our institution between Feb 2010 and Aug 2022 were included. Clinical, histopathologic, and sequencing data were collected and analyzed. Overall survival was estimated using the Kaplan-Meier model. **Results:** Of the 3310 gynecologic cancer patients tested, 522 (15.8%) harbored a RAS mutation. For patients with mutation, median age was 56 (18-87) years, with cancer types including ovarian (43.5%), endometrial (43.4%), cervical (9.2%), and vulvovaginal (2.9%). Most patients (92.2%) had recurrence. The most common histology for each cancer included endometrioid in endometrial (60.8%), low grade serous in ovarian (34.4%), adenocarcinoma in cervical (60.4%), and melanoma in vulvovaginal (66.7%). Mucinous and clear cell differentiations were overrepresented (12.5% each). Median overall survival for all RAS-mutated patients was 69 months (95%CI 59-82), which was significantly better than in wildtype control of 56 months (95%CI 52-59, $p = 0.022$). Mutations observed were in KRAS (85.8%), NRAS (12.8%), and HRAS (3.3%). The most common mutant alleles for each were KRAS G12D (34.5%), KRAS G12V (31.7%), NRAS Q61R (34.3%), and HRAS G12S (17.6%). Of note, the incidence of KRAS G12C was 5.6% (0.8% overall). The most common co-mutations for RAS were PIK3CA (35.7%), PTEN (33.3%), TP53 (32.4%), and ARID1A (20.8%). This trend held for each mutation and cancer type. Of these, 64.7% were potentially actionable alterations, including 91.1% of PIK3CA, 83.7% of PTEN, and 50.0% of ARID1A. RAS pathway targeted therapies were administered to 62 patients (57 MEK, 5 BRAF, 5 KRAS G12C, 4 SHP2). The median overall survival for these patients was significantly improved (101 months, 95%CI 78-160) compared to RAS-mutated patients who did not receive a RAS pathway inhibitor (66 months, 95%CI 53-79, HR 0.7, $p = 0.031$). Of interest, novel KRAS G12C inhibitors showed durable benefit in 3 ovarian (high grade serous, low grade serous, clear cell) and 2 endometrial (mixed endometrioid, clear cell; mixed endometrioid, serous, mucinous) cancers with a clinical benefit rate of 100%, duration of objective response of 22 months, and ongoing responses at 5 and 16 months. **Conclusions:** Gynecologic cancers with RAS mutations have distinct histopathologic distribution and portend improved overall survival. The most commonly actionable co-mutations were PIK3CA, PTEN, and ARID1A, which may aid in combination therapy design. RAS pathway targeted therapy is associated with improved overall survival in this cohort and should be considered. Research Sponsor: None.

UPGRADE-A: Phase 1 expansion trial of the NaPi2b-directed antibody drug conjugate (ADC) upifitamb rilsodotin (UpRi) in combination with carboplatin in patients with high-grade serous ovarian cancer (HGSOC). *First Author: John L. Hays, Wexner Medical Center and The James Cancer Hospital, Ohio State University, Columbus, OH*

Background: UpRi is a first in class NaPi2b ADC with a novel scaffold-linker-payload that is designed to enable high drug-to-antibody ratio and controlled bystander effect. NaPi2b is a sodium-dependent phosphate transporter protein broadly expressed in HGSOC, with limited expression in healthy tissues. Interim data from a previous phase 1b study of heavily pretreated HGSOC patients reported clinical activity and tolerability data for UpRi as a monotherapy, most notably in patients with NaPi2b positive tumors (TPS ≥ 75). Based on these emerging single-agent safety and efficacy data, it is hypothesized that UpRi in combination with carboplatin may provide additional clinical benefit for patients in earlier lines of treatment. UPGRADE-A is a Phase 1 dose escalation (DES) and expansion (EXP) study to evaluate UpRi and carboplatin followed by UpRi maintenance in recurrent platinum-sensitive HGSOC. The DES portion of UPGRADE-A has completed enrollment, and the EXP portion is ongoing. **Methods:** The EXP cohort of UPGRADE-A is enrolling patients with recurrent or metastatic PSOC (defined as having achieved a PR or CR to 4+ cycles in their last platinum containing regimen) who have received 1-3 prior lines of therapy. Up to 1 non-platinum based prior chemotherapy regimen is allowed, provided it is not the most recent line of chemotherapy. The primary objective of EXP is feasibility of UpRi + carboplatin at the RP2D, defined as 60% of patients completing at least 4 cycles of UpRi + carboplatin without discontinuing treatment early for reasons other than disease progression. Secondary objectives include the safety/tolerability, pharmacokinetics, and preliminary anti-neoplastic activity of the UpRi + carboplatin combination. Tumor tissue must be provided (archival or fresh sample) for retrospective NaPi2b assessment. UpRi 30mg/m² + carboplatin (AUC 5) will be administered IV every 28 days for up to 6 cycles, followed by UpRi maintenance monotherapy until disease progression or unacceptable toxicity. Up to 30 patients are expected to enroll in EXP, and the trial is currently open for enrollment. NCT04907968. Clinical trial information: NCT04907968. Research Sponsor: Mersana Therapeutics.

ARTISTRY-7: A phase 3, multicenter study of nemvaleukin alfa in combination with pembrolizumab versus chemotherapy in patients with platinum-resistant epithelial ovarian, fallopian tube, or primary peritoneal cancer (GOG-3063; ENGOT-OV68). *First Author: Thomas J. Herzog, College of Medicine, University of Cincinnati, Cincinnati, OH*

Background: ARTISTRY-7 will evaluate the novel engineered cytokine nemvaleukin alfa (nemvaleukin, ALKS 4230) in patients (pts) with gynecologic cancers. Ovarian cancer (OC) is the 8th most common cause of cancer mortality in women. OC is an area of high unmet need, as many pts become resistant/refractory to frontline platinum-based chemotherapy. In the platinum-resistant setting, standard of care chemotherapy and anti-PD-1 therapy in clinical trials have modest response rates ranging from ~6% to 20% and ~7% to 12%, respectively. Nemvaleukin was designed to selectively bind to the intermediate-affinity interleukin-2 (IL-2) receptor, preferentially activating antitumor CD8⁺ T and natural killer cells with minimal regulatory T cell expansion. This selectivity may provide enhanced tumor killing and improved safety/tolerability vs high-dose IL-2. In clinical studies, nemvaleukin, as monotherapy and in combination with pembrolizumab, has shown clinical benefit in multiple tumor types, including OC. In ARTISTRY-1, in 14 evaluable patients with OC, 4 responses were observed with nemvaleukin + pembrolizumab, including 2 complete responses and 2 partial responses (ORR 28.6%; DCR 71.4%; median DOR 53.4 wks). Nemvaleukin monotherapy activity was also observed (6 melanoma and 4 renal cell carcinoma responses). **Methods:** ARTISTRY-7 (NCT05092360) is an ongoing phase 3, multicenter, randomized study of nemvaleukin and/or pembrolizumab vs chemotherapy. Eligible pts are women (≥ 18 y) with histologically confirmed epithelial OC (high-grade serous, endometrioid, clear cell), fallopian tube cancer, or primary peritoneal cancer. Pts must have had ≥ 1 prior line of systemic therapy (platinum-sensitive setting), ≤ 5 prior lines (platinum-resistant setting), and prior bevacizumab, with radiographic progression on most recent therapy. Pts with primary platinum-refractory disease (progression on first-line platinum therapy) or primary platinum resistance (progression < 3 months after first-line platinum therapy completion) are excluded. Approximately 376 pts will be randomized (3:1:1:3) to receive nemvaleukin 6 µg/kg IV (days 1-5) + pembrolizumab 200 mg IV (day 1) of each 21-day cycle, pembrolizumab or nemvaleukin monotherapy, or chemotherapy, and stratified by PD-L1 status, histologic subtype, and chemotherapy (paclitaxel vs other). Pts will continue treatment until disease progression or intolerable toxicity (maximum 35 pembrolizumab cycles; nemvaleukin can be continued). The primary endpoint is investigator-assessed PFS (RECIST v1.1) in the nemvaleukin + pembrolizumab vs chemotherapy arms. Secondary/exploratory endpoints include overall survival, other antitumor measures, safety, health-related quality of life, and PK/PD effects. Clinical trial information: NCT05092360. Research Sponsor: Alkermes, Inc.

UP-NEXT (GOG-3049/ENGOT-Ov71-NSGO-CTU): A study of upitfiamab rilsodotin (UpRi), a NaPi2b-directed antibody drug conjugate (ADC), in platinum-sensitive recurrent ovarian cancer. *First Author: Debra L. Richardson, Stephenson Cancer Center/University of Oklahoma Health Sciences Center and Sarah Cannon Research Institute, Oklahoma City, OK*

Background: UpRi is a first-in-class NaPi2b-targeting ADC with a novel scaffold-linker-payload that enables high drug-to-antibody ratio and controlled bystander effect. NaPi2b is a sodium-dependent phosphate transporter protein broadly expressed in high-grade serous ovarian cancer (HGSOC) with limited expression in healthy tissues. It is estimated that the majority of HGSOCs have high NaPi2b expression. Studies are being conducted to evaluate UpRi safety and efficacy in platinum-resistant ovarian cancer (PROC), but there remains an unmet need in the maintenance setting for patients with recurrent platinum-sensitive ovarian cancer (PSOC), particularly for patients who have received prior maintenance therapy, are at high-risk of early relapse, and where close monitoring after platinum-based therapy would generally be considered preferable. **Methods:** UP-NEXT is a Phase 3 study evaluating UpRi monotherapy as post-platinum maintenance treatment in recurrent PSOC, enrolling patients with NaPi2b-positive tumors (defined as TPS ≥ 75). Patients must have received 2-4 prior lines of platinum containing chemotherapy, achieved a partial or complete response in their penultimate platinum regimen, and progressed > 6 months after completion of the last dose of platinum in the penultimate regimen. Patients may be enrolled if their best response to the last line of treatment is no evidence of disease, complete or partial response, or stable disease. Prior PARPi treatment is required for patients with a BRCA mutation. Patients who received bevacizumab in combination with their most recent platinum containing regimen are excluded. Patients are randomized 2:1 to UpRi 30mg/m² or placebo, given IV Q4W. The primary endpoint is PFS assessed by BICR, with key secondary endpoint of OS. UP-NEXT is conducted in collaboration with GOG(3049) and ENGOT(Ov71-NSGO-CTU). Approximately 350 patients will be enrolled globally. NCT05329545. Clinical trial information: NCT05329545. Research Sponsor: Mersana Therapeutics.

A randomized trial of olaparib, durvalumab, and cancer vaccine, UV1, as maintenance therapy in patients with BRCAwt with recurrent ovarian cancer: ENGOT-OV56/NSGO-CTU-DOVACC trial. *First Author: Mansoor Raza Mirza, NSGO-CTU & Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark*

Background: Most ovarian cancers (OC) are diagnosed at an advanced stage and despite initial therapy, the disease will often relapse and require further treatment. Thus, there is a need for novel therapeutic options. PARP inhibitors lead to increasing tumour neoantigen, and modulation of the tumour microenvironment, which may facilitate a more profound antitumour immune response. UV1 is a therapeutic cancer vaccine directed against telomerase. Since telomerase is an essential enzyme and universally expressed by most tumor cells, it represents a unique cancer antigen as a basis for immunotherapy (IO). The rationale for integrating immunotherapy as maintenance therapy following chemotherapy is based on preclinical studies which have shown that chemotherapy induces immunogenic cell death leading to increased recognition of the tumor by the immune system. The proposed study is evaluating the use of the therapeutic cancer vaccine UV1 in combination with olaparib and the PD-L1 inhibitor, durvalumab as maintenance therapy after response to platinum-based chemotherapy. **Methods:** The primary objective is to demonstrate efficacy of UV1-olaparib-durvalumab combination maintenance therapy against olaparib in maintenance after platinum combination therapy for BRCAwt patients with relapsed ovarian cancer. Key eligibility criteria include: histologically confirmed, platinum sensitive recurrent OC in response to last platinum-containing chemotherapy, BRCAwt. Patients may be previously treated with PARPi, however prior IO is not permitted. Patients are stratified by HRD status and previous use of PARPi. 184 patients are randomized to three arms (1:1:2): arm A: olaparib single agent, arm B: olaparib-durvalumab and arm C: olaparib, durvalumab-UV1. Duration of therapy: olaparib until progression of disease; durvalumab for 24 months; intradermal UV1, 8 doses within 5 months. Intradermal sargramostim is used as vaccine adjuvant. Primary endpoint is progression-free survival (PFS) of arm C versus arm A. Key secondary endpoints include PFS arm B versus C, patient reported outcomes, and overall survival. This NSGO-CTU sponsored trial is enrolling patients in 11 countries. The following cooperative groups are participating: NSGO-CTU (DK, FIN, NOR, SWE, LTU), BGOG (BE), HeGOG (GRC, CYP), NOGGO (DE), AGO-A (AUT) & DGOG (NL). Clinical trial information: NCT04742075. Research Sponsor: Ultimovacs; Astra Zeneca.

CRI-CCTG-0003/IND.240: An immunotherapy platform study in platinum-resistant high grade serous ovarian cancer (IPROC). *First Author: Helen Mackay, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Identifying new treatments for patients with platinum-resistant high grade serous ovarian cancer (HGSC) is a priority. Although several biological features of HGSC suggest inherent immunogenicity, immunotherapy has had limited efficacy to date. IPROC is an adaptive platform trial designed to evaluate multiple immunotherapy combinations selected and informed by an expert panel. IPROC accommodates both biomarker-agnostic and biomarker-directed combinations. Protocol and sub study specific translational studies are conducted on archived diagnostic tissue and serial prospective blood and tumor sample collection. **Methods:** IPROC is an open-label, multi center, phase II platform trial. Eligibility includes HGSC histology; progression within 6 months of the last platinum regimen; <1 prior line of chemotherapy for platinum resistant disease (unlimited prior lines for platinum sensitive); prior treatment with immunotherapy allowed (provided not discontinued for toxicity), ECOG 0/1. Patients must be willing and able to undergo study procedures. The primary endpoint is ORR (RECIST1.1). Secondary endpoints include iRECIST ORR, RECIST/iRECIST progression free and overall survival and safety. Exploratory objectives include whole exome sequencing and immune profiling of tumor and blood samples to identify biomarkers and new immunotherapy strategies/combinations for future evaluation. Tumor biopsy occurs at baseline, cycle 2 and progression (voluntary) with blood and plasma collected at each cycle and on progression. All sub studies use Simon 2-stage design with 10 patients (pts) enrolled in each stage. At the end of stage 1, in the absence of response, a modified cohort based on biomarker selection may be created through protocol amendment. In each sub study a null hypothesis that the objective response rate (ORR) is $\leq 5\%$ is tested against a one-sided alternative that the ORR is $\geq 25\%$. A combination would be accepted as active if $\geq 4/20$ pts respond with $\alpha=0.02$ and power of 0.76. As of January 19, 2023, 2 sub studies are open and 12 patients have accrued. Sub study A is evaluating the combination of durvalumab and BA3011, a conditionally active anti-AXL humanized monoclonal antibody (IgG1) conjugated to monomethyl auristatin E (MMAE) in AXL overexpressing HGSC. Sub study B is evaluating durvalumab plus BA3021, a CAB anti-receptor tyrosine kinase orphan receptor 2 (ROR2) humanized monoclonal antibody (IgG1) conjugated to MMAE in ROR2 overexpressing HGSC. Further sub studies are planned (NCT04918186). Clinical trial information: NCT04918186. Research Sponsor: Cancer Research Institute.

A phase 1/2 open-label, multicenter, dose escalation and expansion study of AVB-001, an intraperitoneally administered, cell-generated, human IL-2 immunotherapy in patients with platinum-resistant, high-grade, serous adenocarcinoma of the ovary, primary peritoneum, or fallopian tube. *First Author: Shannon Neville Westin, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The potential of cytokines as cancer therapeutics has been limited by short half-life and severe adverse effects associated with high systemic exposure when delivered intravenously. Many strategies are being explored to overcome these limitations. A locoregional delivery approach to achieve high sustained local concentrations in the tumor microenvironment with minimal systemic exposure could widen the therapeutic window. Early experience with free recombinant human IL2 (rhIL-2) given intraperitoneally (IP) showed meaningful clinical activity in relapsed ovarian cancer. Still, the cumbersome delivery procedure requiring indwelling catheters and need for high volume IP infusions leading to frequent complications and poor patient compliance limited the utility of this approach. To overcome these shortcomings, we developed a clinically translatable localized delivery LOCocyte platform composed of polymer encapsulated allogeneic epithelial cells engineered to produce immune effector molecules for local delivery with temporal regulation. The first product, AVB-001, produces native hIL-2, for the treatment of ovarian cancer and other peritoneal malignancies. IP AVB-001 inhibited tumor growth and improved survival in an *in vivo* ID8 ovarian cancer murine model. Sustained IL-2 production with well tolerated high IP concentrations were achieved, with $>100\times$ differential concentration vs. systemic blood levels in both mice and non-human primates. Strong local and systemic immune activating effects, optimized T cell profile and immune memory were observed without concomitant increase of T regs. The first in human study of AVB-001 in patients with advanced ovarian cancer (NCT05538624) is described here. **Methods:** Part 1 dose escalation exploring 4 ascending dose levels (capsules target production of 0.6, 1.2, 2.4, and 3.6 ug hIL2/kg/d) with a Bayesian Optimal Interval 3+3 design, in patients with recurrent high grade serous adenocarcinoma of the ovary, primary peritoneum, or fallopian tube. A minimum of 12 and up to 24 patients will be enrolled to receive one dose of AVB-001 administered IP. The primary objective is to evaluate safety (Incidence and severity of adverse events per NCI CTCAE v5.0), tolerability, and feasibility of delivering AVB-001 IP, and establish the RP2D. Secondary objectives include assessment of antitumor activity (RECIST v1.1, iRECIST), pharmacokinetics, and pharmacodynamic correlates of immune activation. Part 2 will enroll 20 patients at the RP2D with efficacy as the primary objective. This multicenter study will be conducted at 5 sites, currently two sites are open. The first patient was dosed in December 2022. Recruitment in dose level 1 cohort continues. Clinical trial information: NCT05538624. Research Sponsor: Avenge Bio.

TEDOVA/GINECO-OV244b/ENGOT-ov58 trial: Neo-epitope based vaccine OSE2101 alone or in combination with pembrolizumab vs best supportive care (BSC) as maintenance in platinum-sensitive recurrent ovarian cancer with disease control after platinum. *First Author: Alexandra Leary, Gustave-Roussy Cancer Campus, Villejuif, and GINECO, Paris, France*

Background: Besides PARP inhibitors and bevacizumab, there are no approved maintenance therapies after platinum based chemotherapy for patients with a platinum sensitive relapsed epithelial ovarian cancer (OC). Immune checkpoint inhibitors (ICI) as single agents have limited activity in OC. One attractive strategy is to turn OC from immunogenic "cold" to "hot" tumors via vaccination with tumor-associated antigens (TAAs). OSE2101 is a multiple-neoepitope vaccine restricted to HLA-A*02-positive patients (45% of OC patients) targeting 5 TAAs: TP53, MAGE2, MAGE3, CEA and HER2. These neo-epitopes are modified to increase both major histocompatibility complex and the T cell receptor binding affinity. The proof of concept for this approach was recently demonstrated with OSE2101 improving overall survival in a phase III trial in lung cancer progressing after ICI (Besse *et al.* 2021¹). The combination of OSE2101 with an ICI may most effectively harness anti-tumor immunity. **Methods:** TEDOVA is an international randomized open-label, phase II trial evaluating the benefit of maintenance by OSE2101 alone or in combination with PD1 inhibition (pembrolizumab) after platinum based chemotherapy in relapsed OC, previously treated with bevacizumab (if eligible) and a PARP inhibitor (if eligible). Patients (N=180) with CR/PR/SD at the end of chemotherapy are randomized (1:1:2) to: Observation/BSC (Arm A), OSE2101 alone (Arm B), or OSE2101 in combination with pembrolizumab (Arm C). Experimental treatments are continued until progression, or intolerance, for up to 2 years. The primary endpoint is progression-free survival (PFS). Secondary endpoints include overall response rate, safety, time to subsequent first or second treatment (TTST-1, TTST-2) and overall survival. 180 HLA-A*02 positive patients will be randomized. HLA-A*02 negative patients will be followed in a separate observational cohort. The sample size is calculated to provide 90% power to detect an improvement in PFS for Arm C vs Arm A with a HR of 0.57. Three one-sided Log-rank tests will be considered in a pre-defined sequence: H1: C (OSE2101+pembrolizumab) vs A (BSC); H2: C (OSE2101+pembrolizumab) vs B (OSE2101) and H3: B vs A. The type I error will be $\alpha=5\%$. The type II error will be $\beta=10\%$. Tests will be one-sided. Status: The TEDOVA/GINECO-OV244b/ENGOT-ov58 trial is currently recruiting. Clinical trial information NCT04713514. 1. Besse B, Garcia MR, Cobo MA, Quiox E, Madroszyk A, Felip E, et al. LBA47 - Activity of OSE-2101 in HLA-A2+ non-small cell lung cancer (NSCLC) patients after failure to immune checkpoint inhibitors (IO): Final results of phase III Atalante-1 randomised trial. *Annals of Oncology* 2021;32(suppl_5) : S1283-S1346. Uncovering mechanisms of response of pembrolizumab and lenvatinib for the treatment of platinum-resistant high grade serous ovarian cancer. *First Author: Jeffrey How, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite initial response to conventional platinum-containing therapies, the majority of high grade serous ovarian cancer (HGSOC) patients will eventually develop treatment resistance. Despite interest for immune checkpoint inhibitor alternatives, pembrolizumab monotherapy is poor with objective response rates (ORR) ranging between 4.1 - 10%. Poor response may be linked to higher expression of immunosuppressive factors (e.g. VEGF, TGF- β) in the tumor microenvironment (TME). In an immunosuppressive TME, monotherapy with PD-1 inhibitors can induce T-cell dysfunction and apoptosis, leading to innate resistance to pembrolizumab. Preclinical studies of other tumors have demonstrated that lenvatinib can improve T-cell activation and reduce the tumor-associated macrophage population and TGF- β /VEGF/FGF-signaling. In HGSOC, mechanisms of resistance to pembrolizumab and whether this resistance can be overcome by the addition of lenvatinib remain unknown. The objective of this investigation is to uncover the immunologic basis and synergistic mechanisms of action underlying clinical efficacy of pembrolizumab and lenvatinib in HGSOC. Specifically, we will evaluate the dynamic changes in proliferative and dysfunctional T-cell populations in the peritoneal TME (p-TME) of HGSOC patients receiving monotherapy with pembrolizumab or lenvatinib followed by combination therapy. **Methods:** All patients will receive a cycle of monotherapy (pembrolizumab 200 mg IV every 3 weeks or lenvatinib 20 mg po daily) followed by combination therapy (both) up to 35 cycles. Enrolled patients will receive intra-peritoneal port placement for serial peritoneal fluid evaluations (cycle 0 day 1, cycle 0 day 8, cycle 1 day 8, cycle 2 day 1, cycle 3 day 1, cycle 5 day 1, then day 1 of every 3rd cycle) for multichannel flow cytometry and single-cell RNA sequencing. Our primary translational objective is to estimate both the individual and combined effects of pembrolizumab and lenvatinib on T-cell dysfunction (PD1+ CD38+) and proliferation (ki67+) in the p-TME using multichannel flow cytometry on the peritoneal fluid. Secondary clinical objective is ORR. Secondary translational objectives include individual and synergistic effects of monotherapy and combination therapy on T-cell effector function, T-cell memory, and myeloid cell subpopulations. Exploratory objectives include evaluating the dynamic changes in immune and non-immune cells in the p-TME for exceptional responders and non-responders using single cell RNA sequencing. Key eligibility criteria include 1) histologic diagnosis of high grade serous ovarian, peritoneal, or fallopian tube cancer 2) platinum-resistant disease and 3) no prior lenvatinib therapy. The trial is open with 10 patients enrolled at the time of submission. Clinical trial information: NCT05114421. Research Sponsor: Merck.

Oregovomab and non-platinum chemotherapy in PARP inhibitor-resistant ovarian, fallopian tube, or primary peritoneal cancer patients not candidates for platinum retreatment: A multicenter, two-cohort, single-arm phase 2 trial (OPERA/KGOG 3065/APGOT-OV6). *First Author: JUNG-YUN LEE, Yonsei University College of Medicine, Seoul, South Korea*

Background: As PARP inhibitors (PARPi) are becoming the standard of care option for epithelial ovarian cancer (EOC), PARPi-resistant patients are increasing. Moreover, non-platinum single agent chemotherapy in these patients has been found to elicit poor survival outcomes. Oregovomab, an investigational murine monoclonal antibody directed against CA-125, has shown promising efficacy in the previous phase II study of combinational front-line adjuvant chemotherapy. The aim of the present study is to investigate the efficacy of oregovomab + non-platinum-based chemotherapy in PARPi-resistant EOC patients not suitable for platinum-based therapy. **Methods:** OEPRA is a multicenter, investigator-initiated, two-cohort, single-arm phase II trial recruiting PARPi-resistant EOC patients from five sites in South Korea. The trial includes patients with recurrent EOC who have experienced disease progression despite treatment with PARPi and who have either received bevacizumab or are not eligible for bevacizumab treatment. Mucinous histology type is excluded. Patients who have received one to three prior lines of chemotherapy are to be assigned to Cohort 1 (oregovomab 2 mg [C1,2,3,5,7 for five doses] + pegylated liposomal doxorubicin [PLD] 40 mg/m² q4w, n = 28), while patients who have received more than three prior lines of chemotherapy are to be assigned to Cohort 2 (oregovomab 2 mg [C1,2,3,5,7 for five doses] + weekly paclitaxel 80 mg/m² [D1,8,15 q4w], n = 28). A total of 56 patients will be recruited and treated with oregovomab + PLD / weekly paclitaxel until disease progression, unacceptable toxicity, or withdrawal of patient consent. The primary endpoint is objective response rate by RECIST 1.1. Accrual is expected to be completed in 2023, followed by presentation of results in 2024. The study is registered with ClinicalTrials.gov (NCT05407584). Clinical trial information: NCT05407584. Research Sponsor: CANARIABIO Inc.; Yonsei University.

First trial of chemotherapy de-escalation in ovarian cancer (OC): A phase III randomized, open label study of niraparib maintenance after carboplatin and paclitaxel in patients with optimally debulked advanced (homologous recombination deficient) HRD high-grade ovarian cancer in first line therapy (N-PLUS/NOGGO-ov53/ENGOT-ov62). *First Author: Elena Ioana Braicu, Charité-Universitätsmedizin Berlin, Department of Gynecology with Center for Oncological Surgery, Campus Virchow Klinikum and North-Eastern German Society of Gynaecological Oncology (NOGGO) and Stanford University, Berlin, Germany*

Background: OC is the fifth most common cause of death from cancer in women. More than 70% of the patients are diagnosed with advanced disease and less than 40% of women with OC are cured. Currently, the standard therapy in HRD OC is surgical debulking followed by 6 cycles of chemotherapy with subsequent maintenance treatment with poly ADP ribose polymerase (PARP) inhibitors. Within the last decades, no focus was set on the benefits of fewer cycles of chemotherapy, even though there is evidence for comparable efficacy and less toxicity in comparison to more cycles. Chemotherapies are usually associated with side effects, which can be severe and even lead to therapy discontinuation. The data available about the needed number of chemotherapy cycles is weak, especially in the context of PARP inhibition. Furthermore, patients with stage III/IV with optimal cytoreduction are underrepresented in previous studies. In the N-PLUS trial, we hypothesize that recurrence-free survival (RFS) in patients receiving 3 cycles of chemotherapy followed by maintenance with niraparib is not inferior to 6 cycles of chemotherapy followed by niraparib in advanced HRD high-grade OC patients with no visible disease following primary tumor debulking. **Methods:** In this multicenter, randomized, open-label study 650 patients with advanced HRD high-grade OC with no residual tumor mass following primary tumor debulking will be enrolled. Patients will be randomized 1:1 to receive either 3 cycles carboplatin + paclitaxel and maintenance therapy with niraparib (Arm A) or 6 cycles carboplatin + paclitaxel and maintenance therapy with niraparib (Arm B) for a maximum of 36 months. Randomization will be performed according to the results of the NGS analysis and stratified either to BRCAm/LOH-independent or BRCAwt/LOHhigh, FIGO stage III vs. IV, and participating countries. The primary endpoint will be RFS, secondary endpoints will be OS, TFST, TWIST, PFS2, Quality of Life and safety assessments. Clinical trial information: NCT05460000. Research Sponsor: GSK.

Poster Session

GLORIOSA: A randomized, open-label, phase 3 study of mirvetuximab soravtansine with bevacizumab vs. bevacizumab as maintenance in platinum-sensitive ovarian, fallopian tube, or primary peritoneal cancer. *First Author: David M. O'Malley, James Gynecologic Oncology Mill Run, Ohio State University, Columbus, OH*

Background: Elevated folate receptor-alpha (FR α) expression is a characteristic of epithelial ovarian cancer (EOC), thereby providing a rational target for antibody drug conjugate (ADC) development in ovarian cancer. Mirvetuximab soravtansine (MIRV) is an ADC comprising a FR α -binding antibody, cleavable linker, and the maytansinoid DM4, a potent tubulin-targeting agent that has received accelerated approval for patients with FR α positive platinum resistant ovarian cancer. MIRV in combination with BEV has demonstrated clinically meaningful activity, along with acceptable tolerability, in patients with FR α expressing ovarian cancer.¹ **Methods:** GLORIOSA is a randomized, open-label, phase 3 study designed to evaluate the efficacy of in combination with bevacizumab compared with bevacizumab alone as maintenance for patients with FR α -positive recurrent platinum-sensitive epithelial ovarian, fallopian tube, or peritoneal cancers who have not progressed after second line platinum-based chemotherapy plus bevacizumab (which may be given on protocol for patients with high FR α tumor expression). Confirmation of high FR α positivity by immunohistochemistry using the Ventana FOLR1 CDx Assay (high expression; $\geq$ 75% of viable tumor cells staining at 2+ intensity) and 1 prior line of therapy is required for inclusion. GLORIOSA is designed to randomize 418 patients, 1:1 receiving intravenous MIRV at a dose of 6 mg/kg adjusted ideal body weight plus bevacizumab 15mg/kg every 3 weeks or receiving bevacizumab 15mg/kg every 3 weeks until disease progression or unacceptable toxicity. Radiological assessments will be conducted every 9 weeks ($\pm$ 2 weeks) for 72 weeks, and subsequently every 18 weeks ($\pm$ 3 weeks) until progressive disease (PD), death, the start of new anticancer therapy, or withdrawal of consent from the study (whichever occurs first). The primary efficacy endpoint is progression-free survival by investigator and will also be assessed as a sensitivity analysis. The secondary endpoints include objective response rate, quality of life, overall survival, and safety and tolerability. GLORIOSA is a global study that opened for enrollment in December 2022. Exactis-03: A phase I trial of the combination of olaparib and navitoclax in women with high grade serous ovarian cancer and triple negative breast cancer. *First Author: Helen Mackay, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Identifying new therapeutic options for patients (pts) with high grade serous ovarian cancer (HGSC) and triple negative breast cancer (TNBC) is a priority. For pts with pathogenic variants in *BRCA*, the PARP inhibitor (PARPi) olaparib is used to treat TNBC and as maintenance for HGSC. PARPi can induce a senescence-like phenotype in cancer cells with cell survival dependent on anti-apoptotic proteins. The intrinsic apoptotic pathway is regulated by the Bcl-2 family composed of anti-apoptotic proteins (including Bcl-2, Bcl-xL), pro-apoptotic effectors and the pro-apoptotic BH3-only proteins. Increased expression of Bcl-xL occurs in 88% of HGSC. Olaparib and navitoclax, a Bcl-2/Bcl-xL inhibitor, are synergistic in pre clinical models of HGSC and TNBC. Exactis-03 investigates targeting, olaparib-induced senescence as a treatment strategy for pts with HGSC and TNBC. **Methods:** Exactis-03 is a multi-centre phase I trial determining if olaparib can be safely combined with navitoclax in pts with TNBC who have somatic or germline mutations in *BRCA1/2* or *PALB2* and pts with recurrent HGSC who have progressed ≥ 6 months since their last platinum based chemotherapy. Additional eligibility criteria include: ≥ 3 prior lines of treatment for TNBC (no limit for HGSC); for pts with HGSC prior PARPi is allowed provided there was no progression on or ≤ 6 months since discontinuation of the PARPi; ECOG PS ≤ 2 ; ability to absorb study medication and pts must be willing and able to undergo study related procedures. The primary endpoint is identification of the recommended phase II dose (RP2D) of olaparib combined with navitoclax. Olaparib 200mg bid is administered alone for the first 2 weeks. Tumor biopsies will be performed at baseline and on day 7-12 (prior to navitoclax) to evaluate senescence and apoptosis biomarkers and to create 3D organoids and ex vivo microdissected tumor (MDT) models for functional assessment of drug response. Navitoclax is dose escalated with a fixed dose of olaparib in 28-day cycles with 3 pts initially treated at each dose level. If no dose limiting toxicity (DLT) is observed, the dose level will be escalated until $\geq 1/3$ or $\geq 2/6$ patients experience DLT. The RP2D will be defined as the dose level below the one where $\geq 1/3$ or $\geq 2/6$ patients experience DLT. The 2-week lead-in with olaparib alone and one full cycle of the combination (navitoclax/olaparib) must be completed before dose escalation is permitted. Blood samples are collected for pharmacokinetics and serial evaluation of plasma biomarkers. There is an optional tumor biopsy on progression. Exploratory objectives include determining levels of pro- and anti- apoptotic proteins in biopsy samples and evaluation of cell fate decision biomarkers in biopsy tissue and blood (senescence secretome). Patient-derived organoids and ex vivo MDT will be used to explore drug response and sequencing (NCT05358639). Clinical trial information: NCT05358639. Research Sponsor: Grant from Exactis (Networks of Centres of Excellence (NCE), Canadian Institutes of Health Research (CIHR), Natural Sciences and Engineering Research Council of Canada (NSERC), Social Sciences and Humanities Research Council via Exactis PMT; Philanthropic Donation; Ovarian Cancer Canada (Federal).

FLORA-5/GOG3035: Chemo-immunotherapy (paclitaxel-carboplatin-oregovomab [PCO] vs chemotherapy (paclitaxel-carboplatin-placebo [PCP]) as front-line treatment in patients with advanced epithelial ovarian cancer (EOC)—Phase III, double blind, placebo controlled, global, multinational study. *First Author: Lisa Marie Barroilhet, University of Wisconsin, Madison, WI*

Background: Oregovomab, a murine IgGκ1 monoclonal antibody with high affinity binding to tumor associated antigen CA125, renders the target antigen CA125 more immunogenic or “neoantigen-like”. The proposed mechanism action is enhanced antigen processing and presentation to specific T cells. This phenomenon is hypothesized to bypass tumor-associated immune suppression when oregovomab is combined with chemotherapy. In a randomized phase II study, oregovomab, in combination with paclitaxel and carboplatin, (PC) induced tumor immunity and demonstrated significant improvement in median PFS (41.8 months/m) PCO vs 12.2 m PC, HR 0.46, $p = 0.0027$) and median OS (N.E. PCO vs 43.2 m PCP, HR 0.35, $p = 0.043$) in patients with previously untreated EOC. Patients receiving adjuvant chemotherapy were included. Oregovomab combined with PC had a favorable toxicity profile. FLORA-5/GOG3035, the definitive confirmatory global registration trial, is currently recruiting patients in the front-line setting. **Methods:** In this phase 3, multicenter, double-blind, placebo-controlled trial, optimally debulked patients with FIGO III/IV EOC and serum CA125 ≥ 50 U/ml receiving adjuvant (Cohort 1) or patients receiving neoadjuvant chemotherapy post-interval cytoreductive surgery (Cohort 2) will be randomized to PC + oregovomab or placebo (PCO vs. PCP). Patients with germline *BRCA1/2* mutations are excluded. Chemotherapy will be administered every 3 weeks in both cohorts. Oregovomab/placebo is administered simultaneously at cycles 1, 3, and 5 of chemotherapy with an additional dose at 12 weeks following cycle 5 in Cohort 1. Neoadjuvant patients will be administered oregovomab/placebo after debulking surgery at cycles 4 and 6 with two additional doses at 6- and 18-weeks following cycle 6 in Cohort 2. No other front-line maintenance therapy is permitted. The primary objective is PFS determined by RECIST 1.1. Cohort 1 will recruit 372 patients with a 90% power to detect a difference with an alpha of 0.025 and a hazard ratio of 0.65 when 252 PFS events have been observed. Cohort 2 will be analyzed separately recruiting 232 patients with a 90% power to detect a difference with an alpha of 0.025 and a hazard ratio of 0.60 when 165 PFS events have been observed. An interim futility analysis will be performed. Secondary objectives include OS, frequency and severity of AEs, and QoL. Exploratory objectives include iRECIST, TFS, TSST, PFS2, and evaluation of correlative biomarkers. The study is actively enrolling in the US, Canada, Belgium, Italy, Spain, Czech Republic, Hungary, Poland Korea, Taiwan, Mexico Argentina, India and Chile. 518 of the planned 602 patients were enrolled at the time of submission. Clinical trial information: NCT04498117. Research Sponsor: CanariaBio, Inc.

First-in-human phase 1/2 study of ubamatamab, a MUC16xCD3 bispecific antibody, administered alone or in combination with cemiplimab in patients with recurrent ovarian cancer. *First Author: Kathleen N. Moore, Stephenson Cancer Center, University of Oklahoma Health Sciences Center/Sarah Cannon Research Institute, Oklahoma City, OK*

Background: Mucin-16 is a cell surface glycoprotein that is overexpressed in epithelial ovarian cancer (OC). Ubamatamab (REGN4018) is a mucin-16 x cluster of differentiation 3 (MUC16xCD3) bispecific antibody that promotes T cell-mediated cytotoxicity by facilitating contact between cancer cells and T cells. In mouse model studies, ubamatamab demonstrated dose-dependent antitumor activity against MUC16-expressing OC tumor cells.¹ Cemiplimab is an anti-programmed cell death-1 monoclonal antibody. In a Phase 1 study (NCT03564340) in patients with recurrent OC, ubamatamab monotherapy demonstrated an acceptable safety profile, durable clinical activity across a range of doses between 20 mg and 800 mg intravenous (IV) weekly (as measured by RECIST and cancer antigen 125 [CA-125] response rates), and linear pharmacokinetics up to 800 mg IV weekly.² These clinical data support further evaluation of a once every 3-week (Q3W) regimen of ubamatamab alone and in combination with cemiplimab. The study is currently recruiting patients to combination dose escalation, monotherapy dose expansion, and the randomized Phase 2 cohort. **Methods:** In Phase 2, up to 150 patients with advanced platinum-resistant OC and elevated serum cancer antigen-125 will be randomized to three arms (1:1:1) to receive ubamatamab 250 mg IV Q3W or 800 mg IV Q3W as monotherapy, or ubamatamab 250 mg IV Q3W in combination with cemiplimab 350 mg Q3W. All arms will include weekly step-up dosing of ubamatamab (1 mg week 1, 20 mg week 2, and full dose weeks 3 and 4) to limit risk of cytokine release syndrome prior to proceeding to Q3W dosing. Expansion cohorts will use a Simon 2-stage study design, with an interim analysis after the first 20 patients. Any arm with ≥ 3 objective responses will be expanded to 50 patients. The primary objective of the dose expansion phase is to assess the preliminary efficacy of ubamatamab as monotherapy or in combination with cemiplimab, separately by cohort. Secondary objectives include characterization of the safety profile by cohort, and the pharmacokinetics of ubamatamab alone or in combination with cemiplimab, as well as patient-reported outcomes for all cohorts. In this dose expansion phase the primary endpoint will be the objective response rate for each arm as defined by RECIST 1.1 criteria. Secondary endpoints include evaluation of duration of response and progression-free survival as well as further evaluation of safety and pharmacokinetics. Exploratory endpoints include evaluation of baseline tumor MUC16 immunohistochemistry expression and other biomarkers as predictors of response. The impact of ubamatamab on quality of life and physical functioning will also be assessed. References: 1. A phase II, randomized, double-blind study of the use of rucaparib vs placebo maintenance therapy in metastatic and recurrent endometrial cancer. *First Author: Bradley Corr, University of Colorado Cancer Center, Aurora, CO*

Background: There are currently no approved maintenance therapies for metastatic and recurrent endometrial cancer, which carries a dismal long-term prognosis. The PARP inhibitor drug class has demonstrated significant clinical benefit as a maintenance therapy for patients with germline/somatic *BRCA* mutations or homologous recombination deficiency (HRD) in ovarian cancers. However, *BRCA* mutations are not common in endometrial cancer. Loss of function of the tumor suppressor gene *PTEN* has been demonstrated in greater than 80% of endometrioid endometrial cancers¹. *PTEN* loss of function is well known to lead to activation of the PI3K-AKT-mTOR pathway but has also been shown to lead to defects in homologous recombination (HR) DNA repair of double strand breaks². Specifically, *PTEN* silencing leads to decreased RAD51 foci formation. Based on this mechanism, in vitro data on endometrial cancer cell lines has demonstrated sensitivity to PARP inhibitors. Notably, sensitivity of PARP inhibition in *PTEN* loss of function is independent of microsatellite instability (MSI)³. **Methods:** This is a multi-center phase II, placebo controlled, double-blinded study of the use of rucaparib as maintenance therapy in patients with metastatic or recurrent endometrial cancer. A maximum of 138 patients will be randomized 1:1 to receive rucaparib at starting dose of 600mg BID dosing vs. placebo. Standard dose reductions of known toxicities will be followed based on FDA approved indications of rucaparib. Patients will remain on therapy until progression of disease or toxicity induced discontinuation. Eligible patients will have Stage III/IV or recurrent endometrial cancer and must have received one or two prior lines of chemotherapy. All histologic subtypes, including carcinosarcoma will be included. Treatment arms will be stratified on histology, number of lines of prior therapy, and complete vs partial response to prior line of therapy. The primary endpoint is progression free survival (PFS). Secondary endpoints include overall survival (OS), overall response rate (ORR), and toxicity. To date, 79 patients have been enrolled. 1. Mutter GL, Lin MC, Fitzgerald JT, et al. ENGOT-EN20/GOG-3083/xport-EC-042: A phase 3, randomized, placebo-controlled, double-blind, multicenter trial of selinexor in maintenance therapy after systemic therapy for patients with P53 wild-type, advanced or recurrent endometrial carcinoma. *First Author: Ignace Vergote, University Hospitals Leuven, Leuven Cancer Institute, and BGOG, Leuven, Belgium*

Background: Patients (pts) with first-line metastatic or recurrent endometrial cancer (EC) have a poor prognosis. Selinexor is an oral XPO1 inhibitor, which leads to nuclear accumulation of tumor suppressor proteins, including p53. Selinexor is FDA-approved for use in multiple myeloma and diffuse large B-cell lymphoma, and has shown clinical activity in previously treated, advanced EC. Molecular characterization of EC is critical in directing treatment for advanced and recurrent disease. Of the EC molecular subtypes, TP53 wild type (wt) tumors represent 50% of advanced and recurrent tumors. A recent phase 3 study in maintenance after chemotherapy found that, despite the primary endpoint (PFS) not reaching statistical significance, prolonged PFS of oral once-weekly selinexor versus placebo (13.7 months and 3.7 months, respectively) was observed in a prespecified exploratory subgroup analysis of patients with advanced or recurrent TP53wt EC. **Methods:** XPORT-EC-042 (NCT05611931) is a Phase 3 randomized, double-blind, placebo-controlled study designed to evaluate the efficacy and safety of selinexor as maintenance therapy in pts with TP53wt advanced or recurrent EC, who have achieved a partial response or complete response per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 after completing at least 12 weeks of platinum combination chemotherapy $\pm$ immunotherapy for primary stage IV or recurrent disease. Eligible pts must be $\geq$ 18 years of age, have histologically confirmed EC, and TP53wt disease based on NGS sequencing assessed by Foundation Medicine. Pts will be randomized 1:1 with either selinexor 60 mg or placebo once weekly in 28-day cycles until progressive disease, toxicity, or 3 years if in complete response. A total of 220 pts will be enrolled at sites across the United States, Canada, Europe, and Israel. The primary objective is to compare PFS in pts treated with selinexor compared to placebo based on RECIST v1.1 criteria as assessed by the Investigator. Key secondary objective is overall survival. Other secondary objectives are safety, time to first subsequent therapy, time to second subsequent therapy, time from randomization until the second progression event (PFS2), and PFS by a blinded independent central review. Patient enrollment is ongoing. Clinical trial information: NCT05611931. Research Sponsor: Karyopharm Therapeutics.

A randomized phase II study comparing single-agent olaparib, single-agent cediranib, and the combinations of cediranib/olaparib, olaparib/durvalumab (MEDI4736), cediranib/durvalumab (MEDI4736), and olaparib/AZD5363 (capivasertib) in women with recurrent, persistent, or metastatic endometrial cancer. *First Author: B.J. Rimel, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Identifying new approaches for the treatment of advanced endometrial cancer (EC) is a priority. A platform study design allows for a faster investigation of novel drug combinations. NRG-GY012 is an ongoing platform study investigating drug combinations with the PARP inhibitor olaparib (O) and the anti-angiogenic agent cediranib (C). Results from the first set of arms established improved PFS for combination cediranib/olaparib over C alone, but did not meet its prespecified statistical significance. In this second set of arms, based on preclinical data, we are investigating the combination of O with an AKT inhibitor (capivasertib), O with durvalumab and C with durvalumab compared to the reference arm of C alone. **Methods:** This is a multicenter randomized four arm study for patients with recurrent, metastatic or persistent EC. Patients are randomized 1:1:1:1 to cediranib PO 30 mg Daily; olaparib 300 mg PO BID and capivasertib 400mg 4 day on/3 off schedule; olaparib 300 mg PO BID and durvalumab 1500mg q28 days; or the combination of cediranib 20 mg PO Daily 5 days on/2 days and durvalumab 1500mg q28. All treatment cycles are 28 days. Primary endpoint is progression free survival (PFS). The study is powered to detect a doubling in median PFS from 3.6 (based on cediranib alone) to 7.2 months with 90% power, using a one-sided test with $\alpha = 0.05$ per comparison. Forty patients will be enrolled per arm, with an interim futility analysis planned at 50% information time. Eligibility includes endometrioid, serous, and mixed histology EC; at least 1 prior line of chemotherapy (no more than 2 lines for metastatic disease), prior endocrine or immunotherapy alone is allowed; prior treatment with lenvatinib and pembrolizumab is excluded. Archival tumor tissue and blood samples are being collected for translational studies. The study is open across the NRG network; 76 of a planned 168 patients are enrolled to date. Safety analysis at the time of 36 patients enrolled did not demonstrate any new safety signals and the study was approved to continue enrollment. Clinical trial information: NCT03660826. Research Sponsor: U.S. National Institutes of Health.

Poster Session

A phase 2, two-stage study of avelumab and axitinib in patients with mismatch repair-proficient (MMR-P) recurrent or persistent endometrial cancer (EC). *First Author: Elizabeth Katherine Lee, Medical Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Despite significant strides in understanding the molecular pathogenesis of EC, there remain few effective therapies for recurrent disease. Deeper insight into the roles of disordered tumor vasculature and HIF1 α - and VEGF-mediated immunosuppressive effects on myeloid-derived suppressor cells, T-cells, and PD-L1 expression contributed to the development of new targeted regimens. By inhibiting VEGF receptor (VEGFR) and PD-L1 signaling, immunologically "cold" tumors may become inflamed. The combination of the anti-PD-L1 antibody avelumab with axitinib, an inhibitor of VEGFR 1-3 and PDGFR with more potent IC₅₀ inhibitory activity than lenvatinib, has also shown synergistic activity and is FDA approved as first line treatment for patients with renal cell cancer. We therefore hypothesized that this combination would be well tolerated and efficacious in recurrent MMR-P EC. **Objectives:** This is a non-randomized two-stage phase 2 study in patients with MMR-P EC evaluating the activity of combined avelumab and axitinib, as assessed by the co-primary endpoints of (1) frequency of patients surviving progression-free for at least 6 months (PFS6), and (2) the objective response rate (ORR) as measured by RECIST 1.1. **Methods:** Patients must have MMR-P EC and have received at least one chemotherapeutic regimen, with no upper limit on the number of prior lines received. Prior use of immune checkpoint inhibitors (ICI) is excluded. Eligible patients received avelumab 800 mg IV every 2 weeks and axitinib 5 mg orally twice daily until disease progression or unacceptable toxicity. In the first stage of the study, 16 patients were enrolled; if there were $\geq$ 2 objective responses or $\geq$ 2 PFS6 responses, accrual continued to the second stage with enrollment of an additional 19 patients. The combination of avelumab/axitinib would be considered worthy of further study if overall there were $\geq$ 4 objective responses or $\geq$ 8 PFS6 responses. **Results:** As of the data-cutoff in September 2022, a total of 28 patients had received study treatment; one patient withdrew from the study due to toxicity, prior to her first radiographic assessment. The median number of prior lines was 1 (range 1-4). Median follow-up was 12.7 months. Of the 28 patients receiving study treatment, eleven patients (39.3%, 95% CI 21.5%-59.4%) achieved a PR [11/28; 8 confirmed PR (28.6%) and 3 unconfirmed PR (10.7%)]. An additional 39.3% (11/28) had stable disease as best response. Median PFS was 7.3 months (95% CI 3.9-9.0). PFS6 was 59.3% (95% CI 35.7%-76.7%) and at 6 months, 10 patients were still alive and progression-free. Updated efficacy data and safety data will be reported at the time of the meeting. **Conclusions:** With 8 confirmed PRs and 10 PFS6 responses, the co-primary endpoints were met and the combination of avelumab/axitinib is considered worthy of further study in this population of MMR-P EC. Clinical trial information: NCT02912572. Research Sponsor: Pfizer.

Randomized phase III trial in MMR deficient (MMRd) endometrial cancer (EC) patients comparing chemotherapy (CT) alone versus dostarlimab in first line advanced/metastatic setting: DOMENICA study (GINECO-EN105b/ENGOT-en13 study). *First Author: Florence Joly, Centre François Baclesse, Caen and GINECO, Paris, France*

Background: The standard treatment for advanced EC is still platinum-based combination CT, regardless of the histology, molecular status and the patient's profile. However, EC patients are a particularly frail group of patients, often with co-morbidities. Tolerance of CT can be difficult and induce long-term toxicities. In advanced EC disease, MMRd/MSI-H tumors represent 15 to 20 % of cases. Preclinical data suggest that these tumors are more resistant to platinum. On the other hand, anti-PD1 immunotherapy has shown impressive results among MMRd/MSI-H EC patients after platinum-based CT. The aim of this study is to de-escalate the first line advanced/metastatic treatment of patients with MMRd/MSI-H endometrial cancer with the objective to avoid carboplatin-paclitaxel related toxicities by substituting CT with the PD1 inhibitor dostarlimab. **Methods:** DOMENICA is an ongoing international randomized, open-label, phase III trial. 142 patients with MMRd/MSI-H EC Stage III or Stage IV or first recurrent disease without curative treatment (surgery, radiation therapy, +/- adjuvant CT) will be randomized (1:1) to receive either 4 cycles of dostarlimab 500mg every 3 weeks followed by dostarlimab 1000mg every 6 weeks as maintenance up to 2 years or 6 cycles of carboplatin-paclitaxel. A cross over is allowed from the CT arm to the dostarlimab arm at first progression. The maximum treatment duration with dostarlimab will be 24 months. Stratification factors are prior adjuvant CT, prior pelvic radiotherapy. The primary endpoint is the progression-free survival (PFS). Secondary endpoints include overall survival (OS), PFS2, quality of life, best objective response rate, disease control rate, duration of response rate, safety, tolerability, time to first and second subsequent therapy, efficacy of second systemic therapies, pharmacokinetics description and immunogenicity determination. The study is designed to expect a 17.8-months PFS in dostarlimab arm and a 10-months PFS in the CT arm, translating to a hazard ratio of 0.58. A protocol amendment is submitted to increase patient population (with extended eligibility criteria, PFS hypothesis). Status: The DOMENICA/GINECO-EN105b/ENGOT-en13 trial is currently recruiting, the first patient was randomized in April 2022. Clinical trial information: NCT05201547. Research Sponsor: GlaxoSmithKline.

RT-PACE: Phase I/II study of adjuvant whole pelvic hypofractionated radiotherapy for non-metastatic cervical and endometrial cancer. *First Author: Christina H. Son, University of Chicago, Chicago, IL*

Background: Whole pelvic radiation therapy (WPRT) improves locoregional control in women with high-intermediate and high-risk endometrial cancer. The standard treatment course consists of 25-28 fractions (5-5.5 weeks) of 1.8-2 Gy/fraction, and is delivered using intensity-modulated radiation therapy (IMRT), which allows for superior sparing of normal tissue with a subsequent lower rate of acute and late toxicity compared to less conformal treatment techniques. Moderate hypofractionation (HF, >2 Gy/fraction) has been studied in other disease sites, such as breast and prostate cancer, and is associated with lower or comparable toxicity, improved patient convenience, and greater cost savings compared to standard fractionation. However, HF has not been well-studied in the setting of WPRT for gynecologic cancers. **Methods:** This phase I/II multi-institutional study evaluates the feasibility, safety, and toxicity profile of HF-WPRT in women with non-metastatic cervical or endometrial cancers who have undergone curative hysterectomy and are recommended adjuvant WPRT by their treating physician. Concurrent chemotherapy is not allowed, but can be administered sequentially prior to or after WPRT. Para-aortic radiation or nodal boosts are not allowed, however vaginal brachytherapy boost is permissible. Phase I is a safety study of increasing dose-per-fraction. All treatment regimens have an approximate biologic effective dose of 53 Gy ($\alpha/\beta = 10$). A keyboard design is utilized to identify the maximum tolerated dose-per-fraction (MTD), defined in this study as the regimen that is associated with a CTCAE grade 3+ gastrointestinal/genitourinary toxicity rate of $\leq 10\%$ on the last day of WPRT. There are 3 dose cohorts of increasing dose-per-fraction. Phase II will accrue 64 evaluable patients to HF-WPRT using the MTD determined in phase I. The primary endpoint is to evaluate the change in patient-reported gastrointestinal toxicity from baseline to the last day of WPRT using the EPIC bowel score. The study is powered to compare results to the RTOG 1203 IMRT standard fractionation arm. The phase 1 portion of the study completed accrual; the phase II portion opened in April 2022 with a fractionation of 42.56 Gy in 16 fractions. Secondary endpoints include genitourinary toxicity (EPIC, CTCAE), quality of life (FACT-Cx, PRO-CTCAE), financial toxicity (FACIT-COST), and decision-making (Decision Regret Scale). Pelvic control at 2 years is an exploratory endpoint. Clinical trial information: NCT04683653. Research Sponsor: University of Chicago Comprehensive Cancer Center.

The RAINBO MMRd-GREEN trial (GCIG/DGOG/ENGOT-EN14²): A phase III trial on the addition of adjuvant durvalumab to radiotherapy in patients with high-risk MMRd endometrial cancer. *First Author: Merve Kaya, Leiden University Medical Center, Leiden, Netherlands*

Background: The molecular class of endometrial cancer (EC) is both prognostic and predictive in high-risk EC (HREC). The TransPORTEC research consortium showed that patients with MMRd HREC did not benefit from adjuvant chemotherapy added to radiotherapy. MMRd tumors are particularly sensitive to immunotherapy. We hypothesize that adjuvant durvalumab added to standard radiotherapy will increase recurrence-free survival (RFS) in patients with MMRd HREC. **Methods:** MMRd-GREEN is an international, open-label, randomized phase III trial and part of the RAINBO program (NCT05255653). Eligible patients will be allocated (1:1) to adjuvant durvalumab 1500 mg once every 4 weeks for 1 year combined with radiotherapy or standard radiotherapy alone. The primary endpoint is RFS at 3 years. Secondary endpoints are pelvic, vaginal and distant RFS, EC-specific survival, overall survival, treatment-related toxicity, health-related quality of life and exploratory translational research. Main inclusion criteria include histologically confirmed stage IB/II with (substantial) lymph-vascular space invasion (LVI) or stage IIIA-C MMRd EC, after hysterectomy and bilateral salpingo-oophorectomy (regardless of lymphadenectomy or sentinel lymph node biopsy) without macroscopic residual disease. Molecular classification must be performed according to the WHO 2020 algorithm. The target accrual is 316 patients, accounting for a total drop-out rate of 12%. This sample size yields 80% power to detect a 13% increase in the 3-year RFS (hazard ratio 0.58) as a result of the addition of durvalumab, with an accrual duration of 48 months and follow-up period of 30 months. No interim analysis is planned; an independent data monitoring committee will routinely monitor recurrences and adverse events. Enrollment: Since August 2022, the trial is open for recruitment in the Netherlands and per February 10th 2023, the first 3 patients have been enrolled. Activation of more international centers is ongoing. Clinical trial information: NCT05255653. Research Sponsor: KWF Dutch Cancer Society; AstraZeneca.

CCTG EN10: A phase II study of tailored adjuvant therapy in *POLE*-mutated and p53-wildtype/NSMP early-stage endometrial cancer (EC)—RAINBO BLUE and TAPER. *First Author: Jessica N. McAlpine, BCCA, Vancouver Cancer Centre, Vancouver, BC, Canada*

Background: Molecular classification of EC provides an opportunity to personalize treatment for patients with early disease based on prognosis. We hypothesize that de-escalated adjuvant treatment in patients with early-stage *POLE*-mutated (*POLE*mut) or p53wt/NSMP (p53 wildtype/no specific molecular profile) EC is feasible and associated with favourable disease control, QOL and health economics. **Methods:** EN.10 is a Canadian Cancer Trials Group led phase II trial that enrolls two independent cohorts of patients with early stage EC based on tumour molecular status: *POLE*mut (substudy A) and p53wt/NSMP (substudy B). The primary objective is to estimate the 3-year rate of pelvic recurrence. Secondary objectives include estimated 3-year isolated vaginal recurrence, para-aortic recurrence, distant metastasis, survival (recurrence-free, EC-specific, overall survival) and to describe the patient decisional conflict and fear of recurrence. Tertiary objectives: QOL, economic evaluation and interrogation/discovery of additional prognostic biomarkers. Statistical Design: Registration to Substudy A or B is based on molecular classification. Treatment will be deescalated in both substudies; to surveillance-only (all early stage *POLE*mut, and a proportion of NSMP), or vaginal brachytherapy (proportion of NSMP), with NSMP stratification based on histological grade, and lymphovascular invasion. Substudy A can enroll endometrioid, serous, clear cell, undifferentiated and carcinosarcomas whereas Substudy B is confined to endometrioid histotype. Both arms require ECOG 0-2 and hysterectomy+BSO with nodal assessment required for stage II and grade 3 EC. A total of 120 patients with *POLE*mut (Sub-study A) and 180 with p53wt/NSMP ER+ (Sub-study B) EC will be recruited in 3 years. If the upper 95% confidence limit is less than 5% in either of Substudy A, Cohort A1 and Sub-study B or both, it will be concluded that patients in one or both groups have an acceptable low risk of pelvic recurrence at 3 years with molecularly-tailored de-escalated adjuvant treatment. An additional estimated 25 patients with higher risk *POLE*mut EC will be enrolled for an exploratory analysis. Conduct to Date: Study activation Dec 19 2022. Enrollment January 31, 2023: 36 Supported by Canadian Cancer Society, Canadian Institutes of Health Research, Gynecologic Cancer Initiative, BC Cancer Foundation. Clinical trial information: NCT05640999. Research Sponsor: Canadian Cancer Society, Canadian Institutes of Health Research, Gynecologic Cancer Initiative, BC Cancer Foundation.

AFT-50 EndoMAP: A phase IB/II multi-cohort study of targeted agents for patients with recurrent or persistent endometrial cancer. *First Author: Evelyn Cantillo, 525 East 68th St, New York, NY*

Background: The prognosis for women with recurrent or persistent EC after progressing on first-line chemotherapy is poor, with a median overall survival (OS) of 12 months, highlighting the need for more efficacious therapies for this population. Immune checkpoint inhibitors either as monotherapy or when combined with kinase inhibitors have recently demonstrated encouraging response rates in pts with microsatellite instability-high (MSI-H)/mismatch repair-deficient (dMMR) and MS-stable (MSS)/MMR-proficient (MMRp) EC, respectively. Atezolizumab is a humanized monoclonal anti-programmed cell death ligand 1 (PD-L1) inhibitor that has demonstrated monotherapy antitumor activity with an acceptable safety profile in relapsed recurrent EC. Atezolizumab has shown compelling clinical efficacy for pts with certain solid tumors (e.g., urothelial, NSCLC, triple negative breast cancer) as monotherapy and as part of combination therapy. The AFT-50 EndoMAP trial is a platform trial designed to evaluate the efficacy and safety of Atezolizumab in combination with biomarker-defined targeted agents in pts with recurrent or persistent EC. Recognizing pts may have either progressed through or received a checkpoint inhibitor in a prior line of therapy, a non atezolizumab cohort will also be open to enrollment. **Methods:** This is a phase IB/II non-randomized, multicenter, multicohort, biomarker-driven platform study consisting of two cohorts: A (atezolizumab) and B (non atezolizumab). Eligible pts have recurrent or persistent EC and have received no more than 2 prior lines of therapy. FoundationOne CDx (F1CDx) NGS assay will be used for genomic tumor profiling. In cohort A, pts may be eligible for one of the following doublets: Atezolizumab+ipatasertib (PIK3CA/PTEN/AKT1-altered cancers), Atezolizumab+talazoparib (tumors with genomic loss of heterozygosity (LOH) $\geq 16\%$), Atezolizumab+Trastuzumab emtansine (ERBB2/HER2 mutated and/or amplified tumors), Atezolizumab+Tiragolumab (MSI-H and/or TMB>10 mut/MB), and Atezolizumab+bevacizumab (biomarker unmatched). Pts will receive Atezolizumab in addition to the targeted agent (at the study approved dosing schedule) until progression, unacceptable toxicity, pt or physician decision to withdraw from the study, death, or study termination. Pts in cohort B, will be eligible for inavolisib (PIK3CA/PTEN/AKT1-altered cancers) + letrozole. Each cohort will enroll ~20 pts; however, the exact size of the cohort may be adjusted. The primary endpoint for Cohort A is confirmed overall response rate (ORR) for each cohort, and for Cohort B is progression free survival at 6 months. Secondary endpoints include disease control rate, duration of response, OS, safety and tolerability, 6-month PFS (cohort A). As a platform study, additional arms may be added, as supported by evolving understanding of EC and molecular targets. EndoMAP is actively enrolling at 17 sites in the US with a target of 25 sites nationwide. Clinical trial information: NCT04486352. Research Sponsor: Genentech; Alliance Foundation.

GCIG SB-001/NSGO-CTU-PEACE/ANZGOG 1923/2020: Palliation in gynaecology—Patients' expectations and assessment of care. *First Author: Kristina Lindemann, NSGO-CTU, Denmark & Dep. of Gynaecologic Oncology, Oslo University Hospital & Faculty of Medicine, University of Oslo, Oslo, Norway*

Background: Patients with advanced gynaecological cancers who are approaching end of life (EOL) have a high symptom burden and following several prior lines of therapy, a low likelihood of response to further anti-cancer treatment. Despite this, 20-30% of women with gynecological cancer received chemotherapy in the last 30 days of life, with potentially detrimental effects on health and quality of life. Little is known about patients' and carers' perceptions and preferences in this phase of illness. Eliciting patient's values and preferences for EOL care and shared decision-making are central elements of GCIG SB-001/NSGO-CTU-PEACE with the aim of improving patient-centered EOL care. The primary aim of PEACE is to assess the feasibility of collecting data on patient satisfaction towards EOL. Secondary aims include collecting data on patient and carer satisfaction with care, as well as prospective collection of details of their care. **Methods:** PEACE will prospectively enroll patients in Norway and Australia. Key eligibility criteria include: Patients with gynaecological cancer at an advanced stage with a predicted life expectancy of approximately 4 months. Patients may be on anti-cancer treatment or may be under observation/palliative care. In addition, the patient must be able (both physically and cognitively) to complete patient-reported outcome measures independently. The study will also include an appointed carer (not mandatory). Patient and carer satisfaction with care and the importance of domains of care will be assessed with the CANHELP-Lite individualized (Canadian Health Care Evaluation Project) instrument and FACIT (Functional Assessment of Chronic Illness Therapy). Carer's perception of the bereavement period and the quality of the patient's death will be assessed with the CANHELP lite bereavement and the Quality of Death and Dying questionnaire. The study will prospectively collect data on EOL treatment. Patient and carer satisfaction with care and quality of the dying process will be summarized by standard descriptive statistical measures. A sample size of 65 patients would have at least 80% power with 95% confidence to rule out a 60% completion rate in favour of the more interesting 75% rate. Assuming a 10% drop-out rate, PEACE will enrol 73 patients. Enrolment commenced in December 2022. ClinicalTrials.gov Identifier: NCT05142150 Clinical trial information: NCT05142150. Research Sponsor: Radiumhospitalets Legater; Private Practice Fund, Canberra Hospital.

Oral Abstract Session

Concurrent chemoradiotherapy followed by adjuvant cisplatin-gemcitabine versus cisplatin-5-fluorouracil chemotherapy for N2-3 nasopharyngeal carcinoma: A multicentre, open-label, randomised, controlled, phase 3 trial. *First Author: Lin-Quan Tang, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Centre, State Key Laboratory of Oncology in South China, Collaborative Innovation Centre for Cancer Medicine, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangzhou, China*

Background: Patients with N2-3 nasopharyngeal carcinoma have a high risk of failures, despite the current practice of concurrent adjuvant cisplatin-5-fluorouracil (PF) regime. Adjuvant PF regimen may not be adequate for tumor control of high risk patients, emphasizing the need for more effective regimen of adjuvant chemotherapy in N2-3 nasopharyngeal carcinoma. **Methods:** We conducted this multicentre, open-label, phase 3, randomised, controlled trial in four centers in China. Patients aged 18–65 years with stage T1–4N2–3 nasopharyngeal carcinoma were randomly assigned (1:1) to receive concurrent cisplatin (100mg/m² intravenously) on days 1, 22, and 43 of radiotherapy followed by either gemcitabine (1 g/m² intravenously on days 1 and 8) and cisplatin (80 mg/m² intravenously on day 1) (GP) once every 3 weeks or 5-fluorouracil (4 g/m² in continuous intravenous infusion over 96 h) and cisplatin (80 mg/m² on day 1 given intravenously) once every 4 weeks for three cycles. Randomisation was by a computer-generated random number code with a block size of six, stratified by treatment centre and nodal stage (N2 or N3). The primary endpoint was 3-year progression-free survival in the intention-to-treat population. This study is registered in ClinicalTrials.gov, NCT03321539. **Results:** From October 30, 2017 to July 9, 2020, 240 were randomly assigned to PF group (n = 120) or GP group (n = 120). After a median follow-up of 40 months (IQR: 32–48), the 3-year progression-free survival was 83.9% (95% CI 75.9–89.4) in GP group and 71.5% (62.5–78.7) in PF group (stratified HR 0.54; 95% CI, 0.32 to 0.93; p = 0.023). Significantly lower cumulative incidence of locoregional relapse (2.6% vs. 12.5%; HR 0.33; 95% CI, 0.12 to 0.90; Fine-Gray p = 0.030) and distant metastasis (10.4% vs. 20.1%; HR 0.50; 95% CI, 0.26 to 0.98; Fine-Gray p = 0.042) were also observed in GP group than PF group. However, there was no effect on early 3-year overall survival (90.7% vs. 94.0%; HR 1.12; 95% CI, 0.50 to 2.55; log-rank p = 0.779). Overall incidence of treatment-related adverse events was not significant different between the two treatment groups in the concurrent phase. In the adjuvant phase, significant higher incidence of grade 3–4 leucopenia (42 [41.2%] vs. 19 [16.8%], p < 0.001), neutropenia (33 [32.0%] vs. 10 [8.9%], p = 0.001) and thrombocytopenia (9 [8.7%] vs. 2 [1.8%], p = 0.044) was observed in GP group than PF group, whereas the frequency of diarrhea (6 [5.3%] vs. 0 [0%], p = 0.030) and mucositis (21 [18.6%] vs. 7 [6.8%], p = 0.010) was higher in PF group than in GP group. **Conclusions:** Concurrent adjuvant GP regimen significantly improved progression-free survival in patients with N2-3 nasopharyngeal carcinoma with acceptable toxicity. Long term follow-up is needed to confirm the ultimate therapeutic ratio. Clinical trial information: NCT03321539. Oral Abstract Session

Induction chemotherapy plus radiotherapy alone versus cisplatin-based concurrent chemoradiotherapy in locoregionally advanced nasopharyngeal carcinoma: An open-label, non-inferiority, randomized phase 3 trial. *First Author: MingYuan Chen, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Cisplatin-based concurrent chemoradiotherapy (CCRT) has long been regarded as standard treatment for locoregionally advanced nasopharyngeal carcinoma (LA-NPC) due to its favorable local control. However, concurrent platinum is associated with intolerable toxicities and ineffective in preventing distant metastasis. Since IMRT enhances the local control and induction chemotherapy (IC) decreases the risk of distant failure, it is worth exploring whether IC plus IMRT alone regimen could replace CCRT for patients with LA-NPC. **Methods:** This open-label, phase 3, non-inferiority clinical trial was conducted from June 12, 2015 to April 30, 2019. Patients with stage T1–4N2–3 or T3–4N0–1 M0 NPC were randomly assigned (1:1) to receive gemcitabine (1000 mg/m²) and cisplatin (80 mg/m²) IC for 2 cycles followed by IMRT alone or IMRT plus concomitant weekly cisplatin (40 mg/m²) up to 7 cycles. 2-year failure-free survival was set as primary endpoint and non-inferiority margin of 10% was established. Efficacy analysis and safety analysis were dividedly performed in the intention-to-treat and safety population. **Results:** A total of 249 patients were enrolled, including 124 patients in IC group and 125 patients in CCRT group. Median follow-up time was 60 months (IQR, 48–71). 2-year failure-free survival was 90.2% in IC group versus 86.3% in CCRT group, with an HR of 0.818 (95% CI, 0.479–1.397) and absolute difference of 3.9% (1-sided 95%CI, -4.2 to 11.9). No significant differences were observed between groups in overall survival, locoregional relapse, or distant metastasis. Compared with CCRT group, fewer grade ≥3 AEs occurred in IC group (47.5% vs 61.5%, p = 0.015), including leucopenia, anemia, mucositis, nausea and dysphagia. The IC group had significantly better QoL during and short periods after IMRT, including domains of global health status, physical functioning, fatigue, nausea and vomiting, pain, and appetite loss. **Conclusions:** For LA-NPC, gemcitabine and cisplatin induction chemotherapy plus IMRT alone was not inferior in 2-year failure-free survival to concurrent chemoradiotherapy. Clinical trial information: NCT02460887. Research Sponsor: the Key-Area Research and Development of Guangdong Province (2020B1111190001), the National Natural Science Foundation of China (No. 82002857, 82230034, 81874134), Sun Yat-Sen University Clinical Research 5010 Program (No. 2015010, 2018015).

Oral Abstract Session

Results of the multicenter phase II FRAIL-IMMUNE trial evaluating the efficacy and safety of durvalumab combined with weekly paclitaxel carboplatin in first-line in patients (pts) with recurrent/metastatic squamous cell carcinoma of the head and neck (R/M SCCHN) not eligible for cisplatin-based therapies. *First Author: Jerome Fayette, Centre Leon Bérard, Medical Oncology, Lyon, France*

Background: For pts with R/M SCCHN, new standard of care (SoC) has been recently established with pembrolizumab either alone or combined with platinum-5FU (KN 048 – median Overall Survival (OS): 13 months when combined). For pts who need chemotherapy, platinum-5FU-pembrolizumab as first-line treatment appears associated with substantial toxicity that precludes its use in fragile patients. In this context, we investigated the efficacy and tolerance of PDL-1 inhibition with durvalumab combined with weekly carboplatin-paclitaxel as first-line treatment in frail R/M SCCHN pts. **Methods:** This single-arm phase II study enrolled pts in first-line of their R/M SCCHN and not eligible to standard cisplatin-based CT with an ECOG PS of 0 or 1. Pts received 4 cycles of CT (carboplatin AUC2; paclitaxel 80mg/m² both at D1, D8, D15) and durvalumab (D) 1500mg repeated every 4 weeks for a maximum of 12 months. The primary endpoint was OS Rate at 12 months (m). The study used a Fleming A'Hern design (inefficacy boundary: 47% and target efficacy: 65%), requiring 38 successes among 64 pts. Secondary endpoints were Progression-Free Survival (PFS), Time to Treatment Failure (TTF), objective response rate (ORR) and tolerance. **Results:** 64 pts (median age 69.5y; 90.6% males, 62.5% PS1) were included, regardless of their PDL-L1 status. Primary tumors were mainly located in oropharynx (37.5%) and larynx (28.1%) with 37.3% PD-L1 CPS≥20. 54.9% were metastatic. The efficacy rule for OS was met with 40 pts (62.5%, unilateral 95%CI: [51.5%–73.5%]) alive at 12m. With a median follow-up of 27.1 m, median OS was 18.0 m (95% CI [11.9–NR]) and the 24m-OS rate was 45% [32%–57%]. Median PFS was 7.0 m (95% CI [5.4–9.9]) and median TTF was 6.0 m (95% CI [4.7–9]). 44/62 pts (71%) achieved an OR (11.3% complete response and 59.7% partial response). Median duration of response was 5.9 m (95% CI [3.4–9.6]). 20.3% of pts experienced G≥3 adverse events related to D. Toxicity led to permanent discontinuation of D in 3.1% of pts. No D-related death was reported. **Conclusions:** This study performed in fragile patients not amenable to cisplatin-based CT met its primary endpoint on OS and showed a 18 months median OS rate. This combination of durvalumab with weekly carboplatin/paclitaxel was associated with a favorable toxicity profile. Clinical trial information: NCT0372967. Research Sponsor: AstraZeneca.

Oral Abstract Session

Dose expansion results of the bifunctional EGFR/TGFβ inhibitor BCA101 with pembrolizumab in patients with recurrent, metastatic head and neck squamous cell carcinoma. *First Author: Glenn J. Hanna, Dana-Farber Cancer Institute, Boston, MA*

Background: Pembrolizumab (P) is approved to treat patients (pts) with recurrent, metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). BCA101 is a first-in-class bifunctional EGFR antibody fused to a TGFβ immune modulating payload which is well tolerated and has clinical activity as monotherapy and in combination with pembrolizumab in advanced solid tumors (ESMO 2022 731MO). Here we report the results from the interim analysis of an expansion cohort combining BCA101+P as first line therapy in R/M HNSCC. **Methods:** This ongoing single-arm, open-label multicenter dose expansion cohort enrolled pts with R/M HNSCC with a tumor PD-L1 CPS ≥ 1 with no prior systemic therapy for R/M disease, ECOG 0-1, and measurable disease (RECIST v1.1). Pts received BCA101 (1500 mg IV on days 1, 8, 15) with P (200 mg IV on day 1) every 21-days. Primary endpoint: safety; secondary endpoints: overall response rate (ORR), duration of response (DOR), progression-free survival (PFS), overall survival (OS). Exploratory: molecular and immunologic predictors of response. A Simon optimal two-stage design was employed: among 18 evaluable pts in stage 1, >3 pts in response triggered continuation to stage 2 enrolling 21 additional pts targeting an ORR > 35%. **Results:** From 2/2022 to 1/2023, 20 pts enrolled while 18 were evaluable (had first restaging scans) in stage 1. Pts were more often men (n=13, 65%) with a median age of 66 (range: 31-77). Oropharynx (10, 50%) (7/10 (70%) were HPV/p16-pos) and oral cavity (7, 35%) were the most common primary subsites (larynx/hypopharynx: 3). Fifteen (75%) had distant metastatic disease. The ORR in stage 1 was 44% (8 PRs, 4 SD) with a clinical benefit rate (CBR=PR+SD) of 67%; 7/12 (58%) HPV-neg pts achieved a response. Median DOR not reached, but median time on-treatment was 6.7 months (range: 2.7-11.0+) among responders. Ten pts discontinued therapy; all but 1 for PD (n=1 for toxicity). Grade 3+ treatment-related adverse events (TRAEs) were observed in 4 pts (20%, most common: anemia). No treatment-related deaths were observed. Acneiform rash was the most common TRAE of any grade (15, 75%). PFS and OS estimates are forthcoming. Eight (44%) had baseline PD-L1 CPS scores of 0-19, while ten (56%) were ≥ 20. Stage 2 is actively enrolling with completion of accrual expected by the meeting. **Conclusions:** Stage 1 of this dose expansion cohort of BCA101+P shows encouraging anti-tumor activity with additive potential, particularly among HPV-neg pts; and the combination is well tolerated among this R/M HNSCC population. Further investigation is warranted. Study funded by Bicara Therapeutics and conducted in collaboration with Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc. USA (NCT04429542). Clinical trial information: NCT04429542. Research Sponsor: Bicara Therapeutics; Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc. USA.

Oral Abstract Session

Randomised phase III trial of the hypoxia modifier nimorazole added to radiotherapy with benefit assessed in hypoxic head and neck cancers determined using a gene signature (NIMRAD). *First Author: David Thomson, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Tumour hypoxia is an adverse prognostic factor in head and neck squamous cell carcinoma (HNSCC). We assessed whether patients with hypoxic HNSCC benefited from the addition of nimorazole to definitive radiotherapy (RT). **Methods:** NIMRAD was a phase III, multi-centre, placebo-controlled, double-blind trial in patients with HNSCC unsuitable for concurrent platinum chemotherapy or cetuximab with definitive RT (NCT01950689). Patients were randomized 1:1 to receive nimorazole (1.2 g/m² daily, prior to RT) + RT (65 Gy in 30 fractions over 6 weeks) or placebo (taken via the same schedule) + RT. The primary endpoint was loco-regional control (freedom from loco-regional progression, FFLRP) in patients with hypoxic tumours, defined as greater than or equal to the median hypoxia score of the first 50 patients analysed (≥ 0.079), using a validated 26-gene signature. The planned sample size was 340 patients allowing for signature generation in 85%, assumed HR 0.50 for nimorazole effectiveness in the hypoxic group, and requiring 66 loco-regional failures to have 80% power in a two-tail log-rank test at the 5% significance level. **Results:** 338 patients were randomised by 19 UK centres from May 2014 to May 2019, with a median follow-up of 3.1 years (95%CI 2.9-3.4). Hypoxia scores were available for 286 (85%). The median patient age was 73 years (range 44-88); and clinical factors were balanced between the arms, both for the whole population and hypoxic group (Table). There were 36 (25.9%) loco-regional failures in the hypoxic group, where nimorazole + RT did not improve FFLRP (adjusted HR 0.72; 95% CI 0.36-1.44; p=0.35), or overall survival (adjusted HR 0.96; 0.53-1.72; p=0.88) compared with placebo + RT. Similarly, nimorazole + RT did not improve FFLRP or OS in the whole population. In total (n=338), 73% of patients allocated nimorazole adhered to the drug for ≥ 50% of RT fractions. Nimorazole + RT caused more acute nausea compared with placebo + RT (CTCAE v4.0 G1+2: 56.6% vs 42.4%, G3: 10.1% vs 5.3%, respectively; p=0.003), with no differences in other early or late toxicities. **Conclusions:** Addition of the hypoxia modifier nimorazole to RT for locally advanced HNSCC in older and less fit patients did not improve loco-regional control or survival. Clinical trial information: NCT01950689. Research Sponsor: Cancer Research UK.

Oral Abstract Session

Neoadjuvant nivolumab, paclitaxel, and carboplatin followed by response-stratified chemoradiation in locoregionally advanced HPV negative head and neck squamous cell carcinoma (HNSCC): The DEPEND trial. *First Author: Ari Rosenberg, University of Chicago, Chicago, IL*

Background: The role of neoadjuvant immunotherapy in curative-intent head and neck squamous cell carcinoma (HNSCC) remains poorly defined. Survival for locoregionally advanced (LA) HPV negative (-) HNSCC remains poor with two-year survival of ~50%, and substantial treatment-related toxicity with standard chemoradiation (CRT). Given the activity of anti-PD1 in recurrent/metastatic HNSCC, we studied neoadjuvant nivolumab with chemotherapy and the feasibility of subsequent response-stratified CRT in HPV(-) LA HNSCC. **Methods:** The DEPEND trial (NCT03944915) is a phase II trial of nivolumab, paclitaxel, and carboplatin followed by response-stratified CRT for previously untreated stage IVA-B (AJCC-8th edition) HPV(-) HNSCC. The ultimate goal is to evaluate radiation volume and/or dose reduction to decrease long-term toxicities. Eligible patients received three 21-day cycles of nivolumab 360mg day 1, paclitaxel 100mg/m² on days 1/8/15, and carboplatin AUC5 day 1. Patients with ≥ 50% reduction by RECIST 1.1 received response-adapted CRT to 66Gy with elimination of elective nodal volumes; < 50% reduction received standard-dose CRT to 70-75Gy. Post-CRT nivolumab 480mg every 4 weeks for 9 months was administered. The primary endpoint was deep response rate (DRR) defined as the proportion of patients with ≥ 50% reduction. Tumor PD-L1 immunohistochemistry was reported as combined positive score (CPS). **Results:** Thirty-six eligible patients started treatment between September 2019 and June 2022. Median age 59 (range 27-77), 22% female, 80% 20PYH smoking, 39% oral cavity, 19% oropharynx, 25% larynx/hypopharynx, 78% T3/4 and 78% N2/3. PD-L1 CPS ≥ 1 in 58%. The DRR with nivolumab/chemotherapy was 54% (95% CI 0.37-0.72), which met our statistical endpoint. The ORR was 89%. CRT stratification was as follows: Response-adapted CRT (n = 19) and standard-dose CRT (n = 16). At a median follow-up of 14 months, 2-year PFS and OS were 64% (95%CI 0.41-0.80) and 76% (95%CI 0.53-0.89), respectively. By CRT stratification, 2-year PFS was 79% and 46% in response-adapted and standard-dose CRT, and 2-year OS was 86% and 67% in response-adapted and standard-dose CRT, respectively. One patient died from disease progression during neoadjuvant therapy. 2-year distant control in response-adapted and standard-dose CRT arms was 100% and 63%, and 2-year locoregional control was 85% and 92%, respectively. PD-L1 CPS ≥ 1 and < 1 demonstrated DRR of 75% and 27%, respectively (p=0.01). **Conclusions:** Nivolumab-based neoadjuvant chemioimmunotherapy led to deep responses, and response-adapted CRT was associated with favorable survival and locoregional control. PD-L1 expression was predictive of deep response to nivolumab-based neoadjuvant therapy. Late toxicity analysis between treatment arms is planned. Clinical trial information: NCT03944915. Research Sponsor: BMS.

Oral Abstract Session

Immuno-chemotherapy as single treatment modality for larynx preservation (ICoLP): Co-primary endpoints and safety results. *First Author: Renata Ferrarotto, Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Optimal treatment of larynx squamous cell carcinoma (LC) maximizes functional outcomes and survival. Surgery and radiotherapy (RT) may lead to significant morbidity, notably dysphonia and dysphagia. Our group published durable pathologic complete response (pCR) with normal function in 33% of patients (pts) with stage II-IV LC treated with single modality chemotherapy. We hypothesized that pembrolizumab (P), cisplatin (C), and docetaxel (D) will cure a subset of LC pts and preserve larynx function. **Methods:** Eligible pts had stage II-III LC measurable per RECIST 1.1. Treatment consisted of P 200 mg, C 75 mg/m² or carboplatin AUC 6, and D 75 mg/m² IV Q3W. After 2 PCD cycles, pts with radiological response (complete [CR], partial [PR], or stable disease [SD]) received 2 additional PCD cycles. After 4 cycles, pts underwent larynx biopsy. Those with pCR received 4 doses of consolidation P; those without pCR received local therapy (LT; RT or surgery). Co-primary endpoints are disease control rate (DCR; CR+PR+SD) after 2 PCD cycles and pCR rate after 4 cycles. Secondary endpoints include safety, laryngeal preservation rate, relapse-free survival, and swallow function. Per Bayesian design (H₀: 65% DCR, 15% pCR; H₁: 85% DCR, 30% pCR), we reject H₀ if of 25 pts, 19 have DCR or > 7 achieve pCR (10% alpha, 88% power). **Results:** 24 pts enrolled from 8/9/19-12/15/22, 62.5% were stage III (54.2% were T3 and 16.7% were N1); 23 were evaluable for the efficacy endpoints. DCR was 100% with 74% (17/23) being objective responses and 52% CR; pCR rate to date is 77.3% (17/22; 1 pt on-treatment). 6 of 17 (35%) pts with pCR developed recurrence, mostly (4/6) within 4 months of pCR, and were salvaged with LT. 5 pCR lasted ≥ 1 y; 2 additional pCR pts unable to perform serial laryngoscopy or imaging due to loss of insurance (n = 1) or moving to another state (n = 1) have not had clinical recurrence for ≥ 2 ys. The median follow-up is 17.2 mos (range: 1.4 – 39.4 mos). One patient who refused LT at early recurrence was lost to follow-up and eventually underwent a total laryngectomy and RT then recurred locally and died of disease. An additional patient who had pCR with early recurrence received definitive RT with CR, but subsequently developed a solitary lung metastasis treated with RT; 2 pts remain on trial treatment. The most common treatment-related adverse events (TRAE) were fatigue (91.6%), anemia (79%), diarrhea (45.8%), and nausea (41.6%). 10 grade 3-4 TRAE were reported in 5 (20.8%) pts with the most common being neutropenia (3/24, 12.5%) and anemia (2/24; 8.3%). 2 pts discontinued PCD treatment due to toxicity. **Conclusions:** The study reached its primary endpoint with a DCR of 100% (23/23) and a pCR in 77.3% (17/22) of evaluable patients; 5 pCR last ≥ 1 y. Recurrences after pCR occurred stressing the importance of close follow-up. Updated efficacy and swallow function results will be presented at the meeting. Clinical trial information: NCT04030455. Research Sponsor: Merck.

Poster Discussion Session

NEOSPACE trial: Neoadjuvant pembrolizumab-gemcitabine-cisplatin followed by concurrent pembrolizumab-chemoradiation and maintenance pembrolizumab for stage IVA nasopharyngeal cancer (NPC). *First Author: Edwin P Hui, Department of Clinical Oncology, Prince of Wales Hospital, Shatin, Hong Kong*

Background: Stage IVA NPC had the worst prognosis despite the current standard of neoadjuvant chemotherapy and concurrent chemoradiation (CRT). There is no safety and efficacy data combining immune checkpoint inhibitor (ICI) and CRT in NPC. **Methods:** We conducted an open label, single arm, multi-site, phase 2 clinical trial in AJCC 8th Edition Stage IVA (T4 and/or N3, M0) WHO type 2/3 Epstein Barr virus (EBV) +ve NPC (Clinical trial register NCT03734809). The experimental treatment consisted of neoadjuvant pembrolizumab (200 mg D1), gemcitabine (1000 mg/m² D1+8) and cisplatin (80 mg/m² D1) q3w x2 followed by concurrent pembrolizumab (200 mg x3 week 1, 4 and 7) and cisplatin (40 mg/m² weekly x7) during intensity-modulated radiation (IMRT), and maintenance pembrolizumab 200 mg q3w x12 from 4 weeks post-RT. By Fleming one-stage design (type I error 0.05, power 0.80, 10% drop out), planned sample size is 46. Primary endpoint is 2-year (yr) progression free survival (PFS). Secondary endpoints include safety and tolerability. Plasma EBV DNA (pEBV DNA) was monitored. **Results:** Accrual was completed with 46 subjects recruited at two study sites from May 2019 to June 2022 in Hong Kong (n=31) and Singapore (n=15). This protocol specified analysis included 37 subjects with >12 months post-treatment follow up (median 26.8 months, 95% CI 21.3-32.9). Patient demographics: mean age 52 (range 27 - 84); M:F 31:6; ECOG 0=23, 1=14; stages: T4N1-2 (16), T1-3N3 (18), T4N3 (3). Overall compliance rate: neoadjuvant cisplatin 98.6%, gemcitabine 97.7%, concurrent cisplatin 73.7%, pembrolizumab 100% (neoadjuvant), 77.5% (concurrent), 77% (maintenance), IMRT 99.7% (69.96 Gy). Treatment related adverse events (≥ grade 3, >10%): dysphagia (32.4%), mucositis (29.7%), neutropenia (29.7%), radiation dermatitis (24.3%), anemia (18.9%), hyponatremia (13.5%), thrombocytopenia (10.8%). No ≥ grade 4 mucositis/dermatitis. The 2-yr PFS was 69.6% (95% CI 53.8 - 88.5%). At the end of neoadjuvant, CRT and maintenance phases, molecular remission (pEBV DNA = 0) was achieved in 24.3%, 70.3% and 70.3% of patients respectively, which strongly correlated with PFS (p=0.0253, 0.0007 and <0.0001 respectively, Table). **Conclusions:** Pembrolizumab incorporated into neoadjuvant, CRT and maintenance protocol is safe with promising results. This strategy of combining ICI with neoadjuvant chemotherapy and CRT is being tested in several ongoing phase 3 trials in advanced NPC. Clinical trial information: NCT03734809. Research Sponsor: Funding for this Investigator-initiated Research was provided by MSD.

Poster Discussion Session

Final overall survival analysis of JUPITER-02: A phase 3 study of toripalimab versus placebo in combination with gemcitabine and cisplatin as first-line treatment for recurrent or metastatic nasopharyngeal carcinoma (NPC). *First Author: Hai-Qiang Mai, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: There are currently no FDA-approved IO therapies for NPC. Toripalimab in combination with Gemcitabine-Cisplatin (GP) chemotherapy had shown significant improvement over chemotherapy alone in progression-free survival (PFS) as first-line treatment for recurrent or metastatic (r/m) NPC at the interim PFS analysis of JUPITER-02 (NCT03581786) study. The final overall survival (OS) analysis results are summarized here. **Methods:** Patients with r/m NPC (n = 289) were randomized (1:1) to receive toripalimab 240 mg (n = 146) or placebo (n = 143) in combination with GP once every 3 weeks (Q3W) for up to 6 cycles, followed by monotherapy with toripalimab or placebo Q3W until disease progression, intolerable toxicity, or completion of 2 years of treatment. Stratification factors were ECOG performance score (0 vs. 1) and extent of disease (recurrent vs. primary metastatic) at enrollment. The primary endpoint was PFS by an independent review committee. Secondary endpoints included OS and safety. **Results:** By the cutoff date of Nov 18, 2022, when 133 events were reached for the final OS analysis, the median survival follow up was 30.1 months. A significant improvement in OS was observed for the toripalimab arm over the placebo arm: HR = 0.63 (95% CI: 0.45-0.89), two-sided p = 0.0083. The median OS was not reached in the toripalimab arm and was 33.7 months in the placebo arm. The 2-year and 3-year OS rates were 78.0% vs. 65.1%, and 64.5% vs. 49.2% respectively. A consistent effect on OS, favoring the toripalimab arm, was observed in nearly all subgroups, including PD-L1 high and PD-L1 low expression subgroups. No new safety signals were identified in the toripalimab arm since the interim report. The incidence of Grade ≥3 adverse events (AEs) (89.7% vs 90.2%) and fatal AEs (3.4% vs 2.8%) were similar between two arms. However, AEs leading to discontinuation of toripalimab/placebo (11.6% vs 4.9%), immune-related (irAEs) (54.1% vs. 21.7%) and Grade ≥3 irAEs (9.6% vs. 1.4%) were more frequent in the toripalimab arm. **Conclusions:** The addition of toripalimab to GP chemotherapy as 1st-line treatment for r/m NPC provided clinically important and highly significant OS advantage over GP alone with a manageable safety profile. These results support the use of toripalimab with GP chemotherapy as the new standard care for this population. Clinical trial information: NCT03581786. Research Sponsor: Shanghai Junshi Biosciences.

Poster Discussion Session

Dual PD1 and CTLA4 immune checkpoint blockade and hypofractionated radiation in patients with salivary gland cancers. *First Author: Cristina P. Rodriguez, University of Washington, Seattle, WA*

Background: No systemic therapy standard of care exists for recurrent/metastatic malignancies of the salivary glands (SGC) and immune checkpoint inhibitors (ICIs) have low response rates. Preclinical data in solid tumors suggest synergistic antitumor effects of ICIs with hypofractionated radiation (XRT). This study explored the safety and activity of nivolumab (N) and ipilimumab (I) with palliative XRT. **Methods:** This phase I/II open label single arm trial enrolled patients (pts) with incurable SGCs (WHO 2017) with evidence of progression, ECOG 0-1, no prior antiPD1 or CTLA4 directed therapy, RECIST 1.1 measurable disease excluding the XRT site. Pts received N 3mg/kg IV Q 2 weeks x 12 doses followed by 480 mg IV Q4 weeks x 8 doses and I 1 mg/kg IV Q6 weeks x 4 doses. XRT was given to a total dose of 24Gy in 3 fractions every other day over 1 week (wk) and initiated 2 wks after the first dose of N and I. Research blood collection was obtained prior to wks 1, 8 and 16. The primary endpoint was safety and tolerability using CTCAE v. 4, secondary endpoints were objective response rates (ORR) by RECIST 1.1 criteria in non-radiated sites of measurable disease, overall survival (OS) and progression free survival (PFS). The study was approved by the FHCC IRB and registered on clinicaltrials.gov (NCT03749460). **Results:** Between 4/2019 and 5/2022, 20 pts were enrolled, the median age was 58 (range 27-77) years, 10 (50%) were male, 12 (60%) had ECOG 0, and 7 (35%) were Asian. Most common histologies were adenoid cystic 9 (45%) and salivary duct 4 (20%), 15 (75%) had no prior systemic therapy. Ten (50%) had both local and distant disease, 14 (70%) had commercial NGS testing, all had TMB < 10mut/Mb, MSI-stable tumors. All patients completed XRT with the most common XRT site being the lung 13 (65%) and bone 7 (35%). The median number of N doses received was 12 (range 3-20) and I doses 4 (range 1-4). Enrollment was halted until first 6 pts were assessed for dose limiting toxicities during initial 12 wks of treatment, none were observed. Among all pts enrolled, 5 (20%) Grade 3 AEs were observed: adrenal insufficiency, hypokalemia, lung infection, hypotension, and mania. No grade 4/5 toxicities were observed. One pt was not evaluable for RECIST 1.1 due to rapid disease progression: partial responses were observed in 4 (20%: 2 pts with salivary duct, 1 acinic cell and 1 adenoid cystic) with a median duration of 15.5 months (mos) (range 6-16 mos), stable disease in 6 (30%) all lasting 6 mos or greater, and progressive disease in 9 (45%). With a median follow-up of 16 mos, median OS was 25 mos (95% CI: [1.56, 2.59]) and median PFS was 7.2 mos (95% CI: [0.21, 1.56]). Exploratory correlative peripheral blood analysis is ongoing and will be reported. **Conclusions:** Nivolumab/ipilimumab and palliative XRT results in low rates of severe toxicities, modest ORR but durable ORR/SD. Further work is necessary to explore predictors for response. Clinical trial information: NCT03749460. Research Sponsor: Bristol Myers Squibb.

Poster Discussion Session

Safety and efficacy of immune checkpoint inhibitor (ICI) naïve cohort from study of PDS0101 and pembrolizumab in HPV16-positive head and neck squamous cell carcinoma (HNSCC). *First Author: Katharine Andress Rowe Price, Department of Oncology, Mayo Clinic, Rochester, MN*

Background: Up to 70% of oropharyngeal cancers in the US are reported to be HPV-mediated with most caused by HPV16 infection. First line treatment for patients with unresectable, recurrent or metastatic (R/M) disease is pembrolizumab with or without chemotherapy, but most patients eventually experience disease progression. PDS0101 is a novel, investigational HPV16-targeted immunotherapy that stimulates a potent, targeted T cell attack against HPV16-positive cancers. **Methods:** VERSATILE-002 (NCT04260126) is an open-label, non-randomized, Simon 2-stage study evaluating the combination of PDS0101 and pembrolizumab in subjects with HPV16-positive R/M HNSCC in 2 cohorts: ICI-naïve and ICI-refractory. All subjects receive pembrolizumab IV Q3W with PDS0101 SC administered concurrently during Cycles 1, 2, 3, 4, and 12 (max 5 doses). The primary endpoint of the study is confirmed Best Overall Response per RECIST 1.1. Herein we update the safety, PFS, and OS data for the ICI-naïve subjects. **Results:** Forty-eight subjects who received at least one cycle of combination therapy (safety population) had a median age of 62.5 (range 45 – 83), were 93.8% male, 93.8% White, and 62.5% ECOG 0. Among this population, the median overall treatment duration in months was 3.5 (range 0.0 – 19.5). The median number of PDS0101 doses was 4 (range 1 – 5); 56.3% received 4 doses and 22.9% received 5 doses. The median number of pembrolizumab doses was 5 (range 1 – 29); 27.1% received ≥10 doses. Efficacy was evaluated in 34 subjects (47.1% with CPS ≥20) who had assessment of tumor response following treatment (efficacy population). Tumor reduction (maximum percent change from baseline) was seen in 23 (67.6%) subjects. Nine subjects (26.5%) had confirmed response including 1 CR and 8 PR, 15 subjects had SD (44.1%), and 9 subjects had PD (26.5%). One subject was not evaluable (2.9%). The median PFS was 10.4 months (95% CI 4.2, 15.3). Among the safety population, median overall survival was non-estimable due to the ongoing survival status of study subjects. The estimated 12-month OS rate was 87.1%. Thirty-three (68.5%) subjects had mild or moderate (Grade 1 or 2) PDS0101-related TRAE (TRAE); the most common were fatigue and injection site reactions (ISRs). Only 3 subjects (6.3%) had Grade 3 TRAEs: fatigue, ISR, blood alkaline phosphatase increased, and hyperglycemia. No subjects had Grade 4 or 5 TRAE. No subject came off study due to toxicity. **Conclusions:** PDS0101 with pembrolizumab is well tolerated in this ICI naïve R/M HPV-associated HNSCC population. Median PFS was 10.4 months which compares favorably to published median PFS of 2-3 months for approved ICIs when used as monotherapy in patients with similar PD-L1 levels. The estimated 12-month OS of 87.1% is promising compared to published results of about 36-50%. These results justify a confirmatory randomized, controlled study. Clinical trial information: NCT04260126. Research Sponsor: PDS Biotechnology.

Poster Discussion Session

Phase II trial of adjuvant de-escalated radiation + adjuvant nivolumab for intermediate-high risk P16+ oropharynx cancer. *First Author: Heath Devin Skinner, UPMC Hillman Cancer Center, Department of Radiation Oncology, Pittsburgh, PA*

Background: Treatment de-intensification for resected, human papillomavirus (HPV)-associated oropharyngeal squamous cell carcinoma (OPSCC) is an area of active investigation, with a goal of providing a less toxic adjuvant regimen compared to the current standard of care 66 Gy of radiation (RT) combined with concurrent cisplatin defined in recently reported as Arm D of the ECOG3311 trial. Here, the programmed death 1 (PD-1) antibody nivolumab was added to de-intensified RT in high risk, resected HPV+ OPC. **Methods:** Eligible patients included transorally resected pathologic stage III or IVA HPV+ OPSCC using p16 immunohistochemistry, featuring high-risk neck disease factors (gross extracapsular extension >1mm or ≥5 positive lymph nodes) to mirror ECOG3311 Arm D patients accrued. Positive margin status was excluded except by PI approval. Postoperative treatment consisted of accelerated fractionation RT (50 Gy over 4 weeks) concurrent with nivolumab at 240 mg every 2 weeks, followed by 6 months of adjuvant nivolumab biweekly or monthly. The primary endpoint was progression-free survival (PFS). Swallowing and quality of life patient reported outcome (PRO) measures were collected at baseline and defined intervals after treatment. **Results:** Forty-one patients (n=41) were accrued and were analyzed. Forty of 41 patients remain alive with a median follow-up of 30 months (range 1 – 49 months). The probability of 3-year overall survival is 97% (95% CI = 90% - 100%) and the probability of 3-year PFS is 86% (95% CI = 68% - 100%). Two patients developed recurrent disease, one of whom died. One patient developed isolated metastasis while a second developed local, regional, and distant metastasis. The most common adverse grade ≥3 adverse events were lymphocytopenia (n=24), dysphagia (n=2) and oral mucositis (n=2). One grade 4 sepsis/multi-organ failure was reported. Comparison of PRO results with those observed in ECOG3311 trial are underway and will be reported. **Conclusions:** De-intensification of adjuvant treatment adding nivolumab to RT is tolerable and demonstrates favorable clinical outcome for high-risk, resected, HPV+ HNSCC patients. Further targeted immunotherapy combinations are warranted. Clinical trial information: NCT03715946. Research Sponsor: U.S. National Institutes of Health.

A phase 1 dose-escalation and expansion study of CUE-101, a novel HPV16 E7-pHLA-IL2-Fc fusion protein, given as monotherapy and in combination with pembrolizumab in patients with recurrent/metastatic HPV16+ head and neck cancer. *First Author: Christine H. Chung, Moffitt Cancer Center, Tampa, FL*

Background: Immuno-STATs are modular T cell engagers engineered to selectively activate tumor-antigen specific CD8+ T cells via targeted delivery of cytokines. CUE-101, the first Immuno-STAT in clinical trials, is composed of a human leukocyte antigen (HLA) complex, HLA-A*0201, a peptide epitope derived from the HPV16 E7 protein, and 4 molecules of attenuated human interleukin-2 (IL-2) designed to bind, expand, and activate HPV16-specific CD8+ T cells for the treatment of HPV16+ cancers. **Methods:** CUE-101-01 is an ongoing first-in-human study in HLA-A*0201 patients with HPV16+ recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC). Escalating doses of CUE-101 monotherapy (0.06 mg/kg to 8 mg/kg) and in combination with pembrolizumab (1 mg/kg to 4 mg/kg + 200 mg pembrolizumab) were evaluated, followed by expanded enrollment at the recommended phase 2 dose (RP2D). Patients with R/M HNSCC refractory to ≥ 1 platinum-based or checkpoint inhibitor therapy received CUE-101 monotherapy. Patients with previously untreated PD-L1+ R/M HNSCC received CUE-101 + pembrolizumab as first-line treatment. Therapy was administered every 3 weeks until disease progression or intolerable toxicity. Safety, pharmacokinetics (PK), pharmacodynamics (PD), and anti-tumor activity were assessed. **Results:** As of January 12, 2023, 67 patients were enrolled. A MTD was not established in monotherapy or combination-treated patients; 4 mg/kg of CUE-101, alone or in combination with pembrolizumab, was chosen as the RP2D dose in both cohorts. Monotherapy RP2D enrollment is complete and combination RP2D enrollment is ongoing. Frequent adverse events include fatigue (45%), anemia (34%), chills (27%), infusion related reactions (25%), constipation (22%), lymphopenia (22%) and nausea (22%). CUE-101 PK data demonstrate dose-dependent increases in drug exposure sustained with repeat dosing. PD data demonstrate selective expansion of HPV-16 E7₁₁₋₂₀-specific CD8+ T cells, sustained increase in NK cells and transient increase in Treg cells. Among 19 evaluable monotherapy RP2D patients, 1 PR and 6 durable SD (SD ≥ 12 weeks) were observed, with mOS of 24.4 months (9.1, NA). Among 12 evaluable RP2D combination patients to date, 5 PRs, and 2 durable SDs have been observed, with 71% (5/7) of patients expressing PD-L1 CPS ≤ 20. **Conclusions:** CUE-101 facilitates the targeted delivery of high concentrations of IL-2 to relevant tumor-specific CD8+ T cells. We demonstrate safety and tolerability with encouraging PD signals and antitumor activity with monotherapy and in combination with pembrolizumab in HPV+ R/M HNSCC patients. Enrollment continues in the CUE-101 and pembrolizumab combination cohort. Clinical trial information: NCT03978689. Research Sponsor: CUE Biopharma Inc.

Poster Discussion Session

Correlation of CDKN2A genomic alterations with tumor response to palbociclib given before chemoradiation therapy (CRT) to patients with human papillomavirus (HPV)-negative, locally advanced head and neck squamous-cell carcinoma (LA-HNSCC): A single-arm, phase 2 trial. *First Author: Peter John Oppelt, Washington University School of Medicine, St. Louis, MO*

Background: Cell cycle deregulation is ubiquitous in HNSCC. In HPV-negative disease, the most common genomic alteration of cell-cycling included *CDKN2A* deletions (57%), mutations (27%) or hypermethylation (12%). Selective CDK4/6 inhibition arrested cell cycling and inhibited tumor growth in cell-line and xenograft models of HPV-negative HNSCC, and *CDKN2A* alterations were predictive of response. An exploratory analysis of a double-blind, randomized, phase 2 trial of patients with HPV-negative recurrent/metastatic HNSCC showed that *CDKN2A* alterations were associated with better overall survival (OS) with palbociclib and cetuximab vs placebo and cetuximab (median 9.7 vs 4.6 months, HR 0.38). OS was similar between the two arms in patients without *CDKN2A* alterations. A phase 2 basket trial of patients with *CDKN2A*-altered head and neck cancers observed that palbociclib resulted in a target lesion decrease in 25% of patients. Collectively, these data warrant further studies to delineate predictive biomarkers of response to selective CDK4/6 inhibitors in HPV-negative HNSCC. **Methods:** The primary aims of this single-arm, phase 2 trial were to determine the objective response rate (ORR) of HPV-negative, LA-HNSCC to palbociclib, and to correlate responses to somatic *CDKN2A* alterations. HPV-negative disease was defined as SCC of the larynx, hypopharynx or oral cavity, or SCC of the oropharynx if negative for p16 by IHC and/or high-risk HPV-RNA by ISH. Genome sequencing (FoundationOne CDx/Tempus XT) was performed on tumor tissue obtained before treatment. Patients received palbociclib 125 mg/d orally on days 1-21 of each 28-day cycle. Tumor response was assessed using RECIST 1.1 with CT scans performed pre and post two cycles of palbociclib. Patients then received CRT. A sample size of 24 patients yielded an 80% power if the ORR was ≥38%, using an exact binomial test of one sample proportion comparison with an upper one-sided nominal significance level of 0.05 and null ORR of ≤17%. **Results:** 24 patients enrolled and completed two cycles of palbociclib: primary site (larynx-15; hypopharynx-4; oropharynx-4, oral cavity-1), clinical stage (III-7; IV-17), and smoking history (yes-23; no-1). The ORR with palbociclib was 41.7%. Best tumor response included: CR (1), PR (9), SD (13), and PD (1). *CDKN2A* altered disease was identified in 15 patients (62.5%) [mutation: 8, deletion: 7]. Tumor response to palbociclib occurred in 10 of 15 patients (66.7%) with *CDKN2A* altered disease versus 0 of 9 patients (0%) without *CDKN2A* altered disease (p=0.002, Fisher's Exact Test). **Conclusions:** The primary hypothesis was met: the ORR with palbociclib in HPV-negative, LA-HNSCC was 41.7%. The ORR with palbociclib was significantly higher in *CDKN2A* altered disease. Clinical trial information: NCT03389477. Research Sponsor: Pfizer.

Poster Discussion Session

Olaparib, a poly (ADP-ribose) polymerase (PARP) inhibitor, in combination with pembrolizumab and carboplatin as first-line treatment of recurrent or metastatic head and neck squamous-cell carcinoma (RM-HNSCC): A single-arm, phase 2 trial. *First Author: Jared Cohen, Washington University Siteman Cancer Center, St. Louis, MO*

Background: The homologous recombination deficiency (HRD) phenotype is common in HNSCC and is due to mutation and promoter hypermethylation of DNA repair genes (*BRCA1, BRCA2, ATR, ATM, and FANCD*) and *PTEN*. In pre-clinical models of HNSCC, HRD sensitizes tumor to PARP inhibition and to additive antitumor activity of PARP inhibition in combination with platinum agents. PARP inhibitors also activate the STING pathway and upregulate PD-L1 expression, resulting in synergistic antitumor activity when given with PD-1 inhibitors. Olaparib is a highly selective PARP inhibitor that has been safely combined with pembrolizumab and carboplatin. **Methods:** In this single-arm phase 2 trial, patients with RM-HNSCC, no prior therapy for RM disease, and adequate performance status and organ function received up to six 21-day cycles of olaparib (200 mg bid orally days 1-10), pembrolizumab (200 mg IV day 1), and carboplatin (AUC 5 IV day 1), followed by up to twenty-nine 21-day cycles of olaparib (oral 300 mg bid days 1-21) and pembrolizumab (200 mg day 1). Treatment continued until discontinuation criteria were met. The primary endpoint was objective response, assessed by an independent radiologist using iRECIST. The primary hypothesis was that this regimen would result in a higher objective response rate (ORR) than historically reported with 5-FU, pembrolizumab and a platinum agent in similar patients. A Simon optimal two-stage design tested the null hypothesis (H_0 : ORR $\leq$ 36%) versus the alternative hypothesis (H_1 : ORR=62%) at a type I error rate of 10% and 90% power. In the first stage, up to 13 patients could be accrued. If $\geq$ 6 responses occur, 16 additional patients will be accrued. The null hypothesis will be rejected if $\geq$ 14 responses are observed in these 29 patients. At the end of the first stage, an interim analysis was performed to assess olaparib delivery during cycles 1 and 2 with the goal of 100% delivery in $\geq$ 80% of patients. We report the results of the primary endpoint and olaparib delivery for the first stage of the trial. **Results:** Twelve patients enrolled into the first stage of the trial. Key characteristics included median age 62 years (range 59-74), tobacco history (Y=5; N=7), primary site (oropharynx=7; oral cavity=4; larynx=1), HPV status (positive: 6; negative: 6) and PD-L1 status (CPS $\geq$ 1; 1-19: 4; $\geq$ 20: 7). Tumor response occurred in 8 patients (ORR 67%). The best tumor response to date was CR (1), PR (7), SD (3) and PD (1). Olaparib delivery during cycles 1 and 2 was 100% for all patients. **Conclusions:** Among patients with RM-HNSCC, first-line treatment with olaparib, pembrolizumab and carboplatin resulted in an ORR of 67% during the first stage of the trial. Olaparib delivery was 100%. Enrollment into the second stage is ongoing. Clinical trial information: NCT04643379. Neoadjuvant nivolumab alone or in combination with relatlimab or ipilimumab in resectable head and neck squamous cell carcinoma (HNSCC). *First Author: Robert L. Ferris, Hillman Cancer Center, Pittsburgh, PA*

Background: PD-1 inhibition using nivolumab (nivo) monotherapy is modestly effective in metastatic HNSCC. Neoadjuvant trials using nivo may permit development of more effective combinations in surgically resectable HNSCC. We evaluated combinations with nivo plus additional immune checkpoints, CTLA-4 (ipilimumab, ipi) and LAG-3 (relatlimab, rela). **Methods:** Phase II randomized trial of neoadjuvant nivo alone (240 mg q2 weeks), or with ipi (1 mg/kg q3 weeks) or rela (160 mg q4 weeks) for 4 weeks prior to surgery. Response was scored using RECIST and standard pathologic response criteria. Patients were stratified by p16, PD-L1, and LAG-3, with staining assessed by immunohistochemistry. Freshly digested tumors were subjected to single cell RNA sequencing (scRNAseq) for T cell receptors and gene pathways to identify biomarkers of response or progression. The Cochran-Armitage trend test was used to explore associations with increasing pathological response efficacy. **Results:** 41 patients (pts) have been enrolled, with 33 evaluable for this analysis. Of these 33, median age is 63 (32-81), primary site oral cavity (n=25), oropharynx (n=5, 3 HPV), larynx (n=3), clinical T2 (n=5), T3 (n=12), T4 (n=13), and cN0/1 (n=22), cN2 (n=9), and PD-L1 CPS $>$ 1 (n=25). There were no serious study drug-related AEs or unexpected surgical delays/complications. Pathologic response (Table) was more frequent with nivo/rela (11/13) vs. nivo/ipi (6/10) or nivo (4/10). Partial ($>$ 50%) or major ($>$ 90%) pathologic responses were more frequent and deeper in the combination arms. Minor ($<$ 50%) pathologic responses were more frequent with nivo/rela, and similar between nivo/ipi and nivo. There was no association between RECIST response, PD-L1, or LAG3 and pathologic response. Combined PD-L1 and LAG3 expression was not associated with pathologic response in the nivo/rela arm, however more patients with combined positivity had a $>$ 50% response (4 vs. 0). Expansion of CD8 $^{+}$ T cells, as well as expanded proportion of CD8 $^{+}$ CXCL13 $^{+}$ T cells in responder tumors were identified in post-treatment specimens using scRNAseq. **Conclusions:** Neoadjuvant nivo/ipi or nivo/rela combinations were safe and associated with promising pathologic responses compared to nivo monotherapy. Anti-tumor CD8 $^{+}$ T cell populations and targetable pathways are emerging in responder patients. The trial continues to enroll and further evaluation of this strategy is warranted. Clinical trial information: NCT04080804. Research Sponsor: U.S. National Institutes of Health.

RECIST and pathologic response.

	RECIST				Pathologic Response

Poster Discussion Session

Enfortumab vedotin in the previously treated advanced head and neck cancer (HNC) cohort of EV-202. *First Author: Paul Swiecicki, Department of Internal Medicine, Division of Hematology/Oncology, University of Michigan Medical School, Ann Arbor, MI*

Background: Globally, HNCs accounted for an estimated 932,000 new cases and 467,000 deaths in 2020. Nectin-4 is expressed in a majority of HNCs. Given the poor prognosis (median survival $<$ 1 y) of recurrent/metastatic disease in patients (pts) with head and neck squamous cell carcinoma, effective treatments are needed. Targeting Nectin-4 with an antibody-drug conjugate (ADC) may be a novel strategy. Enfortumab vedotin (EV) is a Nectin-4 directed ADC approved for treatment of adults with locally advanced or metastatic (la/m) urothelial carcinoma previously treated with platinum-containing chemotherapy and PD-1/L1 inhibitor based on survival benefit shown in the phase 3 EV-301 trial. Use of EV for HNC is investigated in EV-202 (NCT04225117). **Methods:** In this multicohort, open-label phase 2 study, pts with previously treated la/m solid tumors not amenable to curative-intent treatment and Eastern Cooperative Oncology Group performance status 0-1 were enrolled into tumor-specific cohorts. For the HNC cohort, pts must have progressed/relapsed/discontinued treatment for toxicity after 1 platinum-based therapy for la/m disease and no more than 2 lines of cytotoxic therapy in the la/m setting. Unless contraindicated, pts must have received a programmed cell death protein 1/ligand 1 (PD-1/L1) inhibitor (based on PD-1/L1 expression). Pts received EV 1.25 mg/kg intravenously on days 1, 8, and 15 of a 28-d cycle until disease progression/discontinuation criteria were met. Primary endpoint was confirmed objective response rate (ORR; per RECIST v1.1) per investigator assessment. Secondary endpoints were duration of response (DOR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety/tolerability. **Results:** As of April 11, 2022, a total of 46 pts were in the HNC cohort; median follow-up was 9.33 mo. Median age was 65 y, 87% of pts were men, and most had received $\geq$ 2 lines of systemic therapy in the metastatic setting. Histology at diagnosis was squamous cell carcinoma for 45 (97.8%) pts and "other" for 1 pt. ORR was 23.9% (n = 11). Median DOR was not reached. DCR was 56.5% (n = 26). Median time to response was 1.74 mo. Median PFS and OS were 3.94 and 5.98 mo, respectively. Common adverse events (AEs) were fatigue, alopecia, and peripheral sensory neuropathy (28.3% for each; n = 13). Grade $\geq$ 3 AEs occurring in $>$ 1 pt were anemia (n = 3), decreased neutrophil count (n = 2), and malignant neoplasm progression (disease progression of HNC; n = 2). Of treatment-related AEs of special interest for EV, skin reactions occurred in 45.7% of pts, peripheral neuropathy in 32.6%, and hyperglycemia in 4.3%. **Conclusions:** In pts with heavily pretreated HNC, antitumor activity of EV monotherapy and tolerability, with manageable adverse events, was observed, consistent with that in previously studied populations with advanced urothelial carcinoma. Further investigation of EV activity in HNC is warranted. Clinical trial information: NCT04225117. Research Sponsor: Astellas Pharma, Inc. and Seagen Inc.

Poster Discussion Session

Neoadjuvant cemiplimab with platinum-doublet chemotherapy and cetuximab to de-escalate surgery and omit adjuvant radiation in locoregionally advanced head & neck squamous cell carcinoma (HNSCC). *First Author: Winston Wong, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Locoregionally advanced (LA) HNSCC treated with surgery can carry significant functional morbidity, further intensified by adjuvant (adj) radiation (RT) often with concurrent chemotherapy. Although the pathologic response rate of anti-PD1 therapy is modest, combination approaches may provide enhanced clinical benefit. This pilot study evaluates whether the combination of neoadjuvant cemiplimab + platinum-doublet chemotherapy + cetuximab is safe, feasible, and effective in pathologic down-staging to reduce the extent of surgery and justify omission of adj RT. **Methods:** 10 patients (pts) with resectable LA HNSCC who would warrant adj RT per clinical stage were enrolled. Neoadjuvant treatment consisted of cetuximab loading dose with cemiplimab followed by 3 cycles of chemotherapy (cisplatin or carboplatin + docetaxel) with cetuximab and cemiplimab prior to definitive surgical resection. Standard of care adj RT +/- chemotherapy was administered based on pathologic staging. Pts with ypT0-2N0 tumors without adverse features or ypT0-1N1 tumors with minimal residual disease ($<$ 10% viable tumor) were offered 6 months of adj cemiplimab in lieu of RT. Primary endpoint was safety (defined by dose limiting toxicity (DLT) related to the addition of cemiplimab to this combination regimen). Secondary endpoints included feasibility (defined as no surgical delay $>$ 20 weeks from start of neoadjuvant therapy due to treatment toxicity) and pathologic down-staging allowing for omission of adj RT. **Results:** 10 pts completed treatment with no DLTs and surgical delays. 8/10 (80%) pts were clinically staged as T3/T4 and 5/10 (50%) were N2b/c (AJCC 7th Ed). Pathologic down-staging was observed in 9/10 (90%) pts after neoadjuvant therapy. 60% had a major pathologic response and 40% had a complete pathologic response. 6/8 pts and 7/10 pts who would have required a mandibulectomy and free flap, respectively, did not require it following neoadjuvant treatment. Of the 5/10 (50%) pts who were eligible for omission of adj RT, 4 did not undergo RT and 3 received adj cemiplimab. All pts remain disease-free at a median follow-up of 16 months. The most common adverse events (AEs) of any grade (G) were rash (80%), nausea (70%), fatigue (50%), and diarrhea (50%). 2/10 (20%) pts experienced a G3 or G4 immune-related AE attributed to the addition of cemiplimab. One pt developed G3 transaminase elevation prior to surgery and 1 pt experienced G3 myasthenia gravis and G4 myocarditis (resolved) outside the DLT window. **Conclusions:** Neoadjuvant cemiplimab with platinum-doublet chemotherapy and cetuximab has an acceptable toxicity profile, is feasible in pts with LA HNSCC, and led to notable pathologic down-staging allowing for reduction in extent of surgery and omission of adj RT. Further evaluation of this regimen is clearly warranted. Clinical trial information: NCT04722523. Research Sponsor: Regeneron Pharmaceuticals; The Sierra Initiative on the Management of Head and Neck Cancer Side Effects; Investigator Initiated Trial RFA, Department of Medicine, Memorial Sloan Kettering Cancer Center.

The Quarterback trials: A phase 2 series of sequential studies of induction chemotherapy followed by reduced dose chemoradiation for human papillomavirus positive oropharynx cancer. *First Author: Marshall R. Posner, Division of Hematology and Medical Oncology, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Human Papilloma Virus (HPV) oropharynx cancer (HPVOPC) is highly curative. Current standard of care treatment recommendations result in over treatment with chemoradiotherapy (CRT) across all stages of the disease and lead to significant long-term morbidity. The Quarterback (QB) trials (NCT01706939, QB1; NCT02945631, QB2a/2b) applied induction chemotherapy (IC) with modified Taxotere, cis-platinum and 5-fluorouracil (TPF) and reduced dose chemoradiotherapy (rdCRT) in very advanced HPVOPC. The primary endpoints were local regional control (LRC) and progression-free survival (PFS) at 3 years. **Methods:** Patients with locally advanced HPVOPC and High Risk (HR) features (radiographic ECE, T4 primary, $\geq$ N2c disease or non-HPV16 HR genotype) or who were candidates for organ preservation were entered on sequential trials of 3 cycles of TPF IC followed by rdCRT to 5600 cGy with weekly carboplatin. The only variable in IC treatment were 3 sequential reductions of 5-fluorouracil from 800 to 500 mg/M²/day across the trials (QB1, QB2a/2b). Major inclusion criteria were: molecularly documented high risk HPV and $\leq$ 20 pack year smoking history. Patients were eligible for rdCRT if they had a significant clinical response to IC. The hypothesis for non-inferiority was that LRC and PFS at 3 years would be at least 85% and 80%, respectively, based on results from RTOG 1029. Analysis was limited to those patients who received or were randomized (QB1) to rdCRT. **Results:** Of 45 subjects treated with rdCRT, 35 (78%) had HR features. Overall survival (OAS) is 39 (87%), LRC 39 (87%), PFS 35 (78%) with a median follow up of 57m (range: 12-120). Kaplan Meyer 3 year LRC is 88% (95% CI: 79-99), PFS 86% (95 CI 76-97) and OS 93% (95% CI 86-100). 2 subjects (4%) developed an in-field non-HPV, p53 positive squamous cancer and 1 (2%) died. 1 subject (2%) died of non-HPV related disease (SLE); 2 (4%) developed distant metastases; 4 (9%) subjects are alive after recurrence. Disease specific survival is 40/43 (93%). 19 patients signed consent and did not receive rdCRT: 8 were randomized to standard dose (QB1), 2 withdrew consent, 5 had an inadequate response to IC and 4 were screen failures. All 15 treated with IC are alive and disease free. There are no treatment related deaths. **Conclusions:** TPF IC in HPVOPC with HR features, followed by rdCRT met its predetermined statistical goals for LRC, PFS and OAS. Treatment was tolerable and toxicity was manageable. Compared to other Phase 2 and 3 de-escalation trials this approach is reasonable, effective and feasible. QB1 demonstrated improved quality of life in rdCRT with 5600 cGy compared to standard chemoradiotherapy. Randomized trials to establish de-escalation as a standard of care are warranted. Further de-escalation of treatment to further reduce acute and long-term radiation toxicity in HR populations appears feasible. Clinical trial information: NCT01706939; NCT02945631. Research Sponsor: Philanthropy.

Tazemetostat, a selective EZH2 inhibitor, with pembrolizumab as treatment of anti-PD-1 resistant head and neck squamous-cell carcinoma (HNSCC): A phase 1-2 trial. *First Author: Sidharth Puram, Washington University School of Medicine, St. Louis, MO*

Background: EZH2 is the catalytic subunit of PRC2, which catalyzes H3K27me3 of target gene promoters and silences transcription of several cancer-related genes. EZH2 overexpression is common in HNSCC and correlated with methylation of several tumor suppressor genes. EZH2 siRNA downregulated EZH2 mRNA and protein and reduced colony formation in an EZH2-expressing HNSCC cell line. EZH2 inhibitors decreased H3K27me3 in HPV + and - cell lines. Tazemetostat, an EZH2 inhibitor, upregulated expression of HLA class I molecules in anti-PD-1-resistant HNSCC cell lines and mouse models, and increased antigen-specific CD8+ T cell proliferation, IFN- γ production, CXCL10 expression, and tumor cytotoxicity. In an anti-PD-1-resistant HNSCC model, tazemetostat and an anti-PD-1 suppressed tumor growth. The primary aims of this phase 1-2 trial were to establish 1) the recommended phase 2 dose (RP2D) of tazemetostat given with pembrolizumab and 2) the objective response rate of this regimen among patients (pts) with anti-PD-1 resistant, PD-L1 positive HNSCC. We report the results of Phase 1. **Methods:** In phase 1, eligible pts had recurrent/metastatic (RM) HNSCC, adequate performance status and organ function, and ability to swallow study drug. A 3+3 dose-escalation phase 1 design was used to assess 3 dose-levels of tazemetostat (400, 600, and 800 mg orally twice daily) with pembrolizumab (200 mg IV). Cycle 1 was 35 days, with tazemetostat given on days 1-35 and pembrolizumab on day 15. Subsequent cycles were 21 days, with tazemetostat given on days 1-21 and pembrolizumab on day 1. Dose-limiting toxicity (DLT), assessed during cycle 1, was defined as grade 4 neutropenia/thrombocytopenia, grade 3 febrile neutropenia, or study drug-related grades 3-4 non-hematologic adverse events (AEs). Pts must have completed cycle 1 to be evaluable for DLT assessment; otherwise, an equal number of additional pts were enrolled. The RP2D was defined as the highest dose level in which 0 of the first 3 or $<$ 1 of 6 pts experienced a DLT. **Results:** 12 pts enrolled to phase 1: 3 each on the 400 and 600 mg dose-levels of tazemetostat and 6 on the 800 mg dose-level. Key tumor characteristics included primary site (larynx: 4, oral cavity: 3, oropharynx: 3, nasopharynx: 1, cutaneous: 1), HPV status (+: 1, -: 11), and number of lines of prior systemic treatment for RM disease (1-2: 6, $>$ 3: 6). Nine pts were evaluable for DLT; 3 pts on the 800 mg dose-level did not complete cycle 1 and were not evaluable for DLT. DLT events and grade 4-5 AEs did not occur. Grade 3 AEs that occurred after cycle 1 included anemia (2 pts, both at 800 mg dose) and fatigue (1, at 400 mg dose). Across all cycles, the most common AEs included anemia (10 pts), fatigue (9), rash (7), and myalgia (4). **Conclusions:** Among pts with RM-HNSCC, the RP2D of tazemetostat was 800 mg twice daily when given with pembrolizumab. Enrollment to phase 2 is ongoing. Clinical trial information: NCT04624113. Research Sponsor: Epizyme, an Ipsen Company.

Poster Session

Association of neutrophil-lymphocyte ratio (NLR) with clinical outcomes in patients (pts) with recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC) treated with combination of cetuximab and nivolumab (C+N). *First Author: Robin Park, Moffitt Cancer Center, Tampa, FL*

Background: Combination of anti-epidermal growth factor receptor (EGFR) and anti-programmed cell death-1 (PD-1) inhibitors such as C+N is highly efficacious in R/M HNSCC. While PD-1 ligand 1 (PD-L1) combined positive score (CPS) is predictive of anti-PD-1 inhibitor response, there is no predictive biomarker for the combination. NLR is a known prognostic biomarker in HNSCC pts treated with chemotherapy with/without radiation. We evaluated NLR as a potential predictive biomarker in R/M HNSCC pts treated with C+N. **Methods:** The clinical data were obtained from R/M HNSCC pts treated with C+N from a completed clinical trial (NCT03370276) and pts treated with nivolumab or pembrolizumab (N/P) as a standard of care in a retrospective chart review study. NLR were collected at baseline (NLR1) and on-treatment (1-month from the treatment initiation; NLR2). The median NLR was applied as a cut-point. Pts were stratified into NLR-high (H; $>$ median) or -low (L; $<$ median). Time-to-event endpoints were evaluated to assess survival and response at the initiation treatments using the Kaplan Meier and Cox Proportional Hazards Models. Selected variables included in the multivariate (MV) analyses were log2(NLR1 or 2), PD-L1 CPS, p16 and smoking status, and prior exposure to anti-PD-1 inhibitors. **Results:** Total 83 C+N and 40 N/P pts were included. In C+N, the median NLR cut-points were NLR1 6.27 and NLR2 5.98 while they were NLR1 5.87 and NLR2 8.21 in N/P. NLR1-H vs. -L in C+N showed no difference in OS ($p = 0.26$) and progression-free survival (PFS; $p = 0.95$), but NLR2-H had worse OS ($P < 0.001$) and PFS ($P < 0.001$) compared to NLR2-L. Similarly, in N/P, NLR1-H vs. -L did not show difference in OS ($p = 0.23$), but NLR2-H had worse OS ($P < 0.046$) compared to NLR2-L. In C+N, NLR2 (log2(NLR2)) consistently correlated with worse OS [univariate (UV), HR 1.69, CI 1.36-2.12; MV, HR 1.63, CI 1.26-2.11] and PFS (UV, HR 1.63, CI 1.22-2.19; MV, HR 1.70, CI 1.21-2.42). In N/P, PFS and MV analyses were not feasible due to lack of reliable data in the retrospective study. In C+N, NLR2 ($p < 0.001$), but not NLR1 ($p = 0.93$), was correlated with lower best overall response (BOR). Similarly, in N/P, NLR2 ($p = 0.004$), but not NLR1 ($p = 0.12$), was associated with lower BOR. In addition, a significantly larger reduction in NLR on-treatment from baseline (log2(NLR2) - log2(NLR1)) was observed in C+N compared to N/P ($P = 0.005$, Student t-test). **Conclusions:** On-treatment NLR2-H is associated with worse response and survival in pts with R/M HNSCC treated with C+N and N/P. C+N is associated with a greater reduction in NLR compared to N/P, suggesting that the combination enhances a favorable peripheral immunologic response. Further evaluation is warranted to determine the role of NLR as a biomarker of immunotherapy response. Nanoparticle albumin-bound (nab) paclitaxel in combination with nivolumab as treatment of recurrent or metastatic head and neck squamous-cell carcinoma (RM-HNSCC) that progressed on a PD-1 inhibitor: A single-arm, phase 2 trial. *First Author: Jared Cohen, Washington University Siteman Cancer Center, St. Louis, MO*

Background: Drugs bound to albumin selectively target cancer cells with upregulated macropinocytosis, an endocytic nutrient-scavenging process driven by constitutive hyperactivation of the EGFR, RAS, PIK3CA and Syndecan1 signaling pathways that frequently occur in HNSCC. nab-paclitaxel is an active drug in HNSCC and has immunologic effects that can prime an immune response to PD-1 inhibitors, potentially reversing resistance to these agents. These effects include decreased TREGs, increased pro-inflammatory macrophages and differentiation of MDSC to dendritic cells, increased HLA class I expression and antigen presentation, and recruitment of CD8+ CTLs into tumor. **Methods:** In a single-arm phase 2 trial, patients with RM-HNSCC that progressed on a PD-1 inhibitor received 28-day cycles of nab-paclitaxel (125 mg/m² IV days 1, 8, and 15) and nivolumab (480 mg IV day 1). Treatment continued until discontinuation criteria were met. The primary endpoint was objective response, assessed with RECIST1.1 by an independent radiologist. The primary hypothesis was that this regimen would result in a higher objective response rate (ORR) than historically reported with standard chemotherapy or cetuximab in similar patients. A Simon optimal two-stage design tested the null hypothesis (H_0 : ORR $\leq$ 30%) versus the alternative hypothesis (H_1 : ORR = 50%) at the type I error rate of 5% and power 0.80. In the first stage, 15 patients were to be accrued. If $\geq$ 6 responses occurred, 31 additional patients were to be accrued. The null hypothesis will be rejected if $\geq$ 19 responses are observed in these 46 patients. We report the results of the primary endpoint for the first stage of the trial. **Results:** 15 evaluable patients enrolled into the first stage of the trial. Key tumor characteristics and prior treatment history included HPV status (positive: 8; negative: 7), PD-L1 status (CPS 1-19: 7; $\geq$ 20: 8), # of lines of prior systemic treatment for RM disease (1-2: 12; $\geq$ 3: 3), interval (months) from prior PD-1 inhibitor ($<$ 6: 11; $\geq$ 6: 4), duration (months) on prior PD-1 inhibitor (median: 6, range: 1-16), and best response to prior PD-1 inhibitor (PR: 4; SD: 6; PD: 5). Tumor response to nab-paclitaxel and nivolumab occurred in 7 of 15 patients (ORR 47%). The best tumor response was PR (7), SD (5) and PD (3). **Conclusions:** Among patients with RM-HNSCC that progressed on a PD-1 inhibitor, the ORR with nab-paclitaxel and nivolumab was 47% during the first stage of the phase 2 trial. Enrollment to the second stage is ongoing. Clinical trial information: NCT04831320. Research Sponsor: Bristol-Meyers Squibb; Generous support from Gregory Stubblefield and Nancy Apel.

Prognostic value of circulating Epstein-Barr virus DNA level post-induction chemotherapy for patients with nasopharyngeal carcinoma: A recursive partitioning risk stratification analysis. *First Author: Fang-Fang Kong, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, Shanghai, China*

Background: To evaluate the prognostic value of plasma Epstein-Barr virus (EBV) DNA level post-induction chemotherapy (IC) for patients with nasopharyngeal carcinoma (NPC). **Methods:** A total of 893 newly diagnosed NPC patients treated with IC were retrospectively reviewed. The recursive partitioning analysis (RPA) was performed to construct a risk stratification model. The receiver operating characteristic (ROC) analysis was applied to determine the optimal cut-off value of EBV DNA and compare the predictive validity. **Results:** Post-IC EBV DNA levels and overall stage were independent predictors for distant metastasis-free survival (DMFS), overall survival (OS), and progression-free survival (PFS). The RPA model based on post-IC EBV DNA and overall stage categorized the patients into three distinct risk groups: RPA I (low-risk: stage II-III and post-IC EBV DNA < 200 copies/mL), RPA II (median-risk: stage II-III and post-IC EBV DNA ≥ 200 copies/mL, or stage IVa and post-IC EBV DNA < 200 copies/mL), and RPA III (high-risk: stage IVa and post-IC EBV DNA ≥ 200 copies/mL), with 3-year PFS of 91.1%, 82.6%, and 60.2%, respectively ($p < 0.001$). The DMFS and OS rates in different RPA groups were also distinct. ROC analysis showed that the RPA model had superior predictive efficacy than the overall stage. **Conclusions:** Plasma EBV DNA level post-IC was a robust prognostic biomarker for NPC. We developed a risk stratification model that provides improved DMFS, OS, and PFS prediction over the 8th edition of the TNM staging system by integrating the post-IC EBV DNA level and the overall stage. A phase Ib/II study of GFH018 in combination with toripalimab in recurrent/metastatic nasopharyngeal carcinoma (R/M NPC). *First Author: Hai-Qiang Mai, Sun Yat-sen University Cancer Center (China), Guangzhou, No, China*

Background: The transformed growth factor beta (TGF- β) signaling pathway is dysregulated in carcinogenesis. In NPC patients, upregulation of TGF- β pathway is correlated with disease stage or phenotype due to Epstein-Barr virus (EBV) infection. GFH018, a novel TGF- β RI inhibitor, can inhibit tumor growth through inhibiting the activity of TGF- β RI kinase to block the signal transduction of TGF- β and modulate the tumor immune microenvironment. Preclinical studies showed that GFH018 in combination with PD-1/PD-L1 monoclonal antibody can significantly inhibit tumor growth synergistically. Here we report the preliminary results of combining GFH018 and Toripalimab treating R/M NPC patients (pts). **Methods:** This is a phase Ib/II study to evaluate the safety and efficacy of the combination of GFH018 and Toripalimab in pts with advanced solid tumors. Patients with RM NPC were enrolled to receive GFH018 80mg twice a day (BID) 14-day-on/14-day-off in combination with Toripalimab 3mg/kg every two weeks. Tumor assessment was performed every 8 weeks per Response Evaluation Criteria in Solid Tumor (RECIST) 1.1. **Results:** As of 31 Dec 2022, 32 pts with R/M NPC who had progressed on at least one prior line therapy were enrolled. Sixteen (50%) had received ≥ 3 lines of prior therapies, and 19 (59.4%) had previously received immune checkpoint inhibitors (ICIs) and platinum-based chemotherapies. The median duration of study drug exposure was 7 weeks. Twenty-five pts (78.1%) experienced treatment-related adverse events (TRAEs) of any grades, and 11 pts (34.4%) had ≥ Grade 3. The most common TRAEs (occurring in ≥ 3 pts) were anaemia ($n = 6$, 18.8%), hyponatraemia ($n = 6$, 18.8%), rash ($n = 6$, 18.8%), fatigue ($n = 4$, 12.5%), white blood cell count decreased ($n = 4$, 12.5%), aspartate aminotransferase increased ($n = 3$, 9.4%), back pain ($n = 3$, 9.4%), decreased appetite ($n = 3$, 9.4%), hypokalaemia ($n = 3$, 9.4%), and hypothyroidism ($n = 3$, 9.4%). As of 18 Jan 2023, among the 27 pts with post-baseline tumor assessments, 8 achieved partial response (PR), and 5 stable disease (SD); the overall response rate (ORR) was 29.6%, and disease control rate (DCR) was 48.1%. Six PR and 2 SD were observed among the 12 pts without prior treatment of ICIs; the ORR was 50%, and DCR was 66.7%. Four pts discontinued treatment without any post-baseline tumor assessments due to AEs or withdrawal of consent, and 1 patient is premature for tumor assessment. **Conclusions:** GFH018 combined Toripalimab was well tolerated and demonstrated preliminary efficacy in pts with R/M NPC. Specifically, in pts who had not previously received ICIs, promising antitumor activity was observed supporting further investigation to this group of pts. Clinical trial information: NCT04914286. A phase 1 study of concurrent cabozantinib and cetuximab in recurrent or metastatic head and neck squamous cell cancer. *First Author: Antoine Desilets, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Epidermal growth factor receptor (EGFR) targeting with cetuximab (CTX) is a standard therapy for head and neck squamous cell carcinoma (HNSCC). Resistance to CTX can be mediated by activation of the receptor tyrosine kinase AXL. Cabozantinib (cabo) is a tyrosine kinase inhibitor (TKI) of AXL/c-MET/VEGFR which demonstrated antitumor activity in HNSCC preclinical models. We conducted a phase I trial to assess the safety and efficacy of the cabo-CTX combination in recurrent or metastatic (R/M) HNSCC. **Methods:** Eligibility criteria included RECIST v1.1 measurable disease and incurable R/M HNSCC. Prior treatment with CTX was allowed. Patients received an initial CTX loading dose of 400 mg/m² followed by 250 mg/m² weekly. CTX maintenance dose was later amended to 500 mg/m² biweekly. Cabo was given concurrently on days 1-28 of each 28-day cycle. Primary endpoint was maximally tolerated dose (MTD) of cabo, as identified using a 3+3 dose-escalation design. Tumor responses were assessed every 2 cycles. Secondary endpoints included overall response rate (ORR), progression-free survival (PFS) and overall survival (OS). **Results:** Of 22 patients enrolled between 2018 and 2022, 2 did not start therapy. Among treated patients, median age was 59 (range 33-71) and 90% ($n = 18$) of patients were male. Primary tumor sites included the oropharynx ($n = 13$), oral cavity ($n = 3$), larynx ($n = 2$), hypopharynx ($n = 1$) and unknown primary ($n = 1$). p16 antigenic testing for HPV status was positive in 11 oropharyngeal cancers (85%). Most patients were previously treated with immune checkpoint inhibitors ($n = 19$), chemotherapy ($n = 19$), CTX ($n = 16$), or other TKI ($n = 2$). 12 patients received biweekly CTX dosing at 500 mg/m². Initial cabo dose was 40 mg for the first 11 patients, and 60 mg afterwards (MTD). No dose-limiting toxicity (DLT) was recorded. Common adverse events (AEs) included fatigue (80%), acneiform rash (75%), increased aspartate aminotransferase (AST) (70%), anemia (70%) and hypothyroidism (70%). Grade ≥ 3 AEs occurred in 65% ($n = 13$), including increased AST (45%), increased alkaline phosphatase (15%), increased bilirubin (10%) and erythrocytosis (10%). AEs led to dose reductions in 20% ($n = 4$) and treatment discontinuation in 15% ($n = 3$). In the preliminary efficacy analysis, 4 patients had partial responses (PRs) with an ORR of 20%, including 2 PRs in patients with prior CTX resistance. Disease control rate (DCR) was 75% in the overall population and 75% in those with previous CTX treatment. Median PFS was 3.4 mo and median OS was 8.1 mo. PFS differed according to HPV status, with median PFS 7.1 mo versus 3.1 mo in HPV-positive and -negative patients respectively ($p = 0.03$). **Conclusions:** The cabo and CTX combination showed an acceptable toxicity profile with liver toxicity as a common AE. The regimen showed preliminary efficacy data in patients with R/M HNSCC, including those with prior CTX resistance. Clinical trial information: NCT03667482. Research Sponsor: None.

Effect of extended treatment with IAP inhibitor xevinapant post radiotherapy (RT) on efficacy and the tumor microenvironment (TME) in preclinical models. *First Author: Tsz Lun Yeung, EMD Serono, Billerica, MA*

Background: Xevinapant is a first-in-class, oral IAP (inhibitor of apoptosis protein) inhibitor designed to restore cancer cell sensitivity to apoptosis, induced by RT and chemotherapy, and enhance antitumor immunity. In a randomized phase 2 study of patients with unresected locally advanced squamous cell carcinoma of the head and neck, xevinapant + chemoradiotherapy (CRT) significantly improved 18-month locoregional control and improved 3-year progression-free survival and 5-year overall survival vs placebo + CRT. A phase 3 confirmatory study (TrilynX NCT04459715) and a phase 3 study to evaluate xevinapant + RT in post-operative, high-risk, cisplatin-ineligible patients (XRAY Vision NCT05386550) are ongoing. In these studies, we investigate 3 additional cycles of xevinapant or placebo monotherapy after completing combination treatment. Based on the role of IAPs in apoptosis, immunity, and stromal activation, continual dosing of xevinapant post RT may have additional therapeutic benefits. **Methods:** MC38 syngeneic tumor-bearing mice were treated with vehicle control, RT alone (3.6Gy once daily [QD], 5 days), or RT + xevinapant (100 mg/kg QD, 1, 2, or 4 weeks). To assess treatment-mediated TME modulation, immune cells in tumors were evaluated by fluorescence-activated cell sorting (FACS)-based immunophenotyping, and tumor-specific T cell responses were investigated by enzyme-linked immunosorbent spot (ELISpot) assays. To understand the effect of xevinapant on RT-induced cancer associated fibroblast (CAF) activation, CAF gene expression was profiled on cell lines and patient-derived primary cultures. **Results:** Xevinapant + RT increased antitumor efficacy compared with vehicle control or RT alone. Moreover, RT in combination with extended dosing of xevinapant for 4 weeks significantly improved therapeutic efficacy and prolonged survival compared with RT + shorter xevinapant dosing durations. FACS analysis demonstrated trends of increased numbers of CD8⁺ T cells, natural killer cells, and dendritic cells and decreased numbers of regulatory T cells in mice treated with xevinapant + RT. FACS and ELISpot further suggested an increase in antigen-specific T cell counts from baseline with combination therapy arm vs vehicle control or RT alone. Xevinapant may also suppress RT-mediated CAF activation, as indicated by downregulation of activation markers and CAF-derived secretory proteins. **Conclusions:** In preclinical models, extended dosing of xevinapant for 4 weeks post RT improved antitumor efficacy. Our data suggest that the effect may be, in part, modulated by TME responses, including enhanced antitumor immunity and suppressed pro-tumorigenic phenotype of CAFs. Based on these results, further evaluation is warranted to determine the mechanisms that underscore the therapeutic benefit offered by extended dosing of xevinapant. Phase 2 study of ISA101b (peltopenimut-S) and cemiplimab in patients with advanced HPV16+ oropharyngeal cancer who failed anti-PD1 therapy. *First Author: Anthony H Kong, King's College London, London, United Kingdom*

Background: ISA101b (peltopenimut-S), a therapeutic vaccine against the HPV-specific E6/E7 oncoproteins, induces specific expansion of HPV16 targeted T-cells when given together with cemiplimab, an anti-PD-1 agent. Previously we showed that ISA101 with nivolumab achieved a higher response rate compared to immune checkpoint inhibitor (ICI) alone in trials for patients with recurrent/metastatic (R/M) HPV16+ oropharyngeal cancer (OPC)^{1,2}. **Methods:** In this single arm phase 2 study, patients with R/M HPV16+ OPC with progressive disease (PD) within 6 months after prior 1st or 2nd line anti-PD-1 ICI were treated with ISA101b (subcutaneously 100µg/peptide on days 1, 29, and 50) with cemiplimab (intravenously 350mg as a 3-weekly regimen) until PD. Patients without PD at 6 months were offered a booster ISA101b injection. HPV16 positive tumor status was confirmed by a central reference laboratory with an established PCR assay. The primary efficacy endpoint was defined as overall response rate (ORR) as per RECIST1.1. An analysis was planned at the end of Stage 1, when 26 patients who had received at least one dose of ISA101b had been followed for 6 months. The cut-off date for this analysis, approved by the DSMB, was 31 January 2023. **Results:** Twenty-six patients (mean age 60.7 ± 12.9 years; 22 (84.6%) male and 4 (15.4%) female) enrolled in Stage 1. Median follow-up was 16.2 weeks (range 1.6-78.8). Three patients were confirmed with partial response (PR) (11.5%); two of the 3 patients with PR never responded to previous ICI treatment. In 13 patients (50.0%) best overall response (BOR) was stable disease (SD); in 8 patients (30.8%) BOR was PD. Two (7.7%) patients did not have a tumor assessment after baseline: one patient died on day 8 due to OPC and one patient withdrew consent shortly after enrolment. The clinical benefit ratio (CBR) was 61.5%. Nine (34.6%) patients received a booster injection. At the time of the booster, 2 patients had PR and 5 patients had meaningful (≥6 months) SD. Time to response ranged between 127 and 307 days. Median duration of study treatment was 13.1 weeks (range 1.1-75.9), with 4 patients still on treatment. There were two grade 3 adverse events (AEs) related to ISA101b: erythema at the injection site and diarrhea. Two patients (7.7%) had grade 3 ICI-related auto-immune events. Grade 4-5 AEs related to study treatment did not occur. Median overall survival was 8.1 months (range 0.3-17.5). **Conclusions:** This treatment appears promising for HPV16+ OPC patients who failed prior anti-PD-1 ICI therapy, with an ORR of 11.5% and a CBR of 61.5%. In this small, ongoing study the combination of cemiplimab and ISA101b was well tolerated with a safety profile resembling anti-PD-1 monotherapy. This is the first study of the combination of ISA101b and cemiplimab in 2nd/3rd line R/M anti-PD-1 refractory OPC patients. ¹Massarelli E. *JAMA Oncol* 2019 ²de Sousa LG. *J Immunother Cancer* 2022. Influence of widely targeted quantitative lipidomics on plasma lipid predictors and pathway dysregulation for nasopharyngeal carcinoma. *First Author: Xi Chen, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Dysregulation of lipid metabolism is closely associated with cancer progression. We aimed to establish a prognostic model to predict distant metastasis-free survival (DMFS) in patients with locoregionally advanced nasopharyngeal carcinoma (NPC), based on widely targeted quantitative lipidomics. **Methods:** We measured and quantified the plasma lipid profiles of 179 patients with NPC using widely targeted quantitative lipidomics. Then, patients were randomly split into the training (125 patients, 69.8%) and validation (54 patients, 30.2%) sets. To identify distant metastasis-associated lipids, univariate Cox regression was applied to the training set ($p < 0.05$). We employed a deep survival method called DeepSurv to develop our proposed model based on significant lipid species ($p < 0.01$) and clinical biomarkers to predict DMFS. Concordance index and receiver operating curve analyses were performed to assess model effectiveness. We also explored the potential role of lipid alterations in the prognosis of NPC. **Results:** A total of 665 plasma endogenous lipid species consisting of 27 lipid classes and subclasses from 179 patients with NPC were annotated in lipidomics analysis. Forty lipids were recognized as distant metastasis-associated ($p < 0.05$) by univariate Cox regression. The concordance indices of our proposed model were 0.764 (95% confidence interval (CI), 0.682-0.846) and 0.760 (95% CI, 0.649-0.871) in the training and validation sets, respectively. We also calculated the C-index values of the baseline survival model based only on clinical biomarkers, with 0.718 (95% CI, 0.591-0.845) and 0.672 (95% CI, 0.511-0.833) being detected in the training and validation sets, respectively, indicating the outstanding predictive performance of lipid biomarkers. High-risk patients had poorer 5-year DMFS compared with low-risk patients (Hazard ratio, 26.18; 95% CI, 3.52-194.80; $p < 0.0001$). Moreover, the six lipids were significantly correlated with immunity- and inflammation-associated biomarkers and were mainly enriched in metabolic pathways. **Conclusions:** Widely targeted quantitative lipidomics reveals plasma lipid predictors and pathway dysregulation for locoregionally advanced NPC, the prognostic model based on that demonstrated superior performance in predicting metastasis in NPC patients. Final results from TACTI-002 Part C: A phase II study of eftilagimod alpha (soluble LAG-3 protein) and pembrolizumab in patients with metastatic 2nd line head and neck squamous cell carcinoma unselected for PD-L1. *First Author: Bernard Doger de Spéville, Early Phase Clinical Trials Unit, START Madrid Fundacion Jimenez Diaz, Madrid, Spain*

Background: Eftilagimod alpha (E), a soluble LAG-3 protein, acts as an MHC class II agonist triggering activation of antigen-presenting cells (APC) and CD8 T-cells. Using efti to enhance patients' immunity may lead to stronger anti-tumor responses than observed with pembrolizumab (P) alone. We report final results from Part C of the TACTI-002 trial (NCT03625323) where 2nd line metastatic head and neck squamous cell carcinoma (HNSCC) patients (pts) unselected for PD-L1 were treated with E + P. **Methods:** Pts with metastatic HNSCC, unselected for PD-L1 expression with disease progression on or after 1st line platinum-based therapy (± cetuximab) were enrolled. Primary endpoint (EP) was objective response rate (ORR) by iRECIST. Other EPs included tolerability, progression free survival (PFS), duration of response (DoR), and overall survival (OS). Pts received E (30 mg SC Q2W for eight 3-week cycles and then Q3W up to 1 yr) with P (200 mg IV Q3W up to 2 yrs). Imaging was performed Q9W. PD-L1 was retrospectively assessed using the IHC 22C3 kit. The study was approved by ethic committees and institutional review boards. **Results:** 39 pts were enrolled between Mar 2019-Jan 2021 (cut-off Jul 2022) with HNSCC of oropharynx (38%), oral cavity (32%), hypopharynx (19%) and larynx (16%). Median age was 63 yrs (48-84 yrs) and 90% were male. ECOG PS was 0 and 1 in 35% and 65% of pts. Two pts were excluded from efficacy results due to fatal COVID-19 prior to their first post-baseline scan. The primary EP, ORR by iRECIST, was 30% with 14% complete responders (see table). ORR by RECIST 1.1 was comparable (24%). Median PFS by iRECIST was 2.1 mo with 32% of pts progression-free at 6 mo. Median OS was 8.7 mo with 46% alive at 12 mo. Median DoR by iRECIST was not reached with 17 mo min FU. Responses were seen in all PD-L1 subgroups (see table). ORR, 6-mo PFS, 12-mo OS rates for PD-L1 CPS ≥ 20 were 60%, 53%, 73% with a median OS of 15.5 months. Two pts (5%) discontinued due to adverse events (AE) (fatigue and arthralgia [each grade 2]; pneumonitis [grade 3]) that were related to study treatment (efti and/or pembro). The most common (≥ 15%) AEs were hypothyroidism (21%), asthenia (21%), cough (18%), anemia (18%), weight decrease (18%), and fatigue (15%). **Conclusions:** Efti + pembrolizumab is safe, showing encouraging antitumor activity in platinum and partially cetuximab pre-treated, 2nd line HNSCC patients. TACTI-003 (NCT04811027) a randomized study in 1st line HNSCC is currently recruiting. Response by iRECIST: Clinical trial information: NCT03625323. Research Sponsor: Immunet S.A.

Efficacy and safety of sintilimab plus bevacizumab in metastatic nasopharyngeal carcinoma after failure of platinum-based chemotherapy: An open-label phase II study. *First Author: Nian Lu, Cancer Center, Sun Yat-Sen University, State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangzhou, China*

Background: There are limited treatment options for patients with metastatic nasopharyngeal carcinoma (mNPC) after failure of platinum-based chemotherapy. In this trial, we assessed the efficacy and safety of sintilimab plus bevacizumab in mNPC patients where platinum-based chemotherapy has failed. **Methods:** This was a single-center, open-label, single-arm, phase II trial for mNPC patients progressed after at least one line of systemic therapy. Patients were enrolled and received sintilimab (200 mg) plus bevacizumab (7.5mg/kg) intravenously every 3 weeks. The primary end point was objective response rate (ORR) assessed by investigators following the guidelines of RECIST 1.1. Key secondary end points were progression-free survival (PFS), overall survival (OS), duration of response (DOR), and safety. This trial is registered with ClinicalTrials.gov (NCT04872582). **Results:** Thirty-three patients were enrolled. Median age was 46 years (range, 18-64 years), and 63.6% of patients had previously received two or more lines of chemotherapy for metastatic disease. Median follow-up was 7.6 months (range, 4.1-17.5 months). ORR was 54.5% (95% CI, 36.4-71.9%) with 3 complete responses (9.1%) and 15 partial responses (45.5%). Median PFS was 6.8 months (95% CI, 5.2 months to not estimable). Median DOR was 7.2 months (95% CI, 4.4 months to not estimable). Median OS was not reached. The most common potential immune-related AE was grade 1-2 hypothyroidism (42.4%). Treatment-related grade 3 or 4 adverse events (AEs) occurred in 7 patients (21.2%), including nasal necrosis (9%), hypertension (3%), pruritus (3%), total bilirubin increased (3%) and anaphylactic shock (3%). No treatment-related deaths and severe epistaxis occurred. **Conclusions:** This phase II trial showed that sintilimab plus bevacizumab demonstrated promising antitumor activity and manageable toxicities in mNPC patients after failure of platinum-based chemotherapy. Clinical trial information: NCT04872582. Research Sponsor: National Natural Science Foundation of China (KY013113).

A phase II trial of paclitaxel plus biweekly cetuximab for patients with recurrent or metastatic head and neck cancer previously treated with both platinum-based chemotherapy and anti-PD-1 antibody. *First Author: Taiji Koyama, Department of Medical Oncology and Hematology, Kobe University Hospital, Kobe-Shi, Japan*

Background: An important unmet need in treatment options remains for patients with recurrent or metastatic head and neck squamous cell carcinoma (R/M-HNSCC) previously treated with both platinum-based chemotherapy and anti-PD-1 antibody (PD-1 Ab). Recent retrospective studies suggest that previous treatment with Immune checkpoint inhibitor might augment the efficacy of subsequent chemotherapy. This phase II trial aimed to evaluate the efficacy and safety of paclitaxel plus biweekly cetuximab (PTX+bwCmab) for patients with R/M-HNSCC previously treated with both platinum and PD-1 Ab. **Methods:** This is a single-arm, multicenter phase II trial. Key eligibility criteria were R/M-HNSCC; previous treatment with both platinum-based chemotherapy and PD-1 Ab; ECOG performance status 0 or 1; measurable disease per RECIST v1.1; and adequate organ function. PTX+bwCmab consisted of weekly paclitaxel 100 mg/m² (days 1, 8, 15) and biweekly cetuximab 500 mg/m² (days 1, 15) with a cycle of 28 days. Primary endpoint was objective response rate (ORR). We set a null hypothesis of 10% and alternative of 30% with a one-sided alpha of 0.05 and power of 90%. Secondary endpoints were progression-free survival (PFS), overall survival (OS), disease control rate (DCR), and adverse events (AEs) (CTCAE v5.0). Binominal confidence intervals (CIs) for ORR and DCR were estimated by the exact method. Time-to-event analyses were calculated by the Kaplan-Meier method with 95% CIs. **Results:** Between August 2020 and August 2022, 35 patients were enrolled, of whom 32 were evaluable for response. ORR was 68.7% (95% CI: 49.9-83.8), which met the prespecified criteria for the primary endpoint of ORR. With a median follow-up period for survivors of 16.6 months, median PFS and OS were 5.7 and 13.4 months, respectively. DCR was 93.7% (95% CI: 79.1-99.2). The most common AEs of any grade were skin rash (65%), peripheral nerve neuropathy (45%), neutropenia (40%), fatigue (40%) and paronychia (37%). Grade 3 and 4 adverse events included neutropenia (34%), mucositis (8%), pneumonitis (8%) and febrile neutropenia (5%). These AEs were manageable and no treatment-related death within 30 days was observed. **Conclusions:** PTX+bwCmab showed highly encouraging efficacy and tolerability in R/M-HNSCC patients previously treated with both platinum and PD-1 Ab. Although preliminary, these results suggest that this is a promising treatment option for this hitherto untreatable patient group. Further evaluation is warranted. Clinical trial information: jRCTs051200040. Research Sponsor: None.

Afatinib in patients with recurrent/metastatic (RM) squamous cell carcinoma of the head and neck (SCCHN) harboring alterations in the HER pathway: Results of the B1 cohort of the EORTC-HNCG-1559 trial (UPSTREAM). *First Author: Rachel Galot, Cliniques Universitaires Saint-Luc, Brussels, Belgium*

Background: Afatinib (A) is an irreversible pan-HER inhibitor that improved PFS in second line RM SCCHN after platinum (LUX-H&N1 trial). In a retrospective biomarker analysis, subgroups of pts with p16 negative, PTEN high or *EGFR* amplification SCCHN seem to benefit the most. Other studies suggest that A has activity in tumors with *HER2* gene activation. **Methods:** The UPSTREAM trial is a biomarker-driven umbrella trial of targeted therapies and immunotherapy for RM SCCHN (post-platinum, ECOG 0-1, measurable disease). The B1 cohort was a phase II, randomized, open-label substudy evaluating the efficacy of afatinib (orally, 40mg/day) vs physician's choice (ctrl) (2:1 ratio) in pts with p16 negative RM SCCHN harboring one of the following biomarkers (fresh biopsy): *EGFR* mutation(mut)/amplification(amp) or *HER2* mut/amp or PTEN high by immunohistochemistry (IHC, H-score > 150). Only *KRAS/HRAS/NRAS* wild type tumors were included. The primary endpoint was progression-free survival rate (PFSR) at 16 weeks after randomization. A 2-stage Simon optimal design was applied to arm A (H1 40%, H0 20%, 1-sided α 10%, power 90%) with 17 and 20 pts enrolled in the first and second stage respectively. Secondary endpoints included ORR, toxicity, PFS, and OS. **Results:** 59 RM SCCHN pts were included in the B1 cohort (A: n = 40, ctrl: n = 19). Out of the 59 patients, *EGFR* amp, *HER2* amp and *HER2* mut were found in 6 pts (10%), 1 pt (2%) and 1 pt (2%), respectively. PTEN (IHC) was high in 97%. 55 pts were evaluable (A: n = 38, ctrl: n = 17) (median age: 62, oral cavity: 29%, oropharynx: 36%, hypopharynx: 24%, larynx: 11%). 69% of pts had received $\geq$ 2 lines of systemic treatment for RM disease. 80% were pretreated with cetuximab. In arm A, 13/38 patients were alive and free of objective progression at 16 weeks (34.2%, 1-sided 90%CI, 23.9 $\pm$ inf), meeting the predefined criteria of success. The PFSR at 16W in ctrl arm was 29.4% (5/17). 4 objective responses were observed in arm A (3 PR and 1 CR) (ORR 11%, 95%CI 2.9-24.8%) and 1 PR in ctrl arm (6%). The median duration of response under A was 5.7 mo (range: 3.7-25.9 mo). All responding patients had previously been treated with cetuximab, were PTEN high but none had *EGFR* or *HER2* alterations. The median PFS and OS were 2.2/2.4 mo and 7.2/5.0 mo in the A/ctrl arms, respectively. Grade $\geq$ 3 drug-related AEs were reported in 31% in arm A and 12% in ctrl arm. The most frequent drug-related AE with A were diarrhea (67%, G3:8%), rash (41%, G3: 3%), fatigue (31%, no G3) and mucositis (23%, G3: 3%). **Conclusions:** The B1 substudy met its primary endpoint of PFSR at 16 weeks. Responses were seen in cetuximab pre-treated pts. However, the clinical activity of A in this biomarker-selected population remains limited. Translational research is ongoing to better define potential biomarkers. Clinical trial information: NCT03088059. Research Sponsor: Boehringer Ingelheim.

To test, or not to test, that is the question: A real-world analysis of PD-L1 expression testing patterns in recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC). *First Author: Chris M. Black, Merck & Co., Inc., Rahway, NJ*

Background: PD-L1 expression testing plays an important role in identifying patients who benefit from immunotherapy when treating R/M HNSCC. We aimed to understand how PD-L1 expression testing evaluated by Combined Positive Score (CPS) is used in clinical practice and how testing results impact treatment decision-making. **Methods:** A retrospective cohort study was conducted using the Flatiron Health Advanced Head and Neck database. We included adult R/M HNSCC patients who initiated first-line (1L) treatment between 07/01/19 and 12/31/21 with follow-up until 06/30/22. Patients were excluded if they received platinum therapy within 6 months prior to 1L treatment, had other primary cancers before advanced diagnosis, were treated on protocol, or were tested but did not have any record of date of specimen collected, received, or results returned. Multivariable logistic regression was conducted to assess factors associated with PD-L1 testing decisions before 1L therapy start and the association between testing results and choice of 1L treatment. **Results:** A total of 1,762 patients with R/M HNSCC were included, with 32.0% tested for PD-L1 prior to 1L therapy start, 25.6% tested after, and 42.4% never tested. Most patients were tested using the IHC 22C3 pharmDx assay, an FDA-approved companion diagnostic. Among patients tested before 1L treatment initiation, the most prescribed regimens were pembrolizumab or pembrolizumab + platinum + 5-FU for patients with PD-L1(+) (55.9%, 14.2%) and PD-L1(-) tumors (25.3%, 32.0%), respectively. Patients tested after 1L treatment initiation regardless of CPS and patients never tested were most often prescribed platinum monotherapy for 1L. In a multivariable model, patients who were older, treated in academic settings, HPV(+), or had an ECOG $\geq$ 2 were more likely to get PD-L1 testing before 1L treatment initiation. Compared to CPS < 1, CPS $\geq$ 20 and 1 $\leq$ CPS < 20 were associated with a higher likelihood of receiving immunotherapy (OR=3.36, 95% CI, 1.69-6.75, p <0.001; OR=3.11, 95% CI, 1.59-6.14, p <0.001, respectively). **Conclusions:** As an important part of treatment decision-making, PD-L1 testing by CPS should guide 1L single-agent immunotherapy use, but there are many patients not tested before initiating 1L therapy. Age and fitness, clinical practice setting, and HPV status appear to impact testing patterns. Research Sponsor: Merck & Co., Inc., Rahway, NJ, USA.

Patient characteristics by PD-L1 testing patterns.

	Tested before 1L therapy start (N=564)	Tested after 1L therapy start (N=451)	Never Tested (N=747)

Phase I/IIa clinical trial of a small molecule EBNA1 inhibitor, VK-2019, in patients with Epstein Barr virus-positive nasopharyngeal cancer with pharmacokinetic and pharmacodynamic correlative studies. *First Author: A. Dimitrios Dimitrios Colevas, Stanford Cancer Center, Stanford, CA*

Background: Epstein-Barr Virus (EBV) is associated with a diverse collection of malignancies, including nasopharyngeal carcinoma (NPC). One viral-encoded protein, EBNA1, is consistently expressed in all known EBV-associated malignancies and is critical for the replication and maintenance of the EBV genome in latently infected cells. VK-2019 is a first-in-class, orally bioavailable EBNA1 inhibitor that blocks latent replication and proliferation in preclinical studies. **Methods:** We conducted a Phase I/IIa clinical trial of VK-2019 as a single therapeutic agent in patients with advanced (recurrent or metastatic) NPC. An accelerated titration design allowed dose escalation to proceed rapidly from 60 mg/day to 1800 mg/day. Blood samples for detailed pharmacokinetic analyses were collected after the first and multiple doses. In addition, tumor biopsies were collected from 2 patients at the 1800 mg/day dose level at baseline and during treatment and analyzed for EBV copy number and viral and cellular gene expression. **Results:** A total of 22 advanced NPC patients were enrolled. VK-2019 was well tolerated with mostly grade 1-3 adverse events being reported. VK-2019 is rapidly absorbed with a biphasic distribution and a terminal $T_{1/2}$ of ~12h after single or multiple doses. C_{max} and AUC increases with dose escalation through 920 mg with large variability at 1800mg. Accumulation has been observed with multiple doses up to 460mg. Based on preclinical efficacy models, target exposures are at or above expected activity levels for patients at least on the 920 mg daily dose and above. A partial response (> 30% decrease in tumor size) was observed for one patient. Preliminary results from biopsies from 2 patients show decreases in EBV copy number and viral gene expression (LMP2 and gp150). We also observed decreases in EBER-positive cells in one patient. **Conclusions:** In this study, VK-2019 was well tolerated, exhibiting an excellent safety profile and exposure above in vitro efficacy. An MTD has not been yet established. Preliminary results indicate a decrease in EBV copy number and viral gene expression in latently infected tumor cells in some patients. Alternate dose schedules are justified to determine the clinical efficacy of an EBNA1 inhibitor in patients with advanced NPC. Funded by NCI, R01-CA235633 and Cullinan Oncology. Clinical trial information: NCT04925544. Research Sponsor: U.S. National Institutes of Health; Cullinan Oncology.

Outcomes by time to adjuvant therapy in E3311, a phase II trial of transoral surgery (TOS) followed by pathology-based adjuvant treatment in HPV-associated (HPV+) oropharynx cancer (OPC): A trial of the ECOG-ACRIN Cancer Research Group. *First Author: Robert L. Ferris, Hillman Cancer Center, Pittsburgh, PA*

Background: E3311 is a phase II randomized study of intermediate risk HPV+ OPC patients who underwent TOS by credentialed surgeons and were then treated by pathology-guided, deintensified post-operative treatment. Recent retrospective population data suggest that time to post-operative radiotherapy (PORT) > 6 weeks is associated with worse progression-free survival (PFS). **Methods:** We retrospectively analyzed demographics, pathologic characteristics, and oncologic outcomes in E3311 by time to initiation of PORT (short vs long, exploring both 6 and 7 weeks postop as the cutpoint). Binary and categorical variables were compared using a chi-square test (or a Fisher's exact test for small sample sizes). Ordinal variables were compared using a Wilcoxon rank sum test. PFS and overall survival (OS) were estimated using the Kaplan-Meier method and compared using a log-rank test, which was stratified by intermediate- (Arms B/C) vs high-risk (Arm D). **Results:** Among 321 evaluable patients, the median time to initiation of PORT was 5.1 weeks (range 0.7-15.7); 5.0 (0.7-15.7) for Arm B, 5.1 (2.4-7.0) for Arm C, 5.6 (3.6-7.9) for Arm D. No significant difference in PFS or OS was observed whether PORT commenced by 6 or 7 weeks postoperatively, compared with longer time to initiation of PORT ($p = 0.62$ and 0.65 , $p = 0.30$ and $p = 0.41$, respectively). 3-yr PFS rates were 93.5% (95% CI: 89.4%, 96.0%) among those treated ≤ 6 weeks, and 91.2% (95% CI: 81.4%, 95.9%) among those treated > 6 weeks; 3-yr OS rates were 96.1% (95% CI: 92.7%, 98.0%) among those treated ≤ 6 weeks, and 94.1% (95% CI: 84.9%, 97.8%) among those treated > 6 weeks. No significant differences in outcomes were observed between intermediate risk treatment arms (deintensified (50Gy) or standard dose (60Gy) RT). Additional demographic and pathologic characteristics, including primary site, margin status, histologic grade, stage, and extranodal extension were not significantly different between those with short vs long time to PORT, whether 6 or 7 weeks was used as the cutpoint. There were more T2 tumors in those treated > 7 weeks postop (84% vs. 49%, $p = 0.007$). PS = 1 patients were more numerous among those with shorter time to PORT (10% vs 0%, with the 7 week cutpoint). **Conclusions:** In contrast to retrospective NCDB data, intermediate- and high-risk HPV+ OPC patients enrolled on E3311 had favorable 3-yr PFS and OS rates that were not significantly worse when adjuvant therapy was started > 6 wks or > 7wks. These results argue against a survival advantage for initiation of PORT within 6 or 7 weeks for early-stage HPV+ OPC managed with high-quality transoral resection. The optimal time window to initiate PORT in HPV+ OPC patients remains to be determined. Clinical trial information: NCT01898494. Research Sponsor: U.S. National Institutes of Health.

Efficacy from the ongoing phase I trial Study 1100 with NBTXR3 activated by radiotherapy in combination with nivolumab or pembrolizumab in patients with locoregionally recurrent or metastatic HNSCC. *First Author: Colette Shen, Department of Radiation Oncology, University of North Carolina School of Medicine, Chapel Hill, NC*

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment, yet most patients (pts) ultimately develop ICI resistance. Overcoming this resistance is a major clinical challenge. NBTXR3, a novel radioenhancer composed of functionalized hafnium oxide nanoparticles administered by a single intratumoral injection, locally amplifies the RT dose without adding toxicity to surrounding healthy tissue. In preclinical models, NBTXR3/RT has been shown to enhance tumor cell death and tumor antigen release and to effectively expand T-cell repertoire, thus potentially triggering both local and systemic immune responses to help improve ICI treatment. A phase I trial is ongoing to evaluate NBTXR3/RT in combination with anti-PD-1 in pts with advanced cancers. Here we report early outcomes in pts with locoregionally recurrent (LRR) or metastatic (M+) head & neck squamous cell carcinoma (HNSCC). **Methods:** Study 1100 is a phase I dose escalation/expansion trial [NCT03589339] evaluating NBTXR3 activated by stereotactic body radiotherapy (SBRT) followed by anti-PD-1 therapy (nivolumab or pembrolizumab) in 3 cohorts of pts with advanced solid tumors. Pts are either resistant to prior ICI or naïve. Escalation cohorts were defined by site of injection: H&N lesions, lung metastases, or liver metastases. SBRT was delivered as per standard practice. The primary objective of the escalation part was to determine the NBTXR3/RT/anti-PD-1 RP2D for each cohort. Secondary objectives were feasibility, safety, and anti-tumor efficacy (objective responses). **Results:** 16 pts with LRR or M+ HNSCC were treated in the escalation part. 10 pts were resistant to anti-PD-1, 6 were naïve. 8 pts were HPV+, 7 were HPV-, and 1 had HPV status unknown. 13 pts had M+ disease, of which 9 were anti-PD-1 resistant, 4 were naïve. Overall tumor responses were observed in 31.3% (5/16) with mean duration of response (DOR) for these 5 pts of 14.8 (SD ± 7.64) months, at the time of cut-off (4 pts were still responders). Disease control was observed in 75.0% (12/16). Among M+ pts, overall tumor responses were observed in 23.1% (3/13) with mean DOR for these 3 pts of 12.1 (SD ± 5.83) months (2 were still responders). Disease control was observed in 69.2% (9/13) pts with M+ disease. 25.0% (4/16) pts experienced disease progression, and all had M+ disease. All patients who progressed did so with the appearance of a new (non-treated) lesion. **Conclusions:** Promising early signs of efficacy were observed in HNSCC pts treated with NBTXR3/RT/anti-PD-1, including responses in pts resistant to anti-PD-1 and with M+ disease. Disease control was observed in M+ pts, highlighting the potential for NBTXR3 in this difficult to treat population. Overall, these results support evaluation of NBTXR3/RT/anti-PD-1 in the ongoing expansion part. Clinical trial information: NCT03589339. Research Sponsor: Nanobiotix.

Results from two phase II studies of SI-B001, an EGFR $\times$ HER3 bispecific antibody, with/without chemotherapy in patients (pts) with recurrent and metastatic head and neck squamous cell carcinoma (HNSCC). *First Author: Liqiong Xue, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, China*

Background: SI-B001 is an EGFR $\times$ HER3 bispecific antibody. We present the efficacy and safety results from two ongoing studies of SI-B001, S209 and S206, in recurrent and metastatic HNSCC. **Methods:** S209 included pts with recurrent and metastatic HNSCC progressed on prior anti-PD-1/L1 plus platinum-based chemotherapy (PBC). Pts were treated with SI-B001 16mg/kg IV QW. S206 included pts with recurrent and metastatic HNSCC progressed on prior anti-PD-1/L1 with or without PBC and received no more than two lines of treatment. Pts enrolled in S206 were divided into two groups: Group A, pts without prior exposure to paclitaxel were treated with SI-B001 (12mg/kg IV QW) plus paclitaxel (80mg/m² IV QW); Group B, pts with prior exposure to paclitaxel were treated with SI-B001 (12mg/kg IV QW) plus docetaxel (35mg/m² IV D1D8D15 Q4W). The study endpoints of the two studies were identical. The primary endpoint was objective response rate (ORR) by investigator per RECIST v1.1. Secondary endpoints were ORR by independent central review, progression-free survival (PFS), disease control rate (DCR), duration of response (DOR), overall survival (OS), and safety. **Results:** As of Dec 31, 2022, 11 pts in S209 received SI-B001. Pts had a median of 4 prior lines of therapy. In 9 out of 11 pts who have at least 1 post baseline tumor assessment in S209, ORR (n/N) was 22.2% (2/9), mPFS [95%CI] was 2.7 [1.8-7.9] mo. 29 pts in S206 received SI-B001 plus chemotherapy, including 19 pts in Group A and 10 pts in Group B. In 22 pts who had at least 1 post baseline tumor assessment, ORR was 45.5% (10/22), mPFS was 5.1 [3.7-5.6] mo. 1 nasal sinus cancer pt enrolled had stable disease (SD). 14 out of the 18 pts who have at least 1 post baseline tumor assessment in Group A, ORR was 64.3% (9/14) mPFS was 5.6 [5.1-6.3] mo. 8 out of 10 pts who have at least 1 post baseline tumor assessment in Group B, ORR was 12.5% (1/8), mPFS was 1.9 [1.2-3.7] mo. The most common grade 3 and above treatment-related adverse events (TRAEs) in S209 was Hypomagnesaemia (9%). The most common grade 3+ TRAEs in S206 were rash (16%), anaemia (8%) and white blood cell count decreased (8%). No SI-B001 drug-related deaths occurred in either study. **Conclusions:** SI-B001 plus paclitaxel demonstrated potential improvements in ORR and DCR compared with SI-B001 monotherapy in recurrent and metastatic HNSCC. The toxicity of SI-B001 plus chemotherapy in HNSCC is manageable and tolerable. Clinical trial information: NCT05044897; NCT05054439. Research Sponsor: Sichuan Baili Pharmaceutical Co., Ltd.

Platinum/taxane/pembrolizumab vs platinum/5FU/pembrolizumab in patients with recurrent/metastatic (r/m) head and neck squamous cell carcinoma (HNSCC). *First Author: Lova Sun, University of Pennsylvania, Philadelphia, PA*

Background: Pembrolizumab +/- chemotherapy is standard of care for patients (pts) with r/m HNSCC. Despite approval of platinum/5FU/pembrolizumab based upon the KN-048 study, a taxane is often substituted for 5FU due to ease of administration and tolerability. No studies have directly compared these approaches. We describe nationwide patterns of taxane vs 5FU chemoimmunotherapy in r/m HNSCC and compare survival and time on treatment between the two. **Methods:** This study used the nationwide Flatiron Health electronic health record (EHR)-derived de-identified database, and included pts treated with frontline pembrolizumab plus platinum-based chemotherapy (either taxane or 5FU) for r/m HNSCC. Demographic, cancer, and clinical outcomes were summarized. Categorical variables were compared using Pearson's chi-square test; continuous variables were compared using T-test. Overall survival (OS) was estimated using Kaplan Meier methodology, and compared using log-rank test. Multivariable Cox regression for overall survival adjusting for age, sex, race, year of diagnosis, ECOG performance status (PS), smoking history, primary tumor site, PD-L1, HPV status, cisplatin use, socioeconomic status, insurance, and practice type was performed, with multiple imputation by chained equations for missing variables. **Results:** Of 444 pts, 321 (72%) received 5FU and 123 (28%) received taxane (108 paclitaxel, 15 docetaxel). Use of cisplatin rather than carboplatin was higher in the 5FU group than the taxane group (16.8% vs 4.9%, $p=0.001$). Taxane use was higher in academic vs community practices (50.7% vs 23.9%, $p<0.001$); within community sites, Northeast states had highest taxane use (27.5%) and Western states had lowest taxane use (16.7%). Pts with Medicare or Medicaid were more likely to receive taxane (35.5%) vs commercial (23.6%) or other (26.7%) insurance. OS did not differ between taxane and 5FU groups (mOS 12.7 vs 13.5 months, $p=0.743$). On multivariable Cox regression, HR for death associated with taxane vs 5FU was 1.01 (95%CI 0.73-1.41). HPV positive status was associated with improved survival (HR 0.58, 95%CI 0.40-0.83). $PS>1$ (HR 1.38, 95%CI 0.96-1.98) and cisplatin use (HR 1.37, 95%CI 0.95-1.98) showed non-significant trends towards worse survival. Taxane-treated pts received more treatment cycles (mean 11.3 vs 8.8 cycles, $p=0.015$) and were on treatment slightly longer (mean 6.9 vs 6.0 months, $p=0.289$) than 5FU-treated pts. **Conclusions:** In US pts with r/m HNSCC undergoing chemoimmunotherapy, rates of taxane vs 5FU use vary by academic setting, geographic region, and insurance status. There was no difference in survival between 5FU and taxane, and taxane-treated pts received more cycles of therapy. Platinum-taxane appears to be a non-inferior alternative to platinum-5FU with pembrolizumab for r/m HNSCC, and should be allowed in clinical trials. Research Sponsor: None.

Poster Session

Updated results from a phase 2 study of the oral vascular endothelial growth factor receptor 2 (VEGFR2) inhibitor rivocecanib for recurrent or metastatic (R/M) adenoid cystic carcinoma (ACC). *First Author: Hyunseok Kang, University of California, San Francisco, San Francisco, CA*

Background: ACC is a rare tumor that overexpresses VEGF, primarily affecting salivary glands. Often indolent, it can progress, with metastases common in the lungs, liver, and bone. There are no FDA-approved systemic treatments (tx) for R/M ACC. Rivocecanib is an oral tyrosine kinase inhibitor (TKI) that potently and selectively inhibits VEGFR2. **Methods:** In this single-arm, open-label multicenter trial, patients (pts) with R/M ACC with evidence of $\geq 20\%$ progression by RECIST v1.1 or new lesions within the preceding 6 months (mos) were eligible, with no limit on prior tx. Pts received rivocecanib 700 mg daily until disease progression or withdrawal with pre-planned dose reductions for toxicity. Primary endpoint was overall response rate (ORR) per RECIST v1.1 by investigator (INV) and by Independent Review Committee (IRC). Secondary endpoints included duration of response (DoR), progression-free survival (PFS), time to progression (TTP), overall survival (OS), and safety exploratory analysis included disease control rate (DCR) and ORR using Choi criteria by IRC. **Results:** As of 11/2022, 80 pts (72 evaluable) were enrolled in the US and Korea (53% male; median age, 54 yrs), and 6 pts remain on tx. Primary tumor sites: major (34%) and minor (59%) salivary glands and other (8%). 74 pts (93%) had metastatic disease. 61.3% had prior systemic tx (18% prior VEGFR TKI). INV and IRC-assessed efficacy data are listed in the table. ORR by Choi was 52.5% (53.1% VEGFR TKI-naïve and 50% VEGFR TKI treated). mOS was 25.3 mos (28.3 mos VEGFR TKI-naïve and 22.6 mos VEGFR treated). Common adverse events (AEs) were hypertension (66%), fatigue (64%), and nausea (54%). Grade ≥ 3 AEs that occurred in $>5\%$ of pts were hypertension (43%), stomatitis (8%), fatigue and anemia (6% each). There were 4 Grade 5 AEs (2 epistaxis [1 related], 1 acute respiratory failure, 1 respiratory failure). **Conclusions:** Updated results with additional 9-month follow-up data continue to demonstrate that Rivocecanib has clinical efficacy and a manageable safety profile in pts with R/M ACC. Clinical trial information: NCT04119453. Research Sponsor: Elevar Therapeutics.

Evaluation of ICI sensitivity for pembrolizumab in combination with anti-platelet therapy for patients with recurrent or metastatic squamous cell carcinoma of the head and neck (HNSCC). *First Author: Karthik Chakravarthy, The Pelotonia Institute for Immuno-Oncology, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: This study was proposed to elucidate the impact of combining anti-platelet therapy with an immune checkpoint inhibitor (ICI) in altering the CD8⁺ T cell function in patients with head and neck squamous cell carcinoma (HNSCC). With a total enrollment of 15 of out an expected 20 patients, this report characterizes the findings thus far from the ongoing study. **Methods:** This crossover trial consisted of two different treatment regimens for two groups. Regimen A involved treatment with a PD-1 inhibitor pembrolizumab (200 mg iv over 30 min) every 3 weeks in combination of daily aspirin (81 mg orally) and clopidogrel (75 mg orally) for a total of 6 weeks. Regimen B involved pembrolizumab monotherapy (200 mg iv over 30 min) every 3 weeks for two cycles. Thus far, 15 patients with recurrent or metastatic HNSCC were randomized into the two groups, with Group 1 receiving Regimen A followed by Regimen B, while Group 2 received Regimen B followed by Regimen A. In addition to clinical endpoint, in depth analysis of the peripheral blood mononuclear cells (PBMCs) was also implemented using samples obtained prior to treatment, in between regimens, and at the end of treatment. These samples were then analyzed using a spectral flow cytometer panel specific for human CD8⁺ T cells. Given the 75 percent accrual, we performed analysis with the obtained clinical samples and data. **Results:** Of the 15 patients enrolled into the study, 14 remained on study and completed the trial till endpoint. All 14 patients presented with no overtly significant adverse events (AEs). In terms of clinical response, we observed in Group 1 patients (n=7) a total of 1 CR (complete response), 1 PR (partial response), 2 SD (stable disease), and 3 PD (progressive disease), while Group 2 (n=7) presented with 2 PR, 2 SD, and 3 PD. Spectral flow analysis performed on Group 1 patient samples revealed an increase in the Ki67⁺PD1⁺ proliferative subset post combination treatment (p value < 0.05, paired Student's t-test). This finding indicates a potential increase in proliferation among CD8⁺ T cells after antigen stimulation that may pertain to the combination of anti-PD-1 and anti-platelet therapy. In addition, a higher frequency of Ki67⁺TIGIT⁺ CD8⁺ population (p value < 0.05, paired Student's t-test) was also observed after combination therapy compared to pre-treatment; however, this level was not sustained after combination therapy was ceased, implying that ongoing anti-platelet therapy may be necessary for augmenting ICI. **Conclusions:** Combination of anti-PD1 and anti-platelet therapy demonstrates potential for remodeling the immune component pertaining to CD8⁺ T cells without resulting in overt toxicity. Further analysis of the effects of this combination regimen will be essential to better characterize tumor specific impact. Clinical trial information: NCT03245489. Evaluation of small extracellular vesicles as biomarkers of efficacy with anti-PD-1 mAb therapy in patients with recurrent/metastatic HNSCC. *First Author: Dan Paul Zandberg, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: The development of biomarkers that reliably predict response to anti-PD-1 mAb therapy (IO) is a critical need. Small (30-150 nm) extracellular vesicles (sEV), aka exosomes, are "molecular mimics" of their parent cells. In cancer, plasma sEV are mixtures of tumor-derived exosomes (TEX) and vesicles produced by non-malignant cells. We conducted a retrospective study of R/M HNSCC patients treated with IO to evaluate sEV as predictive biomarkers. **Methods:** We evaluated sEV in plasma of R/M HNSCC patients (n = 24) obtained just prior to initiation of IO. Precleared ultrafiltered plasma was used to isolate total plasma sEV by size exclusion chromatography. Total plasma sEV were separated into two subsets, T cell-derived CD3(+) sEV and TEX-enriched CD3(-) sEV by immunocapture with anti-CD3 mAb. On-bead flow cytometry was used to estimate relative levels of proteins carried on the sEV surface. Specifically, the CD3(-) fraction was evaluated for stimulatory (stim; CD40, CD40L, OX40, OX40L, CD80) and suppressive (supp; TGFb, CTLA4, FasL, PD-L1, PD-1) proteins. Differences between responders (CR/PR/SD) and non-responders (PD) were assessed using Wilcoxon-Mann-Whitney test. Multivariate Cox proportional hazards regression was used to evaluate the relationship between the pre-treatment sEV characteristics and outcome. **Results:** Mean age was 62, 46% had oropharynx (82% HPV+), 17% oral cavity and 29% had larynx/hypopharynx primary. Treatment indication for IO was 46% platinum failure, remainder first line. Best response: 17% PR, 29% SD, and 54% PD. Median PFS and OS were 5.3 and 16.2 months, respectively. Total sEV protein level was not associated with efficacy. Total CD3(+) sEV level was low overall and did not correlate with lymphocyte count or neutrophil/lymphocyte ratio. High CD3(+) sEV level was associated with better OS [HR: 0.16 (95% CI 0.04-0.59), P = 0.007] and PFS [HR: 0.16 (95% CI 0.04-0.58), P = 0.005] but not response. While total TEX and levels of individual stim and supp proteins carried by TEX were not predictive of response, an increased supp/stim ratio was (P = 0.02). Importantly, high TEX supp score and stim score were both associated with better OS [HR: 0.19 (95% CI 0.05-0.77), P = 0.02, and HR: 0.26 (95% CI 0.07-0.95), P = 0.04, resp.]. High PD-L1, but not PD-1 on TEX, was associated with better OS [HR: 0.15 (95% CI 0.04-0.56), P = 0.005]; and PFS: HR: 0.33 (95% CI 0.11-0.94), P = 0.04]. **Conclusions:** Evaluation of two sEV subsets, T cell-derived-CD3(+) sEV and TEX-enriched CD3(-) sEV, indicated their potential utility as predictive biomarkers with IO. High T cell-derived sEV, TEX supp/stim ratio, and TEX PD-L1 expression levels were independently associated with significantly increased efficacy with IO. Our study uniquely analyzed the predictive value of plasma sEV subsets in IO treated R/M HNSCC patients, and evaluation in a larger cohort is warranted. Poster Session

A phase 1 clinical trial of DB-020 intratympanic injections administered prior to high dose cisplatin chemotherapy to reduce ototoxicity. *First Author: Danny Rischin, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: Hearing loss with cisplatin (CP) chemotherapy is common. DB-020 is a formulation of thiosulfate for intratympanic (IT) injection being developed to reduce CP ototoxicity. The primary objective of this Phase 1 study was to evaluate the safety and tolerability of repeated IT injections of DB-020. A secondary objective was to compare hearing changes with DB-020 vs. placebo. **Methods:** Subjects scheduled for at least 3 cycles of CP and cumulative exposure of ≥ 280 mg/m² were randomized to blinded, bilateral, IT injection with DB-020 (12% or 25%) in one ear and placebo in the other, once every 3 or 4 weeks, up to 3 hours before receiving CP. Subjects with moderate or severe hearing loss at baseline were excluded. Ototoxicity was defined by American Speech-Language-Hearing criteria: ≥ 20 dB threshold increase at any one test frequency, or ≥ 10 dB threshold increase in any two adjacent frequencies, or loss of response at three consecutive frequencies where responses were previously obtained. Severe ototoxicity was ≥ 20 dB threshold increase in any two adjacent frequencies. A pre-specified interim analysis evaluated safety, ototoxicity (with Mcnemar's test using the last observation carried forward), and average threshold shifts (from air conduction audiometry, analyzed with a mixed model with repeated measures). **Results:** Nineteen subjects were randomized, with mean age of 57 years (84% male and 100% white) and mean cumulative CP dose 248 mg/m². Most (95%) had head and neck cancers (5% had lung cancer). Seventeen subjects had both baseline and follow-up audiometry, and 16/17 had baseline audiograms within 5 dB of the median threshold for age-matched controls. Free CP systemic levels were similar to reference values. Ear pain (15/19 subjects, 78.9%) and tinnitus (8/19 subjects, 42.1%) were common. Ear pain was more common in DB-020 treated ears, and tinnitus was more common in placebo treated ears. There were no tympanic perforations, no serious adverse events in the category of ear and labyrinth disorders, and no deaths. Ototoxicity was significantly more common and more severe in placebo treated ears (Table). As the overall study objectives were met at this interim analysis, no further enrollment was pursued. **Conclusions:** In this initial clinical trial experience there was no significant safety signal, and DB-020 IT injections showed a meaningful reduction in cisplatin ototoxicity. These results warrant further clinical development. Clinical trial information: NCT04262336. Research Sponsor: Decibel Therapeutics.

Assessment	Placebo ears (n=17)	DB-020 ears (n=17)	p-value vs. placebo
Ototoxicity (250 to 8000 Hz)	88.2%	41.2%	0.0047

Abemaciclib in recurrent/metastatic head and neck squamous cell carcinoma (RM-HNSCC) harboring *CDKN2A* loss, and/or *CCND1* and/or *CDK6* amplification: A phase II multicenter trial. *First Author: Jerome Fayette, Centre Léon Bérard, Lyon, France*

Background: More than half of HPV negative HSNCC harbor genomic aberrations (i.e. *CDKN2A* loss, cyclin D amplification (ampl.)) that activate the cyclin-dependent kinase 4 and 6 (CDK4/6) – retinoblastoma protein (Rb) signalling pathway. Hyperactivated CDK4/6-Rb pathway leads to acceleration of G1/S transition of cell cycle and ultimately to uncontrolled cellular proliferation. We hypothesized that abemaciclib, a CDK4/6 inhibitor, could be a potent targeted strategy by inhibiting this commonly dysregulated pathway in HNSCC. **Methods:** This single arm, multicentre Phase II evaluated the efficacy of abemaciclib (200mg/d orally BID) in molecularly-selected, HPV negative (HPV), RM-HNSCC patients (pts) progressing after at least 1 prior line of platinum and cetuximab. A molecular screening step through centralised CGH-assay was required before treatment start: only pt with tumor harboring CDKN2A loss and/or CCND1 and/or CDK6 ampl. without homozygous deletion of RB1 were eligible to the therapeutic step. The primary endpoint was 8-week non-progression rate (PFR_{8w}) as per central imaging review according to RECIST V.1.1. Secondary endpoints included best overall response rate (BORR), progression free survival (PFS), overall survival (OS) and adverse event (AE) according to NCI-CTCAE V5.0. The study used a Fleming A'Hern design with an inefficacy bound of 15% and a target PFR_{8w} of 40% ($\alpha = 5\%$ one sided, $1-\beta = 90\%$). **Results:** Twenty-six HPV⁺ RM-HNSCC pts (M: 23, F: 3, median age: 59 [range, 42-78], heavily pre-treated [84.6% $\geq$ 2 prior lines]) received at least one dose of abemaciclib. According to central CGH-assay, molecular alterations were *CDKN2A* loss + *CCND1* ampl. + *CDK6* ampl. (n = 1), *CDKN2A* loss + *CCND1* ampl. (n = 10), *CDKN2A* loss (n = 6) or *CCND1* ampl. (n = 9), all with intact Rb. Among the 24 evaluable pts, 7 pts were progression-free at 8 weeks (PFR_{8w}: 29.2% (95% CI 14.6-)). BORR according to central imaging review was stable disease for 7 pts (31.8%) and progressive disease for 11 pts (50%); no objective response was observed. Median PFS and OS were 7.1 weeks (95% CI: 6.9-10.4) and 4.8 months (95% CI: 2.4-7.3), respectively. Most common related AEs ($\geq 20\%$ of pts, all grade) were diarrhea/nausea/vomiting, fatigue and hematological toxicity (anemia, lymphocyte and neutrophil count decreased). Two fatal serious AE potentially related to abemaciclib according to both investigator and sponsor were reported: a case of pulmonary hemorrhage also possibly related to abemaciclib-induced tumor necrosis and a case of myocardial infarction. **Conclusions:** Abemaciclib had limited antitumor activity in RM-HNSCC harboring molecular alteration in CDK4/6 pathway. Clinical trial information: NCT03356223. Research Sponsor: Lilly.

Phase II study evaluating the efficacy of niraparib and dostarlimab (TSR-042) in recurrent/metastatic head and neck squamous cell carcinoma (HNSCC) patients. *First Author: Olga Zamulko, University of Cincinnati Medical Center, Cincinnati, OH*

Background: Patients with recurrent and/or metastatic (R/M) HNSCC have poor overall survival. Immune checkpoint inhibitors (ICIs), specifically programmed death-1 (PD-1) inhibitors, result in durable responses in R/M HNSCC but <20% benefit. Tumor mutational burden (TMB) correlates with ICI response. DNA pathway repair mutations have been reported in 17% of sporadic HNSCC and are associated with higher rates of TMB. Poly (ADP-ribose) polymerase (PARP) inhibition has demonstrated efficacy as a single agent in cancers with a DNA repair defect. We tested the combination of PARP inhibitor (niraparib) with the PD-1 inhibitor (dostarlimab) in R/M HNSCC patients (NCT04313504) with funding support from Tesaro/GSK. **Methods:** Patients with R/M HNSCC who failed at least one line of prior treatment including a PD-1 inhibitor and for whom no surgical or radiation curative options existed were eligible for the study. Patients received niraparib (200 mg daily) beginning one week prior to initiation of dostarlimab (500 mg q3wks x4 followed by 1000 mg q6wks). The primary endpoint was overall response rate (ORR) including complete response (CR), partial response (PR) and stable disease (SD) using RECIST v1.1. Fourteen patients were planned for the first stage and 10 additional patients for the second stage if ≥ 8 patients had a confirmed response. Safety was evaluated by CTCAE v5.0. Tumor PD-L1 immunohistochemistry was performed with 22c3 antibody and reported as combined positive score (CPS). TMB was considered high if ≥ 10 Mut/Mb. **Results:** Ten of 24 planned patients were enrolled. Of the first 10 patients, 8 patients were evaluable by imaging and 1 patient clinically progressed on exam. Of the 9 evaluable patients, there were 0 CR, 1 PR, 1 SD, and 7 with progressive disease (PD). The trial was ended early for futility as it was not possible for at least 8 out of 14 patients to develop response. The patient with a PR remains on treatment past 24 months, was PD-L1 positive, had low TMB and no DDR deficiency. All patients had previously failed a PD-1 inhibitor. One patient had high TMB, 2 patients had a DDR, and 6 patients were PD-L1 positive but 2 patients had insufficient tissue or indeterminate results for sequencing. Grade ≥ 3 adverse events occurred in 70% of patients with most common being hypertension (20%), hyponatremia (20%), and lung infection (20%). **Conclusions:** PARP-1 inhibition and PD-1 inhibition combined does not appear to enhance response over PD-1 inhibitor alone in R/M HNSCC who had previously failed PD-1 inhibitor treatment. However, a more focused population including those with DNA damage response (DDR) mutations and PD-1 treatment naïve may benefit. Clinical trial information: NCT04313504. Research Sponsor: GSK provided funding for this trial; Tesaro.

Personalized therapy for head and neck squamous carcinoma (HNSCC) utilizing tissue proteomics profiling. *First Author: Sheeno P. Thyparambil, mProbe Inc., Rockville, MD*

Background: Chemotherapy is widely used in the treatment of HNSCC, yet no biomarkers for chemotherapy are used for selection of the chemo agent in the treatment of HNSCC. We examined 143 HNSCC cancer using targeted proteomics for the protein expression levels of several chemo agents. These include markers of resistance to platinum agents (ERCC1), anti-tubulin inhibitors (TUBB3) and sensitivity markers for topoisomerase inhibitors (Topo1 – irinotecan, topotecan; Topo2A – doxorubicin, etoposide). We also measured markers for several antibody-drug conjugates (EGFR, Her2, Trop2, FR-alpha, Mesothelin). **Methods:** Tumor areas from Formalin-fixed, paraffin-embedded (FFPE) tumor tissues from clinical samples of HNSCC that were received at our CLIA certified laboratory were microdissected and a selected reaction monitoring mass spectrometry (SRM-MS) quantitative proteomic analysis of 72 protein biomarkers were conducted concurrently from 2-3 sections of FFPE tissue. **Results:** Platinum agents are widely agent in HNSCC cancer. ERCC1, a resistance marker for platinum agents was expressed in 44% of HNSCC. Similarly, TUBB3, a resistance marker for Paclitaxel, docetaxel was also expressed in ~45% of HNSCC. These indicate that ~45% of HNSCC could potentially be refractory to platinum and paclitaxel-based therapy. Additionally, ALDH1A1, a marker for resistance of cyclophosphamide, was expressed in 78% of HNSCC. Temozolomide, an alkylating agent used in other cancer type could be beneficial in 14% of HNSCC because of the lack of resistance marker MGMT. On the other hand, 88% of HNSCC expressed Topo1, which is a sensitivity marker for irinotecan or topotecan based therapy. Additionally, Top1 is also the target for the payload of several ADCs (e.g. trastuzumab deruxtecan and sacituzumab govitecan). Similarly, 55% of HNSCC expressed Topo2A, a target for etoposide and doxorubicin. Additionally, 57% of HNSCC expressed hENT1, a transporter of gemcitabine. HNSCC also expressed various targets for targeted and ADC agents. These include EGFR (86% detected with 37x range of distribution), Her3 (11%), IGF1R (16%), MET (13%), Folate receptor- alpha (18%), Mesothelin (13%), and Trop2 (89% with 134x range of distribution). Her2 was overexpressed (> 750 amol/ug) in 11% of HNSCC, however, it was observed in 46% of HNSCC with a 53x range (276 – 14705 amol/ug), indicating that a significant population of HNSCC might be eligible for low Her2 clinical trials. **Conclusions:** Every cancer is unique, and the ability to analyze 72 protein biomarkers from 2-3 FFPE sections simultaneously at the same time provides a wealth of actionable information for clinical treatment or patient stratification for clinical trials. Research Sponsor: mProbe.

TCR-T cells armored with immune checkpoint blockade in EBV-positive nasopharyngeal carcinoma: The first-in-human phase 1/2 trial. *First Author: Qingzhu Jia, Institute of Cancer, Xinqiao Hospital, Chongqing, China*

Background: Nasopharyngeal carcinoma (NPC) refection and metastasis is common, but therapeutics are limited. As adoptive immunotherapy has emerged as effective against other cancers, engineered T cells bearing a transgenic Epstein-Barr virus (EBV)-specific TCR (TCR-T) represent a viable approach to treat EBV-associated NPC. Given PD-1/PD-L1 induced T cell hypofunction, we herein report preliminary findings of a phase I trial of EBV-targeting TCR-T cells armored with secreted PD-1 blockade for patients who failed in two or more lines of standard therapies. **Methods:** Patients with advanced NPC were consented and screened for EBV serotype and HLA haplotype. EBV+ HLA-A*02+ patients were enrolled in a rapid titration setting to escalate the single infusion dose from 5×10^6 to 1.0×10^7 and 5.0×10^7 /kg TCR-T cells. After safety evaluation, the 5.0×10^7 /kg cohort was expanded for further investigation of combining with IL-2 administration. Fludarabine/cyclophosphamide were administered prior to TCR-T cell transfer as pre-conditioning. Patient monitoring and peripheral blood analysis occurred weekly over the first month and then monthly until disease progression or patient withdrawal. The primary objective was to determine safety and a recommended phase 2 dose (RP2D), while the secondary objective was investigator assessed ORR (RECIST v1.1). **Results:** One patient per TCR-T dose was treated, and, as no dose-limiting toxicity (DLT) has been observed, dose level 3 (5.0×10^7 /kg) was expanded with IL-2 administration upon TCR-T cell infusion. As of January 2023, six patients have been treated. One patient (16.7%) exhibited grade 1 CRS (n=6). No grade 4 treatment-related adverse events (TRAEs) have been observed, with leukopenia and fever being the most common AEs. Two patients (33.3%) were assessed as partial response (PR), with one reaching a response duration of 9 months to date. Three patients (50%) were assessed as stable disease (SD). For all patients, pharmacokinetic analysis revealed that levels of TCR-T cells in peripheral blood peak between 3- and 14-days post-infusion, with a maximum duration of 180 days. **Conclusions:** EBV-targeting TCR-T cells armored with PD-1 blockade are well tolerated. Initial results from this ongoing study indicate that EBV proteins may be safe and effective TCR-T targets to achieve superior outcomes in advanced EBV-positive NPC patients. Clinical trial information: NCT04139057. Research Sponsor: Guangdong TCR Cure Biopharma Technology Co., Ltd, Guangzhou, China.

Clinical adverse events and efficacy (5.0x10 ⁷ /kg TCR-T cells, n=6).

A phase II study of lenvatinib plus pembrolizumab in patients with progressive, recurrent/metastatic adenoid cystic carcinoma. *First Author: Maliheh Mohamadpour, MSKCC, New York, NY*

Background: Recurrent/metastatic adenoid cystic carcinoma (R/M ACC) is a rare salivary gland cancer (SGC) without standard treatments. The multitargeted, antiangiogenic kinase inhibitor lenvatinib (len) has activity in R/M ACC, but immune checkpoint inhibitor (ICI) therapies lack efficacy. Hypothesizing that VEGFR inhibition can enhance ICI-induced responses, we conducted a phase II trial evaluating len plus the programmed death-1 (PD-1) inhibitor pembrolizumab (pem) in two R/M SGC cohorts: ACC and non-ACC. Here we report results from the completed ACC cohort. **Methods:** Patients (Pts) with R/M ACC were enrolled. RECIST v1.1 measurable disease and evidence of progression on imaging performed within 6 months of enrollment were required; any number of prior therapies was allowed. Pts were treated with len 20 mg orally daily and pem 200 mg intravenously every 3 weeks (21-day cycles). The primary objective was to evaluate best overall response rate (ORR), seeking an ORR improvement with len+pem from 15% (previously reported with len alone) to 35%. In the first stage, > 3 confirmed complete and partial responses (cCRs+cPRs) were required among 17 pts to continue to the second stage; > 8 responses among 32 total pts would have been considered positive (1-sided alpha 0.1, power 0.9). Secondary objectives included evaluating progression-free survival (PFS) and safety/tolerability per CTCAE v5.0 criteria. **Results:** 17 R/M ACC pts were enrolled and evaluable for the primary objective. One pt had a cPR for an ORR of 6%, failing to meet the rule for progression to the second stage. Thirteen (76%) pts had stable disease and 2 (12%) progression of disease as best response; 1 pt did not have response assessed. Thirteen (76%) pts experienced some degree of regression in RECIST target lesions (TLs; -1.9% to -42.8%), including 5 (29%) with > -20% regression. Eleven (65%) pts were progression-free for > 24 weeks. Twelve (71%) pts experienced at least one > Grade 3 adverse event related to study treatment. Sixteen pts had at least one treatment interruption or len dose reduction; 2 pts received only 1 cycle of therapy. Five pts were treated beyond first progression without observation of subsequent response. Quality of life data and correlative tissue studies are ongoing. **Conclusions:** The trial failed to demonstrate that len+pem produces a greater ORR in patients with R/M ACC than what was previously reported with len alone. Further investigation into the biology mediating ICI-resistance and development of novel approaches to augment the efficacy of immune-based therapies in ACC are needed. (Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA provided lenvatinib and pembrolizumab for the study.) Clinical trial information: NCT04209660. Research Sponsor: Merck Sharp & Dohme Corp and Eisai.

Low-dose fractionated radiotherapy combined with neoadjuvant chemotherapy for T3-4 nasopharyngeal carcinoma patients: Preliminary results of a phase II randomized controlled trial. *First Author: Mei Feng, Department of Radiation Oncology, Sichuan Cancer Hospital and Institution, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Sichuan, China*

Background: Over 70% of NPC patients were local advanced NPC (LANPC). The 5-year local recurrence-free survival rate is only 70% in T3-4 patients. Neoadjuvant chemotherapy (NACT) followed with concurrent chemoradiotherapy (CCRT) was recommended for LANPC patients. Low-dose fractionated radiotherapy (LDFRT), which is < 100cGy, induces enhanced cell killing by the hyper-radiation sensitivity phenomenon and potentiates effects of chemotherapy. The synergy of LDFRT and NACT has not been used in the clinical practice and few studies focused on it. A single arm study found the ORR of primary site was improved to 90% for head and neck squamous carcinoma patients treated with LDFRT and NACT. Our previous study found the ORR of lymph nodes was higher in LDFRT group for high-risk LANPC patients. However, another study showed there was no significant difference between LDFRT and control group for LANPC patients. So, we aimed to investigate the potential efficacy of this novel neoadjuvant therapy for T3-4 NPC patients. **Methods:** 60 pathological confirmed T3-4 (UICC/AJCC8th) NPC patients were prospectively enrolled in our study. They were randomly assigned to two groups. For the LDFRT group, the patients received 3 cycles of NACT (docetaxel 75mg/m² D1, cisplatin 80mg/m² D1) with LDFRT, and followed with CCRT. LDFRT was delivered as 50cGy per fraction twice a day to primary site on D1,2 for each cycle of NACT. The patients in the control group only received NACT and followed with CCRT. All the patients underwent IGRT. RECIST criteria and CTCAE 5.0 was used to evaluate the ORR and toxicity at post-NACT and the completion of CCRT. **Results:** from Feb 2022 to Dec 2022, 60 T3-4 NPC patients were included, and 30 patients for each group. For the primary site, the median volume reduction rate and the ORR after NACT was significantly improved in LDFRT group (69.27% vs 40.10%, p< 0.001; 93.33% vs 73.33%, p=0.038). For the median volume reduction rate of primary site and lymph node, it was also obviously improved in LDFRT group (86.59% vs 55.43%, p< 0.001). Though there was a tendency of ORR improvement in LDFRT group, but no significant difference (96.67% vs 83.33%, p=0.195). After the completion of CCRT, the median volume reduction rate of primary site had an increased tendency in LDFRT group (96.16% vs 88.3%, p=0.065), but the ORR had no statistical significance (LDFRT group: CR 45.8%, PR 54.2%; control group: CR 37.5%, PR 62.5%). For the toxicity, the incidence of grade 3-4 adverse events had no difference between two groups (p=0.786). No grade 5 adverse events occurred. **Conclusions:** LDFRT combined with NACT could obviously improve the median volume reduction rate and ORR of primary tumor for T3-4 NPC patients, and the toxicity was similar and tolerable. The novel treatment could be a promising strategy to improve treatment response, and needed to be confirmed further. Clinical trial information: NCT05503914. Research Sponsor: 2022YFS0047.

Phase I/II trial of durvalumab plus tremelimumab and stereotactic body radiotherapy for metastatic head and neck carcinoma: Final results. *First Author: Houda Bahig, Centre Hospitalier de l'Université de Montréal, Montreal, QC, Canada*

Background: Anti-PD-1/PD-L1 is now part of first line therapy in metastatic head and neck squamous cell carcinoma (HNSCC). Stereotactic radiotherapy (SBRT) to metastatic lesions can reduce tumor burden and could be immune-stimulatory. The combination of SBRT with dual-checkpoint blockade with Durvalumab (D, anti-PD-L1) and Tremelimumab (T, anti-CTLA-4) has not previously been tested in HNSCC. We report on the safety and efficacy of this triple treatment combination (TTC) consisting of SBRT sandwiched between cycles of D and T in oligometastatic HNSCC. **Methods:** This is a phase I/II single arm multi-institutional study powered for 35 patients with oligometastatic HNSCC (2-10 lesions) (NCT03283605). D (1500 mg) and T (75 mg) were given for 4 monthly cycles, followed by monthly D for 8 monthly cycles. SBRT to 2-5 lesions was administered during cycle 2. The safety of the TTC was the primary endpoint of the phase I and was evaluated through assessment of Grade 3-5 TTC-related adverse events (AE), based on CTCAE (v 4.03). The primary endpoint of the phase II portion was 6-month progression free survival (PFS), with a predetermined 6-month PFS (6moPFS) rate greater than 27% considered as a positive signal to conduct further research on this combination. **Results:** A total of 33 evaluable patients were recruited (study accrual was interrupted by the COVID pandemic). The table describes patients' characteristics. Patients had received 1, 2 and 3 prior systemic therapy lines in 48%, 21% and 9% of the cases, including 6 (18%) patients who had received prior anti-PD-L1 or anti-CTLA-4 therapies. The median prescribed and maximum SBRT doses were 45 Gy (range: 18-50) and 52.3 Gy (range: 28.1-69) in 3-5 fractions, respectively. Fourteen patients (42%) had Grade ≥ 3 AE attributable to D and T. Only 1 patient developed Grade ≥ 3 AE attributable to SBRT. This patient, who had mucosal radionecrosis after re-irradiation and refused surgical debridement and flap reconstruction, specifically developed 2 Grade 3, 1 Grade 4 and 1 Grade 5 AE. Our primary efficacy endpoint, 6moPFS, was 69.7% (95% CI: 55.6-87.3). Median PFS was 11.9 months (6.94-14.5) and median OS was 25.1 months (17.9-28.4). Rates of complete response, partial response, stable disease and progressive disease were 9%, 21%, 33% and 12%, respectively, with 8 (24%) patients with no evaluable non-SBRT treated lesion. **Conclusions:** The addition of SBRT to dual-checkpoint inhibition led to 1 (3%) additional patient developing severe AE. Best response rates were encouraging. Our primary efficacy outcome, 6mo PFS was attained and was higher than what was expected in this patient population. Clinical trial information: NCT03283605. Research Sponsor: Astra Zeneca.

Safety and efficacy of time restricted eating (TRE) in improving response to immunotherapy in patients with head and neck cancer (HNSCC). *First Author: Humaira Sarfraz, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Advanced head and neck cancer continues to have very poor prognosis. Only a fraction of patients respond to immune checkpoint blocker therapy (ICB), with no effective treatment options for non-responders. Gut microbiome composition and diversity have been associated with response to ICB in many cancers including HNSCC. We, therefore hypothesized that modulation of gut microbiota may improve response to ICB. Time restricted eating represents an attractive strategy to favorably alter the microbiome and improve ICB responses. We conducted a phase I/II nonrandomized study to evaluate safety, feasibility and efficacy of TRE in improving response rates in treatment naïve metastatic HNSCC patients receiving single agent ICB. **Methods:** TRE is a form of circadian aligned nightly fast of 14 hours without reduction in calories. Patients were assigned to TRE vs control in 1:2 ratio, with first response evaluation at 12+/- 3 weeks as end point. Compliance to TRE was monitored via an app ("my circadian app") and daily food logs. Blood and stool samples were collected at therapy initiation, at 1st response assessment and at 6 months. We evaluated stool metagenomics, untargeted stool/plasma metabolomics and serum cytokines as correlatives. We focused on microbial metabolites including indoles and short chain fatty acids (SCFA), which are potent aryl hydrocarbon receptor agonist and immunosuppressive. We also evaluated serum cytokines associated with insulin signaling pathways. **Results:** A total of 43 HNSCC patients receiving single agent pembrolizumab were accrued, 15 in the TRE arm and 28 in control arm. TRE was well tolerated without any study dropouts, weight loss or any adverse events attributable to the intervention. TRE was associated with significant improvement in disease control rate (DCR) at 3 months and at 6 months (3 month DCR 85% in TRE vs 50% in the control arm, p<0.0001, 6 month DCR 64% in TRE vs 39% in control arm, p=0.0004). Responders in both TRE and control arm had lower relative abundance of microbial immunosuppressive indole metabolites, butyric acid (NR vs R: 0.67 vs 0.58, p=0.05) and IGF1 (NR vs R: 0.42 vs 0.39, p=0.02). TRE led to a similar change in microbial metabolites including decrease in abundance of 5 Hydroxyindole acetic acid, Indole 3 acetic acid (IAA), Indole Carboxaldehyde, Indole acrylic acid, butyric acid (control vs TRE: 0.68 vs 0.58, p=0.03) and IGF1 (control vs TRE: 0.4 vs 0.3, p=0.03.) **Conclusions:** We report a novel phase I/II study of TRE in HNSCC patients and demonstrate excellent safety, feasibility and marked improvement in efficacy of ICB. The effect of TRE may be mediated via changes in microbial metabolome and insulin signaling pathways. TRE represents an attractive and safe strategy to improve treatment responses to ICB and needs to be explored in phase III expansion studies. Association of pretreatment lymphocyte-monocyte ratio with survival outcome in patients with head and neck cancer treated with chemoradiation.
First Author: Brian Yu, Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY

Background: Lymphocyte-monocyte ratio (LMR) from peripheral blood has been suggested as a biomarker to assess the extent of inflammation in several solid malignancies. However, the role of LMR as a prognostic factor in head and neck cancer (HNC) was unclear in several meta-analyses, and there is a paucity of literature including patients in North America. We performed an observational cohort study to evaluate the association of pre-radiation LMR with survival outcomes in North American patients with HNC. **Methods:** A single-institution database was queried for patients with non-metastatic HNC who underwent curative-intent definitive chemoradiation from 6/2007 to 4/2021 at the Roswell Park Comprehensive Cancer Center. Patients were excluded if they underwent induction chemotherapy or postoperative radiation. Primary endpoints were overall survival (OS) and cancer-specific survival (CSS). The association of LMR with OS and CSS was examined using nonlinear Cox proportional hazard model using restricted cubic splines (RCS), Cox multivariable analysis (MVA), and Kaplan-Meier method. LMR was stratified into high and low based on its median. Logistic MVA was performed to identify variables associated with low LMR. Propensity scored matching was used to reduce selection bias. Subgroup analyses were performed among those with available human papillomavirus (HPV) status. **Results:** A total of 476 patients (391 male [82.1%], median [interquartile range] age, 61 [55-67] years) met our criteria. Median follow up was 45.3 months (interquartile range 22.8-74.0). The nonlinear Cox regression model using RCS showed that low LMR was associated with worse OS and CSS in a continuous fashion without plateau and crossed the hazard ratio of 1 at LMR 3.4 for both OS and CSS. On Cox MVA, higher LMR as a continuous variable was associated with improved OS (adjusted hazard ratio [aHR] 0.90, 95% confidence interval [CI] 0.82-1.00, $p = 0.04$) and CSS (aHR 0.81, 95% CI 0.70-0.94, $p = 0.005$). The median value of LMR was 3.8. On logistic MVA, patients with other racial background (adjusted odds ratio [aOR] 0.85, 95% CI 0.74-0.97, $p = 0.02$) and positive HPV status (aOR 0.82, 95% CI 0.72-0.94, $p = 0.005$) were less likely to have low LMR. Higher T staging was associated with low LMR (aOR 1.15, 95% CI 1.04-1.27, $p = 0.005$). A total of 186 pairs were matched with well balanced baseline characteristics. LMR lower than 3.8 remained associated with worse OS (HR 1.60, 95% CI 1.13-2.28, $p = 0.009$) and CSS (HR 1.69, 95% CI 1.07-2.67, $p = 0.03$). In the subgroup of 319 patients (67.0%) with available HPV data, LMR status was not associated with both OS and CSS regardless of HPV status. **Conclusions:** Low LMR was associated with worse OS and CSS. Low LMR was also associated with higher T staging, negative HPV status, and White race. Further studies are warranted to evaluate the role of such prognostic marker to tailor interventions. Association between locoregional failure and NFE2L2/KEAP1/CUL3 pathway mutations in NRG/RTOG 9512: A randomized trial of hyperfractionation vs. conventional fractionation in T2N0 glottic squamous cell carcinoma (SCC).
First Author: Li Guan, Stanford University, Stanford, CA

Background: Radiotherapy (RT) is the primary treatment for patients with T2N0 glottic SCC. ~30% of these patients experience locoregional relapse despite dose escalation. Mutations in the NFE2L2/KEAP1/CUL3 pathway have been linked to radioresistance preclinically and in small retrospective studies. We tested the hypothesis that patients with T2 glottic SCCs having these mutations would show radioresistance and more local (LF) and locoregional failures (LRF) when treated with RT compared to those without, using samples from a phase III trial. **Methods:** Of 250 randomized patients with T2N0 glottic SCC receiving definitive RT in RTOG 9512, 119 had available biospecimens that were subjected to amplicon-based next generation sequencing (appropriate to low-input DNA from biopsy specimens) to assess for presence of NFE2L2/KEAP1/CUL3 mutations without regard to outcomes. The association between binary mutation status and LF, LRF, disease-free survival (DFS), and overall survival (OS) was assessed using (cause-specific) Cox models (2-sided alpha of 0.05). LR/LRF rates were estimated by the cumulative incidence method and DFS/OS rates by the Kaplan-Meier method. **Results:** Nineteen of 119 patients (16.0%; 95% confidence interval [CI] 9.4, 22.6) had mutations in the NFE2L2/KEAP1/CUL3 pathway. Patient and tumor characteristics were similar between those with and without mutation. There were 32 LF, 37 LRF, and 80 DFS events, and 52 deaths. Patients with mutation compared to those without had significantly higher LF and LRF rates (Table). Median DFS was 0.9 years (95% CI 0.4, not reached) for the mutation group compared to 4.2 years (95% CI 3.2, 6.4) for those without. The hazard ratio (HR) for DFS was significantly higher for the mutated compared to the non-mutated group in the first 2 years after randomization but declined thereafter (Table), likely due to limited events after 2 years in the mutation group. There was no significant difference in OS between the two groups (HR = 0.76; 95% CI 0.35, 1.6; $p = 0.48$). **Conclusions:** NFE2L2/KEAP1/CUL3 pathway mutations may predict radiation treatment failure in T2N0 glottic cancer. They may also be a prognostic biomarker for DFS, but the current evidence supports the harmful effect of these mutations only during the first 2 years from randomization. Clinical trial information: NCT00002727. Evaluation of tumor mutation burden (TMB) in tumor (tDNA) and plasma cell free DNA (cfDNA) in patients (pts) with recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC) treated with a combination of cetuximab and nivolumab (C+N).
First Author: Christine H. Chung, Moffitt Cancer Center, Tampa, FL

Background: High TMB is associated with immune checkpoint inhibitor (ICI) response in many solid tumors. However, obtaining sufficient tumor specimens for testing in a routine clinical setting could be a challenge. We evaluated TMB from whole-exome sequencing (WES) of cfDNA as a surrogate for tDNA TMB in R/M HNSCC pts treated with C+N. **Methods:** Archived formalin fixed paraffin embedded tumors, serially collected plasma (pre-treatment, on-treatment, and time of disease progression/end of treatment), peripheral mononuclear blood cells, and clinical data were obtained from R/M HNSCC pts treated with C+N from a completed clinical trial (NCT03370276). Nucleic acids were extracted using AllPrep DNA/RNA Mini Kit (Qiagen). Libraries were constructed using KAPA HyperPrep Kit with Library Amplification (KK8504) and IDT's duplex UMI adapters. Hybridization and capture were performed using IDT's XGen hybridization kit. Whole exome sequencing was performed using Illumina NovaSeq S4 flowcells (paired 151bp runs). Data preprocessing including point mutation calling, filtering, CNV calling, and purity and ploidy estimation were performed using the Getz Lab CGA WES Characterization pipeline. TMB for each sample was calculated based on the number of mutations with cancer cell fraction > 0.75 as determined by ABSOLUTE and normalized to the 35Mb targeted for exome capture. **Results:** A total of 88 tDNA, 226 cfDNA, and 30 normal DNA (nDNA) from 82 pts were sequenced. To date, sequencing data from 13 matched tDNA/cfDNA/nDNA samples and 34 matched cfDNA/nDNA samples with sufficient tumor purity were available for analyses. The median TMB was 2.4 mut/Mb (range 0.46-17.5) in tDNA and 1.8 mut/Mb (range 1.1-12.6) in cfDNA. There was a high correlation between tDNA/cfDNA pairs in TMB ($r = 0.826$, $p = 1.5 \times 10^{-16}$, Pearson correlation). The median TMBs in tDNA and cfDNA obtained at different time points or treatment course did not differ significantly in 22 patients with at least two cfDNA timepoints ($p = 0.26$ paired t-test of log-transformed TMB). There was no difference between responder (R) vs. non-responder (NR) in cfDNA TMBs (two-sample t-test $p = 0.7$ between 2 R and 12 NR) and tDNA TMBs (two-sample t-test $p = 0.25$ between 6 R and 21 NR). However, tDNA TMB was higher in R compared NR in a subset of pts who did not have prior treatment with ICI (two-sample t-test $p = 0.05$ between 5 R and 2 NR). **Conclusions:** TMB in tDNA and cfDNA is highly correlated and suggests the possible use as a surrogate marker for tTMB. High TMB in cfDNA derived from ICI-naïve patients appears to have a prognostic value. Further evaluation is warranted to determine the role of cfDNA TMB as a biomarker of ICI response. A proteomic signature associated with prognosis in HPV-related locally advanced oropharyngeal squamous cell carcinoma (LA-OPSCC).
First Author: Jia (Jenny) Liu, The Kinghorn Cancer Centre, St Vincent's Hospital, Darlinghurst, NSW, Australia

Background: Although HPV-related LA-OPSCC is associated with better prognosis than HPV-negative disease, ~30% of cases relapse despite curative-intent chemoradiotherapy. New prognostic biomarkers are needed to rationalise curative-intent treatment without compromising efficacy. We aimed to develop a proteomic signature associated with risk of recurrence from diagnostic biopsies of patients with HPV-positive OPSCC. **Methods:** We analysed 139 formalin fixed paraffin embedded archival core biopsy specimens from 124 patients with HPV-related (p16 IHC positive) T1-4N0-3M0 LA-OPSCC tumours. All patients were treated with definitive chemoradiotherapy at the Princess Alexandra Hospital (Brisbane, Australia) between 2007-2019. The cohort included 50 patients with recurrence less than five years from diagnosis and 74 age/performance-status matched patients with no recurrence. Proteomic analysis was performed utilizing data-independent acquisition mass spectrometry (DIA-MS). A proteomic prognostic signature associated with recurrence free survival (RFS) at five years was the primary endpoint of interest. It was developed using a computational pipeline comprising an initial univariate Cox model step, followed by multiple runs of multivariate Cox models with Least Absolute Shrinkage and Selection Operator (LASSO) regularization, and then a final step of recursive feature selection. **Results:** A total of 7,597 proteins were quantified and 665 were differentially expressed proteins between tumour and normal adjacent tissues. There were 5,199 proteins remaining in the tumour samples after filtering. RFS was significantly (q -value < 0.05) associated with 252 proteins, whose functions are enriched in adaptive and innate immunity and MAPK6/MAPK4 signalling pathways. A 16-protein signature associated with RFS stratified patients into low, intermediate, or high-risk groups (C -index = 0.885, $p < 0.0001$). The 16-protein signature outperformed clinico-pathological covariates including age, stage, ECOG and smoking history with the highest area under the receiver operating characteristic curve (AUROC 0.95). **Conclusions:** DIA-MS-based proteomics on core biopsies can be used to risk stratify HPV-related OPSCC patients. A 16-protein signature associated with RFS was successfully identified as a basis for future studies. Validation of this proteomic prognostic signature in independent cohorts is required and may be used to inform future clinical trials to better tailor upfront therapy. Single-cell RNA and T cell receptor (TCR) sequencing in patients with HPV-positive head and neck squamous cell carcinoma (HNSCC) after induction CTLA4 and PD-1 immune checkpoint blockade (ICB). *First Author: Xianli Jiang, Department of Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Combination CTLA-4 and PD-1 ICB results in durable responses in patients with recurrent and metastatic HNSCC and therefore justifies further investigation in the induction or neoadjuvant setting. **Methods:** We investigated features of the tumor immune microenvironment (TIME) associated with MHR after induction CTLA-4 and PD-1 ICB in patients with newly diagnosed HPV-positive HNSCC. Tumor samples were collected at baseline and on treatment from 31 patients enrolled in a phase 2 trial of a 6-week cycle of CTLA-4 and PD-1 ICB induction followed by dose/volume-adapted IMRT (50-66Gy) concurrent with cycle 2. Tumors were evaluated for histological response and single-cell RNA sequencing (scRNA-seq) and scTCR-seq were performed on the 10X genomics platform. After stringent clustering and annotation of scRNA-seq data, 76,319 CD8⁺ and 78,622 CD4⁺ T cells with paired TCR sequence data were evaluable for transcriptomic, TCR repertoire and clonotype differentiation analysis. **Results:** Percent reduction in tumor viability on histology correlated significantly with reduction in tumor cell proportion in scRNA-seq data ($R^2 = 0.7$). Thirteen (48%) of 27 patients with paired samples (missing data due to COVID) had MHR, defined as $\leq 10\%$ residual tumor viability on ICB treatment. Through TCR tracing, over 100 T cell clonotypes that expanded significantly ($p < 0.05$, Fisher's exact) post-ICB were identified. Highly expanded clonotypes resided mainly in exhausted CD8⁺ T cell clusters and exhibited a tissue resident memory (TRM) phenotype. Examination of their functional states revealed a variety of T cell modulatory trajectories, including reverse transition from exhausted to less exhausted states and from memory to functional states. When compared to patients without MHR, those with MHR had significantly higher ICB-induced TCR clonotype expansion ($p = 0.025$, Wilcoxon), reductions of activated Tregs ($p = 0.003$, Wilcoxon) and terminally exhausted CD8⁺ T cells ($p = 0.003$, Wilcoxon), and increase of polyfunctional CD8⁺ T cells ($p = 0.014$, Wilcoxon). A lasso regression model associated T cell expansion, basal 7-gene TRM and 5-gene effector scores, and on-treatment proliferation score and effector cell proportion with percent reduction in tumor viability ($R^2 = 0.66$). **Conclusions:** In HPV-HNSCC, induction CTLA4 and PD1 ICB lead to extensive reinvigoration of CD8⁺ T cell clonotypes with both an exhausted and TRM phenotype, revealing a high degree of plasticity of distinct T cell clones. Paired RNA and TCR profiling facilitated identification of potentially tumor reactive and ICB-responsive T cells and clonotypes and identified several TIME features associated with tumor cell death. Clinical trial information: NCT03799445. Research Sponsor: Cancer Prevention and Research Institute of Texas.

Association of HPV genotype and phylogenic clade with oropharyngeal cancer outcomes. *First Author: Michael Wotman, MD Anderson Cancer Center, Houston, TX*

Background: Human papillomavirus (HPV) is a causative agent of oropharyngeal squamous cell carcinoma (HPVOPC). There are multiple different HPV genotypes based on variations in the nucleotide sequence of the L1 capsid, with HPV16 being most common in HPVOPC (85%). HPV genotypes can be further classified into phylogenic clades, including alpha-9 (A9) and alpha-7 (A7). HPVOPC is associated with a more favorable prognosis than HPV-negative disease, but the impact of specific HPV genotype and phylogenic clade on patient outcomes is not well understood and has profound implications for de-escalation studies in HPVOPC. **Methods:** A retrospective cohort study was conducted at a large multicenter health system. Patients diagnosed with non-metastatic HPVOPC or unknown primary from 2012-2021 and treated with curative intent were included. Low-risk HPV types (6, 11, etc) and local recurrences were excluded. HPV molecular typing was prospectively performed according to institutional protocol. Cox regressions were used to measure the effect of HPV genotype (16 versus non-16) on overall survival (OS) and event-free survival (EFS). Gender, smoking status, alcohol use, ECOG performance status, T stage, N stage, and subsite (oropharynx versus known primary) were covariates. A secondary survival analysis according to high-risk HPV clade (A9 versus A7) was also performed. **Results:** The total cohort included 520 patients, the majority of whom were HPV16 (86.9%, $n = 452$), A9 clade (97.1%, $n = 505$), oropharynx primary (94.8%, $n = 493$), male (86.9%, $n = 452$), white (72.5%, $n = 377$), non-Hispanic (74.2%, $n = 386$), non-active smokers (88.3%, $n = 459$), ECOG 0 (75.6%, $n = 393$), and N2 stage (65.2%, $n = 339$). The most common non-16 HPV genotypes were 18 ($n = 7$), 33 ($n = 21$), and 35 ($n = 29$). HPV genotype was not associated with OS (HR = 1.64, 95% CI 0.85-3.16, $p = 0.14$) or EFS (HR = 1.15, 95% CI 0.64-2.07, $p = 0.65$). A7 clade was associated with a worse OS compared to A9 in the univariate analysis (HR = 3.43, 95% CI 1.07-10.97, $p = 0.04$), but not in the multivariate analysis (HR = 1.67, 95% CI 0.45-6.17, $p = 0.44$). Finally, HPV clade was not associated with EFS (HR = 1.38, 95% CI 0.34-5.60, $p = 0.66$). **Conclusions:** While HPV genotype was not associated with survival differences in patients with HPVOPC, HPV A7 clade only predicted worse OS in univariate analysis. Although the total cohort size was large, this analysis was limited by small numbers of subjects with non-16 HPV genotypes and non-A9 clade, which is reflective of the predominance of HPV16 in HPVOPC. Thus, a pooled multicenter collaboration is needed to further address this question. Moreover, future studies should investigate whether outcomes may be related to intratypic HPV16 variants that affect oncoprotein function and/or immunogenicity. Detection of a subgroup of HPVOPC with possible inferior outcomes has important implications for studying treatment de-escalation in HPVOPC. Research Sponsor: Philanthropy.

Introduction of E-Score: A gene expression score to characterize immunogenic versus oncogenic HPV expression in HNSCC. *First Author: Bailey Fabiny Garb, University of Michigan, Ann Arbor, MI*

Background: Human Papillomavirus (HPV) integration in the human genome occurs in a majority of HPV(+) head and neck squamous cell carcinomas (HNSCC), with direct and indirect effects on host gene expression and tumorigenesis. Although previous studies showed that HPV integration in HNSCC is overrepresented in genes often somatically mutated in head and neck, lung, and urogenital cancers, reports are mixed for whether patients with HPV integration have worse clinical outcomes. These disparate results may be due to differences in how integration is defined. Integration can often lead to partial loss of the viral genome (e.g. HPV genes E1, E2, or E5) with retention of the oncogenes E6 and E7, which led to a low E2/E7 expression ratio being used as a biomarker for integration. Conversely, others have used the direct detection of DNA or RNA HPV-human breakpoints to identify tumors harboring integrated HPV. HPV integration and the retention or deletion of HPV genes can dramatically change the expression of HPV genes, and we hypothesize it also affects the host immune response. Hypothesis: Loss of non-oncogenic HPV genes relative to E6 and E7 levels reduces immunogenicity, leading to weakened immune cell infiltration and worse clinical outcomes. **Methods:** Bulk RNA sequencing data from HPV(+) HNSCC tumors ($n = 136$) was used to characterize the differences in retention or loss of HPV genes and calculate the E-Score as the sum of the logCPM of HPV genes E1, E2, E4, and E5 relative to E7. Cell type deconvolution was performed using ComBat to correct for batch effects, and CIBERSORTx to quantify cell type proportions within the tumor samples. Kaplan-Meier estimates of recurrence and overall survival (OS) were calculated, and Cox proportional hazards tests with covariates were used to test for association with recurrence and OS. To test the correlation between immune cell type inferred proportions and E-Score, T-Tests were performed between samples with high and low E-scores. **Results:** Low E-Score was significantly associated with recurrence ($p = 0.012$) but not with OS ($p = 0.39$) in the multivariate model accounting for age, tumor stage (AJCC8), smoking status, drinking status, BMI, marital status, and molecular tumor subtype (defined as IMU or KRT). For integration positive samples ($n = 66$), higher E-Score, suggesting lower rates of HPV gene loss, was correlated with higher percentages of dendritic cells ($p = 0.044$), macrophages ($p = 0.021$), and CD8⁺ T Cells ($p = 0.024$), but not CD4⁺ T cells ($p = 0.14$). This significance did not hold when looking at integration negative samples. **Conclusions:** These results suggest that HPV+ HNSCC patients with a loss of E1, E2, E4 and E5 tend to have less immune cell infiltration and are more likely to have recurrence. We conclude that E-Score is a potential prognostic biomarker of recurrence in HPV+ HNSCC and potential predictive biomarker for immunotherapy. Research Sponsor: U.S. National Institutes of Health.

Spatial genomics to reveal an immunosuppressive tumor microenvironment after chemoradiation in head and neck cancer patients. *First Author: Jennifer Hsing Choe, Duke University Medical Center/Duke Cancer Institute, Durham, NC*

Background: Although chemoradiotherapy (CRT) remains the cornerstone of management for locoregionally advanced head and neck squamous cell carcinomas (HNSCC), recurrence occurs in ~50% of patients. We sought to characterize the impact of CRT on the tumor microenvironment (TME) and identify factors associated with progression. Emerging spatial biology technologies, such as NanoString GeoMx Digital Spatial Profiler (DSP), enable spatially defined whole-transcriptomic profiling of cells along the tumor-stromal interface in tumor biopsies to resolve immune cell identities, activation states and signaling pathways in adjacent tumor cells. We used a multimodal approach including immunohistochemistry (IHC), bulk tumor gene expression and spatial genomics to characterize paired pre- and post-CRT tumor samples from HNSCC patients. **Methods:** 20 patients with locoregionally advanced HNSCC who had undergone curative intent CRT and developed subsequent recurrence requiring salvage surgery from June 14, 2010 to June 14, 2020 were retrospectively identified at Duke University Medical Center. Matched formalin-fixed paraffin embedded tumor specimens collected prior to CRT and at salvage surgery were compared via IHC for markers of immune infiltration and PDL1 expression, bulk tumor whole transcriptomic profiling, and spatial transcriptomic analysis of tumor and stroma using DSP were further examined in "early" progressors (< 6 months after CRT) and "late" progressors (≥ 6 months after CRT). **Results:** IHC analyses demonstrated significant reductions in T-cell immune populations (total CD3⁺, CD8⁺, 4-1BB⁺ cell density [$p < 0.001$]) after CRT. PDL1⁺ expression was similar before and after CRT. Neither T-cell infiltrate nor tumor PDL1 levels at surgery were associated with progression. Bulk tumor gene expression analysis demonstrated that macrophage and fibroblast markers were increased post-CRT. In early progressors, molecular dissection of the tumor-stromal interface using DSP expression profiling revealed macrophage associated genes (*CD68*, *MRC1/CD206*, *CD163*, *F13A1*) at salvage surgery had a more pronounced increase in macrophage markers in stroma with enriched M2 genes compared to late progressors. **Conclusions:** Integrated spatial analysis with high resolution transcriptomics and IHC suggest CRT induces an immunosuppressive environment characterized by decreased T-cell infiltration and an influx of putative immunosuppressive macrophages. We hypothesize that tumor associated macrophages and/or fibroblasts may contribute to immunosuppression due to "reprogramming" of the TME after CRT. This exploratory study suggests that patients with progressive disease after chemoradiation may benefit from additional immunoregulatory therapies that ameliorate the immunosuppressive TME. These findings will be further validated in a larger cohort of patients. Research Sponsor: Genmab US.

Clinical validity of TTMV-HPV DNA liquid biopsies for the diagnosis and surveillance of HPV-associated oropharyngeal carcinoma. *First Author: Scott A. Roof, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: While there are several HPV biomarker assays, a commercially available assay evaluating tumor tissue modified viral DNA (TTMV-HPV DNA) (NavDx, Naveris Inc, Natick, MA) has shown impressive results in clinical trials and small cohort studies. Our aim was to establish the clinical efficacy of plasma TTMV-HPV DNA testing in the diagnosis and surveillance of HPV-associated OPSCC in a contemporary, real-world clinical setting. **Methods:** In this retrospective analysis, we evaluated the accuracy of the TTMV-HPV DNA assay in detecting HPVOPSCC in the diagnostic (pre-treatment) and surveillance phases of care between April 2020 and October 2022. For the diagnostic cohort, patients with OPSCC and at least one TTMV-HPV DNA measurement prior to initiation of primary therapy were included in the analysis. For the surveillance cohort, all TTMV-HPV DNA tests performed 3 months after completion of primary therapy for pathologically confirmed HPV-associated OPSCC were evaluated, regardless of pre-treatment TTMV-HPV DNA testing. Patients with suspected recurrence, but without pathologic confirmation, were excluded. HPV status was defined utilizing positive p16 staining on immunohistochemistry (93.2% diagnosis; 97.9% surveillance) or HPV polymerase chain reaction/in situ hybridization (79.6% diagnosis; 89.7% surveillance). **Results:** In the diagnostic cohort, 163 patients were included. The cohort included mostly men (87%) with median age 63, of which 93.3% had HPVOPSCC versus 6.7% had HPV negative OPSCC. The sensitivity in pre-treatment diagnosis was 91.5%; its specificity was 100%. In the surveillance cohort, 591 tests conducted in 290 patients were evaluated. 23 patients had pathologically confirmed recurrences. The assay demonstrated 79.2% sensitivity and 100% specificity in detecting the recurrences. Positive predictive value was 100% and negative predictive value was 98.2%. The median lead time from positive test to pathologic confirmation was 28 days, 6/18 (30%) had lead time >50 days (maximum 507 days). **Conclusions:** The commercially available NavDx TTMV-HPV DNA assay demonstrated 100% specificity, and therefore excellent positive predictive value, in both diagnosis and surveillance. However, the sensitivity was lower, 91.5% for the diagnosis cohort and 79.2% for the surveillance cohort, signifying that a negative value may require further work-up. Further studies will be required to determine the optimal timing of testing and how results should inform treatment decisions. Research Sponsor: None.

2x2 Tables for diagnosis (A) and surveillance (B) cohorts.

Peripheral blood epigenetic immune-profiling and survival outcomes with anti-programmed death (PD)-1 based therapy in recurrent/metastatic (R/M) squamous cell carcinoma of head and neck (SCCHN). *First Author: Kartik Sehgal, Center for Head and Neck Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Most patients with R/M SCCHN do not derive durable benefit from standard-of-care anti-PD-1-based therapy. The currently utilized biomarker, PD-ligand-1 combined proportion score is limited by the availability and heterogeneity of tumor samples. There is an unmet need to develop easily accessible peripheral blood-based biomarkers for response to immunotherapy. **Methods:** We are conducting a prospective multi-center study to identify peripheral blood derived DNA-based methylation biomarkers measured in patients with R/M SCCHN on treatment with FDA-approved anti-PD-1 based therapy. DNA isolated from these samples undergo bisulfite conversion, methylation profiling using Illumina EPIC microarray, and cellular deconvolution to generate peripheral blood immune profiles (PMID 35140201), including granulocytic (g) and monocytic (m) myeloid derived suppressor cell (MDSC) scores. Associations between baseline peripheral blood immune profiles before the start of treatment with progression-free survival (PFS) and overall survival (OS) were evaluated using Kaplan Meier curves and Cox proportional hazards models adjusted for age and sex. Additionally, logistic regression models adjusted for age and sex were utilized to investigate the baseline immune profiles between subgroups of patients who received anti-PD-1 monotherapy with durable clinical benefit for at least 1 year (Group A) versus progression or death within 100 days (Group B) from start of therapy. **Results:** 61 patients with R/M SCCHN who received anti-PD-1 based therapy as of Oct 31, 2022, were eligible for this preliminary analysis. Mean (SD) age of the entire population was 66.4 (11.8) years, 82% were male. gMDSC score was the only immune parameter with a statistically significant association with PFS (HR 2.6 (1.40 – 4.87) independent of age and sex, with higher scores stratified by median value associated with shorter PFS (Median PFS: 75 days vs. 145 days). Memory CD4 T cells, total CD4 T cells, percentage of T regulatory /CD4 cells, and absolute memory B cells were significantly associated with OS in this population, independent of age and sex (Table). Among the subgroup treated with anti-PD-1 monotherapy, Group A with durable benefit (n = 7, 86% male, mean age: 64.7 years) had significantly higher proportion of CD4 naïve/total CD4 cells (p = 0.03), and significantly lower gMDSC (p = 0.015) & mMDSC (p = 0.000049) scores, compared with Group B (n = 27, 78% male, mean age: 66.4 years). **Conclusions:** Peripheral blood DNA-based epigenetic immune profiling can recognize clinically relevant methylation biomarkers of benefit from anti-PD-1 therapy before the start of treatment. Research Sponsor: U.S. National Institutes of Health.

	Hazards ratio (HR) for OS	p value
CD4 memory	0.19	0.006
CD4 total	0.19	0.006
Treg/total CD4	3.89	0.018
Absolute B memory	2.88	0.028
Neutrophils	2.54	0.086

Spatial relationships and immune subsets in the tumor immune microenvironment of head and neck cancers. *First Author: Leanne E. Henry, University of Michigan, Ann Arbor, MI*

Background: The tumor microenvironment provides important insights into cancer behavior and its response to treatment. In particular, the cellular composition and spatial arrangement of tumor immune infiltrates are associated with patient prognosis and survival. We optimized and employed a novel method using readily available hematoxylin and eosin (H&E) slide images, termed the G-cross score, which reflects immune cell infiltration levels and their proximity to tumor cells. The G-cross score is calculated by estimating the probability distribution of immune cells, of any type, within a certain distance from a tumor cell, with higher scores indicating greater immune cell infiltration. However, because G-cross scores are calculated from H&E slides, the method is unable to distinguish among immune cell types. Using head and neck squamous cell carcinoma (HNSCC) patients having both G-cross scores and bulk RNA-seq data, we determined which subset of tumor-infiltrating immune cell types best correlate with G-cross scores, and its predictive and prognostic value. **Methods:** G-cross scores were calculated for 425 HNSCC samples from University of Michigan, of which 64 had paired bulk RNA-seq data. We applied the cell-type deconvolution tool, CIBERSORTx, to identify immune cell type proportions based on RNA-seq data. G-cross scores were correlated against cell-type deconvolution results, immune cell activation expression signatures, and validated gene expression-based radiosensitivity index scores. Pearson's correlation coefficient and p-value using HPV status as a covariate in a linear model was calculated for each comparison. For survival and recurrence analysis, Cox proportional hazards multivariate regression was performed using the entire 425 sample cohort. **Results:** G-cross scores were significantly correlated with total T cells (R = 0.52, p = 4.63×10⁻⁵), B cells (R = 0.33, p = 2.08×10⁻²), and dendritic cells (R = 0.46, p = 7.71×10⁻⁴), but not macrophages or mast cells. G-cross scores also had a positive correlation with T cell activation (R = 0.46, p = 2.17×10⁻⁴) and B cell activation (R = 0.53, p = 1.24×10⁻⁴) and were correlated with radiation sensitivity (R = -0.44, p = 6.67×10⁻⁴). Survival analysis showed higher G-cross scores were associated with a longer time to recurrence and improved overall survival (p = 3.0×10⁻⁴). **Conclusions:** G-cross scores are mainly driven by T cell and dendritic cell levels among tumor-infiltrating lymphocytes and are correlated with B and T cell activation. Importantly, G-cross scores also correlate with gene expression profiles associated with response to radiotherapy as well as time to recurrence and overall survival. G-cross scores may be an important biomarker of radiation response and indicative of protective immune subsets for HNSCC patients. Research Sponsor: U.S. National Institutes of Health.

The impact of genetic predisposition to depression on quality of life in patients with head and neck cancer immediately post-treatment: A longitudinal study. *First Author: Melissa Henry, 3755 Cote Sainte-Catherine, Montreal, QC, Canada*

Background: The primary aim of this study was to investigate the contribution of genetic predisposition to depression, through polygenic risk scores (PRS), on quality of life levels in patients with head and neck cancer (HNC) immediately post-treatment period (i.e., 3 months post-diagnosis). **Methods:** Prospective longitudinal study of 223 consecutive adult patients with HNC (72% participation) newly diagnosed with a first occurrence of primary HNC, including saliva samples analyzed using the Illumina PsychChip, psychometric measures, Structured Clinical Interview, and medical chart reviews. **Results:** Level of quality of life at 3 months on the FACT-G+H&N was predicted by (r² = 0.51, r² adj. = 0.33, p = 0.001) the polygenic risk score for depression (standardized b = -0.28, p = 0.01) and a previous history of suicidal ideation (standardized b = -0.25, p = 0.04). Other variables were non-significant in the analyses: sociodemographic (i.e., age, sex, education, living alone), psychosocial (i.e., SCID current and past diagnoses (trend), past history of abuse), and medical variables (i.e., cancer stage and site, HPV status, functional status/ECOG, treatment). **Conclusions:** Our results outline the importance of attending to genetic predisposition and past history of suicidal ideation as markers for quality of life compromise immediately post-treatment in patients with head and neck cancers. Strategies are needed to address psychosocial vulnerability early-on as part of pre-habilitation in the treatment of patients with head and neck cancer. Radiotherapy alone versus concurrent or adjuvant chemoradiotherapy for nasopharyngeal carcinoma patients with negative Epstein-Barr virus DNA post-induction chemotherapy. *First Author: Fang-Fang Kong, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, Shanghai, China*

Background: Induction chemotherapy (IC) plus concurrent chemoradiotherapy has been recommended as the standard treatment for locoregionally advanced nasopharyngeal carcinoma (LA-NPC). However, concurrent chemotherapy was associated with increased toxicities, poor tolerance, and low completion rates. The aim of this study was to compare the efficacy and toxicity of IC+ radiotherapy (RT) and IC+ concurrent or adjuvant chemoradiotherapy (IC+CCRT/AC) in patients with negative post-IC EBV DNA. **Methods:** A total of 547 NPC patients with negative plasma EBV DNA post-IC were included. Patients were classified into the IC+RT group and the IC+ concurrent or adjuvant chemoradiotherapy (IC+CCRT/AC) group. Locoregional relapse-free survival (LRFS), distant metastasis-free survival (DMFS), overall survival (OS), and progression-free survival (PFS) were estimated and compared using the Kaplan-Meier method. Propensity-score matching (PSM) was performed to balance the variables. **Results:** The median follow-up time was 37 months. The 3-year LRFS, DMFS, OS, and PFS rates for the whole group were 92.2%, 92.4%, 96.4%, and 84.4%, respectively. There was no significant difference in LRFS, DMFS, OS, and PFS between the IC+RT and the IC+CCRT/AC group both before PSM (3-year rates of 91.1% vs. 92.6%, $p = 0.94$; 95.6% vs. 91.5%, $p = 0.08$; 95.2% vs. 96.8%, $p = 0.80$; 85.9% vs. 84.0%, $p = 0.38$) and after PSM (90.7% vs. 92.7%, $p = 0.77$; 96.8% vs. 93.7%, $p = 0.29$; 94.5% vs. 93.9%, $p = 0.57$; 84.7% vs. 85.6%, $p = 0.96$). Multivariate analysis demonstrated that treatment schedule was not an independent predictor for survival rates. Patients in the IC+RT group had fewer treatment-related acute toxicities and better tolerance. **Conclusions:** IC+RT displayed similar survival outcomes as IC+CCRT/AC for NPC patients with negative post-IC EBV DNA. Our current data seems not to support the routine use of concurrent or adjuvant chemotherapy after IC for unselected patients. Research Sponsor: None.

One-year reductions in cisplatin-related chronic kidney disease (CKD) in patients with head and neck (HNC) cancer treated with avasopasem manganese: A prespecified analysis from the phase 3 ROMAN trial. *First Author: Bryan G. Allen, The University of Iowa Hospitals & Clinics, Iowa City, IA*

Background: Cisplatin-induced acute kidney injury (AKI), acute kidney disease (AKD), and chronic kidney disease (CKD) are associated with increased production of reactive oxygen species, notably superoxide, in conjunction with alterations in mitochondrial electron transport chain complex activities in tubular epithelial cells (Mapuskar et al. *Antioxidants* 2021;10:1329). These pathologies can be targeted and thereby inhibited by increasing superoxide dismutase activity, which converts superoxide to hydrogen peroxide. The investigational new drug avasopasem manganese (AVA), a selective dismutase mimetic, ameliorated cisplatin-induced kidney injury in mice (Mapuskar et al. *Redox Biol* 2019;20:98). Preclinical results also demonstrate that AVA does not interfere with cisplatin anticancer activity (Mohanty et al. *Cancer Res* 2018;78[13 suppl]:Abstract 2929). Consistent with this, a retrospective analysis of 1- and 2-year kidney function of a limited subset of patients treated in a randomized, placebo (PBO)-controlled phase 2b trial of AVA to reduce severe oral mucositis (SOM) from radiotherapy and cisplatin (CRT) suggested that AVA prevented or reduced cisplatin-related CKD compared to PBO (Steinbach et al. *J Clin Oncol* 2020;38[15 suppl]:Abstract 12071). **Methods:** The ROMAN phase 3 trial (NCT03689712; ITT $n = 407$) of CRT in combination with AVA or PBO demonstrated improved incidence, duration, and onset of SOM by AVA ($n = 241$) vs PBO ($n = 166$) (Anderson et al. *J Clin Oncol* 2022;40[16 suppl]:Abstract 6005). In ROMAN, prospectively defined follow-up of serum creatinine (sCr) and estimated glomerular filtration rates (eGFR) were assessed every 3 months for 1 year following 7 weeks of CRT. **Results:** At 1-year follow-up, AVA was associated with significant improvements in preservation of eGFR ($P = 0.0008$) and sCr ($P = 0.006$) levels vs PBO. Grade 3+ CKD (eGFR < 60 mL/min) results through 12 months show 10% AVA vs 20% PBO (relative risk 0.55, $P = 0.0043$). Regarding cisplatin schedule, patients receiving Q3W therapy show grade 3+ CKD of 12% AVA vs 22% PBO; patients receiving QW therapy show AVA 9% vs PBO 19%. During treatment, nominal reduction of the incidence of AKI adverse events (0.8% AVA vs 3.6% PBO) was also observed. **Conclusions:** At 1-year follow-up, AVA appears to reduce cisplatin-related CKD in the study population and may also reduce cisplatin-related AKI during treatment. These results carry significance beyond CRT for HNC, potentially impacting platinum-containing regimens in other cancers. Clinical trial information: NCT03689712. Multimodal detection in plasma of molecular residual disease (MRD) in locally advanced head and neck squamous cell carcinoma (LA-HNSCC). *First Author: Enrique Sanz Garcia, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Despite intensive therapy, 30% of patients (pts) with LA-HNSCC relapse. Published data shows that MRD detection during follow up (FU) may predict relapse, e.g. human papillomavirus (HPV) DNA in p16+ pts post radiation (RT) or chemoradiation (CRT); or circulating tumor DNA (ctDNA) post surgery. MRD detection using multiple assays after definitive RT/CRT has not been reported. **Methods:** We enrolled pts with high risk LA-HNSCC (stage III HPV+, III-IVB HPV-) treated with curative intent: surgery $\pm$ adjuvant therapy, RT or CRT. Plasma was collected pre-treatment at baseline (B), at 4-6 weeks (FU1) and 8-12 weeks (FU2) post-treatment. RaDaR, a personalized liquid biopsy assay that targets patient specific somatic variants identified in whole exome sequencing (WES) from matched tumor tissue, was used to detect ctDNA, reported as estimated Variant Allele Fraction (eVAF). Cancer Personalized Profiling by deep sequencing (CAPP-seq) was used as a tumor naïve assay for ctDNA, reported as mean VAF. HPV sequencing (HPV-seq) in all and digital PCR (dPCR) in p16+ pts were used to detect HPV DNA. Relapse free survival (RFS) was estimated using Kaplan Meier and associations of ctDNA or HPV DNA with RFS using log-rank test. Assays were compared with Spearman correlation. **Results:** A total of 89 plasma samples from 35 pts were collected prospectively; 32 pts with at least a FU sample were evaluable; 26 had both. Median age was 63 years (34-71). Most pts were stage III HPV+ ($N = 16$, 50%) and received CRT ($N = 25$, 78%). No pts had clinical or radiological residual disease at FU2. Median FU was 18.3 months (5.1-25.9), there were 7 clinical relapses. RaDaR was applied in 17 pts with WES in matched tissue, including 6 with relapse. ctDNA at B was detected in 15/17 (88%). eVAF at B was not associated with RFS ($p = 0.98$). Two pts relapsed < 1 year after RT/CRT and had eVAF $> 0.001\%$ in FU2 sample; lead time to relapse was 100 and 245 days. FU1 sample of a pt who relapsed > 1 year post-CRT was close to the threshold for ctDNA+ with eVAF 0.0001%; lead time was 494 days. Three pts who received CRT relapsed > 500 days from FU2 sample (ctDNA-). CAPP-seq was applied to 29 pts; mean VAF correlated with eVAF at B ($r = 0.75$) but not at FU. ctDNA+ at FU using CAPP-seq was not associated with RFS ($p = 0.25$). HPV-seq was applied to 32 pts; specificity and sensitivity was 100% at B. Among p16+ pts with FU sample ($N = 15$), HPV DNA was detected in 4/4 with relapse and not in those without, predicting shorter RFS ($p < 0.01$). dPCR detected HPV DNA in 2/4 pts with relapse. HPV-seq and dPCR correlation was high at B ($r = 0.99$), lower at FU2 ($r = 0.66$). **Conclusions:** HPV DNA and ctDNA can be detected in LA-HNSCC before and after definitive therapy. RaDaR but not CAPP-seq may detect MRD in pts who relapse within 1 year after RT/CRT with a significant lead time. HPV-seq may be more sensitive than dPCR to detect HPV DNA in MRD. Validation in an interception study is planned (NCT04599309). Research Sponsor: Princess Margaret Cancer Centre; BMO Chair of Precision Medicine.

Induction chemotherapy with nedaplatin, docetaxel and 5-fluorouracil followed by concurrent nedaplatin and radiotherapy in locoregionally advanced nasopharyngeal carcinoma: A single arm, open label, phase II clinical trial. *First Author: Chen Fangzheng, Affiliated Cancer Hospital & Institute of Guangzhou Medical University, Guangzhou, China*

Background: To evaluate the efficacy of induction chemotherapy with nedaplatin, docetaxel and 5-fluorouracil followed by concurrent nedaplatin combined with radical radiotherapy in locoregionally advanced nasopharyngeal carcinoma (LA-NPC). **Methods:** This is a prospective, single-arm, open-label, phase II trial. Patients with aged 18-65 years, newly diagnosed stage III-IVa (except T3-4N0) nasopharyngeal carcinoma were enrolled. Eligible patients received induction chemotherapy with docetaxel (60 mg/m² intravenously on days (D) 1, 22 and 43), Nedaplatin (60 mg/m² intravenously on D 1, 22 and 43) and fluorouracil (600 mg/m² per day as a continuous 120 hours (h) infusion on D 1-5, 22-26 and 43-47) every three weeks for three cycles, thereafter received intensity-modulated radiotherapy (IMRT) concurrently with nedaplatin (100mg/m² intravenously on D 1, 22 and (or) 43) every three weeks for two or three cycles. The primary end point was objective response rate (ORR). The secondary end points included overall survival (OS), progression-free survival (PFS), distant metastasis-free survival (DMFS) and local recurrence-free survival (LRFS). **Results:** Between March 2020 and June 2021, a total of 32 patients with LA-NPC were enrolled. With a median follow-up duration of 14.0 months (IQR 11.7-16.3), 32 patients (100%) achieved ORR at three months after treatment. The 12-month PFS was 95.7% (95% CI 87.3% to 100%) and the 12-month OS was 100%. The most common grade 3 or 4 adverse events during induction chemotherapy were neutropenia (3 [9.4%]), diarrhea (3 [9.4%]) and hepatotoxicity (3 [9.4%]), followed by leucopenia (2 [6.3%]) and fatigue (1 [3.1%]). The most common grade 3 or 4 adverse events during concurrent chemotherapy were mucositis (3 [9.4%]), leucopenia (1 [3.1%]), neutropenia (1 [3.1%]) and thrombocytopenia (1 [3.1%]). All of these adverse events were manageable. **Conclusions:** Induction chemotherapy with nedaplatin, docetaxel and 5-fluorouracil followed by concurrent nedaplatin combined with radical radiotherapy showed promising antitumor activity and manageable toxicities in patients with LA-NPC. Further phase III randomized controlled trials are warranted to validate our findings. Clinical trial information: NCT04834206. Research Sponsor: Affiliated Cancer Hospital & Institute of Guangzhou Medical University Clinical Research 5555 Program, Wu Jieping Medical Foundation (320.6750.2020-13-11).

Induction chemotherapy and toripalimab for larynx preservation in resectable locally advanced laryngeal/hypopharyngeal carcinoma: Preliminary results of INSIGHT study. *First Author: Xiaomin Ou, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Previous studies have demonstrated excellent pathological response of induction PD-1 inhibitor with chemotherapy for locally advanced head and neck cancer. To our knowledge, there is scarce evidence on induction chemotherapy (ICT) and PD-1 inhibitor in organ preservation for patients (pts) with laryngeal/hypopharyngeal carcinoma. Hence, the aim of this study is to evaluate the efficacy and toxicities of ICT and PD-1 inhibitor (Toripalimab) followed by radiotherapy or surgery, for pts with resectable locally advanced laryngeal/hypopharyngeal carcinoma. **Methods:** This is a single-arm phase II study. Pts with histopathologic confirmed, resectable locally advanced laryngeal/hypopharyngeal squamous cell carcinoma and ECOG PS 0-1 were eligible. Three cycles of ICT (paclitaxel 175mg/m² d1, cisplatin 25mg/m² d1-3) combined with PD-1 inhibitor (Toripalimab 240mg d0) were given. Response assessment (RECIST 1.1) was performed post-ICT. Pts with complete response (CR)/partial response (PR) of primary tumor received concurrent chemoradiation, followed by maintenance therapy of Toripalimab for eight cycles. Otherwise, pts were referred to surgery, followed by adjuvant radiation (RT)/chemoradiation (CRT), and then maintenance therapy of Toripalimab. The primary endpoint is larynx-preservation (LP) rate at 3 months post-RT. Forty-two pts were planned. Based on a two-stage Fleming design (one-sided α :10%, power: 80%), if at least 22 pts attained LP of the first 27 pts in stage I or at least 32 pts attained LP of the 42 pts at the end of stage II, the null hypothesis would be rejected. The cohort would enroll 15 more pts in stage II if 19-21 pts in stage I observed LP, and the study would be terminated if the number of pts with LP were less than 18 in stage I. **Results:** A total of 27 pts were enrolled. By the cut-off date Feb 8th, 2023, all reached at least 3 months of follow-up post-RT. Median age was 63 (53-74) years with 92.6% male. Hypopharyngeal cancer accounted for 66.7%. 74.1% were T3 to T4, and 77.7% were N2 to N3. Six cases had primary invasion of esophagus and five pts underwent pretreatment tracheostomy. ORR of ICT was 85.2%. Afterwards, 21 pts were treated with concurrent CRT, while 6 pts received surgery of primary tumor. At 3 months post-RT, 23 pts attained organ preservation and the LP rate was 85.2%. With a median follow-up of 13.5 months, 1-year OS rate, PFS rate and LP survival rate was 83.1%, 79.5% and 79.4%, respectively. During ICT, 22.2% of pts experienced grade 3-4 treatment-related AEs (TRAEs). The most common grade 3-4 TRAEs were nausea and neutrophil count decreased. **Conclusions:** The primary endpoint LP rate was met. In this cohort of extensive locally advanced laryngeal/hypopharyngeal carcinoma, ICT and Toripalimab followed by radiotherapy or surgery resulted in satisfactory short-term LP rate and encouraging survival. Clinical trial information: NCT04995120. Research Sponsor: Shanghai Junshi Biosciences Co., Ltd.

Induction therapy of toripalimab combined with docetaxel and cisplatin in locally advanced hypopharyngeal squamous cell carcinoma (HPSCC): A single-arm, phase II clinical trial. *First Author: Chunmei Bai, Peking Union Medical College Hospital, Beijing, China*

Background: PD-1 (programmed cell death protein-1) inhibitors combination with chemotherapy has a significant efficacy and approved indications in the first-line treatment of head and neck squamous cell carcinoma (HNSCC), but the efficacy of these combination therapies in locally advanced hypopharyngeal squamous cell carcinoma (HPSCC) remains unexplored. We conducted a single-arm, phase II trial to assess the efficacy and safety of toripalimab (a novel PD-1 inhibitor) combined with chemotherapy as induction treatment in locally advanced HPSCC. **Methods:** Patients with locally advanced HPSCC (cT1N+M0 or T2-4NanyM0, AJCC 8.0) were eligible. All patients received 2 cycles of intravenous docetaxel (75mg/m²), cisplatin (75mg/m²) and toripalimab (240mg) on day 1 every 21 days, followed by radical surgery or concurrent chemoradiotherapy (CCRT) with cisplatin (100mg/m², q21d). The primary endpoint was objective response rate (ORR) assessed by investigators per RECIST v1.1. Secondary endpoints were major pathologic response (MPR), 2 year disease-free survival (DFS) rate in patients received surgery, 2 year progression-free survival (PFS) rate in patients received CCRT and 2 year overall survival (OS) rate in all patients. **Results:** From July 2020 to January 2023, 34 patients (median age: 59, range: 46-72, male: 100%, stag IV: 100%) were enrolled. Patients with stage IVA an IVB disease were 19 (19/34, 55.9%) and 15 (15/34, 44.1%), respectively. 33 patients completed 2 cycles induction treatment and efficacy evaluation (1 patient dropped out). The evaluated ORR was 54.5%, including 3 pts achieving complete response and 15 achieving partial response. PD-L1 status (combined positive score, CPS) were known in 8 patients, ORR were 80% (4/5) and 66.7% (4/6) in patients with CPS $\geq$ 20 and CPS $\geq$ 1, respectively, 2 patients with CPS < 1 had stable disease. Treatment-related grade 3-4 adverse events occurred in 45.5% (15/33) of patients, leukopenia (42.4%) and neutropenia (3.1%). Immune-related AEs were acceptable, 1 patient (1/33, 3.0%) experienced grade 2 interstitial pneumonia and 2 patients (2/33, 6.1%) experienced grade 1 rash. In the following treatment, 27 patients (27/33, 81.8%) performed CCRT. 4 patients (4/33, 12.1%) underwent surgery followed by CCRT and 2 patients (2/33, 6.1%) refused further treatment. Among these 17 patients finished CCRT and radiological assessment, 9 patients (9/17, 52.9%) had complete response, 7 patients (7/17, 41.2%) had partial response and 1 patient (1/17, 5.9%) had progressive disease. Survival data not mature by cut-off date. **Conclusions:** Induction therapy of toripalimab combined with docetaxel and cisplatin was well tolerated and highly efficient for locally advanced HPSCC. Clinical trial information: NCT04296747. Research Sponsor: Shanghai Junshi Biosciences Co., Ltd.

A pilot phase II trial of neoadjuvant camrelizumab plus nab-paclitaxel and cisplatin (NeoCPC) for locoregionally advanced, resectable squamous cell carcinoma of the head and neck. *First Author: Di Wu, Sun Yat-Sen University Cancer Centre, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, Guangdong, China, Guangzhou, Guangdong, China*

Background: For resectable squamous cell carcinoma of the head and neck (HNSCC), novel therapeutic approaches are still needed to improve outcomes. Neoadjuvant immunotherapy (NICT) is considered as a potentially effective strategy. We therefore conducted a pilot phase II trial to explore the efficacy and safety of neoadjuvant camrelizumab plus nab-paclitaxel and cisplatin (NeoCPC) in patients with locoregionally advanced, resectable HNSCC. **Methods:** In this open-label phase II trial, patients with untreated locoregionally advanced, resectable HNSCC (T2–T4, N0–N3b, M0; AJCC, 8th Edition) received NICT with camrelizumab (200 mg), nab-paclitaxel (260 mg/m²) and cisplatin (60 mg/m²) on day 1 of each 21-day cycle for three cycles, followed by radiotherapy or surgery. The primary endpoint was objective response rate (ORR) per RECIST version 1.1. Secondary endpoints included pathologic complete response (pCR), major pathologic response (MPR), safety, disease-free survival (DFS), and overall survival (OS). Genomic biomarkers (genetic mutations, tumour mutational burden [TMB] and immune microenvironment) in baseline tumor samples were explored. **Results:** Between April 2021 and January 2022, 48 patients were enrolled (median age, 59 years [range 27–73]; 42 men [87.5%]). After completion of neoadjuvant therapy, patients underwent surgery (27, 56.3%), chemoradiotherapy (15, 31.2%), radiotherapy (five, 10.4%) or continued immunotherapy as maintenance therapy (one, 2.1%). At a median follow-up time of 415 days, the ORR was 89.6% (43/45). Of the 27 patients who had surgery, 17 (63.0%) patients had an MPR, including 15 (55.6%) with a pCR. Patients with ORR were more likely to achieve pCR. One patient died of lung metastasis 6 months after completion of treatment. The 1-year OS and DFS rates were both 97.9%. Only 3 (6.3%) patients had grade 3 treatment-related adverse events (AEs): one with pneumonitis and two with neurotoxicity. No unexpected immune-related AEs were observed. For genetic analysis, the most frequently mutated genes were TP53 (77.1%), CDKN2A, FAT1, CND1 and NOTCH1. The lower radiographic tumor regression percentage was observed in TP53-altered ($p=0.01$) and TERT-altered ($p=0.002$) patients, whereas higher percentage was observed in HPV-positive patients. The median TMB was 3.15 mutations/MB. No significant difference was observed in TMB between patients with ORR and non-ORR (stable disease). There was a significant correlation between density of M1-like macrophage cells, CD8+ T cells in tumor area and radiographic tumor regression percentage ($p=0.009$, $p=0.0005$, respectively). **Conclusions:** NeoCPC showed promising efficacy with a high ORR and pathologic response rate for locoregionally advanced, resectable HNSCC, with an acceptable safety profile. Clinical trial information: NCT04826679. Research Sponsor: China Postdoctoral Science Foundation: 2022M713612.

Nab-paclitaxel plus cisplatin versus docetaxel plus cisplatin and 5-FU induction chemotherapy followed by concurrent chemoradiotherapy in locally advanced nasopharyngeal carcinoma: A multicenter parallel controlled phase III trial. *First Author: Xing Lv, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Although several large phase III clinical trials and meta-analysis have demonstrated significant clinical benefit of docetaxel combined with cisplatin and 5-FU (TPF) chemotherapy in head and neck cancer, serious adverse reactions are unsatisfactory. Therefore, this study was designed to evaluate the efficacy and safety of nab-paclitaxel plus cisplatin (TP) versus TPF induction chemotherapy (ICT) followed by concurrent chemoradiotherapy (CCRT) for locally advanced nasopharyngeal carcinoma (LA-NPC). **Methods:** In this open-label, phase 3 trial, patients were randomized 1:1 to received TP (260 mg/m² nab-paclitaxel and 80 mg/m² cisplatin on days 1 and 22) or TPF (60 mg/m² docetaxel and 60 mg/m² cisplatin on days 1 and 22; 3 g/m² 5-FU on days 1-5 and 22-26) every 3 weeks for 2 cycles, both groups of patients received CCRT (100mg/m² cisplatin and IMRT on days 43 and 64) every 21 days for 2 cycles. The primary endpoint was failure-free survival. Secondary endpoints included overall survival, objective response rate (ORR), quality of life and safety. **Results:** From January 2019 to July 2021, 281 patients were randomized to TP ($n=142$, TP arm) or TPF ($n=139$, TPF arm). The median age was 44 years (range, 20-63) in the TP arm and 45 years (range, 18-69) in the TPF arm. The pathological stages were 40.85% stage III and 59.15% stage IVA in the TP arm, while those of the TPF arm were 43.17% stage III and 56.83% stage IVA. There were 99.30% and 97.12% undifferentiated nonkeratinizing carcinoma in the two groups, respectively. All patients had Karnofsky performance status of 90. ICT was completed in 98.93% (100% in the TP arm and 97.84% in the TPF arm). The median relative dose intensity of nab-paclitaxel and cisplatin were 99.96% and 99.81% in the TP arm, 99.83%, 100% and 100% for docetaxel, cisplatin and 5-FU in the TPF arm, respectively. The ORR were 80.28% in the TP arm and 78.26% in the TPF arm after two cycles of ICT. 85.77% (83.10% in the TP arm and 88.49% in the TPF arm) completed the CCRT. After two cycles of CCRT, the ORR were 99.25% and 99.24%, respectively. 3 months after completion of all treatment, the ORR were 99.25% and 99.25%, respectively. During ICT, all treatment-related adverse events occurred in 40.14% of patients in the TP arm and 57.55% in the TPF arm. The most frequent grade 3 adverse events were neutropenia (0.70% vs 2.16%), leucopenia (0 vs 2.88%), diarrhea (0 vs 0.72%) in the TP arm and in the TPF arm. Over the entire course of treatment, the most common was 1 grade adverse events, and no patient developed grade 4 adverse events in the two groups. **Conclusions:** In this study, TP regimen showed similar trends in the ORR but excellent safety profile in patients with LA-NPC compared with TPF regimen, suggesting a potential therapeutic option for this population. Prospective study of integrating post-radiotherapy [¹⁸F] fluorodeoxyglucose-positron emission tomography/computed tomography scan and plasma Epstein-Barr virus DNA in surveillance of locoregionally advanced nasopharyngeal carcinoma. *First Author: Lin-Qun Tang, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Centre, State Key Laboratory of Oncology in South China, Collaborative Innovation Centre for Cancer Medicine, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangzhou, China*

Background: To evaluate the role of [¹⁸F] fluorodeoxyglucose-positron emission tomography/computed tomography (FDG-PET/CT) scan at 12-weeks after the end of Radiotherapy (RT) integrated with plasma EBV DNA in surveillance and standardized implementation of locoregionally advanced nasopharyngeal carcinoma (LA-NPC). **Methods:** This prospective study was conducted in patients with stage III-IVa LA-NPC. FDG-PET/CT examination and plasma Epstein-Barr virus (EBV) DNA measurements was performed pretreatment and at 12-weeks after the end RT. The primary study endpoint was the negative predictive value (NPV) and other supporting diagnostic test characteristics of 12-weeks FDG-PET/CT for the surveillance of residual locoregional disease and new distant metastasis. **Results:** From June 2018 to December 2019, 506 eligible patients were enrolled and entered follow-up (median, 45 months). At 12 weeks after the end of RT, there were 22 (4.3%) patients have residual locoregional disease, 30 (5.9%) patients developed distant metastasis and 6 (1.2%) patients presented both residual locoregional disease and distant metastasis. The NPV of 12-weeks FDG-PET/CT for overall residual diseases and distant metastasis was 96.3% (95% confidence interval [CI], 94.0%-97.8%) with sensitivity of 72.4% (95%CI, 58.9%-83.0%), specificity of 93.3% (95%CI, 90.5%-95.4%), positive predictive value (PPV) of 58.3% (95%CI, 46.1%-69.6%) and accuracy of 90.9% (95%CI, 88.4%-93.4%). In EBV DNA-based risk subgroups, the NPV of 12-weeks PDG-PET/CT was 96.8% (95%CI, 94.5%-98.2%) in patients with undetectable 12-weeks plasma EBV DNA and 87.0% (95%CI, 65.3%-96.5%) in patients with detectable 12-weeks plasma EBV DNA. **Conclusions:** 12-weeks PDG-PET/CT was reliable in the surveillance of LA-NPC and could help optimize the follow-up strategy and provide implications for timely and effective therapeutic regimen, especially for patients in different EBV DNA-based risk groups. Induction chemotherapy with nanosomal docetaxel lipid suspension (NDLS), cisplatin, and fluorouracil in patients with locally advanced head and neck squamous cell carcinoma. *First Author: Ghanashyam Biswas, Sparsh Hospital and Critical Care, Bhubaneswar, India*

Background: Nanosomal docetaxel lipid suspension (NDLS), a polysorbate-80 and ethanol free formulation, was developed to overcome the toxicity issues and to improve disease outcomes associated with conventional docetaxel. We evaluated the safety and efficacy of NDLS based TPF (NDLS, cisplatin and 5-fluorouracil [FU]) induction chemotherapy in patients with inoperable/unresectable Locally Advanced Head and Neck Squamous Cell Carcinoma (LA HNSCC). **Methods:** In this multicentric, single arm, open label, Phase IV clinical study, patients with inoperable/unresectable LA HNSCC received induction chemotherapy with NDLS (75 mg/m²; Day 1), cisplatin (75 mg/m²; Day 1) and 5-FU (750 mg/m²/day for 5 days) based TPF regimen every 3 weeks (q3w) for 4 cycles followed by radiotherapy. The study outcomes were overall response rate (ORR), disease control rate (DCR), progression-free survival (PFS) and overall survival (OS). **Results:** Fifty patients were enrolled in this study. Most of the patients belonged to the age group of 35-64 years (86%) and had a WHO performance status of 1 (66%). In the modified intent-to-treat (mITT) population (n = 40), the ORR after NDLS based TPF induction chemotherapy was 42.5%, which increased to 60.0% after loco-regional therapy. In the per-protocol (PP) population (n = 14), the ORR was 64.3%, which increased to 80.0% after loco-regional therapy (Table). At 2 years, the PFS and OS rates were 82.5% and 87.5%, respectively, in the mITT population and 85.7% and 100% respectively, in the PP population. The most common grade 3/4 adverse effects reported were neutropenia (10%), leukopenia (6%), febrile neutropenia (4%), asthenia (2%), diarrhea (2%), and thrombocytopenia (2%) respectively. Grade 3/4 infusion-related reactions, hyperglycemia or neuropathy were not reported. **Conclusions:** NDLS based induction chemotherapy was effective and well-tolerated in the treatment of inoperable LA HNSCC and showed high response rates. Clinical trial information: CTRI/2017/12/010938. Research Sponsor: Intas Pharmaceuticals Ltd.

CT radiomic signature to predict overall survival and chemotherapy benefit in stage I and II HPV-associated oropharyngeal carcinoma. *First Author: Bolin Song, Emory, Atlanta, GA*

Background: Chemoradiation is the standard of care for human papillomavirus (HPV)-associated oropharyngeal squamous cell carcinoma (OPSCC). However, not all patients would benefit from chemotherapy, especially patients with low-risk characteristics. We aim to develop and validate a prognostic and predictive radiomic image signature (pRis) to inform survival and chemotherapy benefit in stage I and stage II HPV-associated OPSCC. **Methods:** Radiographic scans for 491 patients with stage I and stage II HPV-associated OPSCC were acquired from 4 independent sources and divided into three cohorts D₁-D₃. D₁ comprised computed tomography (CT) scans from 60 radiotherapy treated patients and was used to identify prognostic features via a LASSO Cox model to predict overall and disease-free survival. The prognostic performance of pRis was evaluated on two test sets (D₂, n = 162; D₃, n = 269) using concordance index (C-index). An integrated nomogram was developed to demonstrate the incremental value of the pRis to the existing clinical factors for individualized survival estimation. Patients from D₂ and D₃ who received either radiotherapy alone or chemoradiation were used to validate pRis as predictive of added benefit of chemotherapy. **Results:** Seven radiomic features were selected to construct the image biomarker pRis, which was found to be prognostic of overall survival (OS) on univariate analysis in D₂ (hazard ratio [HR] = 2.14, 95% confidence interval [CI], 1.1-4.16, p = 0.02) and D₃ (HR = 2.74, 95% CI, 1.34-5.62, p = 0.006). Chemotherapy was associated with improved OS for high-pRis patients in both D₂ (radiation vs chemoradiation, HR = 4.47, 95% CI, 1.73-11.6, p = 0.002) and D₃ (radiation vs chemoradiation, HR = 2.99, 95% CI, 1.04-8.63, p = 0.04). In contrast, chemotherapy did not improve OS for low-pRis patients, which indicates these patients did not derive additional benefit from chemotherapy and could be considered for treatment de-escalation. **Conclusions:** The proposed radiomic signature was prognostic of patient survival and the binary pRis group informed chemotherapy benefit for stage I and II HPV-associated OPSCC patients. Research Sponsor: U.S. National Institutes of Health.

Hazard ratios and p values for patients receiving radiation alone vs chemoradiation according to pRis groups.		
	Hazard ratio (Confidence interval)	P value
D2, High-pRis	4.47 (1.73 – 11.6)	0.002
D2, Low-pRis	2.56 (0.745 – 8.77)	0.136
D3, High-pRis	2.99 (1.04 – 8.63)	0.04
D3, Low-pRis	0.28 (0.05 – 1.49)	0.135

Neoadjuvant pembrolizumab, GX-188E, and GX-17 in patients with human papillomavirus-16- and/or 18-positive head and neck squamous cell carcinoma: Single-arm, phase 2 trial with single cell transcriptomic analysis and artificial intelligence-powered spatial analysis. *First Author: Hye Ryun Kim, Department of Internal Medicine, Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: With the increasing prevalence of head and neck squamous cell carcinoma (HNSCC) associated with human papilloma virus (HPV) infection, effective treatment strategies for HPV-positive HNSCC are urgently needed. Here, we present the results of neoadjuvant checkpoint blockade of pembrolizumab, therapeutic HPV DNA vaccine of GX-188E, and long-acting interleukin-7 of GX-17 for patients with resectable HPV-16 and/or 18-positive HNSCC. **Methods:** In this single-arm, phase 2 trial, patients with resectable HPV-16 and/or 18-positive HNSCC were enrolled. Patients were given pembrolizumab 200mg on day 1 and day 22; GX-188E 2mg on day 1, 8, and 22; and GX-17 1200 ug/kg on day 8 before surgical resection. Major pathologic response (MPR; defined as residual viable tumor of less than or equal to 10%) was primary endpoint with null and alternative hypothesis of MPR rate ≤5% and ≥35%, respectively. Secondary objectives were safety, recurrence, and survival. **Results:** Of the 11 patients included, all underwent surgical resection after neoadjuvant treatment without delays in surgery or increased surgical complications. MPR was achieved in seven patients (63.6%) and pathologic complete response was achieved in four patients (36.3%), which met the primary endpoint. Single cell RNA sequencing of baseline and post-treatment paired specimens revealed that the proportion of follicular helper T cell cluster, featured with *CXCR5* and *BCL6* expression, was significantly increased among tumor-infiltrating immune cells, accompanied with the reinvigoration of CD8 T cell cluster toward less exhausted phenotypes, represented with the upregulation of *TCF7* and *CD28* expression. In addition, artificial intelligence-powered spatial analysis revealed that triple combination significantly increased the density of tumor-infiltrating lymphocytes, completely converting immunodesert and immune-excluded type of tumor to inflamed immune phenotype. **Conclusions:** Neoadjuvant pembrolizumab, GX-188E, and GX-17 showed promising activity and manageable safety profile in patients with resectable HPV-16 and/or 18-positive HNSCC. Therapeutic induction of brisk immune responses significantly reshaped the tumor microenvironment and associated with pathologic regression, warranting further investigation of pembrolizumab, GX-188E, and GX-17 for patients with HPV-positive HNSCC. Clinical trial information: NCT05286060. Research Sponsor: None.

Development of CT-based radiomic model to predict 5-year progression-free survival (PFS) in locally advanced head and neck squamous cell carcinoma (LAHNSCC) treated with definitive chemoradiation. *First Author: Gema Bruixola, Department of Medical Oncology- INCLIVA Biomedical Research Institute - Hospital Clinico Universitario- University of Valencia, Valencia, Spain*

Background: Definitive chemoradiation is the current standard treatment in LAHNSCC. Prognostic biomarkers that enable to reliably predict LAHNSCC disease progression are needed to stratify the risk of progression to tailor treatment intensity in future clinical trials. Imaging biomarkers have emerged as promising alternatives to non-invasively predict patient outcomes. Aim: to identify an imaging signature to predict progression-free survival (PFS) in LAHNSCC. **Methods:** A single-center, retrospective, observational study was designed. Clinical data and pre-treatment CT images from LAHNSCC patients treated with definitive chemoradiation from 2014 to 2022 were collected. Manual tumor segmentation was performed slice by slice by a qualified image technician and supervised by a radiologist with 20+ years in HNSCC using the DICOM viewer of Quibim platform. A total of 108 radiomic features (shape and textures) were extracted from each region of interest. Feature reduction techniques were applied to select the characteristics used in the classification model. The primary endpoint of this study was 5-year PFS. Random Forest, Support Vector Classifier (SVC), Logistic Regression, Gradient Boosting (GB) and Extreme Gradient Boosting classification models were used. A 5-fold cross validation strategy was followed to evaluate the performance of the models in terms of AUROC, sensitivity, specificity, and accuracy. The importance of each feature in the model was measured by applying the Shapley Additive exPlanations (SHAP) method. **Results:** Baseline CT exams from 102 LAHNSCC patients were included; 50% and 23% were stage IVA and IVB, respectively. The remaining 27% (stage II [3%] and stage III [24%]) were treated in an organ-preservation intention. 67% of patients presented locoregional or distant progression at 5 years. All radiomic features (108) and 6 clinical variables were used in the predictive model, for which a cross-validation was performed. GB as the feature selection technique and SVC as the classification model provided the best results. The final model was able to predict 5-year PFS with an average AUC of 0.82 (95% CI: [0.73, 0.91]), a sensitivity of 0.69 (95% CI: [0.57, 0.81]), a specificity of 0.82 (95% CI: [0.7, 0.94]) and an accuracy of 0.73 (95% CI: [0.62, 0.84]). From most to least important, features contributing to the predictive model were: TNM stage (SHAP: 0.038), glszm Small Area Emphasis (SHAP: 0.026), glcm Idmn (SHAP: 0.023), glszm Large Area High Gray Level Emphasis (SHAP: 0.018) and glrlm Run Entropy (SHAP: 0.015). **Conclusions:** Radiomic biomarkers from pre-treatment CT images in combination with TNM stage were predictive of 5-year PFS to chemoradiation in LAHNSCC patients and might be helpful for patient risk stratification. Further validation of these imaging biomarkers is ongoing. Research Sponsor: INCLIVA Biomedical Research Institute - University of Valencia.

Neoadjuvant low-dose radiotherapy, tislelizumab, combined with albumin-bound paclitaxel and cisplatin in resectable locally advanced head and neck squamous cell carcinoma (NeoRTPC02): The first-stage result from an open label, single-arm, two stage, phase II clinical trial. *First Author: Zhigang Liu, The Cancer Center of Affiliated Dongguan Hospital of Southern Medical University, Dongguan, Guangdong, China*

Background: Neoadjuvant immunotherapy and chemotherapy has been explored in phase I/II clinical studies in head and neck squamous cell carcinoma (HNSCC), confirming its safety and efficacy. However, the pathological complete response (pCR) / major pathological response (MPR) rate still needed for improvement. Recent studies revealed that low dose radiotherapy can overcome immunosuppressive tumors by reversing immune desertification when combining immunotherapy. Here, we conducted this clinical trial to explore the efficacy and safety of neoadjuvant low-dose radiotherapy, PD-1 inhibitor, combined with chemotherapy in resectable locally advanced head and neck squamous cell carcinoma. **Methods:** This was an open-label, single-arm, phase II clinical trial. Patients with untreated, histologically confirmed HNSCC staging III-IVB were included. The eligible patients were scheduled to be administered neoadjuvant low-dose radiotherapy (1GY/1F, D1, D2, D8, D15, Q3W), PD-1 inhibitor tislelizumab (200 mg D1, Q3W), combined with albumin-bound paclitaxel (100mg/m², D1, D8, D15, Q3W) and cisplatin (25mg/m², D1, D8, D15, Q3W) for two cycles. Radically surgical resection was planned to conduct 3-4 weeks after neoadjuvant therapy. The primary endpoint was pCR rate. The second endpoints consisted of MPR rate, objective response rate (ORR), RO resection rate, safety, non-surgery-delay rate and quality of life. 25 patients will finally be enrolled in this study. Simon's two-stage design was adopted, and 10 patients should be included in the first stage. If 2 or more of the first 10 patients reached pCR, the second stage would be successfully entered. **Results:** By Jan 10, 2023, 10 patients were enrolled. 7 out of 10 patients successfully received the study regimen and finished the operation on schedule. Our primary endpoint of first stage was met. 4/7 (57%) patients achieved pCR at the primary site, 3/7 (43%) patients achieved MPR. The pCR/MPR rate was 100%. RO resection rate was 100%. Totally 9 patients underwent MRI scan pre and post neoadjuvant therapy, and the assessment per RECIST criteria were as follow: 0/9 (0%) CR, 6/9 (66%) PR, 3/9 (33%) SD. The treatment-related adverse events (TRAES) were manageable. The most shared adverse events of grade 1/2 were anorexia (89%), anemia (89%) and nausea (66%). No surgical delay was observed. **Conclusions:** Neoadjuvant low-dose radiotherapy, tislelizumab, combined with albumin-bound paclitaxel and cisplatin contributed to an outstanding pCR/MPR rate of 100% (pCR rate of 57% and MPR rate of 43%) at present, and was generally tolerated in locally advanced HNSCC. The second stage is ongoing. Clinical trial information: NCT05343325. Research Sponsor: BeiGene Co., Ltd. and CSPC Co., Ltd.

Neoadjuvant chemoimmunotherapy for the treatment of locally advanced laryngeal and hypopharyngeal squamous cell carcinoma: A single-arm phase 2 clinical trial. *First Author: Yanfeng Chen, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China*

Background: Standard treatment for patients with locally advanced laryngeal and hypopharyngeal squamous cell carcinoma (LHSCC) is total laryngectomy, which seriously affects the quality of life. Neoadjuvant treatment with Nab-paclitaxel plus cisplatin (TP) has favorable efficacy with acceptable toxicity for laryngeal preservation in LHSCC. Programmed death 1 (PD-1) blockade plus chemotherapy has shown a survival benefit and recommended as the first-line treatment in recurrent or metastatic head and neck cancer, but the safety and activity in the combination of TP and PD-1 blockade in locally advanced LHSCC need investigation. **Methods:** In this single-center, single-arm, phase 2 trial, newly diagnosed pts with stage T3-4N0-3M0 laryngeal SCC or T2-4N0-3M0 hypopharyngeal SCC were recruited. Eligible patients received chemotherapy [Nab-paclitaxel 240 mg/m² plus cisplatin 75 mg/m² and toripalimab[240 mg, d1]every 3 weeks for 3 cycles. After induction treatment, patients achieving clinical partial response (cPR) or complete response (cCR) received definitive radiotherapy, while those with stable diseases (SD) and progression disease (PD) received surgery plus adjuvant radiotherapy. Toripalimab was given intravenously once every 3 weeks for up to 10 cycles, including 3 cycles before. The primary endpoint was the objective response rate (ORR) according to RECIST 1.1 by investigator assessment to neoadjuvant chemoimmunotherapy. The secondary endpoints included laryngectomy-free survival (LFS), disease failure-free survival (DFS) and overall survival OS at 2 years, quality of life (QOL) and toxic effects. **Results:** From October 2020 to May 2022, 25 patients received neoadjuvant chemoimmunotherapy (median age 58 years; 23.9% men), 52% (13/25) and 48% (12/25) were hypopharyngeal and laryngeal squamous cell carcinoma. 80% (20/25) were clinical T3/4 and 64.0% (16/25) ≥N2. After neoadjuvant chemoimmunotherapy, 2 patients achieved CR, 21 achieved PR, with an ORR of 92% (23/25), 23 patients with CR/PR of the primary tumor received concurrent radiotherapy and immune maintenance therapy, 2 patients with SD/PD received laryngectomy. At a median follow-up of 17 months (range 8-27 months), 1-year DFS was 88.0%, 1-year OS was 96.0%, 1-year LPS was 92.0%. Respectively, only grade 1-2 adverse events occurred in 100% of patients, including loss of appetite (100%), anemia (92.0%), nausea (84.0%), vomiting (52.0%), hypothyroidism (16.0%), peripheral neuritis (20%), leukopenia (12.0%), rash (12.0%). **Conclusions:** Neoadjuvant treatment with TP plus toripalimab achieved impressive ORR and 1-year LPS rate with manageable toxicities in patients with LHSCC. Further follow-up is needed to confirm the long-term efficacy. Clinical trial information: ChiCTR2000033506. Research Sponsor: None.

Impact of acute kidney injury on overall survival in postoperative patients with head and neck cancer who received chemoradiotherapy with cisplatin: A supplementary analysis of a phase II/III trial of JCOG1008. *First Author: Yoshinori Imamura, Kobe University Hospital, Kobe, Hyogo, Japan*

Background: A randomized phase II/III trial of JCOG1008 demonstrated that chemo-radiotherapy (CRT) with weekly cisplatin at 40 mg/m² (Weekly arm) was noninferior to 3-weekly cisplatin at 100 mg/m² (3-weekly arm) in terms of overall survival (OS) for postoperative high-risk head and neck cancer (hazard ratio [HR], 0.69 [99.1% CI, 0.37 to 1.27 < 1.32]; *J Clin Oncol* 2022; 40: 1980-90). Acute kidney injury (AKI) is a major dose-limiting toxicity of cisplatin. Here, we investigated the impact of AKI on OS in patients treated with CRT in JCOG1008. **Methods:** A total of 251 patients who were treated with CRT in JCOG1008 were analyzed. AKI was defined as an increase in serum creatinine of ≥0.3 mg/dL or a 1.5-fold or more increase from baseline (≥stage I) within 30 days after completion of CRT, based on the AKI Network classification/staging system. OS in the two arms was compared by the development of AKI using the log-rank test. **Results:** The total incidence of AKI in the weekly arm was lower than that in the 3-weekly arm (38 of 122 [31.1%] vs. 56 of 129 [43.4%]). The incidence of stage II/III AKI was also lower in the weekly arm (8 of 122 [6.6%] vs. 19 of 129 [14.7%]). Total cisplatin dose was similar in patients who did and did not develop AKI in the weekly arm, but was lower in patients who developed AKI in the 3-weekly arm (Table). Moreover, no difference in OS was observed between patients who did and did not develop AKI in the weekly arm (HR, 1.06 [95% CI, 0.53 to 2.10]), whereas patients who developed AKI in the 3-weekly arm had poorer OS than those who did not (HR, 1.83 [95% CI, 1.04 to 3.21]). **Conclusions:** In this supplementary analysis of JCOG1008, development of AKI impacted OS in the 3-weekly arm, but not in the weekly arm. Consistent exposure to cisplatin through weekly fractionated administration appears of greater clinical significance than cumulative dose, providing maintenance of treatment intensity and better kidney safety, and likely also improving outcomes. Clinical trial information: JRCTS031180135. Research Sponsor: National Cancer Center Research and Development Funds (29-A-3, 25-B-2, and 2020-J-3); AMED under Grant Nos. Neoadjuvant tislelizumab combined with APF for patients with locally advanced head and neck squamous cell carcinoma: A prospective single-arm clinical trial. *First Author: Jing Yan, The Comprehensive Cancer Centre of Nanjing Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China*

Background: Seeking out a more effective and less-toxic regimen is necessary for patients with locally advanced head and neck squamous cell carcinoma (HNSCC). The aim of this study is to evaluate the efficacy and safety of neoadjuvant anti-programmed cell death-1 antibody tislelizumab combined with APF (albumin-bound paclitaxel, platinum and fluorouracil) followed by surgery or concurrent chemoradiotherapy. **Methods:** In this prospective, single-center, single-arm clinical study, previously untreated patients with locally advanced HNSCC, aged 18-75 years without severe comorbidities and contraindications to immunotherapy are enrolled. Eligible patients received A (200 mg/m² d1) P (60 mg/m² d1- d2) F (600 mg/m² CIV120h) induction chemotherapy along with tislelizumab (200 mg d1) every 3 weeks. The curative effect is evaluated (RECIST 1.1) after 3 cycles and a multidisciplinary team discuss whether to perform surgery. For patients undergoing surgery, treatment is completed if there is no residual and extra-capsular lymph node invasion; in case of positive surgical margin, or extracapsular lymph node invasion, or residual lymph nodes, patient will receive concurrent chemoradiotherapy (tumor bed and neck lymph drainage area 66 Gy~70 Gy, P 60 mg/m²). Those not suitable for surgery will receive radical concurrent chemoradiotherapy (GTV 66Gy~70Gy, PTV 50Gy, P 60 mg/m²) within 3 weeks after neoadjuvant treatment. The primary endpoint of efficacy evaluation is the pathological complete response (pCR) rate. Safety evaluation indicators include vital signs, laboratory indicators and adverse events (NCI CTC AE4.0). **Results:** From Apr 2022 to Jan 2023, 12 patients are screened and enrolled. For the 7 patients who complete 3 cycles of neoadjuvant therapy, 3 patients (42.8%) successfully undergo surgery, with 2 patients (28.5%) achieving pCR and 1 patient (14.3%) achieving major pathological response (MPR). For the other 4 patients, 1 patient (14.3%) achieve pCR by multipoint biopsy of the primary lesion and 2 patients (28.5%) obtain radiologic partial response (PR) by MRI. 1 patient' lymph nodes tend to increase during radiotherapy and that patient withdraw from clinical trial and undergo salvage surgery. The objective response rate (ORR) of neoadjuvant treatment is 85.7% and pCR rate is 42.9%. Grade 2 or higher AEs during neoadjuvant therapy include grade 2 liver function damage (n = 1, 8.3%), grade 3 myelosuppression (n = 1, 8.3%). 1 (8.3%) patient developed radiation-related oral mucositis (RTOG 2). No other obvious adverse reactions of radiotherapy, chemotherapy or immunotherapy are observed. **Conclusions:** Combining Tislelizumab with APF followed by surgery or radical concurrent chemoradiotherapy is feasible and effective in patients with locally advanced HNSCC, and further studies are needed to verify its effectiveness and safety. Safety and immunogenicity of TG4050: A personalized cancer vaccine in head and neck carcinoma. *First Author: Christian H.H. Ottensmeier, The Clatterbridge Cancer Centre NHS Foundation Trust, Liverpool, United Kingdom*

Background: Despite adjuvant therapy, over 50% of surgically treated head and neck squamous cell carcinoma (HNSCC) patients (pts) experience a recurrence of disease. Systemic stimulation of cellular immunity against tumor mutations using a viral vaccine may be an ideal modality to clear residual cancer cells. For this purpose, we developed a pipeline for the design of TG4050, a personalized cancer vaccine (PCV) using a Modified Vaccinia Ankara (MVA) viral vector. We report here preliminary safety and immunogenicity data from a phase I TG4050 study. **Methods:** Surgically resected stage III or IV, HPV negative HNSCC pts were enrolled in the study. pts must have achieved clinical remission after adjuvant chemoradiotherapy. A PCV for each pt was manufactured with up to 30 neoantigens identified using a state-of-the-art machine learning algorithm, from next generation sequencing (NGS) data. Pts randomized to arm A received the PCV after completion of primary treatment. Pts randomized to arm B received the PCV in the event of relapse, in conjunction with second line therapy. The PCV schedule consisted of an induction period of 6 weekly administrations, followed by booster doses once every 3 weeks for up to one year. Immune cells were collected by leukapheresis at baseline and at day 64. Primary endpoint was safety. Secondary endpoints included feasibility, disease free survival and immune response as assessed by ex-vivo IFN γ -ELISPOT. **Results:** At the time of data cut-off, a total of 31 pts were randomized, 15 in arm A and 16 in arm B. A vaccine was successfully designed for all randomized pts. Pts had no evidence of disease at baseline either at the clinical or molecular level, as assessed by ctDNA assessment. All adverse events (AEs) were mild to moderate and most were injection site reactions. Median follow-up was 9.2 months in arm A vs 7.6 months in arm B. None of the pts in arm A experienced relapse vs. 2 in the arm B. Immune monitoring demonstrated priming of a polypeptidic T cell response against the PCV in 100% of pts in arm A, among pts evaluated to date, with a mean of 9 responses per pt (6-19). Responses were observed regardless of HLA genotype, and without cross-reactivity to the wildtype antigen. Baseline tumor analyses revealed challenging genomic and immune profiles such as low TMB (avg of 3.06 $\pm$ 0.86 Mut/Mb), a majority of immune-desert tumors, and a low expression of important immune related factors including PD-L1 (16 pts out of 17 had a negative to moderate PD-L1 expression). **Conclusions:** Our preliminary data demonstrate that TG4050 is safe, well tolerated, and capable of inducing T cell responses in cold tumors. In summary viral based, PCVs designed to induce tumor-specific neoantigen may be associated with a safe tolerance and an improved outcome in HNSCC pts. Clinical trial information: NCT04183166. Neoadjuvant durvalumab and tremelimumab in resectable locally advanced SCC of the oral cavity: DUTRELASCO study. *First Author: Michel Bila, University Hospitals Leuven - Catholic University Leuven, Leuven, Belgium*

Background: Promising rates of response to ICI have been observed in patients with OSCC. This is phase I/II study with focus on biological changes observed in sequential tissue acquisition. **Methods:** Eligibility criteria: Resectable OSCC stage IV Description of each treatment arm: Arm A: durvalumab (1500 mg) on day -14 and 6 cycles adjuvant Arm B: durvalumab (1500 mg) and tremelimumab (75 mg) combination on day -14 and 6 cycles adjuvant Primary endpoint: Biological response in tumor tissue by means of difference in CD8+ lymphocyte infiltration density (TIL) and % remaining viable tumor cells. Secondary endpoints: Recist v1.1 OS PBMC and plasma analysis scRNA-seq Statement of study design: open-label, prospective stratified, phase I/II study. **Results:** No ICI related toxicity interfered with surgery. 50 % of patients presented with at least 1 severe AE. There was no difference between both arms. 2 year OS is 64% in arm A and 80% in arm B. Both arms show a significant increase (p = 0.01) in TILs. We observed a significant decrease in viable tumor cells (p < 0.01). No objective pathological response with > 50% decrease of viable tumor cells was observed. T-cell expansion varied although a positive correlation between T-cell expansion and radiologic tumor shrinkage was demonstrated (p < 0.001). T-cell expansion was tumor-specific (p = 0.749). Differential gene expression analysis comparing expanding T-cells in tumors observed increased expression of effector/activation markers and immune cell homing in expanding T-cells, but reduced expression of naïve and immune regulatory markers. By also profiling tumor-draining lymph nodes, we observe that the addition of aCTLA4 affects the lymph nodes and primes CD4+ naïve T-cells, triggering their expansion. Systemically PD-1 expression in both CD4+ and CD8+ T cells is increased together with an upregulation of activation markers after ICI. 2 baseline plasma factors with predictive capacity for clonotype response were identified: baseline LAG-3 and B7.2(CD86). **Conclusions:** A 14-day window may be considered ethically sound, it might not provide sufficient time for evaluating pathological response. It is both safe and feasible to use neoadjuvant ICI treatment in OSCC. While the initial toxicity is low and does not interfere with standard of care surgical procedures, adjuvant treatment may result in higher toxicity. Response to ICI is not dichotomous but rather a continuous variable which we represent here as clonotype expansion. A positive correlation was demonstrated between T-cell expansion and radiologic tumor shrinkage after one cycle of ICB. T-cell expansion was tumor-specific and gene expression analysis observed increased expression of activation markers here further supporting this as a surrogate marker. Combination therapy facilitates expansion of both CD4+ and CD8+ T-cells versus just CD8+ T-cells with aPD-L1 alone. Clinical trial information: NCT03784066. Combined pulsed radiotherapy (QUAD shot regimen) with immune checkpoint inhibition (ICI) to enhance immune response for LAHNSCC in patients considered ineligible for curative intent therapy. *First Author: Jennifer F. De Los Santos, Grandview Cancer Center, Birmingham, AL*

Background: Elderly patients with head and neck cancer (HNC) represent a growing population that would benefit from novel, less toxic approaches. Recent negative trial results adding ICI to chemo-RT for LAHNSCC (Javelin, Keynote 412) suggest that total nodal irradiation may create an immunosuppressive tumor microenvironment (TME), blunting the efficacy of ICI. This study was undertaken to use pulsed QUAD SHOT as an in-situ vaccine by stimulating the TME prior to delivery of ICI, excluding elective nodal sites, to enhance the immune response. **Methods:** 33 pts (20 males/13 females), with a median age of 81, seen at two community hospitals, ineligible for curative therapy, were treated with pulsed dose QUAD shot regimen to gross disease (44.4-59.2 Gy) spaced 3 weeks apart with addition of an approved ICI (Pembrolizumab or Cemiplimab). ERT was directed ONLY to GTV p+/n. ICI was administered in most pts after the 1st QUAD shot to enhance immune response. ICI was continued adjutantly until a > Grade 3 adverse event (AE) or progression of disease (POD). Pts with either advanced cutaneous or mucosal SCC were included (cSCC, mSCC). 39% presented with N1-2 adenopathy, and 24% presented with recurrent disease. PD-L1 status were not routinely obtained. **Results:** The median number of ICI cycles delivered was 5 (range 2-24). All pts completed at least 3 QUAD shots. Overall LRC for all 33 pts was 69.7%, with a mean follow-up of 11 months (1-39). LRC for 33 pts at 1 and 2 years after the end of radiation were 61.07% and 55.52%, respectively. The percentage of pts free from elective regional recurrences at 1 and 2 years was 87.13% for both cSCC and mSCC groups. Six pts (18%) experienced distant failure. Freedom from distant failure at 1 yr after QUAD shot completion by pathology was 100.00% for cSCC and 77.08% for mSCC. DFS for all 33 pts at 1 and 2 yrs were 59.39% and 37.12%, respectively. DFS at 1 year for cSCC was 100% and 53% for mSCC. Median DFS for the mSCC was 13.8 months. Overall survival for all 33 pts was 45.45% with a median OS time of 17.7 months. 1 and 2 year OS rates were 65% and 33%. Overall toxicity was low and manageable. Gr 3 mucositis occurred in 1 patient and 5 (15%) developed Gr 2 AE's. Gr 3/4 IMAR's were observed in 3 pts and included infusion reaction, colitis, and fatigue/FTT and were discontinued. 4 pts required post QUAD PEG's unrelated to radiation toxicity and due to POD. **Conclusions:** In elderly, frail, or comorbidly ill pts with LAHNC, the addition of ICI to involved field pulsed QUAD shot regimen tripled the median OS rate from prior publications with QUAD shot alone from 5.7 months to 17 months in our series. The low percentage of failure in the elective nodal beds was very encouraging based on our hypothesis. This approach represents the next step in an evolution away from conventional RT approaches that engender greater toxicity and warrants further study. Are we ready for biomarker driven, radiation dose-adaptable de-escalation studies for HPV+ oropharyngeal cancer? *First Author: Krzysztof Misukiewicz, Hematology and Medical Oncology, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Plasma circulating tumor modified viral human papillomavirus (HPV) DNA (TTMV) is a sensitive and specific biomarker of HPV+ oropharyngeal squamous cell carcinoma (HPVOPC). Patients with unresectable locally advanced (LA) HPVOPC are currently treated with induction chemotherapy (IC) and standard (sd) or reduced dose (rd) of chemoradiation (CRT). Post IC TTMV can be used in the future to help assign patients to sdCRT or rdCRT. This approach may help to maintain high efficacy and minimize long-term side effects of CRT in HPVOPC. **Methods:** Patients with LA HPVOPC and High Risk (HR) features (radiographic ECE, T4 primary, >N2c, and isolated lung metastases) were treated with 3 cycles of TPF IC followed by rdCRT to 5600 cGy with weekly carboplatin in responders, sdCRT in clinical non-responders and in M1 patients who also received SBRT to isolated biopsy proven lung metastases. Patients with > 20 pack year smoking history were excluded. Patients were eligible for rdCRT if they had a significant clinical response to IC and were participating in the QB2 trial (NCT02945631). **Results:** Fourteen subjects had pre and post IC TTMV testing available for analysis. 9/14 subjects after IC received rdCRT to 5600 cGy with weekly Carboplatin. 2 subjects were removed from the QB study for clinically inadequate response, 1 withdrew consent and 2 were M1 and treated for cure. All 5 underwent sdCRT 7000 cGy. 13/14 patients had TTMV testing done prior IC, 1 subject had TTMV done after the start of cycle 1 of IC; all 14 of them had a pretherapy or (1 subject) immediate post infusion positive elevated TTMV test. 11/14 subjects developed negative TTMV after 1 or 2 cycles IC. 3/14 subjects after 1 cycle and additional 6/14 subjects after 2 cycles of IC developed negative TTMV. 3/14 subjects still had abnormal TTMV after 3 cycles of IC; 2/3 subjects underwent 7000 cGy. Remaining 1/3 had a negative repeat TTMV prior to CRT and underwent rdCRT with 5600 cGy. TTMV testing was done for all subjects after completion CRT and all were negative. All subjects in addition to standard surveillance had TTMV testing done during their surveillance visits. 2 subjects developed recurrent HPVOPC after CRT: 1 locoregional and 1 metastatic (elevated TTMV after IC; sdCRT). **Conclusions:** In contrast to NCCN guidelines, rdCRT in many academic institutions has become a standard for HPVOPC. We have demonstrated a prompt reduction of TTMV to 0 in a subset of patients receiving 1 cycle and in a majority after at least 2 cycles of IC. The small sample size of our study lacks the statistical power to demonstrate that the failing to attain negative TTMV after/during IC is associated with a poor prognosis and warrants more aggressive therapy. TTMV biomarker response may have important prognostic value in delivering primary therapy and warrants further larger and more structured studies. Research Sponsor: None.

Use of machine learning derived features from CT and H&E whole-slide images to predict overall survival in head and neck squamous cell carcinoma. *First Author: Bolin Song, Emory, Atlanta, GA*

Background: Computed tomography (CT) and H&E whole-slide images (WSI) have been found to carry rich prognostic information for patients diagnosed with head and neck squamous cell carcinoma (HNSCC). However, most machine learning models aimed for outcome prediction only took advantage of single image modality. In this work, we developed and validated a prognostic machine learning method incorporating both CT and WSI to predict overall survival in HNSCC patients. **Methods:** Matched radiographic CT scans and digitized WSI were acquired from the Cleveland Clinic for 167 HNSCC patients, including 120 HPV-associated oropharyngeal cancer and 47 laryngeal cancer. Both primary tumor and the largest suspicious lymph node were annotated on CT scans and primary tumor was delineated on H&E WSI. We split the dataset into training and validation set using a 7:3 ratio, which resulted in 119 patients in the training set and 48 for hold-out validation. We applied a machine learning model (M_ML) using both CT and WSI as input to perform end-to-end predictions of overall survival. We used the harrell's concordance index (C-index) to evaluate the prognostic performance. Finally, we performed the multivariable cox proportional hazard analysis adjusting for clinicopathological variables (i.e. age, gender, smoking pack-year (PY), AJCC 7th edition overall stage, and treatment modality) to validate the independent prognostic significance of the model. **Results:** The combined machine learning model M_ML (C-index = 0.81) outperformed the model using CT images alone (C-index = 0.63) and WSI alone (C-index = 0.64) on the validation set. In multivariable analysis, M_ML is still statistically significant accounting for clinicopathologic factors (p = 0.0007). **Conclusions:** This pilot study shows that a multi-omic machine learning model utilizing both radiographic CT and digitized WSI can predict HNSCC overall survival and outperforms models using only a single modality. Research Sponsor: U.S. National Institutes of Health.

Variables	Hazard Ratio (Confidence interval)	p values
Age	1.05 (0.95 - 1.16)	0.36
Gender (Male vs Female)	8.72 (0 - 100)	0.99
Smoking PY	1 (0.97 - 1.03)	0.85
Clinical T stage (3, 4 vs 1, 2)	1.79 (0.32 - 9.98)	0.51
Clinical N stage (2, 3 vs 0, 1)	2.65 (0.32 - 21.76)	0.36
Treatment (CRT vs RT)	0.27 (0.02 - 3.17)	0.30

10-year outcomes of technically unresectable oral cancers with neoadjuvant chemotherapy: Real-world data and implications for clinical practice. *First Author: Aditya Dhanawat, Tata Memorial Centre, Mumbai, India*

Background: Neo-adjuvant chemotherapy (NACT) followed by response assessment is the standard treatment algorithm for locally advanced oral cavity squamous cell carcinomas (OCSCC) in the Indian subcontinent. The 3-drug NACT regimen (Docetaxel-Cisplatin-5-FU) has shown improvement in progression free survival (PFS) and overall survival (OS) over 2-drug regimen (Docetaxel-Cisplatin) in a phase-3 randomised study. We have analysed the 10-year outcomes with this treatment algorithm. **Methods:** This was an institutional review board approved retrospective analysis of a prospectively collected dataset of borderline resectable OCSCC patients who received NACT. Adults with an eastern co-operative oncology group (ECOG) performance status (PS) 0-2 deemed technically unresectable in a multi-disciplinary clinic were included. All patients received 2-3 cycles of 3-weekly NACT. Patients with good general condition (GC) who became resectable underwent surgery followed by appropriate adjuvant therapy. Patients who were unresectable received definitive chemoradiation (CRT), palliative chemotherapy, radiotherapy or best supportive care based on GC. The OS was calculated from date of diagnosis to date of death. Kaplan-Meier method was used for estimation of 10-year OS and impact of different regimens on OS was calculated using the log-rank method. **Results:** A total of 3266 patients were analysed, of which 2857 (87.5%) were males. The median age was 46 years (IQR: 39 - 54). The most common subsites were buccal mucosa (54.7%), tongue (30.4%) and alveolus (7.9%). Patients presented with either stage IVA (51.3%) or IVB (48.7%). The major indications for NACT were edema up to zygoma (42.2%), involvement of hyoid (22.6%), and high infra-temporal fossa (11.5%). The most common NACT was Docetaxel-Cisplatin (50.2%) followed by Docetaxel-Cisplatin-5-Fluorouracil (29.0%) and Paclitaxel-Carboplatin (13.3%). Planned number of NACT cycles could not be completed by 361 (11.1%) patients. Of 3266 patients, 929 (28.4%) underwent surgery followed by adjuvant CRT (26.7%) or adjuvant RT (1.3%); 13.1% underwent definitive CRT, 35.8% received palliative chemotherapy, while 11.7% defaulted for definitive treatment. Pathological complete response was seen in 76 (8.2%) patients, while 871 (93.8%) achieved negative margins and 338 (36.4%) had extra-nodal extension. The median OS was 9 months (95% CI: 8.6 - 9.4). NACT with more than 2-drugs had an OS of 13.2 months (95% CI: 12 - 14.4) vs 7.5 months (95% CI: 7.1 - 7.97) for 2-drug regimens. The 10-years OS was also higher for more than 2-drugs regimen - 21% (95% CI - 17.4% - 24.9%) vs 5.14% (95% CI: 3.28% - 7.6%) (p = 0.000). 10-years OS of patients who underwent surgery vs those who did not was 22.28% vs 3.98% (p = 0.000). **Conclusions:** NACT with more than 2-drug regimens had survival benefit over 2-drug regimens in technically unresectable OCSCC. Research Sponsor: None.

Tislelizumab plus chemotherapy as induction treatment followed by chemoradiotherapy or surgery in locally advanced hypopharyngeal squamous cell carcinoma: A single-arm, phase II trial. *First Author: Lin Gui, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China*

Background: Induction chemotherapy (ICT) followed by chemoradiotherapy (CRT) is the standard of care for locally advanced hypopharyngeal squamous cell carcinoma (LA HPSCC). We aimed to assess whether add immunotherapy to ICT further improving patient outcomes. **Methods:** In this phase II, single-arm study, eligible pts aged 18-70 yrs diagnosed with stage III-IVB (AJCC 8th) HPSCC received induction therapy with tislelizumab (200 mg), cisplatin (75 mg/m²) and nab-paclitaxel (260 mg/m²) Q3W for 3 cycles. After assessment by multidisciplinary team, pts received surgery or CRT. The primary endpoint was objective response rate (ORR). Secondary endpoints include major pathologic response (MPR) in surgery group, disease control rate (DCR), 2-yr PFS rate in CRT group and 2-yr DFS rate. **Results:** 29 pts were enrolled (median age, 61 y; 97% male; stage III/IVA/IVB, 7%/90%/3%) from May to Nov 2022. Median follow-up was 22.3 months, no disease progression occurred in all patients. For all pts, the post-induction ORR and DCR were 82% and 100%. In surgery group (n = 10), all pts achieved R0 resection, and 5 (50%) pts reached pathological complete response (pCR). A patient with stable disease underwent a total laryngectomy achieved pCR by postoperative pathologic evaluation. Grade 3 and 4 treatment-related adverse event (TRAE) reached 82.8%, and mainly come from chemotherapy-related neutropenia. There was no TRAE leading to treatment discontinuation. **Conclusions:** These early data suggested that tislelizumab plus chemotherapy as induction treatment followed by chemoradiotherapy or surgery was safe and had the potential to provide clinical benefits for patients in LA HPSCC. The inconsistency between radiographic and pathological evaluation needs further exploration. Further follow-up is needed to confirm the long-term efficacy. Clinical trial information: ChiCTR2200060094. Research Sponsor: None.

A multicenter, single-arm phase 2 study of surufatinib plus toripalimab for patients with locally advanced or metastatic radioactive iodine-refractory differentiated thyroid cancer. *First Author: Dongmei Ji, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: For patients (pts) with radioactive iodine-refractory differentiated thyroid cancer (RAIR-DTC), there presents a considerable therapeutic challenge with poor long-term outcomes. The open-label, multi-cohort, single-arm phase 2 study was performed to evaluate surufatinib (a small-molecule inhibitor of VEGFR 1-3, FGFR1 and CSF-1R) in combination with toripalimab (an anti-PD-1 antibody) in pts with RAIR-DTC. **Methods:** Eligible pts were with locally advanced or metastatic RAIR-DTC who were not amenable for surgery or external beam radiotherapy, with a radiologically confirmed disease progression within 12 months before treatment, and with ≥ 6 months since last radioiodine treatment. Enrolled pts received surufatinib 250 mg orally, QD, plus toripalimab 240 mg IV, Q3W, until disease progression or reaching the maximum treatment duration with toripalimab of 24 months, or other protocol-specified criteria. The primary endpoint was objective response rate (ORR) per RECIST 1.1. **Results:** From March 2020 to November 2021, 15 pts were enrolled and received a median duration of 11.1 months of the combination treatment, with a median age of 61 years (range: 37-74). 9 (60%) pts were male, and 12 (80%) had papillary thyroid cancer. Of the 13 pts with PD-L1 immunochemical results, 6 pts had PD-L1 CPS $\geq 1\%$. As of 28 Dec 2022, the median follow-up duration was 22.11 months. Of the 15 pts with at least one post-baseline tumor assessment, the confirmed ORR was 33.3% (5 PRs) and DCR was 93.3%. mDoR was 8.34 months. mPFS (95%CI) was 10.91 months (4.01, NA). mOS was not reached, and 12-month OS rate was 100%. 14 (93.3%) pts had treatment-emergent adverse events (TEAEs), and 10 (66.7%) pts reported grade ≥ 3 TEAEs, most commonly ($\geq 10\%$ pts) with hypocalcemia (20%), diarrhea (20%) and hypertension (13%). There was no death due to TEAE in the study. **Conclusions:** Surufatinib plus toripalimab showed encouraging antitumor activity and tolerable safety profile in pts with locally advanced or metastatic RAIR-DTC. Clinical trial information: NCT04169672. Research Sponsor: HUTCHMED Limited.

Phase II prospective trial of induction chemotherapy for advanced sinonasal squamous cell or poorly differentiated carcinoma. *First Author: Kevin J. Contrera, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The standard treatment for resectable advanced sinonasal carcinoma is surgery followed by adjuvant therapy. Despite aggressive therapy, disease control and survival have historically remained poor. The role of induction chemotherapy (IC) has not been fully assessed. The objective of this study is to prospectively evaluate IC for local disease control, organ preservation, and response-based local treatment selection. **Methods:** This is a phase II, open-label, single-center trial of patients with previously untreated, resectable and nonresectable, locally advanced squamous cell or poorly differentiated carcinoma of the nasal cavity or paranasal sinuses. Eligible patients were > 16 years of age, had an ECOG Performance Status of 0-1, and stage II-IV, MO disease. Patients were treated with an IC regimen of docetaxel, cisplatin, and fluorouracil (TPF) for 2 cycles, then evaluated for response using clinical (symptoms and nasal endoscopy) and radiographic (RECIST 1.1 and PET) assessments. Those who achieved an objective response received a third cycle followed by chemoradiotherapy (CRT); non-responders underwent surgery with adjuvant radiotherapy. The primary endpoints were overall response rate (ORR) and 2-year local disease control. Secondary endpoints included disease-specific survival (DSS), overall survival (OS), disease-free survival (DFS), organ preservation, patterns of failure, and treatment toxicity. **Results:** 31 patients were enrolled between 2008 and 2020, of which 28 were evaluable for efficacy. Disease was T4a (57%) or T4b (21%), N+ (38%), and would have required maxillectomy (89%), craniotomy (54%), or orbital exenteration (29%). After IC, the ORR was 82.1% (7.1% complete response, 75.0% partial response), and the non-response rate was 17.9% (17.9% stable disease, 0% progressive disease). Patients then underwent CRT (79%) or surgery (21%). Following CRT, salvage surgery was performed for 41% of patients. Grade 3 or 4 adverse events occurred in 18% of patients. The 2-year local control rate was 53.6%. The 2-year DSS rate was 75% (median DSS not reached). For patients alive at 2 years, 63% had organ preservation (avoiding maxillectomy 38%, craniotomy 13%, orbital exenteration 38%). The median DFS and OS were 19.2 and 47.4 months, respectively. Factors associated with worse OS were nonwhite race ($P = .035$), T4 category ($P = .037$), overall stage IV ($P = .038$), and paranasal sinus subsite ($P = .002$). Surgery did not have significantly different OS than CRT ($P = .86$). **Conclusions:** This phase II study demonstrates the validity of induction chemotherapy as a guide for local treatment selection in patients with advanced sinonasal carcinoma. A majority of patients achieved disease control and organ preservation. The median survival was 4 years in a cohort with very advanced locoregional disease, with no survival difference between CRT and surgery. NCT03493425. Clinical trial information: NCT00707473. Larotrectinib (laro) long-term efficacy and safety in patients (pts) with tropomyosin receptor kinase (TRK) fusion thyroid carcinoma (TC). *First Author: Maria E. Cabanillas, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) gene fusions are oncogenic drivers in a variety of tumor types, including TC. Laro is a first-in-class, highly selective, central nervous system (CNS)-active TRK inhibitor approved for tumor-agnostic use in pts with TRK fusion cancer based on a rapid, robust, and durable objective response rate (ORR) in both adult and pediatric pts with various cancers. Here, we report data on the subset of pts with TRK fusion TC treated with larotrectinib with long-term follow-up. **Methods:** Pts with TRK fusion TC enrolled in three laro clinical trials (NCT02576431, NCT02122913, NCT02637687) were included. Laro was administered at 100 mg twice daily to most pts; two pediatric pts received 100 mg/m². Responses were assessed per independent review committee (IRC) using RECIST v1.1. Data cut-off: July 20, 2022. **Results:** As of data cut-off, 30 pts were eligible for efficacy assessment by IRC. The median age was 61.5 years (range 6-80) and the median time since initial cancer diagnosis was 5.0 years (range 0-46). The gene fusions involved *NTRK1* ($n = 14$; 47%) or *NTRK3* ($n = 16$; 53%). Fifteen pts (50%) received no prior systemic therapies, and six (20%) received ≥ 2 ; 23 (77%) received prior radioiodine. ORR was 63% (95% confidence interval [CI] 44-80); three (10%) complete response, 16 (53%) partial response (PR), five (17%) stable disease, four (13%) progressive disease, and two (7%) not evaluable. For pts classified as differentiated TC (DTC; $n = 23$), the ORR was 78% (95% CI 56-93). For pts classified as anaplastic TC (ATC; $n = 7$), the ORR was 14% (95% CI 0-58). All four pts with CNS metastases at baseline had a PR. Median time to response was 1.9 months, and median duration of response (DoR) was 43.3 months (95% CI 21.6-not estimable [NE]) at a median follow-up of 32.3 months. Median progression-free survival was 35.5 months (95% CI 23.4-NE) at a median follow-up of 34.0 months. Median overall survival (OS) was not reached (NR; 95% CI 48.7-NE) at a median follow-up of 46.4 months; the 48-month OS rate was 71% (95% CI 54-88). Median OS was NR (95% CI 48.7-NE) in DTC and 8.8 months (95% CI 2.6-NE) in ATC. At data cut-off, five pts who had disease progression continued treatment for ≥ 4 weeks due to continued clinical benefit. Treatment-related adverse events (TRAEs) were predominantly Grade 1-2. Grade ≥ 3 TRAEs were reported in two (7%) pts (anemia and decreased lymphocyte count). There were no treatment discontinuations due to TRAEs. **Conclusions:** Laro continues to demonstrate a rapid and durable response, extended survival, and a favorable safety profile in pts with TRK fusion DTC. Limited single-agent activity was observed in ATC. These results support the wider adoption of next generation sequencing panels, which include *NTRK* gene fusions, in pts with advanced TC prior to the initiation of any systemic therapy. Clinical trial information: NCT02576431, NCT02122913, NCT02637687. Research Sponsor: Bayer HealthCare Pharmaceuticals, Inc.

Poster Session

A phase II trial of nivolumab for patients with platinum-refractory recurrent or metastatic salivary gland cancer. *First Author: Yoshiaki Nagatani, Department of Medical Oncology and Hematology, Kobe University Hospital, Kobe-Shi Chuo-Ku, Japan*

Background: Salivary gland cancer is rare and has various pathological subtypes. With this rarity and heterogeneity, the therapeutic contribution of chemotherapy, including immune checkpoint inhibitors, for recurrent or metastatic salivary gland cancer (RM-SGC) has not been elucidated. The purpose of this trial was to investigate the efficacy and safety of nivolumab for patients with platinum-refractory RM-SGC. **Methods:** This open-label, single-arm, multicenter phase II trial was conducted at 9 centers in Japan. Eligible patients had platinum-refractory recurrent or metastatic salivary gland cancer with measurable lesions by RECIST v1.1 and an Eastern Cooperative Oncology Group performance status (ECOG PS) of 0, 1, or 2. Nivolumab 240 mg/body was administered intravenously every 2 weeks until progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR). We set the null hypothesis at 3% and the expected at 15% with a one-sided alpha of 0.1 and power of 80%. Secondary endpoints were disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** Twenty-four patients (16 males; median age, 65.5 years [range, 34-78 years]) were enrolled between March 2018 and January 2022. Pathological types were salivary duct carcinoma (n = 10), adenoid cystic carcinoma (n = 6), adenocarcinoma not otherwise specified (n = 5), mucoepidermoid carcinoma (n = 2), and acinic cell carcinoma (n = 1). In the majority of cases the primary site was a major salivary gland (n = 21), namely the parotid gland in 16 patients and submandibular gland in 5. The primary endpoint of ORR was 8.3% (2/24, 80% CI, 2.2-20.6%), with 2 partial responses (PR) in patients with salivary duct carcinoma (2/10, ORR: 20.0%). DCR was 29.2% (7/24, 2 in PR and 5 in stable disease), and all of the other 17 patients (70.8%) showed progressive disease (PD) on first disease evaluation at 12 weeks. With a median follow up for survivors of 32.0 months, median PFS and OS were 3.0 months (95% CI, 2.8-3.2 months) and 25.0 months (95% CI, 10.9-39.1 months), respectively. There was no new safety concern with nivolumab monotherapy. **Conclusions:** This phase II trial of nivolumab monotherapy for patients with platinum-refractory RM-SGC did not meet its primary endpoint of ORR. Although nivolumab monotherapy may be worth further development in salivary duct carcinoma, these results may raise concerns over nivolumab monotherapy for RM-SGC. Translational research to elucidate the immune microenvironment of each pathological type is under investigation. Clinical trial information: UMIN000029636. Research Sponsor: None.

Darolutamide for patients with androgen receptor positive salivary gland cancers (DISCOVERY): The results of phase 2 study of darolutamide monotherapy. *First Author: Susumu Okano, National Cancer Center Hospital East, Kashiwa, Chiba, Japan*

Background: There is no standard first-line treatment for recurrent/metastatic (R/M) or unresectable locally advanced (LA) salivary gland cancer (SGC). Androgen receptor (AR) overexpression is known to be particularly high (43-92%) in SDC, depending on histology, and has been identified as a potential molecular target for SGC treatment. However, the clinical utility of this approach has not been well investigated. Here, we evaluated the efficacy and safety of darolutamide for patients with AR-positive SGC. **Methods:** Eligibility included LA or R/M, SGC histologically confirmed positive for AR by the central laboratory; PS 0-1; adequate organ function; and no suitable local therapy. The study consists of two sequential components: a monotherapy part with darolutamide alone (monotherapy part) and a combination part with darolutamide and goserelin (combination part). Darolutamide was given orally at 1,200 mg daily until disease progression or unacceptable toxicity. Primary endpoint for the monotherapy part was overall response rate (ORR) as determined by the investigator. Secondary endpoints were ORR by independent central review (ICR), clinical benefit rate (CBR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety. (ClinicalTrials.gov NCT05694819). **Results:** From Mar 2020 to Jan 2021, 24 patients were enrolled in the monotherapy component. Median age was 64.6 years and 23 were male. ECOG PS was 0/1 in 18/6 cases. Pathological diagnosis was salivary duct carcinoma, adenocarcinoma NOS, and carcinoma ex pleomorphic adenoma in 16, 4 and 4 patients, respectively. ORR by investigator was 8.3% (90% CI 1.5-24.0) and ORR by ICR was 20.8% (95% CI 7.1-42.2). CBR and DCR were 41.7% (95% CI 22.1-63.4) and 58.3% (95% CI 36.6-77.9), respectively. Median PFS and OS were 5.7 months (95% CI, 1.9-15.2) and not reached (95% CI, 15.5-not estimable [NE]), respectively, with a median follow-up period of 19.1 months. Nine patients (37.5%) had grade 3 or 4 treatment-related adverse events. There were no treatment-related fatal adverse events. **Conclusions:** This is the first prospective trial of darolutamide for AR-positive SGC. The response rate by ICR and other secondary endpoints confirmed clinically meaningful activity and a well-tolerated safety profile. Patient enrollment to the combination component is now ongoing to evaluate additional benefits. Clinical trial information: NCT05694819. Research Sponsor: Bayer pharmaceutical company.

Clinical and genomic characterisation of adenoid cystic carcinoma of the head and neck, lung, and breast. *First Author: Emily Heathcote, The Christie Hospital NHS Foundation Trust, Manchester, United Kingdom*

Background: Adenoid cystic carcinoma (ACC) arises most commonly within the major salivary glands and other exocrine glands. ACC is typically a slow growing disease with high rates of recurrence many years after diagnosis. To inform post-operative surveillance and to provide comparator data for non-randomised studies, we sought to perform clinical and genomic characterisation of a cohort of 450 ACC patients, comparing outcomes between salivary ACC and other primary sites. **Methods:** 450 patients with ACC underwent clinical review at 4 UK NHS institutions. Electronic records were reviewed to extract clinical and demographic data. In 225 patients, DNA-based next-generation sequencing was performed to identify alterations in the most frequently altered genes in ACC (NOTCH1, ARID1A, KDM6A, SETD2, or TP53). Kaplan-Meier survival analyses calculated the time to first confirmed recurrence (TTFR) and overall survival from diagnosis (OS-diag) and from first confirmed recurrence (OS-rec). **Results:** Of 450 ACC patients, the primary site was most frequently the major salivary gland (44.7%; 201/450) comprising parotid (86), submandibular (96), sublingual (9) and salivary NOS (12). Other primary sites were sinonasal (99/450; 22.0%), upper aerodigestive (69/450; 15.3%), tracheobronchial (46/450; 10.2%), breast (16/450; 3.6%), skin (10/450; 2.2%), lacrimal (7/450; 1.6%), and other (2/450; 0.4%). Complete survival data were available in 440 patients. Recurrent/metastatic disease was confirmed in 69.8% (314/450). For these patients, the median TTFR was 4.5 yrs and for those with recurrence, the median OS from recurrence (OS-rec) was 4.8 yrs. The median TTFR in major salivary ACC was 5.8 yrs (95% CI 4.3 - 7.0). In comparison, the shortest median TTFR was seen in tracheobronchial (2.9 yrs, 95% CI 1.6 - 6.8; p = 0.019) and sinonasal ACC (3.8 yrs, 95% CI 2.9 - 5.0; p = 0.004). Breast ACC showed a differing survival pattern compared with major salivary ACC. Although the OS-diag in these two groups was not significantly different (9.75 yrs and 11.3 yrs respectively, p = ns), breast ACC showed a significantly increased TTFR (9.8 versus 4.4 yrs, p = 0.067), and a significantly reduced OS-rec (0.75 versus 4.8 yrs, p = < 0.001). KDM6A mutation was seen more frequently in primary sites outside the major salivary glands (p = 0.005). However, there was no relationship between primary tumour site and mutations in NOTCH1, ARID1A, SETD2 or TP53. **Conclusions:** In this real-world multi-centre UK study, tracheobronchial and sinonasal ACC have significantly shorter TTFR than major salivary ACC. This study suggests that breast ACC has a similar OS from diagnosis to major salivary ACC, but has an increased TTFR and shorter OS following recurrence. This may have implications for follow-up protocols after primary treatment of breast ACC, and initiation of systemic therapy following recurrence. Safety and early efficacy results of phase 1 study of affinity tuned and trackable AIC100 CAR T cells in ICAM-1 positive relapsed and/or refractory advanced poorly differentiated and anaplastic thyroid cancers. *First Author: Samer Ali Srour, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ICAM-1, a cell surface glycoprotein, is overexpressed in most ATC and PDTC. AIC100 is a 3rd-generation CAR T cell with micromolar affinity to ICAM-1, tuned lower than most CARs used to date in pre-clinical studies. Affinity tuned AIC100 are expected to selectively bind and kill tumor cells while safely sparing healthy cells. AIC100 also co-expresses somatostatin receptor 2 (SSTR2), which enables *in vivo* monitoring of AIC100 distribution and expansion by DOTATATE PET/CT scan. **Methods:** The objectives of this phase 1 dose escalation study are to assess the safety, preliminary efficacy and to determine RP2D of AIC100 in patients with ICAM-1⁺ relapsed/refractory PDTC or ATC. 3 dose levels (DL) are being explored-DL1 at 1x10⁶, DL2 at 1x10⁶ and DL3 at 5x10⁶ AIC100. AIC100 is received as a single infusion two days after completing lymphodepletion with Fludarabine/Cyclophosphamide. FDG and DOTATATE PET/CT scans are used to assess response and to track AIC100 *in vivo*, respectively. Response is assessed by RECIST1.1, starting at end of treatment (day 42 post AIC100). AIC100 is manufactured using Afflymune's Tune and Track CAR T cell platform. **Results:** As of Feb 14, 2023, 6 pts (4 ATC; 2 PDTC) with a median age of 59.5 yrs (48-70) were infused with AIC100, 3 each in DL 1 and 2. AIC100 was successfully manufactured for all patients and all infusion products met target transduction efficiency. No serious adverse events or DLTs were reported. Two patients had grade 1 CRS. No ICANs was reported. In 3 evaluable patients in DL1, 1 patient had stable disease with decreased FDG activity in PET that correlated with increased activity in the DOTATATE scan. From the 3 pts infused in the DL2, one is evaluable for efficacy at day 42. This is a patient with relapsed ATC who achieved PR with 42% reduction in target tumor lesion and remains in PR at 3 mths. The target lesion in this patient showed increased DOTATATE avidity at d14 post AIC100 infusion. This was followed by decreased FDG and DOTATATE avidity at d42 post AIC100 infusion, concomitant with decreased size, suggesting biological activity 42 days after CAR T infusion. Evaluation of CAR transgene demonstrated transient peripheral blood CAR T cell expansion. The second patient couldn't be assessed due to early withdrawal for disease-related toxicity. The 3rd patient in DL2 remains in the DLT period, pending efficacy evaluation. **Conclusions:** AIC100 demonstrated an excellent safety profile in DL1/DL2 treated patients with ATC and PDTC with no DLTs observed. The objective and relatively durable partial response in the first evaluable patient in the DL2, a patient with metastatic ATC who failed multiple lines of therapy, is unprecedented and very encouraging. Further investigations of AIC100 are ongoing at DL2 and DL3 to determine the RP2D. Clinical trial information: NCT04420754. Research Sponsor: Afflymune Therapeutics, Inc.

Predictive biomarkers of benefit to axitinib plus avelumab in patients with recurrent/metastatic adenoid cystic carcinoma (R/M ACC). *First Author: Camilla Oliveira Hoff, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ACC is a heterogeneous malignancy with no standard treatment for patients (pts) with R/M disease. Two distinct ACC subtypes have been identified proteogenomically, which contribute to ACC's biological variability. ACC-I is enriched with NOTCH activating mutations and MYC overexpression and has a poor prognosis (median survival [mOS] = 3.4 years). ACC-II has upregulation of TP63 and presents with an indolent disease course (mOS = 23.2 years). In a phase II trial of axitinib (VEGFR inhibitor) plus avelumab (PD-L1 inhibitor) in R/M ACC, clinical benefit was heterogeneous. We hypothesized that ACC subtype and gene expression profile are associated with benefit to axitinib plus avelumab. **Methods:** Cohort of 28 R/M ACC pts with radiological or clinical progression within 6 months (mos) of enrollment in the axitinib plus avelumab trial (NCT03990571). Target transcriptome profile including 19,616 probes was generated using HTG Transcriptome Panel [HTP]. Gene expression was used to identify ACC subtypes (ACC-I vs. ACC-II). Confirmed overall response rate (ORR), disease control rate (DCR), and progression-free survival (PFS) per RECIST v1.1 was assessed for each ACC subtype. An analysis of genes associated with benefit vs. no benefit from axitinib plus avelumab was conducted for the overall population and per ACC subtype. Benefit was defined as disease control (partial response [PR] or stable disease [SD]) and PFS longer than the median PFS. PFS > 6 mos was not used to define benefit due to the significant differences in PFS between ACC subtypes. **Results:** Out of 28 pts, 14 (50%) were classified as ACC-I and 14 (50%) were ACC-II. For ACC-I, ORR was 14.3% (2/14; 95%CI: 1.8-42.8%), DCR was 35.7% (2 PR + 3 SD; 95%CI: 12.8-64.9%) and median PFS was 1.86 mos (95%CI: 1.81-8.61 mos). For ACC-II, ORR was 21.4% (3/14; 95%CI: 4.7-50.8%), DCR was 100% (3 PR + 11 SD; 95%CI: 76.8-100%) and median PFS was 10.5 mos (95%CI: 7.40-NA). PFS was significantly longer for ACC-II vs. ACC-I (HR 0.19 [95%CI: 0.08 - 0.49], p = 0.0002). Through the previously defined benefit vs. no benefit cutoff, ACC-I had a 42.9% (6/14) and ACC-II had a 50.0% (7/14) benefit rate. Benefit in all ACC pts, ACC-I and ACC-II was associated with high expression of immune-related genes, especially B and T-lymphocyte function. Angiogenesis-related genes were not significantly upregulated in the benefit group as previously reported in renal cell carcinoma pts treated with the same combination. **Conclusions:** Clinical outcomes to axitinib plus avelumab were distinct between ACC-I and ACC-II subtypes, with ACC-II pts demonstrating an improved DCR and significantly longer PFS. Gene expression analysis revealed high expression of immune function-related genes in patients who benefited from axitinib plus avelumab in both ACC subtypes, indicating possible biomarkers predictive of benefit from the combination in ACC. Clinical trial information: NCT03990571. Research Sponsor: U.S. National Institutes of Health; Pfizer.

Retrospective analysis of genetically matched therapies in salivary gland cancer entities using a real-world database in a tertiary salivary gland cancer expertise center. *First Author: Jetty A.M. Weijers, Department of Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Salivary gland cancer (SGC) is a rare cancer and includes twenty-two different entities. In the Radboudumc SGC expertise center, a real-world database was set up to uniformly collect data of SGC subtypes. More than 500 SGC patients have been enrolled and collection of data for 261 patients is currently completed. Here, we describe the retrospective analysis of genetic aberrations found in different SGC entities and the treatment of selected recurrent/metastatic (R/M) patients with genetically matched therapies (GMT). **Methods:** All SGC patients in the SGC registry of Radboudumc between 2017 and 2022 whose tumors underwent next generation sequencing (NGS) and/or gene fusion analysis within standard of care or clinical trial were included in this analysis. Both primary tumor specimen and metastatic tissue have been used for molecular analyses. GMT was given in basket trials or on basis of compassionate use for clinically relevant genetic aberrations that are considered actionable nowadays. **Results:** NGS and/or gene fusion analysis data was available for 162 out of 261 patients, and most frequently in salivary duct carcinoma (SDC) patients (82/162). The number of patients with genetic aberrations differed between SGC entities. In 112 patients at least one genetic aberration and/or gene fusion was detected regardless of whether the target was druggable. Ninety-three patients out of 112 patients had R/M disease. Both a gene fusion and one or more mutations were found in six patients (adenoid cystic carcinoma [AdCC], n = 3; SDC, n = 2; and secretory carcinoma [SC], n = 1). Depending on the SGC subtype, in 14.3 - 100% of the R/M cases with genetic aberrations and/or gene fusions a GMT was started (SDC, 14/60; AdCC, 3/21; SC, 2/2; mucoepidermoid carcinoma, 2/4). The most given GMT among patients were monoclonal antibodies and tyrosine kinase inhibitors (TKI), respectively in nine and eleven patients, moreover immunotherapy was started in one patient. For example, eight SDC patients were treated with ERBB2 targeting agents (4/8 mutations; 4/8 copy number variants in ERBB2), showing a complete response in three patients. Additionally, one partial response and two stable diseases were observed, two patients were lost of follow-up. Two SC patients treated with a TKI based on the presence of the *ETV6-NTRK* gene fusion showed radiologically a partial response. **Conclusions:** In 69% of the SGC patients at least one genetic aberration and/or gene fusion was found, and in 23% of the R/M cases GMT was administered. Response differs between entities and GMT; a complete response was achieved after initiation of GMT in several patients. These data justify the use of NGS and gene fusion analysis in all salivary gland cancer entities, notably in subtypes lacking standard systemic therapies as this could offer other therapeutic options. Monitoring epithelial, epithelial-mesenchymal, and mesenchymal circulating tumor cells on papillary thyroid cancer following thyroidectomy: A prospective cohort study. *First Author: Eunju Park, CytoDx Inc., Seongnam, South Korea*

Background: Monitoring the effectiveness of cancer-removal surgery is challenging in most cases. Therefore, robust and non-invasive techniques have been developed, and liquid biopsy is an apparent method for that purpose. In this prospective cohort study, we examined whether one type of liquid biopsy, an enumeration of circulating tumor cells (CTCs), can monitor the effectiveness of thyroidectomy in patients with papillary thyroid cancer (PTC). **Methods:** From January 2021 to January 2022, we recruited 62 PTC patients who had operated on isthmectomy, lobectomy, and total thyroidectomy for this study at Seoul National University Bundang Hospital. The blood samples from the recruited patients were collected before surgery and two weeks and three months after the surgery for CTC detection. We collected peripheral blood samples by venipuncture from each patient in EDTA tubes and stored them at 4°C until isolation and characterization of CTCs (within 6 hours). **Results:** We found the CTCs in 87% (54/62) of PTC patients, with an average number of 8.0. This number significantly decreased after thyroidectomy, with an average of 5.3 and 4.3 post-operation of two weeks and three months, respectively. In the peripheral blood of PTC patients, the CTCs with epithelial-mesenchymal and mesenchymal phenotypes were significantly more frequent than the epithelial phenotype of CTCs. Furthermore, PTC patients with lymphatic invasion, lymph node metastasis, or BRAF V600E mutation showed significantly decreased CTC count after surgery. **Conclusions:** PTC patients had a significantly higher number of CTCs undergoing epithelial-mesenchymal transition and showed a significant decrease in CTC count after surgery. This indicates that liquid biopsy using CTC enumeration can satisfy the purpose of monitoring the effectiveness of cancer-removal surgery. Clinical trial information: KCT0008179. Research Sponsor: CytoDx Inc.

¹⁷⁷Lu-PSMA radioligand therapy for patients with recurrent/metastatic (R/M) salivary gland cancer (SGC): A phase II pilot study. *First Author: Carla M.L. Van Herpen, Department of Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands*

Background: New treatments are warranted due to limited systemic treatment options for SGC patients (pts). Gallium [68Ga]Ga prostate-specific membrane antigen (PSMA) PET imaging results in SGC pts have demonstrated PSMA expression of SGC and thus indicated that PSMA radionuclide therapy may be a useful option, especially in the case of adenoid cystic carcinoma (AdCC) and salivary duct carcinoma (SDC) subtypes. Therefore, this study (EudraCT number 2019-003857-27) evaluated the safety and efficacy of PSMA-targeted radionuclide therapy in AdCC and SDC pts. **Methods:** This was a single-center, single-arm, phase II pilot study. R/M AdCC (n = 10) and SDC (n = 5) pts with sufficient PSMA tracer uptake on [⁶⁸Ga]Ga-PSMA PET imaging, i.e., ≥ 1 lesion ≥ 1.5cm with PSMA expression above mean liver level, were treated with 2-4 cycles of 7.4 GBq [¹⁷⁷Lu]Lu-PSMA-I&T, with an interval of 6 ± 1 weeks. Baseline imaging was repeated for evaluation 4 weeks after cycle 2; in case of progressive disease (PD) per RECIST 1.1 the treatment was discontinued; otherwise, pts received the full treatment (4 cycles). All pts received whole body post-therapeutic imaging after 1, 24, 48, 72 h and 7d after each cycle. The primary endpoint was safety. Secondary endpoints include the objective response rate, progression-free survival (PFS), and overall survival (OS). **Results:** Between 6-2020 and 2-2023, 15 AdCC pts and 10 SDC pts were screened for eligibility. Five AdCC pts and 8 SDC pts were screen failures due to insufficient PSMA expression in 11 pts (AdCC n = 4; SDC n = 7) or due to brain metastases in 2 pts (AdCC n = 1; SDC n = 1). Ten AdCC and 2 SDC pts received at least one cycle of 7.4 GBq [¹⁷⁷Lu]Lu-PSMA-I&T. The most observed adverse events (grade 1-2) included: nausea (75%), dry mouth (75%), fatigue (67%), and anemia (58%). Two pts (17%) developed grade 3 toxicity: lymphocytopenia (n = 1) and hyponatremia (n = 1). No grade 4-5 toxicities were observed. Two pts (AdCC n = 1; SDC n = 1) received only 1 treatment cycle due to early PD. The interim-treatment evaluation resulted in the discontinuation of treatment after 2 cycles in an additional 3 AdCC and the second SDC pts due to PD. Six AdCC pts received the full treatment (4 cycles); no responses were observed; 3 pts (75%) showed stable disease of more than 3 months after treatment completion (5, 15 and 21 months); 3 pts showed PD at 3 months after treatment completion. Median PFS in 10 AdCC pts was 6.7 months (95%CI: 0.0-15.1); OS was not reached after a median follow-up of 11.9 months. **Conclusions:** [¹⁷⁷Lu]Lu-PSMA-I&T treatment in SGC pts is well-tolerated. The efficacy in AdCC was limited; only stable disease was achieved in 3 out of 10 pts. In most screened SDC pts, PSMA expression was insufficient to undergo [¹⁷⁷Lu]Lu-PSMA-I&T treatment; the 2 SDC pts included showed early PD. Dosimetry analyses will be performed to calculate the delivered radiation doses to organs at risk as well as tumor lesions. Clinical trial information: EUCTR2019-003857-27. Artificial intelligence (AI) analysis of tumor-infiltrating lymphocytes (TILs) in hematoxylin and eosin (H&E) slides to explore immune phenotypes in papillary thyroid cancer. *First Author: Myungwoo Nam, Lincoln Medical and Mental Health Center, Bronx, NY*

Background: Different biomarkers have been discovered to predict response to immunotherapy but the variability of response exists. TILs are a potential biomarker as infiltration of CD8+ T cells in the tumor microenvironment (TME) was related to treatment response to PD-1 blockade. Advanced well-differentiated papillary thyroid cancer (PTC) has limited standard-of-care treatment options and can exhibit a poor prognosis when exhausted. Our study aimed to classify the TME of PTC according to TILs. **Methods:** Using the TCGA PTC data, samples were classified into three immune phenotypes (immune-'desert', immune-'excluded', and 'inflamed') based on peri-tumor lymphocyte density from analysis of H&E slides using an AI model (Lunit SCOPE). Immune and stromal cell infiltration was inferred using xCell. Cytolytic scores (CYT) and thyroid differentiation scores (TDS) were calculated using mRNA expression. **Results:** Total of 383 samples were included. Immune phenotype analysis showed 183 (47.7%) 'desert', 133 (34.7%) 'excluded', and 67 (17.4%) 'inflamed'. Median age at diagnosis was the lowest in 'inflamed' (inflamed 41.5 vs excluded 47 vs desert 50, $p = 0.002$). TNM stages were as follows in the order of stages 1 to 4: inflamed 49/4/8/3, excluded 64/13/32/16, and desert 86/28/40/19. BRAF V600E mutation was most prevalent in 'excluded' (97/133, 72%), followed by 'inflamed' (32/67, 47.7%) and 'desert' (51/183, 27.8%). CYT was the highest in 'inflamed' (median: inflamed 186 vs excluded 53 vs desert 39, $p < 0.001$). TDS was the highest in 'desert' (median: inflamed -0.3 vs excluded -0.69 vs desert 0.73, $p < 0.001$). The 6 cell types with the most statistically significant difference in infiltration were activated dendritic cells (aDCs), DCs, B cells, epithelial cells (EpCs), CD8+ central memory T cells, and CD4+ memory T cells. The 'inflamed' showed the highest median value for all of these cells except EpCs. The cells with the highest median value in 'excluded' included EpCs, sebocytes, and immature DCs. The cells with the highest median value in 'desert' were lymphatic endothelial cells (ECs), ECs, and osteoblasts. Three immune phenotypes were associated with differential outcomes in disease-free survival (log-rank for trend, p -value = 0.01). There was no difference in overall survival. **Conclusions:** Our results suggest that 15% of PTC can have immune features which were related to a higher rate of response to immunotherapy across different tumor types. A previous study showed that PTC with a low TDS or BRAF V600E mutation is related to increased immune response indices. In our study, TDS or BRAF V600E mutation status could not distinguish the 'inflamed' from other phenotypes. This suggests that immune phenotype classification through TILs can provide distinct information about the TME of PTC. Research Sponsor: None.

Poster Session

A phase 2 study of magrolimab combination therapy in patients with recurrent or metastatic head and neck squamous cell carcinoma: ELEVATE HNSCC. *First Author: A. Dimitrios Dimitrios Colevas, Stanford Cancer Center, Stanford, CA*

Background: Novel combination therapies are needed to extend survival in patients (pts) with recurrent or metastatic head and neck squamous cell carcinoma (RM-HNSCC). Magrolimab is a monoclonal antibody that blocks CD47, a "don't eat me" signal often overexpressed on HNSCC cells. CD47 blockade by magrolimab induces macrophage-mediated phagocytosis of tumor cells and has shown preclinical activity and promising clinical efficacy in hematologic malignancies. Certain chemotherapies, including taxanes, enhance phagocytic signals on tumor cells, leading to potential synergistic antitumor activity when combined with magrolimab. This study is evaluating the safety, tolerability, and efficacy of magrolimab combination therapy in pts with RM-HNSCC. **Methods:** This open-label study includes 2 safety run-ins and 2 phase (ph) 2 cohorts. Safety run-in 1 includes pts with RM-HNSCC untreated in the RM setting to receive magrolimab + pembrolizumab (pembro) + platinum (cisplatin or carboplatin) + 5-fluorouracil (FU); safety run-in 2 enrolls pts with locally advanced or RM-HNSCC treated with 1-2 lines of prior systemic therapy in the locally advanced or RM setting who received magrolimab + docetaxel. Magrolimab is given intravenously as a 1-mg/kg priming dose on cycle 1 day 1 (C1 D1) to mitigate on-target anemia and 30 mg/kg on D8 and D15. Magrolimab 30 mg/kg is given on C2 D1, D8, and D15 and 60 mg/kg on D1 of C3+. Once the recommended ph 2 dose is determined, the ph 2 cohorts will follow the same dose schedules. In ph 2 cohort 1, pts receive magrolimab + pembro + platinum + 5-FU (arm A), pembro + platinum + 5-FU (arm B), or magrolimab + zimberelimab (anti-PD-1) + platinum + 5-FU (arm C). Pts enrolled in ph 2 cohort 3 receive magrolimab + docetaxel. An optional safety run-in and ph 2 cohort (cohort 2) of magrolimab + pembro in PD-L1+ RM-HNSCC may be opened at sponsor's discretion. Pembro, platinum, 5-FU, and docetaxel are given per standard of care. Reasons for treatment discontinuation may include unacceptable toxicity or disease progression. Safety is monitored throughout the study. Primary endpoints of the safety run-ins cohorts were incidence of adverse events and dose-limiting toxicities per CTCAE v5.0. Primary endpoints for the Ph 2 cohorts are progression-free survival (PFS) by independent central review (cohort 1 arm A vs B) and investigator-assessed objective response rate (ORR) by RECIST 1.1 (cohorts 2, 3). Secondary endpoints include magrolimab pharmacokinetics and antidrug antibodies (safety run-in, ph 2 all cohorts), ORR assessed by independent central review, investigator-assessed PFS by RECIST 1.1 (all cohorts) and overall survival (all cohorts), duration of response, and pt-reported outcomes. Planned enrollment is ~230 pts. Clinical trial information: NCT04854499. Research Sponsor: Gilead Sciences, Inc.

XRAY Vision: A phase 3 study of xevinapant plus radiotherapy (RT) for high-risk, cisplatin-ineligible patients with resected, locally advanced squamous cell carcinoma of the head and neck (LA SCCHN). *First Author: Robert L. Ferris, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: The current standard of care for patients with resected LA SCCHN who are at high-risk of disease recurrence and are cisplatin eligible is chemoradiotherapy (CRT; cisplatin + RT). For patients at high risk of disease recurrence who cannot receive cisplatin, treatment options are limited, and there is currently no treatment specifically recommended by international guidelines. Xevinapant is a first-in-class, small-molecule IAP (inhibitor of apoptosis protein) inhibitor that has been shown to restore cancer cell sensitivity to apoptosis, thereby enhancing the effects of chemotherapy and RT. In a randomized phase 2 study in patients with unresected LA SCCHN, treatment with xevinapant + CRT was associated with a 53% lower risk of death after 5 years of follow-up and reduced the risk of death or disease progression by 67% after 3 years of follow-up vs placebo + CRT. In preclinical SCCHN models, xevinapant + RT alone also demonstrated antitumor activity. These promising clinical and preclinical data provide a strong rationale for combining xevinapant and RT in cisplatin-ineligible patients with LA SCCHN. **Methods:** XRAY Vision (NCT05386550) is a randomized, double-blind, placebo-controlled, phase 3 study comparing xevinapant or placebo in combination with intensity-modulated RT (IMRT) in patients with resected LA SCCHN who are ineligible for cisplatin and have a high risk of relapse. Eligible patients must have histologically confirmed cancer of the oral cavity, oropharynx, hypopharynx, or larynx; undergone surgery with curative intent 4 to 8 weeks before the start of treatment; high risk of relapse; no residual disease by computed tomography scan; and ineligible for cisplatin (meeting ≥ 1 of the following criteria: estimated glomerular filtration rate < 60 mL/min/1.73 m²; hearing loss [grade ≥ 2 audiometric hearing loss or grade ≥ 2 tinnitus]; grade ≥ 2 peripheral neuropathy; and if aged ≥ 70 years old, unfit according to the G8 questionnaire [score ≤ 14]). Other eligibility criteria include ECOG performance status of 0 or 1 and adequate hematologic and hepatic function. Approximately 700 eligible patients will be randomized to oral xevinapant (200 mg/day on days 1-14 of a 3-week cycle) or placebo for 3 cycles + standard fractionation IMRT (66 Gy in 33 fractions, 2 Gy per fraction, 5 days per week) followed by 3 cycles of xevinapant or placebo. The primary endpoint is disease-free survival. Secondary endpoints include overall survival, time to subsequent cancer treatments, safety, and health-related quality of life. Patients will be followed up for a minimum of 60 months. Enrollment is planned in 27 countries, including the US, and countries in South America, Europe, and Asia. The study started in October 2022, and recruitment is ongoing. Clinical trial information: NCT05386550. Research Sponsor: The healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

Palbociclib + cetuximab versus cetuximab in patients with CDKN2A-altered, anti-PD-1 resistant, HPV-negative head and neck squamous cell carcinoma (HNSCC): A phase 3 trial. *First Author: Jessica C. Ley, Washington University School of Medicine, St. Louis, MO*

Background: Cell cycle deregulation is ubiquitous in HNSCC. In HPV-negative HNSCC, the most common genomic cell-cycling alteration involves *CDKN2A*, which results in loss of p16 expression, hyper-activation of CDK4/6-cyclin D1, unrestrained cell cycling and tumor progression. The modest antitumor activity of cetuximab in HPV-negative HNSCC may be due to unregulated cell-cycling events downstream of EGFR. In cell-line, xenograft, and PDX models of HPV-negative HNSCC, selective CDK4/6 inhibition arrested cell cycling and inhibited tumor growth. *CDKN2A* alterations were predictive of efficacy. Palbociclib, a selective CDK4/6 inhibitor, in combination with an EGFR inhibitor synergistically reduced the viability of HPV-negative HNSCC cell lines. An exploratory analysis of a double-blind, randomized, phase 2 trial (PALATINUS) showed that overall survival (OS) was numerically superior in patients with *CDKN2A* altered, HPV-negative recurrent/metastatic (RM) HNSCC treated with palbociclib + cetuximab vs those treated with placebo + cetuximab (median 9.7 vs 4.6 months, HR 0.38); however, OS was similar between the two treatment arms in patients without *CDKN2A*-altered disease. Also, the TAPUR trial showed that palbociclib decreased target lesions in 25% of patients with *CDKN2A*-altered HN cancers. These data provide justification for a randomized trial of palbociclib + cetuximab vs cetuximab in patients with *CDKN2A*-altered, HPV-negative RM-HNSCC. Enrollment was limited to patients with anti-PD-1 resistant disease, since current treatments fail to improve OS in these patients. **Methods:** The primary aim of this open-label, phase 3 trial is to determine the OS of patients with *CDKN2A*-altered (mutation or deletion), anti-PD-1 resistant, HPV-negative HNSCC treated with palbociclib + cetuximab (Arm 1) vs cetuximab (Arm 2). Eligibility also requires 1-3 lines of prior therapy and no cetuximab for RM disease. Patients are randomized (2:1) to Arms 1 or 2, stratified by prior platinum or cetuximab (if given with curative-intent therapy). Patients receive 28-day cycles of palbociclib 125 mg/d orally on days 1-21 + cetuximab 400 mg/m² IV cycle 1 day 1, then 250 mg/m² weekly (Arm 1) or cetuximab (Arm 2). Tumor response is assessed using RECIST 1.1. A two-stage sequential design, including one interim and a final analysis, was planned. We hypothesized that the median OS of Arm 1 will be 9.7 months and of Arm 2 4.6 months. O'Brien-Fleming method was used to calculate the sample size at each stage and derive the boundaries of two-sided hypothesis with early stopping to reject or accept H_0 (HR = 1). Assuming 22 months enrollment and 12 months follow-up, 66 patients (Arm 1: 44; Arm 2: 22) will be enrolled in the first stage. If the study continues, an additional 15 patients will be enrolled (total Arm 1: 54; Arm 2: 27) which achieves 80% power at a two-sided α 0.05. Clinical trial information: NCT04966481. Research Sponsor: Pfizer; Joseph Sanchez Foundation.

Phase 2 trial of retifanlimab (anti-PD-1) in combination with INCAGN02385 (anti-LAG-3) and INCAGN02390 (anti-TIM-3) as first-line treatment in patients with PD-L1-positive recurrent/metastatic squamous cell carcinoma of the head and neck. *First Author: Ezra E.W. Cohen, Moores Cancer Center, University of California San Diego, La Jolla, CA*

Background: Anti-PD-(L)1 therapies have improved clinical outcomes in PD-L1+ squamous cell carcinoma of the head and neck (SCCHN). However, many patients either do not respond or develop resistance, partly due to additional immune checkpoint receptors including LAG-3 and TIM-3, which are frequently coexpressed with PD-1 on tumor-infiltrating lymphocytes. In preclinical studies, LAG-3 and TIM-3 blockade showed synergistic activity with PD-1 inhibition, and triple blockade improves T-cell reinvigoration and antitumor efficacy over single/double combinations. Emerging clinical evidence also supports blockade of PD-1, LAG-3, and TIM-3 as a promising combination approach in checkpoint inhibitor-naïve patients. This study aims to assess the efficacy and safety of the anti-PD-1 antibody, retifanlimab, in combination with INCAGN02385 (anti-LAG-3) and INCAGN02390 (anti-TIM-3) antibodies as first-line treatment in PD-L1+ recurrent or metastatic SCCHN. **Methods:** This randomized, double-blind, multicenter, phase 2 study (NCT05287113) includes patients with previously untreated, recurrent or metastatic, PD-L1+ (combined positive score [CPS] $\geq 1\%$) SCCHN and ECOG status of 0 or 1. Approximately 162 patients will be randomized 1:1:1 to receive (1) intravenous (IV) retifanlimab 500 mg every 4 weeks (Q4W) plus placebo controls, (2) retifanlimab plus IV INCAGN02385 350 mg Q2W plus placebo, or (3) retifanlimab plus INCAGN02385 plus IV INCAGN02390 400 mg Q2W. Patients will be stratified at randomization by LAG-3 expression (tumor proportion score $\geq 5\%$ vs $< 5\%$), PD-L1 CPS (1% - 19% vs $\geq 20\%$), and human papillomavirus p16 status (positive vs negative; oropharyngeal tumors only). Treatment will be administered in 4-week cycles for up to 2 years. The primary endpoint is progression-free survival (PFS; defined per Response Evaluation Criteria in Solid Tumors [RECIST] v1.1). Secondary endpoints are objective response rate per RECIST v1.1, duration of response, disease control, overall survival, and safety. Sample size calculation is based on a median PFS of 3 months, based on historical data for anti-PD-1 monotherapy in the first-line treatment setting for PD-(L)1+ advanced/metastatic SCCHN. PFS, overall survival, and duration of response data will be analyzed by the Kaplan-Meier method. Patient enrollment is ongoing. Clinical trial information: NCT05287113. Research Sponsor: Incyte Corporation.

A phase 2, open-label, multicenter study investigating efficacy and safety of RP3 oncolytic immunotherapy combined with other therapies in patients with locoregionally advanced or recurrent squamous cell carcinoma of the head and neck. *First Author: Kevin Joseph Harrington, The Institute of Cancer Research, The Royal Marsden Hospital, London, United Kingdom*

Background: Head and neck (HN) cancers were estimated to account for $> 50,000$ new cancer diagnoses and $> 11,000$ deaths in the US in 2022. Squamous cell carcinoma of the head and neck (SCCHN) comprises about 90% of HN cancers. For locally advanced (LA) SCCHN, standard initial therapy is concurrent chemoradiation therapy (CCRT) or definitive resection followed by adjuvant radiation $\pm$ chemotherapy; $> 50\%$ of patients (pts) relapse within 2 years. For recurrent/metastatic (R/M) SCCHN, standard first-line therapy includes immune checkpoint inhibitors (anti-PD-1) $\pm$ chemotherapy or cetuximab, chemotherapy $\pm$ cetuximab, or salvage surgery; prognoses are poor, and benefit of anti-PD-1 therapy is generally limited to pts with positive PD-L1 combined positive score (CPS). RP3 is an enhanced potency, modified version of herpes simplex virus type 1 expressing the fusogenic gibbon ape leukemia virus glycoprotein with the R sequence deleted (GALV-GP-R-), an anti-CTLA-4 antibody-like molecule, and costimulatory CD40- and 4-1BB-activating ligands. Intratumoral (IT) RP3 delivery may promote immunogenic tumor cell death and systemic antitumor response (abscopal effect), both of which may be further enhanced by standard therapies (eg, chemotherapy, anti-PD-1). This phase 2 study will evaluate the efficacy and safety of RP3 combined with other therapies in pts with advanced, inoperable LA or R/M SCCHN. **Methods:** Pts in the LA cohort (up to ~ 100 pts) must have inoperable, previously untreated, high-risk SCCHN eligible for curative intent CCRT and will be randomized 1:1 to receive RP3 + standard of care cisplatin-based CCRT, followed by nivolumab (nivo), vs CCRT alone. A formal safety assessment will be performed 3 weeks after the tenth patient randomized to RP3 + CCRT + nivo has completed CCRT. RP3 will be injected IT into primary tumor sites and/or superficial or deep nodal lesions. Pts in the RP3 group will receive up to 4 doses of RP3 every 3 weeks (Q3W; first dose at a concentration of 1×10^6 plaque-forming units [PFU]/mL; subsequent doses 1×10^7 PFU/mL). Nivo will be given at 240 mg Q2W or 480 mg Q4W (after CCRT completion, concurrent with fourth RP3 dose, for up to 1 year). The primary endpoint for the LA cohort is progression-free survival. Pts in the R/M cohort (up to ~ 30 pts) must have R/M SCCHN eligible for first-line systemic therapy for locoregional recurrence and/or distant metastases and PD-L1 CPS < 20 , and will receive RP3 + nivo + carboplatin/paclitaxel. RP3 will be injected IT as described above for up to 8 doses Q3W (first dose 1×10^6 PFU/mL; subsequent doses 1×10^7 PFU/mL; carboplatin/paclitaxel started at first RP3 dose). Nivo will be given as above, concurrent with third RP3 dose, for up to 2 years. The primary endpoint for the R/M cohort is overall response rate. Clinical trial information: NCT05743270. Research Sponsor: Replimune Inc.

A phase 2 study of neoadjuvant lenvatinib in locally advanced invasive thyroid cancer. *First Author: Amr Hesham Abdelhamid Ahmed, Division of Thyroid and Parathyroid Endocrine Surgery, Department of Otolaryngology-Head and Neck Surgery, Massachusetts Eye and Ear Infirmary, Harvard Medical School, Boston, MA*

Background: Lenvatinib is a multiple receptor tyrosine kinase (RTK) inhibitor that has demonstrated meaningful benefit in radioiodine (RAI)-refractory differentiated thyroid cancer (DTC). In SELECT, lenvatinib significantly prolonged progression-free survival (PFS) and was associated with an overall response rate (ORR) of 65% in patients with RAI-refractory DTC, with the greatest degree of tumor shrinkage occurring in the first 2 cycles. The robust activity of lenvatinib in DTC suggests that neoadjuvant treatment in patients presenting with bulky neck disease may make surgery more feasible, allows for optimal surgical outcomes and less aggressive surgical management. Neoadjuvant lenvatinib to improve surgical outcomes in locally advanced DTC has not been studied to date. This phase 2 study will examine the efficacy and safety of lenvatinib prior to thyroidectomy, with the goal of achieving more favorable surgical outcomes. **Methods:** This is a Simon two-stage Phase 2 open-label multicenter clinical trial for adult patients who meet the following criteria: have been diagnosed with locally advanced or persistent/recurrent thyroid and/or cervical nodal DTC, deemed at risk for R2 resection (surgical margins with macroscopic tumor) (as evident by vocal cord paralysis by laryngoscopic exam, imaging documenting extrathyroidal/extranodal extension, or major vessels involvement), have measurable disease per RECIST v1.1, have an ECOG performance status ≤ 1 , and no contraindication to surgery. A total of 28 patients will be enrolled from three centers (Massachusetts General Hospital/Massachusetts Eye & Ear Infirmary (MGH/MEEI), Memorial Sloan-Kettering Cancer Center (MSKCC), and MD Anderson Cancer Center (MDACC)). Participants will receive up to 6 cycles of lenvatinib prior to surgery depending on response. Participants will undergo restaging at the end of cycle 2, 4, and 6. Participants with sufficient response to treatment who projected to achieve an R0 or R1 resection will stop lenvatinib and proceed to surgery within 7-10 days from the last dose. Participants who do not have a sufficient response who are tolerating treatment, will receive an additional 2-4 cycles of lenvatinib, followed by surgery. The primary objective is the R0 (surgical margins free from tumor)/R1 (surgical margins free from macroscopic tumor) resection rate. Secondary outcome measures include R0/R1 resection rates in each of 5 pre-specified anatomic target interfaces (perithyroid muscles, cartilage, esophagus, recurrent laryngeal nerve, major vessels), evaluation of the change in surgical morbidity complexity MGH/MEEI-MSKCC-MDACC (MMM) score and the Invasive Thyroid Class, ORR prior to surgery per RECIST v1.1, and the safety of lenvatinib in this patient population. The study is currently accruing with 11 patients enrolled at time of submission. Clinical trial information: NCT04321954. Research Sponsor: Eisai.

A phase 2 open-label study of conditionally active biologic ozuriftamab vedotin (BA3021) in failed PD-1/L1 treatment of patients with recurrent or metastatic squamous cell carcinoma of the head and neck. *First Author: Alan Loh Ho, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Ozuriftamab vedotin (BA3021) is a conditionally active biologic (CAB) anti-receptor tyrosine kinase orphan receptor 2 (ROR2) humanized monoclonal antibody (IgG1) conjugated to monomethyl auristatin E (MMAE) using a cleavable linker (CAB ROR2 ADC) (Short, et al., 2014, Chang, et al. 2021). Conditional and reversible binding by CABs is designed to reduce off-tumor toxicity and immunogenicity, avoid tissue-mediated drug deposition, and improve pharmacokinetics (PK). ROR2 is a cell-surface transmembrane receptor protein tyrosine kinase highly expressed in several tumor types including head and neck squamous cell cancer (HNSCC). Increased ROR2 expression has been associated with tumor resistance to chemotherapy, programmed death-1 (PD-1) inhibitors, molecular targeted therapy, and radiation therapy. A pronounced unmet need exists as the majority of patients with recurrent or metastatic HNSCC experience disease progression with existing therapies (Chow 2020). **Methods:** BA3021-002 is a multi-center, open-label, single-arm Phase 2 study (n=40) designed to evaluate the efficacy and safety of BA3021 in patients previously treated with PD-(L)1 with ROR-2 expressing recurrent or metastatic HNSCC. Eligible patients include those with measurable disease by Response Evaluation Criteria in Solid Tumors (RECIST) Version 1.1 criteria. Failure to prior treatment is defined as documented disease progression after no more than one PD-1/L1 inhibitor either administered as monotherapy or in combination therapy. Pharmacokinetic (PK), pharmacodynamic (PD), immunogenicity, and biomarker assessments will be performed. Enrollment is ongoing (NCT05271604) References: Chang, H.W., Frey, G., Liu, H., Steinman, L., Boyle, W.J. and Short, J.M. Proc. Natl. Acad. Sci. 2021 Mar. 2; 118(9). Chow LQ. Oral NRC-2694-A in combination with paclitaxel as therapy for recurrent and/or metastatic head and neck squamous cell carcinoma (R/M-HNSCC) that progressed on or after an immune checkpoint inhibitor (ICI): A multi-center, single-arm, phase 2 trial. *First Author: Douglas Adkins, Washington University School of Medicine, St. Louis, MO*

Background: HNSCC is the seventh most common cancer worldwide. Patients with R/M disease have limited treatment options and a poor prognosis. The USFDA has approved two ICI agents to treat R/M-HNSCC: pembrolizumab given as monotherapy or with platinum-based chemotherapy for first-line treatment of R/M disease and nivolumab (or pembrolizumab) monotherapy for treatment of disease that progressed on or after platinum-containing chemotherapy. In each setting, the ICI improved overall survival (OS); however, the absolute magnitude of the OS benefit was modest and most patients experienced disease progression within one year. There are no agents with regulatory agency-approval that are used to treat R/M-HNSCC that progressed on or after an ICI. Drugs commonly used in this setting have limited activity and include cetuximab (an epidermal growth factor receptor [EGFR] inhibitor), paclitaxel, docetaxel, a platinum, or 5-fluorouracil. Hence, there is an important unmet medical need to develop more effective treatments for R/M-HNSCC that progressed on or after an ICI. NRC-2694-A is an orally administered EGFR tyrosine kinase inhibitor, discovered and developed by NATCO Pharma Ltd., India. Based on the responses from Phase-I and Phase-II trials of NRC-2694-A in India, NAT2694US study is designed to evaluate the safety and efficacy of Oral NRC-2694-A in combination with paclitaxel in patients with R/M-HNSCC, who progressed on or after ICI therapy. **Methods:** NAT2694US is a multi-center, single-arm, Phase 2 study (NCI ClinicalTrials.gov Identifier: NCT05283226) with an estimated enrolment of 46 patients. Eligible patients are >18 years of age with an ECOG performance status of 0-2 and histologically confirmed unresectable, measurable R/M-HNSCC (of the oral cavity, oropharynx, hypopharynx, and larynx), radiological disease progression on or after ICI therapy, and no prior taxane for R/M disease. Patients receive 300 mg of oral NRC-2694-A once daily and 175 mg/m² of paclitaxel IV infusion once every 21-day cycle for 6 cycles or more. Tumor response assessment with CT/MRI scans is performed every 6 weeks. The primary endpoint is objective response rate (ORR) using RECIST v1.1 performed by the investigator. The study uses a Simon's 2-stage design with ORR H₀: 30% and H₁: 50% using a one-sided Type-1 error rate = 0.05. In Stage 1, fifteen patients are to be enrolled for tumor assessment. If objective response is observed in at least 6 of these 15 patients, then Stage 2 would be opened with the inclusion of 31 additional patients, leading to a total enrolment of 46 patients. The observation of objective response in at least 19 of 46 patients would reject the null hypothesis in favour of the alternative hypothesis. Enrolment to the NAT2694US trial is currently ongoing in USA. Clinical trial information: NCT05283226. Research Sponsor: NATCO Pharma Ltd.

Poster Session

A phase II trial of neoadjuvant nivolumab, docetaxel, and cisplatin therapy followed by surgery and radiation therapy for resectable high-grade salivary gland carcinoma. *First Author: Sehhoon Park, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: Salivary gland carcinomas (SGCs) are rare entities that contribute to approximately 5% of head and neck malignancies. The current standard therapy for resectable SGC is complete surgical resection with adjuvant radiotherapy or chemoradiotherapy. However, the patients with high-grade histological subgroup tumors have the highest risk of regional and distant metastasis as the primary cause of treatment failure. The previous evidence demonstrates that neoadjuvant chemotherapy showed a statistically significant advantage in survival for patients with head and neck cancer. Based on the success of neoadjuvant immune checkpoint inhibitors (ICI) in preventing disease recurrence and achieving pathologic complete response (pCR) in different types of cancer, we designed this study by incorporating nivolumab combined with neoadjuvant cytotoxic chemotherapy in patients with potentially resectable high-grade SGCs. **Methods:** This study is the phase II, open-label, single-center study of nivolumab in combination with docetaxel, and cisplatin as a neoadjuvant therapy in high-grade resectable SGCs. All the patients must be confirmed with pre-defined high-grade histology and clinically node-positive. As the representative inclusion/exclusion criteria, all the patients must not receive prior cancer therapy in advance to study enrollment, including another kind of immunotherapy, cytotoxic chemotherapy, or radiotherapy. Three cycles of nivolumab (360mg), docetaxel (60mg per m²), and cisplatin (60mg per m²) are applied every three weeks. Three weeks after the last treatment, the patient is re-evaluated for the surgery and will undergo surgery within seven weeks after the last treatment. Based on the surgical pathologic outcome, additional radiotherapy will be initiated between 4 to 8 weeks after the surgery per the following guidance; R0: 59.4Gy/25fx; R1 or R2: 59.4Gy/25fx with optional boost 6.6Gy/3fx. The primary objective is the major pathologic response rate defined by ≤10% of tumors composed of viable tumors. Complete resection rate, response rate, downstaging at pathologic staging, two-year distant metastasis free-survival, disease-free survival, overall survival, safety results, surgical outcomes of facial nerve function, completeness of post-neoadjuvant surgery will be analyzed as the secondary objectives. The sample size was calculated using H₀ of mPR ≤25% and H₁ of mPR ≥50%, according to the one-arm binomial model (power of 90% and one-sided alpha of 0.05). A total of 50 patients will be recruited, include 40 evaluable patients. This study is currently recruiting patients at Samsung Medical Center, South Korea. The first subject received treatment in Nov. 2022 and three patients received the treatment. The time point for the primary analyses is Q3.2025. (ONO-4538-X78). Clinical trial information: NCT05727410. Research Sponsor: None.

Phase 2 trial of three schedules of CUE-101 administered before surgery or chemoradiotherapy in HLA-A*0201 positive patients with HPV16+ OPSCC. *First Author: Jesse Meir Zaretsky, Washington University School of Medicine, Department of Medicine, Division of Oncology, St. Louis, MO*

Background: Patients with locally advanced HPV+ OPSCC have a favorable prognosis; however, 10-40% will experience disease recurrence after curative-intent therapy (CIT). 80-90% of cases are caused by HPV genotype 16. HPV16 E7 is a promising HPV target as there is little variation among isolates and high epitope affinities for HLA-A*0201 have been identified. HLA-A*0201 is the most common class I allele in the USA, expressed in 40-50% of people of European descent. We aim to lower the recurrence rate in these patients by activating tumor antigen-specific CD8+ T cells. CUE-101 is a novel fusion protein comprised of HLA-A*0201, an HPV16 E7 epitope (aa residues 11-20), a reduced affinity human IL-2 variant, and an effector attenuated human IgG1 Fc domain. In pre-clinical models, CUE-101 demonstrated selective binding, activation, and expansion of HPV16 E7₁₁₋₂₀-specific CD8+ T cells. In the murine TC-1 tumor model, a murine surrogate of CUE-101 (mCUE-101) increased the frequency of tumor-infiltrating E7-specific CD8+ T cells and improved survival. Animals that remained tumor-free rejected TC-1 tumors upon re-challenge, demonstrating functional immunologic memory. In an ongoing phase 1 trial (NCT03978689) of HLA-A*0201+ patients with recurrent HPV16+ OPSCC, CUE-101 was well tolerated, resulted in expansion of target HPV16 E7₁₁₋₂₀-specific CD8+ T cells, and showed durable disease control in some patients. In this Phase 2 trial (NCT04852328), CUE-101 will be administered to HLA-A*0201+ patients with HPV16+ OPSCC before CIT. The aims of the trial are to evaluate the safety, tolerability, and pharmacodynamic and immunologic activity of CUE-101 in these patients. **Methods:** This is a non-randomized Phase 2 trial of three schedules of CUE-101 administered before CIT to HLA-A*0201+ patients with HPV16+ OPSCC. HPV16 status of tumor will be assessed by PCR. Safety assessments will be performed, and blood and tumor samples collected, at baseline and after CUE-101 administration. Following CUE-101, CIT will be administered. Each schedule will enroll 10 patients. CUE-101 (4 mg/kg IV) will be administered 14 days (Schedule A), 14 and 7 days (Schedule B), or 7 days (Schedule C) before day 1 of CIT. If Schedule A is safe and tolerable, Schedule B and then C will commence. A schedule will be deemed safe and tolerable if ≤2 patients experience grade 3-4 TRAEs and/or treatment-related delays of >7 days from the planned date of CIT. Immunologic activity is defined as measurable observation of or increases in HPV16-specific T cells in post-CUE-101 blood and/or tumor samples, relative to baseline, as assessed by either ELISpot or tetramer staining and flow cytometry. Exploratory measures of immune activity will be assessed by single-cell RNAseq and immunofluorescence in tumor samples. A schedule will be considered active if immunologic activity is observed in ≥3 patients. Clinical trial information: NCT04852328. Research Sponsor: Cue Biopharma, Inc.

A single-arm, multi-institutional, phase 2 study of a pembrolizumab-based organ preservation strategy for locally advanced larynx cancers: SMART-KEY (LACOG 0720) trial. *First Author: Thiago Bueno Oliveira, A.C. Camargo Cancer Center, São Paulo, Brazil*

Background: Standard treatments for locally advanced larynx cancers include concurrent cisplatin/radiation therapy, or induction chemotherapy followed by radiation therapy alone, with the goal of organ preservation. Both strategies have been shown to achieve similar laryngectomy-free survival (LFS), but failed to improve overall survival (OS) compared with radiation therapy alone or surgery followed by radiation therapy. Although cisplatin given concurrently with radiation therapy is commonly used for organ preservation, there are concerns regarding long-term outcomes, such as late toxicities. Pembrolizumab with chemotherapy has been shown to improve OS in recurrent/metastatic head and neck squamous cell carcinomas (HNSCCs). Additionally, pembrolizumab combined with radiation therapy has been shown to be safe in locally advanced HNSCC. LACOG 0720 is designed to evaluate a pembrolizumab-based, cisplatin-free, and concurrent chemoradiation therapy-free regimen for larynx preservation, in an attempt to improve outcomes and avoid late toxicities. **Methods:** LACOG 0720 is a phase 2, single-arm, multicentric trial assessing patients with newly diagnosed squamous cell carcinoma of the larynx (glottic or supraglottic) and clinical stages III, IVA, or IVB (AJCC 8th Ed.). Patients with large volume T4 disease (invasion through the cartilage or extension > 1 cm to the base of the tongue) or T1 disease are excluded. Patients receive 3 cycles of induction chemo-immunotherapy (carboplatin AUC6, paclitaxel 175 mg/m², and pembrolizumab 200 mg, IV every 21 days [q21D]), followed by concurrent radioimmunotherapy (Intensity-modulated radiation therapy with pembrolizumab 200 mg IV q21D for 3 cycles), followed by consolidation immunotherapy (pembrolizumab 200 mg IV q21D for 11 cycles). The primary endpoint is two-year LFS rate. Secondary endpoints include two-year larynx dysfunction-free survival, OS, overall response rate, short-term and long-term toxicities, causes of death, patterns of failure, and quality of life. Predictive biomarkers of response and survival will be evaluated as exploratory analysis. The sample size was calculated based on the primary endpoint. Using the Chi-square Test for One Proportion and considering a one-sided 10% significance level, 39 patients are needed to achieve 80% power to detect the difference between the null hypothesis; that the true laryngectomy-free survival at two years is 59%, and the alternative hypothesis that the laryngectomy-free survival at two years is 75%. From Feb 2022 to Feb 2023, 24 patients were enrolled in 10 Brazilian centers. Results are expected in July 2024. NCT04943445. Clinical trial information: NCT04943445. Research Sponsor: Merck & Co.; Merck Sharp & Dohme (MSD).

Response-adapted therapy for locally advanced nasopharyngeal carcinoma based on clinical response and circulating Epstein-Barr virus DNA level post induction chemotherapy. *First Author: Chaosu Hu, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: For locally advanced nasopharyngeal carcinoma (NPC), the mainstay treatment is cisplatin-based concurrent chemoradiation (CCRT). Recent phase III clinical trials have demonstrated that induction chemotherapy (ICT) plus CCRT, compared with CCRT alone, further improved progression-free survival (PFS). However, not every patient has good response to ICT. Evidence has accumulated that those with poor response to ICT, or those with detectable Epstein-Barr Virus (EBV) DNA post ICT, correlated with poorer PFS. In addition, real-time monitoring of plasma EBV DNA response adds prognostic information, and has the potential utility for risk-adapted treatment intensification in NPC. The aim of this study is to clarify whether response-adapted strategy based on clinical efficacy and EBV DNA response confers survival benefit to patients with locally advanced NPC. **Methods:** This is an open-label, 3-arm, phase II study. Patients with pathologically confirmed, locally advanced NPC (III-IVA, excluding T3N0M0, 8th AJCC staging system), with pretreatment detectable plasma EBV DNA level and ECOS PS 0-1 were eligible. Patients will receive one cycle of GP-based ICT. After one cycle of ICT, plasma EBV DNA and head and neck MR are performed. Based on clinical efficacy (evaluated per RECIST 1.1 criteria) and changes of plasma EBV DNA after one cycle, patients will be divided into three arms. Patients with good response (Arm A: Early Responders, undetectable EBV DNA level and CR/PR) will directly receive CCRT. Patients with intermediate response (Arm B: Intermediate Responders, detectable EBV DNA and CR/PR/decreased SD; or undetectable EBV DNA yet without CR/PR) will be randomized to experiment subgroup (GP combined with Toripalimab for two additional cycles then CCRT and maintenance Toripalimab treatment) and standard subgroup (GP for two additional cycles then CCRT). Patients with poor response (Arm C: Treatment Resistant, increased EBV DNA level, or PD/enlarged SD) will be switched to TP regimen combined with Toripalimab, followed by CCRT and maintenance Toripalimab treatment. Sample size calculation is based on 2-year PFS rate for arm B as the primary endpoint (one-sided $\alpha = 0.10$, power = 0.80). Our target sample size is estimated to be 198-240, among them 168 for arm B. Secondary endpoints include adverse events determined by CTCAE v5.0, ORR at 3 months post-CRT, 2-year locoregional recurrence-free survival (LRFS) rate, 2-year distant metastasis-free survival (DMFS) rate, 2-year overall survival (OS) rate, as well as quality of Life for arm B. Exploratory endpoints include 2-year PFS rate, LRFS rate, DMFS rate, OS rate, ORR at 3 months post-CRT, adverse effects, and quality of life for arm A and arm C. This trial opened to accrual in July 2022 and the recruitment is ongoing. Clinical trial information: NCT05628922. Research Sponsor: Shanghai Junshi Biosciences Co., Ltd.

Poster Session

CCTG HN11: SPECT-CT guided elective contralateral neck treatment (SE-LECT) for patients with lateralized oropharyngeal cancer—A phase III randomized controlled trial. *First Author: John R. de Almeida, University Health Network, Toronto, ON, Canada*

Background: Lymphatic mapping identifies neck lymph nodes at risk for cancer spread in patients with lateralized oropharyngeal (OPC) squamous cell carcinoma. We hypothesize that a lymphatic mapping guided approach to radiotherapy (RT) treatment of the contralateral neck will enable safe de-escalation of therapy with acceptable disease control with potential benefits in RT related toxicity, QOL, swallowing function and economics. **Methods:** HN.11 is a Canadian Cancer Trials Group international multi-centre, non-inferiority randomized phase III trial comparing a lymphatic mapping-guided approach for management of the contralateral neck (experimental) vs. bilateral neck radiation therapy (RT) (control). The primary objective is to determine if a lymphatic mapping-guided approach for management of the contralateral neck has a non-inferior disease-free survival (DFS) compared to bilateral neck RT. Secondary objectives: To compare swallowing related QOL, xerostomia, isolated contralateral neck failure, overall survival, loco-regional failure, distant metastases, RT-related toxicities, patient reported adverse events (PRO CTCAE), gastrostomy tube usage, and economics indicators (resource utilization, lost productivity, financial toxicity, EQ5D). Exploratory objectives: Swallowing function using video fluoroscopic swallow studies, head and neck-cancer specific QOL, patterns of lymphatic drainage, radiomic prediction of contralateral lymphatic drainage, correlation of tumour somatic mutations and ctDNA with disease recurrence. **Statistical Design:** The target sample size is 510 patients. The experimental arm will be considered non-inferior if the upper limit of the one sided 95% confidence interval (CI) of the estimated hazard ratio (HR) does not exceed 1.46 (non-inferiority margin of 6.5% for 2-year DFS). In the primary intention-to-treat (ITT) analysis, the study has 81% power, with a one-sided type I error rate of 5%, assuming 5 years of accrual, 3-years of follow up to observe 178 DFS events, and a 5% loss to follow up. If non-inferiority is demonstrated in the ITT analysis, a secondary per-protocol analysis will be performed, analyzing those patients treated as per their allocation, with 80% power to detect non-inferiority of the experimental arm assuming a conservative 10% cross-over from the experimental to the control arm (i.e. failed lymphatic mapping). **Conduct to Date:** Study activation September 29, 2022. First enrollment was February 10, 2023. Supported by Canadian Cancer Society, Canadian Institutes of Health Research, National Cancer Trials Network (NCTN). Clinical trial information: NCT05451004. Research Sponsor: Canadian Cancer Society, Canadian Institutes of Health Research, National Cancer Trials Network (NCTN).

KEVLAR: A phase 2b, multi-institutional, randomized, blinded, controlled trial to assess the safety and efficacy of two schedules of RRx-001 vs. standard of care in attenuating severe oral mucositis (SOM) in patients receiving concomitant chemoradiation (CRT) for the treatment of locally advanced squamous cell carcinomas (SCC) of the oral cavity (OC) or oropharynx (OPC). *First Author: Tony R. Reid, EpicentRx, Inc., La Jolla, CA*

Background: The results of an open-labeled Phase 2a trial suggested that infusion of RRx-001 (bromonitroazidine), a nitrogen-containing NLRP3 inhibitor and Nrf2 activator, attenuated the course and severity of SOM associated CRT (cisplatin/IMRT) in cancers of the mouth or OPC without impeding tumor response. The primary efficacy objectives of KEVLAR are to replicate the findings of the earlier trial and to determine if a higher dose of RRx-001 (8 mg x 4 doses prior to CRT) will favorably impact overall SOM incidence. **Methods:** KEVLAR is a planned Phase 2b study to be conducted at about thirty sites in North America. Approximately 216 patients with pathologically confirmed SCCs of the OC or OPC will be randomized equally into one of 3 cohorts: Arm 1 will receive RRx-001, 8 mg/dose infusions twice weekly during the 2 weeks prior to CRT start; Arm 2 will receive RRx-001, 4 mg/dose in the same schedule; Arm 3 will receive best supportive care only. All patients will receive intensity modulated radiation therapy (IMRT) in 2.0-2.2 Gy fractions/weekday to a cumulative radiation dose of up to 72 Gy. CRT must include cisplatin administered either weekly (40 mg/m²) or tri-weekly (100 mg/m²). Radiation fields must include at least two oral sites at SOM risk planned to receive at least 55 Gy. Mucositis indicators will be assessed twice weekly by trained evaluators. OM will be scored centrally using WHO criteria from the first day of CRT until resolution of ulcerative OM (WHO grade ≤ 1). Adverse events will be evaluated using NCICTCv5 criteria. Patients will be followed for 24 months post the last day of radiation and tumor response will be recorded quarterly using RECIST criteria. Research Sponsor: None.

Randomized phase I/II trial of TheraT vectors expressing HPV16 specific antigens with neoadjuvant chemotherapy followed by transoral robotic surgery (TORS) or risk/response stratified chemoradiotherapy (CRT) for locoregional HPV16+ oropharyngeal cancer (OPC). *First Author: Ari Rosenberg, Department of Medicine, University of Chicago, Chicago, IL*

Background: HPV+ OPC is associated with excellent survival, yet standard therapy leads to substantial treatment-related toxicity. Among various de-escalation strategies, response adaptive de-escalation which selects pts based on neoadjuvant response is promising with excellent survival and reduced toxicity. Strategies to further deepen responses may allow more pts to be de-intensified which may improve survival and further reduce toxicity. As generation and maintenance of the HPV16+ malignant state of a cell requires the consistent expression of HPV-specific E7 and E6 oncoproteins, they represent a potential immunotherapy target, inspiring the development of HPV-specific immune activators, such as HB-200 platform. This platform contains two replicating live-attenuated vectors based on either lymphocytic choriomeningitis virus (HB-201) or Pichinde virus (HB-202), which express the same non-oncogenic (but highly antigenic) HPV16 E7E6 fusion protein and infect antigen presenting cells to induce and activate tumor-specific T cell responses. Data from in vivo models and early phase clinical studies indicate that HB-201 monotherapy and HB-201/HB-202 alternating two-vector therapy induces a robust antigen-specific circulating T cell response and anti-tumor activity, suggesting potential to provide therapeutic benefit to pts with HPV16+ OPC. Based on these studies we hypothesized that incorporation of the HB-200 platform with neoadjuvant chemotherapy followed by risk/response-stratified de-escalation in our ongoing randomized phase I/II study may deepen responses and facilitate de-escalation in a greater proportion of pts (NCT05108870). **Methods:** Eligible pts must have previously untreated HPV16+ OPC with T3-4 or N2-3 (AJCC-7th edition). Very low-risk disease with T1-2 and N0-1 are excluded. Pts receive neoadjuvant therapy with either HB-201 or HB-201/HB-202 alternating two-vector therapy for 3 doses in combination with carboplatin AUC 5 day 1 and paclitaxel 100mg/m² on days 1/8/15 of 21-day cycle for three cycles followed by risk/response adapted locoregional therapy with transoral robotic surgery (TORS) or RT to 50Gy (single-modality), CRT to 50Gy with cisplatin (intermediate de-escalation), or CRT to 70Gy with cisplatin (regular dose CRT). Eight pts have been enrolled in phase I portion with planned 74 pts (37 pts per arm) in phase II. The primary endpoint is deep response rate defined as proportion of patients with ≥ 50 shrinkage per RECIST v1.1. Secondary endpoints include OS, PFS, locoregional and distant control, and safety/tolerability. Exploratory analyses will include cell free HPV-DNA, and tissue/blood-based assessment of specific anti-tumor immunity. Clinical trial information: NCT05108870. Research Sponsor: Hookipa Pharma.

Phase 2 study of bintrafusp alfa in recurrent/metastatic olfactory neuroblastoma. *First Author: Dara Mark Bracken-Clarke, Center for Immuno-Oncology, CCR, NCI, NIH, Bethesda, MD*

Background: Olfactory neuroblastoma (ONB, esthesioneuroblastoma) is a rare malignant tumor of the nasal cavity, believed to arise from the basal cells of the olfactory neurosensory epithelium. ONB is often locally advanced at diagnosis with high rates of spread both locoregionally and systemically. Current therapy for locoregional disease is local resection with adjuvant (chemo-) radiotherapy. Actionable mutations are rare, and treatment options for recurrent or advanced, non-resectable, disease are limited and include off-label combination chemotherapy (most frequently platinum-containing) and somatostatin-directed therapies (ONB expresses somatostatin receptors). These are based on limited data, with response rates poorly characterized. Bintrafusp alfa is a first-in-class, bi-functional TGF- β "trap"/anti-PD-L1 fusion protein. Analysis of ONB has demonstrated both PD-1/PD-L1 (London et al, 2018) and TGF- β ligand expression (Romani et al, 2021). Pre-clinical and clinical data in advanced solid tumors demonstrate enhanced antitumor activity with combination PD-L1/TGF- β blockade, with responses observed independently of high PD-L1 levels (Strauss et al, 2020). Thus, combination PD-L1/TGF- β blockade in ONB is a rational approach in a setting of unmet clinical need. **Methods:** This study is a Phase 2 single-site, single-arm clinical trial of bintrafusp alfa (1200mg IV every 2 weeks for up to 26 doses) for patients with recurrent or metastatic ONB. Participants must co-enroll to the ONB Natural History study at the NCI (NCT4755205). Patients must not be candidates for local therapy, have received at least 1 line of systemic therapy (including a platinum salt), have RECIST 1.1 measurable disease and have adequate organ function. Prior checkpoint inhibitor therapy is permitted with patients cohorted according to checkpoint exposure; up to 21 checkpoint-naïve and 8 checkpoint-resistant patients will be enrolled. The primary objective is objective response rate by RECIST 1.1 with secondary endpoints including safety and tolerability, duration of response and overall survival; exploratory endpoints include pharmacokinetic analyses, PD-L1 and immune cell correlative analyses. The trial follows a Simon two-stage design, requiring ≥ 1 response in the first 12 patients. Tumor biopsy at enrollment is optional. Imaging for response assessment is planned for 8-week intervals and PET scan (preferably ^{68}Ga -DOTATATE) will be obtained for all patients at baseline and first restaging, then on an individualized basis per radiology advice. This study is presently open at the NCI with 5 patients enrolled as of January 2023. Clinical trial registry: NCT05012098. Clinical trial information: NCT05012098. Research Sponsor: U.S. National Institutes of Health.

IMRT followed by pembrolizumab in the adjuvant setting in anaplastic cancer of the thyroid (IMPAACT): Phase II trial adjuvant pembrolizumab after IMRT in ATC. *First Author: Maria E. Cabanillas, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Anaplastic thyroid carcinoma (ATC) has historically been an almost uniformly rapidly fatal disease. In patients with loco-regional disease with no distant metastasis (stage IVB), and without a targetable mutation, a combination of external beam radiation delivered via intensity modulated techniques (IMRT) +/- concurrent cytotoxic chemotherapy is the current standard of care. However, the relapse rate is very high within the first year of diagnosis. Our data show that 90% of ATCs express PD-L1, with 43% having expression levels greater than 50%. A clinical trial with an anti-PD1 drug in ATC patients with active disease showed that patients with ATC had a response rate of 19%. Additionally, as tumor PD-L1 expression has been linked to radioresistance and there is a need to target micrometastatic disease, using adjuvant checkpoint inhibitor is a rational strategy in these patients. **Methods:** This is an open label, single center, phase 2 trial of adjuvant pembrolizumab after external beam radiation to the primary tumor in patients with stage IVB ATC. The primary cohorts will include those with gross, locoregional disease who have completed treatment with IMRT +/- concurrent radiosensitizing chemotherapy. Patients will be treated with adjuvant pembrolizumab (400mg IV Q6 weeks for up to 9 cycles), 2-6 weeks after completion of radiation. Patients will be enrolled based on dose of radiation in cohort 1 (high dose group, > 51 Gy), cohort 2 (palliative dose group, < 50 Gy). Cohort 3, consisting of those who underwent surgery followed by IMRT plus concurrent chemotherapy will be an exploratory cohort. Restaging scans will be performed every 12 weeks after enrollment. MRI brain will be repeated every 6 months in the absence of evidence of progression. The primary endpoint is median PFS (from the start of adjuvant pembrolizumab) in cohorts 1 and 2. Secondary endpoint is median overall survival in cohorts 1 and 2. Cohort 3 (5 patients) will have an exploratory endpoint, to estimate the median disease-free survival (DFS). Statistics: Survival analyses will be performed using the Kaplan-Meier method. Based on historical data, the median PFS for unresected patients is 6.8 months. For an expected improvement of median PFS by 3.7 months, with a combined total of 30 evaluable patients in cohorts 1 and 2, we anticipate having 80.0% power using 1-sided 10% alpha for a one-sample log rank test. The trial began enrollment in July 2022. This trial is sponsored by philanthropic funds and Merck. ClinicalTrials.gov ID NCT05059470. Clinical trial information: NCT05059470. Research Sponsor: Merck; Philanthropic funds.

Oral Abstract Session

Biologic indicators of donor socioeconomic disadvantage and recipient mortality following allogeneic hematopoietic cell transplantation. *First Author: Jennifer M. Knight, Medical College of Wisconsin, Milwaukee*

Background: Allogeneic hematopoietic cell transplantation (HCT) carries significant risks, with low socioeconomic status (SES) being predictive of increased mortality. Our team recently discovered that socioeconomic disadvantage among unrelated HCT donors results in decreased recipient overall survival (OS) and increased treatment-related mortality (TRM) within a cohort from the Center for International Blood and Marrow Transplant Research (CIBMTR). We also demonstrated that upregulation of the stress- and SES-related gene expression profile termed the ‘conserved transcriptional response to adversity’ (CTRA) is associated with low SES and worse outcomes among HCT recipients. Here, we hypothesize that donor immunologic characteristics associated with neighborhood socioeconomic disadvantage (CTRA) will confer prognostic risk to HCT recipients as indicated by inferior long-term recipient outcomes. **Methods:** Among a subset of the above cohort for which donor whole blood samples were available from the CIBMTR repository, we evaluated whether donor cell CTRA gene regulation was associated with inferior HCT outcomes at 3 years in recipients being treated for hematologic malignancy. Multivariable models adjusted for donor and recipient characteristics evaluated associations between donor CTRA and recipient OS, TRM, disease free survival (DFS), relapse, and acute and chronic graft versus host disease. Results were considered significant if $P < 0.05$. **Results:** We identified 263 donor-recipient pairs for study inclusion. Median recipient age at hematologic malignancy diagnosis was 53 years (range 19-77), 46% were female, and 54% had acute myeloid leukemia. Donors were 35% female and median age at donation was 31 years (range 18-60). In RNA sequencing data from HCT donors, greater CTRA expression was associated with reduced OS (covariate-adjusted $HR = 1.94/CTRA\ SD$, 95% CI [1.01, 3.71], $p = .046$) which was driven predominantly by increased TRM (adjusted $HR = 5.04$, [2.20, 11.50], $p = .0001$). These clinical outcomes are consistent with those observed to be associated with donor SES in our prior work. Donor cell effects on transplant outcomes derived predominantly from the pro-inflammatory component of the CTRA (OS: adjusted $HR = 1.67$, [1.20, 2.33], $p = .0026$; TRM: adjusted $HR = 2.21$, [1.21, 4.06], $p = .010$) and emerged above and beyond the effects of the recipients’ own SES, as well as multiple other recipient disease, treatment, and demographic factors. Donor CTRA was not associated with relapse, DFS, or other transplant outcomes. **Conclusions:** For the first time, we show that transcriptome patterning among HCT donors, consistent with neighborhood SES disadvantage, results in adverse recipient HCT outcomes. These findings suggest that SES has a biologic impact at either the stem or immune cell level that persists even when transplanted into a new host. Oral Abstract Session

Disparities in outcomes among hospitalized unhoused patients with cancer in the US. *First Author: Kanan Shah, NYU Grossman School of Medicine, New York, NY*

Background: Cancer is the 2nd leading cause of death among death among unhoused adults in the US. Use of aggressive medical interventions and costs during hospitalizations remains unstudied in the unhoused population. **Methods:** All hospitalized adults age ≥ 18 with a principal cancer diagnosis were identified in the 2016-2020 National Inpatient Sample (NIS). Logistic regression tested associations between unhoused status and: cost of care, mortality, and receipt of invasive procedures/systemic therapy. Adjusted analysis accounted for patient demographics, socioeconomic status, comorbidities, and effect modification of housing status by length of stay (LOS). **Results:** A total of 9,030 unhoused and 2,758,693 housed adults with cancer were included in the study. There were significant ($p < 0.01$) differences in age < 65 years (77% unhoused vs 41% housed), male sex (75% vs 53%), race (Black, 25% vs 13%; White, 58% vs 71%), and insurance type (Private, 6% vs 27%; Medicaid, 53% vs 11%). There were also differences by primary cancer diagnosis, with higher rates of lung (17% vs 14%) and liver (8% vs 3%) cancers. Unhoused persons received less chemotherapy inpatient (5% vs 7%) and fewer overall procedures (48% vs 58%), while experiencing longer LOS (median 6 vs 4 days). On adjusted analyses, unhoused adults were had lower odds of receiving invasive procedures (aOR [95%CI], 0.34 [0.27-0.42]) or systemic therapy (0.41 [0.20-0.85]); and were less likely to have a higher-than-median cost of stay 0.47 [0.39-0.57]). Additionally, unhoused adults were 35% and 20% less likely to have a higher-than-median cost of stay or die while hospitalized (95% CI 0.59 – 0.71 and 0.67 – 0.96, respectively). When accounting for the possibility of housing status being modified by LOS, unhoused persons remained significantly less likely than housed persons to receive inpatient procedures (aOR 0.38, 0.47, and 0.60 for short, medium, and long LOS, respectively; $p < 0.001$ for each) or have high cost of stay (adjusted OR 0.55, 0.71, 0.70, $p < .001$ for each), though the differences by housing status were attenuated with longer length of stay. **Conclusions:** In this first nationwide analysis of hospitalizations among unhoused adults with cancer, unhoused patients remained significantly less likely to receive invasive procedures or systemic therapy. These disparities in inpatient management despite the higher prevalence of more aggressive cancers and comorbidities among the unhoused highlight missed opportunities to improve cancer care. Oral Abstract Session

Evaluation of potential socioeconomic and racial/ethnic disparities in all-cause mortality in adolescent and young adult patients with cancer. *First Author: Scott Henderson, Kaiser Permanente Bernard J. Tyson School of Medicine, Pasadena, CA*

Background: Adolescent Young Adult (AYA) cancer patients, aged 15-39, have historically been understudied. For older adults, socioeconomic (SES) and racial/ethnic disparities in mortality have been demonstrated, but less is known about survival disparities for AYA patients. Most existing studies do not account for the influence of insurance status and access to care. To address this gap, we evaluated the association of SES and race/ethnicity with overall mortality for AYA cancer patients who were members of an integrated health delivery system with relatively equal access to care. **Methods:** Patients diagnosed with cancer at age 15-39 years old in Kaiser Permanente Southern California between 2010-2018 were included. The fourteen most common AYA cancer types within our cohort were included (excluding thyroid cancer due to low mortality rate). The Neighborhood Deprivation Index (NDI) was used as a marker of SES. Patients were placed into NDI quartiles (Q1: least deprived-Q4: most deprived). Mortality rate per 1,000 patient years was calculated for each racial/ethnic group and NDI quartile. Multivariable cox model was used to estimate hazard ratios (HRs) for all-cause mortality. Models included race/ethnicity and NDI subgroup simultaneously, adjusting for sex, age and stage at diagnosis, and cancer type. **Results:** A total of 6,380 patients (59% female, median age: 33) were followed for a maximum of ten years. Racial/ethnic distribution was 45% Hispanic, 36% non-Hispanic White, 10% non-Hispanic Asian/Pacific Islander, 7% non-Hispanic Black, 2% Other/Unknown. Overall mortality was 21.8 deaths per 1,000 person years. Crude mortality rates were higher among Non-White racial/ethnic groups (Asian/Pacific Islander: 26.7, Black: 26.2, Hispanic: 25.6, Other/Unknown: 30.3) compared to White patients (16.4). In the adjusted model, Hispanic ($HR = 1.32$, 95% confidence interval [CI] 1.03-1.50, $p = 0.004$) and Black ($HR = 1.35$, 95% CI 1.00-1.83, $p = 0.05$) patients experienced significantly higher risk of all-cause mortality compared to White patients. No mortality differences were observed between Asian/Pacific Islander and White patients. Patients from more deprived neighborhoods had higher mortality risk (Q1: 19.9, Q2: 19.8, Q3: 24.1, Q4: 27.4). In the adjusted model, there was no significant difference in all-cause mortality between Q1 and Q2-Q4 [Q2 ($HR = 0.88$, 95% CI 0.71-1.10), Q3 ($HR = 0.94$, 95% CI 0.75-1.17), Q4 ($HR = 0.96$, 95% CI 0.76-1.22)]. **Conclusions:** Our study suggests that for insured AYA cancer patients with similar access to care, Hispanic and Black patients have increased risk of all-cause mortality as compared to White patients, while no significant SES survival disparities were observed. These findings warrant further investigation, awareness, and intervention to address inequities in cancer care among vulnerable populations. Research Sponsor: None.

Oral Abstract Session

Risk of early mortality in patients with cancer experiencing adverse financial events. *First Author: Hiba Khan, University of Washington/Fred Hutch Cancer Center, Seattle, WA*

Background: Patients with cancer are at higher risk for experiencing severe adverse financial events (AFE) compared to similar individuals without cancer. Among persons with cancer, those experiencing bankruptcy have poorer survival. In this study, we sought to determine whether AFEs less severe than bankruptcy have an increased risk of death among patients with cancer. **Methods:** Records for all patients diagnosed with a solid tumor between 2013 and 2018 were identified through the Western Washington State SEER cancer registry and were linked to quarterly credit reports from TransUnion. Patients who survived at least 2 years from date of diagnosis were included. Cancer patients experiencing any AFE, defined as third-party collections, charge-offs, delinquent mortgage payments, tax liens, foreclosures, and reposessions within 2 years of diagnosis were compared with cancer cases who did not experience these events. After adjusting for age, sex, race, area deprivation index, rural/urban status, marital status, AFE at diagnosis, cancer type, and stage of cancer, we fit a Cox proportional hazards model to examine the relationship between AFEs and overall survival, and also fit a separate model for each cancer type. **Results:** A total of 64,637 patients were diagnosed with cancer between 2013 and 2018, and survived 2 years post-diagnosis. The overall population was 84% white, 53% female, and had a median age of 64. 12,698 patients experienced any severe financial event. The adjusted hazard ratio for mortality among patients who did versus did not experience an AFE was 1.22 (95% CI, 1.145-1.299, $p < 0.001$), with age > 65 , Asian/Pacific Islander race, greater area deprivation index, and higher stage of cancer associated with increased risk for mortality. Among differing cancer types, patients with prostate cancer who experienced an AFE had the highest risk of death compared with patients with prostate cancer who did not experience an AFE ($HR\ 1.703$, 95% CI, 1.395 to 2.08, $p < 0.001$). **Conclusions:** Patients with cancer who experience severe AFEs within 2 years of diagnosis are at higher risk for mortality after adjusting for sociodemographic and clinical factors. When comparing within separate cancer groups, this association is strongest among patients with prostate cancer. Current analysis is limited by restricting population to those who survived at least 2 years after diagnosis; future work will expand population to include patients who died at any time point. Further research should investigate mechanisms for this increased mortality risk, to inform potential interventions and policy solutions, especially among the prostate cancer population. Research Sponsor: Kathryn Butler Foundation, Texas 4000 Foundation.

Cancer Type	HR	95% CI	p value
All	1.22	1.145 to 1.299	<0.0001
Prostate	1.703	1.395 to 2.08	<0.0001
Breast	1.18	0.993 to 1.403	0.0606
Colorectal	1.172	0.984 to 1.397	0.0759
Lung	1.169	0.998 to 1.37	0.0533
Other	1.149	1.049 to 1.259	0.0027

Oral Abstract Session

Health insurance continuity and survival among children, adolescents, and young adults with blood cancer: An analysis based on SEER-Medicaid data.

First Author: Xu Ji, Emory University School of Medicine, Atlanta, GA

Background: Many previously uninsured patients do not receive Medicaid coverage until the point of, or after, cancer diagnosis, which may delay access to life-saving therapies. We examined whether continuous Medicaid coverage prior to diagnosis (vs. gaining Medicaid at, or after, diagnosis) provides a survival benefit in children and adolescents/young adults (AYAs) newly diagnosed with blood cancer. **Methods:** Using the linked SEER cancer registry-Medicaid enrollment data, we assessed coverage during the six months prior to, the month of, and the six months after cancer diagnosis (13-month window) in 29,873 children and AYAs (aged 0-39 years) diagnosed with blood cancer in 2006-2013. To measure insurance continuity, we categorized patients who had: (1) continuous Medicaid (enrolled for ≥ 6 months prior to through diagnosis), (2) newly gained Medicaid at/after diagnosis (enrollment only at or ≤ 6 months after diagnosis), (3) other patterns of non-continuous Medicaid, (4) private insurance, (5) other insurance, or (6) uninsured/unknown insurance. The last three groups contain patients in SEER not linked to Medicaid enrollment data; these patients' insurance at diagnosis was available in SEER. Kaplan-Meier (KM) survival curve of 5-year overall survival was stratified by insurance continuity category. Associations between insurance continuity and survival were examined using Cox proportional hazard models, for all blood cancers combined and by cancer type (leukemia, lymphoma, myeloma). Models also adjusted for age, sex, race/ethnicity, rurality, neighborhood socioeconomic status, and diagnosis year. **Results:** Of our sample, 44.1% had private insurance, followed by Medicaid (28.3%), other insurance (9.6%), and no insurance (3.9%) or unknown insurance (14.1%). Of Medicaid-insured patients, 44.9% had continuous Medicaid, 38.9% gained Medicaid at/after diagnosis, and 16.2% experienced other noncontinuous patterns. The KM-estimated 5-year survival probability was 89.3% for privately insured patients, followed by other insurance (88.1%), continuous Medicaid (78.2%), other patterns of noncontinuous Medicaid (74.3%), and newly gained Medicaid at/after diagnosis (70.6%; $p < 0.001$). In multivariable analysis, patients who newly gained Medicaid at/after diagnosis had a hazard ratio (HR) for death of 2.63 (95%CI=2.42-2.87), whereas patients with continuous Medicaid and those with other noncontinuous patterns had HRs of 2.08 (95%CI=1.90-2.28) and 2.31 (95%CI=2.04-2.60), respectively, compared to privately insured patients. This finding persisted across blood cancer types. **Conclusions:** Less than half of Medicaid-insured children and AYAs with blood cancer had continuous insurance coverage prior to and following cancer diagnosis. Lacking continuous Medicaid coverage was associated with inferior survival. Research Sponsor: The Leukemia & Lymphoma Society.

Oral Abstract Session

Association of medical debt and cancer mortality in the US. First Author: Xin Hu, Emory University School of Public Health, Atlanta, GA

Background: Medical debt is associated with non-medical and medical financial hardship, such as food and housing insecurity, as well as delaying or forgoing recommended health care. This study examines county level associations between medical debt and cancer mortality in the US. **Methods:** We conducted a county level ecological study, using 2018 medical debt data from the Urban Institute linked with 2015-2019 mortality data from the National Centers for Health Statistics. All US counties with non-missing information on medical debt and other covariates were included. Primary outcomes were age-adjusted mortality rates per 100,000 person-years for all malignant cancers and by cancer type. Multivariable linear mixed models were used to estimate the association of percent of population with medical debt with cancer mortality, adjusting for county level sociodemographic characteristics. Additional analyses examined the association between median amount of medical debt per person and cancer mortality for the subset of counties with these data. Models were weighted by county level population size, with standard errors clustered at the state level. **Results:** Among 2,943 counties, an average of 19.8% of the population had medical debt, ranging from 0% to 53.6% across counties. Higher percentages of the population with medical debt were observed in non-metro areas, counties with higher percentages of non-Hispanic Black people, adults without high school education, living below poverty level, uninsured, or unemployed. One percentage point increase in the population with medical debt was associated with a 1.12 (95% CI=1.02-1.22) increase in age-adjusted mortality rate (per 100,000 person-years) for all malignant cancers, a 0.47 (95% CI=0.43-0.52) increase for lung cancer, a 0.09 (95% CI=0.07-0.11) increase for colorectal cancer, and a 0.06 (95% CI=0.04-0.07) increase for female breast cancer. Among 1,949 counties with the amount of medical debt available, each \$100 increase in median medical debt was associated with a 0.86 (95% CI=0.52-1.21) increase in age-adjusted mortality rate for all malignant cancers. Associations between increases in median medical debt and increased mortality rates were statistically significant for major cancer types. **Conclusions:** Medical debt is associated with significantly higher cancer mortality at the county level. Policies increasing access to affordable health care may improve cancer outcomes. Research Sponsor: None.

Association of medical debt and age-adjusted mortality rates.

Cause of Death	Any Medical Debt	Median Medical Debt, in hundreds
All malignant cancers	1.12 (1.02, 1.22)	0.86 (0.52, 1.21)
Lung and bronchus	0.47 (0.43, 0.52)	0.33 (0.18, 0.47)
Prostate	0.03 (0.02, 0.04)	0.03 (-0.002, 0.07)
Female breast	0.06 (0.04, 0.07)	0.05 (0.01, 0.09)
Colorectal	0.09 (0.07, 0.11)	0.06 (0.01, 0.11)

* Adjusted for county level education, racial/ethnic composition, metro status, uninsured and unemployment rates.

Oral Abstract Session

The impact of single gene testing (SGT) on subsequent comprehensive genomic profiling (CGP) success in community oncology practice for advanced non-small cell lung cancer (NSCLC): Results from a prospective observational reference laboratory testing program. First Author: Mary K Nesline, Labcorp Oncology, Durham, NC

Background: CGP concurrently tests tumor tissue for guideline-recommended predictive biomarkers for optimal therapy selection and identification of clinical trials in NSCLC patients. A common practice in the community oncology setting is to first order SGT, then consider CGP when SGT results are negative or after treatment failure. Given the limited tissue available and the scope of alterations not tested by SGT, we sought to characterize the effects of prior SGT on subsequent CGP testing success, and therapeutic opportunities identified by CGP beyond SGT for NSCLC patients in the community setting. **Methods:** Reference laboratory information systems were used to prospectively contact clinicians across 80 community practices who ordered at least 1 SGT for guideline-recommended genomic variants in NSCLC. CGP was offered for their patients prior to SGT or upon receipt of negative SGT results. SGT included individual assays for *BRAF*, *EGFR*, *KRAS*, *MET* exon 14 skipping mutations; *ALK*, *RET*, and *ROS1* rearrangements; and PD-L1 IHC. CGP included DNA-seq for mutations, copy number variants in 523 genes including guideline-recommended genomic variants, MSI, and tumor mutational burden; RNA-seq for rearrangements/fusions/splice variants; and PD-L1 IHC. **Results:** Among a total of 580 NSCLC patients with CGP ordered (May 2021-December 2022), 168 (29%) had ≥ 1 SGT ordered prior to CGP (median=5). No patients had all SGT performed, with untested cases ranging from 10% for *ALK* to 90% for *MET* exon 14. The same FFPE tissue block was used for CGP in 150/168 (89%) of cases with prior negative SGT. Compared to CGP-only cases, CGP for cases with prior negative SGT was canceled twice as often at tissue review (16% vs 7%; $p=0.01$), had higher DNA extraction failures (13% vs 8%; $p=0.09$), and lower DNA sequencing success (70% vs 83%, $p<0.001$). CGP detected guideline-recommended variants in 51% of all cases. Among prior negative SGT cases, frequencies were higher in genes where SGT was performed less often and is less sensitive than CGP RNA-seq (*RET* fusions, *MET* exon 14 skipping). CGP also identified guideline-recommended variants in genes with no SGT offered during the study period (*ERBB2* mutations, *NTRK2/3* fusions), as well as variants with emerging evidence for FDA expedited program-designated clinical trial therapies in 28% of patients, including *NRG1* fusions and *BRAF* non-V600E, *KEAP1*, *KRAS* non-G12C, *NFE2L2*, *STK11*, and TP53 Y220C mutations. **Conclusions:** Prior negative SGT doubled subsequent CGP test cancellations for NSCLC due to tissue insufficiency and increased CGP DNA extraction failures. SGT practice in the community oncology setting does not meet practice guideline recommendations and negatively impacts the potential benefit of subsequent CGP for NSCLC patients. Research Sponsor: Eli Lilly and Company.

Oral Abstract Session

Clinical value of timely targeted therapy (TT) for patients with advanced non-small cell lung cancer (aNSCLC) with actionable driver oncogenes (ADO). First Author: Thomas Stricker, Tennessee Oncology, Nashville, TN

Background: Recent real-world studies observed that some aNSCLC pts with ADO initiated non-targeted therapy (non-TT) before biomarker test results became available. This study assesses the clinical impact of the timing of first line (1L) TT in aNSCLC pts with ADO. **Methods:** In a retrospective analysis of the nationwide Flatiron Health electronic health record-derived de-identified database, pts aged ≥ 18 years, diagnosed (Dx) with aNSCLC between 1/1/2015-10/18/2022, had ADO (*ALK*, *BRAF*, *EGFR*, *RET*, *MET*, *ROS-1*, or *NTRK*) based on biomarker testing ≤ 90 days of advanced Dx, and received 1L treatment (tx) were included. Cohorts were defined by tx patterns after test result: Cohort 1 received 1L TT ≤ 42 days; Cohort 2 initiated 1L non-TT before or after testing but switched to TT ≤ 42 days; Cohort 3 initiated non-TT before or after testing and did not switch to TT ≤ 42 days. Pts were followed from test results + 42 days until 11/30/2022 or death, whichever earliest. Multivariate Cox regression evaluated real-world progression-free survival (rwPFS) and overall survival (OS) between cohorts. **Results:** A total of 5156 aNSCLC pts with ADO were included: 79% were treated in the community setting and 56% received NGS testing. Most common ADO were *EGFR* and *ALK* for both Cohort 1 (78% and 13%) and Cohort 2 (67% and 24%); *EGFR* (39%) and *BRAF* (35%) for Cohort 3. Cohort 3 included more rare mutations (*MET*, *NTRK*, *RET*). Statistically significant differences were observed in gender, race/ethnicity, practice type, and area-level socioeconomic status across all cohorts. There was no significant difference in outcomes observed between Cohort 2 and 1, but significantly inferior outcomes in Cohort 3 vs 1. **Conclusions:** Our findings demonstrated better outcomes with upfront 1L TT vs non-TT in aNSCLC pts with ADO. The comparable outcomes between pts who received 1L TT after test result and pts who switched to TT ≤ 42 days of test result available underscore the importance of timely tx decisions based on ADO detection in lieu of tx-switch at progression. Opportunities remain to improve utilization of NGS to identify all ADO upfront to inform the appropriate 1L TT when indicated. Research Sponsor: Genentech Inc./F. Hoffmann-La Roche.

Outcomes by tx pattern in aNSCLC pts with ADO.

	Median (95% CI) rwPFS, months	rwPFS adjusted Hazard Ratios (HRs)	Median (95% CI) OS, months	OS adjusted HRs

Oral Abstract Session

Practice- and provider-level inequities in next-generation sequencing (NGS) testing by race/ethnicity for patients (pts) with advanced non-small cell lung cancer (aNSCLC) treated in the community setting. *First Author: Gregory A. Vidal, The West Cancer Center, Germantown, TN*

Background: Inequities in NGS testing in pts with aNSCLC are well documented. Here, we examined elements of total inequity in NGS testing for pts with aNSCLC treated in the US community setting, in terms of within and between inequities at the practice and provider level. **Methods:** Using the nationwide, deidentified, electronic health record–derived Flatiron Health database, we studied pts with aNSCLC diagnosed in April 2018 or later and treated in the community setting. Testing quality was defined as an NGS result reported ≤60 days after advanced diagnosis. Total-practice inequity was the average percentage-point (pp) difference in the rate of testing quality for non-Latinx Black or Latinx pts compared with non-Latinx white pts. Within-practice inequity was the average pp difference in testing rates at a practice weighted by overall practice enrollment. Between-practice inequity was the covariance between a practice’s overall testing rate and the extent of practice-level racial/ethnic underrepresentation. We estimated these inequities at the practice and provider levels using a Bayesian approach. **Results:** Our study included a total of 12,045 pts (9,981 non-Latinx white, 1,528 non-Latinx Black, and 536 Latinx pts). Both within- and between-practice inequities contributed to total inequity in NGS testing for non-Latinx Black and Latinx pts compared with non-Latinx white pts (Table). For non-Latinx Black pts, between-practice inequities were estimated as 57% (3.77 pp/6.56 pp) of the total inequity in NGS testing; for Latinx pts, the contribution of between-practice inequity was 39% (3.13 pp/8.01 pp). At the provider level, between-provider inequities were the dominant contributor to total inequity in NGS testing for both non-Latinx Black and Latinx pts, accounting for 86% (5.88 pp/6.87 pp) of total provider-level inequity for non-Latinx Black pts and 64% (5.36 pp/8.43 pp) for Latinx pts. **Conclusions:** Inequities within and between practices, as well as between providers, are meaningful contributors to total inequity in NGS testing. Additional healthcare equity initiatives are needed to identify potential causes for lagging practices/providers to address inequities in NGS testing. Research Sponsor: Genentech Inc./F. Hoffmann-La Roche.

Average percentage-point difference in NGS testing inequity in Pts with aNSCLC.		
vs non-Latinx White pts (95% credible interval), %*	non-Latinx Black	Latinx
Practice level		
Total	6.56 (3.91, 9.17)	8.01 (3.81, 12.23)
Within	2.79 (–0.22, 5.72)	4.88 (–0.47, 10.18)
Between	3.77 (2.43, 5.13)	3.13 (–0.02, 6.24)
Provider level		
Total	6.87 (4.23, 9.46)	8.43 (4.17, 12.65)
Within	0.99 (–2.16, 4.11)	3.07 (–2.56, 8.56)
Between	5.88 (4.09, 7.65)	5.36 (1.73, 9.01)

* Negative values indicate higher NGS testing rate in non-Latinx Black or Latinx pts vs non-Latinx White pts.

Poster Discussion Session

How patient-clinician education can strengthen partnerships and promote tangible actions to improve clinical trial diversity in breast and lung cancer trials. *First Author: Tariqa Ackbarali, PlatformQ Health Education, Needham, MA*

Background: Some of the greatest disparities in cancer care are related to clinical trial access for our patients. To address the racial/ethnic disparities in breast and lung cancer clinical trials, a tethered educational initiative was designed to empower patients, assess current clinician perceptions/practices, and improve awareness of real-world perspectives of clinical trials. **Methods:** Two, one-hour online, interactive, video-based programs were designed for patients, caregivers, and providers. This patient/caregiver program was hosted on CancerCoachLive and MedLive in November, 2022, while the provider program was hosted on ClinicalSeriesLive in December, 2022 and will remain on-demand until December 2023. This initiative was conducted in collaboration with TOUCH, the Black Breast Cancer Alliance, BlackDoctors.org, Moffitt Cancer Center, CancerCare, and the Lung Cancer Research Foundation. Herein, we report on an analysis from patients and providers regarding clinical trial diversity, behavioral impact, and qualitative insights. **Results:** As of data cut-off (02/10/23), 1,425 participants have engaged across both educational programs. Of participating patients, 46% were non-White (non-Hispanic), 36% were in remission, 36% were not on active treatment, and 29% were newly diagnosed. Following the program 81% were motivated to take one or more actions over the next two months: the most common actions being to research clinical trials (38%) or discuss clinical trials with a clinician (19%). Post-activity, 79% were confident to very confident discussing clinical trials with a clinician. Critical data related to clinician preferences was assessed and demonstrated a 23% increase in confidence from pre- to post-activity in improving diversity in clinical trial participation with preferences observed in both breast and lung cancers to offer clinical trials for newly diagnosed and second recurrence settings. Of those who are being offered clinical trials in the community setting, there was a higher likelihood for patients to be offered a clinical trial if their subtype was HER2+ breast cancer subtype or NSCLC with an actionable mutation. Data collection continues as this initiative is ongoing. Qualitative data including clinician write-in examples of behavioral impact and patient perspectives from the interviews will be shared. **Conclusions:** The outcomes discussed herein reveal a willingness from patients/caregivers to engage in clinical trial discussions and participate in clinical trials, if eligible. These educational programs positively impacted clinician motivation to address barriers to enrollment and clinical trial eligibility with their patients. Real-world accounts of patient experiences provide different perspectives that can help improve approaches to improve clinical trial diversity. Strategies to increase accrual of underrepresented populations in Alliance NCTN trials. *First Author: Electra D. Paskett, The Ohio State University, Columbus, OH*

Background: Accrual of underrepresented populations (URPs-racial and ethnic minorities, women, rural populations, and younger and older populations) to clinical trials has been historically low, hampering progress in cancer treatment, symptom intervention and prevention for all. In 2018, the Alliance for Clinical Trials in Oncology (Alliance), as a part of the NCI’s National Clinical Trials Network (NCTN) and a Research Base for the NCI Community Oncology Research Program (NCORP) began a multi-pronged strategy to increase accrual of underrepresented minorities by race and ethnicity (URMs) to both treatment and cancer control trials conducted by the Alliance. **Methods:** Alliance leadership set a goal of 20% accrual for racial and ethnic minorities to all trials in 2018. The Health Disparities Committee (HDC) implemented several strategies over time including leadership promotion/expectation of goals; funding junior investigators and special projects focusing on URPs; working groups for specific populations in HDC; HDC co-chairs to selected protocols; translation services of patient facing materials; opening studies at NCORP Minority Underserved Sites; real time monitoring of accrual demographics, by Alliance and by site; protocols addressing aims for specific populations; closing protocol enrollment to majority populations; and increasing the study sample size to enroll additional minority participants to allow for analyzing intervention effects by subgroups. **Results:** Accrual data from 117 NCTN and NCORP trials led by Alliance was included from 2014-2022. Over time, accrual of racial and ethnic minorities increased from 13.6% to 25.3% for treatment and 13% to 21.5% for cancer control trials. This results in overall increase from 13.5 % to 23.6% of URMs for all trials, a 74.8% improvement. **Conclusions:** Intentional approaches to increase URMs has led to an increase in URM accruals to Alliance trials. Future strategies include implementation of the Alliance Patient Questionnaire to prospectively measure the prevalence of specific social determinants of health among patients enrolled to further expand the understanding and address the needs of unique population accrued to Alliance trials. In addition, accrual of women, rural populations, and younger and older adults (65+ years) are now being monitored over time to increase all URP accruals. Poster Discussion Session

Mediators of racial/ethnic inequities in clinical trial participation among US patients with cancer, 2011-2022. *First Author: Jenny Guadamuz, Flatiron Health, New York, NY*

Background: In 2024, the US Food & Drug Administration will require drug sponsors to implement plans to improve racial/ethnic diversity in clinical trials. While minoritized populations are less likely to participate in cancer trials, it is unknown whether social determinants of health (SDOH) explain these inequities. Here we identified SDOH factors that contribute to racial/ethnic inequities in clinical trial participation among patients with 22 solid and blood cancers. **Methods:** This retrospective study used the nationwide Flatiron Health electronic health record-derived de-identified database of adult patients with cancer (2011-2022). Area-level SDOH (e.g., predominant race/ethnicity [proxy for segregation]) contextualizing where patients live were defined using the American Community Survey tract data. Patients were followed from cancer-specific diagnosis to clinical study drug receipt (proxy for trial participation), death, or last recorded activity. Associations of race/ethnicity and SDOH factors on trial participation were assessed using Cox proportional hazards models adjusted for clinical factors (diagnosis year, age, sex, performance status, stage, and cancer type). To elucidate which SDOH explain racial/ethnic inequities, mediation analysis was performed using nonlinear multiple additive regression trees models. **Results:** This study included 233,556 patients (median age: 68 years, 50.0% women; 65.6% non-Latinx [NL] White, 8.5% NL Black, 5.0% Latinx). Black and Latinx patients were more likely to live in marginalized areas (i.e., disproportionately minoritized, low socioeconomic status, limited English proficiency, and low vehicle ownership) than White patients. Overall, 4.9% of patients participated in trials. Fewer patients from community practices or in marginalized neighborhoods participated in trials. Black (3.4%; hazard ratio [HR] 0.55, 95% confidence interval [CI]: 0.51- 0.60) and Latinx patients (3.6%; HR 0.57, CI: 0.52-0.63) were less likely to participate in trials than White patients (5.8%). Black-White trial inequities were substantially mediated (58%, CI: 47%-68%) by practice type (e.g., community vs. academic center, 13%, CI: 10%-15%) and area-level SDOH (e.g., segregation [33%, CI: 25%-44%] and vehicle ownership [12%, CI: 8%-15%]). Mediators explained 55% (CI: 38%-71%) of the Latinx-White trial participation inequity; area-level SDOH—including segregation (29%, CI: 13%-37%), limited English proficiency (15%, CI: 9%-25%), and vehicle ownership (8%, CI: 5%-12%)—were the most important mediators. **Conclusions:** SDOH factors, especially manifestations of structural racism such as segregation, explained a substantial proportion of racial/ethnic inequities in trial participation among patients with cancer. These findings can inform targeted efforts to increase racial/ethnic diversity in cancer trials. Research Sponsor: Flatiron Health.

Poster Discussion Session

Comparison of incident breast cancer cases in the largest national US tumor registries. *First Author: Jennifer Kay Plichta, Department of Surgery, Duke University Medical Center, Durham, NC*

Background: National tumor registries, such as the NCDB (National Cancer Database) and SEER (Surveillance, Epidemiology, and End Results Program), have been used to explore numerous research questions related to trends in disease incidence, treatment patterns, and outcomes. However, some have criticized that they may not fully represent the general population. As such, we sought to compare the incident breast cancer cases in the NCDB and SEER to a national population cancer registry. **Methods:** All patients diagnosed with malignant or in situ breast cancer 2010-2019 were selected from the NCDB (Fall 2022 release) and SEER-22 (November 2021 release) and compared to breast cancer patient counts from the US Cancer Statistics Public Use Database (USCS, 2021 submission). Patient frequencies were summarized by age, sex, race/ethnicity, and year of diagnosis. Percent case coverage was estimated as the number of patients in the NCDB or SEER divided by the number of patients in the USCS. Chi-square tests were used to compare patient counts across data sources. **Results:** In total, the USCS database reported 3,047,509 patients diagnosed with breast cancer between 2010-2019, of which, 77.5% (N=2,362,477) were included in the NCDB and 46.0% (N=1,403,272) in SEER. Over time, case coverage steadily improved for the NCDB (72.8% in 2010 to 81.5% in 2019), while only a minor increase was observed in SEER (46.0% in 2010 to 46.6% in 2019). When compared to the USCS, case ascertainment was notably lower for individuals age ≥ 50 in both the NCDB and SEER (both $p < 0.001$). The overwhelming majority of patients were captured by the NCDB (age < 50 : 81.7%; age ≥ 50 : 76.6%) while SEER identified approximately half (age < 50 : 49.4%; age ≥ 50 : 45.3%). Case ascertainment also varied significantly by patient sex across registries (both $p < 0.001$). For male breast cancers, 84.1% were captured in the NCDB, only 77.5% of female patients were included. In contrast, case coverage in SEER was better for females than males (46.1% vs 43.5%). Notably, registries varied significantly by race/ethnicity (both $p < 0.001$). Case coverage in the NCDB was highest for non-Hispanic White (78.2%), non-Hispanic Black (77.7%), and non-Hispanic Asian or Pacific Islander (72.5%) patients, and it was lowest for Hispanic (56.4%) and non-Hispanic American Indian/Alaska Native (41.1%). In SEER, case coverage was highest for non-Hispanic Asian or Pacific Islander (78.1%) and Hispanic (69.6%) patients, and it was considerably lower for all other subgroups (non-Hispanic Black 44.8%, non-Hispanic White 42.4%, and non-Hispanic American Indian/Alaska Native 36.6%). **Conclusions:** National US tumor registries provide data for a large sampling of breast cancer patients, and case coverage has improved over time. However, significant differences in case coverage were observed based on age, sex, and race/ethnicity, suggesting that analyses using these data sets should be interpreted with caution. Enhancement in line of therapy (LoT) derivation from real-world data (RWD) from electronic health records (EHR) via integration of medical claims data. *First Author: Smrita Agrawal, ConcertAI, Bengaluru, Karnataka, India*

Background: Clinical RWD derived from EHRs is becoming increasingly important for clinical research, trial design, regulatory decisions etc. These applications require identification of lines of therapy (LoT) which are typically not captured in EHR and must be abstracted from other clinical and medication data. EHR data has significant missingness which can be complemented with other data sources such as medical claims data. In this study, we demonstrate how our proprietary line of therapy algorithms for solid cancers show significant improvements when built using integrated EHR and claims data when compared to EHR data alone. **Methods:** For this analysis, ConcertAI's RWD360 dataset integrated with a large administrative open-claims dataset ($> 90\%$ overlap) for 14 solid cancer indications (Breast, Bladder, Lung, Prostate, Pancreas, Melanoma, Liver, Head & Neck, Renal, Colorectal, Melanoma, Ovarian, Thyroid, Endometrial) was used. The date of advanced/metastatic diagnosis used as the index date for LoTs was derived from the EHR data and medications from both EHR and claims data were used. We ran our LoT algorithms on EHR data with and without claims data and evaluated the impact of integrating claims data on the quantity and quality of LoT output. **Results:** The inclusion of medication data from claims significantly increased (7-22%) the number of patients for which LoTs could be extracted from the EHR data. Furthermore, we observed increases in number of lines per patient, length of lines and medications per line across cohorts. The distance between index date and 1st line start date was shortened in a subset (2-12%) of patients as a result. In a small fraction of cases, we even observed removal of false lines as some of the lines moved to adjuvant/neoadjuvant setting by filling in missing medication from claims. Overall, 7-39% patients in the LoT cohorts were impacted by addition of claims. Results for a few cancer types are presented in Table 1. We also compared the top LoTs derived from the integrated dataset against the standard of care for that cancer and observed very good concordance. **Conclusions:** Deriving LoTs by integrating data from multiple data sources such as EHR and claims can significantly improve its accuracy. Research Sponsor: None.

Impact analysis of claims integration on LoTs for 5/14 solid cancer cohorts.

Cancer Indication	Breast	Lung	Prostate	Pancreas	Renal
# Pts with LoTs before claims integration	49826	53961	24309	12584	6639
# Pts with LoTs post claims integration	54557	57806	27191	13631	7478
# Pts added due to addition of claims	5034	3960	3019	1066	866
# False positive pts removed due to claims integration	303	115	137	19	27
# Pts with enhanced LoTs	18104	5421	9417	1461	1733
# Pts with decrease in days between index date and LoT start date	3680	1318	3018	308	442
# Total pts impacted	23441 (47.1%)	9381 (17.6%)	12436 (51.7%)	2527 (20.2%)	2626 (39.5%)

Pts, patients.

Big data in oncology: Challenges and solutions. *First Author: Neil J. Shah, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Oncology care is complex and often multimodal. With recent technological advances, only a fraction of data is structured feasibly for research. Here we present a step-by-step method of building a novel comprehensive pan-cancer oncology data model using standard data definitions and industry-standard benchmarks. **Methods:** A team of 133 members was assembled including a project manager, bioinformatic engineers, business analysts, biostatisticians, data stewardship experts, clinical curators, and quality assurance (QA) managers. We first identified data domains that capture a comprehensive patient journey, leveraging existing oncology data models as a starting point, including NAACCR, PRISMM (Deb Schrag & Eva Lepisto), and mCODE (ASCO). A common data model was developed using standard terms plus 5-10 disease specific elements (DSE). REDCap was used as the database platform, as it is HIPAA compliant and allows customizations. The data was stored in AuroraDB using an architecture and products that provide scalability from both an integration and consumption perspective. **Results:** We identified 10 data domains, including 186 distinct elements: demographics (20), comorbidities (2); cancer diagnosis & staging (27), pathology (45), imaging (18), medications (11), oncology responses (11), radiation treatments (14), cancer surgeries (11), cancer genomic (19), tumor markers (8), and vitals (8). Standard ontologies were used, including ICD-O-3 histology codes, ICD-10 comorbidities codes, CPT cancer surgeries codes, and CTCAE 5.0 for toxicities. We identified a data steward for each tumor type across medical oncology, surgery, pathology, radiology, and radiation oncology domains who aided curator training and the identification of DSE. QA managers and analysts performed 20% source data verification. In addition, we built REDCap rules (applicable across a form), and complex queries (applicable across multiple forms). To support QA and clinical engagement, interactive Tableau dashboards were constructed. In addition, timing and quality errors were monitored via Tableau dashboards at the individual curator level to provide timely feedback, leading to improved data quality and curation efficiency in real time. The Medical oncology and radiology domains were the most time-consuming, whereas Cancer diagnosis was the most difficult to curate. **Conclusions:** We collected genomic and phenomic data for 15,579 patients across six tumor types to date. Collecting comprehensive oncology data across tumor types is possible but requires institutional support, collaboration between clinical & informatics teams, and a dedicated QA team. Research Sponsor: Memorial Sloan Kettering Cancer Center.

Tumor Type (15,579)	REDCap based rule (N)	Complex Queries (N)	Average time to complete a case (minutes)	Average number of forms per record
Lung (6,308)	224	66	196	50
Sarcoma (2,862)	228	50	269	56
Prostate (2,252)	134	50	346	72
Bladder (1,427)	198	54	235	60
Kidney (1,197)	227	61	193	58
Uterine (1,533)	224	48	123	42

End-of-life spending analysis of randomized trial of machine learning nudges to prompt serious illness communication among patients with cancer. *First Author: Ravi Bharat Parikh, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Early serious illness conversations (SICs) between oncology clinicians and patients in the outpatient setting may improve mood and quality-of-life among patients with cancer. However, the impact of early SIC "nudges" on end-of-life spending is unknown. **Methods:** This was a secondary analysis of a stepped-wedge randomized trial (NCT03984773) that randomized 9 medical oncology practices and their high-risk patients at a large academic institution to a behavioral intervention to increase SICs (performance reports and peer comparisons; precommitments for high-risk patients; weekly opt-out text prompts before high-risk encounters) vs. standard of care, between June 2019 and April 2020. We identified high-risk patients using a machine learning (ML) algorithm predicting 180-day mortality. This secondary analysis included 1187 (957 intervention, 230 control) patients with complete data who died by December 2020. We abstracted spending (defined as inflation-adjusted reimbursements for acute care [inpatient + ED], office/outpatient care, intravenous chemotherapy, other therapy [e.g. radiation], long-term care, and hospice) from the institution's accounting system; we captured spending at University of Pennsylvania inpatient, outpatient, and pharmacy settings. To evaluate intervention impacts on spending, we used a two-part model: first, logistic regression to model zero versus nonzero spending, and second, generalized linear models with gamma distribution and log-link function to model daily mean spending in the last 180 days of life. Models were adjusted for clinic and wedge fixed effects and clustered at the oncologist level. **Results:** Median age at death was 68 years (IQR 15.5), 317 (27%) patients were non-White, and 448 (38%) patients had a SIC prior to death. The intervention was associated with lower mean spending in the last 180 days of life (mean daily spending \$377.96 [intervention] vs. \$449.92 [control]; adjusted mean difference -\$75.33, 95% CI -\$136.42, -\$14.23, $p = 0.016$) (Table), translating to \$13,559 total adjusted savings. Intervention patients incurred lower mean daily spending for chemotherapy (adjusted difference -\$51.35, $p < 0.001$), office/outpatient care (-\$14.59, $p < 0.001$), and other therapy (-\$10.35, $p = 0.043$). The intervention was not associated with differences in end-of-life spending for acute care utilization, long-term care, and hospice. Results were consistent for spending in the last 30 and 90 days of life and after adjusting for age, race, and ethnicity. **Conclusions:** A ML intervention to prompt SICs led to end-of-life savings, driven by decreased chemotherapy and outpatient spending. Clinical trial information: NCT03984773. Research Sponsor: U.S. National Institutes of Health.

Unadjusted spending in last 180 days of life.

	Intervention	Control
Total Spending	\$69,977	\$82,110
Mean Daily Spending	\$378	\$450
Acute Care	\$202	\$200
Outpatient	\$24	\$39
Chemotherapy	\$113	\$164
Other Therapy	\$29	\$40

Biosimilar uptake and cost savings analysis before and after implementation of a pharmacist-driven substitution program within a National Community Oncology Network: One-year follow-up. *First Author: Melody Chang, American Oncology Network, Fort Myers, FL*

Background: As of December 2022, 22 of the 40 biosimilar approvals in the United States, are used for the treatment of cancer or for the supportive care of patients with cancer. Our organization is a network of community oncology practices, representing 107 oncologists at 76 locations across 17 states. Because our network faces formulary selection and reimbursement challenges related to a diverse payor mix across multiple states, we sought to see the impact of utilizing regional clinical pharmacists (RCPs) to assist with selection of the most cost-effective biosimilar products. **Methods:** In October 2021, our network initiated an RCP-driven biosimilar substitution program, whereby the RCP acts as a liaison between providers and financial teams to evaluate existing drug orders and their financial impact. We previously presented data on the financial impact to payors and providers before and after implementation of the program from 4/1/2021 to 4/1/2022. This study evaluates the one-year results following program implementation. Additionally, outcomes related to biosimilar utilization as well as financial impacts to payors, patients, and providers were assessed. Payor savings is defined as the difference of the calculated 80% Medicare ASP+6 for the administered biosimilar compared to the originator; patient savings is defined as the difference of the calculated 20% Medicare ASP+6 co-insurance for the administered biosimilar compared to the originator; provider savings is defined as the difference between the invoiced cost of the biosimilar compared to the originator. **Results:** By the end of 2022, preferred product utilization was achieved for >90% of bevacizumab, trastuzumab, and rituximab orders. Use of the preferred pegfilgrastim product increased from <20% in 4/2021 to >60% by 12/2022. Use of filgrastim biosimilar product increased from <75% in 4/2021 to >90% by 4/2022, then decreased to 55% by 12/2022 due to trending ASP. Payor preference prevented biosimilar switching in approximately 34% of cases. **Conclusions:** Use of institution-preferred biosimilar products increased across all agents in this study after implementation of the RCP-driven biosimilar substitution program, except for filgrastim. Significant cost savings were noted for payors, patients, and providers. Barriers to switching to institution-preferred products included non-medical switching requirements by payors, patient assistance and compassionate use programs, and patient and/or provider preferences. Research Sponsor: Part of this research was made possible through a competitive independent medical education grant supported by Pfizer, Inc. All data, analysis, and content are independent of industry influence.

Time Period	Payor Savings	Patient Savings	Provider Savings	Total Savings
4/1/2021-9/30/2021	\$8.0 million	\$2.0 million	\$11.3 million	\$21.3 million
10/1/2021-4/1/2022	\$10.8 million	\$2.7 million	\$10.6 million	\$24.1 million
1/1/2022-12/31/2022	\$26.4 million	\$6.6 million	\$23.5 million	\$56.5 million

A multi-level system quality improvement project to reduce disparities in lung cancer screening: The Sylvester Lung Screening Project. *First Author: Nicole Ann Gay, UM/Sylvester Comprehensive Cancer Center, Miami*

Background: Racial disparities in lung cancer mortality and screening have been well documented in the USA. Annual screening with low dose Computed Tomography (CT) scans is completed in fewer than 6% of the eligible population. Research suggests that many factors contribute to low screening uptake, including barriers to care at patient, clinician, healthcare system, and community levels. In collaboration with the American Cancer Society, the University of Miami/ Sylvester Cancer Center underwent a multi-level system quality improvement (QI) project with the goal to decrease lung cancer screening disparities and improve guideline concordant lung cancer screening across the health care system. **Methods:** During the one-year multi-level QI project, interventions were put into place to increase lung cancer screening exams via improvements in EMR- identification of eligible patients, patient navigation and expanded provider education services in primary care clinics. Patient level interventions included a marketing campaign, patient navigation, and interpreters to address language barriers. The Patient-interface of the EMR 'Health Maintenance Gap' was optimized to alert eligible patients about screening. In addition, a full-time lung cancer screening navigator provided culturally competent, patient-centered counseling, while allowing for an increased capability to manage a higher volume of patients. Provider level interventions included teaching sessions about lung cancer screening and motivational communication skills, and BPA alerts. The primary outcome was the change in the number of screened patients. **Results:** With the implementation of these multi-level interventions, there was a twenty five percent improvement in the number of lung cancer screening exams completed during the project period January 2022- December 2022 compared to 2021 baseline, from 20 to 25%. The screening rate was highest among Hispanics (12%), followed by Blacks (8%), and Non- Hispanic Whites (NHW) (6%). The majority of LDCT results were Lung RADS Category 1 or 2 (93%). **Conclusions:** Multi-level interventions that target patients, clinicians, and the health care system can improve lung cancer screening rates in a short-term period. Developing patient-centered, culturally competent interventions is key to reducing disparities in lung cancer screening. This QI intervention was strengthened by tailoring intervention components to the educational primary care physicians and simplifying the referral process. Research Sponsor: American Cancer Society.

The impact of adverse financial events on healthcare utilization and treatment costs at the end of life. *First Author: Chipo Natasha Kwendakwema, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Patients with cancer are at higher risk of bankruptcy and other adverse financial events (AFE) compared to similar individuals without cancer. However, little is known about how AFEs affect cancer care, particularly at the end of life (EOL). We investigated the association between AFEs, healthcare utilization, and healthcare costs at the EOL among patients with cancer. **Methods:** Western Washington Surveillance Epidemiology and End Results (SEER) cancer registry cases were linked to credit records from TransUnion and to claims from commercial payers and Medicare. Patients with AJCC Stage I-IV solid tumors who died between January 2013 and December 2019 and who had continuous enrollment in commercial or Medicare insurance for the 6 months prior to death were included. Emergency department (ED) and inpatient (IP) visits in the last 3 months of life, place of death, and mean healthcare costs per patient (paid by insurer) were compared between patients with versus without AFEs (charge-offs, third-party collections, tax liens, delinquent mortgage payments, foreclosures, or repossessions). A multivariate logistic regression analysis was used to evaluate the association between AFEs, ED or IP visits (>1 of either), and inpatient death, adjusting for sociodemographic factors, comorbidities, payer type, and cancer stage. Two-sample t tests were used to compare mean per-patient costs in the last 6 and 3 months of life among patients with versus without an AFE. **Results:** A total of 13,545 patients (median age 75, 54% male) were included, of which 15.6% experienced an AFE. Patients with AFEs were more likely to have multiple ED or IP visits (OR 1.19, CI 1.07-1.34) and die in a hospital (OR 1.37, CI 1.22-1.55) (Table). Younger age, higher Carlson Comorbidity Index (CCI), and being partnered were also associated with greater EOL healthcare utilization while race, sex, payer type, and cancer stage were not. Mean total healthcare costs were higher in patients with AFEs than those without in the last 6 months (\$66,232, vs. \$55,831, p<0.0001) and 3 months (\$39,664 vs. \$33,638, p<0.0001) of life. **Conclusions:** We demonstrated an independent association between AFEs as measured in credit records, increased EOL healthcare utilization, and greater per-patient costs in the months before death. These findings suggest that addressing patient financial hardship could improve their EOL experience and decrease healthcare costs. Research Sponsor: Kathryn Butler Foundation, Texas4000 Foundation.

Predictors of EOL healthcare utilization.		
Predictors*	Multiple ED or IP visits	Inpatient death
AFE	1.19 (1.07-1.34), p<0.002	1.37 (1.22-1.55), p<0.0001
Age < 65	1.22 (1.06-1.40), p<0.005	1.19 (1.02-1.37), p<0.023
CCI > 1	1.27 (1.15-1.39), p<0.0001	1.31 (1.20-1.46), p<0.0001
Partnered	1.16 (1.06-1.26), p<0.001	1.17 (1.06-1.29), p<0.001

*Reference: no AFE, age 65+, CCI 0, no partner. Other predictors (not significant): race, payer type, cancer stage, and area deprivation index.

Guideline-concordant use of olanzapine as part of a 4-drug antiemetic regimen for high emetic risk chemotherapy across the state of Michigan. *First Author: Ashley Bowen, Michigan Oncology Quality Consortium, Ann Arbor, MI*

Background: Chemotherapy-induced nausea and vomiting (CINV) is a feared side effect of cancer treatment. If not adequately controlled, CINV can negatively affect both quality of life and increase the costs of care. Clinical practice guidelines from both ASCO and NCCN recommend inclusion of olanzapine as part of a 4-drug antiemetic regimen in patients receiving high emetic risk chemotherapy (HEC). Uptake of olanzapine has been low, however, in part due to oncologists' lack of familiarity with the medication, lack of awareness or agreement with the guidelines, and lack of olanzapine inclusion on prepopulated order sets. Current labeling of olanzapine as an antipsychotic poses an additional barrier. The purpose of this project was to increase guideline-concordant prescribing of olanzapine as part of a 4-drug antiemetic regimen in patients receiving HEC in practices that are part of the Michigan Oncology Quality Consortium (MOQC), a physician-led consortium of nearly 90% of oncologists in Michigan. **Methods:** In 2019, MOQC began measuring guideline-concordant HEC prophylaxis with a 4-drug regimen of olanzapine added to corticosteroids, a 5HT3RA, and an NK1RA as part of its measure set. A quality improvement intervention was initiated that consisted of 1) dissemination of baseline measure performance and regular reporting of practice and state-level performance to MOQC practices, 2) information support through sharing of guidelines at biannual meetings (2019, 2022) and state-wide CINV education to improve prescriber knowledge and beliefs and support the practices in updating prepopulated antiemetic order sets, and 3) addition of value-based reimbursement in 2021 to encourage practice change. Measure performance was assessed using ASCO's Quality Oncology Practice Initiative (QOPI) program. **Results:** The patient sample included 5,703 patients. MOQC practices increased the guideline-concordant prescribing of olanzapine as part of a 4-drug antiemetic regimen in patients receiving HEC round over round from R1 2019 to R1 2022 (p<0.0001). **Conclusions:** MOQC has facilitated increased use of olanzapine as part of a 4-drug antiemetic regimen in patients receiving HEC through practice education, reporting, and value-based reimbursement. Ongoing work will focus on practices with low uptake and on demonstrating the impact of this important practice change on patient outcomes. Research Sponsor: None.

Poster Discussion Session

Impact of a web-based decision aid on socioeconomically disadvantaged patients' engagement in decision making (Alliance A231701CD). *First Author: Jessica R. Schumacher, Department of Surgery, University of Wisconsin, Madison, WI*

Background: Increased patient engagement in decision making may mitigate disparities in breast cancer surgical care. Socioeconomically disadvantaged patients disproportionately experience barriers to engagement. Decision aids (DA) increase engagement by providing information, establishing role expectations during the consult, and increasing confidence in surgeon interactions. The objective was to test the effectiveness of a surgical web-based DA in increasing engagement among breast cancer patients in clinics that care for a high proportion of socioeconomically disadvantaged patients. **Methods:** A stepped wedge trial was conducted with 10 NCI Community Oncology Research Program clinics (Alliance for Clinical Trials in Oncology Research Base, 6/19-12/21). Clinics were randomized to time of transition from usual care (UC) to delivery of a web-based DA. Patients with stage 0-3 breast cancer eligible for surgery provided consent prior to a surgical consult. Socio-economic disadvantage was assessed with the Area Deprivation Index measured at the zip+4 level and dichotomized. Patient engagement was measured by Patient's Self-Efficacy in Patient-Physician Interactions (PEPPI-5, follow-up survey) and count of Active Patient Behaviors (Street protocol, audio recorded consult). Intervention effects were tested with linear mixed-effects models, accounting for surgeon and clinic-level clustering, time, and enrollment post-COVID. Heterogeneity of treatment effect by socioeconomic disadvantage was assessed with an interaction term. **Results:** 573 patients enrolled. 44% (136/309) reviewed the DA. No significant difference in engagement was observed comparing DA and UC for PEPPI-5 (-0.80 [95% CI -2.13, 0.54], $p = 0.24$) or Active Patient Behaviors (2.52 [CI -4.11, 9.15], $p = 0.46$). Enrollment post-COVID was associated with increased Active Patient Behaviors (9.59 [CI 1.76, 17.43], $p = 0.02$) but no change in PEPPI-5 (-1.31 [CI -2.88, 0.26], $p = 0.10$). No heterogeneity of treatment effect was observed. **Conclusions:** In this trial conducted in clinics that serve diverse populations, no significant relationship was observed between a web-based DA and patient engagement. Conducting this stepped wedge trial during the pandemic was challenging. Future analyses will explore the impact of COVID on outcomes and effect of the decision aid for patients who reviewed it. UG1 CA189823; AHRQ R01HS025194; <https://acknowledgments.alliancefound.org>. Clinical trial information: NCT03766009. Research Sponsor: Agency for Healthcare Research and Quality; U.S. National Institutes of Health.

The Man Van: Mobile targeted case finding for prostate cancer. *First Author: Masood Moghul, Royal Marsden Hospital NHS Trust, London, United Kingdom*

Background: Early intervention is potentially lifesaving in prostate cancer. The debate for screening continues with recent developments suggesting the arguments in favour are becoming stronger however, barriers to access remain. The Man Van project is designed to address these with a highly novel community-based targeting of high-risk groups on a mobile unit. **Methods:** A bespoke mobile health vehicle was moved to 8 community-based locations in areas of high deprivation indices in London, UK, inviting men for a health check consisting of: general health questionnaires, blood pressure, height/weight, HbA1c for diabetes and a PSA test. Telemedicine was used to inform patients of outcomes. Direct referrals to secondary care was performed. Community engagement was utilised to increase uptake using: primary healthcare centres, religious organisations and community centres. **Results:** Between December 2021 and December 2022, 618 men were seen at our Man Van clinics at a range of community settings (non-attendance rate 24%). The highest uptake was in locations where there was collaboration with primary care to recruit patients. The median age of attendees was 56 years, range 25-87. 43% of attendees were non-white (20% black). The median BMI was 27.7, range 16.2-50.5. 422 PSA tests were performed with 14 prostate cancers (3.3%) found till date. 9 (64%) of these cancers were grade group 2 (all > 5% pattern 4) or 3. Of patients diagnosed with prostate cancer the median age was 59 years, range 48-73, 10 were black (71%), median PSA 6.85 g/L, range 0.81-45, median IPSS score was 9.5, range 2-31, median IIEF-5 was 16, range 1-25. The IPSS score was significantly higher ($P < 0.05$) in men diagnosed with prostate cancer. 1 bladder (G3pT1) and 1 oesophageal cancer (T3N2M1) were also found. 3 patients had either HGPIN or ASAP, 3 patients had renal stones, 2 urethral strictures were found. 334 HbA1c tests were performed with 18 diabetics diagnosed (5.4%). 46 patients (7.4%) required input for benign urinary symptoms and 20 for erectile dysfunction (3.2%). Primary care referrals were as follows: 171 for hypertension (27.6%), 43 for an elevated BMI (7.0%), 37 for mental health issues (6.0%), 43 for excess alcohol intake (7.0%), 51 for smoking cessation assistance (8.3%). Significantly more patients 45 years were referred for primary care follow-up versus < 45 years ($P < 0.01$). Service evaluation questionnaires showed overwhelmingly positive support for the service. **Conclusions:** The Man Van initiative is a novel method of linking primary and secondary care for a range of health checks, including PSA. By improving community awareness and access in high-risk groups we demonstrate high uptakes for health checks including for prostate cancer and a willingness to engage with health improvement measures. As well as comparatively high levels of prostate cancers diagnosed at early stages, high levels of other health conditions were found; improving the economic value of the service. Research Sponsor: NHS England.

Curating clinical trials: Helping patients find hope by exploring clinical trial opportunities. *First Author: Rhonda Abdel-Nabi, University of Windsor, Windsor, ON, Canada*

Background: Clinical trials are essential to the advancement of clinical therapies. However, only 5% of cancer patients enroll in clinical trials (CTs) due to limited accessibility. Given that greater participation in CTs is associated with better patient outcomes, patients from smaller centres are at a disadvantage. The Clinical Trials Navigators (CTN) program was established by Hamm (2022) to help patients in smaller communities navigate and enrol in CTs, resulting in clinical trial enrolment of 7% of patients. This study will provide updated results on the impact of the CTN program as it has expanded. **Methods:** Between March 2019 to September 2022, 241 patients were enrolled in the CTN program. Five Clinical Trials Navigators (CTNs) receive referrals from various sources: physicians, patients, and patient support groups. CTNs review medical information submitted and search five CT registries. Eligibility criteria is scrutinized. A second review of the CT list is conducted by two physicians to ensure accuracy. The number of potential trials is recorded at each step of review. Data collected includes: patient disease, stage, and number of prior therapies, time from referral to death, number of potential trials, number of trials that were phase I or phase II / III / IV, number of outgoing referrals, locations of the identified trials, and successful enrolment onto CTs. Patient information and results were inputted and analysed using REDCap. REB Category A approval has been granted on August 31, 2022. REB approval number is 22-439. **Results:** 41 Canadian cancer patients used the CTN program. The updated study found that 75.9% of patients were in stage IV of their disease, and 51% had at least two prior lines of therapy. 61.4% of patients deceased at last follow up, with a range of 0.3-37.5 months from CTN program referral to death, and a median of 5.9 months. CTNs identified a range of zero to 26 trials for each patient with a median of three trials: a range of zero to 10 phase I trials were found, and a range of one to eight phase II / III / IV trials were found. 25.5% of patients referred to a CT enrolled onto the recommended trial. The expanded CTN program resulted in CT enrolment of 8.5% of patients that follow-up information is available for. **Conclusions:** One quarter of patients referred to a CT by the CTN program were successfully enrolled, highlighting the CTN program as a successful tool to identify CTs for cancer patients and improve CT accrual. 8.5% of all patients with available follow-up information that participated in the CTN program were enrolled onto clinical trials. Further investigation into reasoning for early high mortality rates should be assessed. New initiatives to improve uptake of the CTN program are ongoing. Association of social vulnerability with delays in starting guideline-adherent adjuvant therapy among patients with head and neck cancer. *First Author: Joshua Lee Cagle, Medical University of South Carolina, Charleston, SC*

Background: For patients with head and neck squamous cell carcinoma (HNSCC), initiation of postoperative radiation therapy (PORT) within 6 weeks of surgery is recommended by NCCN Guidelines and is the only Commission on Cancer Quality Metric for HNSCC due to the robust association of PORT delays with mortality and recurrence. Prior studies have identified that racial and ethnic minority and under-insured patients are at increased risk for PORT delay. However, no studies have examined the role of social vulnerability (i.e., social determinants of health such as education, housing, and transportation) in explaining disparities in PORT delay. To address this gap, this study seeks to evaluate the association of social vulnerability with delays in starting guideline-adherent PORT for patients with HNSCC. **Methods:** This is a multicenter retrospective cohort study of adult patients with HNSCC undergoing surgery at 3 urban academic centers followed by adjuvant therapy from 2018-2020. The primary outcome was delay in initiating guideline-adherent PORT (i.e., > 6 weeks [42 days] postoperatively). Time-to-PORT (TTP) was analyzed as a secondary outcome. Census-tract level Social Vulnerability Index (SVI) scores were calculated as a national percentile rank (0 to 1) with higher scores indicating greater social vulnerability. Multivariable logistic regression (MLR) was used to evaluate the association of SVI with PORT delay. Kaplan-Meier curves and a log-rank test were used to evaluate differences in TTP between patients in the highest social vulnerability quartile (SVI > 0.75) vs those in the lowest social vulnerability quartile (SVI ≤ 0.25). **Results:** The study included 505 patients undergoing surgery and adjuvant therapy. The mean age was 62.1 ± 11.9 years; 71% were male, 14% were Black and the most common tumor subsite was oral cavity (61%). The rate of PORT delay was 52% (95% CI 48-57%). Median TTP was 43 days (IQR 35-55 days). The mean overall SVI score was 0.48 ± 0.27. An increase in SVI of 0.25 was associated with a 33% increase in the odds of PORT delay (OR=1.33, 95% CI=1.08 to 1.63; $p=0.0067$) on MLR adjusted for facility, age, race, ethnicity, health insurance status, cancer subsite, rurality, and distance to the surgical facility. Patients in the highest SVI quartile had a significant increase in TTP relative to those in the lowest SVI quartile (log-rank $p=0.012$; median TTP = 47 and 42 days, respectively). **Conclusions:** In this multi-institution study, over half of patients with HNSCC experience delays in starting PORT. Increased census-tract level social vulnerability is associated with a greater risk of delayed initiation of guideline-adherent PORT. These data can be used to: 1) enhance existing risk prediction models and identify patients at-risk for PORT delay who might benefit from a targeted intervention and 2) improve institutional level risk-adjustment for case mix. Analysis and optimization of equitable US cancer clinical trial center access by travel time. *First Author: Hassal Lee, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY*

Background: Racially minoritized and socioeconomically disadvantaged populations are underrepresented in cancer clinical trials. Data-driven, quantitative approaches are required to address this inequity. Here, we systematically analyze the geographical distribution of self-identified racial and socioeconomic demographics within commuting distance to cancer clinical trial centers and all hospitals U.S.-wide. **Methods:** We calculate self-identified racial and socioeconomic demographics of populations living within 30-, 60-, and 120-minute one-way driving commute times from U.S. cancer clinical trial centers and all U.S. hospitals. Data sources include the U.S. 2020 census (for race and socioeconomic data), OpenStreetMaps (for calculation of commuting times), NCT trial registry (for cancer clinical trial quantification), NCI Designated Cancer Centers List, Nature Index of Cancer Research Health Institutions and National Homeland Infrastructure Foundation-Level Data (for U.S.-wide hospital and cancer clinical trial center identification). Data analysis was conducted in R, and *Ggplot2* used for all data visualizations. **Results:** Analysis of clinical trial numbers between 2012–2022 identified 78 high-volume U.S. cancer trial centers. Compared to U.S. national averages, these centers are in areas with socioeconomically more affluent populations (+27.6K USD [95% CI +23.1 to 32.8K] median income unpaired mean difference; -0.073 [95% CI -0.063 to -0.084] deprivation index unpaired mean difference), with higher proportions of affluent self-identified White individuals (+10.1% unpaired mean difference [95% CI +6.8 to +13.7%]). The top 10th percentile of all U.S. hospitals (N=7,623) show a range of absolute sum difference from 2.4% to 35% from equal racial representation of White, Black/African American and Asian/Mixed/Other groups. For each U.S. city above 500,000 inhabitants, we compile map overlays that display all prospective hospitals within commutable distance to racially diverse and socioeconomically disadvantaged populations. These maps may inform the design of future clinical trials or investigations in enrollment and retention strategies for clinical trials. **Conclusions:** Our analysis identifies biases in the socio-demographics of populations living within commuting distance to U.S.-based cancer trial sites and enables the determination of more equitably commutable prospective satellite hospital sites that could be mobilized for enhanced racial and socioeconomic representation in clinical trials. Other recruitment barriers still need to be tackled to ensure racial and socioeconomic demographics within the geographical vicinity of a clinical site can translate to equitable trial participant representation. Research Sponsor: Cold Spring Harbor Laboratory.

Evaluating social vulnerability impact on care and prognosis of head & neck-nervous system cancers in the US. *First Author: Salim Lutfallah, Louisiana State University Health and Sciences - School of Medicine, New Orleans, LA*

Background: In the current literature, the association between social determinants of health (SDH) and head & neck-nervous system cancer (HNNsC) is limited by the narrow scope of SDH assessed and the broad classifications of HNNsC. Our study utilizes the CDC-Social Vulnerability Index (SVI) to assess both the individual and collective impact of four social determinant themes on various HNNsC in US adults. **Methods:** This study utilized the SEER database to evaluate 116,373 adult patients from 1975-2017 who presented with HNNsC. Patients were assigned SVI scores based on county-of-residence at the time of diagnosis, encompassing total-SVI score and 4 sub-scores of socioeconomic status, minority-language status, household composition, and housing-transportation. Using these scores, univariate linear regressions were used to assess patient care (months of follow-up) and prognosis (months of survival). **Results:** As total-SVI score increased, decreases in months of follow-up (MOF) and months of survival (MOS) were observed for many HNNsC tumors (p less than 0.001) when comparing the lowest to highest vulnerability cohorts. There was a decrease ranging from 3.55-36.6% in the MOF, with the largest decreases occurring in embryonal, anaplastic oligodendroglioma, and anaplastic ependymoma tumor types, with the largest sub-score contribution coming from socioeconomic status for these three disease classes. Similarly, there was a decrease ranging from 6.90-45.81% in the MOS, with the largest decreases occurring in anaplastic ependymoma, anaplastic astrocytoma, and pilocytic astrocytoma tumor types with the largest sub-score contribution coming from socioeconomic status for these three disease classes. Increases in vulnerability within SDH themes contributed significantly to these total-SVI trends in MOF and MOS, with each social determinant impacting different disease classes to varying extents. Socioeconomic status was the most impactful sub-score for MOF in nine of fourteen disease classes, followed by housing-transportation and household composition, each leading the impact of two of fourteen disease classes, and minority-language status leading the impact of one of fourteen disease classes. Similarly, socioeconomic status was the most impactful sub-score for MOS in eight of fourteen disease classes, followed by housing-transportation leading the impact of three of fourteen disease classes, household composition leading the impact of two of fourteen disease classes, and minority-language status leading the impact of one of fourteen disease classes. **Conclusions:** The results of this study show that with increasing social vulnerability, there is a significant decrease in both the care (follow-up) and the prognosis (survival) of US adults with HNNsC and highlight which SDH contributes more to disparities. Are enrollment criteria for phase II and III clinical trials in acute myeloid leukemia arbitrarily restrictive? *First Author: Andrew Hantel, Division of Population Sciences, Dana-Farber Cancer Institute, Boston, MA*

Background: Ethical clinical research requires fair subject selection and a favorable risk-benefit ratio. Enrollment criteria can unfairly exclude patients if they are not based in safety. There are few data regarding variability within criteria, which can also represent unfair exclusion, or for acute myeloid leukemia (AML). **Methods:** We assessed enrollment criteria use and variability for frontline phase II and III therapeutic AML trials from 2010-2019 listed on Clinicaltrials.gov. Drug safety profiles were obtained from protocols, publications, and FDA labels. FDA publications guided a standardized abstraction and coding process. Associations between criteria and safety profiles were identified using χ^2 and t-tests. Regression modeling identified differences in infectious disease (ID) exclusion by sponsor adjusted for trial phase, year, size, and safety profiles. **Results:** 190 trials were eligible; 159 (84%) were phase II and 32 (17%) phase III. Trials were sponsored by the National Institutes of Health (NIH; 50; 26%), industry (109; 57%), and academic investigators (AI; 108; 57%). Exclusions and variability are shown in the table. ID exclusions were for HIV (96; 51%) and hepatitis B (60; 32%) and C (64; 34%). Older adults were considered as over 60 (42 trials; 39%), 65 (23; 21%), 70 (13; 12%), or 75 years (18; 17%). There was no association between QTc limits and the use of QTc prolonging drugs (criteria presence p=0.2; mean 450 vs 474 ms, p=0.3) or renal function limits and nephrotoxic drugs (presence p=0.2; mean 1.65 vs 1.67 ULN, p=0.8). Hepatitis B and C exclusions were associated with the use of drugs linked to viral reactivation (OR 2.1 [95% CI 1.1,3.9], 2.0 [95% CI 1.1,3.7]). This was not the case for HIV (OR 1.2 [95% CI 0.7,2.2]). Industry sponsorship was independently associated with hepatitis B and C exclusion (OR 3.0 [95% CI 1.2,7.3], 3.3 [95% CI 1.4,4.7]) and AI sponsorship with HIV exclusion (OR 2.5 [95% CI 1.4,5.5]). **Conclusions:** There is substantial variability in enrollment criteria for AML clinical trials. Many criteria are related to risks, but some exclusions and variability are not clearly based in safety. Avoiding arbitrary exclusions will likely enhance trial representativeness and enrollment rates. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology; U.S. National Institutes of Health.

Association of measures of socioeconomic deprivation with healthcare utilization in elderly patients enrolled in SWOG cancer clinical trials. *First Author: Dawn L. Hershman, Columbia University Medical Center, New York, NY*

Background: Reducing unplanned Emergency Room (ER) visits and hospitalizations is an important strategy for improving value. Patients enrolled in clinical trials are treated per protocol. While demographic factors have been associated with increased healthcare utilization, less is known about measures of socioeconomic deprivation (SD), which may be a proxy for structural barriers to access. We tested whether ER and hospital stays are more common among trial participants who live in areas of SD or have Medicaid insurance (MI). **Methods:** We examined ER visits and hospitalizations among cancer patients ≥ 65 years treated on SWOG clinical trials from 1999-2018 using trial data linked to Medicare claims. Neighborhood socioeconomic deprivation (NSD) was measured using patients' zip code linked to the Area Deprivation Index (ADI), measured on a 0-100 scale and categorized into tertiles (T1-T3). Higher ADI (T3) denotes areas of higher deprivation. Type of insurance was classified as Medicare alone or with Commercial, versus Medicare + MI. Outcomes were ER visits, hospital stays, and costs, all in the first year. Demographic, clinical, and prognostic factors were captured from trial records. Generalized estimating equations (GEE) were used, accounting for clustering by cancer type. Regression models were adjusted for age, race, and a study-specific prognostic risk score, and stratified by study and treatment. ADI and Insurance were considered separately to reflect neighborhood-level and individual-level measures of SD. **Results:** In total, N = 3,027 participants from 27 trials in bladder, breast, colorectal, lung, myeloma, and prostate cancers were analyzed. Median age was 71 years, 3% had Medicare + Medicaid and 22.3% were in the Highest ADI tertile. In all, 983 (32%) patients experienced hospitalization, and 1094 (36%) visited the ER. In multivariate GEE, patients living in more deprived areas were more likely to experience hospitalization (OR for ADI T3 compared to T1: 1.36, 95% CI, 0.95-1.94, p=.09) and to visit an ER (OR for ADI T3 compared to T1: 1.33, 95% CI, 1.08-1.63, p=.008). Overall, patients from the most deprived areas had a 61% increase in risk of either ER visit or hospitalization (OR for ADI T3 compared to T1: 1.61, 95% CI, 1.23-2.10, p<.001). Patients with MI were 86% more likely to visit an ER in the first year (OR 1.86, 95% CI, 1.49-2.33, p<.001). No increased risk of hospitalization was observed. **Conclusions:** Despite participation in cancer clinical trials, patients living in areas with higher deprivation or those with Medicare + MI had an increased risk of unplanned ER visits. These findings suggest that neighborhood deprivation and economic disadvantage may increase ER visits for socioeconomically vulnerable older patients with cancer. Efforts are needed to ensure adequate resources to prevent unplanned use of acute care in vulnerable populations. Research Sponsor: U.S. National Institutes of Health.

Racial disparities in utilization of first line targeted therapies for metastatic breast cancer. *First Author: Yehoda M. Martei, University of Pennsylvania, Department of Medicine (Hematology - Oncology Division), Philadelphia, PA*

Background: This study evaluated whether there were racial disparities in utilization (decomposed as change in proportion of eligible patients initiating therapy over time and time to treatment initiation (TTI)) to CDK4/6 inhibitors and pertuzumab since FDA approval as first line (1L) treatment for ER+/HER2- and HER2+ metastatic breast cancer (MBC), respectively. **Methods:** This cohort study used the nationwide Flatiron Health electronic health record-derived de-identified database. Included women were ≥ 18 years old, diagnosed with de novo or recurrent MBC, who received 1L therapy, and documented as non-Hispanic White (NHW) or non-Hispanic Black/African American (NHB). Two cohorts were generated for patients with ER+/HER2- MBC diagnosed 3/2015-10/2021 and HER2+ MBC diagnosed 7/2012-9/2021. We estimated temporal trends in the proportion of NHW and NHB patients receiving respective therapy using logistic regression with natural cubic splines for time trends and tested for changes in uptake over time within each group as well as differences in trends between groups. A similar model was used for TTI among treatment initiators, using linear regression models. In addition to time and race, regression models included age, ECOG performance status, insurance, Medicaid expansion status, practice type, and proportion of black patients per practice among patients who met both cohort criteria. **Results:** 8318 patients (NHW=7006; NHB=1312) met ER+/HER2- cohort criteria and 2321 (NHW=1915; NHB=406) met HER2+ cohort criteria. There was a significant change over time in the proportion of NHW ($p<0.0001$) and NHB ($p<0.0001$) initiating 1L CDK4/6 inhibitors (Table). Temporal trends were also significantly different between NHW and NHB ($p<0.0001$). Higher ECOG performance status (OR=0.85 per unit increase, 95%CI 0.80-0.90; $p<0.001$) and an increasing proportion of black patients seen at practice (OR=0.45, 95%CI 0.29-0.71; $p<0.001$) were independent predictors of lower odds of initiating CDK4/6 inhibitors. Overall, 43% NHW vs 41% NHB received pertuzumab respectively. There was no significant difference in uptake trends for pertuzumab between NHW and NHB ($p=0.41$). There was no significant difference in the temporal trends of TTI for either CDK4/6 inhibitors ($p=0.74$) or pertuzumab ($p=0.84$). **Conclusions:** Utilization of CDK4/6 inhibitors steadily increased over time, however $> 25\%$ of eligible patients did not receive the drug, and less than half of individuals who met indication for pertuzumab were prescribed it. Racial disparities were significant for oral CDK4/6 inhibitors but not for intravenous pertuzumab. Research Sponsor: Flatiron Health, Inc.

Healthcare coverage, access, and affordability among adult immigrant cancer survivors in the United States. *First Author: Patricia Mae Garcia Santos, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Cancer is a leading cause of morbidity and mortality among US immigrants; however, barriers to care remain understudied. This study assessed disparities in health insurance, health care access, and affordability among immigrant cancer survivors in the United States. **Methods:** Adult cancer survivors aged ≥ 18 years who participated in the 2019-2022 National Health Interview Survey were classified as 1) natives 2) foreign-born (FB) citizens or 3) noncitizens. Logistic regression tested for associations between nativity/citizenship and insurance, access (i.e., urgent care, emergency room (ER), hospital admissions), and affordability (assessed by social determinants of health [SDoH]: financial hardship, food insecurity, housing assistance). Separate models adjusted for demographics, socioeconomic status, and comorbidities. **Results:** A total of 8,923 adults (90% natives, 7% FB citizens, 3% noncitizens) were included in the study. There were baseline differences in age < 65 (42% natives vs 61% FB citizens vs 76% noncitizens), female sex (57% vs 59% vs 73%), non-White race (15% vs 64% vs 77%), and Hispanic ethnicity (31% vs 62% vs 5%) between groups (all $p<0.05$). More noncitizens had household incomes $< 125\%$ of the federal poverty line (12% vs 18% vs 35%). On adjusted analysis, noncitizens were 3x as likely as natives to be uninsured (2.99 [1.36-6.53]; $p=0.006$) and FB citizens were 2x as likely to have Medicaid (2.10 [1.35-2.35]; $p=0.001$). Financial hardship was 1.5x more common among FB citizens (1.50 [1.18-1.91]; $p<0.001$) while receipt of housing assistance was $> 2x$ more common among FB citizens (2.98 [1.82-4.88]; $p<0.001$) and noncitizens (2.37 [1.08-5.22]; $p=0.03$). While more FB citizens (18%) and noncitizens (33%) were food insecure (vs. 11%), there were no associations with nativity/citizenship (Table). There were no significant differences in health care access across groups. **Conclusions:** In this nationwide analysis of adult cancer survivors, although there were no differences in health care access/utilization, immigrants and foreign-born citizens had higher rates of uninsurance and affordability concerns—suggestive of barriers to care. This may portend worse health outcomes in cancer survivorship. Research Sponsor: None.

Impact of free hospital-provided rideshare service on radiation therapy completion rates: A matched cohort analysis. *First Author: Eric Chen, University Hospitals Seidman Cancer Center, Department of Radiation Oncology, Cleveland, OH*

Background: Radiation therapy (RT) is generally given in consecutive daily sessions over multiple weeks. This poses challenges for patients who face barriers such as limited access to public or private transportation, limited financial resources, lack of social support, and long distances to healthcare facilities. Delayed or incomplete RT increases risk for worse clinical outcomes. The potential of rideshare service, which uses a private vehicle for hire arranged through a phone-based application or website, to facilitate timely RT is understudied. **Methods:** Retrospective data was collected on patients who received RT at a single institution from 2017-2022. Patient demographic and treatment characteristics were compared between those who did and did not utilize free hospital-provided rideshare service. RT completion rates were analyzed for a 1:1 matched non-rideshare cohort using optimal matching with the scaled Euclidean distance metric, to balance age, sex, race, performance status, number of fractions prescribed, Area Deprivation Index (ADI), distance to treatment center, year of diagnosis, treatment site, intent, and modality. ADI is a validated composite measure of community-level socioeconomic deprivation. **Results:** Of 2,906 patients who underwent RT, 58 utilized free hospital-provided rideshare service. Rideshare utilizers had a lower median age (60 vs 66, $p=.02$), and were more likely to identify as Black or African American (60 vs 22%, $p<.0001$) compared to non-rideshare utilizers. Rideshare utilizers also had higher ADI scores (median 9 vs 5, $p<.0001$), indicating higher socioeconomic disadvantage, and travelled shorter distances for treatment (median 5.0 vs 14.7 miles, $p<.0001$). More rideshare utilizers underwent RT for curative intent (79 vs 50%, $p<.0001$), concordant with a higher number of fractions prescribed (median 28 vs 5, $p<.0001$) as well as longer treatment course duration (median 39 vs 13 days, $p<.0001$). The most common treatment sites were head and neck (31%) and breast/chest wall (22%) for rideshare utilizers, and pelvis (27%) and brain (21%) for non-rideshare utilizers ($p<.0001$). Volumetric modulated arc therapy followed by 3D conformal were the most common treatment modalities in both groups. The matched cohort analysis revealed that RT completion rates were significantly higher for rideshare vs non-rideshare utilizers at 96 vs 81% ($p=.01$) overall, and 98 vs 78% ($p=.01$) for patients undergoing treatment with curative intent. **Conclusions:** Even after adjustment for socioeconomic, clinical, and treatment characteristics, utilization of free hospital-provided rideshare service was associated with improved RT completion rates. These findings are notable as the majority of rideshare utilizers come from socioeconomically marginalized communities, and would otherwise be expected to face significant barriers to RT completion. Associations of loneliness and mortality risk among cancer survivors in the United States. *First Author: Jingxuan Zhao, American Cancer Society, Atlanta, GA*

Background: Loneliness (i.e., the subjective feeling of being isolated from others), has been linked to multiple adverse health outcomes, including chronic conditions such as heart disease, mental health disorders, and higher risk for early mortality. However, associations between loneliness and worse health outcomes have not been thoroughly examined in cancer survivors. This study examined associations between loneliness and mortality risk among cancer survivors in the U.S. **Methods:** Cancer survivors were identified from the 2008-2018 Health and Retirement Study, a nationally representative longitudinal survey conducted biannually among individuals aged ≥ 50 years, with follow-up was through December 31, 2020. Loneliness was measured at every 4 years using an abbreviated 11-item version of the UCLA Loneliness Scale Version 3. Example items include feelings of lacking companionship and isolation from others. Items were summed to create total loneliness scores, which were categorized into four levels: 11-12 (low/no loneliness), 13-15 (mild loneliness), 16-19 (moderate loneliness), and 20-33 (high loneliness). Time-varying Cox proportional hazard models were used to examine the association of loneliness and mortality risk among cancer survivors, while accounting for measurements at multiple time points. Sex, marital status, educational attainment, number of health conditions other than cancer, and year since cancer diagnosis were included in multivariable models. **Results:** Among 5808 person-years, there were 724 deaths during the study period. Compared to the low/no loneliness group, survivors reporting greater loneliness had higher hazard ratios (HR), indicating higher mortality risks; the highest HR observed was among the high loneliness group (HR:1.90, 95%CI:1.58-2.29), following a dose-response association (Table). HRs were attenuated after adjusting for sociodemographic characteristics, but findings were largely unchanged, and HRs remained highest for the high loneliness group (HR:1.71, 95%CI:1.39-2.12). **Conclusions:** Any elevated loneliness was associated with higher mortality risks among cancer survivors. Programs to screen for loneliness among cancer survivors and to provide social support to those in need are warranted. Research Sponsor: None.

Association of loneliness and mortality risk among cancer survivors.

Loneliness Score	Unadjusted HR (95%CI)	Adjusted HR (95%CI)

Outcomes of Black (B) versus White (W) patients (pts) with metastatic hormone-sensitive prostate cancer (mHSPC) treated with androgen deprivation therapy (ADT) with or without orteronel (Ort): Analysis of pt-level data from SWOG-1216 phase 3 trial. *First Author: Nicolas Sayegh, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Despite more aggressive prostate cancer (PCa) at presentation and higher mortality in real world, B pts with metastatic hormone resistant PCa did not have inferior outcomes than W pts when both were enrolled in clinical trials (PMID: 33951180). In the phase 3 S1216 trial, treatment with Ort, a novel CYP17 axis inhibitor, significantly improved progression-free survival (PFS) but not overall survival (OS) compared to bicalutamide (Bic) in pts with mHSPC receiving ADT. This trial enrolled the greatest number of B pts in a phase 3 trial in this setting to-date. We hypothesized that given comparable access to care as experienced in a clinical trial, outcomes in B pts would be similar to those of W pts in the mHSPC setting. **Methods:** Eligibility: Pts with mHSPC were enrolled. Only pts self-identifying as B or W were included in this analysis. PFS and OS for each group were estimated using Kaplan-Meier method. A multivariate analysis (MVA) adjusting for disease characteristics was conducted using a Cox proportional hazards model. **Results:** Among 1279 participants, 135 (10.6%) were B; 1077 (84.2%) were W. B and W were equally distributed between treatment arms, and had respectively similar proportion of pts with Gleason score ≥ 8 (61.3 vs 62.1%), Zubrod score ≥ 2 (5.1 vs 3.4%) and extensive disease (48.1 vs 48.7%). However, B pts, as compared to W, were younger (65.8 vs 68.4 yrs, $p=0.001$) and had a higher median baseline PSA (54.7 vs 26.7 ng/mL; $p<0.001$). PSA responses (≤ 0.2 ng/mL) at month 7 were similar in both groups ($p=0.296$). Overall, B vs W had similar median PFS (2.3 vs 2.9 yrs, $p=0.71$) and OS (5.5 vs 6.3 yrs, $p=0.65$). MVA confirmed similar PFS and OS after adjusting for known prognostic factors (Table). No interaction between race and treatment was observed (P-value interaction PFS= 0.77 and OS= 0.91). **Conclusions:** We demonstrate that even though B pts present with more aggressive disease in mHSPC setting, they did not have statistically significant worse OS and PFS than W pts and treatment effect was also similar for both racial groups. Equitable access to care may negate historical differences in outcomes among B vs W pts with advanced PCa. Funding: NIH/NCI/NCTN grant U10CA180888, U10CA180819; and Millennium Pharmaceuticals (Takeda Oncology). Univariate and MVA of PFS and OS. Selection biases in the systematic collection of breast biobank specimens. *First Author: Yael Bar, Massachusetts General Hospital, Boston, MA*

Background: A breast biopsy tissue biobank is a valuable resource for studying breast cancer biology and treatment response. However, underrepresentation of patient populations in biobanks limits the generalizability of findings. The aim of this study was to assess potential age and racial/ethnic disparities in the recruitment process for an institutional breast biopsy tissue bank. **Methods:** Ultrasound-guided (USG) research biopsy cores were collected immediately after routine clinical biopsy from January 2019 to October 2022 at a large academic center. Study eligibility included patients (pts) aged > 18 years undergoing USG clinical breast biopsy with a radiographically evident mass ≥ 0.6 cm in the longest dimension. Eligible pts, identified by a research associate on the day of the biopsy, were invited to participate at the discretion of the radiologist performing the biopsy. Those approached either consented or declined a research biopsy. Demographic and clinical data of eligible pts were extracted from the EMR. **Results:** 2449 pts underwent USG breast biopsy and 1309 were deemed eligible for a research biopsy. Of the eligible population, 564 (43%) consented to the study, 322 (25%) declined, and 423 (32%) were not approached. Consented pts were younger compared to those who declined or to those not approached (median age 49, 51, and 51 years, respectively; $p = .01$). Comparison of study groups by age and race categories are shown in the table. Pts > 70 were less likely to be approached compared to pts < 70 ($p = .01$). However, The likelihood of pts being approached to consent did not differ significantly with age ($p = .09$). Of the eligible pts, 951 (73%) were White, 327 (25%) were non-White (10% Asian, 8% Black, 1% Hispanic, and 7% other race), and race was unknown for 31 (2%) pts. White and non-White pts were equally likely to be approached ($p = .3$). However, approached non-White pts were significantly less likely to consent compared to White pts ($p = .01$). Within the non-White population, Black pts were more likely to decline a research biopsy, with only 50% of approached Black pts consenting compared to 66% of White pts, 61% of Asian pts and 55% of pts of other race. **Conclusions:** We found disparities based on age and race/ethnicity in participation in a breast biopsy tissue biobank. Older pts were less likely to be offered participation but equally likely to consent when invited, while Black pts were equally likely to be offered participation, but less likely to consent when invited, compared to other racial subgroups. Our findings support targeted interventions to increase participation across diverse subgroups of pts. Research Sponsor: None.

Beyond transportation: Financial hardship, food insecurity, and care access barriers among US cancer survivors with transportation barriers to care. *First Author: Changchuan Jiang, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Health care payers and providers increasingly focus on addressing social determinants of health (SDoH) in order to reduce disparities in care and patient outcomes in the US. Transportation barriers to health care, a key SDoH, are associated with increased emergency department use and mortality risk among cancer survivors. Transportation barriers may also be associated with other potentially addressable aspects of SDoH and access barriers. To inform future interventions, we examined financial hardship and barriers to timely care among cancer survivors with transportation challenges in a nationally representative sample. **Methods:** We identified 18,140 adults with a history of cancer from the 2011-2018 National Health Interview Survey. Transportation barriers were defined as delay in care due to lack of transportation over the past 12 months. Primary outcomes included 1) medical financial hardship (FH) in any of the three following domains: material (problems paying medical bills), psychological (worrying about medical bills), and behavioral hardship (delaying/forgoing care due to cost); 2) food insecurity (worrying food would run out); and 3) delayed care due to other factors (long wait times, inability to get an appointment quickly). We estimated the proportion of survivors who report any financial hardship, food insecurity, or other factors that lead to care delays than survivors without transportation barriers (86.0% vs 45.3%, $p<0.001$). Additionally, survivors with transportation barriers were more likely to experience medical financial hardship (73.2% vs 38.3%, $p<0.001$), including material (50.3% vs 27.1%, $p<0.001$), behavior (57.5% vs 20.4%, $p<0.001$), and psychological (33.5% vs 15.4%, $p<0.001$) hardship than survivors without transportation barriers. Additionally, survivors with transportation barriers were more likely to experience food insecurity (43.9% vs 12.0%, $p<0.001$) and care delays due to other factors (45.6% vs. 11.6%, $p<0.001$). **Conclusions:** Most cancer survivors with transportation barriers to care also report struggling financially and experiencing additional barriers to timely care. Findings highlight the importance of screening and addressing social needs and comprehensive interventions to address barriers to care access in this vulnerable population. Research Sponsor: None.

County-level jail incarceration and cancer mortality in the US. *First Author: Jingxuan Zhao, American Cancer Society, Atlanta, GA*

Background: Incarceration has been linked to poor community health outcomes, such as worse preterm births and mortality in the US, although little research has examined cancer outcomes. This study examined associations of county-level jail incarceration and cancer mortality. **Methods:** Annual county-level local jail incarceration rates (1990-2018) were obtained from the Vera Institute of Justice. We calculated annual county-level mortality rates (2000 -2019) with invasive cancer as the underlying cause of death (ICD-10 codes: C00-C97) using National Vital Statistics System. Associations of county-level jail incarceration and cancer mortality overall, and by sex, race, and common cancer sites were examined with generalized estimating equations with Poisson distribution and standard errors clustered at county level. To assess the short-, medium-, and long-term associations, we used lagged county-level incarceration rates by 1, 5, and 10 years prior to mortality rates in separate analyses. **Results:** Over the 20-year study period, each 1 per 1000 increase in county jail incarceration rate was associated with a 1.2% increase in cancer mortality rate in the short-term (model with 1-year lags, rate ratio (RR): 1.012, 95% CI: 1.009–1.015) and 1.1% increase in medium-term (5-year lags (RR: 1.011, 95% CI: 1.008–1.014) and 0.8% increase long-term (10-year lags (RR: 1.008, 95% CI: 1.004–1.012). After adjusting for county-level sociodemographic characteristics, the RRs were attenuated but remained statistically significant. Jail incarceration was associated with higher cancer mortality for all common cancers included in the study (Table) and for White people, but not for Black people. The magnitude of associations was similar for medium- and long-term effects (5- and 10-year lags, respectively). **Conclusions:** Higher county-level jail incarceration rates were associated with higher county-level cancer mortality rates, underscoring the collateral health consequences of mass incarceration. Efforts to identify interventions to decrease the cancer mortality burden in these communities are warranted. Research Sponsor: None.

An intersectional approach to cervical cancer screening disparities by race/ethnicity and immigrant status. *First Author: Jane J. Chen, Warren Alpert Medical School of Brown University, Providence, RI*

Background: Racial/ethnic minority and immigrant groups individually experience lower rates of cervical cancer (CC) screening. Although immigrants represent large proportions of racial/ethnic minorities, few studies have explored the interacting health consequences of these social categories. Intersectionality is a theoretical framework which recognizes that studying social categories independently cannot capture their cumulative effects on health. In the context of CC screening, only one study took this approach but did not analyze several important barriers to care. This study aims to analyze the joint influence of race/ethnicity and immigrant status on screening and identify barriers unique to each intersectional group. **Methods:** Data from the National Health Interview Survey years 2005, 2010 and 2015 were drawn from IPUMS. Analyses were restricted to those eligible for CC screening (n=17,941). Multivariable logistic regression was used to model the interactional effect of race/ethnicity and immigrant status on screening up to date (UTD) status adjusting for confounders. Variables reflecting socioeconomic status (SES), access to care, acculturation and language were separately included to see whether they explained identified disparities. Finally, amongst women not UTD on screening, reasons for this were analyzed. All analyses were adjusted for complex survey design. **Results:** US born Non-Hispanic Black women had higher odds of being UTD on screening (OR 1.63, 95% CI [1.23, 2.18]) while immigrant Non-Hispanic White (OR 0.45 [0.29, 0.71]), immigrant Asian (OR 0.29 [0.2, 0.42]) and immigrant Hispanic/Latinx women (OR 0.51 [0.39, 0.67]) had lower odds compared to US born Non-Hispanic White women. Adjusting for SES (OR 0.87 [0.65, 1.16]) and access (OR 1 [0.74, 1.36]) attenuated the ORs for immigrant Hispanic/Latinx women but not immigrant Asian and White women. Adjusting for acculturation attenuated the ORs for immigrant Hispanic/Latinx (OR 0.84 [0.58, 1.22]) and White women (OR 0.68 [0.42, 1.12]) only. Adjusting for language increased but did not attenuate the ORs for all immigrant groups. Analyses of reasons for not screening showed immigrant Non-Hispanic White, Black and Asian women had greater proportions selecting "Didn't need or know needed this test" versus other groups (10-12% vs. 5.4-8.4%). **Conclusions:** Immigrant status continues to explain much of the CC screening disparities previously attributed to race/ethnicity. SES and access to care remain important barriers for immigrant Hispanic/Latinx women but less so for other immigrant groups. This study reveals that acculturation is an important barrier for immigrant Non-Hispanic White and Hispanic/Latinx women, possibly representing disparities in knowledge. Language barriers may also contribute in all immigrant women. Further intersectional studies are needed to identify remaining barriers. Research Sponsor: None.

The association between continuity of Medicaid enrollment and cancer survival in young adults diagnosed with cancer. *First Author: Kimberly J. Johnson, Washington University in St. Louis, St. Louis, MO*

Background: Disparities in young adult cancer survival between individuals with Medicaid and private insurance have been reported. To further understand the association between insurance-related access to healthcare and young adult cancer survival, we used Surveillance, Epidemiology, and End Results (SEER)-Medicaid linked data to test two hypotheses: 1) Those linked to Medicaid have lower cancer survival than those not linked, and 2) those with discontinuous enrollment in Medicaid around the time of diagnosis have lower survival than those with continuous enrollment. **Methods:** SEER-Medicaid linked data from 2006 to 2013 were obtained. Follow-up for vital status was through 2018. We included individuals diagnosed with a first malignant primary cancer diagnosed between 20 to 39 years. We excluded individuals who were linked to Medicaid enrollment records in multiple states during the same year. Individuals were defined as Medicaid-linked if they were linked to Medicaid in any U.S. state or the District of Columbia from 2006 to 2013. Medicaid enrollment was classified as continuous (enrolled within both the three months before and after diagnosis) and discontinuous (enrolled only within the 3 months before or after diagnosis or only at diagnosis). We used survival analysis methods including Kaplan-Meier (KM) curves and Cox Proportional Hazards (PH) regression models to evaluate survival differences in association with Medicaid linkage and enrollment timing after adjusting for race and a measure of census tract poverty. **Results:** Our analytic dataset included 137,259 young adults, among which there were 22,955 cancer deaths. KM curves showed consistently lower survival probabilities over time in young adults who linked vs. those not linked to Medicaid and in those with discontinuous vs. continuous enrollment (p < .0001). Adjusted Cox PH regression models indicated that those who linked to Medicaid had a 2.19 (95% CI 2.14-2.25) times higher hazard of death vs. those who did not link. Those with continuous and discontinuous Medicaid enrollment had a 1.91 (95% CI 1.84 to 1.99) and 3.32 (95% CI 3.19 to 3.45) times higher hazard of death, respectively, vs. those not linked to Medicaid. Similar patterns were consistently observed for specific cancer types. **Conclusions:** These results confirm an insurance-associated disparity in a national sample of young adult cancer patients and provide additional information on risks in association with Medicaid enrollment continuity. These results further support the critical need for consistent health insurance coverage in young adults and for additional research to understand social, economic, and access-related factors leading to lower survival in the Medicaid population. Lowering administrative burdens for Medicaid enrollment, eligibility, and renewal are potentially important strategies for improving cancer outcomes. Research Sponsor: None.

Associations of cancer history, food insecurity, and nonmedical financial worry and mortality risk in the US. *First Author: Zhiyuan Zheng, American Cancer Society, Atlanta, GA*

Background: Cancer survivors often face substantial out-of-pocket medical costs, which can adversely affect their financial well-being. Cutting expenses on food and housing to save money are common coping strategies. However, little is known about the extent to which food insecurities and non-medical financial worries affect mortality risk after consideration of medical financial hardship. **Methods:** The 2013-2018 National Health Interview Survey (NHIS) and the NHIS linked mortality files with vital status through December 31, 2019 were used to identify cancer survivors (ages 18-64: n=5,110; ages 65-79: n=4,949) and individuals without a cancer history (ages 18-64: n=115,643; ages 65-79: n=24,785). Medical financial hardship included 3 domains: material, psychological, and behavioral. Food insecurity (e.g., worry about food running out) and non-medical financial worries (e.g., paying for monthly bills and housing) were separately summarized and categorized as severe, moderate, and minor/none levels. Using age as the time scale, associations of cancer history, food insecurity and non-medical financial worry and mortality risk were examined with weighted Cox proportional hazards models. Adjusted models included medical financial hardship, sex, educational attainment, marital status, health insurance, comorbid conditions, and survey year. All estimates accounted for complex survey design. **Results:** In our sample, about 13.8% (ages 18-64) and 7.9% (ages 65-79) reported moderate to severe levels of food insecurity, respectively; 32.1% (ages 18-64) and 19.2% (ages 65-79) reported moderate to severe levels of non-medical financial worries, respectively. In adjusted analyses, cancer survivors had increased mortality risk. After controlling for medical financial hardship, food insecurity was associated with higher mortality risk in both age groups, following a dose-response relationship (Table); Non-medical financial worry was associated with higher mortality risk in the 65-79 age group (Table). **Conclusions:** Standardized and comprehensive assessment of financial hardship and other social needs, such food insecurity, is essential to identify and mitigate adverse economic impacts of cancer. Research Sponsor: None.

Association of Medicaid expansion with timely receipt of treatment and survival among patients with HER2-enriched breast cancer. *First Author: Kewei Sylvia Shi, American Cancer Society, Atlanta, GA*

Background: HER2-enriched breast cancer (estrogen and progesterone receptors negative and HER2-positive) has no worse prognosis than other breast cancers if it is treated with HER2-targeted therapy. Medicaid expansion under the Affordable Care Act (ACA) has been shown to be associated with improved access to care and outcomes for many cancers, but its impact on care for HER2-enriched breast cancer is unknown. To fill this gap, we examined the association of Medicaid expansion with receipt of guideline-concordant treatment, time to treatment, and survival among newly diagnosed nonelderly women with HER2-enriched breast cancer. **Methods:** Women aged 18-62 years newly diagnosed with HER2-enriched breast cancer between 2010 and 2018 were identified from the National Cancer Database. Our primary outcomes included receipt of stage-based guideline-concordant treatment, initiation of treatment <60 days, and stage-specific 2-year overall survival. A difference-in-differences (DD) approach compared outcome changes following the expansion in Medicaid expansion vs. non-expansion states. A linear probability model estimated treatment outcome, and a flexible parametric survival model evaluated survival. All models were clustered at the state level and adjusted for age group, race/ethnicity, rurality of residence, zip code-level income, comorbidity, and diagnosis year. **Results:** A total of 31,354 patients with HER2-enriched breast cancer were included, including 19,255 in expansion states and 12,099 in non-expansion states. Compared to patients in expansion states, patients in non-expansion states were more likely to be racial/ethnic minorities, uninsured, and diagnosed at late-stage. Medicaid expansion was not significantly associated with changes in receipt of surgery for stage I-III disease but was associated with an increase of 4.42 percentage points (ppt, 95% CI: 0.09, 8.74) in receipt of chemotherapy/targeted therapy for stage IV disease, with an increase from 90.4% pre-expansion to 92.8% post-expansion in expansion states and a decrease from 93.7% to 91.9% in non-expansion states. Medicaid expansion was also significantly associated with a 2.41 ppt increase in initiating guideline-concordant treatment within 60 days (95% CI: 0.66, 4.17; 83.5% to 82.5% in expansion states vs. 86.6% to 83.7% in non-expansion states), and a 1.18 ppt increase in two-year survival rate (95% CI: 0.03, 2.33; 94.0% to 94.9% in expansion states vs. 94.3% to 94.1% in non-expansion states). The increase in two-year survival associated with Medicaid expansion was most prominent for stage III patients (DD=3.63 ppt; 95% CI: 0.64, 6.62). **Conclusions:** Medicaid expansion was associated with increased receipt of timely treatment and improved 2-year survival among nonelderly women newly diagnosed with HER2-enriched breast cancer. Disparities in uptake of novel therapies for acute myeloid leukemia. *First Author: Andrew Hantel, Division of Population Sciences, Dana-Farber Cancer Institute, Boston, MA*

Background: Multiple novel therapies have recently been approved to treat acute myeloid leukemia (AML). Inequities in the uptake of novel treatments have been seen in other cancers but are not known for this population. **Methods:** We performed a retrospective analysis of the nationwide Flatiron Health electronic health record (EHR)-derived de-identified database. We assessed sociodemographic associations with novel AML therapies use within two-years of Food and Drug Administration (FDA) approval from 1/2014-8/2022. Therapies were: glasdegib, venetoclax, ivosidenib, midostaurin, CPX-351, gilteritinib, enasidenib, and gemtuzumab ozogamicin (GO). Univariable associations were assessed using χ^2 testing. Logistic regression modeling of community practices assessed associations between novel therapy receipt and sociodemographics adjusted by treatment year. Variable categories are shown. **Results:** Of 8081 patients in 280 clinics, 3102 (38%) received at least one novel therapy. The cohort was predominantly older (69; interquartile range [57, 77]), male (56%), non-Hispanic (NH)-White (88%), and treated at a community practice (75%). There were 4808 patients treated within 24-months of a novel therapy approval, of which 1937 (40%) received a novel therapy. Venetoclax represented 59% of novel treatments prescribed. Bivariate associations were seen between novel therapy receipt within 24-months of approval and high SES and non-Hispanic (NH)-White race-ethnicity; similar associations were seen when assessed at the treatment regimen level. In a logistic regression model of community practices (N=2,459), older patients (OR 1.01; 95%CI 1.00, 1.02), females (OR 1.2; 95%CI 1.0, 1.4), and those from high (vs low) SES (OR 1.4; 95%CI 1.1, 1.6) were more likely to receive novel therapy; there were no associations with sex or race-ethnicity. **Conclusions:** In this large national database of adults with AML, almost half received novel therapy within 24-months of FDA approval. Though there was no dichotomous difference in uptake by race-ethnicity in community practices, younger and more affluent patients were more likely to receive novel therapy, concerning for disparities in uptake. Research Sponsor: American Cancer Society; Conquer Cancer Foundation of the American Society of Clinical Oncology; U.S. National Institutes of Health.

Racial and ethnic disparities in employment of patients and caregivers following breast cancer diagnosis. *First Author: Marisa C. Weiss, Breastcancer.org, Ardmore, PA*

Background: Breast cancer (BC) can negatively impact employment, risking healthcare benefits, financial security and quality of life, especially for underserved minority populations. To better understand the impact of BC diagnosis and treatment on employment, Breastcancer.org conducted an online survey. **Methods:** Between 6/7-7/12/2022, Breastcancer.org community members were recruited to participate in an anonymous survey in English or Spanish via email, social media, or website ads. Eligible participants were US residents, age ≥ 18 , and diagnosed with BC within the past 10 years. Consented participants answered questions on socio-demographics, financial toxicity, and employment status. **Results:** Of 2,420 screened, 1,710 met eligibility, and 1,437 participated (84% participation rate). Mean age and time since diagnosis was 46 and 2 years, respectively; 75% were in active treatment for non-metastatic (89%) or metastatic (11%) BC. Patients identified as 60% White (n=868), 26.7% Hispanic (n=384), 8% Black (n=121), or 4% Other (n=64). 94% were women. BC negatively impacted employment for 92% of patients. Full-time employment went from 62% at diagnosis to 40% by the time of the survey. This was more pronounced in metastatic (56% to 25%) vs non-metastatic (63% to 42%) patients (p=0.015). 64% attributed employment changes to their diagnosis, noting reduced hours/income (40%), job change (26%), disability (13%), permanent job loss (13%), and/or early retirement (12%). 36% noted changes in their caregiver's employment status as well with 30% of caregivers having reduced hours/income, 30% taking time off work, and 27% changing jobs; 9% of caregivers had permanent job loss and 10% retired early. Hispanic patients were younger (p<0.001) and more likely to have young children (p<0.001) and take unpaid leave (p=0.02). (Table). BC diagnosis was also more likely to impact their caregiver's employment (58%, vs White 25% or Black 41% patients, p<0.001). **Conclusions:** Breast cancer can cause significant, lasting negative effects on employment status for patients and caregivers that can decrease financial security of the entire family unit. Hispanic patients and individuals with metastatic disease appear to be at highest risk. Legislative protections and financial support may be required to mitigate the significant financial toxicity of a cancer diagnosis, especially for the most vulnerable. Talk, test, and take one click to curb prostate cancer mortality. *First Author: Sandhya Cautha, Bronxcare Health System, Bronx, NY*

Background: Prostate cancer remains the most commonly diagnosed cancer and the second leading cause of cancer-related death in men in the United States. BronxCare Health System (BCHS) serves the Bronx neighborhoods of Morris Heights, Fordham South, and Mount Hope, notable for the highest prostate cancer incidence rate in New York City as per the American Cancer Society Cancer Action Network report 2019, highlighting the need for prostate cancer screening among the patient population we serve. An anonymous voluntary paper survey was performed in 2019 at BCHS to determine primary care physician understanding and implementation of current PSA testing guidelines. The study showed that primary care providers at BCHS approach PSA testing in a wide variety of ways and screen a wide age range of patients suggesting a need for intervention. An electronic medical record (EMR) decision support tool activated during primary care visits for men aged 55-69 years was implemented beginning January 1, 2021 which facilitates the provider and patient engagement in a shared decision-making discussion. This a follow-up study to determine the effect of this EMR application on PSA order rates and prostate cancer diagnosis rates at BCHS. **Methods:** The total number of patients who had PSA and lipid panel (LP) screening were extracted from the EMR of BCHS for potentially eligible men (aged 55-69) seen during primary care visits during the years 2016-2022. LP is done annually as a part of routine screening for adults aged 55-69 and is taken as an equivalent of primary care visits. PSA screening rates were compared to LP screening rates to control for unforeseen variables. Similarly, the number of newly-diagnosed prostate cancers among the same population of men was extracted for the years 2016-2021. Data for 2022 is still not available. 2016-2020 are pre-EMR and 2021 and 2022 are post-EMR flag years. The pre and post-EMR flag PSA and prostate cancer diagnosis numbers were compared by calculating Z scores and p-values. **Results:** The year-wise PSA, LP, and newly-diagnosed prostate cancers (PC) are tabulated below. The proportion of men who had PSA testing among all men aged 55-69 who had LP testing in each pre-EMR flag year was compared to each post-EMR flag year. A significant increase (p < 0.00001) was noted in the proportion of men who had PSA screening after implementation of the EMR application. Similarly, the proportion of men with newly-diagnosed prostate cancer among all men aged 55-69 who had PSA screening significantly increased after EMR application (p < 0.00001). **Conclusions:** A decision support tool embedded in the EMR has been an effective approach in increasing prostate cancer screening rates and may help curb prostate cancer mortality in our patient population as early detection in right men at the right age has the potential to reduce prostate cancer mortality. Depression, systemic inflammation, and exposure to discrimination among sexual and gender minority (SGM) cancer survivors. *First Author: Charles Stewart Kamen, University of Rochester Medical Center, Rochester, NY*

Background: Our prior research shows that SGM cancer survivors experience high rates of depression, due in part to exposure to discrimination. Depression among cancer survivors in general has been linked to markers of systemic inflammation including peripheral blood interleukin (IL)-6, tumor necrosis factor alpha (TNF α), and C-reactive protein (CRP). To date, no studies have examined the association of these markers with depression among SGM cancer survivors in the context of discrimination. **Methods:** Cross-sectional patient-reported data and serum samples were collected from 66 SGM cancer survivors (see Table). Depression was assessed by the Patient Health Questionnaire (PHQ)-9, discrimination by the Harassment, Rejection, and Discrimination Scale (HHRDS), IL6 and TNF α by multiplex assay, and CRP by ELISA. We used a clinical cut-point for depression of 10 on the PHQ-9, indicating moderate depressive symptoms, and assessed associations between continuous variables using bivariate correlations and multivariate linear regressions. **Results:** More SGM cancer survivors exceeded the clinical cut-point for depression (15.9%) than cancer survivors in prior general population samples (11.3%). Higher depression among SGM cancer survivors was associated with higher levels of exposure to discrimination (r=0.28, p=0.03), TNF α (r=0.30, p=0.02), and CRP (r=0.39, p=0.002); exposure to workplace discrimination, specifically, was associated with higher levels of CRP (r=0.32, p=0.02). In multivariate models controlling for demographic and clinical characteristics, CRP remained a significant predictor of depression (β =0.34, p=0.01). **Conclusions:** This study replicates prior findings of high levels of depression among SGM cancer survivors. It provides preliminary evidence that markers of inflammation, specifically CRP, are uniquely predictive of depression among SGM cancer survivors in the context of exposure to discrimination. These findings need to be replicated in larger samples and evaluated for potential use in providing supportive cancer care to SGM survivors. Research Sponsor: U.S. National Institutes of Health.

Association of major adverse financial events and later stage cancer diagnosis in the US. *First Author: Robin Yabroff, American Cancer Society, Atlanta, GA*

Background: Studies have documented an increased risk of bankruptcy and other financial hardships for individuals following a cancer diagnosis in the US. Few studies, however, have examined how patients' financial situation prior to cancer diagnosis is associated with cancer stage at diagnosis. This study assessed the prevalence of the specific major adverse financial events (AFEs) of bankruptcies, liens, and evictions prior to cancer diagnosis and their association with later stage diagnosis. **Methods:** Individuals aged 21 to 69 years diagnosed with cancer during 2014-2015 were identified from the SEER population-based registries for Seattle, Louisiana and Georgia. Registry data were linked with LexisNexis consumer data to identify patients with a history of court-documented AFEs. All AFEs occurring at any time prior to cancer diagnosis were identified. The association of AFEs and later stage cancer diagnoses (Stages III/IV) was assessed with sex-specific multivariable logistic regression. **Results:** Among 101,649 individuals diagnosed with cancer linked to LexisNexis data, 36,791 (36.2%) had a major AFE reported prior to diagnosis. The most recent event occurred a mean of 7.8 years prior to diagnosis. For individuals with an AFE, one-third experienced multiple events. Within each registry, AFEs were most common among non-Hispanic Black, unmarried, and low-income individuals. However, even in the highest income group, 27% had a prior AFE. Individuals with prior AFEs were more likely to be diagnosed with later stage cancer than individuals with no prior AFE (males-odds ratio (OR) 1.09; 95% CI, 1.03 to 1.14; $P < .001$ and females-OR 1.11; 95% CI, 1.06 to 1.17; $P < .0001$), after adjusting for age, race and ethnicity, marital status, income prior to diagnosis, registry, and type of cancer. The association between a major AFE and later stage diagnosis was observed regardless of when the event occurred relative to cancer diagnosis. **Conclusions:** In this novel cancer registry, LexisNexis consumer data linkage, we found that one-third of individuals newly diagnosed with cancer had a pre-diagnosis bankruptcy, lien, or eviction. Individuals with these AFEs were more likely to have later stage diagnosis, even after accounting for traditional measures of socioeconomic status, such as income. The prevalence of pre-diagnosis AFEs underscores patient financial vulnerability at the time of their cancer diagnosis, even before experiencing any subsequent financial burden associated with cancer treatment. Our findings are especially timely, with growing efforts by health care providers to screen and address patient social needs as part of oncology care. Research Sponsor: None.

Racial disparities in cancer mortality in patients with gastrointestinal malignancies following Medicaid expansion. *First Author: Naveen Manisundaram, Department of Surgery, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Racial minorities experience disparities in receipt of cancer treatment and survival. The optional Medicaid expansion provision of the Affordable Care Act provided federal funding to participating states to improve healthcare access for disadvantaged populations by expanding Medicaid eligibility criteria. This study aimed to investigate the effect of Medicaid expansion on racial disparities in mortality among patients with gastrointestinal malignancies. **Methods:** A cross-sectional cohort study of patients with pancreatic ductal adenocarcinoma (PDAC), colorectal cancer (CRC), and gastric adenocarcinoma (GC) of any stage was conducted using the National Cancer Database (2009-2019). Difference-in-difference analysis (DID) was performed to compare adjusted 2-year mortality separately among Black and White patients residing in Medicaid expansion states (MES) and non-expansion states (non-MES) before (2009-2013) and after (2014-2019) expansion. Differences in receipt of surgery and chemotherapy were also evaluated. **Results:** A total of 86,052 patients were included for analysis, including 19,188 patients with PDAC, 60,404 with CRC, and 6,460 with GC. Two-year mortality decreased among Black patients with PDAC residing in MES compared to non-MES following expansion (DID -9.4%, $p < 0.001$) (Table). Mortality also decreased among Black and White patients with CRC in MES compared to non-MES following expansion (DID -4.2%, $p < 0.001$ and -2.9%, $p = 0.047$). Among patients with GC, Black patients in MES experienced a marked reduction in mortality compared to non-MES (DID -7.7%, $p = 0.07$). Both Black and White stage 3-4 PDAC patients had an increase in receipt of chemotherapy in MES following expansion (DID 3.7%, $p = 0.28$ and DID 2.7%, $p = 0.20$). Rates of surgery, but not chemotherapy receipt, increased among Black patients with stage 4 CRC in MES following expansion (DID 5.7%, $p = 0.03$ and 1.0%, $p = 0.66$, respectively). A greater increase in receipt of chemotherapy was observed among Black patients with stage 4 GC in MES than in non-MES (DID 11%, $p = 0.06$). **Conclusions:** Medicaid expansion was associated with a greater reduction in 2-year mortality rates for Black patients residing in MES than for those in non-MES. Existing racial disparities in mortality remained the same or worsened in non-MES but in almost all cases were mitigated in MES following Medicaid expansion. Research Sponsor: U.S. National Institutes of Health.

Difference in adjusted 2-year mortality in black compared to white patients in expansion (MES) and non-expansion states (non-MES) following Medicaid expansion.

What is your preferred language? Evaluating equal access to oncology clinical studies for non-English-speaking participants. *First Author: Dame Idossa, University of Minnesota, Minneapolis, MN*

Background: Oncology clinical research studies (CRS) are essential for developing new therapies and improving patient outcomes, yet the lack of diversity among research participants remains an issue. The logistical complexity of participating in CRS, lack of funding, limited location of study sites, socioeconomic barriers, and the exclusion of non-English speakers (NES) likely contribute to this lack of diversity. In this study, we sought to evaluate what proportion of oncology CRS exclude NES. **Methods:** We searched ClinicalTrials.gov on December 28, 2022, to identify registered oncology CRS in the most prevalent cancer types: breast, lung, colorectal, and prostate cancers. Only US based studies were included. We reviewed the inclusion and exclusion criteria of each study and identified those that excluded NES. Trials with available informed consent forms (ICFs) were examined to evaluate length, available languages, and readability. Descriptive analysis and chi-squared tests were used to explore associations between study characteristics and the exclusion of NES. **Results:** We identified 12,393 CRS, of which 2527 were excluded due to duplicates listed under more than one cancer type. Of 9866 evaluable studies, 1195 (12%) explicitly excluded NES individuals from participating. Of these, 161 (13%) allowed Spanish-speaking participants. Breast cancer trials had the highest proportion of CRS which excluded NES (17%), followed by trials in colorectal (13%), prostate (9%), and lung (7%) cancer. When analyzed by funding sources, studies funded by academic institutions had the highest proportion of CRS that excluded NES individuals (24%) compared to 15% of NIH funded, 19% of other government-funded, and 2% of industry-funded studies ($p < 0.001$). Compared to interventional studies, observational research studies were more likely to exclude NES (11% vs 20%; $p < 0.001$). Notably, most CRS did not have ICFs available online. Of the 242 (2%) studies that had ICFs available for review, only 3 (1%) had ICFs available in another language – all of which were in Spanish. Furthermore, many ICFs were lengthy, with a median of 11 pages (range 1-54), and complex, with a median readability of 12th grade Flesch Kincaid level (range 6-26). **Conclusions:** Many oncology CRS, especially those funded by academic institutions, exclude NES, impacting 1 in 10 individuals in the US. This exclusion is not always explicit, making it likely that our findings underestimate the issue. Requiring English proficiency for research study participation will continue to contribute to the underrepresentation of historically excluded populations and NES patients with cancer from clinical trials and other research studies. Eliminating exclusionary criteria based on language and providing adaptive resources for NES participants is crucial for ensuring that oncology research is inclusive and grounded in equity. Sexual orientation and gender identity data collection among NCI community oncology research program (NCORP) practices: A 5-year landscape update. *First Author: Elizabeth Jane Cathcart-Rake, Department of Medical Oncology, Mayo Clinic, Rochester, MN*

Background: National organizations (ASCO, ACS, ACCR) have advocated for routine collection of sexual orientation and gender identity (SOGI) in cancer clinics to advance cancer health equity. In 2017, only 24% of NCI Community Oncology Research Program (NCORP) practices collected sexual orientation (SO) data, while 10% collected gender identity (GI) data; recent progress in collection is unknown. **Methods:** In 2022, NCORP practices again completed a Landscape Assessment to assess research capacity (funding support from 2UG1CA189824) and were asked whether they routinely collect SOGI data in the electronic health record (EHR). The proportions of practices reporting collection of SO and/or GI data and population level differences over time were calculated using Fisher's exact tests. Univariate associations between SOGI data collection and site-related variables were evaluated using logistic regression; significant associations were then tested in separate multivariate logistic regression models. **Results:** 271 practices responded to the Landscape Assessment; 42% (114) reported that they routinely collect SO data, 58% (157) reported that they collect GI data; both were significantly higher than 2017 ($p < 0.001$). Compared to other regions, practices in Northeastern states were significantly more likely to report collecting GI, but not SO. Practices with higher proportions of White patients were also more likely to collect GI ($p < 0.001$). Practices with community outreach staff were more likely to collect SO (Table 1). There were no significant differences in SOGI collection by Medicaid/Medicare patients, new cancer cases per year, or practice ownership. In both 2017 and 2022, sites in Southern states were less likely to collect GI than sites in other regions. **Conclusions:** Progress was made in SOGI collection between 2017 and 2022, but fewer than half of NCORP sites routinely collect SOGI data; in spite of national guidelines. Further examination of the cultural context of SOGI collection could inform efforts to improve data collection in the South and other regions. The lack of data on sexual and gender minority patients in the EHR contributes to health inequity and deficiencies in patient-centric care. Research Sponsor: U.S. National Institutes of Health.

Patient-level interventions to increase guideline concordant treatment among Black breast cancer patients: Can they close the racial gap in survival after diagnosis? *First Author: Juan Yanguela, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: While we have seen impressive improvements in breast cancer (BC) survival over the last few decades, substantial racial disparities persist. Inequities in the receipt of guideline-concordant treatment contribute to worse survival in Black BC patients. Previous studies have shown that patient-level disparity reduction interventions (e.g., patient navigation) can significantly increase guideline-concordant treatment receipt among Black patients, with positive spillover effects in nonBlack patients. The aim of this study was to estimate the potential impact of disparity reduction interventions on racial inequities in survival after BC diagnosis in North Carolina. **Methods:** We used data from the Cancer Information and Population Health Resource, which links multipayer claims to North Carolina's cancer registry for biological women diagnosed with BC in 2004-2017. We calculated Black/nonBlack disparities in the receipt of chemotherapy (CTx) within 4 months of diagnosis for patients ages <70 with hormone-receptor negative stage I-II BC (CTx cohort; N=2223) and the receipt of endocrine therapy (ET) within 12 months of diagnosis for stage I-III hormone receptor-positive BC (ET cohort=16220). We then simulated the potential increase in the proportion of patients receiving CTx and ET if proven patient-level disparity-reduction interventions were implemented across the state. Based on the literature, we assumed that the effects of these interventions in increasing treatment receipt would be same in the CTx and ET cohorts. We estimated the effect of this potential increase in CTx and ET receipt on 10-year overall survival using cohort-, race-, and treatment receipt-stratified Markov models. We report confidence bounds representing 95% of simulation results. **Results:** Over the 2004-2017 period, 72.9% and 70.8% of Black patients in our cohorts received CTx and ET, respectively. This was significantly lower than among nonBlack patients ($p<.05$). State-wide implementation of disparity reduction interventions could increase CTx and ET receipt among Black patients to 86.7% (80.9-92.5%) and 84.2% (78.5-89.9%), respectively. As a result, the racial 10-year survival gap would decrease from 9.4 to 8.1 (5.7-10.5) percentage points in the CTx cohort, and from 6.2 to 5.4 (4.0-6.7) percentage points in the ET cohort. **Conclusions:** Patient-level interventions can reduce disparities in guideline-concordant-treatment receipt. However, increases in treatment receipt alone would not be enough to close the racial survival gap, suggesting that, in isolation, patient-level interventions are unable to eliminate disparities. Action on the structural factors that disadvantage Black BC patients is needed. Our team is conducting community-engaged work to share and interpret these findings. The intersection of neighborhood-level disadvantage and overall lung cancer survival. *First Author: Kathleen Kennedy, Department of Hematology Oncology University of Illinois of Chicago College of Medicine, Chicago, IL*

Background: Despite recent advances in lung cancer therapeutics leading to considerable improvement in survival, disparities continue to persist among socially disadvantaged populations. Although the reasons underlying this phenomenon are uncertain, we posit that neighborhood-level factors could play a role. Furthermore, neighborhood disadvantage may lead to epigenetic changes which promote malignant progression. This study aimed to determine the effects of neighborhood-deprivation index (NDI), a validated 13-factor-based measure, that combines income, education, employment, and housing in a neighborhood, on lung cancer mortality. **Methods:** A retrospective cohort study assessed the relationship of NDI with survival weighted by age, stage, and DNA methylation among biopsy-proven lung cancer from two U.S. medical centers, Johns Hopkins University and the University of Illinois Chicago, between 2008-2020. In our analysis, U.S.-standardized NDI values for each year of sample collection were computed at the U.S. census tract level and categorized into quartiles. Participants' residential addresses were geocoded to U.S. census tracts and linked to NDI quartiles. DNA extraction from liquid biopsy samples was performed for quantification of DNA methylation. **Results:** The study included 184 lung cancer patients, with 89 in the low-deprivation group and 95 in the high-deprivation group. The high-deprivation group had a higher percentage of females (57% vs. 48%), a higher percentage of African Americans (AA) (50% vs. 36%), a lower pack-year smoking history (30 vs. 39 median pack-years), and a higher percentage with stage IV disease (28% vs. 20%) than the low-deprivation group. Overall, NDI was significantly higher among AA when compared with Whites ($p=0.003$) and associated with lung cancer stage at diagnosis with an odds ratio of 1.17 ($p=0.02$). There was a significant correlation between DNA methylation and stage for HOXA7, SOX17, ZPF42, TAC1 and HOXA9. Only HOXA7 DNA methylation correlated with NDI ($p=0.003$). The high-deprivation group had a significantly shorter survival duration compared to the low-deprivation group, with a 1-year survival rate of 79% vs. 90%, a 2-year survival rate of 70% vs. 84%, and a 5-year-survival rate of 51% vs. 73% ($p=0.02$). After adjusting for age at diagnosis, stage, and DNA methylation status, belonging to the high-deprivation group was associated with a higher mortality risk with a hazard ratio of 2.02 ($p=0.04$). **Conclusions:** Neighborhood-level socioeconomic status and DNA methylation may be associated with late stage lung cancer at diagnosis; whereas NDI shows a potential association with shorter survival and increased mortality risk. Higher neighborhood deprivation among AA suggests that changes in health care policy that account for neighborhood-level indices of socioeconomic deprivation may enable more equitable improvement of lung cancer mortality. Disparities in clinical trial enrolment at a Canadian comprehensive cancer centre: A 15-year retrospective study. *First Author: Gilla Shapiro, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Disparities in clinical trials limit the generalizability of study findings and perpetuate disparities in treatment access and outcomes, but there is a paucity of data in the Canadian context. The objective of this study was to examine disparities in cancer clinical trial enrollment at a large, comprehensive Canadian cancer center. **Methods:** We conducted a retrospective cohort study of clinical trial enrollment among all newly diagnosed cancer patients (N=154,880) at the Princess Margaret Cancer Centre in Toronto, Canada (2006-2021). Multivariable Bayesian hierarchical logistic regression with random effect for most responsible physician was used to examine the correlates of clinical trial enrollment, comparing the population of enrolled and non-enrolled patients. Odds ratios were adjusted for patient variables (sex, age at diagnosis, language, geography, primary care provider), and census tract-level marginalization (residential instability, material deprivation, dependency, ethnic concentration), disease variables (cancer site and disease stage at diagnosis), and provider variables (most responsible physician (MRP), and MRP's sex, language, medical training, and department). **Results:** Overall, 11.2% of patients enrolled (n=17,400) in a clinical trial, with 5-, 10-, and 15-year cumulative incidences of 12%, 15%, and 18%, respectively. Small, but significant differences were observed between enrollees and the overall patient population. Lower odds of enrollment were observed in patients who were female (adjusted odds ratio [AOR], 0.82; 95% confidence interval [CI], 0.78-0.86; $p<.001$), ≥ 65 years (AOR vs <40, 0.61; 95% CI, 0.56-0.65; $p<.001$), non-English language speakers (AOR vs English, 0.72; 95% CI, 0.67-0.77; $p<.001$), lived ≥ 250 km away from the cancer center (AOR vs <15km, 0.71; 95% CI, 0.62-0.80; $p<.001$), or lived in areas with greater material deprivation (AOR, 0.94; 95% CI, 0.93-0.96; $p<.001$) or higher ethnic concentration (AOR, 0.96; 95% CI, 0.94-0.98; $p<.001$). Greater odds of enrollment were found in patients with metastatic disease (AOR, 1.19; 95% CI, 1.13-1.25; $p<.001$) and in those with a primary care provider (AOR, 1.69; 95% CI, 1.55-1.85; $p<.001$). **Conclusions:** Disparities were observed in clinical trial enrollment, despite a publicly funded health care system. While broader prospective data collection efforts are critical to better understand the influence of patient, provider and system factors on clinical trial enrollment, these findings suggest the need for targeted strategies to increase diversity in clinical trial access. Impact of the COVID-19 pandemic on insurance transitions among commercially insured cancer patients in Washington state. *First Author: Scott David Ramsey, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Insurance transitions following cancer diagnosis can disrupt care and impact outcomes. The COVID-19 pandemic impacted employment for millions of Americans, threatening their ability to maintain insurance. Using a large database linking commercial insurance to cancer registry records, we evaluated insurance transitions among newly diagnosed cancer patients in the pre- and post-COVID periods. **Methods:** We linked Western Washington SEER cancer registry records and enrollment records from two commercial insurers covering 3 million persons and Medicaid in Washington State. Eligible persons were ages 18-63 and commercially insured in the 12 months prior to their first cancer diagnosis. Post-diagnosis follow-up periods were stratified into pre-COVID (January 2017 – February 2020) and post-COVID (March 2020 – December 2020). We created logistic regression models to look at factors associated with (1) disenrollment for any reason and (2) transition to Medicaid, accounting for age, sex, race, year of diagnosis, cancer site, AJCC stage, comorbidities, and Area Deprivation Index (ADI), and diagnosis during the pandemic. **Results:** Among 5,458 newly diagnosed solid tumor patients enrolled in commercial plans pre-COVID, 16.9% disenrolled for any reason over 12 months following diagnosis. Among disenrollees, 10.0% transitioned to Medicaid. Patients with Lung, Oral, and Myeloma cancers had the highest disenrollments (21.2%, 21.0%, and 19.3% respectively). Among the 1,224 diagnosed post-COVID, 9.7% disenrolled for any reason. Among those who disenrolled, 21.0% enrolled in Medicaid. Patients with Leukemia, Melanoma, Oral, and Gynecologic cancers had the highest disenrollments (23.3%, 14.5%, 13.6%, and 13.6% respectively). In logistic regression, persons diagnosed after the pandemic were less likely to disenroll compared to the pre-pandemic period (Table). Transitions to Medicaid was not greater post-Pandemic. Advanced stage, comorbidity, and living in high ADI regions were significantly associated with transitioning to Medicaid. **Conclusions:** Newly diagnosed cancer patients with commercial insurance during the COVID-19 pandemic were substantially less likely to disenroll than those diagnosed before the pandemic. The findings may reflect pandemic-related preferences for job stability during a time of personal and societal crisis. Research Sponsor: Andy Hill Care Fund.

Translated consent documents (CDs) and use in non-industry sponsored studies (NISS). *First Author: Maria A Velez, Department of Medicine, Division of Hematology/Oncology, UCLA, Los Angeles, CA*

Background: Patients (pts) from historically underrepresented groups often have limited English proficiency (LEP). One challenge specific to obtaining consent from these pts to participate in clinical trials is the need for translated CDs. CD translation leads to enrollment delays and increases costs to study sponsors. We hypothesized that NISS, for which the principal investigator pays translation costs, would consent proportionately fewer pts with a primary language other than English and pts with LEP compared to industry sponsored studies (ISS). **Methods:** Pts' primary language and English proficiency were assessed for all 12,082 consent events with appropriate available data at the Jonsson Comprehensive Cancer Center from 2013 to 2018. Pts with LEP were pts (or parent/guardian for pediatric pts) who had a primary language other than English, and the electronic health record indicated that the pt required a translator within 6 months of the consent date. CD language was documented per chart review when available, and when not, languages of available IRB-approved CDs were evaluated. The proportion of consent events for pts with a primary language other than English and with LEP were compared between NISS and ISS using generalized estimating equations, and the odds of signing CDs in the pts primary language were evaluated by multivariable analyses. Discrepant CD language data was evaluated by McNemar's test. All analyses were performed using SAS 9 (SAS Institute, Cary, NC, USA). **Results:** Pts with a primary language other than English represented 8.1% of consent events in ISS vs 4.4% in NISS ($p<0.001$) and 5.5% vs 2.8% ($p<0.001$) for pts with LEP. Pts with a primary language other than English represented 4.5% vs 1.2% of consent events utilizing CDs in the pts' primary language in ISS vs NISS ($p<0.001$) and 3.7% vs 0.9% ($p<0.001$) for pts with LEP. On multivariable analyses, the odds for pts with a primary language other than English of signing CDs to a NISS was 0.74 (CI, 0.63-0.94, $p=0.005$), and of signing CDs in their primary language was 0.38 (CI, 0.27-0.52, $p<0.001$) compared to pts whose primary language was English. The odds for pts with LEP of signing CD to a NISS was 0.74 (CI, 0.58-0.95, $p=0.02$), and signing CDs in their primary language was 0.35 (CI, 0.25-0.50, $p<0.001$) compared to pts whose primary language was English. Of 52 pts who signed CDs for both ≥ 1 NISS and ≥ 1 ISS, 18 signed in discrepant languages, with 16 of those 18 signing translated CDs for the ISS but not the NISS ($p=0.002$). **Conclusions:** Although the role of cost as an effect driver cannot be proven in a retrospective analysis, consistent with our hypothesis, the proportion of consent events utilizing appropriately translated CDs for pts with a primary language other than English and pts LEP was lower in NISS vs ISS, driven by lower odds of signing CDs and lower frequency of signing translated CDs. Approaches that reduce translation costs for investigators should be investigated. Research Sponsor: Jonsson Comprehensive Cancer Center Seed Grant.

Disparities in lung cancer screening in a diverse urban population and the impact of a community-based navigational program. *First Author: Hina Khan, The Warren Alpert Medical School of Brown University, Providence, RI*

Background: Lung cancer (LC) is the leading cause of cancer death in the US in both men and women; causing 25% of all cancer deaths. Annual lung cancer screening (LCS) with a low-dose CT (LDCT) in high-risk individuals (aged 50-80 with a >20 pack-year smoking history) decreases LC deaths by 20% and is recommended by USPSTF. Despite the efficacy, uptake of LDCT remains low at 6% nationally, and 13% in Rhode Island. Patient (pt) and provider perceived barriers, along with racial, ethnic and socioeconomic disparities widen the gap. We evaluated the implementation of a LCS navigation program at an urban community health center (CHC) with a multiethnic, socioeconomically underserved population. **Methods:** A bilingual (English and Spanish speaking) pt navigator was integrated into routine clinic practice at a large primary care CHC group, across 4 sites, starting in January 2022. The navigator's role was to assess pt and provider awareness of the LCS process, assess for systemic barriers, and provide navigational support for the LDCT process. Pts eligible for LCS at the CHC from 1/2022 to 12/2022 were retrospective examined; 50 to 80 years and a >20 pack-year smoking history. The navigator administered a questionnaire to assess barriers to LDCT and demographic variables. **Results:** A total of 360 eligible pts were seen across the CHC practice in 2022, of which 149 (41.4%) agreed to undergo LDCT after counseling and shared decision making and 28% of these (n 101) completed LDCTs. 153 of the eligible pts completed the survey questionnaire. Of these, 50% were females; 40% were Hispanic/Latinx, 40% were non-Hispanic/Latinx and 22% declined to answer. Majority, 61% were white, 10% African American/Black and 28% declined to answer. A sizeable proportion were non-English speaking (34%) and resided in cities with Rhode Island's lowest per-capita incomes (Pawtucket 48%), Central Falls (32%) and North Providence/Providence (10%). In assessing barriers to LCS, 46% of pts were not aware of the LCS process and 44% were unaware that LCS was covered by health insurance; 58% of eligible pts did not recall their PCP discussing LCS. Of the LDCTs resulted available at the time of analysis, 84% were Lung RADS-1 and 16% Lung RADS-4 category. **Conclusions:** Our study highlights the unique barriers to LCS in an urban multiethnic community. While access to LCS remains an issue, pt awareness of the lung cancer screening process was the major barrier. A patient navigation program is critical to the success of LCS in a community, by providing education to patients and providers and the necessary logistical support needed in the LDCT process. With a community based navigational program, we demonstrate a significant increase in lung cancer screening rates in our population to 28% as compared to the state LCS rate of 13%. Examining clinical trial eligibility for oncology patients with human immunodeficiency virus (HIV): A global cross-sectional analysis. *First Author: Umar Abdullahi, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: People Living with HIV (PLWH) are at higher risk of developing cancer, and malignancy is the most common cause of death in PLWH in the USA. In 2017 a joint research statement by the American Society of Clinical Oncology and Friends of Cancer Research (ASCO-FCR) examined trial inclusivity, stating PLWH should not be excluded from clinical trials due to HIV positivity alone without justification. It also provided guidance for designing trial inclusion criteria using CD4 count, use of antiretroviral therapy (ART), ART-related drug interactions and HIV-associated complications. To review incorporation of ASCO-FCR recommended wording and current compliance, we examined global eligibility for PLWH in clinical trials. **Methods:** Clinicaltrials.gov was searched on 15 Nov 2022 for open and recruiting trials worldwide, using terms 'advanced cancer' and 'interventional'. Trials lacking systemic treatment were deemed non-evaluable. Evaluable studies' eligibility criteria were manually reviewed for specific criterion excluding PLWH or diagnosis/history of immunodeficiency (outright exclusion). Therapy type and study phase were captured and their relationships to outright exclusion were significance tested using odds ratios (OR) with 95% confidence intervals (CI). **Results:** The search rendered 2388 evaluable clinical trials. Eligibility criteria outrightly excluded PLWH in 1194 (50%) , of which 1113 (93%) were early phase trials (Phase 0-2). 206 evaluable trials (8.6%) permitted inclusion of PLWH aligned with ASCO-FCR guidance, including 3 (0.1%) with a cohort for PLWH. AIDS-defining illness was an exclusion criterion in 27 trials (1%), and specific interactions to ART in 10 (0.4%). Early phase trials had a significantly higher likelihood of outright exclusion of PLWH when compared with late phase trials (OR 2.98; 95% CI 2.16-4.11, $p<0.0001$). Trials investigating immunomodulatory agents were more likely to outrightly exclude PLWH than those investigating other drug classes (OR 1.60; 95% CI 1.36-1.88, $p<0.0001$). Criteria which may implicitly exclude PLWH were identified, including 204 (8.5%) citing active/chronic/severe infection, 189 (7.9%) listing CYP and P-gp interaction criteria and 3 (0.1%) "immunodeficiency". **Conclusions:** Despite adequate time to incorporate, most currently recruiting oncology clinical trials do not use ASCO-FCR guidance for including PLWH. Half of evaluated trials excluded PLWH without reason. Early phase and immunotherapy trials were significantly more likely to exclude PLWH without exception, despite data to support immunotherapy use for PLWH. Covert inclusionary barriers exist in criteria that lack HIV-specific guidance, and this may further exclude PLWH. Consideration of recommendations and guidance in eligibility criteria for oncology trials is critical to address current inequities in care for PLWH and cancer. Research Sponsor: None.

Racial disparity in dose intensity of early-stage breast cancer chemotherapy. *First Author: Margaret Q. Rosenzweig, School of Nursing, University of Pittsburgh, Pittsburgh, PA*

Background: There are persistent, entrenched racial disparities noted in breast cancer outcomes. A basis for these disparities can be racial inequality for stage matched Black vs. White women in receiving early-stage breast cancer (ESBC) chemotherapy dose intensity of, at minimum, 85% or more of chemotherapy (historic gold standard) within prescribed timeframe. Our study measured dose reductions, early terminations, and overall dose intensity of ESBC chemotherapy in urban breast cancer centers and compared by race. **Methods:** Using a longitudinal, comparative descriptive design, treatment characteristics were measured in women receiving ESBC cancer chemotherapy in seven cancer centers in Western PA and Eastern Ohio. Dosing scheduled was calculated per patient chemotherapy prescription. Actual dose was measured as percentage of chemotherapy received / prescribed in "prescribed time," meaning exact, ideal time to complete chemotherapy calculated from dose initiated without delay, dose reduction or early stoppage. The second measurement, "in any time," measured chemotherapy completed over any course of time, incorporating delays and reductions. Results were dichotomized according to 85% of prescribed dose for both outcomes and compared by patient self-reported race (Black or White). **Results:** This study was conducted from August 2017 through June 2022. N=260 patients, race self-reported as 100 Black (38.5%) and 160 White (61.5%). Overall, n=36 (13.8%) had early termination of therapy. Early termination was more common for Black patients, 21%, vs 10% for White patients ($p=.04$). N=100 (38.3%) of all patients had some dose reduction, racially divided by 46.4% of Black patients vs. 34.3% of White patients, NS. By projected endpoint, Black patients received 77% (SD 24.1) of prescribed chemotherapy; White patients 86.7% (SD 16.6), $p=.001$. By "in any time" endpoint, Black patients received 86.5%, (SD 22.8) of prescribed therapy, White patients received 93.5% (SD 13.2), $p=.002$. By "in any time" measurement, 15% of White patients and 25% of Black patients did not receive the gold standard of 85% of prescribed chemotherapy. N= 7 of delays or terminations were due to disease progression, or poor response, and rarely, (n=4) to patient nonadherence. Largely, delays and early cessation were due to chemotherapy toxicity. **Conclusions:** Racial disparities in dose intensity and alterations of prescribed ESBC chemotherapy must be eliminated. Further examining the racial differences around dose delays and early chemotherapy termination, including racial barriers to patient-clinician communication around chemotherapy related toxicity, is essential to ensure equitable ESBC care and outcomes. A quantitative synthesis of disparities in the inclusion of racial/ethnic minorities and older women in breast cancer trials. *First Author: Mahnoor Islam, Medical University of South Carolina, Charleston, SC*

Background: Trials that inadequately include underrepresented minority (URM) populations widen inequities in cancer care. We assessed reporting patterns, representation, and trends of URM representation in breast cancer (BC) trials. **Methods:** We analyzed all phase 2/3 trials for age disparity and trials recruiting from the US for racial/ethnic disparity amongst BC RCTs (1990-2021). Enrollment-incidence ratios (EIR), which compare trial proportions (TP) from age subgroups against global estimates of incidence in the corresponding age group (from Global Burden of Disease) and racial/ethnic subgroups against US-population-based incidence in the corresponding racial/ethnic group (from SEER 22), were calculated. Individual-trial EIRs were pooled using random-effects meta-analyses. EIRs of <0.80 indicated meaningful underrepresentation, while EIRs >1.20 indicated meaningful overrepresentation. Meta-regression was used to explore associations between key trial characteristics and EIR, and trends in EIR over the last three decades. **Results:** Of 842 global trials with 490,657 participants, 232 (27.6%) reported the number of participants in specific age strata and 144 (17.1%) reported outcomes by age. Only 60 trials recruited exclusively from the US. Of these, 41 (68.3%) reported race and 24 (40.0%) reported ethnicity, and 2 (3.3%) analyzed outcomes by race. Older adults aged ≥65 years (TP: 24.3%; EIR: 0.53 [95% CI: 0.47-0.60]) and Hispanic women (TP: 5.3%; 0.54; 0.40-0.75) were underrepresented across global trials and US-only trials respectively. Black women were significantly underrepresented in trials that led to FDA approval (0.38; 0.25-0.58) but not in US-only trials. Stratified analysis by BC subtype (with subtype-specific population incidence) showed underrepresentation of Black women in US-only trials for HER2+ BC (0.66; 0.47-0.93), Hispanic women in ER+ BC (0.42; 0.20-0.90), Asians in triple-negative BC (0.24; 0.11-0.53), and older women in HER2+ BC (0.35; 0.31-0.40) and triple-negative BC (0.36; 0.29-0.45). From 1990-2021, the representation of older women declined significantly (meta-regression coefficient for EIR: -0.4 per 10 years), while Black and Hispanic representation showed no significant change. Black (p = 0.02) and Hispanic representation (p = 0.05) worsened significantly in larger trials. **Conclusions:** Published reports of BC trials do not consistently report the inclusion of URM. Older and Hispanic women were consistently underrepresented, whereas Black women were underrepresented in large, practice-changing trials. Research Sponsor: None.

Representation of each subgroup given as an EIR with a 95% confidence interval.		
	US-only	Trials that led to FDA approval
White	0.97 (0.95-1.00)	0.85 (0.74-0.96)
Black	1.02 (0.75-1.39)	0.38 (0.25-0.58)
Asian	1.27 (0.63-2.56)	2.59 (1.85-3.63)
Hispanic	0.54 (0.40-0.75)	0.67 (0.42-1.07)

Source of funding and enrollment disparity in cancer clinical trials. *First Author: Irbaz Bin Riaz, Mayo Clinic, Phoenix, AZ*

Background: Recent findings that Black and Hispanic patients were significantly underrepresented in industry-sponsored prostate cancer trials warrant a detailed investigation across cancer types to assess the association between funding source and enrollment disparities. **Methods:** Phase II/III clinical trials in prostate, breast, colorectal, and lung cancers reporting age, gender, race/ethnicity, and reporting NIH or industry as the funding source were considered eligible for inclusion. For age, and gender analysis, all trials were considered eligible. For race/ethnicity analysis, trials recruiting from the United States (US) were considered eligible. Enrollment-incidence ratios (EIR) comparing trial proportion from age/gender or racial/ethnic subgroups against global cancer incidence in the corresponding group (from Global Burden of Disease) or US-population-based incidence in the corresponding racial/ethnic subgroup (from SEER 22), were computed. Trial-level EIRs were pooled using a random-effects model and subsequently stratified by funding source. A univariate meta-regression was conducted to assess the temporal changes in EIR by each funding category. **Results:** Of 42,390 studies initially identified, 2234 trials (1989-2021) met the eligibility criteria. Regarding age, 361 (16%) trials reported age categories by 65 years threshold. Of 698 trials recruiting from the US, 498 (71%) reported race, and 198 (28%) reported ethnicity. Regarding representation, older adults were under-represented (EIR: 0.66; 95% CI: 0.62-0.70) in the industry but not in NIH-sponsored clinical trials (0.79; 0.62-1.00). Regarding gender, no significant disparity was observed regarding the enrollment of men and women in colorectal and lung cancer clinical trials. In terms of race, there was a greater under-representation of Black patients in industry sponsored trials (0.29; 0.26-0.32) as compared to NIH-sponsored clinical trials (0.65; 0.57-0.74) [P_{int} <0.01]. Asian patients were significantly overrepresented in industry sponsored trials (3.17; 2.69-3.74) but not in NIH sponsored clinical trials (1.43; 0.85-2.41) [P_{int} <0.01]. Hispanic patients were significantly under-represented in both, industry (0.27; 0.22-0.34) and NIH-sponsored clinical trials (0.35; 0.22-0.55) [P_{int} 0.32]. Secondary analyses including trials recruiting exclusively from the US, and analyses by specific cancer types showed consistent results. Recruitment of older adults, men, and Black patients is decreasing over time. **Conclusions:** There is a consistent under-representation of older adults in industry-sponsored, and of Black and Hispanic patients in both industry-sponsored and NIH-sponsored clinical trials. The under-representation of Black patients is likely to be greater in industry-sponsored trials, which has worsened over the last three decades. Research Sponsor: None.

Poster Session

Disparities in intensity of care at the end-of-life for patients with gastrointestinal cancer. *First Author: Gladys M. Rodriguez, Division of Oncology, Stanford University School of Medicine, Stanford, CA*

Background: Racial/ethnic minority patients experience disparities along the cancer continuum. Studies show that racial/ethnic minorities with cancer have higher rates of intensity of care at the end-of-life (EOL) compared to non-Hispanic Whites (NHW). Less is known whether disparities in intensity of care at EOL exist among racial/ethnic minority patients with a gastrointestinal (GI) cancer. **Methods:** Using the California Cancer Registry linked to hospital discharge data, we conducted a retrospective study of patients ≥18yrs with upper GI, pancreatic, or colorectal cancer who died from 2005-2018. We evaluated if race/ethnicity was associated with EOL intensity of care defined as hospital/ED visit or death, ICU, intubation, CPR & dialysis within 14-days of death. We used logistic regressions to calculate odds ratios adjusting for age, socioeconomic status (SES), insurance, geography, stage, comorbidities, and NCI-designated centers. **Results:** 189,837 patients with GI cancer died: 41,389 (21.8%) with upper GI, 46,554 (24.5%) with pancreatic & 101,894 (53.7%) with colorectal cancer. 118,995 (62.7%) were NHW, 14,146 (7.5%) Black, 33,802 (17.8%) Hispanic & 22,894 (12.1%) Asian/Pacific Islander (API). Median age was 74.6 yrs, 54.1% male, 85.9% lived in urban areas, 48.9% had Medicare, 16.1% had low SES & 35.7% had Stage 4. Black, Hispanic, and API patients compared to NHW had higher odds of intensity of care at EOL (Table). **Conclusions:** This study shows disparities in intensity of care at the EOL among racial/ethnic minorities with GI cancers. Solutions are urgently needed to reduce such disparities in care. Research Sponsor: National Institute on Minority Health and Health Disparities of the National Institutes of Health under Award Number K23MD013474; Conquer Cancer Foundation of the American Society of Clinical Oncology.

CONSENT: Randomized controlled trial of enhanced informed consent compared to standard informed consent to improve patient understanding of early phase oncology clinical trials. *First Author: Abhijit Pal, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: Early phase oncology clinical trials have become increasingly complicated in terms of patient selection and trial procedures. Informed consent has been contentious due to potential ethical issues associated with performing experimental research on patients with advanced cancer who lack standard treatment options. Prior research has shown significant gaps in patient understanding regarding the nature and intent of these trials. CONSENT aimed to test whether enhanced informed consent can improve clinical trial comprehension. **Methods:** We randomized patients eligible to participate in one of four investigator-initiated early phase oncology clinical trials at the Royal Marsden Drug Development Unit to either a control arm or an experimental arm, stratified by age and educational level. The control arm received the full-length trial PIS, followed by electronic or paper administration of the Quality of Informed Consent Questionnaire Parts A (QuIC-A). The experimental arm received the full-length trial PIS, exposure to a two-page study specific aid and 10 online educational videos (both co-designed with patients and clinicians), followed by administration of the QuIC-A. The primary endpoint was the difference in the QuIC-A score between the control and experimental arm. The accrual target was at least 17 evaluable patients per arm to detect an 8-point difference (80% power, alpha 0.05). **Results:** 23 patients were accrued to the control arm (17 evaluable) and 22 patients (18 evaluable) were accrued to the experimental arm. Patients were evaluable if they had completed the QuIC-A. 38% of the participants were over the age of 65, 91% identified as White, 56% had completed a university degree and 97% spoke English at home. We did not observe a significant improvement in the primary endpoint in evaluable patients – control (QuIC-A - 76.5/100) vs experimental arm (QuIC-A - 77.4/100), p value = 0.39 (one sided, two sample t-test). 20 participants provided feedback on the enhanced consent materials via a study questionnaire –75% found both the 2-page study aid and the videos not at all distressing or uncomfortable and 85% found them either quite useful or very useful. **Conclusions:** This is the first prospective randomized trial evaluating the impact of communication interventions on informed consent in advanced cancer patients considering early phase oncology clinical trials. The co-designed interventions were deliverable online and were acceptable and useful for patients. We did not demonstrate an improvement in the primary endpoint with a high QuIC-A score observed in the control arm- this could be explained by the study population which was highly educated, White and spoke English at home. Future studies should focus on groups with lower literacy and from culturally and linguistically diverse backgrounds. Clinical trial information: NCT04407676. The patient experience of prior authorization for cancer care: Anxiety, delays, and the erosion of trust. *First Author: Fumiko Chino, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Prior authorization (PA) requires healthcare providers to obtain pre-approval from insurance for medical care. While PA is intended to promote evidence-based standards and reduce unnecessary care, it requires clinicians and patients to navigate an often-complex approval process. Delays or denied care can be particularly problematic for patients with cancer and their experience with PA remains unexplored. **Methods:** Social media recruitment enrolled adult cancer patients with a self-reported personal experience with PA to an anonymous online survey of investigator-designed questions on their experience. Descriptive statistics and univariate tests characterized survey responses, and multivariable analysis, controlling for age, diagnosis, race/ethnicity, and education, assessed associations with healthcare and insurance trust and delays in care. **Results:** 178 patients completed the survey; they were mostly women (90%), non-Hispanic white (84%), college graduates (81%), young [18-39 (42%), 40-54 years old (34%)] with private insurance (86%). PA was most frequently required for imaging (71%), IV chemotherapy (48%), surgery (47%), radiation (34%). Most care was ultimately given as recommended (58%); however, 20% of respondents didn't receive recommended care due to delays or denials, and 9% received recommended care but paid out-of-pocket. PA delayed 69% of care, with 51% of patients noting a delay ≥ 2 weeks. Delays did not vary by demographic, clinical, insurance, or treatment factors (all $p > .05$). 67% of patients had to personally get involved in the PA process by either calling their insurance (53%) or filing an appeal (25%); 20% of patients and/or their caregivers spent ≥ 11 hours dealing with PA issues. Overall PA experience was rated as "bad" (40%) or "horrible" (32%) for most respondents. Self-reported PA-related anxiety was significantly higher than self-reported baseline anxiety (mean = 74 vs mean = 37, 0-100 scale, $t = 16.6$, $p < .001$) and was significantly correlated with time spent on PA ($\rho = .16$, $p = .04$) and overall PA experience ($\rho = .34$, $p < .001$). While 18% felt PA made them trust their cancer team less, 89% said it made them trust their insurance company less, and 83% said it made them trust the healthcare system less. Patient involvement in the PA process (vs. healthcare team handling) was associated with higher-than-expected trust in their cancer team ($\chi^2 = 19.6$, $p < .001$), and increased odds of distrusting their insurance company ($\beta = 5.7$, 95% CI: 1.8, 17.6) and distrusting the healthcare system ($\beta = 3.2$, 95% CI: 1.3, 7.9). Having to file appeal was associated with 2.9 increased odds (95% CI: 1.2, 7.2) of experiencing a delay in care. **Conclusions:** PA practices may substantially delay care for patients with cancer increasing anxiety and eroding trust in healthcare. Streamlining the PA process could both allow optimal quality of care and improve the patient experience with cancer care. Poster Session

Survival analysis of patients treated at oncology practices with more aggressive end-of-life practice patterns. *First Author: Maureen Canavan, Yale School of Medicine, New Haven, CT*

Background: Despite national focus on measuring and reducing end-of-life (EOL) systemic treatment among cancer patients, recent studies show a consistently high use of systemic anticancer therapy (SACT) at the EOL, as well as a shift to more targeted therapies. A criticism of measures that focus on deceased populations is that they do not account for patients who received treatment at the same time in their disease trajectory and had a positive response to therapy. We sought to explore whether being treated at an oncologically aggressive (OA) practice (defined as higher practice-level EOL SACT treatment rates), was associated with a survival benefit among patients in six common cancer types. **Methods:** This survival analysis used the nationwide Flatiron Health electronic health record (EHR)-derived de-identified database. We included all adult patients with a confirmed diagnosis of metastatic disease in breast (mBC), colorectal (mCRC), renal cell carcinoma (mRCC) or pancreatic cancer (mPanc), or advanced disease in non-small cell lung (aNSCLC), or bladder cancer (aUC), between 2015 and 2019. The primary exposures were the practice-level risk-standardized 30-day EOL SACT rates calculated among decedents. The primary outcome was real-world overall survival (rwOS) among all patients. Adjusted hazard ratios (aHR) for each quintile of increasing OA EOL SACT rates (Q2-Q5) were estimated using disease-specific Cox proportional hazard models (reference: Q1), adjusting for patient and practice-level factors. Bonferroni correction was applied to account for multiple comparisons. **Results:** A total of 78,446 patients from 144 practices were included in the analysis with most patients seen at less OA practices (Q1-Q2). Patients seen at most OA practices (Q5) were less likely to be < 65 (32.5% vs 38.9% in Q1), Black (6.3% vs 12.2%), have Medicare (5.9% vs 10.7%) or Medicaid (1.5% vs 4.1%). After adjusting for covariates, there was no statistically significant difference in rwOS between patients treated at the most (Q5) and the least OA practices (Q1; table). However, there was variation among the moderately OA practices. Patients with mPanc seen at moderately OA (Q2-Q4) had 12% to 19% lower hazards of deaths (aHR range 0.81-0.88), compared to those at the least OA practices (Q1), but these associations were not statistically significant (Bonferroni corrected p -values > 0.05). **Conclusions:** When using rates of SACT at EOL to define OA practices, patients treated at these practices do not have improved survival. Research Sponsor: This study was sponsored by Flatiron Health Inc, which is an independent subsidiary of the Roche group.

aHRs for most OA practice quintile (Q5) compared with least OA practice quintile (Q1) by disease.		
Disease	aHR (95% confidence interval)	p-value
mBC (N = 11,627)	0.93 (0.76 - 1.15)	0.501
mCRC (N = 15,786)	0.89 (0.72 - 1.09)	0.257
mRCC (N = 4,617)	0.97 (0.70 - 1.34)	0.845
mPanc (N = 7,349)	0.86 (0.71 - 1.05)	0.135
aNSCLC (N = 34,163)	0.94 (0.87 - 1.02)	0.119
aUC (N = 4,792)	0.94 (0.69 - 1.28)	0.703

Use of direct oral anticoagulants (DOACs) in oncology: A phase IV study on impact of edoxaban treatment in Italian patients with cancer with venous thromboembolism during antineoplastic therapy (EDO1 trial, GOIRC 05-2018). *First Author: Filippo Giovanardi, IRCCS AUSL Reggio Emilia, Reggio Emilia, Italy*

Background: The EDO1 Study (EUDRACT 2018-003833-14) was designed to evaluate venous thromboembolism (VTE), a common complication of cancer and cancer therapy. VTE contributes to mortality and morbidity, and may interfere with therapy. When drafting the protocol, the standard treatment for VTE consisted of low-molecular weight heparin followed by vitamin K antagonists. DOACs are as effective as vitamin K antagonists in the treatment of VTE. Edoxaban has been confirmed to be effective and safe in the treatment of VTE. Adverse events (AEs) associated with DOACs can delay or interfere with chemotherapy; to date, data regarding the impact of Edoxaban treatment on cancer treatment AEs are scanty. **Methods:** In this multicentric, phase IV study, patients receiving an antineoplastic treatment (and candidates for at least 3 additional months of treatment) and diagnosed with VTE, received Edoxaban as per clinical practice. Patients received between 6 and 12 months of Edoxaban and were evaluated at baseline and after 1, 3 and 6 months. Primary endpoint was the impact of Edoxaban-related AEs on antineoplastic therapy, defined as delays/interruptions/reductions due to adverse drug reactions (ADR) related to Edoxaban (bleeding, hepatobiliary toxicity, renal toxicity, anemia, hypersensitivity reactions). As secondary endpoint, we assessed patient-reported outcomes (PROs) during treatment with Edoxaban (health-related quality of life: FACT-G, expectations and satisfaction with anticoagulant treatment: PACT-Q2 and ACTS). For each tool, mean scores at each time point were calculated. **Results:** One hundred and fifty patients were enrolled, 147 patients were evaluable. The Incidence density rate of antineoplastic therapy delay/interruption/reduction due to ADR related to Edoxaban was 0.8% per person-month (90% CI: [0.4; 1.5%] and 95% CI: [0.4; 1.6%]). For all the patient-reported outcomes, mean scores were maintained at different time points. **Conclusions:** The results of the study clearly show that the edoxaban treatment is well tolerated and has no relevant impact on the delivery of cancer treatments. Results in terms of quality of life and patients' satisfaction with anticoagulant treatment are reassuring. Clinical trial information: EUDRACT 2018-003833-14. Research Sponsor: GOIRC.

The IMPACT of an interdisciplinary goals-of-care program on readmission rates at a comprehensive care center. *First Author: Cerena Leung, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Unplanned readmissions are associated with substantial distress for patients and their families. We hypothesized that goals-of-care (GOC) discussions, by improving goal-concordant care, may reduce unplanned readmissions. However, only a handful of studies have specifically examined this question. We assessed the implementation of a system-wide multicomponent interdisciplinary GOC (myGOC) program on the 30-day unplanned readmission rate and other hospital outcomes for medical patients at our comprehensive cancer center. **Methods:** In this retrospective cohort study, we compared the 30-day unplanned readmission rates in consecutive medical patients during the pre-implementation period from May 1, 2019 to December 31, 2019 and the post-implementation period from May 1, 2020 to December 31, 2020. The primary outcome was the 30-day unplanned readmission rate as defined by Vizient. Secondary outcomes included 7-day unplanned readmission rates, inpatient do-not-resuscitate (DNR) orders and supportive care consults. A multi-variate analysis model was used to examine the association between 30-day unplanned readmission rates and the implementation of the myGOC program adjusting for age, sex, race, index hospitalization type, and Sequential Organ Failure Assessment (SOFA) score. **Results:** This study included 7028 and 5982 unique medical patients during the pre- and post-implementation period, respectively. The 30-day unplanned readmission rates decreased from 13.7% before to 12.0% after implementation of the myGOC program. After adjusting for covariates, the myGOC implementation remained significantly associated with a reduction in 30-day unplanned readmission rates (OR [95% CI] 0.85 [0.77, 0.95], $p=0.003$). Other factors significantly associated with a decreased likelihood of a 30-day unplanned readmission were hematologic malignancies (vs. solid: 0.71 [0.64, 0.79]), White race (vs. Hispanic: 0.86 [0.75, 0.98]), an inpatient DNR order (0.30 [0.25, 0.37]), an ICU admission (0.58 [0.48, 0.71]), and an emergent admission (vs. elective: 0.86 [0.76, 0.99]). We also observed a significant decrease in 7-day unplanned readmission rates (0.75 [0.64, 0.89], $p=0.0009$), an increase in inpatient DNR orders (1.48 [1.35, 1.63], $p<0.0001$) and an increase in supportive care consults (1.22 [1.13, 1.31], $p<0.0001$) post-implementation. **Conclusions:** Implementation of a system-wide multicomponent GOC intervention was associated with a significant reduction in 30-day unplanned readmission rates after accounting for other key clinical factors. Reducing infusion center wait times in a resource-limited setting. *First Author: Amy Little Jones, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Time toxicity is increasingly recognized as an important factor in quality of life in cancer patients, and this effect may be amplified in under-resourced oncology settings. In the safety-net oncology center at Parkland Health (PH), wait time from infusion appointment check-in to treatment start was 147 minutes in June 2022, which led to significant patient frustration, delays in care, and staff dissatisfaction. We aimed to decrease wait time by 20% by December 2022. **Methods:** Baseline wait time data for patients getting infusions in the oncology infusion center was collected daily from the electronic medical record (EMR) time stamps of check in and infusion start (first IV medication given), and the average time was calculated. A value stream map detailing the steps required to start infusion with time stamps was produced. Stakeholders were queried to identify causes of delay, an Ishikawa diagram was constructed, and a priority matrix was developed to determine the most impactful interventions. The first PDSA cycle (July-Oct 2023) intervention consisted of working group formation and implementation of separate infusion pathway for patients getting injections ("fast track"). The second PDSA cycle (Nov-Dec 2023) intervention was rescheduling infusion-only patients to the least congested times of the day to relieve the bottleneck that occurred in the late mornings for patients with labs or provider visit prior to infusion. Patients and infusion center providers were surveyed about their perception of wait times. **Results:** Average wait times decreased from 147 minutes to 131 minutes during first PDSA cycle, a 10.8% improvement from baseline. From Nov-Dec 2023 during second PDSA cycle, wait time improved to 127 minutes, a 15.7% improvement from baseline. The average daily number of infusions and injections increased from 106/day baseline to 115/day by Dec 2023; an increase of 8.5%. Qualitative surveys of patients and infusion providers endorsed increased satisfaction with infusion process. **Conclusions:** Using established quality improvement methods, we improved average wait times for Parkland Health oncology infusion patients by 15.7% over a 6 month period. While we did not meet our goal, we increased daily capacity to treat patients by 8.5% while improving overall infusion wait time. We also improved perceptions of quality of care. Trends of using immune checkpoint inhibitors near end of life in limited resources setting: Experience of single cancer center in the MENA region. *First Author: Kamal Hosni Al-Rabi, Department of Internal Medicine, King Hussein Cancer Center, Amman, Jordan*

Background: Immune checkpoint inhibitors (ICIs) are standard of care nowadays in the treatment of many solid tumors as single agent or in combination. Recent literature suggested increased use of ICI near end of life; our aim was to find the characteristics of the patients who received ICI 30 days or less before their death. **Methods:** Data of patients with advanced solid tumors who have (ICI) therapy and died with disease were retrospectively retrieved. Patients were categorized into those dying within 30 days of the last dose of ICI and those receiving the last dose of ICI more than 30 days before death. Variables of potential interest were compared between the two groups by the Chi-square and independent sample t -tests as appropriate. **Results:** A total of 411 patients were included in this analysis; 135 (33%) received the last dose of ICI within 30 days of death and 276 (67%) received their last dose more than 30 days before death. Major cancer types included: lung ($n=214$; 52%), kidney ($n=61$; 15%), melanoma ($n=44$; 11%), head and neck ($n=41$; 10%), and others ($n=154$; 37%). Patients' characteristics: median age = 58, majority were males (310; 75%), 105 (26%) had ECOG PS ≥ 3 , and 147 (36%) had brain metastasis. Patients who received the last dose of ICI within 30 days of death had more frequent ICU admissions (50 (37%) vs. 60 (22%), $p=0.001$), and were less likely to die under the care of the hospice care service (22 patients (16%) vs. 84 (31%), $p=0.001$). In addition, patients who received the last dose of ICI within 30 days of death were more likely to have a full code status (89 (66%) vs. 147 (53%), $p=0.015$), and have received a lower number of doses of ICI treatments (mean number of doses: 4.2 vs. 6.5 doses, $p=0.001$). We did not observe any significant difference between the two groups regarding type of cancer, age, gender, ECOG PS, presence of brain metastasis, number of hospital admissions, dying inside hospital, and number of emergency room visits. **Conclusions:** Immune checkpoint inhibitors may be overused near end of life which leads to minimal clinical benefits, less likelihood of dying under hospice care, and utilization of ICU resources. Research Sponsor: None.

The effects of social determinants of health on colorectal cancer screening. *First Author: Isabelle Franklin, Kaiser Permanente Bernard J. Tyson School of Medicine, Pasadena, CA*

Background: Colorectal cancer is the 3rd leading cause of cancer death in the United States yet has consistently lagged in screening rates compared to other cancers. While patient-reported barriers have been previously described, few studies have analyzed how patients' social needs affect screening rates. **Methods:** This cross-sectional study includes 3974 Kaiser Permanente (KP) patients ages 50-75 years who completed the 2020 KP National Social Needs Survey. Survey respondents were from the seven KP regions of Southern California, Northern California, Colorado, Washington, Northwest, Georgia, and Hawaii. Five Social Needs categories were assessed: Financial Strain, Housing Instability, Transportation Issues, Social Isolation, and Food Insecurity. Being up to date on CRC screening was determined from patients' KP electronic health records, defined as meeting HEDIS criteria for screening. Multivariate analyses compared the level of social need to the respondents' completion of colorectal screening between the years of 2019-2021, adjusting for age, sex, race/ethnicity, diagnostic category group (DxCG), neighborhood deprivation index (NDI), and insurance type. **Results:** Among the 3974 survey respondents, 92.2% were up to date on their colorectal cancer screening. Not being up to date on CRC screening was significantly associated with having any social need and having severe needs in four of the five social need domains adjusted for sociodemographic and health status (Table). Patients were less likely to be screened if they had severe financial strain (OR 0.54, 95% CI 0.40-0.73), severe social isolation (OR 0.52, 95%CI 0.38-0.71), severe transportation issues (OR 0.33, 95% CI 0.18-0.61), and severe food insecurity (OR 0.41, 95% CI 0.27-0.62). No significant association between screening status and the domain of severe housing instability were found (OR 0.74, 95% CI 0.52-1.06). **Conclusions:** Respondents with financial strain, social isolation, food insecurity, and transportation issues had lower odds of being up to date with colorectal cancer screening. Future efforts aimed to improve colorectal cancer screening rates should assess patients' social needs and target ways to address these potential barriers to screening. Research Sponsor: Kaiser Permanente Bernard J. Tyson School of Medicine.

Odds of colorectal cancer screening by social needs.

Parameter	Adjusted Odds Ratio ¹	95% CI
Severe Financial Strain (Yes vs No)	0.54	0.40 0.73
Severe Social Isolation (Yes vs No)	0.52	0.38 0.71
Severe Food Insecurity (Yes vs No)	0.41	0.27 0.62
Severe Housing Instability (Yes vs No)	0.74	0.52 1.06
Severe Transportation Issue (Yes vs No)	0.33	0.18 0.61
Any Severe Social Need (Yes vs No)	0.54	0.42 0.70

¹ Receipt of colon cancer screening adjusted for age, neighborhood deprivation index, sex, DxCG risk score, race/ethnicity, primary spoken language, insurance type.

Profile of toxicities and quality of life in long-term survivors treated with immunotherapy: A prospective cross sectional trial. *First Author: Paolo Bossi, Medical Oncology Unit, Department of Medical & Surgical Specialties, Radiological Sciences & Public Health, University of Brescia, ASST Spedali Civili, Brescia, Italy*

Background: Long-term cancer survivors (LTS) patients (pts) treated with immunotherapy (IT) represent a relatively new population whose characteristics, such as long-term toxicities, quality of life (QoL), and financial toxicities, need to be elucidated in a real-world setting. The aim of this study is to evaluate long-term toxicities in patients free of disease progression and treated with IT. **Methods:** This is a cross-sectional, multicentric study, involving ten Italian centres. Pts should have started IT (as monotherapy or combination, either in curative or adjuvant setting) more than 2 years before accrual and they needed to be progression free at last follow up (fup). Subjects who discontinued IT for disease progression or who started any subsequent line of systemic treatment were excluded. We retrieved baseline demographic and clinical characteristics of the pts, as well as haematological and biochemical exams at the start of IT (baseline) and at the last fup. We also assessed the patient's toxicities (according to CTCAE v5.0) at last fup and we submitted to each patient three questionnaires: PRO-CTCAE (selection of questions), EORTC QLQ C30, and FITALY (for financial toxicities), which were analysed according to subdomains. **Results:** We enrolled 141 LTS pts treated with IT from 2013 to 2022. Median age was 69 years (35-88), most were male (72%), and still receiving IT at time of last fup (72%). Primary tumour was in lung (43%), genito-urinary tract (26%), or melanoma (14%). IT included pembrolizumab and nivolumab in 40% and 32% of cases, respectively. The median global health status of QoL was 83 (IQR 25). Any toxicities > G2 negatively impacted on individual functional scales (physical, p=0.02; role, p= 0.06; and social p=0.08). A higher baseline Charlson Comorbidity Index was associated with worse global health status (p=0.02) at last fup. Most frequent low grade adverse events were fatigue, dyspnoea, and insomnia; younger age (< 65 years) was associated with higher pain (p=0.04). PRO-CTCAE questionnaires showed that the prevalent complained symptoms were rheumatological and cutaneous, regardless of tumor site. The most affected domain of financial toxicities was financial stress, including costs for out of pocket medications and transports. Pts with melanoma (p=0.01), with skin toxicities (p=0.04), and younger than 65 years (p=0.01) were at higher risk of financial toxicities (global score). **Conclusions:** Overall QoL is well preserved in LTS treated with IT. At long term fup, the pts complained mostly about rheumatological and skin adverse events. Financial stress due to out of pocket costs was the most affected financial toxicity domain. Baseline comorbidities predicted a worse long-term global health status, while young age, skin toxicities and melanoma predicted higher financial toxicities. Research Sponsor: ASCAPE Grant.

Just ASK: A quality improvement project to enhance smoking assessment and treatment. *First Author: Graham W. Warren, Medical University of South Carolina, Charleston, SC*

Background: Persistent smoking after cancer diagnosis causes adverse clinical outcomes. ASCO and other organizations view smoking assessment and treatment as indicators of high-quality cancer care. Yet, adoption of clinical practice guidelines like the 3As (Ask, Advise and Assist) for smoking assessment and treatment has been slow and inconsistent in cancer care settings. **Methods:** Led by the American College of Surgeons Cancer Programs' Commission on Cancer (CoC) and National Accreditation Program for Breast Centers (NAPBC), the "Just ASK" national quality improvement project focuses on enhancing smoking assessment and treatment in cancer care settings. All CoC/NAPBC programs (~2000) were invited to participate, which consisted of educational webinars, online resources, and 3 online surveys (baseline, 6- and 12-month) collecting information on smoking assessment and treatment practices, plus other variables (e.g., organizational priority, implementation barriers). Program participation was incentivized by fulfillment of accreditation standards. **Results:** In total, 776 programs (731 CoC, 45 NAPBC), participated. At baseline, most programs strongly endorsed the importance of addressing smoking within cancer care and the majority of programs reported routinely assessing smoking (90%) and advising all patients reporting current smoking to quit (71%). However, routine delivery of evidence-based smoking cessation assistance (e.g., quitline referral, cessation medications, counseling services) was low (all < 30%). Program retention was excellent (91%). As shown in the table, the 12-month follow-up revealed marked improvements in evidence-based Ask, Advise and Assist, practices. **Conclusions:** At enrollment, the importance of addressing smoking was evident and high rates of smoking assessment were reported. At 12-month follow-up, marked improvement was reported in all quality indicators of the 3As. These findings guided the sharing of strategies for improving patient assessment, clinical workflow and documentation. Suboptimal delivery of smoking cessation assistance persisted despite overall improvements, which highlight persistent challenges and opportunities for implementing smoking assessment and treatment in cancer care settings. Research Sponsor: U.S. National Institutes of Health.

Assessment and Treatment Practices	Baseline (n=776) Always or Usually	12-month follow up (n=703) Always or Usually
Ask patients about smoking	696 (90%)	690 (98%)
Advise patients to quit smoking	553 (71%)	588 (84%)
Assist patients in quitting	323 (42%)	424 (60%)
Provide self-help information	209 (27%)	395 (56%)
Refer patients to Quitline	219 (28%)	367 (52%)
Refer patients to tobacco treatment specialist in cancer program	204 (26%)	289 (41%)
Provide individual counseling in person	141 (18%)	190 (27%)
Prescribe FDA approved cessation medications	136 (18%)	179 (25%)

Multimodal interventions targeting identified barriers to improve lung cancer screening in northeast Georgia. *First Author: Swathi Kanakamedala, Northeast Georgia Medical Center, Gainesville, GA*

Background: Lung cancer is the leading cause of cancer deaths with over 50% of patients diagnosed at an advanced stage. Lung cancer screening (LCS) guidelines were recently updated in 2021, which expanded the age group and reduced the pack years, and thereby increased eligibility. However, the underutilization of low dose computed tomography (LDCT) scans is seen nationwide. In 2015, the National Health Interview Survey found that only 3.9% of eligible adults underwent LCS. The barriers for LCS identified in national literature included failure of electronic medical records (EMR) to notify providers of eligible patients, lack of insurance coverage, patient refusal, and lack of patient and provider awareness. This quality improvement project was performed to improve LCS in primary care clinics (graduate medical education [GME] and non-GME) at a tertiary medical center in northeast Georgia by addressing these barriers. **Methods:** In GME clinics, the goal was to double LDCT scans from 14 to 28 monthly. In non-GME clinics, the goal was to increase LDCT scans by at least 50% from 28 to 42 weekly. LDCT scans performed between January 1st to May 31st 2022 was used as baseline data. The interventions spanned over six months, from June 1st to November 30th 2022. Multimodal interventions were used to target various barriers. Accurate tobacco history in the EMR was improved by participating in the nationwide Just Ask Campaign. Flyers posted in clinics provided information on current guidelines and a QR code for patients to determine their LCS eligibility. Provider reference guides highlighted LCS guidelines and billing codes. Community events and social media were used to spread LCS awareness. **Results:** During the implementation phase, the average monthly LDCT scans increased to 23 scans in GME clinics and 40 scans weekly in non-GME clinics. In GME clinics, the goal of 28 scans monthly was achieved in one out of six months. In non-GME clinics, the goal of 42 scans weekly was surpassed in four out of six months. The Long-Range Acoustic Device (L-RAD) scoring system helped diagnose three cancers in the GME clinics and about one cancer for every 10 L-RAD4 in non-GME clinics. The baseline period LDCT scans of 78 (GME) and 656 (non-GME) increased to 177 (GME) and 1109 (non-GME) during the intervention period. **Conclusions:** This multimodal approach in addressing known barriers to increase LCS across primary care clinics in a single healthcare system is feasible and was associated with short-term improvements. Although the targets were not met every month, there was a notable improvement during the intervention period. A major limitation was the inability to determine which intervention had the greatest impact. A newly identified barrier was the lack of follow up scans being ordered by providers. This project demonstrates the potential to increase LCS using a multimodal approach, which can be implemented in similar healthcare systems. Research Sponsor: None.

Use of germline testing in patients with prostate, pancreatic, or ovarian cancer in Washington (WA) state. *First Author: Qin Sun, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Germline genetic mutations are seen in approximately 10-15% of patients with prostate, pancreatic, and ovarian cancer. While universal germline testing is recommended for patients with these cancers to inform both familial risk and therapeutic approach, underutilization of germline testing has been reported. We investigated the rates of and factors associated with germline testing in a population-based sample of patients with prostate, pancreatic, and ovarian cancer in WA state. **Methods:** We linked Washington state cancer registry records from 2017-2019 with claims records for two large commercial insurers, Medicare, and Medicaid. Patients with prostate (metastatic, regional node-positive, or high-risk localized), pancreatic, and ovarian (including fallopian tube and peritoneum) cancer who were diagnosed in 2017-2019 were identified. Using claims from this database, we identified patients who received germline testing in the first two years of diagnosis. We excluded those who were not continuously enrolled in a health plan during the testing period of interest or died within 3 months of diagnosis. We used a multivariate logistic regression model to investigate factors associated with germline testing. **Results:** Among 2,077 patients, 429 (20.7%) received germline testing. Testing rates were 6.3% (53 of 842 patients) in prostate cancer, 15.4% (118 of 765 patients) in pancreas cancer, and to 54.9% (258 of 470 patients) in ovarian cancer; median time to testing for prostate, pancreas, and ovarian cancer was 162, 133, and 64 days respectively. Testing rates were higher in later years, in patients with more advanced stage cancers and lower in Asian patients and patients with more comorbid conditions. **Conclusions:** Despite guideline recommendations, germline testing rates are low among cancer patients in WA state, with the lowest rates in prostate cancer patients and in Asian and higher comorbidity populations. Underutilization of germline testing may not only adversely affect treatment, but also represents a missed opportunity for testing of high-risk families. Further studies should identify and address barriers to germline testing in high-risk populations. Research Sponsor: Fred Hutchinson Cancer Center.

Reporting of patient reported outcomes in randomized clinical trials (RCTs) in non-small cell lung cancer (NSCLC) patients (pts). *First Author: Laura Palmeri, Syneos Health, Farnborough, United Kingdom*

Background: A patient-centric approach to clinical trials has become necessary, with regulators emphasizing the importance of pts' experience. PRO is of utmost relevance for pts with cancers such as NSCLC, that are likely to be highly symptomatic and/or with an unfavorable prognosis. **Methods:** To evaluate the rate at which PRO included in clinical trials are made publicly available when trial results are published, we searched Citeline Trialtrove, a registry of clinical trials, for NSCLC phase 3 RCTs, recruiting during 2017-2022, with PRO listed - regardless of publication type. We excluded supportive care, radiotherapy, and unpublished trials. We identified publications associated with the trial, and extracted various parameters, including if PRO outcome was published. **Results:** Of 122 NSCLC RCTs identified, 66 listed at least 1 PRO. Trials were reported as full-text (43), abstract (9), 1 only in a trials registry; 13 not published. Fifty-three trials were included, all had PRO as a secondary endpoint. The sponsor was industry in the majority of the trials. Most enrolled stage III/IV NSCLC pts, and 1st/2nd line or maintenance. 24 PRO tools were used, mainly EORTC QLQ LC13 (35 trials), EORTC QLQ C30 (34), EQ-5D-5L (14), LCSS (8), EQ-5D-3L (6). Seven trials listed 1 tool, 26 listed 2, 18 listed >3. PRO was reported in 36 (68%) of the published trials. In the subgroup of trials with disease control (DC) benefit and no overall survival (OS) benefit, PRO was reported in 15/21 (71%) trials. PRO benefit was shown in 9 of them. Of 43/53 trials published as full-text, 31 (72%) had PRO reported. A benefit in at least 1 PRO tool was reported in 21 studies, 9 did not show a PRO benefit; in 5 trials, only descriptive and no comparative analysis of PRO was reported. Of the 21 trials with PRO benefit, 19 had a DC benefit and 10 had also OS benefit. PRO was reported together with the first reporting of other outcomes in 18 (50%) trials, and after 7-32 months after the initial one in 18 trials. **Conclusions:** Of 122 RCTs only 66 had at least 1 planned PRO, and only 35 had it published. Even where full-text was available or no OS benefit shown, about 1/3 of the trials did not report PRO. Characteristics as disease stage, therapy line, sponsor, and primary endpoint did not differ between all included trials and those reporting PRO. The reporting rate increased compared to our previous report yet it is not satisfactory. The importance of quality of life and pts centric outcomes, and the great efforts needed from pts and operators to collect the data, should translate into routine, timely and appropriate reporting of PRO to allow a thorough assessment of treatment effect. Machine learning and postoperative complications: Determining risk before surgery in patients with cancer. *First Author: Matthew C Hernandez, City of Hope National Medical Center, Duarte, CA*

Background: In patients with advanced cancer who need unplanned surgery, shared decision making is complex. Surgical risk assessment with high accuracy and in real time may help improve prediction of postoperative outcomes. We previously trained and tested an explainable machine learning model (MLM) to estimate postoperative Clavien-Dindo grade 3 or higher (CD 3+) complication risk in cancer inpatients undergoing unplanned surgery. In this prospective validation study, we report the performance of the MLM Surgical Risk Score (SRS) in the prediction of postoperative outcomes as well as determine association of the risk score with hospital length of stay and mortality. **Methods:** A MLM SRS for cancer inpatients requiring an unplanned, same-hospitalization major surgery was generated using real-time patient specific EHR data. The SRS was integrated into surgeon preoperative workflow. Postoperative outcomes including complications, length of hospital stay, and 30-day mortality were reported. The SRS was dichotomized as high or low based on prior validation threshold for postoperative CD3+ complication development. Model performance was assessed with area under receiver operating characteristic (AUROC) and area under precision-recall curves (AUPRC). Differences in outcomes between high and low-risk SRS groups were studied using Mann-Whitney U test and Fisher's exact test. **Results:** During the study period, 135 cancer inpatients were assessed by surgeons for 166 major unplanned operations. Of the 166 operations, 126 were completed and 40 were cancelled. The SRS was high in 81 (49%) and low in 85 (51%). The most common cancer diagnosis was colorectal (n=39, 28.8%). Operations performed with the highest frequencies were for enteral access (e.g.gastrostomy) followed by exploratory laparotomy and enterectomy. CD 3+ complications were identified in 31% of the completed operations (n=39/126) and included death (n = 10); abscess (n=4); postoperative hemorrhage (n=3); and anastomotic leak (n=2). The SRS predicted CD 3+ complications with a precision of 47% and recall of 73%, resulting in an AUROC of 0.75 and AUPRC of 0.58. When comparing patients with high-risk to low-risk SRS, median overall LOS was 10 vs 7 days (p=0.013), median LOS after operation was 9 vs 6 days (p=0.003), 30-day mortality was 19.0% vs 5.3% (p=0.015), and 30-day postoperative mortality was 13.2% vs 3.3% (p=0.04). **Conclusions:** In this prospective study, preoperative SRS generated from a trained MLM on real-time EHR data demonstrated an excellent ability to predict individual risk of postoperative complications. In addition, patients with high SRS have longer postoperative LOS and increased mortality. By improving discrimination of risk of postoperative complications and informing on treatment outcomes, integration of the MLM SRS into the consenting process may enable better informed decision making in cancer inpatients. Incidence of infusion related reactions of daratumumab-hyaluronidase-fihj: Pre-post intervention study of premedication omission. *First Author: Kashyap Padmaraju, University of Chicago Medical Center, Chicago, IL*

Background: Daratumumab-hyaluronidase-fihj subcutaneous (Dara-SQ) is utilized frequently in the treatment of newly diagnosed and relapsed/refractory multiple myeloma (MM). Initially approved as an intravenous formulation, daratumumab (Dara-IV) showed significant infusion related reactions (IRRs), requiring premedication (acetaminophen, diphenhydramine, dexamethasone, and some add montelukast) prior to each dose. Dara-SQ was shown to be noninferior to Dara-IV with significantly fewer IRRs. Despite the reduced IRR risk, indefinite premedication is also recommended in the package insert for Dara-SQ. Given that IRRs are rare after the first dose of Dara-SQ and premedication extends the time for patients in an infusion center, we investigated whether premedication may be safely omitted after the first cycle. **Methods:** This pre-post interventional quality improvement study included all patients aged 18 years or older diagnosed with MM or amyloidosis that received at least one dose of Dara-SQ between July 1st, 2020 – December 31st, 2022. Omission of premedication (excluding dexamethasone) after four doses of Dara-SQ was introduced June 1st, 2022. The pre-interventional arm followed standard of care with premedication continued (Arm 1) and post-interventional arm included patients with premedication omitted after fourth dose (Arm 2). Patient demographics, prior therapy, Dara-IV exposure, and premedication usage were collected to evaluate the primary endpoint: incidence of IRR after premedication omission. Secondary analysis included any IRR prior to intervention, timing of reaction, reaction management, and post-reaction management. **Results:** A total of 102 patients (63 in Arm 1 and 39 in Arm 2) were included in the study, with a median age of 69 (38-86) years old; 52% African American and 54% male. IRR prior to fourth dose occurred in 1.6% (1/63) for Arm 1 vs. 5.1% (2/39) for Arm 2 [p= 0.6], Dara-IV exposure was 52.4% (33/63) in Arm 1 vs. 10.2% (4/39) in Arm 2 [p= 0.02], and indication was newly diagnosed MM in 21% (13/63) of Arm 1 vs. 41% (16/39) of Arm 2 [p= 0.03]. For the primary objective, there were zero reactions in both arms. All three reactions prior to fourth dose occurred after the first dose of Dara-SQ, with a median time to reaction of 4.8 hours. These were all grade 2 per CTCAE v5.0, with all patients discharged home after reaction, and all patients received subsequent Dara-SQ without issues. For the two reactions prior to fourth dose in Arm 2, premedication was omitted after 6 doses in one patient and 8 doses in the other with no further issues on subsequent doses. Estimated therapy time saved was 194 hours, with an estimated savings of \$145,500 thus far. **Conclusions:** IRRs to Dara-SQ occur early, are rare, and mild in course. Omitting premedication after a minimum of four Dara-SQ doses is safe and carries substantial time savings for patients and infusion centers. Research Sponsor: None.

Data driven insights from multiple OCM practices to optimize care for managing high-risk cancer patients across multiple cancer types. *First Author: Srisairam Achuthan, Integra Connect, West Palm Beach, FL*

Background: Medicare's Oncology Care Model (OCM) aims to improve the quality and coordination of care for cancer patients. Previously, Integra Connect (IC) developed machine learning (ML) based risk prediction models called Integra Predict (IP) for In-Patient Admissions, Emergency Department Visits and End-of-Life in active chemotherapy patients within the next six months. The patients were risk-stratified with the purpose of optimizing clinical resources utilization. Our objective is to demonstrate the insights derived from an updated IP version applied to OCM patients from three IC network practices: P₁ (a multi-state network of community oncology practices), P₂ (a single site community oncology practice) and P₃ (a regional network of oncology practices connected to academic medical institution). **Methods:** For training the ML models, 90,417 OCM reconciliation episodes from PP4-PP8 (Jan. 2018-June 2020) from 10 distinct IC practices were used. The models comprise 37 features: 12 adverse events (within last 6 month of episode start date), 7 comorbidities (in the past irrespective of lookback period), 7 latest vital sign measurements recorded within 30 days of date of prediction, 11 demographic and other clinical attributes. Based on LogLoss, 54 ML experiments were performed leading to three best algorithms to predict the risk for In-Patient Admissions, Emergency Department Visits and End of Life. To generalize our ML approach, we leveraged an additional holdout dataset in periods PP9 and PP10 (July 2020 - June 2021) pertaining to practices P₁, P₂ and P₃ with 6378, 973 and 5921 episodes, respectively. Matthew Correlation Coefficient (MCC) was chosen as the metric to test the generalizability of the models. For each model, the variance of MCC was then computed. To uncover secondary factors influencing clinical care, top-3 frequently reported adverse events and top-5 comorbidities were determined. **Results:** For each ML model, the variance of MCC applied to the holdout dataset was low (order of 10⁻⁴). Types of cancers reported differed within P₁, P₂ and P₃. However, across these practices, irrespective of the cancer type, the most frequently reported adverse events (pain, anemia, and cachexia) and comorbidities (cardiovascular disease, chronic pulmonary disease, dyspnea at rest, dorsopathies and renal disease or failure) observed were the same. **Conclusions:** Low variance in MCC implies ML models are applicable to different types of community oncology practices. A care coordination program for high-risk cancer patients involving the monitoring of pain, cachexia and anemia can lead to optimal utilization of clinical resources within these practices. Program expansion involving optimal management of comorbidities such as cardiovascular disease, chronic pulmonary disease, diabetes, dyspnea at rest and renal disease or failure may yield additional benefits. Palliative care consultation and end-of-life outcomes in a retrospective cohort of patients treated with immune checkpoint inhibitors. *First Author: Chance H. Bloomer, Wake Forest Baptist Medical Center, Winston-Salem, NC*

Background: Immune checkpoint inhibitors (ICI) can prolong survival for various cancers and are generally available as treatment options for most patients because of their favorable adverse effect profile. Although ICIs provide treatment for many patients who would otherwise be out of options, their variable and often delayed efficacy may postpone the de-escalation of care at the end of life. Palliative Care consultation (PCC) is well-established among patients receiving cytotoxic chemotherapy, but its effectiveness is less certain among patients receiving newer treatment modalities. We aimed to test the association of PCC with end-of-life (EOL) outcomes among patients treated with an ICI for any type of cancer. **Methods:** We created a retrospective registry of all patients who received at least one dose of ICI for any indication between 2/1/2011 and 4/7/2022 at a comprehensive cancer center and its outreach clinics. The investigators created a secure, cloud-based registry (REDCap), validated it with data quality rules, and resolved all discrepancies; clinical research specialists at Vasta Global captured most of the data. We used the chi-square test to compare categorical variables, defined statistical significance as $p < 0.05$, and used SAS version 9.4 for analyses. The study had institutional IRB approval. **Results:** The cohort consisted of 3,142 patients with lung cancer (45%) as the most common cancer type, followed by melanoma (14%) and head and neck squamous cell carcinoma (9%). ICI was most often given in the first line setting (46%) with good baseline performance status (ECOG 0-1, 50%). 915 (29%) patients had PCC, which was associated with a higher rate of code status de-escalation from "Full Code" at any point before death (92% vs. 87%, $p = 0.007$). There was no association between PCC and either the initiation of ICI within 30 days of death (7% vs. 5%, $p = .0172$) or any dose of ICI within 14 days of death (5% vs. 6%, $p = 0.33$). Among patients with a confirmed location of death (1013, 32%), PCC was associated with a similar rate of death in the hospital at any level of care (30% vs. 28%, $p = 0.51$). **Conclusions:** PCC was associated with code status de-escalation before death but similar risks of late ICI dosing or inpatient status at the time of death. Further studies are needed to risk-stratify patients starting ICI to identify the subgroups that would benefit the most from PCC. Research Sponsor: U.S. National Institutes of Health.

Use of statistical process control charts to identify impactful implementation strategies for an ePRO-based symptom management program across the SIMPRO Consortium. *First Author: Jim W Doolin, Dana-Farber Cancer Institute, Boston, MA*

Background: Collecting electronic patient reported outcomes (ePROs) reduces the burden of cancer and prevents acute care hospitalizations. However, broad implementation in the routine care setting remains challenging, partly because the optimal implementation strategies – actions that are most likely to encourage adoption and use – are not known. Since 2019, the SIMPRO Consortium has deployed an ePRO-based symptom management program (eSyM) across 6 community-based cancer centers. **Methods:** We used statistical process control (SPC) charts to identify variation due to special versus common causes (random variation) for one key performance indicator (KPI) – the weekly ePROs response rate. All 6 SIMPRO sites contributed data for this analysis: 3 for chemotherapy patients and 3 for surgery patients. Sites had to have at least 18 months of KPI data; information from the first 4 months after eSyM rollout were excluded to account for program ramp-up. The KPI was calculated as the number of patients who submitted an ePRO questionnaire divided by the number eligible to submit a questionnaire each week. The upper and lower confidence limits were set at ± 2 sigma to allow for 95% of observations to fall within the limits. Three rules were applied to identify special cause variation: 1) astronomical points (outside sigma limits), 2) shifts (8 or more points above or below a center line), and 3) trends (6 or more points consecutively ascending or descending). Implementation strategies that mapped to special cause variations were selected as those most likely to impact the KPI. **Results:** Across the 6 sites that deployed eSyM, the mean KPI performance ranged from 19.7%-35.7%. SPC charts detected multiple special cause variations in the KPI at all 6 sites, though the patterns varied by site. All sites demonstrated positive and negative astronomical variations as well as positive and negative shifts. Three sites demonstrated negative trends; no sites demonstrated positive trends. Direct patient outreach was the implementation strategy most frequently associated with special cause variation, followed by changes in promoting the ePRO program to clinical staff. Positive changes were associated with strategy initiation; negative changes were associated with strategy discontinuation. **Conclusions:** Applying SPC charts to a KPI from the eSyM deployment highlighted the effect of personal communication with patients and providers, suggesting that these implementation strategies could offer value to other sites deploying eSyM. The absence of positive trends early in eSyM program deployment underscores the need to identify better implementation strategies and allocate more resources to foster program adoption and sustainability. Applying SPCs to other KPIs, such as symptom severity and healthcare utilization, could improve eSyM deployment and impact. Research Sponsor: U.S. National Institutes of Health.

Mortality among oncology patients with multiple unplanned hospital admissions. *First Author: Thomas J Roberts, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Previous work has shown that patients with solid tumors with an unplanned hospital admission have a median overall survival of approximately six months, and readmission rates are high within this patient population, especially near the end of life. However, the relationship between multiple unplanned hospital admissions and survival and whether patient characteristics are associated with differences in survival have not been studied in this patient population. **Methods:** We recorded all hospital admissions to an inpatient oncology unit for patients with solid tumors from October 1, 2021, through September 30, 2022 and categorized admissions as planned (chemotherapy administration or desensitization) or unplanned. For all unplanned admissions we reviewed the electronic health record for unplanned admissions in the previous six months. For patients with one or more prior unplanned admission, we captured demographics, admitting diagnosis, discharge disposition, and vital status including date of death. We examined median overall survival for patients with two unplanned hospital admissions within six months, median survival for patients with three or more unplanned hospital admissions within six months and 90-day survival in patients with two or more unplanned admission. We also used multivariate Cox proportional hazards models to evaluate whether patient demographics, cancer type, and hospital length of stay were associated with differences in survival. **Results:** There were 1,561 unplanned admissions during the period of analysis. Of these admissions, 692 (44%) were preceded by at least one unplanned admission within the prior six months. A total of 400 patients had two or more admissions. Forty-five percent of readmitted patients had a diagnosis of gastrointestinal malignancy. Median overall survival for patients after a second unplanned admission was 76 days (95% CI 60 - 110), and median overall survival after a third unplanned admission was 50 days (95% CI 35 - 99). Median overall survival was 49 days (95% CI 39 - 67) for readmitted patients with a length of stay of at least seven days. Ninety-day survival was 45% (95% CI 39 - 51) among patients with two admissions and 34% (95% CI 26 - 43) among patients with three or more admissions. In multivariable models, longer length of stay was associated with decreased survival (HR 1.03, 95% CI 1.01-1.05). Age and sex were not associated with differences in survival, and overall survival was similar across all disease groups except head and neck, which was associated with improved survival (HR 0.42, 95% CI 0.21-0.85). **Conclusions:** Patients with solid tumors with multiple unplanned hospital admissions in less than six months represent a distinct population with exceptionally poor outcomes, regardless of the primary tumor site and patient demographics. This easily identifiable population may benefit from targeted interventions to improve the quality of end-of-life care. Research Sponsor: U.S. National Institutes of Health.

The association between systemic anticancer therapy (SACT) at the end of life (EOL) and acute care use among patients treated at oncology practices participating in the Oncology Care Model (OCM). *First Author: Maureen Canavan, Yale School of Medicine, New Haven, CT*

Background: Receipt of chemotherapy near EOL has been shown to harm patient and caregiver experience, increase hospitalizations, intensive care unit (ICU) and emergency department (ED) use and drive-up costs. As rates of chemotherapy at EOL have declined, we have seen increases in the rates of immunotherapy at EOL. It is unknown whether use of EOL immunotherapy is associated with the same pattern of higher downstream acute care use and cost. Using data from OCM, a Centers for Medicare and Medicaid Services (CMS) alternative payment model, we evaluated the relationship between SACT type and acute care utilization within 30 days of death. **Methods:** Using anonymized Integra Connect data for OCM episode claims attributed to 8 multi-site OCM practices between July 2016 and December 2021, we stratified patients by SACT type received within 30 days of death (immunotherapy (IO), chemotherapy (CT), or none) and used chi-square tests to compare the proportion of decedents who had inpatient admission, ICU stay, ED visits without inpatient admission, and hospice use within 30 days of death. **Results:** Among 14,169 OCM decedents, 2,227 (15.7%) received IO within 30 days of death, 6,627 (46.8%) received CT and 5,315 (37.5%) received no SACT (table). Patients who received no SACT at EOL were significantly more likely to start hospice within 30 days of death (76%) and to be in hospice for ≥ 3 days prior to death (61%) compared with IO (65% and 40%) and CT patients (59% and 37%) respectively (all p -values < 0.05). Patients who received IO or CT were significantly more likely to have an inpatient stay within 30 days of death (66% and 68% respectively) compared with patients who received no SACT at EOL (58%, p -values < 0.001). No difference in ED visits within 30 days of death between IO (18%), CT (20%), and no SACT (19%) $p < 0.270$. **Conclusions:** Patients who received chemotherapy or IO therapy within 30 days of death had higher proportion of inpatient admissions, ICU stay and lower rates of hospice than patients who received no SACT at the EOL. Patients who did not have any SACT at EOL were more likely to utilize hospice services and for a longer time. Further research should explore whether these findings are generalizable to patients outside of OCM and the magnitude of costs associated with these acute care metrics. Research Sponsor: None.

Acute care and hospice utilization within 30 days of death by SACT treatment within 30 days.

Real-world program-based lung cancer care. *First Author: Wei Liao, Baptist Cancer Center, Memphis, TN*

Background: Low dose CT screening (LDCT) and lung nodule programs (LNP) promote early lung cancer detection, improve survival; Multidisciplinary Care Programs (MDC) promote guideline-concordance. The impact of such program-based care on 'real-world' population-level lung cancer survival and mortality is uncertain. We evaluated program-based lung cancer care versus care outside structured programs in a large community healthcare system. **Methods:** We linked prospective observational databases for LDCT, LNP and MDC with the Tumor Registry of Baptist Cancer Center facilities across Mississippi, Arkansas and Tennessee, categorizing all lung cancer patients between 2011 and 2021, according to program- (LDCT, LNP, MDC) versus non-program-based care. We compared stage distribution, care patterns, survival and mortality by standard statistical methods. **Results:** Of 12,089 patients, 250 (2%), 1236 (10%), 1045 (7%) and 9558 (79%) were diagnosed through the LDCT, LNP, MDC or no program, respectively; non-program-based care sequentially diminished from 96% in 2011 to 67% in 2021, diagnosis through LDCT increased from 0.3% to 7%, LNP from 0.9% to 21%; and MDC alone decreased from a high of 13% in 2015 to 5% in 2021. Black persons, 28% of the whole cohort, were 13% of LDCT, 25% of LNP, 31% of MDC, and 28% of non-program-based care recipients (p = 0.0005). Median (IQR) tumor size was 20mm (13 – 34), 25mm (17 – 44), 35mm (20 – 55) and 35mm (20 – 55), respectively (p < 0.0001); 40-46% of patients across programs had adenocarcinoma; clinical stage was I or II in 58%, 48%, 38% and 29% and IV in 16%, 27%, 31% and 42% in the respective programs (p < 0.0001). 2609 patients (21.6%) had surgery, including 49.2%, 37.7%, 36.1% and 17.2% in LDCT, LNP, MDC and non-program-based care respectively, among whom aggregate pathologic stage was I in 76%, 71%, 54% and 60% (p = 0.0005). Surgery was the sole treatment modality in 27.6%, 21.5%, 12.9% and 10.6%, respectively (p < 0.0001). Despite higher proportions with more advanced pathologic stage, 30.8% of recipients of non-program-based care received adjuvant therapy, compared to 42% among recipients of program-based care, including 39.0%, 37.1% and 49.3% in LDCT, LNP and MDC, respectively (p < 0.0001); 8.7% of patients in programs received no treatment, compared to 20.1% of non-program-based care. Aggregate 5-year overall survival rates were 60% (95% CI: 52% - 69%), 45% (95% CI: 42% - 49%), 30% (95% CI: 27% - 33%), and 18% (95% CI: 17% - 19%), respectively (p < 0.0001). Adjusting for age, sex, race, patient-level rurality and histology, with non-program-based care as reference, the aHR were 0.3 (95% CI: 0.234 – 0.373), 0.51 (95% CI: 0.464 – 0.556, and 0.66(95% CI: 0.607 – 0.712). Results were consistent even without patients who received no treatment. **Conclusions:** Program-based care was associated with more favorable lung cancer characteristics, better quality of care and survival. Disseminating program-based care should be explored as a matter of urgent public policy. Research Sponsor: Baptist Memorial Health Care Foundation for initial funding support: Grant # 15BD03.

The association of HIV and other risk factors with triple-negative breast cancer in South African women. *First Author: Jacob Dubner, Columbia University Medical Center, New York, NY*

Background: Breast cancer (BC) mortality in South Africa (SA) is double that of the United States. The aggressive triple-negative breast cancer (TNBC) subtype comprises 20.9% of BC cases among Black women in Southern Africa. SA has the second highest HIV prevalence worldwide, but if and how HIV affects the risk of developing TNBC is not well understood. **Methods:** Using the South African Breast Cancer and HIV Outcomes (SABCHO) prospective cohort of newly diagnosed BC patients from six public hospitals in SA, we evaluated the association of HIV with risk of TNBC relative to other BC subtypes. We developed multivariable logistic regression models to test for this association while adjusting for key demographic and reproductive risk factors. **Results:** Of 3,883 women with BC, 16.4% had TNBC and 23.0% were HIV-positive. The overall median age of BC diagnosis was 55 years. Among HIV positive patients, the median age of BC diagnosis was 45 years, without a difference between TNBC and non-TNBC cases (p = 0.244). Only 7.2% of women were nulliparous (4.6% in TNBC and 7.6% in non-TNBC subgroups). Of women who had at least 1 full-term pregnancy, 11.2% did not breastfeed, without a difference between TNBC and non-TNBC cases (p = 0.292). In our final multivariable logistic regression model, HIV-positive status was associated with increased risk of TNBC relative to non-TNBC (OR: 1.40; 95% CI: 1.12-1.74, compared to HIV-negative with BC). Parity without breastfeeding was also associated with increased risk of TNBC relative to non-TNBC (OR: 1.72; 95% CI: 1.07-2.84, compared to nulliparous with BC). HIV status and the combined parity/breastfeeding variable had no statistically significant interaction. In exploratory analyses, measures of HIV control at time of BC diagnosis were not associated with BC subtype. **Conclusions:** In this large prospective case-only study conducted in SA, we found that women living with HIV were more likely than HIV-negative women to have TNBC (relative to other BC subtypes), regardless of the extent of HIV control. Whether this relationship is mediated by immune mechanisms or other factors should be the focus of future research. Our findings highlight the importance of rigorous BC screening and early detection among HIV-positive women given their increased relative risk of developing TNBC. Proportion of patients in phase I solid tumor oncology trials receiving treatments that are clinically efficacious. *First Author: Carlos Umberto Muzlera, Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada*

Background: Phase I trials are frequently regarded as possessing therapeutic intent by patients, oncologists, and governing medical bodies alike. While obtaining initial observations of clinical activity of investigational agents is an aim of phase I trials, such estimates utilize surrogate measures, such as objective response rate, which are difficult to conceptualize and less meaningful to a vulnerable patient population compared to clinical endpoints. Furthermore, phase I studies lack a comparator arm. To date, there are no published estimates of the probability a phase I solid tumor participant receives a treatment at a dose that has greater clinical efficacy than the standard of care for their disease setting. Such data is required to enable fully informed decisions around consent. **Methods:** A random sample of 1000 phase I solid tumor oncology trials conducted world-wide, initiated between 2007 and 2012, and enrolling 29,953 patients was obtained from 2223 eligible trials on ClinicalTrials.gov. ClinicalTrials.gov, PubMed, Embase, Medline, and ASCO reports were queried between December 1, 2022 and February 1, 2023 for randomized, controlled phase III trials testing the same regimen and indication as that used in each phase I trial. Phase III trials were considered positive if they demonstrated statistically significant superiority over an acceptable standard of care at the time of enrolment of the corresponding phase I trial with respect to overall survival, health related quality of life, or a validated surrogate for these clinical endpoints. All statistical tests were 2-sided. **Results:** A total of 0.82% (245) phase I trial patients received a treatment at a dose that was subsequently demonstrated in a randomized, controlled phase III trial to have statistically superior clinical efficacy over an acceptable standard of care at the time of phase I trial enrolment for the same disease setting. The mean objective response rate for both published and unpublished sampled phase I trials in the advanced or metastatic setting was 4.2%. Meta-regression showed a statistically significantly greater proportion of patients receiving a clinically efficacious therapy in biomarker trials (rate ratio = 3.78., 95% CI = 1.15 – 10.24, P = 0.02) and trials with an expansion cohort (rate ratio = 3.12, 95% CI = 1.05 – 8.89, P = 0.03). Proportions were statistically significantly lower for first in class treatments (rate ratio = 0.21, 95% CI = 0.03 – 0.76, P = 0.03). **Conclusions:** One in 122 patients in phase I solid tumor trials received a treatment that subsequently demonstrated superior clinical efficacy over the standard of care at the time of phase I trial enrolment. Considering published estimates of serious adverse events rates of 10-19%, this reveals low therapeutic value for phase I trial participation. Research Sponsor: None.

Breast cancer staging for patients with “low risk” disease: Are they all the same? *First Author: Jennifer Kay Plichta, Department of Surgery, Duke University Medical Center, Durham, NC*

Background: Studies have shown that a low (<11) Oncotype DX recurrence score (RS) is associated with better survival outcomes. RS is currently included in the AJCC prognostic staging criteria. Not all patients with a low RS are downstaged. It has been suggested that a low RS should further downstage patients regardless of other disease factors. We explored survival outcomes for patients with a low RS to assess if additional patients should be downstaged. **Methods:** Using the National Cancer Database, female patients ages 18-75 with invasive unilateral pT1-3, pN0-1, MO hormone receptor positive (ER+ and/or PR+), HER2- breast cancer and a RS <11, diagnosed 2010-2018 were identified. Patients who received neoadjuvant treatment were excluded. Patients were grouped based on the AJCC 8th edition prognostic stage (IA, IB, IIA, IIB, IIIA). Variables were summarized, and unadjusted overall survival (OS) was estimated using the Kaplan-Meier method. Cox proportional hazards models were used to estimate the association of stage with OS after adjustment for available covariates. **Results:** Of the 54,961 patients with a RS <11, median follow-up was 57.7 months (95% CI 57.3-58.1), and median age was 61yo (IQR 52-67). Most tumors were grade 1 (37.6%) or 2 (56.9%) with ductal histology (75.3%). The median tumor size was 1.5 cm (IQR 1-2), and most were pN0 (83.3%). Although most patients with a RS <11 were stage IA (94.2%), some had a higher stage assignment (5.1% stage IB, 0.6% IIA, 0.1% IIB, <0.01% IIIA). Most patients (93.4%) received endocrine therapy (ET), and few (3%) received chemotherapy. Patients treated with chemotherapy more often had younger age, lobular histology, higher grade, larger tumor size, and/or pN+ disease (all p<0.001). Unadjusted OS was reduced with higher stage (log-rank p<0.001), and this remained true when limited to only those who received ET without chemotherapy (log-rank p<0.001). After adjustment for relevant covariates including treatment, higher stage remained associated with worse OS [stage IA: ref; IB: HR 1.66 (95% CI 1.34-2.05); IIA: HR 2.29 (95% CI 1.44-3.65); IIB: HR 2.48 (95% CI 1.03-5.95); overall p<0.001]. **Conclusions:** For patients with a low RS, survival outcomes vary with current AJCC prognostic disease stage, suggesting that not all patients with a RS <11 should be downstaged based on RS alone. Anatomic and other non-genomic factors remain relevant when assessing prognosis. Research Sponsor: Duke University Medical Center; U.S. National Institutes of Health.

OS rates (95% CI) by AJCC prognostic stage among those with RS <11, treated with surgery and endocrine therapy without chemotherapy (RS <11).

AJCC Prognostic Stage	N	1yr OS	3yr OS	5yr OS

Trends in the use of maintenance therapy in ovarian cancer. *First Author: Naomi N. Adjei, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Emerging maintenance therapies in advanced ovarian cancer (OC) remain of high interest since 70% of patients (pts) will relapse and ultimately succumb to OC. This study analyzes nonclinical factors associated with maintenance therapy (MT) in OC. We define MT in OC as the use of polyADP-ribose polymerase inhibitors (PARPi) and/or bevacizumab (bev) following platinum-based chemotherapy. **Methods:** We used data from Optum's de-identified Clinformatics Data Mart Database F to conduct an analysis of OC pts with Medicare or commercial health insurance. Pts were included if they had 1 inpatient or 2 outpatient diagnosis codes for OC from 01/2017 to 12/2020 and received platinum-based chemotherapy after diagnosis. Pts were excluded if they did not have continuous coverage from diagnosis until 6 months after completion of platinum-based chemotherapy or death. MT was identified by insurance claims for PARPi or bev received within 6 months after completion of platinum-based chemotherapy. Descriptive statistics were used to summarize patient characteristics. Multivariable logistic regression was used to evaluate associations between pts' nonclinical characteristics and MT use. Trends in MT use were reviewed by year. Subgroup analysis comparing trends in PARPi use to bev use was also performed. The median time from last chemotherapy until initiation of MT was 22 days. **Results:** 5,652 pts were included in the study with a median age of 70 years. The majority were white (70.7%), Medicare-insured (71.8%), and treated in the South (42.8%). 33.6% of pts received MT and 66.4% of pts received neither PARPi nor bev. More pts received bev alone (19.6%) compared to PARPi alone (10.3%) or combination MT (3.7%). Olaparib was the most commonly prescribed PARPi. After adjusting for insurance type, both PARPi and bev use increased significantly over time from 2017 to 2021. Pts with more comorbidity burdens (i.e. higher Elixhauser comorbidity index) were more likely to receive MT compared to pts with less comorbidity [OR (95% CI): 1.44 (1.26-1.65)]. MT use was significantly associated with treatment in the South compared to the Northeast [1.22(1.01-1.46)] and younger age, pts > 76 years were less likely to use MT compared to pts < 56 years old [0.78 (0.62-0.98)]. In the subgroup analysis, PARPi use was significantly associated with age, race and region compared with no MT use, while bev use was not associated with these factors. **Conclusions:** Age, comorbidity status, and geographic location of treatment were associated with MT use. The increasing use of MT over time is consistent with published data since both agents have demonstrated a progression free survival advantage and have tolerable toxicity profiles. With increasing focus on MT in OC, a better understanding of nonclinical factors associated with MT use is imperative to eliminating potential disparities in OC outcomes. Real-world analysis of cardiac, gastrointestinal, and hematologic toxicities between commonly used antiemetics in everyday oncology clinical practice. *First Author: Kavitha Beedupalli, Louisiana State University (Shreveport) Program at Feist-Weiller Cancer Center, Shreveport, LA*

Background: Antiemetics are highly effective in chemotherapy-induced nausea and vomiting. We utilized Food and Drug Administration Adverse Event Reporting System (FAERS) database to evaluate adverse events (AEs) caused by selected antiemetics commonly used in outpatient oncology practice. **Methods:** We analyzed the FAERS database to assess the cardiac, gastrointestinal (GI), and hematologic AEs for metoclopramide, olanzapine, ondansetron, and promethazine from 2013 through 2022. The disproportionality signal was analyzed by calculating Reporting Odds Ratio (ROR) with a 95% confidence interval (CI)—considered significant when the lower limit of 95% CI was > 1. **Results:** A total of 20,302 AEs were identified, out of which 8,135 (40.1%) were cardiac—arrhythmia and QTc prolongation; 8,656 (42.5%) were GI—nausea/vomiting, constipation/diarrhea, abdominal pain/discomfort, and dyspepsia; and 3,511 (17.3%) were hematologic—leukopenia, thrombocytopenia, anemia, and pancytopenia. Compared to other antiemetics, promethazine and olanzapine had higher cardiac and hematologic AEs, respectively, whereas metoclopramide, followed by ondansetron had higher GI AEs (Table). **Conclusions:** Antiemetics are readily available and effective, yet the preference for a particular drug or drug combination varies. Our study highlights selected antiemetics AEs in order to help individualize treatment for this often challenging and frequently encountered entity. Research Sponsor: None.

Survival of patients with solid tumors and sepsis admitted to intensive care in a tertiary oncology center: A retrospective analysis. *First Author: Sam Smith, Imperial College London, London, United Kingdom*

Background: Sepsis is a life threatening organ dysfunction caused by a dysregulated host response to infection. Patients with cancer are at high risk of developing sepsis and requiring admission to the intensive care unit (ICU). Patients with cancer and sepsis have been found to have worse survival than non-cancer patients, with 90 day survival for cancer patients ranging from 28% to 72%. Survival differs between studies due to multiple factors including variably mixed haemato-oncology and solid tumor cohorts and varying definitions of sepsis. Our objectives were to accurately assess short, medium and long term survival of patients admitted to ICU with a solid tumor and sepsis and to identify the best predictors of 90 day survival at admission. **Methods:** We conducted a retrospective cohort survival analysis. We identified adults (aged 18 years and over) admitted to ICU with sepsis and a solid tumor between 1st January 2011 and 31st December 2020 at a tertiary oncology center with hospitals at two sites (London and Surrey, United Kingdom). We defined sepsis using the Sepsis-3 definition. The primary outcome was 90 day survival, but we also calculated 30 day, 180 day, 1 year and 5 year survival. Survival was calculated excluding patients lost to follow up. Univariate and multivariate analyses were undertaken to identify factors that differed between survivors and non-survivors at day 90. We used the parametric accelerated failure time model for multivariate analysis to generate time ratios (TR). **Results:** 625 patients were identified, with 131 patients lost to follow up by 5 years. The median age was 64 years (Interquartile Range 54-71) and 56% were male. 84.8% (530/625) survived to ICU discharge. The 30, 90 and 180 day survival rates were 72% (439/610), 59.5% (353/593) and 51.7% (300/580) respectively. 1 year survival was 38.7% (221/571) and 5 year survival 8.1% (40/494). Multivariate analysis identified the presence of localized (TR 7.85, 95% CI 4.00 -15.41) or regionalized disease (TR 4.71, 95% CI 2.74-8.08) compared to distant metastatic disease, surgery on the day of admission (TR 6.78, 95% CI 3.24-14.19), lactate (TR 0.80, 95% CI 0.74-0.87), SOFA score (TR 0.84, 95% CI 0.79-0.89), previous radiotherapy (TR 0.53, 95% CI 0.32-0.88), previous medical cancer treatment (TR 0.67, 95% CI 0.42-1.07), bacteremia (TR 2.14, 95% CI 1.25-3.64) and albumin (TR 1.06, 95% CI 1.02-1.10) as independent predictors of 90 day survival. **Conclusions:** This study of solid tumor patients admitted to ICU is one of the largest to date with the longest follow up period, providing up to date survival data to inform clinicians and patients. Patients with solid tumors and sepsis admitted to ICU have short and medium term survival rates comparable to non-cancer populations and therefore the presence of cancer should not prevent ICU admission. Prior oncological therapies may affect survival in patients admitted to ICU with sepsis. Research Sponsor: None.

Multicenter, retrospective population-based study on the incidence of medication-related osteonecrosis of the jaw in patients with breast cancer with bone metastases. *First Author: Christine Brunner, Department of Gynecology and Obstetrics, Medical University of Innsbruck, Innsbruck, Austria*

Background: Antiresorptive therapy with bisphosphonates or denosumab is standard care for patients with primary or secondary osseous metastasized breast cancer. The most important toxicity of this class of drugs is medication-related osteonecrosis of the jaw (MRONJ). MRONJ represents a major medical burden and impairs quality of life. Based on recent studies, the risk of MRONJ occurrence ranges from 1% to 3%. The objective of this study was to assess the population-based incidence of MRONJ in breast cancer patients with bone metastases in Tyrol, Austria. **Methods:** This retrospective multicenter study was conducted between 2000 and 2020 at nine centers across Tyrol, Austria, including 8,860 patients with breast cancer. Depending on whether patients with bone metastases received denosumab, bisphosphonates or denosumab following bisphosphonates they were allocated to one of three groups. Data was collected using an electronic case report form (e-CRF) and managed via the web-based database AskiMed. MRONJ incidences with 95% confidence intervals and the differences between the median of cumulative incidences were calculated in patients treated with bisphosphonates and/or denosumab. **Results:** A total of 639 patients had bone metastasis and received antiresorptive therapy. MRONJ was diagnosed in 56 (8.8%) patients. Regarding the 292 (45.7%) patients treated with denosumab alone, the MRONJ incidence was 11.6% (95%CI 8.2%-15.9%). The group of patients treated with only bisphosphonates included 255 (39.9%) patients; their MRONJ incidence was 2.7% (95%CI 1.1%-5.6%). Of the 92 (14.4%) patients receiving both antiresorptive therapies consecutively, the MRONJ incidence was 16.3% (95%CI 9.4%-25.5%). Thus, a total of 49 (12.8%) MRONJ cases were detected in patients using denosumab alone as well as using the combination of denosumab following bisphosphonates. Patients treated with denosumab developed a MRONJ in median 60 months earlier than with bisphosphonates alone or followed by denosumab. The hazard ratio for MRONJ from start of therapy of denosumab compared to bisphosphonates alone or followed by denosumab was 7.9 (3.8-16.2; p-value < 0.0001). **Conclusions:** This study showed a substantially higher MRONJ incidence for denosumab alone or bisphosphonates followed by denosumab in the tyrolean cohort when compared to other recent studies. Future comparative real-world-evidence research provide explicit benefit-harm tradeoffs to inform treatment decision making. Research Sponsor: None.

Real-world evidence to inform clinical insights on tissue-agnostic approvals of therapies. *First Author: George W. Sledge, Caris Life Sciences, Phoenix, AZ*

Background: Many tissue-agnostic (TA) approvals were based on clinical trials with limited patient numbers without covering all tissue types (TT), raising the question of whether these indications were truly tissue agnostic. Real world evidence (RWE) offers an opportunity to investigate TTs not included in clinical trials/studies to answer this question. Herein we investigate the seven TA approvals to date in a large real world database and report clinical outcomes. **Methods:** A total of 186,581 tumors from over 35 TTs tested with comprehensive molecular profiling including NextGen sequencing of DNA and RNA were investigated for TA alterations (TMB-High (≥ 10 mutations/MB), MSI-H/MMRd, BRAF V600E mutations and NTRK1/2/3/RET fusions) at Caris Life Sciences (Phoenix, AZ). Time-on-treatment (TOT) from RWE was obtained from insurance claims and calculated from treatment start to finish. Kaplan-Meier estimates were calculated for molecularly defined patient cohorts. Significance was determined as p values of <0.05 . **Results:** Among all tumors, 21.2% carried at least one TA alteration, 17.2%, 3.4% and 0.6% had 1, 2 or 3 alterations, respectively. TMB-H in 18.7%, MSI-H/dMMR was seen in 3.9%, BRAF V600E in 2.8% of tumors, NTRK1/2/3 and RET fusion seen in 0.16% and 0.23%. TA alterations were most prevalent in BCC (86%) & SCC (82%) of skin, MEL (71%), THCA (51%) and NSCLC (44%) and least in liposarcoma (0), meningioma (0.7%) and GIST (1.4%). Among tumors treated based on TA indications, substantial variability of TOT among TTs was observed (see table). Looking at TTs included (INC) and not included (nINC) in KEYNOTE-158 and other studies for TMB-H and pembro, median TOT for nINC was similar to INC (N=242 vs 2322, 6.1 m vs 6.3 m, p = 0.55). Nevertheless, statistically significant differences in median TOTs were seen across nINC when comparing TMB-H vs. TMB-L (6.1m vs. 2.9m, HR: 0.58 [95% CI: 0.50-0.67], p<0.001) and in a subset of 838 MSS tumors (4.9m vs. 2.8m, p<0.001). **Conclusions:** RWE data adds substantially to our understanding of the demographics of TA indications and suggests that some TA treatment benefits may be tissue-specific. Recent TA indications will require further accumulation of cases to draw meaningful conclusions regarding whether TA indications are, in fact, tissue agnostic. Research Sponsor: None.

RWE of TA-positive pembro-treated tumors from 11 selected TTs (TMB-H TT group 1 had significantly longer TOT (months) than group 2; MSI-H TT group A had longer TOT than B; b longer than C all p<0.05).

Malnutrition risk at diagnosis and influence on survival in patients with solid tumors at a large academic cancer center. *First Author: Kunal C. Kadakia, Levine Cancer Institute, Charlotte, NC*

Background: Malnutrition is common in cancer patients and negatively impacts quality of life, tolerance to anti-cancer therapies and is associated with poor prognosis. It is, however, unclear if patient-reported malnutrition risk at initial diagnosis is related to overall survival (OS) in solid tumor oncology outpatients in the United States. **Methods:** A cohort of 3,562 patients who completed the malnutrition screening tool (MST), a validated assessment of malnutrition risk, at initial diagnosis of any stage solid tumor and had available survival data were analyzed. The primary objective was to evaluate the relationship of high malnutrition risk (≥ 2 of 5 = high risk for malnutrition, H-MST) to OS and was assessed using Kaplan Meier techniques and Cox proportional hazards models. Unadjusted analyses were performed, and adjusted multivariable analyses evaluated the impact of H-MST on OS controlling for key clinical baseline confounders. **Results:** The median age was 63 years (IQR: 54-71), with 62% females and 81% White. Most common cancer sites were breast (28%), gastrointestinal (GI, 21%), and thoracic (13%) and 80% were non-metastatic. Median follow up was 48.3 months. H-MST was associated with lower OS in the unadjusted model, median OS in months was 32.5 [H-MST] vs not reached in low MST [L-MST] (HR 3.3, 95% CI 2.9-3.7, p = < 0.001). Multivariable analysis confirmed that H-MST remained independently associated with OS when controlling for age, sex, cancer site, stage, BMI, and symptom scores. Landmark OS rates at 50 months were 60% [H-MST] vs. 69% [L-MST] (HR 1.51 95% CI 1.3-1.7, p = < 0.001). Adjusted subgroup analyses by cancer site showed the independent impact of H-MST was relatively similar across groups (Table). **Conclusions:** High malnutrition risk at initial diagnosis was independently associated with shorter survival across a large representative cohort of solid tumor oncology outpatients. The screening occurred before any anti-cancer therapy and it is noteworthy most had non-metastatic disease. These data highlight the need for systematic screening to identify patients at malnutrition risk who need additional assessment early during cancer. Further research on how to optimize allocation of limited nutrition resources for those with high malnutrition risk is needed. Research Sponsor: None.

	Sample Size/Number of Events	50-month survival rate (High-MST, %)	50-month survival rate (Low-MST, %)	HR (95% CI) High MST vs Low MST	P-Value

Site of metastasis (SoM) and its impact on clinical outcomes in 8 cancer cohorts. *First Author: Rohini George, ConcertAI, Bengaluru, Karnataka, India*

Background: The prognosis of metastatic cancer is in general poor. This can be affected by several factors including age, histology, treatment choices & SoM etc. **Methods:** This retrospective study leverages ConcertAI's deeply curated Patient360 datasets for 8 solid cancers to assess the impact of SoM on the outcomes of patients. For the purpose of this analysis, we focused on the most common SoM (bone, brain, lung & liver). Patients had either a Single SoM (SSM) or Multiple SoM (MSM) and we focused this analysis on patients with SSM. The overall survival (OS) & progression free survival (PFS) from the date of metastasis as well as the time to metastasis (TTM) from initial diagnosis were determined for each cohort. We also computed a consolidated OS & PFS for all patients with MSM. **Results:** 140K patients were included in this study of which 60K patients had a SoM. The distribution of SoM is dependent on the primary cancer type. For example, in breast & prostate cancer, bone metastasis accounts for 50-80 % of the metastatic cohort whereas it is only 8-21% in lung & melanoma. As expected, the overall values of OS/PFS were primarily governed by the primary cancer type (Table), but this analysis provides further interesting insights: 1. Within a cohort, there were significant differences in the prognosis of patients based on the SoM. Brain & liver had a poorer prognosis compared to the other SoM across most cohorts. 2. The relative prognosis for some SoM were dependant on the primary cancer type. For example, there was a very significant difference between the OS/PFS values in the breast cancer cohort when comparing brain vs bone as SoM. However, in the lung cancer cohort, this difference was less pronounced, and the trend was flipped. 3. For some cohorts the SSM for certain sites had a worse prognosis than the MSM. In breast cancer the OS of the brain & liver SoM was worse than the MSM. 4. The TTM is also dependent on the primary cancer and there is a correlation between the average TTM and the OS of the cohort. **Conclusions:** The patterns of cancer metastasis and the absolute and relative prognosis for a particular SoM is dependent on the primary cancer type. Such insights from a large real-world data study can impact clinical decisions regarding the aggressiveness of treatment based on the primary cancer type as well as the metastatic site. Real-world behavioral restriction practices of cancer patients (pts). *First Author: Eliya Shachar, Sourasky Medical Center, Oncology Division, Tel Aviv-Yafo, Israel*

Background: Quality of life (QoL) assessments do not measure pts' ability to maintain normal daily activities during cancer therapy. Misbeliefs might promote avoidance of activities perceived as dangerous, compromising pts QoL. We examined the daily practices of actively treated pts with cancer. **Methods:** A locally validated questionnaire at the Tel-Aviv Sourasky Oncology Division was distributed internationally using the Belong.life social and professional digital health platform. We examined real-world pts reported practices, provided voluntarily and anonymously. The survey consisted of 15 questions, including demographic, clinical, behavioral parameters and sources guiding and supporting pts practices. Independent clinical and demographic variables were analyzed. Statistical analysis was performed, and a multivariate logistic regression was conducted to identify factors predicting restrictive behaviors. **Results:** The study population comprised 1,395 pts receiving active cancer therapy, reporting their outcomes from the Belong digital platform. Most respondents were from the United States (1082, 77.70%) and Israel (223, 16%), over the age of 40 (1309, 93.8%), and female (987, 70.75%). Most common tumor types were breast (394, 28.24%) and gastrointestinal cancers (199, 14.26%). The majority of pts (1,005, 72.88%) reported on at least 1 adopted limitation in daily activities, and 305 (21.86%) maintained more than half of these constraints. Daily life restrictions included avoiding sun exposure (779, 57.83%), international travel (417, 33.33%), indoor public places (malls, etc) (431, 33.13%), hair dyeing (271, 22.72%), domestic tourism (284, 21.93%), contact with friends and family (231, 17.69%), children and grandchildren (202, 16.33%), outdoor public spaces (190, 14.62%), and contact with pets (135, 10.41%). Multiple sources were implicated by the pts as guiding their behavior, with the most common being health-care professionals (951, 65.95%), followed by both non-medical authorities and health-care team (320, 22.19%), and non-medical advisors, including internet, pts forums, partners, friends, and family (171, 11.86%). Pts who maintained strict ($\geq 50\%$ of the limitations) and less strict restrictions, demonstrated no significant association between country of origin (p = 0.118), and education level (p = 0.3591). A significant association was noted between younger age (p = 0.0014), female sex (p = 0.0141) and primary cancer site (p < 0.0001), and the adoption of strict restrictions. **Conclusions:** The majority of pts reported compromised daily activities, which are likely attributed to misconceptions about therapy and disease, deleteriously impacting QoL, therefore, impeding their ability to continue to conduct a complete and meaningful life. These findings require development of tools examining patients' real-daily life activity as an additional endpoint in clinical trials. Research Sponsor: None.

Measuring variation in the quality of systemic anti-cancer therapy delivery across hospitals: A national population-based evaluation. *First Author: Jemma Megan Boyle, London School of Hygiene and Tropical Medicine, London, United Kingdom*

Background: To date, there has been little systematic assessment of the quality of care associated with systemic anti-cancer therapy (SACT) delivery across national healthcare systems. We evaluated hospital-level toxicity rates during SACT treatment as a means of identifying variation in care quality. **Methods:** All colorectal cancer patients receiving SACT within 106 English National Health Service hospitals between 2016 and 2019 were included. Severe acute toxicity rates were derived from hospital administrative data using a validated coding framework. Variation in hospital-level toxicity rates was assessed separately in the adjuvant and metastatic settings. Toxicity rates were adjusted for age, sex, comorbidity, performance status, tumour site, and TNM staging. **Results:** Of the 8,173 patients receiving SACT in the adjuvant setting, 2,074 (25%) had a toxicity with adjusted hospital-level rates varying from 11% to 49%. Of the 7,683 patients receiving SACT in the metastatic setting, 3,625 (47%) had a toxicity with adjusted hospital-level rates varying from 25% to 67%. Compared to the national mean toxicity rate in the adjuvant cohort, six hospitals were more than 2 standard deviations (2SD) above, and four hospitals were more than 2SD below. Similarly, in the metastatic cohort, six hospitals were more than 2SD above, and seven hospitals were more than 2SD below the national mean toxicity rate. **Conclusions:** There is substantial variation in hospital-level severe acute toxicity rates in both the adjuvant and metastatic settings, despite comprehensive risk-adjustment. Ongoing reporting of this performance indicator can be used to focus further investigation of toxicity rates and stimulate quality improvement initiatives to enhance care. Research Sponsor: None.

Real-world response endpoints in patients with mNSCLC treated with chemotherapy across real-world datasets. *First Author: Brittany Avin McKelvey, Friends of Cancer Research, Washington, DC*

Background: Response Evaluation Criteria in Solid Tumors (RECIST) based response rate (RR) is used for efficacy evaluation in clinical trials and relies on imaging data collected at specified timepoints for uniform assessment. In routine clinical practice, the method and timing of response assessment can vary, and imaging data from electronic health records (EHR) and other real world (rw) sources may not be available, making RECIST-based assessment of rw-response rate (rwRR) using rw data (RWD) challenging. Friends of Cancer Research formed a multi-stakeholder partnership to assess available data attributes to measure response across RWD sources to inform development of a consistent method for measurement. **Methods:** The study included seven EHR data partners who identified and analyzed a cohort of 1,380 patients (pts) with metastatic non-small cell lung cancer (mNSCLC) treated with first-line platinum doublet chemotherapy, following a common protocol and statistical analysis plan. The availability and frequency of data components to assess response including raw images, radiology imaging reports, and clinician response assessments from provider notes were assessed. Response endpoints measured included rwRR, rw-duration of response (rwDOR), and the association of rwR with rw-overall survival (rwOS), rw-time to treatment discontinuation (rwTTD), and rw-time to next treatment (rwTTNT). **Results:** The availability of data components varied across RWD sources (Table). Images were not widely accessible, thus response was analyzed using clinician response assessments (median proportion of pts evaluable, 77.5%). Of these assessments, the majority relied on imaging interpretation. The median rwRR was 46% with a median rwDOR of 119 days. The table provides median rwTTD, rwTTNT, and rwOS across data sources. **Conclusions:** The rwRR among pts with mNSCLC calculated using the clinician assessment was relatively consistent across all RWD sources, with consistent trends in time to event endpoints. While variability in the availability of data components to assess response was observed, the demonstrated feasibility of response endpoints based on clinician assessment suggests further exploration may inform drug effectiveness evaluation with RWD. Research Sponsor: Friends of Cancer Research (Non-profit).

Tumor lysis syndrome in solid tumors: A retrospective cohort study of the National Inpatient Sample from 2016 to 2019. *First Author: Akshit Chitkara, University of California Riverside, Riverside, CA*

Background: Tumor lysis syndrome (TLS) is a life-threatening oncologic emergency. Patients with a rapidly proliferating tumor or high tumor burden after cytotoxic chemotherapy, predominantly in hematologic malignancies, are at increased risk of TLS. The advancement in therapeutic strategies of oncology in the past few decades has expanded the spectrum of malignancies associated with TLS. A dearth of literature on the incidence of TLS in various solid malignancies exists. Using the National Inpatient Sample (NIS) data, this study aims to highlight the solid malignancies at risk of TLS, highlight the demographic factors, and draw a comparison with that in hematological malignancies. **Methods:** The NIS 2016-2019 dataset was analyzed utilizing univariate and multivariate logistic regression analysis for the predictors of TLS (P<0.05). StataCorp. 2021. Release 17. College Station, TX: StataCorp LLC, BE version with Stata's svy command, and appropriate weights, were used to perform the analysis. The overall fit was analyzed using Receiver Operative Curves (ROC), and sensitivity analysis was analyzed using the e-value package. **Results:** From 2016-2019, a total of 51,385 (48,917-53,853) hospitalizations had an incidence of TLS. We included 16,249 cases of TLS in patients treated for the ten most common malignancies in the US. We found that older age, male sex, and black race were associated with higher odds of TLS. It was reported highest in large hospitals and urban non-teaching hospitals. The regional distribution of the TLS suggests the highest odds in the Western region. The odds of getting TLS were highest among Leukemias and Lymphomas, respectively. Among solid tumors, the odds of getting TLS were highest in uterine cancer patients, followed by lung, breast, pancreatic, and liver cancer among the top five. (Table). **Conclusions:** In this study, we conclude that solid tumors, mainly uterine, followed by lung and breast, have significantly higher odds of TLS, more so in larger or non-teaching hospitals. There is a need to establish specific management guidelines to prevent these TLS cases that will improve the morbidity and mortality associated with TLS and help build more cost-effective treatment regimens. Research Sponsor: None.

Demographic Characteristics	OR of TLS	95% CI	Hematologic Malignancies	OR of TLS	95% CI
Age	1.01	1.006 to 1.009	Leukemias	56	52.59 to 59.84

Molecular testing utilization in patients with advanced non-small cell lung cancer (NSCLC) in Washington (WA) state. *First Author: Lauren Shih, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Therapies targeted at driver mutations (e.g. EGFR, ALK) in NSCLC have contributed to improved patient survival. While current guidelines recommend that all patients diagnosed with stage IV NSCLC undergo molecular testing to determine eligibility for targeted therapies, real-world testing patterns have not been well described. In a retrospective study using cancer registry and insurance claims, we evaluated rates of molecular testing in a population-based sample of NSCLC patients in WA. **Methods:** We linked WA state cancer registry records from 2017-2019 with claims records for Medicare, Medicaid, and two large commercial insurers. Patients diagnosed with stage IV NSCLC who had continuous insurance enrollment for 2 months prior to and 12 months following diagnosis were identified. Using insurance claims data, we identified patients who received any molecular testing (either testing for specific markers or comprehensive molecular profiling). We compared proportions of patients who received and did not receive molecular testing by insurance type, race, ethnicity, gender, and diagnosis (Dx) year. We performed a multivariate regression analysis to determine factors associated with completion of molecular testing. **Results:** 1048 eligible patients were identified. The median age was 70. Patients were predominately insured by Medicare (62.6%) and non-Hispanic white. 90.3% of all patients underwent molecular testing. Molecular testing rates were similar between white and non-white patients (90.4% vs 89.2%, p=0.647). Testing rates were significantly lower among Hispanic patients vs non-Hispanic patients (77.8% vs 90.7%, p=0.018). Testing rates were lowest among Medicaid enrollees (86.4%) compared to Medicare (88.4%), commercial (97.2%) or multiple insurances (94.9%) (p=0.0018). A multivariate analysis demonstrated that patients age ≥65 and Medicaid patients were less likely to receive molecular testing while females were more likely to receive testing; year of Dx did not impact testing rates (Table). **Conclusions:** While the rate of adherence to recommended molecular testing was high in the overall cohort, testing rates were lower in Hispanic patients, older patients, males, and those with Medicaid insurance. Given the therapeutic implications of testing, drivers of these observed disparities warrant further study to ensure equitable access to efficacious treatment. Research Sponsor: Fred Hutchinson Cancer Center.

Disparities in PI3K/mTOR inhibitor use, toxicities, and outcomes among patients with metastatic breast cancer. *First Author: Claire Sathe, New York Presbyterian Hospital/Columbia University Irving Medical Center, New York, NY*

Background: Advances in breast cancer treatment have led to improvements in survival among patients with metastatic breast cancer (MBC). Nevertheless, Black patients and patients with lower socioeconomic status (SES) continue to bear a disproportionate mortality burden. Furthermore, because landmark trials for novel anticancer agents lacked racial diversity, their toxicity profile for minority patients remains uncertain. Our study examines the impact of race and other sociodemographic characteristics in the use and toxicity outcomes of PI3K and mTOR inhibitors (PI3K/mTORi). **Methods:** We conducted a retrospective analysis of EHR-derived data from the Flatiron Health Database (FHD). A dataset was constructed to include patients with hormone receptor-positive, HER2-negative MBC diagnosed between 1/1/2011 and 1/31/2022. Outcomes included PI3K/mTORi use, rates of hyperglycemia and dose reduction, and time on treatment. Multivariable logistic regression was used to evaluate factors associated with use and outcomes. **Results:** A total of 13,388 patients with MBC were included in our analysis, of which 2,620 (19.6%) received PI3K/mTORi (78.3% everolimus, 14.7% alpelisib, 6.9% both agents). Overall, 67.5% of all patients were categorized as White, 9.8% as Black/African-American (Black/AA); 18.9% were >75 years old; 10.1% were treated at an academic site; 4.0% had Medicaid insurance. Insurance through Medicaid was associated with lower use of PI3K/mTORi compared to commercial insurance (15.6% vs 18.8%; OR: 0.76, 95% CI: 0.59-0.99, p=0.04), as was advanced age (10.9% for >75 years old vs 22.9% for <60 years old; OR: 0.68, 95% CI: 0.58-0.80, p<0.001) and poorer performance status at diagnosis (15.1% for ECOG $\geq$ 2+ vs 22.9% for ECOG 0; OR: 0.84, CI: 0.72-0.98, p=0.03). Odds of PI3K/mTORi use were almost 50% higher for patients treated at an academic center (OR: 1.46, CI: 1.06-2.05, p=0.02). While Black/AA patient had lower rates of use than White patients (17.4% vs 20.1%), they had similar odds of receiving PI3K/mTORi on multivariable analysis (OR: 1.00, CI: 0.85-1.17, p>0.9). Black/AA patients experienced higher rates of hyperglycemia on PI3K/mTORi than White patients (67.6% vs 52.5%). On multivariable analysis, odds of hyperglycemia were twice as high for Black/AA patients (OR: 2.1, CI: 1.33-3.35, p<0.01). However, rates of dose reductions and time on PI3K/mTORi therapy did not differ significantly among White vs Black/AA patients. **Conclusions:** This analysis of real-world data suggests that lower SES is associated with decreased PI3K/mTORi use. Efforts to improve access to these life-prolonging agents are warranted. Of concern, we also found racial disparities in toxicity outcomes, with Black patients having twice the risk of hyperglycemia. Greater attention to the tolerability of novel agents in diverse populations is warranted. Research Sponsor: American Cancer Society; Breast Cancer Research Foundation.

Decomposing racial differences in financial hardship among older cancer survivors. *First Author: Elizabeth Davis, Boston University, Boston, MA*

Background: Despite Medicare coverage, financial hardship is a prevalent issue among older cancer survivors, particularly among those belonging to a racial/ethnic minority. Sociodemographic, clinical, and area-level factors may mediate this relationship; however, no studies have assessed the extent to which these factors contribute to disparities. **Methods:** Surveys assessing financial hardship after cancer were completed by 721 patients age 65+ of Black or white race completing primary cancer treatment for breast, prostate, colorectal, prostate cancer or lymphoma at University of Alabama at Birmingham between 2000 and 2019. Financial hardship included material, psychological, and behavioral domains. Material hardship included ever 1) borrowing money/going into debt, 2) filed for bankruptcy, 3) worried about paying large medical bills, and 4) made any other financial sacrifices due to cancer. Psychological hardship was measured by asking if participants were ever worried about paying large medical bills related to cancer, its treatment or effects of treatment. Behavioral hardship was measured by asking if participants were unable or delayed in obtaining medical care, tests, treatments or prescriptions in the last 6 months. Non-linear Blinder-Oaxaca effect decomposition methods evaluated the extent to which individual-level sociodemographic, clinical, and area-level factors contributed to racial disparities in financial hardship. **Results:** Median age at survey was 78 (IQR = 73-82), majority were female (53%) and non-Hispanic White (84%). The most common cancers were breast (34%) and prostate (27%), followed by lung (17%), lymphoma (9%) and colorectal (14%). Ninety percent were diagnosed at an early stage and median time from diagnosis to survey was 8y (IQR = 5-12). There were no significant clinical differences between Black and white patients. Overall, 22% reported any financial hardship; 14% material, 3% behavioral, and 14% psychological. Black, compared to White participants reported significantly (p < 0.001) higher rates of overall (39% v 18%), material (29% v 11%), and psychological (27% v 11%) financial hardship. Notably, Black patients had higher rates of being unable to cover cancer-related costs (23% v 7%), worrying about paying large medical bills (27% v 11%), and having to borrow money or go into debt (9% v 3%). Overall, the observed characteristics explained 81% of racial differences in financial hardship among cancer survivors, primarily by differences in income (24%), cancer diagnosis and stage (22%), and area deprivation (15%). **Conclusions:** These results identify primary contributors to racial disparities in financial hardship among older cancer survivors, which can be used to develop interventions aimed at eliminating inferior healthcare outcomes experienced by certain racial groups, inform policy, and allocate resources to those at greatest risk for financial hardship. Commercial vs. Medicaid insurance and use of high-priced anticancer treatments. *First Author: Aaron Philip Mitchell, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Financial incentives presented by the larger markups on cancer drugs among commercial payors may result in increased use of high-priced drugs among commercially insured vs. Medicaid insured patients. We evaluated the association between patient insurance type and the likelihood of receiving higher-priced treatments. **Methods:** We linked cancer registry, administrative claims, and demographic data for individuals diagnosed with cancer in North Carolina from 2004-2011, who had either commercial or Medicaid insurance. We selected cancer types with multiple FDA-approved, guideline-recommended chemotherapy options, and large differences in price between the higher-priced and lower-priced options during the study period: advanced colorectal, lung, and head-and-neck cancer (HNC). The primary outcome was receipt of the higher-priced treatment option, and the primary exposure was insurance type: commercial vs. Medicaid. We estimated risk ratios (RR) for the association between insurance type and higher-priced treatment using log binomial models with inverse probability of exposure weights to control confounding by age, county-level poverty prevalence, and selected comorbidities. We assessed for potential modification of the RR by setting (hospital outpatient vs. physician office) and academic designation (NCI-designated comprehensive cancer center vs. other); these were exploratory analyses due to sparse data and subsequently limited confounding control. **Results:** Of 812 patients: 209 (26%) had Medicaid insurance; 311 (38%) had NHC, 263 (32%) colon or rectal cancer, and 238 (29%) lung cancer. The crude risk of higher-priced treatment was 36% (215/603) for commercially insured and 27% (57/209) for Medicaid insured (RR:1.31, 95%CI 1.02-1.67). After weighting the association was attenuated (RR:1.15, 95%CI 0.81-1.65). While limited by imprecision and the potential for uncontrolled confounding, exploratory subgroup analysis suggested that, compared to Medicaid insurance, commercial insurance was associated with numerically higher risk of higher-priced treatment among patients treated by non-NCI designated providers (RR:1.53, 95%CI 1.14-2.04), and within both the physician office (RR:1.36, 95%CI 0.95-1.95) and hospital outpatient (RR:1.08, 95%CI 0.58-2.02) settings, but lower risk of high-priced treatment within NCI cancer centers (RR:0.39, 95%CI 0.22-0.71). **Conclusions:** Individuals with Medicaid vs. commercial insurance access high-priced treatments at a similar proportion after accounting for differences in case mix, morbidity, and SES. However, modification of the association by and academic setting, observed in exploratory subgroup analysis, suggests the possibility that insurance type may affect treatment for some patient groups. This study was limited by focus on a single state and the potential for residual confounding. The evolving landscape of chemotherapy for the treatment of early-stage breast cancer from 2006-2019: Results of a retrospective cohort study. *First Author: Jenna Bhimani, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Chemotherapy has been a part of the evolving landscape of treatment for women with early-stage breast cancer (EBC). Over the last 20 years, standard treatment has included over 20 different drug combinations recommended by the National Comprehensive Cancer Network (NCCN), with nearly 45 variations on dosing and schedule across drug combinations. Little is known about the real-world landscape of chemotherapy used in EBC and how treatment patterns have changed with the advent of new standards of care. We evaluated chemotherapy patterns for women with EBC in the Optimal Breast Cancer Dosing (OBDC) Study, which uses electronic health record (EHR) data from KPNC (Kaiser Permanente Northern California) and Kaiser Permanente Washington (KPWA). **Methods:** In a cohort of 34,322 women diagnosed and treated for primary stage I-IIIa breast cancer aged 18+ at KPNC and KPWA, we explored patterns of chemotherapy use over time, from 2006 to 2019. We conducted stratified analyses based on receipt of pertuzumab and/or trastuzumab, due to their longer treatment duration. **Results:** Overall, 13,383 (39.0%) women received intravenous chemotherapy, with a decline observed in receipt of chemotherapy over time (40.5% in 2006 vs 35.9% in 2019) (p-trend<0.001). Of the women who received chemotherapy, 8.5% received neoadjuvant treatment, increasing from 4.1% in 2006 to 14.5% in 2019 (p-trend<0.0001). The average duration of chemotherapy was 5.4 months in 2006, increasing to 6.3 months in 2019 (p-trend<0.0001), and the number of chemotherapy infusion visits increased from an average of 10.7 visits in 2006 to an average of 12.5 in 2019 (p-trend<0.0001). Of those who received chemotherapy, 26.8% received trastuzumab or pertuzumab, with receipt of trastuzumab/pertuzumab increasing over time (p-trend<0.0001). For those receiving trastuzumab/pertuzumab, there was a decrease in treatment duration and average number of chemotherapy administration visits (p-trend<0.0001 for both). Conversely, for those not receiving trastuzumab/pertuzumab, there was an increase in the treatment duration and average number of visits (p-trend<0.0001 for both). **Conclusions:** While the prevalence of women receiving chemotherapy in our cohort has decreased since 2006, there has been a marked increase in neoadjuvant chemotherapy among those women receiving chemotherapy, as well as an increase in both the duration of chemotherapy treatment and number of associated chemotherapy administration visits, a pattern specifically observed in non-trastuzumab/pertuzumab containing regimens. The change in average duration and number of visits represents a shift in treatment patterns for patients and providers. Understanding trends in breast cancer chemotherapy is useful to inform clinical care and administrative planning for sites delivering chemotherapy for early-stage breast cancer. Integrating the 31-gene expression profile test into clinical decision-making to guide risk-aligned care decisions for patients with stage I-III cutaneous melanoma: NCI-SEER Analysis. *First Author: David Hyams, Desert Surgical Oncology, Rancho Mirage, CA*

Background: Cutaneous melanoma (CM) management depends on an estimate of recurrence risk or death. Because of recognized disease risk and drug efficacy, pembrolizumab immunotherapy has been approved for stage IIB-C patients. However, it is a treatment with potential financial and biological toxicities with 16% of patients experiencing severe treatment related adverse events. Improved risk stratification could identify individuals for whom more selective management would be appropriate. In collaboration with the NCI Surveillance, Epidemiology, and End Results (SEER) program, which includes information on patients tested with a 31-gene expression profile (31-GEP) test in an unbiased and unselected manner, we confirm the 31-GEP adds independent prognostic value in patients with stage I-III CM, and investigated whether the 31-GEP could identify stage IIB-C patients who might reasonably avoid adjuvant therapy while also identifying patients with stage I disease who might benefit from more aggressive diagnostic and/or therapeutic intervention. **Methods:** SEER registries linked CM cases diagnosed 2013-2018 to 31-GEP test results provided by Castle Biosciences (9,207 matched) using a registry trusted third party (honest broker), including subsets of stage IIB-IIC (n=775) and stage I (n=5,651) melanoma. The primary endpoint was melanoma-specific survival (MSS). The 31-GEP risk-groups included Class 1A (low), Classes 1B/2A (intermediate), and Class 2B (high). Each was compared using Kaplan-Meier analysis and the log-rank test. **Results:** In the overall cohort, patients with a Class 1A result had a significantly higher 5-year MSS than a Class 1B/2A or Class 2B result (97.4% vs. 93.5% vs. 83.3%, $p < 0.001$). In multivariable analysis, a Class 2B result (HR=3.26, $p < 0.001$) and positive lymph node status (HR=3.41, $p < 0.001$) were the strongest predictors of diminished MSS. In stage IIB-C, 18.8% (146/775) of patients received a Class 1A result with an associated 5-year MSS of 89.1% (vs. Class 2B: 76.6%, $p = 0.001$), despite the absence of pembrolizumab approval for the evaluated SEER population. Alternatively, 4.6% (260/5,651) of patients with stage I disease had a Class 2B result, with an associated 5-year MSS of 92.3% (vs. Class 1A: 98.0%, $p < 0.001$). **Conclusions:** The SEER database allowed a non-biased analysis of a large cohort of patients with stage I-III CM who were tested with the 31-GEP. The 31-GEP identifies patients, including those with stage IIB-C disease, with favorable outcomes and could help physicians and patients decide whether to pursue adjuvant therapy. Moreover, the 31-GEP identifies high-risk patients, including those with stage I disease, for whom more aggressive follow-up and early intervention should be considered. Evaluating depth of disparities in relation to relative survival rates: Analysis of SEER data. *First Author: Alma Habib, Ohio State University Wexner Medical Center, Columbus, OH*

Background: Prior studies have identified widening survival disparities between Black vs White patients (pts) in solid tumors with higher 5-year relative survival rates (RSR), a surrogate for higher amenability to treatment (Tehranifar et al., 2009). Given major advancements in treatment for hematologic malignancies leading to higher RSR, we sought to evaluate whether disparities worsened with higher RSR, especially among Black pts compared to White pts, in the modern era of therapy. We hypothesized that racial disparities would be larger in malignancies with higher amenability, as measured by 5-year RSR. **Methods:** We identified first hematologic malignancies among pts ages ≥ 18 years diagnosed between 2009-2019 in a collection of 17 Surveillance, Epidemiology and End Results (SEER) Program registries. We treated RSR as a continuous variable. Cox proportional-hazards model was used to correlate RSR and race with overall survival (OS) controlling for other pt characteristics. The interaction between RSR and race was included in the model to test if the racial effect on OS differed at various RSR levels. **Results:** We identified 363,340 pts who met inclusion criteria. Median age was 66 years and 55% were male. 82% were White and 10% Black. With a median follow-up of 48 months (mos), median RSR was 68.2% and median OS was 101 mos (95% CI 100-102 mos). Black pts had a lower median RSR than White pts, 63.8% vs 68.9%, and lower median OS, 90 mos (95% CI 87-93 mos) vs 99 mos (95% CI 98-100 mos). On univariable analysis, all variables were statistically significant given the large sample size. On multivariable analysis (MVA), Black pts had a higher risk of death than White pts. The interaction between 5-year RSR and race was highly significant ($p < 0.01$, not shown in Table), as indicated by slightly increasing hazard ratios (HRs) reflecting Black-White survival differences with increasing RSR level (i.e., as RSR increased, Black pts had slightly worse OS than White pts) (Table). **Conclusions:** We hypothesized that with increasing RSR, Black-White disparities might increase, as all effective therapies which contribute to improved RSR might not be equitably available to all populations. We observed that statistically significant disparities were present across RSR levels and increased only minimally for those with hematologic malignancies with higher RSR. In conclusion, disparities are prevalent in hematologic malignancies despite the degree of amenability to treatment. Research Sponsor: None.

Demographic disparities in lung cancer mortality and trends in the United States between 1999 and 2020: A population-based CDC database analysis. *First Author: Alexander Didier, The University of Toledo College Of Medicine and Life Sciences, Toledo, OH*

Background: Lung cancer is the leading cause of cancer-related mortality in the US and is projected to account for 127,070 deaths in 2023. While the lung cancer mortality rate has been decreasing over the last decade, demographic disparities in mortality still exist. We sought to determine the impact of demographic factors on lung cancer mortality and trends in the US. **Methods:** We queried the Centers for Disease Control database for mortality statistics with an underlying cause of death of lung and bronchus cancer (ICD-10 code C34.0.x) between the years 1999 – 2020. Age-adjusted mortality rates (AAMR) were calculated per 100,000 deaths. We assessed the AAMR by demographic variables, including race (Hispanic, Non-Hispanic White, Non-Hispanic Black, Non-Hispanic Asian or Pacific Islander, Non-Hispanic American Indian/Native American), geographic density (Urban, Suburban, Rural), sex, age (25-44, 45-64, 65+ years), and US Census Region. Temporal trends were evaluated using Joinpoint regression software. Average annual percent change (AAPC) was considered statistically significant if $p < 0.05$. **Results:** Between 1999 and 2020, lung cancer led to 3,380,830 deaths. The AAMR decreased by 42% from 55.1 to 31.8 with an associated AAPC of -2.6% ($p < 0.001$). In 1999, men had an AAMR of 76.8, almost twice as high as women, who had an AAMR of 40.2. These differences became less pronounced over time, and in 2020 men had an AAMR of 38.1, while women had an AAMR of 26.9. Between 1999 and 2020, rural populations experienced the highest AAMR at 52.3, and the slowest rate of decrease at -1.7% annually ($p < 0.001$), compared with urban populations who experienced the lowest AAMR of 40.6 and fastest AAPC decrease of -3.1% ($p < 0.001$). Non-Hispanic Black individuals experienced the highest AAMR at 49.8, with an annual decrease of -3.0% ($p < 0.001$), followed by Non-Hispanic White individuals who had an AAMR of 48.5 with an annual decrease of -2.5% ($p < 0.001$). Subgroup analysis demonstrated that Non-Hispanic Black men who resided in rural counties experienced the highest mortality at 60.2, with an associated decrease of -2.9% annually ($p < 0.001$). States in the 90th percentile of mortality included Arkansas and Kentucky; states in the 10th percentile of mortality included Hawaii and Utah. The West experienced the fastest decrease at -3.1% annually ($p < 0.001$), while the Midwest experienced the slowest decrease at -2.0% annually ($p < 0.001$). **Conclusions:** While lung cancer mortality has been decreasing since 1999, not all demographic groups have experienced the same rates of decline, and disparities in outcomes remain prevalent. Vulnerable subgroups may benefit from targeted interventions, such as tailored smoking cessation education and efforts to increase participation in clinical trials. Expansion of screening CT scans and telehealth platforms may also improve access to care for these populations. Research Sponsor: None.

Association between severe adverse event management and overall survival in patients treated with immune checkpoint inhibitor with advanced non-small-cell lung cancer. *First Author: Jarushka Naidoo, Beaumont RCSI Cancer Center, Dublin, Ireland*

Background: The impact of severe adverse event (sAE) management (mgmt) on clinical outcomes in cancer patients (pts) receiving immune checkpoint inhibitor (ICI) therapy has not been fully examined. We aimed to evaluate the association between mgmt of sAEs and overall survival (OS) in pts receiving ICIs for advanced non-small cell lung cancer (aNSCLC). **Methods:** Data were drawn from the ConcertAI Patient360 dataset, a curated EMR-based US oncology database representing 19,000+ NSCLC patients. aNSCLC pts who initiated ICI in the first 3 lines of anti-cancer therapy from 1/15 - 8/31/21 with no record of clinical trial enrollment or diagnosis of a second primary cancer were included. sAEs (dermatologic, gastrointestinal, endocrine, hepatic, respiratory, rheumatic, renal, and cardiac) and mgmt actions were curated from unstructured data from ICI initiation through the earliest of: 100 days after ICI discontinuation, start of a non-ICI regimen, end of study period, or death. Cox regression was used to evaluate the association between sAE mgmt actions (as time-varying covariate) and OS adjusting for baseline characteristics including line of therapy. The earliest sAE and mgmt action per patient were examined in OS analysis. **Results:** 3,211 pts were identified (median [IQR] age 67 [13] years, 55.1% male). Median [Q1-Q3] duration of follow-up from ICI initiation was 8.2 [3.3-17.5] months. Most pts had advanced disease at initial diagnosis (82.0%) and started ICI in first line (61.6%). The most common ICI regimens in the first 3 lines were nivolumab (29.5%) and pembrolizumab + carboplatin + pemetrexed (29.1%). 8.6% of pts had at least one sAE, most often diarrhea (3.5%). Median [Q1-Q3] time from ICI initiation to first sAE was 84 [34-211] days. Mgmt actions any time after first sAE included anti-cancer treatment interruptions [dose reduction (4.0%), hold (20.6%), discontinuation (2.2%)], sAE treatment [corticosteroids (71.8%), immunosuppressive drugs (2.5%)], hospital admission [hospitalization (57.4%), emergency department visit (24.6%)], and other/unknown (4.3%). Overall, median [95% CI] OS was 13.6 [12.6-14.6] months. Compared with pts with no sAEs, pts with sAEs whose earliest mgmt action was hospital admission (N=155) or sAE treatment (N=71) had a higher risk of all-cause mortality (adjusted HR [95% CI] 1.61 [1.38-1.88] and 1.53 [1.22-1.91], respectively). Pts with sAEs first managed with anti-cancer treatment interruptions (N=39) had similar risk of all-cause mortality (0.91 [0.66-1.25]) compared with pts with no sAEs. **Conclusions:** Pts with sAEs first managed with hospital admission or sAE treatment had shorter OS than those with no sAEs. No difference was observed for sAEs first managed with anti-cancer treatment interruptions. Findings suggest early treatment interruption for sAEs does not impact OS. Research Sponsor: Bristol-Myers Squibb.

Intrathecal drug delivery systems for cancer pain control: Insights on current contemporary practices in the US. *First Author: Vasudha Goel, University of Minnesota, Minneapolis, MN*

Background: About a third of cancer survivors report moderate to severe pain. Intrathecal drug delivery system (IDDS) is an implantable pain control option for treating intractable chronic pain not responsive to systemic opioid therapy. Studies on the current practices in the US around the utilization of IDDS for cancer pain are lacking. **Methods:** The Nationwide inpatient sample (NIS) dataset is funded by the Agency for healthcare research and quality (AHRQ) for multistate healthcare research & decision-making. Adult patients admitted to hospitals with a primary or secondary cancer diagnosis between 2016-19 were included. Patients undergoing IDDS implantation were identified using the validated International Classification of Diseases, 10th Revision, Procedure Coding System codes (00HU33Z Insertion of infusion device into spinal canal, percutaneous approach and 0JH80VZ Insertion of infusion pump into abdomen subcutaneous tissue and fascia, open). Baseline demographics, hospital characteristics, and type of cancer associated with IDDS implantation were evaluated in the study. **Results:** 22,895 patients underwent IDDS surgery amongst 7.06 million hospitalizations from 2016-19. The IDDS cohort consisted of patients in the 65-79 years age group (40.49%), female sex (50.42%), and Caucasian ethnicity (75.82%). Most IDDS surgeries were performed in large, urban teaching hospitals. **Conclusions:** Despite recommendations supporting IDDS use, a small minority received the treatment with significant racial & socioeconomic disparities in IDDS use. Research Sponsor: None.

Development of natural language processing (NLP) models for extracting key features from unstructured notes to create real-world data (RWD) assets for clinical research at scale. *First Author: Smity Agrawal, ConcertAI, Bengaluru, Karnataka, India*

Background: RWD derived from Electronic Health Records (EHR) has detailed clinical information about patient journeys that can assist in clinical research, trial design, safety assessments etc. However, much of the vital information is locked away in unstructured clinical texts and needs to be converted to structured format to be useful for downstream applications. We demonstrate how this can be achieved at scale with a high degree of accuracy through NLP. **Methods:** NLP models were developed to extract data for 11 clinical variables from unstructured notes of ~98k lung cancer patients and merged with the structured data into a common data model (Table). These models were a combination of domain knowledge, rule-based models, machine learning models, and deep learning models. The increase in fill rate per variable over structured data only was used to quantify the improvement by NLP. The accuracy of the models was assessed against a manually curated dataset comprising of 752 patients. **Results:** The NLP models significantly improved the fill rate of key clinical variables and were able to extract the information from clinical notes with high accuracy (Table). For some variables such as NSCLC/SCLC status, surgery, tumor grade and histology, all or most of the data was extracted via NLP. Metastatic status via NLP included distant metastasis, locally advanced disease and no metastasis whereas in the structured data, only data for distant metastasis was present. In the case of Performance Status (PS), even though a significant number of patients had at least 1 PS recorded in the structured data, NLP significantly increased longitudinal capture, thus increasing the density of this variable per patient. **Conclusions:** NLP models can be developed and used to enrich structured RWD data by extracting information from unstructured documents thus significantly improving the utility of this data for downstream applications. Given the high accuracy of these models and the scale at which they can be run, this can be a good alternative to human curation or can augment human curation enabling the creation of very large-scale datasets for clinical research. Research Sponsor: None.

The safety of seasonal influenza vaccination among patients prescribed immune checkpoint inhibitors: A self-controlled case series study using administrative data. *First Author: Alicia Ann Grima, Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada*

Background: Immune checkpoint inhibitor (ICI) therapy for cancer patients carries a risk of severe immune-related adverse events (IRAEs). Since vaccines are immunomodulatory, administering seasonal influenza vaccinations to individuals on ICI therapy may exacerbate this risk. However, these vaccines provide substantial benefit to this at-risk population. As severe IRAEs are rare, previous vaccine safety studies in this population have been underpowered and have shown conflicting results. **Methods:** We used health administration data on adult Ontarians who initiated ICI therapy and received an influenza vaccine between January 1, 2012, and December 31, 2019. We conducted a self-controlled case series study, with a pre-vaccine control period (12-weeks post-ICI initiation to 14 days before vaccine), risk period (42 days post-vaccine), and a post-vaccine control period (until observation end). Each individual contributed a maximum of 2 years of person-time. Emergency department (ED) visit(s) and/or hospitalization for any cause was used as a surrogate measure of severe IRAE frequency. We fitted a fixed effect Poisson regression model incorporating seasonality and time to estimate incidence. **Results:** We identified 1133 patients who received an influenza vaccine on ICI therapy. The majority were aged ≥66 years (72.7%), male (62.8%), and had lung cancer (53.9%). A quarter (25.9%) experienced an ED visit and/or hospitalization during the observation period. The rate of ED visits and/or hospitalization per person-days in the risk and control periods were similar, with an incidence rate ratio of 1.04 (95% CI: 0.75, 1.45). Subgroup and sensitivity analyses revealed similar findings. **Conclusions:** Receipt of a seasonal influenza vaccine was not associated with an increased incidence of ED visit or hospitalization among adults on ICI therapy. The results from this analysis suggest no significant safety concern with administering influenza vaccines to this patient population. Research Sponsor: Canadian Immunization Research Network (CIRN).

A pragmatic, single-arm clinical trial of a dose-adjustment algorithm for preventing cytopenia-related delays during FOLFOX chemotherapy. *First Author: Gabriel A. Brooks, Dartmouth Cancer Center, Lebanon, NH*

Background: Unplanned delays are common during FOLFOX chemotherapy, and cytopenias (neutropenia and/or thrombocytopenia) are the most common cause of delays. We evaluated a novel, provider-driven FOLFOX dose-adjustment algorithm designed to reduce unplanned delays while maintaining chemotherapy dose intensity. **Methods:** We conducted a pragmatic, single-arm clinical trial to evaluate the FOLFOX dose adjustment algorithm (NCT04526886). The algorithm prescribed graded chemotherapy dose reductions without delay on day 1 of cycles 2-6 for patients with an absolute neutrophil count (ANC) of 750 to 1499/microL and/or a platelet count of 50 to 99 K/microL. The algorithm prescribed a delay when ANC was less than 750 or platelet count was less than 50 on day 1 of cycles 2-6. Chemotherapy dose adjustments and delays for reasons other than cytopenias were at the discretion of the treating provider. Patients receiving initial treatment with FOLFOX chemotherapy (with or without concomitant monoclonal antibodies) were eligible. Subjects received standard chemotherapy doses in cycle 1 (bolus 5-FU 400 mg/m2, oxaliplatin 85 mg/m2, and infusional 5-FU 2400 mg/m2/46 hours). Use of granulocyte colony stimulating factor (G-CSF) was not permitted, except for patients who had already experienced an unplanned delay. The primary outcome was any unplanned delay prior to completion of day 1 of cycle 6 of chemotherapy (with an interval of >18 days between cycles.) We tested whether the incidence of any unplanned delay was less than the historical rate of 43%, using a one-sample test of proportions. Chemotherapy relative dose intensity (RDI) over cycles 1-6 was a key secondary outcome. **Results:** 48 of 54 enrolled subjects were evaluable. The median age was 66, and 50% were female. The most common primary cancer sites were colorectal (n = 31) and gastroesophageal (n = 12). Metastatic cancer was present in 67%, and 35% received a concurrent monoclonal antibody. Sixteen of 48 subjects had any unplanned delay before completing cycle 6 (33%, 95% CI 0.22-0.47, p = 0.08 for comparison with historical proportion of 43%), and 7 subjects had any cytopenia-related delay (15%, CI 0.07-0.27). Twenty-one subjects (44%) had one or more algorithm-driven chemotherapy dose reductions without a delay, and 8 cycles were delivered without delay with an ANC of 750-999 (without G-CSF). The mean (median) chemotherapy RDIs were: bolus 5-FU, 65% (67%); oxaliplatin, 85% (90%); and infusional 5-FU, 92% (97%). **Conclusions:** The 33% observed incidence of any unplanned chemotherapy delay was nominally but not significantly lower than the historical rate of 43%. The incidence of any cytopenia-related delay was 15%, lower than the historical rate of >30%. Further refinement and evaluation of the FOLFOX dose adjustment algorithm may help to reduce unplanned delays and their attendant disruptions and costs for patients and providers. Clinical trial information: NCT04526886. Research Sponsor: Dartmouth Cancer Center.

Assessment of patient reported outcomes (PROs) completion patterns in patients with cancer: Examining real-world data. *First Author: Nada Al-Antary, Henry Ford Health System, Detroit, MI*

Background: Use of Patient Reported Outcomes (PROs) in clinical practice plays a major role in improving care, quality of life, hospitalization, emergency room visits and consequently improving overall survival. However, robust information on real-time assessment of PROs in cancer patients is insufficient, as most available data are limited to specific populations enrolled in clinical trials. This thereby increases disparities among minorities of race, age, and socioeconomic status, creating a barrier between the benefits of PROs and these underserved populations. This study examines the response rates, patterns and characteristics of patients completing PROs in a tertiary cancer center. **Methods:** Patients with a cancer diagnosis and an oncologic provider visit at a tertiary cancer center were offered an opportunity to complete Patient Reported Outcome Measures (PROMs) between August 2020 and July 2022. We used the National Institute of Health's computer adaptive tests Patient-Reported Outcomes Measurement Information System (PROMIS) instruments in pain interference, physical function, fatigue, and depression. Seven days prior to their clinical appointment, patients were assigned the PROMIS instruments in MyChart, then offered in-clinic completion with a tablet at check-in, if not completed online. A decision tree model was employed to assess the factors that may influence patients' PROMs completion (age, gender, race, marital status, insurance, stage, comorbidity score, and provider specialty and location). **Results:** A total of 8,535 patients were offered the PROMIS CAT version 2.0 instrument during the study period. The two most important factors that determine whether a patient completed PROMs in order of importance were provider specialty and patient race. Patients were more likely to complete PROMs if they had a visit with a provider in Radiation Oncology (RC) or Surgery specialty compared with Medicine or Supportive Oncology specialty (40.86% versus 29.68%). Among patients who had a visit with a provider in RC or Surgery specialty, there was a better chance of PROMs completion with White race compared to Black or Other races (45.83% versus 33.69%). Of those who had a visit with a provider in Medicine or Supportive Oncology specialty, there was a better chance of PROMs completion with Other or White races compared to Black race (32.40% versus 22.19%). **Conclusions:** We found that provider specialty and patient race were the most important factors influencing patients' PROMs completion. In order to realize the full benefit of PROs in patient care, multilevel interventions can be employed to increase patient-provider utilization of PROs. Moreover, efforts should focus on a patient-centered design to address patient and provider barriers impeding PROs accessibility and completion. Research Sponsor: None.

Using real-world evidence (RWE) in regulatory decision making: A study of 6 oncology approvals with RWE included in the product label. *First Author: Jihong Zong, Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ*

Background: The 21st Century Cures Act in 2016 enhanced the FDA's ability to include the use of real-world data (RWD) and consideration of RWE in the development and approval of new medical products. Currently, limited assessments of the use of RWE in FDA approved oncology product reviews exist in the literature. This study was conducted to determine how RWE was used in FDA decisions for oncology drug approvals between 2015 and 2022. **Methods:** A systematic review of FDA submission documents and product labels available on the FDA website from 2020 to 2022, in addition to an exhaustive manual search of grey literature and the results of a targeted literature search from 2015 to 2019 were used to identify RWE that were included in FDA submission documents and in approved product labels. **Results:** In total, 124 oncology product evaluations were reviewed in the 2020 to 2022 literature search. Twenty-nine oncology product NDAs and BLAs included RWE to support efficacy, safety, or indication, of which the majority (n=26) ultimately had RWE accepted as evidence by the FDA for the submission. In these cases, RWE was used to add context (n=16), to support the indication or safety (n=7), to provide substantial basis for indication or safety (n=2), as a statistical comparison (n=2), or for informational purposes only (n=1). Feedback from the FDA reviewers for reasons RWE studies were not considered during product approval reviews included methodology issues, sample size concerns, and omission of patient level data. Ultimately, across the 2015 to 2019 targeted literature review and the 2020 to 2022 FDA submission document review, 6 oncology product labels incorporated RWE: pembiciclib, uridine triacetate, lutetium Lu 177 DOTATATE, bevacizumab-adv, naxitamab-gqgk, and decitabine/cedazuridine. RWE was used to support the initial indication for the majority of products (n=5) and also supported label expansion (n=1). RWE was incorporated in the product label postmarketing experience section (n=3), the clinical studies section (n=2), and the warnings/precautions section (n=1). **Conclusions:** These results suggest that RWE has become an important part of regulatory decision-making for oncology drug approval. Twenty-six of 29 RWE studies were accepted as evidence for the submission. For the 6 oncology products that include RWE in the product label, RWE was most frequently used to support the initial indication and was included in the post-marketing experience section. These examples show consistent use of RWE since the approval of the 21st Century Cures Act and provide evidence of a promising new direction with the creation of the FDA guideline/program for RWE. Molecular diagnostic classification for cancers of unknown primary (CUP): Post-testing diagnosis and treatment impact analysis from real-world claims data. *First Author: Zachary Rivers, Tempus Labs, Inc., Chicago, IL*

Background: Next-generation sequencing-based molecular diagnostic classifiers can help identify the tissue of origin for CUP, and enable the selection of site-specific therapies (as opposed to empiric chemotherapy) for this vulnerable population with high unmet need. NCCN guidelines do not endorse the use of tissue of origin classifiers as standard of care for CUP patients due to limited clinical evidence. Here, we linked results of a commercial molecular diagnostic classifier with claims data to understand how this test impacted patient care. **Methods:** We assessed de-identified claims data from the Komodo Healthcare Map (a database including provider visits, laboratory tests, procedures, imaging, and prescriptions) linked to the Tempus Tumor Origin (TO) test—a machine learning classifier that uses RNA-seq data to classify tumors into one of 68 histological subtypes. Eligible patients had pathologist-confirmed CUP and were classified as one of 9 subtypes (each having n>10). Impact was determined by identifying either one or more new diagnostic codes or new subtype-related medication claims following TO testing. **Results:** We analyzed data from 490 patients: 483 for the diagnosis analysis and 213 for the medication analysis (206 patients appear in both, due to differences in timing of diagnosis vs. medication claims). We found that post-TO testing, 49.9% (n=241) of patients had a diagnostic code change, 63.8% (n=136) had a treatment change, and 41% (n=85) had both. In total, 59.6% (n=292) of patients were impacted by the use of this classifier, with variation according to predicted subtype (Table). Cancer types with specific treatment options were more likely to have changes in diagnostic code or treatment. For CUP predicted as lung adenocarcinomas, 85% of the cases had a new subtype-aligned medication, and 78% were specifically placed on immunotherapy (IO) compared with 24% of overall patients. **Conclusions:** Using real-world claims data, we show that molecular diagnostic testing utilizing Tempus TO impacted care for a majority of CUP patients. This cohort will be followed to identify how TO testing decisions impact outcomes. Research Sponsor: Tempus Labs.

Patient reported outcomes (PROs) collection modalities among patients diagnosed with cancer: Online vs in-person. *First Author: Eric Adjei Boaky, Henry Ford Health System, Detroit, MI*

Background: Patient reported outcomes (PRO) can be valuable clinical tools to embed the voice of patients into the clinical assessment. PROs provide important metrics to guide treatment decision making, improve quality of life, reduce acute care, and extend survival in cancer patients. Different modalities for collecting patient reported outcome measures (PROMs) exist (e.g., electronic, paper, telephone); yet little is known about factors associated with PROMs completion modality. More information on PROMs completion modality may determine addressable barriers. We sought to determine whether patients' sociodemographic and clinical factors differed by completion modality. **Methods:** Beginning in 2021 all patients diagnosed with cancer who had a visit with an oncologic provider at a tertiary cancer center were assigned the National Institute of Health's computer adaptive tests Patient-Reported Outcomes Measurement Information System (PROMIS) instruments in pain interference, physical function, fatigue, and depression through the MyChart patient portal 7 days prior to the visit. If this was not completed at the time of the visit, it was available for completion on a tablet during check-in. The outcome variable was completion modality defined as the method a patient used to complete their PROMs (MyChart vs. In-Person). Multivariable logistic regression model was used to estimate the association between patients' sociodemographic and clinical factors (age, sex, race/ethnicity, marital status, insurance type, stage, provider specialty) and completion modality. **Results:** A total of 2915 patients completed PROMs, of which 54% completed using MyChart and 46% completed in-person. The average age of patients was 59.6 (SD=12.4) years, most were females (63.1%), White (69.4%) and married (59.2%). Compared to male patients, females were less likely to complete PROMs in-person (aOR=0.80, 0.67–0.95). However, patients were more likely to complete PROMs in-person if they were of Black race (aOR=1.85, 1.52–2.24) or Other race (aOR=1.48, 1.12–1.96) vs. White; single (aOR=1.30, 1.05–1.62) vs. married; or have Medicaid/other insurance (aOR=1.52, 1.15–2.01) vs. private insurance. Patients who had visits with a radiation oncology provider (aOR=1.50, 1.20–1.86) or surgical oncology provider (aOR=1.32, 1.07–1.62) were more likely to complete PROMs in-person compared to those who had visits with a medical oncology provider. **Conclusions:** Almost half of the patients completed PROMs in-person during check-in, which was unexpected in the context of trends toward mobile-based patient engagement. Patients in underserved populations were the most likely to complete PROMs in-person. Although offering PROMs remotely may be more efficient and allow monitoring between visits, offering an in-person option helps to capture PROs from underserved populations. Research Sponsor: None.

An assessment of the provider financial risk impacts of adoption of biosimilars in the Medicare Oncology Care Model. *First Author: Joshua A. Roth, Pfizer, Inc., New York, NY*

Background: In 2016, Medicare launched the Oncology Care Model (OCM)—a Value-Based Payment (VBP) initiative providing per-beneficiary prospective payment to providers, and performance-based financial incentives/risks based on cost of care in 6-month ‘episodes’ vs. risk-adjusted benchmarks for cancer patients receiving chemotherapy. Oncology biosimilars may play an important role in managing financial risk in the OCM and other VBP models, but the real-world impact remains uncertain. The objective of this study was to quantify the impact of biosimilar adoption on oncology provider financial risk under the OCM using real-world data. **Methods:** We estimated the impact of biosimilar adoption on provider financial risk from 2019 to 2021 by modeling the methods (episode framing, pricing, & risk adjustment) of the OCM. Cancer episodes were identified from the 5% Medicare Limited Data Set (LDS). The study sample consisted of cancer treatment episodes with use of any of the following agents or their biosimilars: bevacizumab, rituximab, trastuzumab, epoetin alfa, filgrastim, and pegfilgrastim. Financial risk was defined as the difference in observed total cost of care vs. OCM target episode cost. The primary outcome was the difference in financial risk (expressed in nominal \$USD) under observed use of reference and/or biosimilars vs. hypothetical use of 100% reference agent. **Results:** The study sample included 8851 6-month episodes initiating between 1/2019 and 6/2021. Biosimilar adoption resulted in a mean cost reduction of \$1,020 per episode vs. hypothetical 100% use of reference agents. Biosimilar use increased markedly over the study horizon—with 24% of episodes with a biosimilar in Half (H1) 2019, increasing to 65% by H1 2021, and driven by increased use of antineoplastic (1% to 36%) vs. supportive care biosimilar agents (23% to 34%). Mean financial risk reduction grew with the rapid adoption of biosimilars over this period. The average risk reduction in episodes initiating in H1 2021 was about 10 times larger than that seen in episodes initiating in the H1 2019 (\$2060 vs \$201, See Table). Observed mean cost was below the OCM target cost (\$48808) in H1 2021 but exceeded the target cost in all other periods (range: +\$1451 to +\$4966). **Conclusions:** From 2019 to 2021, rapid adoption of biosimilars in Medicare fee-for-service beneficiaries included in the LDS led to substantial cost savings and reduction in risk for cancer episodes evaluated under the OCM methods. Broad adoption of biosimilars is a key strategy that providers in oncology VBP models will need to consider to manage financial risk. Research Sponsor: Pfizer.

Time Period	Observed Episodes	Observed Cost Per Episode	Cost Per Episode with 100% Reference Agent	Reduction in Financial Risk with Biosimilar Use
H1 2019	1985	\$53241	\$53443	-\$201
H2 2019	1779	\$53278	\$53661	-\$383
H1 2020	1760	\$49118	\$50084	-\$966
H2 2020	1606	\$49727	\$51423	-\$1696
H1 2021	1721	\$48587	\$50648	-\$2060

Racial disparities in survival and stage at diagnosis among adolescent and young adult patients with cancer. *First Author: Kekoa A. Tappara, Stanford Cancer Institute, Palo Alto, CA*

Background: Adolescent and young adult (AYA) patients (15-39 years) are an under-recognized population with high risk of select malignancies. Compared to pediatric and adult patients, AYA patients have not achieved improvements in cancer survival. No studies have evaluated overall survival (OS) and stage at diagnosis among all 5 federally recognized races in the US. Here we aim to investigate OS and stage at diagnosis among AYA patients by race. **Methods:** A retrospective cohort study of AYA patients diagnosed between 2004-2017 was conducted with the National Cancer Database. Patients with the 10 deadliest AYA cancers with at least 6 months of follow-up were included. Primary endpoints were OS (time from diagnosis to death) and late stage at diagnosis (stage III/IV or Grade III/IV for central nervous system (CNS) cancer). Kaplan-Meier estimates and log-rank tests assessed OS. OS and late stage were evaluated by race using multivariable Cox proportional hazard (adjusted hazard ratio [aHR]) and logistic (adjusted odds ratio [aOR]) regressions, respectively, with 95% confidence intervals (95%CI). All regressions were adjusted for sociodemographic and cancer characteristics. **Results:** 291,899 AYA patients were included: 64% female, 65% stage I/II, and 62 month median follow-up. Cancer sites included 27% breast, 16% lymphoma, 13% melanoma, 11% testis, 9% CNS, 7% colorectal, 7% cervix, 5% sarcoma, 3% ovary, and 2% lung. Race included 82.3% Non-Hispanic White (NHW), 14.0% Black, 2.9% Asian, 0.5% American Indian and Alaska Native (AIAN), and 0.3% Native Hawaiian and other Pacific Islander (NHPI). OS differed for all cancers by race ($p < .0001$), except for lung ($p = .008$), CNS ($p = .32$), and ovary ($p = .28$). OS was significantly inferior for NHPI, Black, and AIAN but superior for Asian, versus NHW (Table). NHPI had inferior OS (aHR, 95%CI) for melanoma (4.5, 2.0-10.0), colorectal (1.8, 1.3-2.4), lymphoma (1.7, 1.1-2.1), and cervix (1.6, 1.1-2.4) cancers. Black patients had inferior OS for melanoma (1.6, 1.2-2.2), lymphoma (1.5, 1.4-1.6), and breast (1.4, 1.3-1.4) cancers. Asian patients had superior OS for breast (0.7, 0.7-0.8) and lung (0.7, 0.6-0.9) but inferior survival for testis (1.9, 1.3-2.9) cancers. Asian patients had inferior OS for colorectal (1.4, 1.0-1.9). Late stage at diagnosis was higher for NHPI, Black, and Asian patients, compared to NHW patients (Table). **Conclusions:** Both NHPI and Black AYA patients with cancer have higher risk of death and late stage disease at diagnosis, compared to NHW patients. Our data reveal racial disparities among Indigenous AYA patients masked by prior data omission. Research Sponsor: Stanford Cancer Institute – Women Cancer Center’s Innovation Award; Stanford Cancer Institute – SCI Fellowship Award; Stanford Cancer Institute – Cancer Innovation Award.

Race	aHR	95%CI	P	aOR	95%CI	P
White	1.00	Ref		1.00	Ref	
AIAN	1.15	(1.02-1.30)	0.021	1.09	(0.96-1.22)	
Asian	0.90	(0.85-0.95)	<0.001	1.20	(1.14-1.26)	<0.001
Black	1.22	(1.19-1.26)	<0.001	1.40	(1.36-1.43)	<0.001

An application of extrapolating clinical data from single-arm trials to assess comparative effectiveness. *First Author: Kangho Suh, University of Pittsburgh, Pittsburgh, PA*

Background: Single arm studies pose some challenges to determining comparative effectiveness of treatments. Such is the case with the tumor agnostic tropomyosin receptor kinase (TRK) inhibitors, larotrectinib and entrectinib. Larotrectinib and entrectinib are indicated for treatment of advanced cancer in patients (pts) with *NTRK* gene fusions. Lacking head-to-head trials, modeling methods are useful to estimate relative benefit. A direct naïve comparison, where single arms from separate trials are compared, can be used. Here, we estimate and compare long term benefit for pts receiving larotrectinib or entrectinib for *NTRK* gene fusion-positive non-small cell lung cancer (NSCLC) and colorectal cancer (CRC) by extrapolating survival curves to generate expected life-years (LYs) and quality-adjusted life-years (QALYs). **Methods:** We used partitioned survival methods to forecast comparative effectiveness. Larotrectinib survival data were derived from an updated July 2021 analysis of 21 adults (≥ 18 years of age) with NSCLC and 15 pts with CRC (NCT02122913, NCT02637687, and NCT02576431). Survival data for entrectinib were derived from published literature. Extrapolation of results were necessary to estimate long-term outcomes since the mean follow-up was less than three years. Progression free survival and overall survival for both treatments were estimated using several parametric survival distributions (Exponential, Weibull, Log-logistic, and Log-normal), then selecting based on AIC and clinical plausibility. QALYs were estimated by adjusting the time spent in the pre progression and post progression health states by utility values from the literature. A discount rate of 3% was applied to LYs and QALYs. Model uncertainty was evaluated using one-way and probabilistic sensitivity analyses. **Results:** In the larotrectinib trials, response rates were 86% and 33% in NSCLC and CRC, respectively. Exponential curves were fit for both treatments. In the entrectinib trials, response rates were 70% in NSCLC and 29% in CRC. The larotrectinib model estimated 7.3 LYs (95% Credible Interval [CrI]: 3.3, 11.4) and 4.3 QALYs (95% CrI: 2.2, 6.5) in NSCLC and 1.7 LYs (95% CrI: 0.8, 3.2) and 1.3 QALYs (95% CrI: 0.7, 2.3) in CRC. The entrectinib model estimated 2.7 LYs (95% CrI: 1.7, 4.2) and 1.6 QALYs (95% CrI: 1.1, 2.3) in NSCLC and 0.5 LYs (95% CrI: 0.2, 1.6) and 0.4 QALYs (95% CrI: 0.1, 1.1). Compared to entrectinib, larotrectinib produced additional gains of 4.7 LYs and 2.7 QALYs in NSCLC and 1.1 LYs and 0.9 QALYs in CRC. Limitations include non-matched baseline differences in the trial populations. **Conclusions:** In the absence of head-to-head trials, comparative effectiveness can be assessed by extrapolating from single armed studies indicated for the same patient population. Larotrectinib improved survival and quality adjusted survival vs entrectinib. Additional studies are needed to confirm these findings. Research Sponsor: Bayer US LLC.

Real world utilization and disparities in outcome in the use of novel anti-androgen agents for metastatic prostate cancer. *First Author: Samina Hirani, Virginia Commonwealth University Health, Richmond, VA*

Background: Despite advances in treatment, disparities exist in prostate cancer treatment and utilization of treatment resources based on several factors including race and socioeconomic status. As evidence-based guidelines increasingly define novel androgen receptor inhibitors (ARIs) as the standard of care, it is important to understand how the utilization of ARIs impacts the outcome. In this study, we investigated the relationship between the utilization of the two most commonly used ARIs, Abiraterone and Enzalutamide, and survival among patients with metastatic prostate cancer. **Methods:** We conducted a retrospective analysis of patients in the Surveillance, Epidemiology, and End Results (SEER)-Medicare database from January 1st, 2013 to December 31, 2017. All patients aged 18 years and above with metastatic prostate cancer were included. The objective of these study was to determine the utilization of ARIs in different groups (age, race, location, income status and marital status) and investigate the impact of these variables on the survival. Kaplan-Meier survival curves were used for the survival analysis. Patients were stratified by: who received an ARI alone or in combination vs. who did not. Log-rank tests were used to compare the stratified survival probability curves by groups. A multivariate proportional hazards model was used to compare the instantaneous risk of death in metastatic prostate cancer between patients based on selected covariates. All hypothesis tests were two-tailed with a p -value < 0.05 considered statistically significant. **Results:** A total of 5889 patients with metastatic prostate cancer were included in the analysis. The median age was 73 years; 39% of patients received an ARI alone or in combination with other agents. Among the patients who received ARIs, 77%, 15% and 8% were white, black and of other races, respectively. Use of ARIs were more in urban locations (98.1% vs. 1.9% at rural locations) and in patients with higher and mid-level incomes (73.0% vs. 22.7% in low-income group). While survivals were inferior in all subgroups of patients who did not receive ARIs, survivals was better in white race (vs. black and others) as well as in younger age group who received ARIs. However, in the latter group, there was no statistical difference in survival in rural vs. urban locations and low income vs. high and mid-income groups. **Conclusions:** Our study shows that 39% of patients with metastatic prostate cancer in the SEER Medicare population utilized an ARI. There was a significant underutilization of ARIs in non-white, rural locations and low-income subgroup. White race and younger age populations were associated with better survival irrespective of use of ARIs. Among patients who did not receive ARIs, survivals were inferior in rural (vs. urban) and low-income (vs. high and mid-income) patients, but survivals were equivalent in these subgroups who received ARIs. Effects of concomitant gut-microbiome altering medications on immune checkpoint inhibitors therapy: A retrospective study. *First Author: Rohit Singh, University of Vermont Medical Center; Division of Hematology-Oncology, Burlington, VT*

Background: In cancer patients, gut microbiota influences the antitumor immune response, efficacy, and safety of immune checkpoint inhibitors (ICIs). Antibiotics (ATBs), proton pump inhibitors (PPIs), and corticosteroids can alter the distribution of gut microbiota, resulting in dysbiosis, which can potentially reduce the efficacy of ICIs and may contribute to increased incidence of immune-related adverse effects (irAEs). **Methods:** We conducted a retrospective observational study to investigate the influence of concurrent medicines on patients receiving ICIs at the University of Vermont Cancer Center. We examined the medical records of people who received ICIs alone or in combination with chemotherapy or targeted therapy as a first-line therapy between January 2017 and June 2022. Patients who got ATBs, PPIs, and corticosteroids (>10 mg prednisone) one month before commencing ICIs and during the first six months of treatment were compared to those who did not. We looked at the relative risk for overall survival and the occurrence of irAEs in both cohorts. **Results:** We identified 266 patients, of which 99 (37%) have died. The mean age was 64 years, 55% were male, and 97% of the patients were White. Lung cancer was the most commonly identified malignancy at 36%, and 55% of the cancers were stage IV. The median ECOG was 1, and the median Charlson morbidity index was 6. Of the total cohort, 62% received antibiotics, 67% received steroids, 45% received PPIs, 31% received two of the three, and 27% received all three. The relative risk (RR) of death in the cohort which received antibiotics was 1.53 ($p = 0.02$), the cohort which received steroids was 1.73 ($p = 0.006$), and the cohort that received PPIs was 1.61 ($p = 0.006$). For the group that received two or all three medications, the RR was 2.18 ($p = 0.003$). Regarding irAEs, the group that received steroids had a RR of 2.13 ($p = 0.07$); however, most of these patients likely received steroids for an irAE. Antibiotics and PPIs were not associated with a higher risk of irAEs. One of the significant limitations of our study is the small sample size and the retrospective data collection. Data is also confounded because it includes patients who have received ICIs in combination with chemotherapy or other agents. **Conclusions:** Our study suggests that patients who received any of the gut microbiome-modifying medications before starting and within the early phase of ICIs treatments are at higher risk of mortality, likely owing to the poor efficacy of ICIs or possibly because these patients are sicker at baseline. However, we must be judicious with using such medications when patients undergo treatment with ICIs. Large prospective studies looking at this association are needed to understand the risk and potential outcomes. Research Sponsor: None.

Medications	RR for death	P-value
Antibiotics	1.53	0.02
Steroids	1.73	0.006
PPIs	1.61	0.006
Two or more	2.18	0.003

An indirect comparison of elranatamab's (ELRA) objective response rate (ORR) from MagnetisMM-3 (MM-3) vs real-world external control arms in triple-class refractory (TCR) multiple myeloma (MM). *First Author: Luciano J. Costa, University of Alabama at Birmingham, Birmingham, AL*

Background: ELRA is a BCMAxCD3 bispecific antibody being investigated for the treatment of R/R MM. The phase 2 MM-3 trial was single-armed; the aim of this study (NCT05565391) was to contextualize the efficacy data from MM-3 with two real-world (RW) external control arms. **Methods:** A retrospective cohort study was conducted to indirectly compare the efficacy observed in MM-3 Cohort A (BCMA-naïve; N=123) from the 9-month data cut with two US-based oncology electronic health record databases, Flatiron Health (FH) and COTA, as external controls. MM-3 inclusion (eg, prior MM diagnosis, ECOG ≤ 2, refractory to ≥ 1 PI, ≥ 1 IMiD, and ≥ 1 anti-CD38) and exclusion (I/E) criteria (eg, plasma cell leukemia, smoldering MM) were applied to each RW database to obtain comparable patient populations across sources. After imposing MM-3 I/E criteria, comparisons between data sources on ORR were conducted by estimating rate ratios (RRs) using log-binomial regression models (unweighted analysis). RRs were also estimated using both inverse probability treatment weighting (IPTW) and augmented IPTW (doubly robust) analyses to account for key covariates (eg, age, comorbidities, ECOG, ISS, prior lines/refractoriness, cytogenetic risk, extramedullary disease, lab values). **Results:** The 123 patients from MM-3 Cohort A were compared with the 152 and 233 patients identified from the FH and COTA databases, respectively. Treatment regimens in the RW sources included various combinations of PIs, IMiDs, and mAbs, among other agents (eg, selinexor). Across unweighted, IPTW, and doubly robust analyses, the ORR for ELRA was significantly higher than treatments used for TCR MM patients from RW sources (Table; all $p < .05$). **Conclusions:** Among TCR MM patients who resemble those of the MM-3 trial, ELRA showed improved ORR compared with treatments currently used in clinical practice. Research Sponsor: Pfizer.

Real-world outcomes of patients (pts) with malignant solid tumors treated with immune checkpoint inhibitors (ICI) in relation to smoking status: The SAKK 80/19 SMOKER study. *First Author: Tämer El Saadany, Division of Oncology/Hematology, Kantonsspital Graubünden, Chur, Switzerland*

Background: ICIs are the standard of care for the treatment of different advanced solid organ tumors. Especially in advanced non-small-cell lung cancer, never-smokers were shown to have an inferior outcome when compared to ex-smokers/smokers, suggesting that the smoking status could be a predictive marker for survival benefits under ICI treatment. **Methods:** Pts within the Swiss Alpine Tumor Immunology Registry (AlpineTIR) treated with an ICI were differentiated by their smoking status (ex-smokers/smokers versus never-smokers). Overall survival (OS) and progression-free survival (PFS) from the start of the first ICI treatment were analyzed by smoking status. Further, subgroup analyses for OS and PFS were done for the most common disease entities. **Results:** A total of 702 pts were included, from which 455 pts (65%) were ex-smokers/smokers, 213 pts (30%) were never smokers, and 34 pts (5%) had an unknown smoking status. The median follow-up time from the administration of the first ICI to the statistical analysis was 2.7 years (95% CI: 2.3 to 3.2 years). The most frequent tumors were lung cancer (50%), melanoma (13%), renal cell cancer (7%), bladder cancer (6%), and others (24%). Across all indications, the median OS was 1.7 years (95% CI: 1.4 to 2.6 years) for never-smokers ($n = 213$) and 1.5 years (95% CI: 1.2 to 1.8 years) for smokers ($n = 455$) (HR: 1.10, 95% CI: 0.89 - 1.37). The median PFS was 6.3 months (95% CI: 4.4 to 8.3 months) for non-smokers and 6.2 months (95% CI: 5.2 to 7.0 months) for smokers (HR: 1.05, 95% CI: 0.87 - 1.27). In lung cancer pts, the median OS was 1.4 years (95% CI: 0.8 to 2.8 years) for never-smokers ($n = 43$) and 1.4 years (95% CI: 1.2 to 1.7 years) for smokers ($n = 302$) (HR: 1.02, 95% CI: 0.68 - 1.51). In melanoma pts, the median OS was 3.4 years (95% CI: 1.8 to not reached (NR) years) for never-smokers ($n = 54$) and 1.7 years (95% CI: 0.8 to NR years) for smokers ($n = 34$) (HR: 1.35, 95% CI: 0.72 - 2.53). In renal cell cancer pts, the median OS was 1.5 years (95% CI: 1.0 to 3.6 years) for never-smokers ($n = 28$) and 3.5 years (95% CI: 0.6 to NR years) for smokers ($n = 17$) (HR: 0.74, 95% CI: 0.31 - 1.78). In bladder cancer pts, the median OS was 1.8 years (95% CI: 0.6 to NR years) for never-smokers ($n = 17$) and 1.4 years (95% CI: 0.5 to NR years) for smokers ($n = 26$) (HR: 0.88, 95% CI: 0.39 - 1.99). **Conclusions:** No survival difference between smokers and non-smokers with metastatic solid organ tumors treated with ICIs could be detected. Interestingly, even in the subgroup of lung cancer pts, no difference was seen. Based on these data, the smoking status should not guide ICI treatment decisions. Poster Session

The impact of using Elsevier ClinicalPath oncology treatment pathways on survival and cost of care. *First Author: Monica Schmidt, Cone Health, Greensboro, NC*

Background: Cone Health is a 921 bed hospital system in North Carolina with a comprehensive cancer center. Our aim was to determine the value of using Elsevier's ClinicalPath oncology pathways on short-term survival and cost of care from the patient and health system perspectives. Cancer treatment has become more complex as it progresses more toward precision medicine modalities. As such, clinical decision support tools, such as ClinicalPath, have gained traction. Health systems struggle to survive after the COVID pandemic, with residual financial impacts lingering into 2023. It is more important than ever before that health systems focus on value where the patient benefits and financial sustainability are improved. **Methods:** We used a retrospective cohort study design with matching. Exposure was the use of the ClinicalPath decision support tool in Epic (exposed) versus no use of the tool (not exposed). We matched on cancer body site, AJCC clinical stage, the goal of treatment, Elixhauser comorbidity score, and year of a cancer diagnosis. We were able to match 509 exposed to 509 unexposed. Our primary outcomes were 12-month survival from the time of the first treatment and contribution margin. We used a log-rank calculation based on our hazard ratios (Freedman method) to determine the sample size required for each group, assuming a power of 80%. We used a Weibull parametric model to assess 12-month survival with additional covariates. An OLS model was used to evaluate the contribution margin. **Results:** Results demonstrate that when ClinicalPath is used to guide treatment, patients are half as likely to die within 12 months from treatment compared to the unexposed (HR 0.50; 95% CI 0.37-0.68). The OLS contribution model found, on average, that margin has an associated 74.0% (0.74; 95% CI 0.58-0.90) increase when ClinicalPath is used to guide treatment compared to the unexposed. This equates to a crude increase in contribution margin for cancer treatment of \$58,362, on average per case, when ClinicalPath is used. Variable direct costs are higher when using ClinicalPath. This means, on average, it costs more to treat patients on pathway using best available evidence. Still, they have better short-term survival and payers are covering the additional costs given the increase in contribution margin for our system. **Conclusions:** Short-term recurrence free survival is significantly improved when providers utilize ClinicalPath compared to not using the tool consistent with the primary aim of the CDS solution. Newer, more efficacious treatments may have higher initial costs, as expected. Still, the effectiveness of these treatments on survival in the real-world setting is born out in the current study. The higher initial direct costs are counterbalanced by a higher contribution margin per patient providing evidence that improved outcomes in cancer therapy can also provide a positive ROI for provider organizations. Rates of emergency department visits and acute-care hospital admissions after starting chemotherapy or having surgery across six community-based cancer centers. *First Author: Michael J. Hassett, Dana-Farber Cancer Institute, Boston, MA*

Background: Cancer patients who start chemotherapy or have surgery are at risk for serious adverse events, which can include emergency department visits (EDV) and acute-care hospital admissions (ADM). These events are relevant to patients, clinicians, health systems, and policy makers. Few studies have described the frequency and predictors of EDVs and ADMs in the routine care setting. We sought to address this knowledge gap, and to describe the impact of the COVID pandemic on these events, using data from the SIMPRO consortium of six US-based health systems. **Methods:** In 2019, SIMPRO started a phased deployment of an electronic health record-integrated symptom management program (eSyM) as part of the routine care provided to patients with a suspected or confirmed gastrointestinal, thoracic, and gynecologic malignancy. eSyM prompts patients to complete symptom questionnaires and provides symptom management resources for 180 days after starting chemotherapy and 60 days following surgery. This analysis includes all patients, whether they used eSyM resources or not. Outcomes, which were measured using EHR-based encounter data, included the rates of EDVs and ADMs at 30 and 90-days after starting chemotherapy or following discharge from surgery. To account for potential confounding, we used multivariable logistic regression for the 30-day outcomes and Cox regression for the 90-day outcomes. **Results:** From September 2019–December 2022, 8664 patients started chemotherapy and 11,578 had surgery, with 3075 and 2587 patients, respectively, experiencing at least one outcome event (Table). 90-day outcomes varied significantly across health systems for chemotherapy (EDV 2-21%, ADM 5-28%) and surgery (EDV 7-14%, ADM 9-18%) patients. In multivariable analyses, patients who reported an employment status of disabled were more likely to report an EDV (OR 1.73-1.96) and an ADM (ORs 1.52-1.96). Widowed status was associated with greater odds of having an ADM (ORs 1.29-1.30), but not an EDV. Cox regression found chemotherapy recipients experienced lower hazards of an EDV, but not an ADM, during 2020 (coinciding with the start of the COVID pandemic). For surgery patients, there was no significant association between calendar year and EDVs or ADMs. [p<0.001 for all reported values]. **Conclusions:** A meaningful proportion of patients who started chemotherapy or had surgery for a suspected or confirmed malignancy in the routine-care setting had an EDV or ADM within 90 days. Most events occurred within 30 days. Further work is required to ascertain how many of these encounters are avoidable and what structural or procedural interventions could improve outcomes. Clinical trial information: NCT03850912. Research Sponsor: U.S. National Institutes of Health.

Financial toxicity, quality of life, symptom burden, and access to resources in early-phase clinical trial (EP-CT) participants. *First Author: Sienna Durbin, Massachusetts General Hospital, Boston, MA*

Background: EP-CTs are an important therapeutic option for patients, and financial toxicity represents an increasing concern in oncology. Little is known about the financial toxicity of EP-CT participants. We sought to describe financial toxicity in EP-CT participants and assess associations of this factor with patient characteristics, quality of life (QOL), symptom burden, and access to resources. **Methods:** We prospectively enrolled consecutive adults participating in EP-CTs at Massachusetts General Hospital from 04/2021 – 01/2023. Participants completed surveys prior to treatment initiation that assessed financial toxicity (Comprehensive Score for Financial Toxicity [COST tool], higher scores indicate greater financial wellbeing). We adapted a financial toxicity grading scale proposed by the creators of the COST tool to define levels: low (COST $\geq$ 26) and high (COST 0–25). We surveyed QOL (Functional Assessment of Cancer Therapy-General) and symptom burden (psychological: Patient Health Questionnaire-4 [PHQ4]; physical: Edmonton Symptom Assessment System [ESAS]). Patients were asked their concerns regarding access to resources. We explored associations of financial toxicity with patient characteristics, QOL, symptom burden, and access to resources. **Results:** Of 221 eligible patients, we enrolled 196 (median age = 62.3 years [range 31.8-88.6], 57.1% female). Most common tumors were gastrointestinal (33.2%) and breast (20.4%); most (93.7%) had metastatic disease. Patients had an average COST score of 28.4 (SD 9.0), with 33.7% reporting high financial toxicity. Patients with high financial toxicity were more likely to be <65 years (70.0% vs 47.7%, p=0.003), unemployed (44.6% vs 17.7%, p<0.001), lack a college degree (52.3% vs 25.6%, p<0.001), and have income $\leq$ \$60,000 (60.6% vs 25.4%, p<0.001) compared to those with low financial toxicity. Compared to those with low toxicity, patients with high financial toxicity also had lower QOL scores (69.9 vs 77.3, p<0.001) and increased psychological (1.3 vs 0.9, p=0.02) and physical (19.3 vs 15.9, p=0.091) symptom burden, although increased physical symptoms did not reach statistical significance. Those with high financial toxicity were more likely to report concerns regarding access to several resources (housing [10.6% vs 2.3%, p=0.033], bill paying [31.8% vs 3.8% 3.8%, p<0.001], food [9.0% vs 0.7%, p<0.006], employment [21.2% vs 1.5%, p<0.001]; there was no significant difference in transportation [22.7% vs 16.1%, p=0.261]). **Conclusions:** We found that one third of EP-CT participants report high financial toxicity and identified factors associated with higher toxicity. We demonstrated novel associations between high financial toxicity and lower QOL, greater depression, and increased concerns regarding access to resources. Findings highlight the need to address financial toxicity among this population. Research Sponsor: None.

Improved outcomes from reflex comprehensive genomic profiling-guided precision therapeutic selection across a major US healthcare system. *First Author: Brian Piening, Earle A. Chiles Research Institute at Robert W. Franz Cancer Center, Providence Cancer Institute, Portland, OR*

Background: An ever-increasing number of biomarker-guided therapies, some with pan-cancer indications have expanded the oncologist's toolbox for fighting advanced cancer. Despite this, not all advanced cancer patients receive tumor genomic testing, or are tested for a limited number of targets. Still others are tested too late in their care journey to benefit from precision therapy. To assess the impact of removing testing barriers, we developed a reflex testing protocol where comprehensive genomic profiling (CGP) was routinely ordered by pathologists at time of diagnosis for advanced cancer patients. **Methods:** Reflex CGP testing was primarily initiated by the pathologist at the time of advanced cancer diagnosis. Testing was performed between 2019 and 2021 via CGP using the ProvSeq 523 lab-developed test, and testing was performed at no cost to the patient. Post-CGP, stage 4 patients were followed for $\geq$ 12 months. We assessed time to therapy, therapy selection, and overall survival (OS). Therapies were stratified by presence of biomarkers associated with approved targeted therapies (TT), presence of biomarkers for immunotherapies (IO), and/or therapies that were guideline based (GB) and not associated with a specific biomarker. As much key patient information is only consistently available in free-text medical charts, we implemented a novel natural-language processing (NLP) approach based on deep learning and large language models to accelerate abstraction. **Results:** A cohort of 1,423 advanced cancer patients met the study criteria. The median age was 66 years, 53% were female, and 82% white. The 3 most tested tumor types were 22% non-small cell lung cancer, 16% colorectal cancer, and 12% breast. Overall, 49% (N=704) of patients had a biomarker result considered actionable for an approved TT or IO. Median (IQR) time-to-treatment initiation post-CGP was 19 (2-70) days. In patients with no actionable TT or IO biomarkers (N=719), 63% were treated with chemotherapy-based regimens, 11% with GB, 17% with unmatched TT, and 8% with unmatched IO. Of patients who had only an actionable TT biomarker (N=287), 18% received matched TT and 13% received GB. 36% of patients with only an actionable IO biomarker (N=317) received matched IO monotherapy. 48% of patients with both actionable TT and IO biomarkers (N=100) received matched TT or IO monotherapy, and 5% received GB. Across all tumor types, patients receiving a TT had better OS compared to patients receiving chemotherapy with 12 months OS (%) of 70.1 (95% CI=64.4 - 76.3) for TT-treated patients, compared to 62.9 (95% CI=58.8 - 67.3) for chemotherapy only. **Conclusions:** CGP-guided precision therapy use is associated with significantly higher survival in a reflex testing population. A reflex protocol can overcome key barriers to the use and timing of genomic testing to improve access to these life-extending treatment modalities. Evaluation of cachexia and outcomes in patients with aggressive B-cell non-Hodgkin lymphoma. *First Author: Nicholas Demetriou, Feinberg School of Medicine, Northwestern University, Chicago, IL*

Background: Cancer cachexia is a muscle wasting syndrome characterized by anorexia, asthenia, and weight loss. Cachexia rates are as high as 35% for aggressive B-cell Non-Hodgkin Lymphomas (B-NHL), and is considered an independent factor in cancer outcomes compared to other disease burden markers. However, there remains no set protocol to identify hematologic cancer patients at risk for cachexia, and current imaging-based measures for muscle wasting can be costly and burdensome. Weight loss grading scale (WLGS) is a newly validated method to assess cachexia in solid tumor cancers but not hematologic malignancies. This study evaluates the relationship between WLGS and cancer treatment outcomes in B-NHL patients. **Methods:** This was a retrospective cohort study of adult patients with aggressive B-NHL treated between 2005-2020. WLGS grade was used as a cachexia marker to analyze its effect on outcomes. WLGS combines weight loss (since diagnosis) with a patient's BMI at that same time. A grade of 0 indicates no cachexia, and a grade of 4 indicates severe cachexia. Data for WLGS grade was captured for patients at 3- and 12-months post-treatment induction. Survival curve analyses assessed disability-free survival (DFS) (time from induction therapy to a patient requiring rehabilitative, home health, or skilled nursing services), progression-free survival (PFS), and overall survival (OS) outcomes. **Results:** Our cohort included 258 B-NHL patients. Within our study population, 45% were female, with an average age of 57 at diagnosis. B-NHL patients with higher WLGS, defined as a grade $\geq$ 2, composed 22% and 18% of patients at 3- and 12-months post-induction therapy, respectively. Patients with elevated WLGS were found to have significantly higher progression rates compared to lower WLGS grade individuals at 3 months (HR=1.8, p=0.049) and 12 months (HR=2.4, p=0.014) post-induction therapy. Furthermore, higher WLGS patients had significantly greater rates of disability compared with lower WLGS patients at 3 months (HR=1.7, p=0.013) and 12 months (HR=1.7 p=0.025) post-induction therapy. Finally, patients with a WLGS of 4 at 12 months post-induction therapy demonstrated significantly lower OS (HR=323, P<0.0001) than all other patients. **Conclusions:** In conclusion, WLGS, a new marker for cachexia, is highly correlated with morbidity and mortality outcomes in B-NHL patients. Specifically, PFS and DFS were significantly lower in groups with higher WLGS grades, and OS was significantly lower for individuals with a WLGS of 4. Weight and BMI, the two metrics used to calculate the WLGS score, require minimal time and resources to assess. Thus, regularly tracking weight can be an adjuvant screening to imaging and biomarker testing to identify patients at increased risk for disease progression or disability. The accessibility of WLGS tracking would further benefit disease tracking in resource-scarce areas and simplify disease assessment. Research Sponsor: None.

Efficacy-effectiveness gap with immune checkpoint inhibitors in solid cancers: A population based cohort study. *First Author: Saroj Niraula, University of Manitoba/CancerCare Manitoba, Winnipeg, MB, Canada*

Background: Immune checkpoint inhibitors (ICIs) have been central in oncology drug development in the last decade often demonstrating large improvements in overall survival (OS) in pivotal randomized controlled trials (RCTs). Patient selection and/or care may be less stringent in the real world but ascertaining that benefits are translated satisfactorily from pivotal RCTs into the real world is crucial, as patients often base their treatment decisions on outcomes quoted to them from pivotal RCTs. **Methods:** After necessary ethics approvals, we collected relevant data on all consecutive patients with advanced solid cancers treated with ICIs in the province of Manitoba, Canada from inception to June 30, 2022 using pharmacy database and cancer registry. Eight most frequent ICI indications are included here. Survival probabilities were plotted using Kaplan-Meier Method, and descriptive statistics used to report relationship between variables. To put outcomes into perspective, we report real world data alongside that of pivotal RCTs used to support approvals of respective ICIs by Health Canada and the US FDA. **Results:** Eight ICI indications included 992 patients followed for a median of 40 months (range: 21-86 months). Patients required to meet precise provincial formulary criteria to receive ICIs, adopted mostly from the inclusion criteria of the corresponding pivotal RCTs. Median OS was shorter in the real world population not only compared to the experimental arms of the respective pivotal RCTs [by a median of 16 months (range: 3 - 38 months)] but also compared to their control arms [by a median of 3 months (range 3 to 32 months)]. This translated into an average of 51.1% (standard deviation: 20.1) compromise in median OS with ICIs in the real world compared to that observed in respective pivotal RCTs. **Conclusions:** Treatment with ICIs within high standards of practice in a Canadian province overall offered less than half the median OS observed in pivotal RCTs supporting their approvals. Current ICI treatment decisions by patients (and physicians) may therefore be based on highly inaccurate expectations. Our results should inspire rigorous phase IV clinical studies to identify pertinent real-world variables affecting outcomes including treatment related morbidity and mortality, with an ultimate aim to narrow the alarming efficacy-effectiveness gap. Research Sponsor: None.

ICI	Indication	Pivotal RCT Outcomes (months)		Real World Outcomes		
		Median F/U	Median OS (Experimental Arm)	Median OS (Control Arm)	Number of Patients	Median F/U (months)

Electronic health record (EHR)-based machine learning (ML) to predict disease recurrence after surgical resection of early-stage non-small cell lung cancer (eNSCLC). *First Author: Steven Pisano, ConcertAI, Cambridge, MA*

Background: Surgical resection (SR) is a guideline-recommended definitive therapy for patients (pts) with eNSCLC. However, 30–50% pts develop disease recurrence (DR) within the first 5 years (yrs) after surgery. ML applied to routinely collected EHR data could facilitate timely identification of pts at risk of DR who would benefit from enhanced surveillance or initial treatment (Tx) intensification. **Methods:** eNSCLC pts with stage IB–IIIA at the time of SR between Jan 2010 – February 2022 were identified from ConcertAI Patient360 oncology database comprising structured and curated records from US-based EHR. DR was defined as the human-curated earliest advanced/metastatic diagnosis date from SR. Gradient boosting (GB), random forest (RF), and logistic regression (LR) algorithms with 6-fold nested cross-validation were trained and compared to predict the risk of DR or death at 2 yrs from SR. Pts who did not experience DR and were lost to follow-up within 2 yrs from SR were removed. Feature importance was defined using Shapley Additive Explanation (SHAP)-derived odds ratios (OR). Due to low prevalence of DR at 2 yrs, AUPRC was used as performance metric. Pts in the 1st and 4th quartiles of predicted probabilities from XGB model were defined as low-risk vs. high-risk groups. **Results:** Among 3597 pts, median age was 68.3 yrs (IQR 12.5), 51.8% were female, and 8.6% were Black. 24.4% developed DR within 2 yrs. GB, RF, and LR models had similar ability to predict DR at 2 yrs with mean hold-out set AUPRC of 0.33. In GB model, DR prevalence at 2 yrs was 34% in the high-risk vs. 18% in the low-risk group in hold-out set. NO stage, T stage < 3, receipt of adjuvant immune checkpoint inhibitor (ICI), and presence of EGFR mutations were protective against DR at 2 yrs, while history of anemia and congestive heart failure (CHF) were risk factors (Table). SHAP revealed a N stage-by-adjuvant therapy and a N stage-by-CHF interaction: benefit from adjuvant chemotherapy (CT) was limited to higher N stages, while adjuvant ICI was beneficial for all N stages. CHF was a risk factor for lower N stages but not for higher N stages. **Conclusions:** ML applied to structured and unstructured EHRs identified predictors of risk of DR at 2 yrs after surgery in eNSCLC and may identify high-risk pts who would benefit from enhanced surveillance plans and Tx intensification in the eNSCLC setting. The model indicated favorable outcome from adjuvant targeted therapies in EGFR mutated pts. Research Sponsor: ConcertAI.

Endoscopist volume and the quality of colonoscopy of the Korean National Cancer Screening Program. *First Author: Dong Jun Kim, College of Medicine, The Catholic University of Korea, Seoul, Seocho-gu, South Korea*

Background: The Korean government established the National Cancer Screening Program (KNCSPP). The KNCSPP has provided annual faecal immunochemical test (FIT) for adults aged 50 years or older, and colonoscopy or a double-contrast barium enema test to those with positive results from the FIT. High-quality screening colonoscopy is mandatory to achieve maximum possible CRC prevention. The case volume has been shown to correlate with outcomes in surgical specialties. In contrast, relevant data on colonoscopy is limited. This study aimed to assess the quality indicators of organized CRC screening according to annual colonoscopy volume using KNCSPP data. **Methods:** We used the KNCSPP data from 2018 to 2020, which accounted for 378,354 colonoscopy examinations. We used cancer registration data of an extended health insurance program using ICD-11 codes (C18-20). A total of 12,109 CRC patients were registered within 1 year of the date of colonoscopy. We calculated the annual number of colonoscopy examinations by an individual endoscopist. We excluded endoscopists who had a very low or high number of examinations with the highest 1% or lowest 1% as outliers. The final number of endoscopists was 16,552 and colonoscopy examinations were 331,231 during 2018–2020. The annual colonoscopy volume by individual endoscopists was divided into four groups (2–12, 13–24, 25–36, and 37 or more examinations). Multiple linear regression analysis was performed to confirm the association between test accuracy indicators and colonoscopy frequency using a generalized linear model (GLM). We calculated the estimates of the rates for each indicator by adjusting the year. **Results:** The positive and false positive rates, sensitivity, specificity, and positive predictive value were 4.09%, 1.07%, 83.53%, 98.93%, and 74.68%, respectively. The cancer detection and interval cancer rates were 30.53% and 6.29%, respectively. Quality indicators were related to the annual colonoscopy volume of the endoscopist. Endoscopists with a higher annual colonoscopy volume were more likely to have higher sensitivity, specificity, and positive predictive value than those with a lower annual colonoscopy volume. Endoscopists with higher annual colonoscopy volumes were more likely to have lower positive rates, cancer detection rates, false positive rates, and interval cancers rate than those with lower annual colonoscopy volumes. **Conclusions:** This study found that the annual volume of colonoscopy examinations was associated with better colonoscopy quality in an organized CRC screening program. A high colonoscopy load could be a sign of substantial experience and lead to better outcomes, as has been shown for surgery. The relationship between quality indicators and case volume is logical and plausible; therefore, more research is required to determine the number of cases that need to be performed in a year to adequately maintain high colonoscopy quality. An ehealth intervention during radical radiotherapy: Patient-Reported Outcome Side effects (PROSE) study—An emerging approach from sub-Saharan Africa. *First Author: Omolola Salako, Coll of Med, Univ of Lagos, Lagos, Lagos, Nigeria*

Background: PROSE is an electronic patient-reported outcome tool for real-time, remote monitoring of treatment related side-effects. It enables a two way communication between the patient and clinicians. Remote monitoring of treatment related toxicities can eliminate underreporting of side effects (SE), facilitate timely symptom assessment, and improve management of SE. These will thereby reduce morbidity and hospitalization and improve treatment outcomes and quality of life of affected patients. The overarching goal of the study is to enhance the efficiency of the conventional weekly SE clinic using an emerging technology and thereby create evidence for a personalized digital health interventions for cancer patients in Africa. **Methods:** A prospective study among adult cancer patients receiving radical radiotherapy for head and neck, pelvic, and breast cancers at NSIA-LUTH Cancer Centre in Nigeria between March and October 2022. Eligible (≥18 years, KPS≥75%) and consenting participants were trained on to report their SE daily and receive remote clinical advice on proscare.com. The PROSE tool was built as an adapted version of the Patient Reported Outcome version of the Common Terminology Criteria for Adverse Events (PRO-CTCAE). The study participants were monitored throughout their radiotherapy sessions and two weeks thereafter. The cancer care team can review the Patients Reported Outcome (PRO) data through a dedicated log-in portal during the SE clinic. Participants scored their SE daily and EORTC QLQ-30 quality of life surveys were administered thrice during the study and 2 weeks thereafter. SE reports were chosen according to the site of disease; 12 items for head and neck tumors, 9 items for breast tumors, 14 items for female pelvic and 18 items for male pelvic tumors. Patient's PROSE tool application utilization was defined as >50% daily reporting during study period. **Results:** A total of 137 participants were screened, of which 120 met the eligibility criteria. Of the 120 patients eligible, 23 had technical issues with the use of the PROSE tool application and 1 died during the study; thus, 96 participants data were analyzed. More than 40,000 SE reports were generated during the study. SE with highest symptom burden include urinary frequency in male pelvic cancers (n=17), radiation dermatitis in breast cancer (n=40), diarrhea in female pelvic cancer (n=19) and xerostomia in head/neck cancers (n=20). The app utilization rate was 58%. **Conclusions:** There was a moderate utilization (58%) of the PROSE tool application. The PROSE pilot study demonstrated the potential utility of the PROSE application as a promising tool and data resource that offers a great opportunity to improve cancer care and the development of predictive clinical algorithms by engaging patients in their own care and increased SE reporting of acute radiation toxicities. Real-world study of treatment patterns and clinical outcomes in patients with metastatic non-small cell lung cancer (mNSCLC) post-approval of immunotherapy in the community oncology setting. *First Author: Alexander I. Spira, Virginia Cancer Specialists, US Oncology Network, Fairfax, VA*

Background: Clinical outcomes in patients with mNSCLC have improved post-approval of immunotherapy (IO). However, limited real-world data exists describing the evolution of treatment patterns and impact on outcomes in later lines of therapy (LOT). Here we describe the treatment landscape and outcomes of patients with mNSCLC without driver mutations within community oncology settings. **Methods:** This retrospective observational study included adult patients with mNSCLC who initiated first LOT (LOT1) for mNSCLC in the US Oncology Network from 1/1/2015 to 12/31/2020 (followed through 3/31/2022), using structured electronic health records. Patients who initiated LOT1 with a targeted therapy or EGFR/ALK/ROS1 inhibitor during any LOT were excluded. Second, third, and fourth LOT (LOT2, LOT3, LOT4) were assigned using start and stop dates. Treatment patterns up to LOT4 were summarized descriptively by period of treatment initiation (early-IO period: 2015–2017; post-IO period: 2018–2020). Overall survival (OS) and time to next treatment (TTNT) were assessed by LOT using Kaplan-Meier analysis. **Results:** Overall, 11,035 patients met study criteria, of which 3,835 (35%) patients initiated LOT2, 1,264 (11%) patients initiated LOT3, and 393 (4%) patients initiated LOT4 between 2015 and 2020, respectively. From 2015–2017 to 2018–2020, pembrolizumab plus platinum chemotherapy with pemetrexed or paclitaxel as LOT1 increased from 3% (n = 176) to 42% (n = 2,448), and pembrolizumab monotherapy increased from 9% (n = 465) to 26% (n = 1,518). In patients who initiated LOT2, IO followed by docetaxel ± ramucicrumab increased from 1% (n = 15) to 15% (n = 295), whereas this sequence from LOT2 to LOT3 was used in 23% (n = 111) from 2015–2017 and 20% (n = 159) from 2018–2020. Median (95% CI) OS was 13.3 (12.6, 14.0) months vs. 14.7 (13.8, 15.3) months from initiation of LOT1 in 2015–2017 vs. 2018–2020, respectively (P = 0.187). Clinical outcomes by LOT and period of treatment initiation are presented as median (95% CI) in the table below. **Conclusions:** Understanding evolving treatment patterns in the community oncology setting is important for uncovering opportunities for mNSCLC treatment optimization. This descriptive study reveals the increasing use of mono- and combination IO followed by docetaxel ± ramucicrumab in the community setting. Additionally, longer OS was noted in the post-IO period, suggesting possible extended benefits from earlier LOT. Research Sponsor: Mirati Therapeutics.

		2015-2017	2018-2020	Log rank p-value

Racial disparities in hospitalization outcomes among patients with cholangiocarcinoma. *First Author: Inimfon Jackson, Albert Einstein Medical Center, Philadelphia, PA*

Background: Studies have reported on the rising incidence and mortality outcomes among patients diagnosed with cholangiocarcinoma (CCA) but racial disparities in outcomes among inpatients have not been explored in this population. We examined the racial disparities in outcomes among adult hospitalized patients with a diagnosis of CCA. **Methods:** Retrospective cohort analyses were conducted using data from the National Inpatient Sample (NIS), 2016-2020. Multivariate logistic and linear regression models were used to examine the association between race/ethnicity and patient disposition, length of stay, elective admissions, and total hospital charges. **Results:** In the adjusted analyses, while Black patients had 14% higher odds (95% Confidence Interval (CI): 1.04–1.25) of being discharged to a facility/home with home health care versus routine discharge when compared to their White counterparts, Hispanics had 14% lower odds (95% CI: 0.79–0.95). Black patients had 39% higher risk (95% CI: 1.19–1.63) of death versus routine discharge relative to the White patients. Compared to White patients, Blacks (AOR: 1.23; 95% CI: 1.13–1.34), Hispanics (AOR: 1.15; 1.06–1.25) and other race/ethnicities (AOR: 1.20; 1.10–1.31) were more likely to have a length of hospital stay greater than 5 days relative to 5 days or less. Hispanics (β: \$16,789; 95% CI: \$11,480–\$22,099) were found to have higher total hospital charges when compared to the White CCA patients. Additionally, Black (AOR: 0.68; 95% CI: 0.60–0.78) and Hispanic patients (AOR: 0.87; 95% CI: 0.77–0.99) were less likely to be admitted electively to the hospital. **Conclusions:** Despite advances made in treatment of patients with CCA, the prognosis remains poor. We report disparities in various hospitalization outcomes among adult patients with a diagnosis of CCA. Health care providers need to be aware that these disparities exist and health policies should be implemented to narrow the gap in existing disparities. Research Sponsor: None.

Evaluation of studies with commonly used real world data sources submitted to ASCO journals: Initial steps toward furthering transparent reporting. *First Author: Benjamin Bates, Department of Medicine, Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ*

Background: Real world data (RWD) are used to understand treatment, care, and outcomes of patients with cancer. Reporting guidelines for observational studies, such as RECORD (health), RECORD-PE (treatment) and TRIPOD (prediction), were developed to increase the transparency of studies using RWD. These guidelines are not required for publication in ASCO Journals (JCO- Journal of Clinical Oncology, PO- Precision Oncology, OP- Oncology Practice, CCI- Clinical Cancer Informatics, GO- Global Oncology). Our objective was to describe the use of RWD among studies submitted to ASCO Journals and evaluate the applicability of guidelines and adherence to guidelines. **Methods:** ASCO submission system was used to identify all studies submitted to ASCO Journals between 2018–2022. Based on the abstract, the studies were categorized on whether selected RWD were used: SEER, Medicare, National Cancer Database [NCDB], Flatiron, CancerLinQ, IQVIA, Optum, MarketScan. Through manual review of the published manuscripts, we calculated positive predictive value (PPV) of our algorithm to identify the RWD. We estimated acceptance rate. For each study we evaluated the following: (1) linkages with other RWD; (2) applicability of reporting guidelines RECORD, RECORD-PE, TRIPOD; (3) use of flow diagram (RECORD) or study design figure for treatment and outcome assessment (RECORD-PE). **Results:** The PPV of our search algorithm was 79% (95%CI 73–84) but varied by journal (PPV 73–100; p=0.02). Based on our algorithm, among the 16,133 original reports submitted, 1,156 (7.2%) used one of the RWD sources. Overall acceptance rate among RWD sources was 18%. There was variability in submissions and acceptance rate of RWD by journal. OP and GO most and least frequently received a manuscript with the selected RWD 13% and 1%, respectively. GO accepted 77% of manuscripts that used selected RWD (88% of which were SEER). JCO accepted 3.5% of RWD manuscripts. Medicare, SEER, and NCDB were frequently identified data sources (61%, 31%, and 11%, respectively). SEER was linked to Medicare claims, surveys, or other sources in 77% of studies. The other data sources accounted for <5% each, although submission of EHR-linked to claims/registry increased over time (OR 1.26: 95%CI 1.07–1.49). RECORD, RECORD-PE and TRIPOD were applicable to 100%, 10% and 8% of the studies. RECORD-PE and TRIPOD were most applicable to PO/OP/CCI and CCI, respectively. A flow diagram demonstrating selection of participants was present in 31% of the studies. A figure to visualize study design was used in <5% of RECORD-PE relevant studies. **Conclusions:** RWD are commonly submitted and published within ASCO Journals. Reporting guidelines are applicable and particularly important when linkages occur. Studies using oncology RWD may benefit from reporting guidelines tailored to the unique qualities of these data sources and populations. Research Sponsor: None.

Cancer survival (SURVCANCER BRAZIL): Analysis of 132,621 cases from 19 hospital-based registries in southernmost Brazilian state comparing public and private insurance. *First Author: Juliana Giacomazzi, Hayde Health; Instituto Tacchini de Pesquisa em Saude (ITPS); Latin American Cooperative Oncology Group (LACOG); Post Graduate Program in Epidemiology, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil*

Background: Brazilian data for cancer survival are scarce. Therefore, we aimed to describe the 5-year overall survival (OS) of individuals with public and private insurance from Rio Grande do Sul/RS (Brazil) diagnosed with the 17 most incident tumors in the country. **Methods:** Data from 19 of the 27 hospital-based cancer registries from RS were integrated with the Brazilian Information System data. Individuals with confirmed cancer diagnoses between 2005–2017 were included. Passive follow-up time was calculated as the difference between diagnosis and death (from any cause) or censure date. Survival was estimated by Kaplan-Meier method. Comparison between the survival of individuals assisted by public or private insurance was evaluated using hazard ratios (HR) estimated by multivariate frailty and Cox regression models with adjustments for age, sex, and economic status. **Results:** 5-year OS was higher for patients with private health insurance for 13 of the 17 cancers studied. **Conclusions:** The survival trends among cancer patients assisted by public and private health insurance systems reveal vast differences that may be likely attributable to differences in access to early diagnosis and optimum treatment. We hope our results will help government officials understand that ongoing cancer survival surveillance is an indispensable source of information and a key policy tool for public health decisions. Research Sponsor: In part by Roche; fapergs and researchers.

Real-world analysis of commercially insured and Medicare Advantage patients with advanced cancer and rates of molecular testing. *First Author: Stacey DaCosta Byfield, Optum Labs, Eden Prairie, MN*

Background: Guideline-recommended molecular testing has become essential for biomarker-guided clinical decision making, particularly for patients with advanced (adv) disease. Several biomarkers have indications that are tumor type-agnostic (starting with MSI in 2017, NTRK in 2018, TMB in 2020, and RET and BRAF in 2022). Biomarker testing is covered by insurers, both Medicare (covers comprehensive genomic profiling [CGP] and non-CGP panels) and commercial (at least non-CGP). This study aimed to understand utilization of biomarker testing across tumor types. **Methods:** This retrospective analysis used de-identified administrative claims from Optum Labs Data Warehouse. Adult Commercial (COM) and Medicare Advantage (MA) enrollees diagnosed with any 1 of 6 adv cancer types from 1/2018 to 8/2021 were identified; the date of the first claim indicating adv cancer was the index date. Continuous enrollment for 12 months prior to (baseline), and ≥ 6 months post-index date, unless they died (follow-up) was required. Biomarker testing was captured using Current Procedural Terminology (CPT) codes indicating CGP (> 50 gene panels), non-CGP (at most 5-50 gene panels), or CPT code 81479 (unlisted molecular pathology procedure) during the study period. The primary analysis evaluates testing in the follow-up only, with secondary analyses evaluating testing including the baseline (to account for testing prior to the index date). **Results:** We identified 16,931 breast (BC), 16,838 non-small cell lung (NSCLC), 8,755 colorectal (CRC), 4,244 pancreatic (PC), 2,610 ovarian (OC), and 1,231 gastric (GC) adv cancer patients meeting study criteria. Overall biomarker testing rates in the follow-up period were: 37% NSCLC, 19% BC, 41% CRC, 35% PC, 51% OC, 35% GC. The Table shows testing rates by cancer, insurance type, and panel size during follow-up. Testing rates were lower among MA patients compared to COM patients. Even considering baseline and follow-up periods, overall biomarker testing rates were low, and lower among MA compared to COM: 48% NSCLC (53% COM, 47% MA), 27% BC (34% COM, 22% BC), 56% OC (61% COM, 53% MA), 42% PC (53% COM, 38% MA), 47% CRC (56% COM, 42% MA), 41% GC (54% COM, 35% MA). **Conclusions:** Considering guideline recommendations, rates of biomarker testing across tumor types are far from optimal despite insurance coverage for testing. Identification of barriers to biomarker testing and interventions to overcome these are needed to improve adherence to biomarker testing guidelines. Research Sponsor: Illumina.

A comparison of the Optum Clinicogenomics Solid Tumor Database and the SEER Population-Based Cancer Registry. *First Author: Alexa Woodward, Optum Life Sciences, Eden Prairie, MN*

Background: Real-world data (RWD) and real-world evidence (RWE) are increasingly utilized across a range of research and regulatory applications, including biomarker discovery, risk stratification, external control arms, and post-market surveillance. Two-thirds of FDA approvals in 2021 utilized genomic data and the growing interest in targeted therapies will likely continue this trend. While genomics or any one type of RWD alone yields an incomplete view of the patient journey, Optum's clinicogenomic data links de-identified longitudinal clinical and claims data to next-generation sequencing (NGS) results. Ensuring the value of this data requires identifying and limiting biases and maximizing diversity. **Methods:** To evaluate the robustness and representativeness of Optum's Clinicogenomic Solid Tumor Database, we compared demographic and clinical characteristics to the Surveillance, Epidemiology and End Results (SEER) database across 16 solid tumor types. Variables of interest included age at diagnosis, sex, self-identified race, year of diagnosis, and metastatic status. The Optum data was derived from clinical data that includes 156 million lives and claims data that covers 95 million lives. The solid tumor sub-cohort used for this analysis included 157,164 patients diagnosed between January 1, 2011, and December 31, 2021 with linked broad-panel NGS results. SEER Incidence Data included patients diagnosed between January 1, 2011, and December 31, 2018. Using the Optum data, we also report average continuous enrollment and sequential testing frequency across all solid tumor types. **Results:** The overall distributions of age at diagnosis, sex and race were similar across all cancer types, with a few exceptions. On average, SEER had a larger proportions of patients 80 years and older (15% vs 7.2%, all solid tumors) and of Asian race (7.1% vs 3.2%, all solid tumors). Cancer diagnoses in the Optum data increased year over year corresponding with the increasing availability and uptake of genetic testing in oncology, while the SEER data was equally distributed across all years. The average continuous enrollment for solid tumor patients was 8.1 years in the Optum data, and 13% of patients had sequential testing results from > 1 time point. **Conclusions:** Given the increased reliance on RWD and RWE as part of the drug development and regulatory approval processes, ensuring the representativeness of clinicogenomic databases is paramount. This analysis of general patient characteristics across the Optum Clinicogenomics and SEER solid tumor databases found largely similar distributions of key variables. Observed differences between these two representative databases reflect the genetic testing landscape in oncology and provide the opportunity to investigate disparities related to accessing genetic services, corresponding targeted treatment options, and health outcomes. Research Sponsor: Optum.

Prognosis and risk of suicide after cancer diagnosis. *First Author: Connor J Kinslow, Columbia University Medical Center, New York, NY*

Background: Suicide rates are elevated acutely after cancer diagnosis. We sought to create a unifying theory that explains variations in suicide risk across cancer sites, stages, and demographics. Based on the stress-diathesis model, we hypothesized that suicide risk correlates with cancer prognosis and that the impact of prognosis on suicide risk is greatest for populations with higher baseline risks of suicide. **Methods:** We identified all patients with newly diagnosed cancers from 2000-2019 in the Surveillance, Epidemiology, and End Results (SEER) 17 database, representing 27% of U.S. cancers diagnosed over the past 20 years. Multiple primary-standardized mortality ratios (SMR) were used to determine the relative risk of suicide within the first 6 months compared to the general U.S. population, adjusted for age, sex, race, and year of follow-up. We correlated suicide and 2-year overall survival rates for 20 cancer sites using a weighted linear regression model. **Results:** We identified 9,046 suicides among 6,811,940 persons diagnosed with cancer, 1,610 of which occurred within 6 months of diagnosis. There were 5.3 suicides per 10,000 person-years, compared with an expected rate of 1.7 (SMR 3.1 [95% CI 3.0-3.3]). Suicide risk correlated strongly with prognosis (increased risk of 9.5% per percent survival deficit at 2 years, $R^2 = 0.88$, $P < .0001$). The impact of prognosis on suicide risk was greater for demographic groups with higher baseline risks of suicide. For men, the risk of suicide increased by 3 suicides per 10,000 person-years ($R^2 = 0.84$, $P < .0001$) versus 0.3 in women ($R^2 = 0.54$, $P < .0001$). The impact of prognosis on suicide risk was also greater for persons age 60+ and for white (versus black) race. **Conclusions:** Poorer prognosis correlates with suicide risk in patients with cancer and has a greater effect on populations with higher baseline rates of suicide. Our model should provide a useful framework for triaging patients that need increased surveillance or urgent psychiatric referral. Research Sponsor: None.

Disparity in regional recruitment across global cancer trials: A meta-analysis. *First Author: Noureen Asghar, Creighton University, Papillion, NE*

Background: Equitable regional enrollment in clinical trials is critical to addressing global inequities in health care outcomes. Therefore, we quantified disparities in regional recruitment in global cancer trials. **Methods:** Phase II/III clinical trials in prostate (PC), breast (BC), colorectal (CRC) and lung cancer (LC), and reporting regional recruitment were identified from Medline. Global regions were defined as North-America (NA) and South-America (SA), Europe (EU), Africa (AF), Asia (AS), and Australia (AU). For multi-regional trials, enrollment incidence ratios (EIR) which compare region-wise trial enrollment against global estimates of region-wise specific cancer incidence obtained from Global Burden of Disease 2019 database. Trial-level EIRs were pooled using random-effects meta-analysis. A pooled EIR of < 1.0 indicates underrepresentation of a particular region in clinical trial enrollment compared to the actual burden of the specific cancer in that region. Statistical analyses were conducted in R v4.1.2. **Results:** Of the total 2125 trials identified, 1681 (79.1%) trials with 691,800 participants reported information regarding regional recruitment. Among those, only 1400 (65.9%) trials reported proportions of patients from pre-defined regions. A total of 1231 (57.9%) trials were single-regional recruiting patients from EU (589; 47.8%), NA (329; 26.7%), AS (295; 23.9%), AU (10; 0.8%), AF (4; 0.3%), and SA (4; 0.3%). There was significant underrepresentation of patients from AS (EIR: 0.47; 95% CI: 0.41-0.54) in cancer clinical trials. This was consistent across different cancers: PC (0.49; 0.35-0.71), BC (0.63; 0.43-0.94), CRC (0.63; 0.43-0.94), LC (0.39; 0.30-0.50). Similarly, there is a trend of under-representation of patients from AF (0.67; 0.43-1.04). Consistently, patients from were under-represented in PC (0.43; 0.24-0.77) and LC (0.26; 0.09-0.79) trials. Patients from NA (1.27; 1.08-1.51), EU (1.64; 1.57-1.72), and AU (5.41; 3.90-7.51) were significantly over-represented in multi-regional cancer clinical trials. The results are provided in table. **Conclusions:** There is suboptimal reporting of region-wise enrollment in cancer clinical trials. Representation of Africa and Asia in cancer clinical trials appears to be less than their expected share based on their burden of cancer incidence. Research Sponsor: None.

Region	EIR (95% CI)				
	Overall	PC	BC	CRC	LC
AF	0.67 (0.43-1.04)	0.43 (0.24-0.77)	0.73 (0.36-1.49)	1.70 (1.16-2.50)	0.26 (0.09-0.79)

Real world data for venous thromboembolisms (VTEs) in patients with active cancer: Thromboprophylaxis pooled analysis from GMat and ACT4CAT studies. *First Author: Nikolaos Tsoukalas, On behalf of the Hellenic Society of Medical Oncology, Athens, Greece*

Background: Venous Thromboembolisms (VTEs) lead to many negative consequences for patients with active cancer and are reported up to 20%. They affect anticancer treatment plan, increase morbidity, mortality, economic burden, and escalate psychological drain. Current guidelines recommend pharmacologic prophylaxis for thrombosis in ambulatory cancer patients with Khorana score ≥ 2 . **Methods:** GMat and ACT4CAT are prospective observational phase IV studies conducted by HeSMO in Greece. The aim was to record the clinical practice for ambulatory patients with active cancer who received thromboprophylaxis and enrolled after signing informed consent. Studies were approved by the bioethics committee. **Results:** 1157 patients from 26 oncology clinics enrolled who received thromboprophylaxis. Tumor types: gastrointestinal 38.5%, lung 24.8%, urological 12.2%, gynecological 6.9%, breast 6.1% and others 11.5%. Treatment lines: 1st 62.5%, 2nd 15.1%, 3rd 4%, adjuvant 9.7% and neoadjuvant 5.9%. Age ≥ 65 in 55.2%, BMI ≥ 30 in 17.8% and males 59.9%. High-Risk for Thrombosis Agents (HRTAs) received 82.3%: platinum agents (52.9%), antimetabolites (49.0%) and immunotherapy (10.2%). Notably, 52.7% of anticancer agents had potential drug-drug interactions (DDIs) with Direct Oral Anticoagulants (DOACs). High thrombotic risk factors presented in table. Thromboprophylaxis duration was 5.1 ± 3.3 months with: tinzaparin 91.2%, fondaparinux 4.6%, bemiparin 2.3%, enoxaparin 1.2%, rivaroxaban 0.4% and apixaban 0.3%. Intermediate thromboprophylaxis doses of Low Molecular Weight Heparins (LMWHs) received 62% of patients; 50% in adjuvant setting & 72.6% in metastatic. 32 thrombotic events reported (efficacy: 97.2%, 95%CI: 96.3-98.2%) and 26 grade 1 or minor bleedings (2.2%, 95%CI: 1.4-3.1%). Patients receiving intermediate doses of LMWHs had less risk for thrombosis ($p=0.0308$). **Conclusions:** VTEs prophylaxis in ambulatory patients with active cancer was found safe and effective. Apart from Khorana score, metastasis, HRTAs and DDIs seem to affect clinical decision for thromboprophylaxis mainly with LMWHs and often using intermediate doses irrelevant of clinical setting. Cancer Associated Thrombosis (CAT) is not negligible risk for patients and oncologists appeared to be aware about this. Clinical trial information: NCT03292107, NCT03909399. Research Sponsor: None.

Oncologists' receipt of pharmaceutical industry payments and use of non-recommended and low-value cancer care services. *First Author: Aaron Philip Mitchell, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Personal payments from the pharmaceutical industry to US physicians are common and influence physician practice. Prior studies have found that industry payments sway physicians' selection among effective, medically appropriate treatments. However, whether industry payments may be associated with non-recommended and low-value care has not been assessed. The objective of this study was to estimate the association between oncologists' receipt of industry payments and use of non-recommended and/or low-value (NR/LV) interventions. **Methods:** Population-based cohort study using fee-for-service Medicare claims and Open Payments records of industry payments. We identified four NR/LV cancer interventions: 1) denosumab for castrate-sensitive prostate cancer; 2) GCSF for patients at low risk for neutropenic fever; 3) nab-paclitaxel instead of paclitaxel for breast and lung cancer 4) branded drug instead of a generic or biosimilar. Study sample: Medicare beneficiaries with an incident cancer diagnosis (identified by new occurrence of a cancer diagnosis code in proximity to claims for cancer treatment) from 2014-2019. We applied additional requirements as appropriate to identify four sub-cohorts, corresponding to patients at risk for each of the NR/LV treatments, and identified the treating oncologist using claims. The primary exposure was receipt, by a patient's oncologist, of any industry payments for the corresponding NR/LV treatment of interest, within 365 days before the patient's index cancer date. The primary outcome was receipt of the corresponding NR/LV treatment. We fit general linear models controlling for patient characteristics and calendar year. To assess robustness, we also accounted for physician-level fixed effects in separate models. **Results:** Cohort sizes were: denosumab N = 9,799; GCSF N = 271,485; nab-paclitaxel N = 86,394; branded drug N = 13,386. Controlling for patient characteristics and calendar year, industry payment was associated with an increase in the absolute prevalence of denosumab (+17.5% [95%CI: 15.3 to 19.7%]), GCSF (+5.8% [95%CI: 5.4 to 6.1%]), and nab-paclitaxel (+7.6% [95%CI: 7.1 to 8.1%]) use, but lower branded drug use (-4.6 [95%CI: -5.8 to -3.3]). In physician-level fixed effects models, industry payment was associated with increased denosumab (+7.4% [95%CI: 2.5 to 12.2%]) and nab-paclitaxel (+1.7% [95%CI: 0.9 to 2.5%]) use, but not with GCSF (+0.4% [95%CI: -0.3 to 1.1%]) or branded drugs (+1.2% [95%CI: -5.8 to 8.3%]). **Conclusions:** Recent receipt of industry payments by physicians was associated with increased use of several forms of NR/LV cancer treatment. These findings raise quality-of-care concerns regarding physician-industry financial relationships. Additional work is needed to further explore the causal relationship between payments and non-recommended treatments, and between payments and patient outcomes. Cost of genetic testing, delayed care, and suboptimal treatment associated with polymerase chain reaction (PCR) versus next-generation sequencing (NGS) testing strategies in metastatic non-small cell lung cancer (mNSCLC). *First Author: Christine M. Bestvina, University of Chicago, Chicago, IL*

Background: NGS testing for genomic alterations has been found to expedite time to appropriate targeted therapy initiation compared to PCR testing in mNSCLC. This study assessed US payers' costs of testing, delayed care, and suboptimal treatment initiation for PCR versus NGS testing in patients with mNSCLC. **Methods:** A decision tree model evaluated testing for guideline-recommended alterations (EGFR, ALK, ROS1, BRAF, KRAS, MET, HER2, RET, NTRK1/2/3) in patients with newly-diagnosed mNSCLC from first test until appropriate therapy initiation using 1) liquid or tissue NGS (60% [90% tissue, 10% liquid] of patients), 2) exclusionary KRAS test followed by sequential PCR tests (5%), 3) sequential PCR tests (5%), or 4) hotspot panel (30%) PCR tests. The proportion of patients testing positive for a targetable alteration and time to appropriate therapy initiation were evaluated. Cost components included genetic testing, testing-related medical services, delayed care (i.e., costs for medical services while waiting for test results), immunotherapy (IO)/chemotherapy (CTX) initiation prior to test results, and suboptimal treatment initiation after test results (i.e., costs of first-line IO/CTX in patients falsely testing negative for an actionable mutation). **Results:** In a modeled cohort of 1 million members (75% commercial, 25% Medicare), an estimated 1,119 patients had mNSCLC and were tested. The proportion of patients testing positive for a targetable alteration was 45.9% for NGS and 39.4% for PCR testing (Table). Total mean per patient costs were lower for NGS (\$8,866) than for PCR (\$18,252), driven by more rapid treatment with appropriate therapy (2.1 versus 5.2 weeks), resulting in lower delayed care costs and IO/CTX costs prior to test results. **Conclusions:** Results suggest that NGS testing may lead to better patient care and reduced costs to the health system relative to PCR testing. Costs of inappropriate IO/CTX initiation are an important component of increased costs of PCR-based approaches. Research Sponsor: Janssen Scientific Affairs, LLC.

Palliative care as a component of high-value and cost-saving care during hospitalization for metastatic cancer. *First Author: Sifan Lu, SUNY Downstate Health Sciences University, Brooklyn, NY*

Background: Randomized controlled trials have demonstrated that palliative care can improve both quality of life and survival for outpatients with advanced cancer, but there is limited population-based data on the value of inpatient palliative care. We assessed palliative care as a component of high-value care among a nationally representative sample of inpatients with metastatic cancer. We further identified care, patient, and hospital characteristics significantly associated with high costs. **Methods:** This study analyzed hospitalizations of patients ≥ 18 years with a primary diagnosis of metastatic cancer from the National Inpatient Sample (covering 97% of the U.S. population) from 2010-2019. We utilized multivariable mixed-effects logistic regression to assess medical services (receipt of palliative care, invasive medical ventilation (IMV), systemic therapy), patient demographics, and hospital characteristics that were associated with higher charges billed to insurance and hospital costs. We utilized generalized linear mixed-effects models to determine cost savings associated with provision of palliative care. **Results:** Among 397,691 hospitalizations from 2010 to 2019, the median charge per admission increased by 24.9%, from \$44,904 in 2010 to \$56,098 in 2019, while the median hospital cost remained stable at \$14,300. Receipt of inpatient palliative care was associated with significantly lower charges (Odds Ratio [OR], 0.62; 95% CI, 0.61-0.64; $P < .001$) and costs (OR, 0.59; 95%CI, 0.58-0.61; $P < .001$). Factors associated with high charges were receipt of invasive medical ventilation ($P < .001$) or systemic therapy ($P < .001$), Hispanic patients ($P < .001$), and young age (18-49 years, $P < .001$). For-profit hospitals were more likely to bill higher charges (OR, 5.05; 95%CI, 4.78-5.33, $P < .001$) but less likely to incur high hospital costs (OR, 0.51; 95%CI, 0.48-0.54, $P < .001$) than public hospitals. In adjusted generalized linear mixed effects regression, palliative care provision was associated with a \$1,293 (-13.4%, $P < .001$) reduction in costs per hospitalization compared to no palliative care, independent of receipt of invasive care and age. Significant interactions were observed between receipt of palliative care and patient age group (-9.6% for 18-49 years; -14.7% for ≥ 70 years), receipt of IMV (-6.4% for IMV receipt; -14.0% for no IMV), hospital ownership (-19.6% for for-profit; -10.5% for public), and year of hospitalization (-15.4% for 2010; -8.9% for 2019). **Conclusions:** Inpatient palliative care is associated with reduced hospital costs for patients with metastatic cancer, irrespective of age and receipt of aggressive interventions. Assuming inpatient palliative care receipt increases by 50%, we estimate \$4,045,000 in annual national savings. Integration of inpatient palliative care may de-escalate costs incurred through low-value inpatient interventions. Research Sponsor: None.

The role of private insurance characteristics in the out-of-pocket costs of patients with multiple myeloma. *First Author: Hamlet Gasoyan, Cleveland Clinic, Cleveland, OH*

Background: Over the past two decades, the major advances in the treatment of multiple myeloma have improved overall survival considerably. High costs of novel medications and patient out-of-pocket costs were suggested to have a role in treatment disparities but available data on total- and patient-out-of-pocket costs are dated. We examined the costs in privately insured patients with newly diagnosed multiple myeloma in the first year after the diagnosis, based on insurance plan characteristics.

Methods: This retrospective study used the IBM MarketScan Commercial Database for the years 2011–2019, which consists of medical and prescription medications data from 120+ large employers and 40+ health plans in the US. The primary outcome variables were total- and patient out-of-pocket costs during 1 year after the index diagnosis. **Results:** 5,487 privately insured adults with an index multiple myeloma diagnosis during 2012–2018 were identified. Approximately 41% (n=2,240) of the study population received bortezomib, 38.6% (n=2,117) received lenalidomide, and 5.7% (n=314) received carfilzomib during 1 year after the index diagnosis. The median total cost of care in the first year after multiple myeloma diagnosis increased from \$133,938 (interquartile range, \$19,770 – \$292,501, expressed in 2018 USD) in patients diagnosed in 2012 to \$252,559 (\$33,089 – \$380,662) in patients diagnosed in 2018. The median patient out-of-pocket costs were \$3,147 (interquartile range \$1,562 – \$5,441, 2018 USD) in patients diagnosed in 2012 and \$3,711 (\$1,756 – \$6,466) in patients diagnosed in 2018. Among patients diagnosed in 2018, the median patient out-of-pocket cost was \$1,706 (\$902 – \$2,873) for patients with low out-of-pocket cost plans, \$3,428 (\$1,794 – \$6,371) for those with average out-of-pocket cost plans, and \$5,623 (\$3,517 – \$7,810) for patients with high out-of-pocket cost plans. **Conclusions:** While the total cost of care in the first year after multiple myeloma almost doubled during the study period, the patient out-of-pocket costs remained relatively stable. The protections imposed by the Affordable Care Act are likely key in preventing surges in patient out-of-pocket costs. Additional legislative action could help curb the price increases for multiple myeloma medications. Research Sponsor: Dr. Hamlet Gasoyan received support from the Cancer Intervention and Surveillance Modeling Network's Junior Investigator Career Enhancement Research Award.

Year	2012	2013	2014	2015	2016	2017	2018
Median Out-Of-Pocket Cost (Interquartile Range)	3,147 (1,562 - 5,441)	3,505 (1,708 - 5,565)	2,915 (1,464 - 5,099)	2,884 (1,531 - 5,181)	3,363 (1,576 - 5,618)	3,132 (1,483 - 5,299)	3,711 (1,756 - 6,466)
Median Total Cost (Interquartile Range)	133,938 (19,770 - 292,501)	151,713 (27,392 - 297,279)	126,898 (20,134 - 291,692)	161,508 (19,420 - 333,108)	201,603 (27,291 - 350,144)	175,070 (19,831 - 340,040)	252,559 (33,089 - 380,662)

Unnecessary thrombophilia testing reduction: Quality improvement project. *First Author: Konstantin Golubykh, UPMC Harrisburg, Harrisburg, PA*

Background: The American Society of Hematology (ASH) recommends reducing inpatient thrombophilia testing but adherence to these recommendations remains suboptimal. We report the results of a quality improvement (QI) project which aimed to minimize unnecessary testing. **Methods:** We performed retrospective review of records of patients with a new diagnosis of venous thromboembolism (VTE) across 3 hospitals in Central PA from September 2021 to December 2021 to see how many patients underwent thrombophilia workup. Our QI project consisted of education for physicians based on ASH recommendations with lectures, bi-weekly emails, and educational posters. We then performed a second retrospective review of patients admitted under the same conditions between June 1, 2022, and August 31, 2022, to reevaluate thrombophilia testing rates. The cost of testing was extrapolated from institutional hospital cost reports. Descriptive statistics included reporting the categorical variables as number and percent. The categorical variables were compared between groups with Fisher's exact test or the chi-square test. **Results:** During the first study period, 310 patients had new VTE. Provoking factors were found in 269 patients (86.7%) and 41 patients (13.2%) had unprovoked VTE. Overall, 33 out of 310 patients (10%) underwent thrombophilia workup, with a total of 175 tests performed. Thrombophilia testing rate was significantly higher in the unprovoked group (29.3% vs 7.8%, $p = 0.0003$). Both groups have equally received inpatient hematology consult (33.83% vs 47.50%, $p = 0.0920$). Only 16% of thrombophilia tests were recommended by hematology consult while the rest was ordered by the primary team. The cost of all tests ordered outside of hematology recommendation was \$34,083 (\$344 per person). Of the group that got tested regardless of provoking factors, there was no difference between hospital length of stay (2–12 days vs 3–12 days, $p = 0.0665$) or anticoagulation choice. During the second study period, 191 patients had new VTE. Provoking factors were found in 157 patients (82.1%) while 34 patients (17.9%) had unprovoked VTE. Overall, 21 out of 191 patients (10.9%) underwent thrombophilia workup, with a total of 78 tests performed. More testing was ordered in the unprovoked group (26.47% vs 7.64%, $p = 0.0040$). More inpatient hematology consults were performed in the unprovoked group (64.71% vs 40.76%, $p = 0.0110$). Of the hematology consults, 12 out of 21 patients (57%) had thrombophilia testing recommended by hematologist. The rate of thrombophilia testing ordered outside of hematology consultation has decreased from 84% to 43% after our intervention, resulting in a \$16,635 savings for that quarter. **Conclusions:** Our experience confirmed that thrombophilia work up was costly and did not impact quality of care. Despite the relatively low frequency of inpatient workup, eliminating unnecessary testing saved our health system \$16,635 in a 3-months period. Research Sponsor: None.

Estimated life-years gained and resultant cost savings from follow-up colonoscopy after a positive multi-target stool DNA (mt-sDNA) test for colorectal cancer screening in commercially insured and Medicare populations. *First Author: A. Mark Fendrick, University of Michigan, Ann Arbor, MI*

Background: Although follow up colonoscopy (COL) after a positive stool-based colorectal cancer (CRC) screening test is necessary to complete the CRC screening process, follow-up COL rates remain suboptimal, especially among underserved populations. As of January 2023, federal policies require commercial insurers and Medicare to eliminate out of pocket costs for follow-up COL. To estimate the implications of this policy change, we compared the clinical and fiscal outcomes for a simulated cohort receiving a follow-up COL after a non-invasive CRC test (\$0 cost sharing), compared to the same cohort not completing follow-up COL (status quo). **Methods:** Using the validated CRC-AIM model, we simulated a cohort of 6 million average-risk individuals who received mt-sDNA (commercial patients at age 45 and Medicare patients at age 65) and further analyzed only the population with positive mt-sDNA. Life-years gained, CRC incidence, CRC-related mortality and total costs of care (inclusive of CRC screening and treatment) were calculated for a cohort that underwent follow-up COL and compared these outcomes to that same cohort that did not complete follow-up COL. The cost of follow-up COL was assumed to be \$1,576 for Medicare and \$3,086 for commercially insured patients (\$0 out of pocket costs for all). **Results:** Patients undergoing follow-up COL after a positive mt-sDNA experienced more life-years (83 per 1,000 commercially insured patients and 80 per 1,000 Medicare beneficiaries) compared to those who did not undergo follow-up COL. The follow-up COL resulted in reductions in CRC incidence and CRC mortality by 14% and 16% for commercial and 19% and 23% for Medicare beneficiaries, respectively. Compared to those patients with a mt-sDNA positive test result and did not complete follow-up COL, the total cost per patient for those receiving follow-up COL was \$3,339 less for commercially insured (\$15,690 – no follow up vs. \$12,351 – follow up) and \$4,382 less for Medicare beneficiaries (\$19,337 – no follow up vs. \$14,955 – follow up). Total spending for patients receiving follow-up COL was cost-saving when compared to no follow-up as long as the COL costs were less than \$6,269 for commercial plans and \$5,753 for Medicare. **Conclusions:** Completing a follow-up COL after a positive mt-sDNA screening saves lives, enhances equity, and lowers total expenditures. Thus, health care stakeholders should invest in efforts to identify and reduce barriers that ultimately lead to an increase uptake of this potentially lifesaving and cost-reducing intervention. Association between targeted cancer drug net health benefit and uptake, patient out-of-pocket spending, and total spending. *First Author: Kelsey S. Lau-Min, Massachusetts General Hospital, Boston, MA*

Background: Targeted cancer drugs (TCDs) have revolutionized oncology, but they are widely variable in their clinical benefit and are often accompanied by high patient-out-of-pocket (OOP) costs. The ASCO Value Framework uses published clinical trial data on survival, toxicity, and potential for symptom palliation to quantify the net health benefit (NHB) of any given cancer drug. We aimed to evaluate the association between NHB and uptake, patient OOP spending, and total spending for eight oral TCDs approved for the first line treatment of an advanced solid tumor based on one or more clinical trials comparing to a non-TCD control arm. **Methods:** We conducted a retrospective cohort study of incident pharmacy claims for oral TCDs prescribed to patients aged 18–64 years between 2012–2020 in the nationwide Health Care Cost Institute de-identified commercial claims dataset. NHB scores were calculated for each TCD of interest using the ASCO Value Framework and categorized as high (>60), medium (40–60), and low (<40) net health benefit. Distributions of incident 28-day TCD supplies were plotted over time by NHB category. The primary outcome was patient OOP spending (patient copay + coinsurance + deductible), whereas the secondary outcome was total spending (patient OOP spending + pharmacy reimbursement). Generalized linear models were used to evaluate the association between each outcome of interest and TCD NHB, adjusted for cancer indication. **Results:** We included 8,524 incident pharmacy claims for eight TCDs with nine indications in breast cancer, non-small cell lung cancer (NSCLC), melanoma, and pancreatic cancer. NHB scores ranged from 7 (erlotinib for pancreatic cancer) to 81 (crizotinib for ALK-rearranged NSCLC), with 1,145 (13%), 6,608 (78%), and 771 (9%) of pharmacy claims falling into low-, medium-, and high-NHB categories, respectively. Medium- and high-NHB TCDs accounted for the majority of incident TCD prescriptions throughout the study period. Median patient OOP spending was \$18.78 for the first 28-day TCD supply (IQR \$0.00–\$87.57), with 45% of patients paying \$0 and 8% paying >\$1,000 OOP. Patient OOP spending was not significantly associated with TCD NHB category (difference \$0.94, 95% CI -\$49.99–\$51.87 for medium vs low NHB; difference \$58.86, 95% CI -\$28.04–\$145.75 for high vs low NHB). Median total spending was \$10,118.79 (IQR \$6,365.95–\$10,600.37) for an incident 28-day TCD supply. There was a \$1,083.56 increase in total spending for each 10-point increase in NHB score (95% CI \$1,050.27–\$1,116.84, $p < 0.01$ for $H_0 = \$0$). **Conclusions:** Although TCDs are widely variable in their NHB, low-NHB TCDs are not prescribed as frequently as medium- and high-NHB TCDs. Total spending on TCDs is high and positively associated with NHB. Commercially insured patients are largely shielded from high OOP spending on TCDs. Association of early completion of portable medical orders with inpatient costs at end-of-life for patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). *First Author: Marissa LoCastro, University of Rochester School of Medicine & Dentistry, Rochester, NY*

Background: Patients with hematologic malignancies receive more aggressive care at end-of-life (EOL) compared to patients with solid tumors. Costs of care in patients with hematologic malignancies at EOL are high, particularly in the inpatient setting. We previously found that early completion of portable medical orders [termed medical orders for life sustaining treatment (MOLST) in New York state] is associated with less intense care at EOL for patients with AML and MDS. Thus, we hypothesized that early MOLST completion would also be associated with lower inpatient costs at EOL among patients with AML and MDS. **Methods:** We previously conducted a retrospective study of 358 adults patients with AML or MDS treated at Wilmot Cancer Institute and its affiliated sites who died between January 1, 2014, and December 31, 2019. Of these, 271 patients were eligible for cost analysis. Cost of inpatient care received at the University of Rochester Medical Center (URMC) within the last 30 days of life was obtained from our Finance Decision Support Department. Patients were excluded if inpatient costs at EOL were unavailable. **Results:** Mean age of patients was 69 years (N=271, range 20-95); 84% (n=227) of patients were hospitalized within 30 days of death. One-third (34%, n=93) of patients completed a MOLST early (>30 days prior to death) whereas 66% (n=178) either did not complete a MOLST or completed a MOLST late (less than or equal to 30 days prior to death). Mean and median inpatient cost of care for all patients at EOL was \$39,284 and \$19,703, respectively. The rate of hospitalization was lower for patients who completed a MOLST early vs late/never (73.1% vs 90.5%, respectively; $p=0.0003$), although there was no difference in the number of inpatient visits between the two groups (median=1 visit in both groups; $p=0.23$). In addition, median cost of inpatient care was lower for patients who completed a MOLST early vs late/never (\$10,673 vs \$23,177, respectively; $p<0.0001$). After adjusting for age, sex, and diagnosis, there was a trend toward lower EOL costs in patients completing a MOLST early ($p=0.07$). **Conclusions:** In patients with AML or MDS, early MOLST completion may be associated with lower inpatient costs at EOL. Viewing MOLST completion as a surrogate for a goals-of-care discussion, it follows that interventions aimed to increase the frequency of early goals-of-care discussions, advanced care planning, and MOLST completion are likely to improve quality of care and decrease costs at EOL in these patient populations. Maxed out: Reaching the annual maximum out-of-pocket limit among insured patients diagnosed with cancer. *First Author: Matthew P. Banegas, University of California San Diego, La Jolla, CA*

Background: Patients with cancer face potentially high out-of-pocket costs associated with their medical care, which may lead to adverse medical and financial outcomes. Depending on their health insurance plan, patients may have to pay several thousands for medical care costs until they reach the annual maximum out-of-pocket (MOOP) spending limit; after which care costs are covered by insurance. The purpose of this study was to measure the proportion of adult patients who reach their health plan MOOP limit in the year of cancer diagnosis. **Methods:** Electronic health record data from 13,057 patients aged ≥ 18 years, diagnosed with cancer between Jan. 1, 2016–March 31, 2021 [index cancer], with ≥ 12 months of continuous health insurance coverage pre-cancer diagnosis were included. The primary outcome was defined as reaching the MOOP limit in the health plan benefit year of index cancer diagnosis (binary, yes/no). We additionally created a secondary outcome using 3 categories: (i) did not reach MOOP; (ii) reached MOOP prior to cancer diagnosis; (iii) reached MOOP after cancer diagnosis. Descriptive statistics were used to assess the distribution of outcomes across patient characteristics including health insurance type (e.g., commercial), high-deductible health plan (HDHP), cancer type, age at diagnosis, and Census-level household income was included. Multivariable logistic regression estimated the association between patient characteristics and the primary outcome. Complete case analyses were performed using Stata 16.1. **Results:** Patients' mean age was 66 years (standard deviation [sd]: 13) and mean Census-level household income was \$73,100 (sd: \$24,000). Approximately 40% of patients had commercial health insurance and 62% had Medicare; 2% (n=283) had a HDHP. Breast (18%), lung (11%) and prostate (11%) cancers were most common. The mean annual MOOP limit was \$3,040 for commercial plans and \$2,688 for Medicare plans. Among patients with a commercial plan insurance, 46% reached their MOOP limit including 8% before and 37% after cancer diagnosis. For Medicare patients, 20% reached their MOOP limit, including 3% before and 17% after cancer diagnosis. Patients with a HDHP (adjusted Odds Ratio [aOR]: 2.61, 95% CI: 1.96-3.47), breast cancer (aOR: 2.29, 95% CI: 1.84-2.84), and lung cancer (aOR: 2.71, 95% CI: 2.04-3.61) had significantly greater odds of reaching the MOOP than those with a non-HDHP and other cancers. Household income was also significantly associated (aOR: 0.97, 95% CI: 0.95-0.99) with reaching the MOOP. **Conclusions:** A substantial proportion of patients reach the annual MOOP limit during the year of cancer diagnosis, representing a population at high-risk for medical financial hardship. Future longitudinal studies are needed to assess the trajectory of OOP spending and implications on care utilization and health outcomes. Research Sponsor: U.S. National Institutes of Health.

National survey of financial burdens and experience among patients with cancer receiving charitable co-pay assistance. *First Author: Jeffrey M. Peppercorn, Massachusetts General Hospital, Boston, MA*

Background: High healthcare costs can pose a barrier to access and contribute to financial hardship among patients with cancer. Charitable co-pay assistance (CPA) foundations provide financial support to patients facing high out-of-pocket costs, but little is known about the sociodemographic characteristics, financial burdens, views and experience of those receiving assistance. **Methods:** We conducted a national, cross-sectional survey of CPA grant recipients receiving financial assistance from the HealthWell Foundation (charitable CPA foundation) to cover cancer drug costs. The primary outcome of interest was self-reported financial distress (FACIT-COST). Secondary outcomes included measures of out-of-pocket spending, patient perspectives on CPA support, healthcare access and costs, and the impact of financial burden on healthcare utilization. **Results:** Among 1,108 CPA grant recipients, over 20 cancer types were represented, including 30% with solid tumors and 70% hematologic malignancy. Average age of CPA recipients was 72 (range: 41-92), 60% were male, 88% white, 55% college educated, and 67% had annual income < \$60,000. 96% had Medicare (53% Traditional, 43% Advantage, 58% with supplemental insurance), and 66% believed insurance would prevent them from paying high drug costs. However, 54% reported spending > \$500 per month on healthcare, with 39% spending > 10% of household income. Among 17% reporting delays in starting therapy due to cost, 28% reported delay > 4 weeks. Overall, 18% reported skipping medical services due to cost, and 24% believed they would not have received their treatment without CPA. On the COST scale, 56% reported mild financial toxicity (COST 14-25) and 27% moderate/severe (COST < 14) despite CPA. In bivariate analysis, younger age, solid tumor, lower income, female gender, higher anxiety and depression (PHQ4), greater comorbidity, and traditional Medicare were all significantly associated with greater financial distress (lower COST scores, $P < 0.05$ for all). Most (76%) CPA recipients believed that doctors should be aware of costs when making decisions, and 91% supported Medicare negotiating drug prices with manufacturers. With regard to why they required CPA, only 6% attributed it to failure to discuss costs with their doctor, 14% to the healthcare system, 51% to poor insurance coverage, 61% to their financial status, and 82% to high drug costs. Notably, 73% reported a decrease in financial concerns as a result of CPA. **Conclusions:** In this large national sample of CPA grant recipients with cancer, most had Medicare and believed insurance would shield them from high drug costs, yet many reported delays in starting therapy prior to CPA and ongoing financial distress. CPA may play an important role in securing access to therapy but these findings highlight an ongoing need to address financial toxicity and understand potential disparities in access to CPA. Poster Session

A health economic model to assess the impact of prehabilitation on hospital cost savings in gastrointestinal cancer, modelled on English National Health Service tariff. *First Author: Bernarda Zamora Zamora Talaya, Imperial College, London, London, United Kingdom*

Background: Prehabilitation is increasingly being recognised as a high-priority intervention to improve physical and psychological health in cancer patients, prevent treatment-related functional decline and to reduce the incidence and severity of post-surgical complications. The aim of this study is to develop a health economic (HE) model to evaluate the impact of prehabilitation in patients undergoing gastrointestinal cancer surgery. **Methods:** The objective of the HE model is to estimate the impact of prehabilitation on reducing treatment costs. Data was extracted from systematic reviews and meta-analysis on the effects of prehabilitation in gastrointestinal cancer surgery to identify: i) treatment pathway, ii) prehabilitation components (nutrition/exercise/psychological intervention), and iii) effects on three study outcomes (length of hospital stay, reduction of post-operative complications, and reduced Intensive Care Unit (ICU) stay). The modelling study accounts for the number of hospital admissions and unit costs from NHS hospitals, including cost per bed-day from NHS Reference costs 2017-18 and complication costs and ICU cost from NHS Reference National Cost Schedule 2019-20. Double counting has been corrected to account for the compounded effects on length of stay and complications. The HE model considers the average effect of each study outcome and their confidence intervals. This provides a range of potential impact of prehabilitation in terms of cost reduction based on NHS tariff. **Results:** Patient weighted average cost savings from prehabilitation was £785, excluding ICU costs. Breakdown of cost savings include £178.6 from reduced length of hospital stay, £214.8 and £434.5 cost savings originating from reductions in minor and major complications, respectively (excluding ICU complication costs). ICU cost savings from prehabilitation were £1,620. For the NHS, based on 237,000 annual surgical procedures, this amounts up to £186,082,321 in cost savings, from a reduction in complications and 421,840 hospital days, and £52,761,227 from ICU stay. **Conclusions:** In addition to the impact on post-operative complications and hospital stay, this study has demonstrated that prehabilitation results in significant costs savings to healthcare systems. The cost savings are largely from a reduction in the incidence and severity of post-operative complications. The latter contributing to reduced ICU costs. Research Sponsor: None.

Value-driven colorectal cancer survivorship through partnership with primary care. *First Author: Gloria Hui Jia Chan, Department of Haematology-Oncology, National University Cancer Institute, Singapore, Singapore*

Background: The risk of recurrence for colorectal cancer (CRC) is low after 5 years (<1.5% per year) hence, surveillance visits, CEA blood tests and annual CT scans are not recommended beyond this period (NCCN guidelines). Importantly, right-siting survivorship care to the community allows primary care providers (PCP) to focus on preventive health beyond cancer. The National University Cancer Institute, Singapore, a tertiary, academic cancer center developed a program to transition CRC survivorship care to the community after 5-years of active surveillance. Patients (Pts) are discharged to the community with a survivorship care plan and followed-up via phone calls. We hypothesize that by transitioning CRC survivors to the community, we can optimize healthcare resources by reducing specialist visits and tests at the cancer center without compromising outcomes. **Methods:** From July 2018, CRC pts beyond 5-years from diagnosis with no evidence of cancer recurrence were eligible for transition. Pts were followed prospectively to determine date of cancer recurrence, issues preventing transition to the community and a phone survey on pt satisfaction was conducted for those who transitioned to primary care. Data on healthcare utilization amongst pts who transitioned vs. pts who remained in tertiary care was collected. Data cutoff was June 2022. Statistical analysis was performed with IBM SPSS Statistics (v28.0). **Results:** Between July 2018 - June 2022, there were 791 CRC pts who were eligible for transition, of which 534 pts (67.5%) had no clinical issues preventing transition and included in this analysis. 54.3% (N=290) were males and stage distribution of cancers were 14.2%, 34.0%, 47.1% and 4.7% for stages I, II, III and IV, respectively. The mean number of years since diagnosis was 6.88 (range: 5-16 years; SD 2.25). 380 pts (71.2%) were transitioned to the community. There was consistently higher utilization of healthcare resources in the group not transitioned vs. transitioned: mean number of consults (2.86 vs 1.02; $p<0.001$); CEA (1.23 vs 0.31; $p<0.001$); CT scans (0.08 vs 0.05; $p=0.221$) and colonoscopies (0.25 vs 0.16; $p=0.031$). Mean healthcare expenditure (mean gross bill per year) was consistently higher in pts across all categories for the group not transitioned vs. transitioned: consults (\$158 vs \$56; $p<0.001$); CT scans (\$60 vs \$39; $p=0.273$); CEA (\$26 vs \$7; $p<0.001$) and colonoscopies (\$208 vs \$126; $p=0.018$). Importantly, recurrence rates were low with no difference in both groups (0.8% vs 1.3%; $p=0.629$). 82% of CRC pts were satisfied or very satisfied with follow-up care provided by their PCPs on a subsequent survey. **Conclusions:** We have demonstrated value-driven survivorship care by right-siting CRC survivors into the community. Healthcare resources were optimized with reduction in specialist visits and tests which lead to lower costs while recurrence rates remain low. Pt satisfaction in the community was also high. The impact of a cancer-specific novel therapy adjustment (NTA) in Medicare value-based care programs: A simulation exercise. *First Author: Erica Feinberg, US Oncology Network, Dallas, TX*

Background: The Oncology Care Model (OCM) was a value-based care program implemented by the Centers for Medicare & Medicaid Innovation (CMMI) between July 1, 2016, and June 30, 2022, that aimed to provide high-quality care while reducing total cost of care (TCOC). In 2023 CMS plans to implement the Enhancing Oncology Model (EOM), which builds on lessons learned from the OCM. Over 200 novel therapies were approved by the FDA between 2016 and 2022. Novel therapies come with increased cost, leading to concerns that the model could discourage use of novel therapies. CMMI implemented a novel therapy adjustment (NTA) to offset the increased cost of these expensive therapies, when a practice has a higher proportion of novel therapy expenditures. A key change in the EOM is the calculation for NTA at the individual cancer type level compared to full population of episodes in the OCM. We studied the impact of moving from a population-based NTA to a cancer type-based NTA calculation. **Methods:** Claims and performance data from 10 performance periods (PP) in the OCM (PP1 to PP10) for 14 practices in The US Oncology Network were reviewed. Descriptive statistics for the simulation were evaluated to determine changes from population-based NTA to cancer-based NTA. The OCM NTA methodology was deconstructed to apply the NTA at a cancer type level. We performed a simulation exercise by applying cancer specific NTA methodology systematically to the claims and performance data. We then evaluated the impact of NTA on the EOM cancer types. **Results:** 20.95% of the TCOC was attributed to novel therapy expenditures in the OCM for all cancer types (range 0.0% - 49.4%) vs 24.2% (range - 3.5% - 43.7%) of TCOC for the EOM cancer types (high-risk breast, colon, lung, high-risk prostate, myeloma, lymphoma and chronic leukemia) in the same time-frame. 75.5% of the novel therapy expenditures in the OCM came from the 7 EOM cancers. In the OCM only 31.8% of eligible performance periods received a NTA. Had the NTA been applied at the cancer type level, 49.5% of eligible episodes would have received an adjustment. The top cancers with the most novel therapy use as a percentage of TCOC were lung, myeloma and high-risk/ castrate-resistant prostate. The NTA for these practices adjusted the benchmark by an average of 0.56% (range -0.21% to 1.1%) over 10 periods. When applied at a cancer type level, NTA increased the adjustment by 3 times to an average of 1.73% (range -1.16% to 2.11%). **Conclusions:** The NTA applied at a cancer type level would have resulted in more instances where practices would have qualified for a benchmark adjustment. We believe that the EOM approach to NTA applied at a cancer type level is more favorable for participating practices and provides valuable financial protection when incorporating clinically appropriate novel therapy for cancer treatment. We commend CMMI for making improvements to the NTA risk adjustment methodology within the EOM. Research Sponsor: None.

Impact on costs and outcomes of multi-gene panel testing for advanced solid malignancies: A cost consequence analysis using linked administrative data. *First Author: Alberto Hernando-Calvo, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: To date, economic analyses of tissue-based next generation sequencing genomic profiling (NGS) have required models with multiple assumptions, with little real-world evidence on overall survival (OS), clinical trial enrollment or end-of-life (EOL) quality of care. The OCTANE clinical trial (NCT02906943) is a prospective study evaluating the role of NGS for advanced solid tumors in Ontario, Canada. We performed a cost consequence analysis of OCTANE. **Methods:** We undertook a longitudinal, propensity score-matched retrospective cohort study using linked administrative data. OCTANE patients (pts) at Princess Margaret Cancer Centre from August 2016 until March 2019 undergoing NGS panel testing (555 or 163-gene panels) were matched with contemporary controls from across Ontario not enrolled in OCTANE. Patients were matched according to 19 variables including age, sex, place of residence, tumor site, symptom burden, income quintile, comorbidities and prior lines of systemic therapy. Primary outcomes were mean per capita health care costs (2019 Canadian dollars [CAD]) from the public payer's perspective, OS, clinical trial enrollment and EOL quality metrics. Full 2-year follow-up data was available. Sensitivity analyses considered alternative matched cohort specifications. **Results:** There were 782 OCTANE pts with 782 matched controls. Variables were balanced after matching (standardized difference [std. diff.] <0.10). Most common tumor sites were: Ovary (30.4%), endometrium (15.0%) breast (12.3%) and colon (8.6%). OCTANE pts had higher mean healthcare costs than controls (\$79,702 vs. \$59,550), mainly due to costs of oncology visits (\$33,165 vs. \$26,197), outpatient clinic visits (\$8,696 vs. \$5,114) and emergency visits (\$1,723 vs. \$1,373) (all $p<0.05$). Publicly funded drug costs were less for OCTANE pts (\$20,015 vs. \$24,465). Overall, OCTANE enrollment was not associated with improved OS (restricted mean survival time (RMST) [standard error]: 1.50 (± 0.03) vs. 1.44 (± 0.03) years, log-rank $p=0.153$), but OCTANE was associated with longer OS in ovarian cancer (RMST: 1.69 (± 0.05) vs. 1.45 (± 0.06) years, $p=0.011$) and biliary tract tumors (RMST: 1.16 (± 0.13) vs. 0.80 (± 0.11) years, $p=0.02$). Importantly, OCTANE correlated with increased clinical trial enrollment (25.5% vs. 9.5%, $p<0.001$) and better EOL quality due to fewer deaths in hospital (10.2% vs 16.4%, $p=0.003$). Results were robust in sensitivity analysis. **Conclusions:** There was an increase in healthcare costs associated with NGS testing for advanced cancers. The impact on OS was not significant in the overall population, but varied across tumor types. OCTANE was associated with greater trial enrollment, lower publicly funded drug costs and fewer in hospital deaths suggesting important considerations in determining the value of NGS for advanced cancers. Clinical trial information: NCT02906943. Research Sponsor: Ontario Institute for Cancer Research through funding provided by the Government of Ontario (#IA-035 and P.HSR.158) and Canadian Network for Learning Healthcare Systems and Cost-Effective Omics Innovation (CLEO) via Genome Canada (G05CHS).

Assessment of price variation in colorectal cancer screening procedures at US hospitals. *First Author: Ishan Paranjpe, Stanford, Stanford, CA*

Background: Following the 2021 Hospital Price Transparency Final Rule, US hospitals were mandated to publish their insurer-negotiated prices. We identified factors contributing to price variability of colorectal cancer (CRC) screening procedures across the US. **Methods:** We compared prices of colonoscopy, flexible sigmoidoscopy, CT colonography, fecal occult blood test, fecal immunochemical test, and Cologuard across U.S. hospitals using the Turquoise dataset (N = 6,378). Psychiatric, rehabilitation, and pediatric hospitals were excluded. Prices in the top and bottom 1% were also excluded to minimize the effect of outliers. Prices were adjusted by the Medicare Geographic Price Index to account for regional variability. We then compared prices across several subgroups, including National Cancer Institute (NCI) designated hospitals, teaching hospitals, and investor owned hospitals. Significance was assessed using the Kruskal-Wallis test. To quantify price variability across insurance plans within a hospital, we defined the within-center ratio as the 90th percentile rate at a hospital divided by the 10th percentile rate. To quantify variability across hospitals, the across-center ratio was defined as the 90th percentile median rate across all hospitals divided by the 10th percentile median rate. **Results:** 1,460 hospitals reported commercial prices for colonoscopy with a median commercial price of \$1,867 (IQR: \$1,208 - \$2,689). For colonoscopy, the within center ratio was 2.5 (IQR: 1.5 - 3.8) and the across-center ratio was 6.2. Prices for other procedures are provided in the table. Compared to non-investor owned hospitals, prices of colonoscopy (\$2,082 vs \$1,787, $P<0.001$) and flexible sigmoidoscopy (\$2,022 vs \$1,289, $P<0.001$) were significantly higher at investor owned hospitals. Furthermore, across investor classes, hospitals with >5% ownership from private equity firms had the highest median price for both colonoscopy (\$2,898), and flexible sigmoidoscopy (\$2,697). We did not find significant differences in price by NCI designation, academic teaching center affiliation, overall hospital mortality, overall hospital readmission rate, or urban/rural location. **Conclusions:** CRC screening procedure prices vary significantly both within and across hospitals. Private equity and other investor owned hospitals had significantly higher prices compared to non-investor owned hospitals. Research Sponsor: None.

Code type	Code description	Number of centers	Median commercial price, \$ (IQR)	Within center ratio (IQR)	Across center ratio
45378	Colonoscopy	1,460	1,867 (1208 - 2689)	2.5 (1.5 - 3.8)	6.2
45330	Flexible Sigmoidoscopy	1,332	1,473 (823 - 2251)	2.3 (1.4 - 3.9)	15.9
82270	Fecal occult blood test (guaiac)	1,300	16 (7 - 32)	3.2 (1.7 - 6.7)	13.1
82274	Fecal Immunochemical test	1,185	41 (25 - 65)	2.5 (1.6 - 4.3)	5.5
74263	CT colonography	644	1,060 (675 - 1621)	1.8 (1.1 - 3.3)	5.8
81528	Cologuard	199	560 (509 - 1074)	1.7 (1 - 2.6)	3.4

The FOR ME (Fostering Opportunities in Research through Messaging and Education) study: Developing a culturally sensitive narrative intervention to promote equity in clinical trials. *First Author: Neha Hippalgaonkar, University of Illinois Chicago, Chicago, IL*

Background: Black women are more likely to die from breast cancer than women of any other race/ethnicity. Contributing factors to this inequity include structural and socioeconomic determinants of health, differential access to novel therapies, tumor biology and comorbidities. In 2020, only 7.2% of enrollees in clinical trials that led to approval of 3 novel drugs for breast cancer were Black. Underrepresentation of patients from racial/ethnic minority groups in clinical trials is a contributing factor to health disparities. The first aim of this study is to conduct multiple qualitative methods with multi-level stakeholders to identify barriers, facilitators, and intervention priorities that would assist Black breast cancer patients to make informed decisions about participating in clinical trials. Secondly, we aim to create a culturally sensitive, narrative intervention designed to support decision making and motivate Black breast cancer patients to participate in clinical trials. Aim 3 will pilot a study to determine acceptability of the intervention among patients and assess whether it increases clinical trial participation in a safety net oncology practice.

Methods: Community-based participatory research approaches are guiding our research methodologies. First, we are conducting interviews and story circles with Black women with breast cancer, community partners and advocates, and oncologists and clinical trials office staff. These interviews will identify themes to inform intervention content. Next, interviews and focus groups will invite feedback on the educational/motivational content of the intervention and will be used to develop a culturally sensitive script and storyboards. A video production company will produce the narrative intervention. Finally, focus groups and interviews with participant cohorts will provide feedback on the completed intervention. Black women diagnosed with breast cancer will view the intervention in an oncology clinic. Using a pretest/posttest design, we will analyze the acceptability of the intervention and its effect on intention to participate in clinical trials. We will then conduct a quasi-experimental study in a safety net oncology practice to determine whether the rate of clinical trial participation among Black breast cancer patients increases following implementation of the intervention as a standard component of new patient education. Recruitment started in July 2022, and currently, 14 of 30 interviews with patients are completed. Aim 1 interviews with patients, oncologists, clinical trial staff, and advocates are expected to finish by April 2023, and results will be presented. Research Sponsor: American Cancer Society.

Understanding patient acceptance and compliance of a blood-based colorectal cancer screening test. *First Author: Karen Kim, The University of Chicago, Chicago, IL*

Background: The Covid-19 pandemic has caused a significant disruption in healthcare utilization. The halt and delay of CRC screening have led to a substantial decline in CRC screening rates. The backlog and the slow resuming of CRC screening will have significant consequences. Although COVID-19 created challenges in CRC screening, it also presents an opportunity for potential innovative approaches that may improve patient compliance and screening rates, such as a blood-based CRC screening test which can be done at the point of care without preparation. Adherence to CRC screening is poor among vulnerable populations even before COVID-19, and these populations disproportionately receive health care in safety-net settings, such as federally qualified health centers (FQHCs). Thus, FQHCs play a significant role in improving CRC-related outcomes and ensuring health equity. This study will examine patient compliance with CRC screening by offering another option, a blood-based screening test, after failing to complete a stool-based screening test or colonoscopy in six months at three FQHCs.

Methods: The study will use a stepped wedge cluster trial design and include an initial period of no exposure. Each FQHC will have a cluster of 10 to 17 primary care clinics. After the initial no-exposure period, two FQHCs will implement a blood-based CRC screening test at their primary care clinics. Another FQHC will follow nine months later. Each FQHC will contribute to exposed and unexposed observations and function as its own control. This study will collect quarterly data to capture the impact, feasibility, and acceptability over time. The primary endpoint will be assessed by calculating the number of participants who, otherwise, will not have participated in the CRC screening. In addition, the effectiveness of the implementation strategies will be assessed since transferring innovations into real-world settings is complex, and practical strategies are critical to accelerating future implementation and assisting decision-making. The study will recruit patients who fail to complete a CRC screening after six months and meet the inclusion criteria: between 45-75 years of age, average risk for CRC, capable of and willing to give informed consent, and willing to provide a blood sample. For eligible patients, a blood-based CRC screening test developed by a CLIA-certified laboratory and made commercially available (Guardant Health, CA) will be offered at no cost. An order will be obtained from the participant's primary care provider before the blood sample is collected. This study plans to enroll up to 2,400 patients over a 3-year period. Patient compliance is a significant barrier to improving CRC screening, and the key to increasing screening participation is patient acceptance of the screening method. A blood-based screening test may offer an alternative for patients who fail to comply with other CRC screening modalities. Clinical trial information: NCT0536713. Research Sponsor: Guardant Health.

Oral Abstract Session

Safety and efficacy of obecabtagene autoleucel (obe-cel, AUTO1), a fast-off rate CD19 CAR, in relapsed/refractory adult B-cell acute lymphoblastic leukemia (r/r B-ALL): Top line results of the pivotal FELIX study. *First Author: Claire Roddie, University College London, London, United Kingdom*

Background: Obe-cel is an autologous CD19CAR with a fast off-rate CD19 binding domain designed to reduce CAR-T immunotoxicity and improve persistence. Its clinical activity has been tested in r/r paediatric and adult B-ALL trials (CARPALL, Ghorashian S et al., Nat Med 2019; ALLCAR19, Roddie C et al., JCO 2021) and more recently in adults with r/r B-cell malignancies (NCT02935257). Here, we present data from adult r/r B-ALL patients treated with obe-cel in the pivotal FELIX study (NCT04404660). **Methods:** FELIX is an open-label, multi-centre, global, single-arm Phase Ib/II study enrolling r/r B-ALL patients with morphological disease ($\geq 5\%$ BM blasts), measurable residual disease (MRD) ($\geq 0.1\%$ to $< 5\%$ BM blasts), or isolated extramedullary disease (Cohorts A, B and C). CAR-T products were generated using an automated closed process from fresh leukapheresate. Patients underwent bridging therapy as necessary and lymphodepletion with fludarabine (4x30mg/m²) and cyclophosphamide (2x500mg/m²). Patients received a target dose of 410E+6 CAR T cells as a split dose on Day 1 and Day 10. The dosing schedule is based on the % BM blasts performed locally prior to the pre-conditioning. Primary endpoint was overall remission rate (ORR) defined as proportion of patients achieving CR/CRi by central assessment. **Results:** As of 9th September 2022, a pre-specified interim analysis was conducted based on the first 50 patients infused in Cohort A who have been followed for 3 months or discontinued before month 3. The median age was 50 years (range 20-81), 22% had Ph+ B-ALL. The median number of prior lines of treatment was 2 (range 1-5), 42% underwent prior transplant. At screening, patients had a median of 55% BM blasts (range 6-96%) and 26% had EMD. The geometric mean of peak CAR expansion was 126147.6 copies/ug genomic DNA. Persistence was ongoing in majority of responders at last follow-up. Based on central assessment, the CR/CRi was 70% [95% CI: 55%, 82%] (p-value < 0.0001). As of 9th September 2022, a total of 92 patients received obe-cel and were evaluable for safety. 63% developed any grade CRS (3% Grade ≥ 3) at a median of 9 days post-infusion and a median duration of 5 days. Any grade ICANS was observed in 23% (8% Grade ≥ 3) at a median of 15 days post-infusion and of median duration 8 days. Other common Grade ≥ 3 adverse events regardless of causality were febrile neutropenia (25%) and anaemia (20%). **Conclusions:** The pre-specified interim analysis of the FELIX study demonstrated that obe-cel for adult r/r B-ALL is safe with low rates of Grade > 3 CRS and/or ICANS, even in patients with high burden disease. Obe-cel is effective with high CR/CRi rates and ongoing CAR T persistence in the majority of responders. The trial has completed dosing of all patients in Cohort A. Additional data and longer follow up will be reported at the conference. Clinical trial information: NCT04404660. Research Sponsor: Autolus Therapeutics plc.

Oral Abstract Session

Enhanced anti-tumor activity of CD5 CAR T cells manufactured with tyrosine kinase inhibitors in patients with relapsed/refractory T-ALL. *First Author: LaQuisa C Hill, Center for Cell and Gene Therapy, Baylor College of Medicine, Houston Methodist Hospital, Houston, TX*

Background: An effective CAR T cell platform for the therapy of T-ALL requires minimizing CAR-driven fratricide of normal T cells. CD5 is a pan-T-cell surface protein present in ~85% of T-ALL. We developed a 2nd generation CD5 CAR that produces minimal T cell fratricide without additional engineering. Tonic CAR signaling accelerated terminal differentiation of CD5 CAR T cells potentially reducing their potency. In this study, we evaluated whether blocking tonic signaling with tyrosine kinase inhibitors (TKI) ibrutinib and dasatinib improves anti-leukemic activity of CD5 CAR T cells in patients with r/r T-ALL (NCT03081910). **Methods:** In the initial cohort of patients (CH1, n = 8), we generated CD5 CAR T cells from autologous PBMCs followed by expansion in the presence of IL-7 and IL-15 without TKI. In the subsequent cohort (CH2, n = 7) we manufactured cells from autologous (Arm A; n = 4) or HSC donor-derived (Arm B; n = 3) PBMCs in the presence of TKI. A total of 14 pts were treated (9 adult and 5 pediatric; age 11-70 years [median 36 yrs]); one pediatric pt was treated on both cohorts. **Results:** In CH1, all pts received autologous CAR T cells: 1 pt on DL1 (1x10⁷ CAR T cells/m²), 5 on DL2 (5x10⁷ CAR T cells/m²), and 2 on DL3 (1x10⁸ CAR T cells/m²). In CH2, we treated 4 pts on Arm A (one on DL2; 3 on DL3) and 3 pts on Arm B (all on DL1). The overall expansion of CAR T cells was comparable between cohorts, but we observed more sustained persistence of CD5 CAR T cells in pts on CH2. In CH1, one pt experienced a morphologic CR. Of 7 pts treated on CH2, we observed 4 MRD-negative CRs (2 on Arm A and 2 on Arm B). The CAR T cells produced minimal early toxicity with most grade ≥ 3 AEs related to cytopenias, febrile neutropenia and transient abnormal laboratory values. CRS occurred in 3 pts on CH1 and 4 on CH2 (Arm A: n = 1; Arm B: n = 3); all $\leq$ grade 2. No pts developed ICANS. Two pts in CH2 (one on Arm A and Arm B) developed EBV viremia and post-transplant/immunodeficient lymphoproliferative disease (LPD) at wks 5 and 7 post-infusion, respectively. Both were treated with intensive multiagent chemotherapy, and one pt also received EBV specific T cells (EBVSTs) with significant reduction in viral load. Unfortunately, both passed away from complications of treatment for PTLD (unrelated to EBVSTs) with no evidence of residual T-ALL. No other significant infections occurred. **Conclusions:** These results demonstrate CD5 CAR T cells can induce clinical responses in heavily treated patients with r/r T-ALL. Manufacturing CD5 CAR T cells with TKI improved their potency and anti-tumor activity but also possibly suppressed CD5+ virus-specific T-cells thus leading to 2 cases of EBV associated LPD. We have subsequently modified our clinical protocol to administer prophylactic rituximab to EBV seropositive pts and identify a partially matched EBVST line prior to CAR T cell infusion as a strategy to prevent additional cases of LPD in future subjects. Clinical trial information: NCT03081910. Research Sponsor: U.S. National Institutes of Health.

Oral Abstract Session

Outcomes following brexucabtagene autoleucel administered as an FDA-approved therapy for adults with relapsed/refractory B-ALL. *First Author: Gregory Roloff, University of Chicago, Chicago, IL*

Background: In October 2021, brexucabtagene autoleucel (brexu-cel) became the first CAR-T cell therapy to receive FDA approval for adults (≥ 18 yrs) with relapsed/refractory (r/r) B-ALL. Approval was based on Phase II results of ZUMA-3, a single-arm, open-label, multicenter trial which reported on 55 treated patients with CR/CRi achieved in 71%; cytokine release syndrome (CRS) and neurologic toxicities occurred in 89% (grade 3-4, 24%) and 60% (grade 3-4, 25%), respectively. Here, we report outcomes of 76 adults with r/r B-ALL treated with post-approval brexu-cel at 13 U.S. centers. **Methods:** Retrospective data were collected across centers participating in a real-world outcomes collaborative of CAR-T in ALL (ROCCA). Descriptive statistics, Kaplan-Meier methodologies and cumulative incidence functions were used to summarize outcomes. **Results:** Among 76 patients infused, median age was 44 yrs (range, 18-81); 54% were male, 57% were non-Hispanic White (25% Hispanic), and 71% had Ph-neg disease. Median number of previous lines of therapy was 3.5 (range, 1-9) including blinatumomab in 53% and inotuzumab in 37%; 46% had relapsed post-transplant. Prior to apheresis, 69% of patients had active disease ($> 5\%$ marrow blasts or presence of extramedullary disease), including 8 patients with CNS3 disease, 19% had detectable measurable residual disease (MRD) only, and 12% were MRD-neg. Median time from apheresis to infusion was 31 days. Lymphodepletion was predominantly with flu/cy (88%); 5 received cy/cladribine, and one patient each received single agent cy, single agent cladribine, and single agent bendamustine. Among 65 patients at least 28 days post-CAR-T with response assessed, 90.8% achieved CR/CRi, of whom 83% were MRD-neg, including CNS disease clearance in 7/8 CNS3 patients. CRS and ICANS (ASTCT criteria) occurred in 81.6% (grade 3-4, 6.6%) and 59% (grade 3-4, 38.6%), respectively. Median follow-up for survivors was 196.5 days (IQR 135.5-284.5). At last follow-up, 21 patients progressed/relapsed and 13 had died (7 of B-ALL; 6 of neurotoxicity/infection). Cumulative incidence of relapse and death in remission at 180 days were 31.5% (95% CI: 19.7%-44.1%) and 8.9% (95% CI: 3.5%-17.5%), respectively, while six-month PFS and OS were 58.8% (95% CI: 44.6%-70.5%) and 86.7% (95% CI: 75.8%-92.9%), respectively. Eleven patients underwent allogeneic transplant in CR/CRi after brexu-cel; all of whom remain in remission at last follow-up. **Conclusions:** These data are the first to demonstrate post-approval efficacy and toxicity rates of brexu-cel in adults with r/r B-ALL. Unlike the ZUMA-3 population, 31% of patients infused in this real-world cohort lacked morphologically detectable disease and 8 had CNS3 prior to apheresis. Our data confirm high response rates associated with brexu-cel in adult ALL, but also highlight the need for interventions to reduce associated toxicities. Research Sponsor: None.

Oral Abstract Session

Efficacy and safety results from the COMMANDS trial: A phase 3 study evaluating luspatercept vs epoetin alfa in erythropoiesis-stimulating agent (ESA)-naïve transfusion-dependent (TD) patients (pts) with lower-risk myelodysplastic syndromes (LR-MDS). *First Author: Guillermo Garcia-Manero, Department of Leukemia, University of Texas M.D. Anderson Cancer Center, Houston, TX*

Background: Most pts with LR-MDS have limited responses to ESAs, thus there is an unmet need to treat anemia and reduce TD. Here we report interim results from the open-label, randomized phase 3 COMMANDS trial (NCT03682536) comparing the efficacy and safety of luspatercept vs epoetin alfa in ESA-naïve pts with LR-MDS. **Methods:** Eligible pts were ≥ 18 years old with IPSS-R-defined LR-MDS with or without RS, $< 5\%$ bone marrow blasts, sEPO levels < 500 U/L, required RBC transfusions (defined as 2-6 RBC units/8 weeks [wk]) for ≥ 8 wk immediately prior to randomization, and were ESA naïve. Pts were randomized 1:1 to receive subcutaneous luspatercept (starting dose 1.0 mg/kg, titration up to 1.75 mg/kg) once every 3 wk or epoetin alfa (starting dose 450 IU/kg, titration up to 1050 IU/kg) weekly for ≥ 24 wk. Primary endpoint was achievement of RBC transfusion independence (TI) ≥ 12 wk within the first 24 wk, with a mean hemoglobin increase ≥ 1.5 g/dL. Secondary endpoints included achievement of hematologic improvement-erythroid (HI-E) response ≥ 8 wk per IWG 2006 criteria, RBC-TI 24 wk and ≥ 12 wk, and safety. **Results:** As of Aug 31, 2022, 178 pts received luspatercept and 176 epoetin alfa, with median treatment durations of 41.6 and 27.0 wk, respectively. Baseline pt characteristics were balanced across treatment arms. Of 301 pts included in the efficacy analysis, 86 (58.5%) pts receiving luspatercept vs 48 (31.2%) epoetin alfa achieved the primary endpoint of RBC-TI ≥ 12 wk with concurrent mean Hb increase ≥ 1.5 g/dL within the first 24 wk ($P < 0.0001$). HI-E ≥ 8 wk was achieved by 109 (74.1%) luspatercept and 79 (51.3%) epoetin alfa pts ($P < 0.0001$). Within the first 24 wk of treatment, RBC-TI 24 wk and ≥ 12 wk was achieved by 70 (47.6%) and 98 (66.7%) luspatercept pts, respectively, vs 45 (29.2%) and 71 (46.1%) epoetin alfa pts ($P = 0.0006$ and 0.0002). Treatment-emergent adverse events (TEAEs; any grade) were reported by 164 (92.1%) luspatercept and 150 (85.2%) epoetin alfa pts; 8 (4.5%) and 4 (2.3%) pts discontinued due to TEAEs. Treatment-related AEs were reported by 54 (30.3%) luspatercept and 31 (17.6%) epoetin alfa pts. AML progression was reported in 4 (2.2%) luspatercept and 5 (2.8%) epoetin alfa pts. Overall rates of death were comparable between arms during treatment and post-treatment (32 [18.0%] luspatercept, 32 [18.2%] epoetin alfa pts). **Conclusions:** Compared with epoetin alfa, luspatercept led to clinically meaningful and statistically significant improvements in RBC-TI and erythroid response, as well as duration of response. Luspatercept safety results were consistent with previous findings. These data show, for the first time, superiority of an innovative therapy over ESAs in ESA-naïve pts with TD LR-MDS. Luspatercept could represent a new standard of care for pts with TD LR-MDS. Clinical trial information: NCT03682536. Research Sponsor: Bristol Myers Squibb.

7004 Oral Abstract Session

IMerge: Results from a phase 3, randomized, double-blind, placebo-controlled study of imetelstat in patients (pts) with heavily transfusion dependent (TD) non-del(5q) lower-risk myelodysplastic syndromes (LR-MDS) relapsed/refractory (R/R) to erythropoiesis stimulating agents (ESA). *First Author: Amer Methqal Zeidan, Department of Internal Medicine, Yale School of Medicine and Yale Cancer Center, Yale University, New Haven, CT*

Background: Unmet needs remain for red blood cell (RBC) TD pts with LR-MDS R/R or ineligible for ESA. In P2 of the IMerge study (NCT02598661), heavily RBC TD ESA R/R non-del(5q) LR-MDS pts naive to lenalidomide and hypomethylating agents (len/HMA) treated with imetelstat, a telomerase inhibitor, achieved durable and continuous transfusion independence (TI). We report primary data from the P3 study of imetelstat in such pts. **Methods:** Heavily RBC TD ESA R/R non-del(5q) LR-MDS pts naive to len/HMA were randomized 2:1 to receive imetelstat 7.5 mg/kg or placebo every 4 wks. Primary endpoint was 8-wk TI; subgroup analyses included IPSS risk, prior transfusion burden and ring sideroblast (RS) status. Secondary endpoints included 24-wk TI, TI duration and hematologic improvement-erythroid (HI-E). Variant allele frequency (VAF) changes were explored. **Results:** As of Oct 2022, 178 pts were randomized. The primary endpoint was met (Table); 39.8% vs 15.0% of pts receiving imetelstat vs placebo, respectively, achieved 8-wk TI. The rate of 8-wk TI was significantly higher with imetelstat vs placebo across subgroups, including RS negative pts. Median TI duration was significantly longer for imetelstat vs placebo, 51.6 vs 13.3 wks, $P < 0.001$. Pts receiving imetelstat had significantly higher mean hemoglobin ($P < 0.001$) and fewer transfusions ($P = 0.042$) over time than those on placebo. In 3 of 4 genes frequently mutated in MDS, VAF reduction was significantly greater in pts treated with imetelstat than placebo: SF3B1 ($P < 0.001$), TET2 ($P = 0.032$), DNMT3A ($P = 0.019$) and ASXL1 ($P = NS$). SF3B1 VAF reduction correlated with longer TI duration, $P < 0.001$. No new safety signals were identified. The most common Grade 3/4 AEs were thrombocytopenia and neutropenia, with similar rates of Grade ≥ 3 bleeding and infections on imetelstat and placebo. In pts treated with imetelstat, cytopenias were manageable, of short duration, and $>80\%$ were reversible to Grade ≤ 2 within 4 wks. **Conclusions:** For this LR-MDS pt population, imetelstat demonstrated statistically significant and clinically meaningful efficacy with high 8- and 24-wk TI rates, prolonged TI duration and increased hemoglobin. VAF reduction and its correlation to clinical endpoints support imetelstat's disease-modifying potential. Safety results were consistent with prior reported experience. Clinical trial information: NCT02598661. Research Sponsor: Geron Corporation.

7006 Oral Abstract Session

Chemotherapy-free treatment with inotuzumab ozogamicin and blinatumomab for older adults with newly diagnosed, Ph-negative, CD22-positive, B-cell acute lymphoblastic leukemia: Alliance A041703. *First Author: Matthew Joseph Wieduwilt, Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Winston-Salem, NC*

Background: Older adult patients (pts) with Philadelphia-chromosome-negative (Ph-) acute lymphoblastic leukemia (ALL) have poor survival with chemotherapy. The α -CD22 Ab-drug conjugate inotuzumab ozogamicin (InO) and α -CD19/CD3 T-cell engager blinatumomab (blina) were each superior to chemotherapy in Phase III studies in relapsed/refractory B-ALL. Because InO induces high CR rates and blina can induce durable remissions in low burden disease, we conducted a Phase II trial of induction InO then blina for older adults with newly-diagnosed (ND), Ph-, B-ALL. **Methods:** Eligible were pts ≥ 60 years old with ND, Ph-, CD22+ ($\geq 20\%$ of blasts) B-ALL without plan for allogeneic HCT (alloHCT). Pts with CNS leukemia or liver disease were excluded. Induction IA was InO 0.8 mg/m² day (d) 1, 0.5 mg/m² d8, d15 IV on a 21d cycle. Pts with adequate cytoproduction (marrow blasts by $\geq 50\%$ or cellularity $\leq 20\%$) after IA went to IB if in CR/CRi (InO 0.5 mg/m² d1, d8, d15 IV; 28d cycle) or IC if no CR/CRi (InO 0.8 mg/m² d1, d8, d15 IV; 28d cycle). Those without cytoproduction to IA started course II blina. Pts without events in IA/B/C received course II blina CIV (9 mcg/d x 7d then 28 mcg/d x 21d; 14d break; 28 mcg/d x 28d). Pts with CR/CRi to InO received 2 more 28d cycles of blina, others received 3 more. CNS prophylaxis was methotrexate 15 mg intrathecal x 8. The primary endpoint was 1-yr event-free survival (EFS) with a lower limit of a 90% CI for 1-yr EFS $>10\%$ defined as success. EFS was the time from therapy start to failure to achieve CR/CRh/CRi by end Course II, progression, relapse, or death, whichever occurred first. **Results:** Thirty-three eligible pts were treated (1 ineligible, 2nd malignancy). The median age was 71 years (range 60-84). Median WBC count was 3,200/mcl (range 6-38,000). Median CD22 expression was 92% (range 21-100%). Eight pts had therapy-related ALL. The cumulative CR rates through Course IA/B/C and Course II were 85% and 97%, respectively (Table). With median follow up of 22 mo, the 1-yr EFS was 75% (95% CI 61-92%). The 2-sided 90% CI was 63-89% for 1-yr EFS with lower bound above 10% indicating regimen success. Twelve pts had events: 9 relapses, 2 deaths in remission (1 after alloHCT), and 1 death without remission from respiratory failure with sinusoidal occlusion syndrome of liver. The 1-yr OS was 84% (95% CI 72-98%). Nine pts have died, 6 after relapse. **Conclusions:** InO induction then blina consolidation is highly active for ND, Ph-, CD22+ B-ALL. The regimen is an option for older adults and a comparator regimen for future studies. Support: U10CA180821, U10CA180882, U10CA180820 <https://acknowledgments.alliancefound.org>. 7005 Oral Abstract Session

A first-in-human study of CD123 NK cell engager SAR443579 in relapsed or refractory acute myeloid leukemia, B-cell acute lymphoblastic leukemia, or high-risk myelodysplasia. *First Author: Anthony Selwyn Stein, City of Hope National Medical Center, Duarte, CA*

Background: SAR'579 is a trifunctional natural killer (NK) cell engager targeting CD123 antigen and co-engaging Nkp46 and CD16a on NK-cells. SAR'579 facilitates the formation of a cytolytic synapse between NK-cells and CD123-positive tumor cells leading to NK-cell activation and tumor cell killing. We herein report preliminary safety and efficacy data of SAR'579 from a phase 1/2 trial in patients with relapsed or refractory acute myeloid leukemia (R/R AML), B-cell acute lymphoblastic leukemia or high risk-myelodysplasia (NCT05086315). **Methods:** SAR'579 was administered intravenously twice weekly or once weekly (QW), depending on the dose level (DL) for the first 2 weeks of cycle 1 and then weekly for rest of induction cycles. A patient receives approximately three 28-day induction cycles with patients achieving a complete remission (CR) or incomplete hematologic recovery (CRi) per International Working Group criteria transitioning to a 56-day maintenance period with dosing approximately every 29 days. The primary objectives were to establish safety/tolerability and anti-leukemic activity (composite complete remission [CRc] = CR+CRi). **Results:** With a cutoff date of January 27, 2023, total 23 patients with R/R AML across 6 DLs (3 patients DL1 and 4 each in DL2 - DL6) were included in the safety population. The median age was 70 years (range: 21 - 80) with 9 patients (39.1%) reporting prior hematopoietic stem cell transplantation (HSCT) and 16 (69.6%) had prior exposure to venetoclax. Patients received a median of 2 cycles (range: 1 - 7) for median duration of 7 weeks (range: 1 - 25) and escalating doses of SAR'579 between 10 - 3000 μ g/kg/dose in cycle 1 and 100 - 3000 μ g/kg QW for the rest of induction cycles. No dose limiting toxicities (DLTs) were observed among the 21 DLT-evaluable patients, until highest dose of 3000 μ g/kg QW. The most common treatment emergent adverse events (TEAEs) included infusion-related reactions (n = 10 [43.5%]) and nausea (n = 7 [30.4%]). TEAEs were reported in 22 patients (95.7%) with grade 3/4 adverse events (AEs) in 18 (78.3%) and treatment-related AEs in 16 patients (69.6%), respectively. There were 2 cases of cytokine release syndrome (n = 1 grade 1 and n = 1 grade 2) and no case of immune effector cell-associated neurotoxicity syndrome. No patient reported TEAE leading to permanent discontinuation of SAR'579. The CRc rate was 13.0% (3/23 patients evaluable for response). In DLs with a highest dose of 1000 μ g/kg QW, 3/8 (37.5%) patients achieved a CR (2 CR/1 CRi). The median time to first CR/CRi was 16.1 weeks 95% confidence interval (8.1 - Not Estimable [NE]), and the median duration of CR/CRi is NE due to limited follow-up time. **Conclusions:** SAR'579 was well tolerated up to doses of 3000 μ g/kg QW with observed clinical benefit in patients with R/R AML. The trial continues to accrue patients. Clinical trial information: NCT05086315. Research Sponsor: Sanofi.

7007 Oral Abstract Session

A phase I trial of dose-adjusted EPOCH plus inotuzumab ozogamicin (InO) in adults with relapsed/refractory (R/R) B lymphoblastic leukemia/lymphoma (B-ALL). *First Author: Noam Edward Kopmar, University of Washington/Fred Hutchinson Cancer Center, Seattle, WA*

Background: Outcomes for adults with R/R B-ALL remain poor, with existing options limited by efficacy and safety. InO has been combined with low-intensity chemotherapy, the benefit of which is unclear. DA-EPOCH is safe and active as frontline therapy in adults with ALL, so we combined this with InO in adults with R/R B-ALL (NCT03991884). Aims: The primary objective was to estimate the maximum tolerated dose (MTD) of InO when added to DA-EPOCH. **Methods:** Eligible patients (pts) were adults with R/R CD22+ B-ALL with $\geq 5\%$ blood or marrow (BM) blasts or ≥ 1 site of measurable extramedullary disease (EMD); other eligibility criteria included ECOG ≤ 2 and no history of sinusoidal obstructive syndrome (SOS) or chronic liver disease. DA-EPOCH was given on days (d) 1-5 with GCSF. After cycle 1, dose adjustments to EPOCH were made based on hematologic nadirs from the prior cycle. Three dose levels (DL) of InO were studied, with InO given on d 8 + 15 as follows (respectively): 0.3 + 0.3 mg/m² (DL1); 0.6 + 0.3 mg/m² (DL2); and 0.6 + 0.6 mg/m² (DL3). Up to 4 28-d cycles were given. The MTD was the highest DL of InO that yielded $\leq 33\%$ rate of dose limiting toxicity (DLT), defined as grade 4+ non-heme treatment-related adverse events (TRAEs), any SOS regardless of timing, unable to complete 1 cycle due to TRAE, and treatment delays > 3 weeks. After the first 5 pts received DL1, a Bayesian Optimal Interval Design was used. Target accrual was 24 pts. BM and EMD response was assessed by NCCN criteria, with measurable residual disease (MRD) evaluated by multiparameter flow cytometry (MFC) and clonoSEQ. **Results:** 24 pts were screened: all were enrolled and evaluable for DLT and response. Median age was 46 (range: 28-76) years; median prior lines of therapy was 3 (range: 1-16); 13 pts (54%) had previously received allograft (HCT). 5 pts were enrolled at DL1, 8 pts at DL2, and 11 pts at DL3. There were 4 total DLTs: 1 at DL1 (grade 4 sepsis) and 3 at DL3 (grade 4 hyponatremia; delay for pancytopenia; grade 5 SOS after post-study HCT). DL3 was thus determined to be the MTD. No deaths occurred on study. Three pts (12%) had Grade 3 AST/ALT elevation; the SOS rate was 4%. Other grade 3+ non-heme TRAEs seen in >1 pt included infections (6 pts; 9 events), neutropenic fever (7; 8), and oral mucositis (3; 4). In the pts with $\geq 5\%$ blood/BM blasts (n=20), the CR/CRi rate was 85%. By MFC, 70% achieved MRD- (45% after 1 cycle); using clonoSEQ, 33% were MRD-. Of the 6 pts with EMD, 83% responded (4 CR; 1 PR). The per-protocol and intent-to-treat (ITT) overall response rate was 83%. With median follow-up of 12 months (m), the median overall and relapse-free survival were 19 m and 12 m. Nine (38%) pts received post-study HCT. **Conclusions:** The addition of InO to DA-EPOCH in adults with heavily-pre-treated R/R B-ALL is safe, with ITT response rates among the highest reported to date. Many pts proceeded to HCT. Further investigation of this combination is warranted. Clinical trial information: NCT03991884. Research Sponsor: Pfizer; U.S. National Institutes of Health.

Oral Abstract Session

Specialty cancer care and survival in AYA ALL: A U.S. multi-state analysis.

First Author: Lori S. Muffy, Division of Blood and Marrow Transplantation and Cellular Therapy, Stanford University School of Medicine, Stanford, CA

Background: Unlike children with acute lymphoblastic leukemia (ALL) who receive cancer care almost exclusively from pediatric oncologists at specialized cancer centers (SCC; defined here as National Cancer Institute and/or Children's Oncology Group designated cancer centers), adolescents and young adults (AYAs; 15-39 years) in the United States receive care in a variety of settings. Using state-wide population-based data, we sought to describe the health care delivery settings in which AYAs with ALL receive treatment and determine associations between front-line treatment at an SCC and leukemia-specific and overall survival (LSS/OS). **Methods:** We used data from the 2004-2018 California (CA), New York (NY), and Texas (TX) state cancer registries to identify front-line treatment setting of AYAs newly diagnosed with ALL. Multivariable logistic regression models evaluated characteristics associated with receiving treatment at an SCC. Cox proportional hazards regression models evaluated the associations with LSS/OS. All models were adjusted for gender, age, sex, race/ethnicity, socioeconomic status, insurance, and diagnosis year. **Results:** The cohort was comprised of 2283 (CA), 795 (NY), and 955 (TX) AYAs with ALL. Across all states, approximately 70% were ≤ 18 years and 65% were male. Race/ethnicity varied by state: a majority in CA (63%) and TX (64%) were Hispanic, while most in NY were non-Hispanic White (NHW) (50%). Health insurance coverage also varied: most in CA were publicly insured (48%), while most in NY were privately insured (54%); TX had the highest rate of uninsured (18%). Treatment at an SCC occurred in 48.2% (CA), 44.4% (NY), and 19.5% (TX) of AYAs, increasing in CA and NY over time, but remaining unchanged in TX. Among all states, older age and uninsured status were significantly associated with lower odds of treatment at an SCC. In both CA (OR 0.58, 95% CI 0.45-0.74) and TX (OR 0.55, 95% CI 0.35-0.86), Hispanic patients had significantly lower odds of treatment at an SCC than NHW. In NY (OR 0.45, 95% CI 0.31-0.67) and TX (OR 0.49, 95% CI 0.3-0.88), publicly insured AYAs had significantly lower odds of receiving treatment at an SCC than those with private insurance. Front-line treatment at an SCC was significantly associated with both superior LSS (HR 0.73, 95% CI 0.63-0.85) and OS (HR 0.73, 95% CI 0.63-0.85) in CA and superior LSS (HR 0.70, 95% CI 0.51-0.94) and OS (HR 0.61, 95% CI 0.45-0.83) in TX; a non-significant association was seen in NY (LSS: HR 0.86, 95% CI 0.65-1.12; OS: HR 0.83, 95% CI .64-1.08). **Conclusions:** Only 20-50% of newly diagnosed AYA ALL patients receive front-line treatment at SCCs, with age, race/ethnicity, and insurance type independently influencing AYA ALL care setting. We show that the treatment of ALL at an SCC is associated with superior survival, highlighting the importance of statewide and national policy efforts to improve access and reduce inequities in AYA ALL. Poster Discussion Session

Identification and management of clonal hematopoiesis of indeterminate potential (CHIP) in cancer survivors: The Cleveland Clinic experience. *First Author: Teodora Kuzmanovic, Cleveland Clinic, Cleveland, OH*

Background: Clonal hematopoiesis (CH) of indeterminate potential (CHIP) is found in healthy populations as well as cancer patients (pts) and is associated with (w/) cardiovascular disease (CVD), risk of hematologic neoplasms (HN), and all-cause mortality. Germline variants (var) predispose to CHIP. However, described var are nonspecific to solid tumor pts. Identifying CHIP risk factors and mitigation strategies is paramount for improving outcomes. **Methods:** Pts in breast (BC) and head & neck cancer (HNC) survivorship (2020-2023) following curative treatment (tx) were eligible for our 10 year (yr) prospective study of annual next generation sequencing (NGS) and complete blood count (CBC) to identify CHIP. Mutations (mt) were classified as clinically significant (CS) or var of unknown significance (VUS), and as CH (med. VAF 4.7%) or potentially germline (PG; med. VAF 50%). Pts w/ CHIP were managed in both CHIP Clinic (CC) and Preventive Cardiology (PC) for monitoring and CVD reduction. Fisher's exact and ANOVA tests were used for analyses. **Results:** Of 168 pts enrolled (117 BC, 51 HNC), 158 had NGS: 73 yr 1, 85 through yr 2 or 3; 22 pts received chemotherapy (CT), 49 radiation therapy (RT), 72 CT & RT (CRT). Sixty-eight pts (43%) had a mt; 21 (13%) had CHIP (6 w/ PG VUS). CHIP was found to be associated w/ older age (69 vs. 58, $p=0.0002$). The most common CHIP mt were *DNMT3A* ($n=11$), *PPM1D* (6), *TET2* (6), *JAK2* and *TP53* (2). Two pts without yr 1 mt developed CHIP in yr 2. For *PPM1D*, 2 PG VUS were point mt from DNA transitions while 6 CHIP were truncating from transversions and deletions. All pts w/ *PPM1D* had RT (7/8 CRT), suggesting a molecular signature which varies from transition-driven aging. Six pts had thrombocytopenia (TP), 3 w/ *PPM1D* CHIP. TP was more common in CHIP (OR 11, $p=0.0356$) and *PPM1D* (OR 29, $p=0.0016$). In this cohort, anemia was not seen in pts w/ CHIP ($p=0.048$). Normal CBC was 6x less common in pts w/ CRT ($p=2.3 \times 10^{-7}$). Seven CHIP pts were seen by PC; 4 had yr 2 NGS following PC visit. All pts had addition of new/dose escalation of current CVD medication. Two CHIP pts had stable NGS; 2 CHIP & PG VUS pts had clonal changes including mt disappearance and acquisition. Of note, the PG VUS's were assessed for institutional incidence in 3,918 HN pts w/ NGS data and in Mastermind (MM) for frequency of occurrence in published literature. Sixteen PG VUS (40%) occurred at our institution (13 found in MM, 7 classified as rare (avg gnomAD MAF 6×10^{-4}) and associated w/ HN, notably *TET2* ($n=3$). **Conclusions:** This ongoing prospective study is one of the largest to report characteristics and outcomes of CHIP pts in CC/PC and is expected to accrue more in expansion. We anticipate highlighting risk factors for CHIP progression and report novel PG VUS, which may portend health risks based on their prevalence in HN. Furthermore, it appears that a strategy for CVD prevention may promote clonal stability in survivorship pts. Research Sponsor: Velosano.

Poster Discussion Session

Adherence and satisfaction with remote cognitive training in blood or marrow transplant (BMT) survivors: The cognitive training and attitudes towards genetics (cTAG) study. *First Author: Noha Sharafeldin, Department of Hematology & Oncology, School of Medicine, University of Alabama at Birmingham, Birmingham, AL*

Background: Cognitive impairment is prevalent in hematologic cancer survivors treated with BMT. There is a need for remote, accessible, and engaging interventions in order to mitigate adverse cognitive outcomes following treatment. We report on feasibility, satisfaction and preliminary efficacy of a remote cognitive training intervention in BMT survivors. **Methods:** Participants enrolled in the cTAG study were randomized to either using the online brain games Lumosity program daily for 12 weeks, or the waitlist arm. Cognitive function was assessed using a comprehensive battery covering executive function, processing speed, attention, memory and learning domains, and PROMIS Short Form4a for cognitive complaints. Participants' satisfaction was measured using an exit survey. Standardized T-scores (mean: 50; standard deviation: 10), were used for domain-specific outcomes. An intention-to-treat analysis was used to model the change in cognition at 12 weeks compared to baseline, between study arms, controlling for baseline cognitive reserve, age, sex and race/ethnicity to enhance estimate precision. **Results:** Feasibility: 150 eligible patients were approached, 88 (58.7%) consented and 71 (80.7%) were randomized. Fifty-five patients completed the study (28 on active and 27 on waitlist arm). Post-randomization attrition rate was 19.7%. Median age at time of test was 58y (range: 27-74); 60% males, 83.6% Non-Hispanic White and 16.4% non-Hispanic Black, and 49% with low cognitive reserve. There were no significant differences between study arms. Adherence on active arm: Median of 87.5% for 4.9 days/week and 10/12 weeks. Preliminary Efficacy: Compared to the waitlist arm, scores improved for the active arm in attention (2.14 points, SE=1.01, p -value=0.039) and memory domains (5.63, SE=2.40, p -value=0.02). There was no significant change on cognitive complaints between the two arms. Satisfaction: Overall 78.2% of patients had no prior experience with cognitive training, 58.7% felt it helped their recovery, 82.6% found time commitment reasonable, 87% found it easy to follow, fun, engaging and appropriately challenging. The intervention had a 91.3% satisfaction rate; 73.9% indicating they would continue training and 87% would recommend it to others. Participants' perceived benefit from training was highest for attention (89.1%), memory (73.9%), and visual tasks (69.6%). Only 11% of participants perceived benefits for real word tasks. **Conclusions:** The intervention was feasible, favorably rated, and associated with both perceived and objective improvements in attention and memory domains. Remote cognitive training carries several advantages for BMT patients including early and convenient at home administration supporting its clinical utility and potential long-term adoption following treatment. Clinical trial information: NCT03094026. Research Sponsor: Leukemia and Lymphoma Society; Be The Match Foundation.

Poster Discussion Session

Association of Agent Orange and myeloproliferative neoplasms, thrombosis, and bleeding among veterans. *First Author: Andrew Chua Tiu, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: The Myeloproliferative Neoplasms (MPNs) which include Polycythemia Vera (PV), Essential Thrombocythemia (ET), and Primary Myelofibrosis (MF) are acquired stem cell disorders with constitutively activated pathways from shared mutations leading to thrombotic and bleeding complications. Agent Orange (AO) is a chemical herbicide that was utilized during the Vietnam War and was associated with sarcomas and B-cell lymphomas. There is inadequate evidence of the association between AO exposure and development of MPNs, increased risk of bleeding, arterial thrombosis (AT), and venous thrombosis (VT). **Methods:** Utilizing the Veterans Affairs Informatics and Computing Infrastructure (VINCI) database, we performed a case control study from January 1, 2006 - January 26, 2023. We utilized ICD-9 and I0 codes to identify MPN patients, any AT, VT, and bleeding events. Age-matched controls (1:1) were selected from VINCI database. Qualitative data was compared by chi-square test. **Results:** We included all 95,768 MPN patients (0.7% MPN crude prevalence rate), 43,263 ET, 48,854 PV, and 3,651 MF patients. Among all MPNs, 6.4% were female, 93.6% were male, 76% were White, 13.8% Black, 0.8% American Indian, 0.9% Pacific Islander, and 8.5% unknown race. 86.8% of patients with MPN were aged 60 years or older. When comparing MPNs vs. controls, there was increased AT (29.5% vs. 24.5%, $p < 0.0001$), VT (6.7% vs. 3.8%, $p < 0.0001$), and both AT & VT (8.1% vs. 4.2%, $p < 0.0001$). Among female MPN patients, there were 16.2% AT, 6.1% VT, 45.5% bleeding events vs. 30.4% AT, 6.7% VT, and 39% bleeding events among male MPN patients, respectively, $p < 0.0001$. Among MPN patients who are greater than 60 years old, 95.4% had AT, 88% had VT, 94.4% had both AT & VT, and 89.4% had bleeding events. Bleeding events were higher in ET (44%), PMF (41.5%), PV (35%) vs. the control group (24.6%), $p < 0.0001$, and gastrointestinal bleeding was the most common site for both controls and MPNs followed by genitourinary or pulmonary. Among the different races, there is higher AT (range 22.6-31.5%) compared to VT (range 5.3-7.8%). There is a significant association between AO exposure and development of MPNs (odds ratio 1.61, 95% CI 1.57 to 1.65, $p < 0.0001$). There is a higher AT (36%) among MPNs with AO exposure compared to 28.2% in MPNs without AO exposure, $p < 0.0001$. There is a higher AT (28.7%) among controls with AO exposure compared to 24% in controls without AO exposure, $p < 0.0001$. There was 41.2% bleeding event with MPN with AO exposure compared to 39% in MPN without AO exposure, $p < 0.0001$. **Conclusions:** This is the largest database evaluating MPNs, thrombosis, and bleeding in veterans exposed to AO. There is an association of increased risk of development of MPNs, increased AT, and increased bleeding with AO exposure. Further studies including JAK2 mutation, CHIPs, and cardiovascular risk factors will be needed to evaluate contribution to thrombosis and bleeding risk. Research Sponsor: None.

7012 Poster Discussion Session

Updated efficacy and safety data from the AGILE study in patients with newly diagnosed acute myeloid leukemia treated with ivosidenib + azacitidine compared to placebo + azacitidine. *First Author: Stéphane De Botton, Institut Gustave Roussy, Paris, France*

Background: Ivosidenib (IVO) is a potent oral targeted inhibitor of mutant *IDH1*. In the AGILE study in patients (pts) with newly diagnosed *IDH1*-mutated acute myeloid leukemia, IVO plus azacitidine (AZA) significantly improved event-free survival (EFS), overall survival (OS), complete remission (CR), and CR or CR with partial hematologic recovery (CR+CRh) rates v placebo (PBO) plus AZA. As of March 2021, median OS (mOS) was 24 months (IVO+AZA) v 7.9 months (PBO+AZA; HR: 0.44; p=0.0005). Long-term follow-up data are presented. **Methods:** In the double-blind AGILE study, pts were randomized 1:1 to IVO 500 mg QD + AZA 75 mg/m² SC or IV for 7 days in 28-day cycles, or PBO+AZA. Long-term follow-up data (June 2022) for OS, blood count recovery, transfusion independence and safety are described here. **Results:** 148 pts were randomized: 73 to IVO+AZA; 75 to PBO+AZA. Median treatment duration was 10.8 months (IVO+AZA) v 3.2 months (PBO+AZA). Five PBO+AZA pts crossed over to IVO+AZA after March 2021 (Table), and no adjustment was made for crossover in the updated OS analysis. At a median follow-up of 28.6 months, mOS was 29.3 months (95% CI 13.2, not reached) for IVO+AZA v 7.9 months (95% CI 4.1, 11.3) for PBO+AZA (HR 0.42 [0.27, 0.65]; p<0.0001). OS rates were 62.9% and 38.3% at 12 months and 53.1% and 17.4% at 24 months, with IVO+AZA and PBO+AZA, respectively. In the IVO+AZA arm, hemoglobin levels steadily increased from baseline (BL; 88.8 g/L) to cycle 8, and then stabilized; mean platelet count recovered from BL values (72.7 x 10⁹/L) as early as week 8 (171.9 x 10⁹/L) and remained stable; and mean neutrophil counts rapidly increased from BL (0.98 x 10⁹/L) to week 3 (3.99 x 10⁹/L) and week 4 (4.36 x 10⁹/L), and then stabilized to within the normal range. Conversion from BL transfusion dependence (red blood cell and/or platelet transfusion dependence) to post-BL transfusion independence was significantly higher with IVO+AZA than PBO+AZA (53.8% v 17.1%, respectively; p=0.0004). There were fewer neutropenic fever events (27.8% v 33.8%) and infections (34.7% v 51.4%) with IVO+AZA than with PBO+AZA. TEAEs led to discontinuation of IVO+AZA or PBO+AZA in 26.4% and 25.7% of pts, respectively. **Conclusions:** Updated data on OS (>5 months longer mOS and a greater risk reduction in deaths compared to the initial analysis), transfusion independence, blood count recovery and safety confirms the clinically and statistically robust benefit in favor of IVO+AZA at long-term follow up. Patient disposition. Clinical trial information: NCT03173248. Research Sponsor: This study was supported by Agios Pharmaceuticals, Inc. Servier Pharmaceuticals LLC has completed the acquisition of Agios' oncology business.

	Patients, n (%)

Outcomes of 3- versus 5-day administration schedule of consolidation cytarabine in adults with acute myeloid leukemia (AML). *First Author: Kendall Diebold, University of Alabama at Birmingham, Birmingham, AL*

Background: Consolidation therapy with intermediate to high-dose cytarabine is critical to prevent relapse in AML. Cytarabine is typically administered every 12 hours on days 1, 3, 5. Two large studies have examined a condensed 3-day administration schedule in patients <60 years and demonstrated a shorter time to absolute neutrophil count (ANC) recovery without compromising long term outcomes. However, use of this regimen in patients ≥60 years has not been evaluated. Here we report our experience with the condensed administration schedule compared with the standard schedule in patients over and under 60 years. **Methods:** All patients with AML in first complete remission (CR) following intensive induction chemotherapy receiving consolidation at our institution between 1/1/2020 to 12/31/2021 were included in the study. Patients received cytarabine every 12 hours on days 1, 3, 5 (AC135) from 1/1/2020 – 12/31/2020 and cytarabine every 12 hours on days 1, 2, 3 (AC123) from 1/1/2021 – 12/31/2021. All patients received peg-filgrastim support. Data was collected to determine time to ANC recovery >1,000/μL, hemoglobin (Hb) >8g/dL, and platelets >75,000/μL. Comparison of continuous variables between two groups was done using multiple t-tests. **Results:** Between 1/1/2020 - 12/31/2021, 91 patients received at least one cycle of consolidation with 212 individual encounters. 38 patients received all cycles with AC135, 45 received AC123, and 8 received at least one cycle each of AC123 and AC135. Median age of the AC123 cohort was 50.2 years (range 19-72 years) and 54.3 years for the AC135 cohort (range 22-72 years). For patients ≥60 years of age, 33% (71/213) of the encounters were in the AC123 cohort and the rest in AC135 cohort. Median dose of cytarabine was 5,100 mg/dose in AC123 and 4,600 mg/dose in AC135 (p=0.02). Median time to ANC recovery, hemoglobin, and platelets as well as hospital-related outcomes are described in the table. In patients ≥60 years, median time to ANC recovery was 16.5 vs. 18.6 days (p=0.03) and platelet recovery was 17.4 vs. 19.7 (p=0.0008) in AC123 vs AC135 respectively. No neurotoxicity events were noted. Complication rates were similar in both arms. **Conclusions:** Our study demonstrates that AC123, as compared to AC135, is safe and leads to earlier hematopoietic recovery in adults under and over 60 years. AC123 should be considered the preferred schedule of consolidation therapy administration. Research Sponsor: None.

Addition of venetoclax to FLAI induction chemotherapy (VFLAI) improves survival in patients with intermediate and high-risk AML vs FLAI and 3+7: A GIMEMA Italian cooperative analysis. *First Author: Giovanni Martinelli, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRST (IRCCS), Meldola, Italy*

Background: Venetoclax combined with intensive chemotherapy proved to be safe with promising activity. The GIMEMA AML1718 trial (NCT03455504) was based on the administration of venetoclax-FLAI (fludarabine, idarubicin, cytarabine) to intermediate/high-risk ELN2017 AML. **Methods:** To investigate the potential advantage of the addition of venetoclax, patient-level data from GIMEMA AML1718 (V-FLAI group, n=57) were compared to “3+7”-like induction (AML1310, Venditti et al. 2019, 3+7 group, n=445), and to FLAI real-life experience (Guolo et al. 2016, FLAI group, n=155) using a propensity score matching. In the model, we included the following variables: age at diagnosis, gender, ELN2017 risk classification and allogeneic transplant rate. For determining adequate balance, the diagnostic method employed was the standardized mean difference, visualized through a Love plot; a standardized bias score less than 0.2 was used as a criterion. The final weighted sample sizes are 183 (3+7), 54 (V-FLAI) and 155 (FLAI). Weights were calculated with a multinomial logistic regression model. The Odds Ratio (OR) were estimated using logit models. Survival curves were compared by standard and pairwise Log-rank test. **Results:** FLAI, V-FLAI and 3+7 cohorts differed in terms of age (median: 52 vs 54 vs 49 years, respectively, p<0.001), in terms of risk category (p<.001) - since the low risk was not represented both in V-FLAI and FLAI trials -, in terms of transplant rate (45% vs 49% vs 27%, p<0.001) and female sex (43% vs 35% vs 48%, p=0.15). Being more recent, AML1718 had a shorter median follow-up (10.5 vs 75.8 vs 104.8 months). The matching weights produced the best balance, with SMDs <0.18 for all variables. After weighting, the CR rate observed in the V-FLAI group was higher than FLAI and 3+7, as well as MRD-negativity rate. In terms of Odds Ratio (OR) the probability of achieving CR in V-FLAI and FLAI patients was significantly higher compared to 3+7 patients (p=0.01 and p=0.03, respectively). Conversely, V-FLAI and FLAI did not differ in their probability to achieve CR (p=0.34). Concerning MRD, the OR associated to V-FLAI group was significantly higher (namely, a higher probability of MRD-negativity) of that associated to both FLAI and 3+7 treatments (p=0.005 vs FLAI; p=0.001 vs 3+7). Looking at survival outcomes at 12 months, upon weighting, DFS estimate of the V-FLAI group was higher than “3+7” and FLAI (p=0.048). **Conclusions:** VFLAI resulted in a deeper disease response as compared to other regimens. These results highlight the potential benefit of venetoclax added to intensive induction chemotherapy and suggest the role of fludarabine-based regimens as a backbone for high-risk disease. Research Sponsor: None.

	CR (OR)		MRD-negativity (OR)	
	Estimate	p	Estimate	p
FLAI vs 3+7	0.55	0.03	0.22	0.48
V-FLAI vs 3+7	0.91	0.01	1.40	0.001
V-FLAI vs FLAI	0.36	0.34	1.18	0.005

7015 Poster Discussion Session

A randomized, double-blind, phase 3 study of jaktinib versus hydroxyurea (HU) in patients (pts) with intermediate-2 or high-risk myelofibrosis (MF). *First Author: Yi Zhang, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China*

Background: Ruxolitinib and HU are recommended by Chinese MF guideline for splenomegaly. There is an unmet need for new treatments. Jaktinib, a novel JAK and AVCR1 inhibitor, showed promising activity on splenomegaly, anemia, and MF symptoms in a phase 2 study (NCT03886415). Here we present the interim results of a phase 3 study, which assessed the efficacy and safety of jaktinib compared to HU. **Methods:** Pts aged ≥ 18 with primary or post-ET/PV MF, DIPSS Int-2 or high risk, and no prior or ≤10 days' treatment with a JAK inhibitor were enrolled and randomly assigned (2:1) to receive jaktinib 100 mg bid plus HU placebo or HU 0.5g bid plus jaktinib placebo, stratified by DIPSS risk status (Int-2 or high risk). One interim analysis was pre-specified to be conducted when 70 pts completed the week (wk) 24 visit or met the criteria for treatment termination before wk 24. The primary endpoint was the proportion of pts with a spleen volume reduction of ≥ 35% from baseline (SVR35) at wk 24, measured by MRI/CT images and assessed centrally. Secondary endpoints included the best spleen response rate (defined as achieving SVR35 at any time), the proportion of pts with a ≥ 50% reduction in Total Symptom Score (TSS50), improvement of anemia, safety, etc. **Results:** This interim analysis (cut-off: April 8, 2022) included 47 pts receiving jaktinib and 23 receiving HU. 66.0% (jaktinib) and 69.6% (HU) had a baseline hemoglobin (Hb) < 100 g/L. 59.6% (jaktinib) and 69.6% (HU) were JAK2V617F positive. The SVR35 rates at wk 24 were 72.3% for jaktinib vs. 17.4% for HU (p≤0.0001). The best spleen response rates were 80.9% of jaktinib-treat pts vs. 26.1% of HU-treated pts (p=0.0001). The median maximum percentage change from baseline in spleen volume were -46.59% vs. -18.50%. The TSS50 rates at wk 24 were 63.8% for jaktinib vs. 43.5% for HU (p = 0.1163). 5 of 7 jaktinib-treated and two of 5 HU-treated pts who required RBC transfusion at baseline achieved a ≥50% decrease in RBC transfusion by wk 24. In transfusion-independent pts with baseline Hb ≤100 g/L, 39.3% for jaktinib and 15.4% for HU had a ≥20 g/L Hb increase. The most common grade ≥3 hematological treatment emergent adverse events (TEAEs) (jaktinib vs. HU) were anemia (25.5% vs. 43.5%), thrombocytopenia (17.0% vs. 39.1%), leukopenia (2.1% vs. 21.7%), neutropenia (2.1% vs. 21.7%) and decreased lymphocyte count (2.1% vs. 13.0%). Most common non-hematological TEAEs were upper respiratory tract infection (21.3% vs. 21.7%), elevated bilirubin (12.8% vs. 26.1%), fever (12.8% vs. 21.7%) and diarrhea (10.6% vs. 21.7%), predominantly of grade 1 or 2. TEAEs leading to treatment discontinuation occurred in 8.5% of jaktinib and 17.4% of HU. **Conclusions:** Jaktinib demonstrated significant clinical benefits over HU in MF pts for spleen response with improved symptom response and less cytopenias. Jaktinib may be a new treatment option for MF pts, especially for those with anemia. Clinical trial information: NCT04617028. Research Sponsor: Suzhou Zelgen Biopharmaceuticals Co, Ltd.

Poster Discussion Session

Safety and efficacy of luspatercept for the treatment of anemia in patients with myelofibrosis: Results from the ACE-536-MF-001 study. *First Author: Aaron Thomas Gerds, Cleveland Clinic, Cleveland, OH*

Background: Many patients (pts) with myelofibrosis (MF) experience anemia resulting from disease or JAK inhibitor therapy. The open-label, phase 2 ACE-536-MF-001 study (NCT03194542) evaluated the safety and efficacy of luspatercept (LUSPA) for the treatment of MF-related anemia. **Methods:** Eligible pts comprised 4 cohorts based on transfusion dependence (TD, defined as receiving 4–12 red blood cell [RBC] units/84 days [d] immediately up to cycle 1 d 1) and stable ruxolitinib (RUX) treatment; cohort 1: no TD, no RUX; cohort 2: TD, no RUX; cohort 3A: no TD, RUX; cohort 3B: TD, RUX. Pts received subcutaneous LUSPA 1.0 mg/kg (1.33 mg/kg for pts in cohort 3B expansion) with titration up to 1.75 mg/kg in 21-d cycles. Disease response was assessed at d 169 and treatment extended for pts showing clinical benefit; pts were followed for ≥ 3 years (y) post last dose. The primary endpoint was anemia response (defined as 84 consecutive d: ≥ 1.5 g/dL hemoglobin [Hgb] from baseline without transfusion [cohorts 1 and 3A] or RBC transfusion-free [cohorts 2 and 3B]); secondary endpoints included duration of response (DOR), transfusion frequency, change in Hgb level, and symptom response. **Results:** Of 95 pts in the ITT group, the most common reason for treatment discontinuation was lack of clinical benefit at d 169 (n = 28). Median (range) age was 71.0 (50–89) y. Most (54.7%) pts had primary MF, intermediate-risk 2 disease (75.8%), and > 2 y since initial diagnosis (74.7%). Median prior RUX therapy was 18.1 months (cohorts 3A/3B) and 84.7% of pts had baseline transfusion burden 6–12 units/84 d (cohorts 2/3B). Mean treatment duration was 42.8 weeks. Cohort 3B had the highest anemia response rate with 26.3% (95% CI, 13.4–43.1) of pts transfusion independent during the primary treatment period and 31.6% (95% CI, 17.5–48.7) transfusion independent during the entire treatment period; median (range) DOR was 448 d (85–1582). In cohort 3B: 19 (50.0%) pts had reduced transfusion burden by $\geq 50\%$ during the primary treatment period; 8 (21.1%) pts achieved mean Hgb increase ≥ 1.5 g/dL from baseline throughout the entire treatment period and 6 (15.8%) achieved a mean $\geq 50\%$ reduction in symptom score from baseline. Overall, 47.4% of pts had ≥ 1 treatment-related adverse event (TRAE), most frequently hypertension (17.9%, 5.3% grade ≥ 3); 3.2% of pts had a serious TRAE. One TRAE led to LUSPA discontinuation. Two (2.1%) pts had transformation to acute myeloid leukemia. Nine pts died on treatment from: post-procedural hemorrhage, pneumonia, intracranial hemorrhage, septic shock, ischemic stroke, multiple organ dysfunction syndrome, renal failure, pneumonitis, and myelofibrosis (n = 1 each); no deaths were considered related to the study drug. **Conclusions:** In pts with MF, the safety profile of LUSPA was consistent with previous studies and efficacy results showed promising improvements in anemia and transfusion burden in all cohorts. Clinical trial information: NCT03194542. Research Sponsor: Bristol Myers Squibb.

Poster Discussion Session

Spleen volume reduction (SVR) predicts overall survival (OS) in myelofibrosis (MF) patients on pacritinib (PAC) but not best available therapy (BAT): PERSIST-2 landmark OS analysis. *First Author: Helen Ajufu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: MF is a life-limiting malignancy characterized by marrow fibrosis, splenomegaly, and progressive cytopenias. JAK2 inhibitors can reduce spleen volume, which is considered a surrogate for disease response. For example, $\geq 10\%$ SVR on ruxolitinib (RUX) is associated with improved OS among patients with platelet (PLT) counts $\geq 100 \times 10^9/L$. RUX cannot be administered at full dose in patients with lower PLTs, and it is not known whether the association between SVR and OS persists in such patients. PAC is a JAK1-sparing inhibitor of JAK2/IRAK1/ACVR1 that demonstrated SVR benefit vs BAT (including RUX) in PERSIST-2, which enrolled MF patients with PLTs $\leq 100 \times 10^9/L$. Here we present a retrospective landmark OS analysis of the relationship between SVR and OS on PERSIST-2. **Methods:** This analysis includes PERSIST-2 patients who were alive and on study at the start of the 12-week SVR window (study week 10) on PAC 200 mg BID or BAT. Spleen volume was assessed radiographically (MRI or CT). OS was evaluated among SVR responders vs non-responders within each treatment arm using different SVR thresholds ($\geq 35\%$, $\geq 20\%$, $\geq 10\%$, $> 0\%$) and a landmark analysis methodology. OS was compared using the log-rank test. **Results:** Among patients on PAC (n = 89), any SVR ($> 0\%$) at 12 weeks was significantly associated with improved survival (HR = 0.08 [95% CI: 0.01, 0.51], P = 0.0007). Among all SVR response thresholds, SVR $\geq 10\%$ demonstrated the greatest separation in OS curves between responders vs. non-responders on PAC, with no deaths on study among 65 responders compared to 5 deaths among 24 non-responders (HR = 0.0 [95% CI: 0.0, 0.14], P < 0.0001). By contrast, SVR did not predict OS benefit on BAT (n = 84), including RUX (n = 39). For example, 11% (3/28) of patients on BAT who achieved SVR $\geq 10\%$ died compared to a similar number (14%, 8/56) of non-responders (HR = 0.63 [95% CI: 0.17, 2.37], P = 0.49). Of the 28 patients on BAT who achieved SVR $\geq 10\%$, 23 (82%) were treated with RUX. Among these 23 patients, most patients were receiving low-dose RUX at the time of the landmark: 78% were on ≤ 10 mg BID and 43% were on ≤ 5 mg BID. By contrast, the median relative dose intensity on PAC was 100% (200 mg BID) through week 12 among both SVR $\geq 10\%$ responders and non-responders. **Conclusions:** In MF patients with PLTs $\leq 100 \times 10^9/L$, achieving SVR on full-dose PAC was associated with significant OS benefit. By contrast, this association was not found with BAT, even though most responders were on RUX, albeit at low doses. As PAC can be given at full dose regardless of PLT count, it is possible that PAC may offer a unique survival advantage for MF patients with moderate or severe thrombocytopenia who achieve spleen reduction. Clinical trial information: NCT02055781. Research Sponsor: CTI BioPharma Corp.

Poster Discussion Session

Phase 1/2 study of the activin receptor-like kinase (ALK)-2 inhibitor zilugisertib (INCB00928, LIMBER-104) as monotherapy or with ruxolitinib (RUX) in patients (pts) with anemia due to myelofibrosis (MF). *First Author: Prithviraj Bose, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Elevated levels of the iron regulator hepcidin can cause functional iron deficiency anemia; hepcidin dysregulation is central to anemia of chronic inflammation observed in several malignancies such as MF. ALK2 (ie, ACVR1) contributes to MF-associated anemia via hepcidin upregulation. We evaluated the safety and activity of zilugisertib, a selective, oral ALK2 inhibitor, in pts with anemia due to MF. **Methods:** The ongoing open-label, multicenter, phase 1/2 dose-escalation/expansion INCB 00928-104 study (NCT04455841) is evaluating zilugisertib alone (treatment group A [TGA]) or with RUX (treatment group B [TGB]). Eligible pts are ≥ 18 years old with primary/secondary MF of intermediate (Int)-1 (TGB only) or Int-2/high-risk (TGA and TGB) per the Dynamic International Prognostic Scoring System (DIPSS) and are transfusion-dependent or have symptomatic anemia. The primary endpoint is safety and tolerability. Secondary endpoints include efficacy (per anemia response parameters), pharmacokinetics, and pharmacodynamics (eg, hepcidin and iron metabolism parameters). **Results:** 31 pts were enrolled by data cutoff (30Nov2022), with 20 in TGA (50 mg once daily [qd], n = 4; 100 mg qd, n = 4; 200 mg qd, n = 6; 400 mg qd, n = 6) and 11 in TGB (100 mg qd, n = 4; 200 mg qd, n = 5; 400 mg qd, n = 2). Median (range) age was 73 (53–84) y for TGA and 77 (64–85) y for TGB. 65% of TGA pts had received prior RUX therapy. Overall, 90% of pts had Int-2 risk DIPSS, and the remainder had high-risk DIPSS (1 pt in TGA, 2 in TGB). 60% of pts in TGA and 27% in TGB were transfusion-dependent at the time of enrollment. Median baseline (BL) hemoglobin (Hb) was 7.7 (range, 7.10) g/dL in TGA and 8.5 (range, 8.9) g/dL in TGB. BL hepcidin was high in both cohorts (median [range]: TGA, 171 [185–35] ng/mL; TGB, 123 [72–50] ng/mL; normal range, 0–50 ng/mL). At the time of analysis, dose escalation was ongoing in both treatment groups. No dose-limiting toxicities (DLTs) or study drug-related serious adverse events (AEs) occurred in either treatment group. Maximum tolerated dose had not been reached at the time of analysis. Treatment-emergent AEs (TEAEs) were mainly low grade. Grade ≥ 3 TEAEs occurred in 7 pts, with thrombocytopenia the most common (n = 4). Reduction in hepcidin following zilugisertib dosing was observed in TGA and TGB, with maximal hepcidin reduction at 6 h postdose. Hb increase of > 1.5 g/dL from BL occurred in 3 pts (27%) in TGB and 1 pt (5%) in TGA. **Conclusions:** Treatment with zilugisertib monotherapy or in combination with RUX in this patient population was generally well tolerated, with predominantly grade 1/2 TEAEs and no DLTs. Reduced hepcidin levels were observed with both monotherapy and in combination with RUX, and preliminary improvements in anemia were observed, which suggest potential for therapeutic activity. Clinical trial information: NCT04455841. Research Sponsor: Incyte Corporation.

Pelabresib (CPI-0610) monotherapy in high-risk essential thrombocythemia refractory or intolerant to hydroxyurea: Preliminary results from MANIFEST study. *First Author: Francesco Passamonti, University of Insubria, Varese, Italy*

Background: High-risk essential thrombocythemia (HR ET) is characterized by thrombocytosis, thrombohemorrhagic events and systemic symptoms. Pts can experience intolerance, inadequate response or loss of response to first-line cytoreductive therapies (hydroxyurea [HU] or interferon alfa-2a). BET protein inhibition is a novel therapeutic strategy that downregulates inflammatory cytokines and may inhibit differentiation and proliferation of abnormal megakaryocytes involved in ET pathogenesis. Results from the Phase 2 MANIFEST study (NCT02158858) suggested potentially encouraging clinical efficacy in pts with myelofibrosis treated with Pelabresib (PELA), an oral, small-molecule, investigational BET inhibitor. Here we present preliminary results from MANIFEST Arm 4 investigating PELA monotherapy in HR ET refractory or intolerant to HU. **Methods:** Eligible pts had platelets $> 600 \times 10^9/L$ and ≥ 2 symptoms (average score ≥ 3 /TSS ≥ 15). Pts received PELA monotherapy 225 mg QD. The primary endpoint was complete hematologic response (CHR; normalization of platelet count ($\leq 400 \times 10^9/L$), WBC count ($\leq 10 \times 10^9/L$) confirmed after one cycle [after 3 weeks]) and normal spleen size. Secondary endpoints included partial HR (PHR; platelets 400–600 $\times 10^9/L$ and WBC $\leq 10 \times 10^9/L$), symptom improvement ($\geq 50\%$ TSS reduction) and safety. **Results:** As of July 2022, 20 pts with HR ET were treated: median age 64 yrs (42–83), median Hgb 13 (10–16) g/dL, median platelet count 772 (418–1255) $\times 10^9/L$ and median TSS 32.7 (6.9–123). The majority of pts had a hematologic response (90% [18/20] unconfirmed CHR or PHR); confirmed CHR was observed in 40% (8/20) (Table). Median platelet and WBC count at Wk 12 was 446 $\times 10^9/L$ and 8.2 $\times 10^9/L$, respectively. TSS reduction was reported in 86% (12/14 pts); median TSS reduction at Wk 12 was $\sim 31\%$. Hgb levels remained stable through Wk 24. The most common nonhematologic AEs were nausea (60%; 10% Gr 3), diarrhea (35%; 5% Gr 3) and dysgeusia (35%; no Gr 3). Hemorrhagic or thromboembolic events were reported in 30% pts (15% Gr 3). No events of thrombocytopenia and no Gr 4 events or higher were reported. **Conclusions:** Preliminary results from Arm 4 of the MANIFEST study suggest potential clinical benefit with PELA monotherapy in pts with HR ET refractory or intolerant to HU as supported by hematologic responses and symptom improvement. Safety results are consistent with the known safety profile of PELA and as expected in the underlying study population. Clinical trial information: NCT02158858. Research Sponsor: Constellation Pharmaceuticals, Inc., a MorphoSys Company.

Poster Discussion Session

Refining risk stratification in CMML: A comprehensive assessment of the IPSS-M and other molecularly informed models. *First Author: Luis E. Aguirre, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Multiple molecularly-informed models have been designed in hopes of improving prognostication in CMML. More recently the IPSS-M was introduced for MDS and showed improved prognostic accuracy over the IPSS-R. Here we aimed to analyze whether the applicability of the IPSS-M extends to CMML and provide a definitive comparison between all major molecularly-informed models. **Methods:** A total of 367 pts with CMML treated at Moffitt Cancer Center with annotated clinical and molecular data were analyzed. The mean IPSS-M score was used as reference. Correlative analysis between CPSS-Mol, Mayo Molecular (MMM), GFM and IPSS-M was performed. Time-to-event analyses were estimated using Kaplan–Meier. We used Cox regression for survival endpoints. Model discrimination was evaluated using Harrell’s C concordance index. **Results:** We identified 987 driver point mutations involving 21 genes across 367 pts. We identified at least 1 mutation in 96% of pts (n = 352). Median follow-up was 4.4 yrs (3.8-5.0). The most prevalent mts were *TEF2*, *SRSF2*, *ASXL1*, *RUNX1* and *NRAS*. Using the IPSS-M schema, pts were classified as very low (7%, n = 26), low (29%, n = 108), moderate low (21%, n = 76), moderate high (16%, n = 58), high (18%, n = 65) and very high-risk (9%, n = 34). The IPSS-M identified 6 risk categories with mOS of 5.0, 5.1, 3.9, 2.6, 1.7 and 1.1 yrs, ranging from VL to VH (p < .05) and a 4-yr cumulative incidence of AML evolution of 2%, 14%, 17%, 18%, 25% and 14% respectively (p < .05). CPSS-Mol and IPSS-M equally showed improved OS discrimination over the MMM and GFM as demonstrated by an 11% and 6% increase in c-index respectively (0.71 vs 0.60 and 0.65). Similarly, CPSS-Mol outperformed CPSS by 3% (0.71 vs 0.68), as did IPSS-M relative to IPSS-R (6%, 0.71 vs 0.65). A 4-to-4 mapping between CPSS-Mol and IPSS-M risk groups (by merging VL/L and H/VH into LR and HR), resulted in the re-stratification of 57% of pts (n = 202). 22% (n = 15) of LR CPSS-Mol pts were upstaged. 30% (n = 23) of HR pts were downstaged 87 pts (23.7%) developed AML: 34 by 1 (9.2%), 60 by 2 (16.3%) and 79 by 4 yrs (21.5%). There was significant segregation between IPSS-M and CPSS-Mol groups and AML risk (p < .05), but not MMM (p = .191). CPSS-Mol showed the highest accuracy, followed by IPSS-M, MMM and GFM (0.66 vs 0.63 vs 0.57 vs 0.52). We then analyzed the predictive value of the models in pts receiving frontline HMA (n = 146). IPSS-M retained its prognostic accuracy with significant segregation between strata (p < .01), as did CPSS-Mol (p < .01) and MMM (p = .01). **Conclusions:** The IPSS-M can be used reliably in pts with CMML and shows comparable prognostic accuracy to the CPSS-Mol. Both outperformed MMM and GFM. All models retained its predictive value in pts receiving frontline HMA. This carries particular importance in community settings where CMML tends to be misdiagnosed as MDS. In such instances use of the IPSS-M is unlikely to adversely impact outcomes when used to guide treatment decisions. Research Sponsor: None.

Poster Session

Outcomes of 10-day decitabine with venetoclax for AML. *First Author: Alexander Coltoff, Medical University of South Carolina, Charleston, SC*

Background: Venetoclax (VEN) + a hypomethylating agent (HMA) has improved outcomes for patients with acute myeloid leukemia (AML). VIALE-A showed improved overall response rate (ORR) and overall survival (OS) with VEN + HMA in newly diagnosed AML (ND AML); the complete remission (CR) rate was 36.7% and the median OS was 14.7 months. Later, DiNardo et al. reported a trial of 10-day decitabine (DEC10) + VEN with a CR rate of 65.7% and a median OS of 18 months in a ND AML cohort. We report real world outcomes of VEN + DEC10 for AML induction. **Methods:** We reviewed 82 adult patients treated with VEN + DEC10 at our institution. Patients received 1 or 2 cycles of VEN + DEC10 followed by additional cycles of VEN + 5-day decitabine (DEC5) per physician discretion. **Results:** Twenty-four patients had ND AML, 28 had secondary AML (sAML) and 30 had relapsed/refractory (R/R AML) with a median age (years) of 72, 70, and 59 in each group, respectively. Cytogenetics were poor-risk in 13 ND patients (54.2%), 14 sAML patients (50%), and 17 R/R patients (56.7%). Twenty-two patients (26.8%) had *TP53* mutations. Six patients (7.3%) received rasburicase. Neutropenic fever was seen in 46 patients (56.1%), and 34 (41.5%) had documented infections. Thirty-eight patients (46.3%) were re-hospitalized during cycle 1 (C1), at a median of 22 days after starting. The median time from the start of C1 to C2 was 41 days. Thirty-day mortality was 7.3%. In ND AML, ORR was 91.7% and composite CR rate (CRc; CR + CR with incomplete hematologic recovery(CRi)) was 75%. Nine of 15 patients (60%) in CR were negative for measurable residual disease (MRD-). In sAML, ORR was 53.6% and CRc rate was 50% (35.7% MRD- CR). CRc was achieved by eight of 16 (50%) untreated sAML patients vs six of 12 (50%) who were previously treated. In R/R AML, ORR was 56.7% and CRc rate was 43.3% (53.8% MRD- CR). *TP53*-mutated AML had an ORR of 59% and a CRc of 50%. Median OS was 5.5 months in *TP53*-mutant AML, 7.4 months in R/R AML, and was not reached in ND AML or sAML. Fifteen patients (18.3%) received an allogeneic transplant (3 ND, 3 sAML and 9 R/R) in MRD- CR (n = 11), MRD+ CR (n = 2) and CRi (n = 2). At a median of 263 days post-transplant, there were 3 relapses and the median OS was not reached. **Conclusions:** VEN + DEC10 compared favorably with published data, yielding high ORR, CR, and MRD- CR rates in ND AML. CR rate for R/R AML with VEN + DAC10 was similar to that for ND AML in the VIALE-A trial. These results warrant a prospective, randomized trial of VEN + DEC10 vs VEN + DEC5 in AML. Research Sponsor: None.

Implications for acute myeloid leukemia (AML) treatment and care during the COVID-19 pandemic: A Connect Myeloid Registry study. *First Author: Bart L. Scott, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: For patients (pts) with AML, timely treatment is critical. The COVID-19 pandemic broadly disrupted healthcare (eg, decreased blood donations), possibly causing delays in AML treatment and care. To determine the extent of the COVID-19 impact on AML, this analysis examines the effect of the pandemic on managing pts with AML in the Connect Myeloid Registry (NCT01688011). **Methods:** The Registry is a large, US, multicenter, prospective, observational cohort study that includes newly diagnosed pts with AML aged ≥55 y. Pt characteristics (including assessment for transplant) were analyzed from December 2013 to March 2020 (from Registry opening to the start of the pandemic; Period 1), from March 2020 to May 2021 (during major healthcare disruptions; Period 2), and from May 2021 to January 2022 (resource stabilization and increased vaccine availability; Period 3). Monthly COVID-19 incidence was calculated per weekly US government data (CDC COVID Data Tracker; 2023). Rates of visits (office, remote) and transfusions were calculated by monthly events/person-year. Overall survival (OS) was estimated using the Kaplan–Meier method. **Results:** In this analysis, 650 pts were included in Period 1, 87 pts in Period 2, and 36 pts in Period 3; demographics and baseline characteristics were balanced across periods. Prior to the COVID-19 pandemic (Period 1), 25.1% of pts were not assessed for transplant; however, after the onset of the pandemic, this increased (45.5% and 44.4% in Periods 2 and 3, respectively). When monthly US COVID-19 cases increased, in-person visits and transfusion rates generally decreased in the Registry (Table). The proportion of pts receiving oral-containing induction regimens was 49.4% (40/81) in Period 1 (starting in January 2019, due to FDA approval of venetoclax in November 2018) and 50.6% (44/87) in Period 2, with a slight increase to 63.9% (23/36) in Period 3. No significant differences in OS by period were observed. **Conclusions:** In this analysis of pts with AML in the real-world setting, a pattern of increased COVID-19 cases in the US was accompanied by fewer transfusions, fewer in-person visits, and fewer assessments for stem cell transplantation, without a significant impact on OS. Clinical trial information: NCT01688011. Research Sponsor: Bristol Myers Squibb.

Impact of age, prior therapies, and subsequent transplant on long-term outcomes of adults with relapsed or refractory B-cell acute lymphoblastic leukemia (R/R B-ALL) treated with brexucabtagene autoleucel (brexu-cel) in ZUMA-3. *First Author: Bijal D. Shah, Moffitt Cancer Center, Tampa, FL*

Background: Brexu-cel is an autologous anti-CD19 chimeric antigen receptor (CAR) T-cell therapy approved in the US for adults with R/R B-ALL and in the EU for adults ≥26 y with R/R B-ALL based on positive results of ZUMA-3. After 3-y follow-up in ZUMA-3, brexu-cel demonstrated an overall complete remission (CR)/CR with incomplete hematologic recovery (CRI) rate of 71% and a median overall survival (OS) of 26.0 mo in all treated pts (N = 55) and 38.9 mo in pts with CR (n = 31; Shah et al. EU CAR T 2023. Abstract 34). Here we report 3-y outcomes by age, prior therapies, and subsequent allogeneic stem cell transplant (alloSCT). **Methods:** Pts (≥18 y) had R/R B-ALL and received 1 brexu-cel infusion (1×10⁶ CAR T cells/kg) following leukapheresis and conditioning chemotherapy. The primary endpoint was overall CR/CRI rate per independent review. Post hoc subgroup analyses were exploratory, with descriptive statistics reported. **Results:** As of July 23, 2022, the median follow-up in Phase 2 (N = 55) was 38.8 mo (range, 32.7-44.6). The CR/CRI rate (95% CI) was 67% (35-90) for pts < 26 y (n = 12) and 72% (56-85) for pts ≥26 y (n = 43). The median (95% CI) OS was 28.6 mo (0.6-not estimable [NE]) for pts < 26 y and 34.1 mo (15.9-NE) for pts ≥26 y. Grade ≥3 treatment-related adverse events (TRAEs) occurred in 92% of pts < 26 y and in 88% of pts ≥26 y. For pts with 1 prior therapy (n = 10), the CR/CRI rate was 90% (95% CI, 55-100) and for pts with ≥2 prior therapies (n = 45), the CR/CRI rate was 67% (95% CI, 51-80); medians (95% CI) for OS were not reached (NR; 2.1-NE) and 25.6 mo (14.2-38.9), respectively. The incidence of Grade ≥3 TRAEs was 90% for pts with 1 prior therapy and 89% for pts with ≥2 prior therapies. The CR/CRI rates (95% CI) for pts with (n = 25) and without (n = 30) prior blinatumomab (blina) were 60% (39-79) and 80% (61-92). The median (95% CI) OS was 14.2 mo (3.2-26.0) for pts with prior blina and NR (18.6-NE) for pts without prior blina; Grade ≥3 TRAEs occurred in 80% and 97% of pts, respectively. For responders (CR/CRI) who did (n = 10) or did not (n = 29) proceed to subsequent alloSCT, the median (95% CI) OS was NR (7.6-NE) and 38.9 mo (18.6-NE), respectively. Similar efficacy results were observed in a pooled subgroup analysis of Phase 1 and 2 pts treated at the pivotal dose (N = 78), with a median follow-up of 41.6 mo (range, 32.7-70.3). **Conclusions:** Adults with R/R B-ALL benefitted from brexu-cel, regardless of age, number of prior therapies, prior blina exposure, or subsequent alloSCT status. Survival appeared longer in pts with fewer prior therapies and in blina-naïve pts; however, small pt numbers and unmatched baseline characteristics limit interpretation of these results. Additional studies are needed to determine the impact of prior therapies and/or subsequent alloSCT on outcomes of pts who receive brexu-cel. Clinical trial information: NCT02614066. UCHMC 1812: A phase 1b trial of CPX-351 plus gemtuzumab ozogamicin for relapsed/refractory acute myeloid leukemia. *First Author: Daria Louise Gaut, University of California Los Angeles, Los Angeles, CA*

Background: Gemtuzumab ozogamicin (GO) is effective in favorable-risk acute myelogenous leukemia (AML), while its activity is limited in higher-risk AML in part due to multi-drug resistance (MDR) mechanisms, particularly P-glycoprotein efflux pumps. CPX-351 provides a survival benefit in secondary AML, a disease characterized by high MDR activity. The objective of this trial is to utilize CPX-351 as a bulk cytoreduction agent, to first reduce the high MDR leukemia clones, followed by sequential treatment with GO in a more favorable leukemia environment. **Methods:** This was a multicenter phase Ib trial of CPX-351 plus GO in relapsed/refractory (R/R) AML patients with standard 3+3 dose escalation design (NCT03904251). Cohort A was treated with CPX-351 100 u/m² on days 1, 3, and 5 plus GO 3 mg/m² (max 4.5 mg) on day 7. Cohort B was treated with the same regimen plus an additional dose of GO 3 mg/m² on day 4. The primary endpoint was the maximum tolerated dose (MTD), defined as < 2 dose limiting toxicities (DLTs) in the highest dose cohort. Secondary endpoints were IWG complete remission (CR) rate at day 28-42, liver veno-occlusive disease (VOD) rate diagnosed by the Baltimore criteria, and time of hematologic recovery (defined as ANC > 1000/uL and platelet count > 100,000/uL). Patients were enrolled at 4 University of California Hematologic Malignancies Consortium (UCHMC) centers: UC Los Angeles, UC San Francisco, UC Davis, and UC Irvine. **Results:** Thirteen participants were enrolled. The median age was 63 years (range 29-75). Eleven had relapsed disease, and two had refractory disease. Most received one prior line of therapy (n=9). Seven had ELN 2022 adverse-risk disease at initial diagnosis, and two had intermediate-risk disease. The MTD was not reached. DLTs were observed in 1/6 participants in cohort A (grade 3 rash), and 1/6 participants in cohort B (grade 5 intracranial hemorrhage in the setting of severe thrombocytopenia). There were no cases of liver VOD. Of 12 evaluable participants, 4 achieved CR (33%), of whom 3 were negative for measurable residual disease by multiparametric flow cytometry, and 1 one achieved partial remission. The median age of responders was 30 years (range 28-65). The median time to return of normal hematopoiesis in those who achieved remission was 37 days (range 36-43). Three participants received allogeneic hematopoietic cell transplant (alloHCT) following investigational therapy: one remains in remission 34 months post-transplant, one died of infectious complications shortly after alloHCT, and one relapsed at day +60. **Conclusions:** CPX-351 plus two doses of GO 3 mg/m² is a feasible treatment with acceptable toxicity and reasonable marrow recovery kinetics. However, only three participants went on to curative alloHCT. Further evaluation for efficacy in a larger patient population is needed to determine the utility of this regimen in R/R AML. Clinical trial information: NCT03904251. Research Sponsor: Pfizer and Jazz.

Examining safety and durable disease remission in R/R B-ALL after autologous CD19-directed CAR T cells produced by novel PRIMCAR manufacture platform. *First Author: Zhi Yang, Chongqing Precision Biotech Co., Ltd., Chongqing, China*

Background: CD19 chimeric antigen receptor (CAR) T cell therapy has shown promising efficacy in the r/r B-ALL. However, the life-threatening side effect and disease relapse limited its wide application. To overcome these limitations, we established a novel PrimeCAR platform (PRIMCAR) and reported the preliminary safety and effectiveness data of MC-1-50 CAR-T cells before (Shi Qi, et al. J Clin Oncol 2022; 40 [suppl 16]. Abstract 7008). Here, we present updated data. **Methods:** In this Phase I /II study (NCT04271410), MC-1-50 CAR T cells were manufactured by the PRIMCAR platform, which reduces manufacture periods to about 2 days. Patients (pts) received single-dose of MC-1-50 at dose ranged 1-5×10⁵ CAR+/kg (Level 1, 1×10⁵ CAR+/kg; Level 2, 2×10⁵ CAR+/kg; Level 3, 3×10⁵ CAR+/kg; Level 4, 5×10⁵ CAR+/kg). Pts were pre-conditioned with fludarabine (25-30 mg/m²) and cyclophosphamide (200-300 mg/m²) daily for 3 days. Toxicity was graded by CTCAE, CRS and ICANS were graded by ASTCT criteria. **Results:** 19 pts with r/r B-ALL were infused. Disease characteristics and outcomes are shown in the table. No DLTs were reported. 18 pts (94.7%) experienced CRS, including 10 (52.6%) at grade 1, 7 (36.8%) at grade 2, 1 (5.3%) at grade 3, and no ≥ 4 CRS were observed. Three pts (15.8%) experienced ICANS, including 2 (10.5%) at grade 1, 1 (5.3%) at grade 2, and no ≥ 3 ICANS occurred. All patients achieved CR/CRi (BM MRD-) in the first month. All patients received no other anti-tumor therapy until relapse was confirmed. The median DOR was not reached. 6 patients confirmed relapse, including 4 were CD19 negative and 2 were CD19 positive but with CD19 gene mutation at the time of relapse. All patients in 4 dose levels had good CAR-T expansion and exhibited long persistence features. Only 3 patients experienced the loss of CAR-T. **Conclusions:** Treatment of r/r B-ALL at a very low dose resulted in excellent safety profiles while exhibiting a high and durable efficacy. That makes this PRIMCAR platform potential for outpatient administration in the future. Clinical trial information: NCT04271410. Research Sponsor: ChongQing Precision Biotech Co., Ltd.

Efficacy and safety of venetoclax in combination with cytarabine and azacitidine (VAA) in relapsed/refractory acute myeloid leukemia: An open-label, single-arm, phase II study. *First Author: Liangshun You, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China*

Background: While the understanding of AML has been improved over decades, the outcome of relapsed/refractory AML remains dismal. Venetoclax-based regimen has not yet been systematically assessed in R/R AML. Clinical trials of VEN-based regimen designed for R/R AML are urgently needed to further evaluate its efficacy and safety among these patients. We innovatively combined VEN with azacytidine and cytarabine (termed as VAA). **Methods:** a) Patients: Eligible patients aged 18-70 years and had a confirmed diagnosis of relapsed/refractory AML. b) Trial design and regimens: Phase 2, open-label, single-arm, multicenter study of VAA regimen in R/R AML patients. A stepwise ramp-up of VEN dosing was adopted to achieve the target dose (400 mg), beginning with 100mg on day 1, and escalated to 200mg on day 2, and 400 mg on day 3-day 9. Cytarabine (10mg/m²) was administered by subcutaneous injection twice daily from day 1 to 10, and AZA (75mg/m²) was administered by intravenous injection once daily from day 1 to 7. c) End points and assessments: Primary efficacy endpoints were CRc including CR and CRi, PR and MLFS per IWG for AML. Secondary endpoints were OS and DOR. The safety endpoints were adverse events graded per CTCAE. d) Statistics analysis: As of the date of submission, 29 patients have completed efficacy evaluation and 1 patient is still in the trial. This study was designed to detect a target CRc rate of 65% (historical rate 40%), with 80% power and type 1 error rate at 0.05, and the planned sample size was 31 patients. All P values were two sided. **Results:** a) Patients: 30 R/R AML patients were enrolled.b) Efficacy: The CRc rate among all patients was achieved in 62.1% (18/29), including CR in 34.5% and CRi in 27.6% patients, following with 13.8% patients obtaining PR. CRc rates were preserved across subgroups with 59.1% (13/22) in ELN intermediate/adverse group, 62.5% (5/8) in those who ≥65 years and 50.0% (7/14) in those whose baseline bone marrow count ≥30%. Noticeably, CRc rate in patients diagnosed with M4/5 reached 72.7% (8/11). With a median follow-up of 6.95 months, median OS and median DOR are not yet reached. Estimated 12-month OS was 86%, and Estimated 12-month DOR was 62.6%. In ELN intermediate/adverse risk patients, the median DOR was 7.5 months. Estimated 12-month OS rate and DOR rate were 84.3% and 63.8%, respectively. Patients with prior bone marrow count less than 30% and with no prior HMA-based therapy were associated with favorable estimated 12-months DOR rate. The regimen had similar efficacy in patients younger than 65 years compared with those >65 years. c) Safety: No TLS events were observed. No treatment-related deaths occurred. **Conclusions:** VAA regimen represents a feasible and safe new choice for R/R AML patients, especially with satisfactory effect in ELN intermediate/adverse group and in those with advanced ages. Clinical trial information: chict2100051119. Research Sponsor: None.

Survival outcomes with CPX-351 vs 7+3 by baseline bone marrow blast percentage in older adults with newly diagnosed high-risk or secondary acute myeloid leukemia: A 5-year follow-up study. *First Author: Ellen K. Ritchie, Weill Cornell Medicine, The New York Presbyterian Hospital, New York, NY*

Background: CPX-351, a dual-drug liposomal encapsulation of daunorubicin and cytarabine in a synergistic 1:5 molar ratio, is approved for newly diagnosed therapy-related acute myeloid leukemia (AML) or AML with myelodysplasia-related changes in the US and Europe following positive efficacy and safety data from the pivotal phase 3 clinical trial (NCT01696084). A previous exploratory analysis of the trial data (median follow-up 20.7 months) showed improved survival outcomes with CPX-351 vs conventional 7+3 chemotherapy in adults with newly diagnosed high-risk or secondary AML (sAML) irrespective of baseline bone marrow (BM) blast percentage. Here we report 5-year follow-up data (median follow-up 60.9 months) to provide insights into the longer-term efficacy and safety of CPX-351 in these patient subgroups. **Methods:** Patients (60–75 years) with a pathologic diagnosis of AML (high-risk/sAML) per the WHO 2008 criteria (≥20% blasts in peripheral blood or BM) and an ECOG PS of 0–2 were randomized to receive CPX-351 or 7+3 chemotherapy. In these post hoc subgroup analyses at 5 years follow-up, overall survival (OS), event-free survival (EFS) and complete remission (CR) were assessed by baseline BM blast percentage. The analysis included patients with low (< 20%) BM blasts to account for changes in blast count thresholds in the updated WHO AML classification. **Results:** Overall, median OS and EFS were longer with CPX-351 vs 7+3 in each subgroup; median OS was greatest in low blast subgroups for both treatments (Table). Higher CR rates were observed with CPX-351 vs 7+3 irrespective of baseline BM blasts. Median Kaplan-Meier (KM)-estimated survival rates increased with CPX-351 vs 7+3 across BM blast subgroups. The CPX-351 safety profile was comparable across BM blast subgroups and consistent with the known safety profile of 7+3. **Conclusions:** These 5-year follow-up data suggest that CPX-351 results in improved outcomes irrespective of baseline BM blast percentage vs conventional 7+3 chemotherapy in older adults with AML. Clinical trial information: NCT01696084. Research Sponsor: Celator Pharmaceuticals, Inc., now a subsidiary of Jazz Pharmaceuticals.

First-in-human trial of tocilizumab in combination with a standard induction chemotherapy in newly diagnosed acute myeloid leukemia patients: The phase 1 T0CILAM study. *First Author: Pierre Peterlin, CHU de Nantes, Service d'hématologie Clinique, Nantes, France*

Background: Numerous studies have pointed out the pathological role of deregulated expression of Interleukin-6 (IL-6) in cancers. In acute myeloid leukemia (AML), IL-6 promotes chemo-resistance and correlates with poor prognosis. One explanation is that AML cells express IL-6 receptor (R) and self-produce IL-6 at once, favouring blast proliferation and survival. Therefore, IL-6 blockade may represent a new promising therapeutic strategy for AML. Here, we have tested Tocilizumab (Toci), an anti-IL-6R antibody, in combination with a standard AML induction chemotherapy. **Methods:** This was a monocentric Phase 1 study testing three escalating doses of Toci (4, 6 and 8 mg/kg) administered at day (d) 8 of a standard AML induction chemotherapy (Idarubicin 8 mg/m² d1 to d5 + cytarabine 100 mg/m² d1 to d7). All adults (> 18 yo) with a newly diagnosed (excluding patients (pts) with a favorable risk according to ELN-2017 classification if < 60 yo) or a relapsed/refractory AML were eligible. The main objective was to determine the maximum tolerated dose of Toci for further phase 2/3 studies. Patients had to be included 2 by 2, according to a continual reassessment method while targeting a related-experimental drug toxicity level < 30%. A maximum of 12 pts had to be included. Toxicity was evaluated using NCI version5 criteria. Responses were evaluated according to ELN-2017 criteria between d30/d45 of induction. Also, IL-6 and Toci plasma levels were assessed. All pts gave informed consent and the trial was registered at Clinical trials under NCT04547062. **Results:** Between Dec/2020 and Dec/2022, 12 pts were treated, including 2 pts at 4 mg/kg, 2 at 6 mg/kg and 8 at 8 mg/kg of Toci. The median age was 66 yo (range: 56-73), all pts had a newly diagnosed AML, ELN risk was intermediate: 25%; unfavorable: 75%. No dose limiting toxicity related to Toci was documented. Two pts died during induction, 1 of infection and 1 of cerebral haemorrhage. Complete remission (CR) rate for evaluable pts was 90% (n = 9/10). After induction, 7 received a consolidation and 7 were allo-transplanted. With a median follow-up of 600d, 4 patients have relapsed and 7 have died, 1-y OS and LFS were estimated at 43% (21-88%) and 39% (19-82%), respectively. Dosages of IL-6 (pg/mL) showed a significant increase after Toci injection (median 23,2 (2.6-53.5) vs 202,9 (21.1-6189.2) after 8d and 481,5 (53.8-7327.4) after 15d), suggesting a good saturation of the targets (IL6-R) on AML cells and a potential anti-leukemic effect. Median dosages of Toci (µg/ml) were higher 8d and 15d after injection at L2 (34.8; 17.2) and L3 (38.5; 12.9) compared to L 1 (10.9; 1.4). **Conclusions:** The combination of Toci to a standard AML intensive induction appears to be very safe providing both high CR rate and the expected biological effect. We now recommend a dose of 8 mg/kg of Toci given at d8 of induction for further phase 2/3 studies. Clinical trial information: NCT04547062. BOS-371, a monoclonal antibody against IL1RAP: Characterization in pre-clinical models of AML. *First Author: Kip A West, Boston Pharmaceuticals, Cambridge, MA*

Background: IL1 receptor accessory protein (IL1RAP) is a cell surface protein overexpressed on leukemia stem cells (LSC) and progenitors in AML, CML and high-risk MDS. It is an indispensable co-receptor for the IL1 superfamily, but its role reaches beyond anti-apoptotic pathways. IL1RAP directly interacts with and potentiates signaling of FLT3 and c-KIT which have significant roles in AML pathogenesis. High IL1RAP is correlated with poor prognosis and IL1 blockade attenuates expansion of LSCs. Thus, targeting IL1RAP has emerged as a promising immunotherapeutic approach for myeloid malignancies. BOS-371 is a humanized monoclonal antibody targeting IL1RAP that has been Fc-engineered to enhance its capacity to induce antibody directed cell cytotoxicity (ADCC) and deplete IL1RAP-expressing AML cells. **Methods:** The preclinical activity of BOS-371 was characterized using multiple assays. In vitro analysis included: binding affinity in IL1RAP-expressing cell lines; inhibition of IL1-dependent signaling as measured by IL1 α -stimulated secretion of IL6 from MRC5 lung cancer cells; measurement of ADCC in co-cultures of human NK cells with either IL1RAP-expressing cell lines or primary AML cells; and cell growth by monitoring metabolic activity of primary AML cells. In vivo efficacy of BOS-371 was determined in AML models: MV4-11 and ML2 cells (CDX) implanted in NOG and NOD-SCID mice, respectively, and patient-derived (PDX) leukemia cells implanted in NOG mice. **Results:** BOS-371 binds with high affinity to IL1RAP-expressing cells (average EC50 337pM) leading to potent inhibition of IL1 signaling (IC50 600pM). Co-culture assays in the presence of BOS-371 showed potent induction of ADCC with an EC50 of 60-70pM (cell lines) or 4-11pM (primary cells) and 80-100% cell lysis (both cell lines and primary cells). The ability of BOS-371 to impact AML cell growth exclusively through inhibition of IL1 signaling was measured in a panel of 15 primary AML samples. Incubation with BOS-371 led to IC50s ranging from 20-700nM in responsive samples. Evaluation of BOS-371 activity in vivo showed that administration of BOS-371 resulted in significant anti-leukemic activity. In CDX studies, BOS-371 treatment led to > 50% decrease in systemic disease and engraftment in bones and organs. The results observed in CDX AML models were reproduced in PDX mouse models of AML, where decreases in both peripheral (> 70%) and bone marrow (> 50%) disease burden in response to BOS-371 were observed. **Conclusions:** These findings demonstrate that BOS-371 binds with high affinity to IL1RAP, potently inhibits IL1 signaling and induces ADCC, leading to anti-leukemic activity in vitro and in vivo. The preclinical results support the clinical investigation of BOS-371 for the treatment of myeloid malignancies. A Phase 1 trial is currently in development. Research Sponsor: Boston Pharmaceuticals.

Cardiotoxicity of CPX-351 vs 7+3 in patients with untreated high-risk acute myeloid leukemia. *First Author: Joshua Mitchell, Cardio-Oncology Center of Excellence, Washington University School of Medicine, St. Louis, MO*

Background: CPX-351, a dual-drug liposomal encapsulation of daunorubicin and cytarabine in a synergistic 1:5 molar ratio, is approved for newly diagnosed, therapy-related acute myeloid leukemia (AML) or AML with myelodysplasia-related changes in the United States and Europe. While CPX-351 demonstrated improved overall survival and a similar safety profile vs 7+3 in the phase 3 clinical trial (NCT01696084), the safety of CPX-351 related to cardiac function has not been fully described, an important consideration, due to the known cardiotoxicity risk from anthracyclines. This post hoc analysis assessed the impact of CPX-351 vs 7+3 chemotherapy on cardiac impairment in a subset of adults with newly diagnosed high-risk or secondary AML (sAML) from the phase 3 trial. **Methods:** In the phase 3 trial, 309 patients (60-75 years old; AML according to WHO 2008 criteria) were randomized 1:1 to receive CPX-351 (100 units/m² on days 1, 3 and 5; days 1 and 3 for second induction) or 7+3 (cytarabine 100 mg/m²/day for 7 days [5 days for second induction] and daunorubicin 60 mg/m² on days 1-3 [days 1-2 for second induction]). Cardiac impairment was determined by cardiac adverse events (AEs) as well as echocardiogram (ECHO) measures including left ventricular ejection fraction (LVEF) and global longitudinal strain (GLS), which were assessed at baseline and two follow-up visits. **Results:** The study population included 102 patients (CPX-351, n = 57; 7+3, n = 45) with normal baseline LVEF (LVEF > 53%) and at least one post-baseline ECHO measure (LVEF or GLS). Median (min, max) age was 68 (60, 75) years for CPX-351 vs 66 (60, 75) years for 7+3. The mean cumulative dose of daunorubicin while on study was lower for patients receiving CPX-351 vs 7+3 (378 vs 570 mg, respectively). Lower proportions of CPX-351 vs 7+3-treated patients had LVEF < 53% (12% vs 31%) or GLS $\leq$ 18% (25% vs 38%) at follow-up 1 or 2. A clinically significant change in LVEF (> 10% decrease from baseline and LVEF < 53%) or GLS (> 12% relative decrease from baseline and GLS < 18%) was less common in patients treated with CPX-351 vs 7+3 (9% vs 20% and 21% vs 44%, respectively) at follow-up 1 or 2. The frequency of any cardiac AE by treatment group was similar for both CPX-351 and 7+3 (40% vs 42%). Tachycardia was the most common cardiac AE in CPX-351-treated patients (21% vs 9% in 7+3-treated patients), while atrial fibrillation was the most common cardiac AE in 7+3-treated patients (11% vs 4% in CPX-351-treated patients). **Conclusions:** The results of this post hoc analysis of data from the phase 3 trial show that CPX-351 is associated with less cardiotoxicity in adults with newly diagnosed high-risk or sAML, when compared with 7+3. The lower mean cumulative doses of daunorubicin while on study with CPX-351 appear to result in better cardiac outcomes with CPX-351 vs 7+3 chemotherapy. Characteristics of CPX-351, such as liposomal delivery, may also contribute to this effect but require further study to confirm this. Clinical trial information: NCT01696084. Identification of factors to predict low risk febrile neutropenia admissions in patients with acute myeloid leukemia (AML) following intensive chemotherapy. *First Author: Khushboo Pal, University of Washington, Seattle, WA*

Background: Febrile neutropenia (FN) is the most common reason for hospital readmission following chemotherapy for AML. Standard practice for FN in AML is hospitalization for rapid administration of IV antibiotics, thus FN is a major driver of healthcare resource utilization and cost. Whether this approach is justified in all situations is unknown. While FN risk models have been developed focusing on solid tumors, factors predicting uncomplicated courses of FN in AML, which may allow identification of patients suitable for outpatient management, have not been studied. We therefore examined whether baseline clinical characteristics could predict which AML patients with FN have a lower risk of progression to severe illness. **Methods:** We retrospectively reviewed medical records from 7/29/2014-12/24/2022 to identify adults with FN (fever >38.3C and white blood count <1000/ μ L). Included were patients with high-grade myeloid neoplasm (>10% blasts in blood/marrow) who received intensive chemotherapy (cytarabine dose $\geq$ 100 ² /day) within 8 weeks. We collected baseline clinical and disease variables. Outcomes were: infections identified, hospital length of stay (LOS), intensive care unit (ICU) admission, and survival. A "low-risk [LR]" outcome was defined as a LOS <72hrs without ICU admission or inpatient death. Univariate and multivariable (MV) logistic regression models were used to assess covariate associations with outcomes. **Results:** We identified 350 FN admissions in 198 patients with a median age 62 (range: 21-87) yrs. 63% were newly diagnosed and 37% relapsed/refractory. 12% had prior transplant. Median duration of neutropenia prior to fever was 12 (1-287) days. 46% had transfusion <24 hours prior to fever. The median LOS was 5 (1-56) days. 9% of patients went to ICU and 6% died inpatient. Overall, 15% of admissions were classified as LR. 57% had an infection identified. The table shows factors in MV analysis that predicted an infection identified or high-risk (HR) admission. **Conclusions:** Only 15% of AML admissions for FN were LR. Factors that predict HR outcomes in standard FN models such as the MASCC score—e.g. age, prior fungal infection—were not predictive of HR outcomes in AML. As a next step, we will compare our model to other published models used to predict poor outcomes after FN, which have not been developed or validated in AML. Research Sponsor: None.

MV model for infection identification and high-risk admission following FN in AML.

Shattering myths regarding Hispanic ethnicity and survival in acute myeloid leukemia: Insights from the National Cancer Database. *First Author: Naveen Premnath, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Previous smaller studies suggest that despite younger age at presentation, Hispanic patients (HP) with acute myeloid leukemia (AML) have worse prognosis than non-Hispanics patients (NHP). **Methods:** We queried the National Cancer Database (NCDB) between 2004 to 2017 for adults aged ≥ 18 years for a diagnosis of AML using the ICD-O-3 diagnosis code. Baseline characteristics and outcomes were compared. **Results:** A total of 144,146 patients with AML were identified during the study period of which 9173 were Hispanic (6.4%). The median age at diagnosis was 66 years overall. Hispanics were younger at presentation with median age 55 compared to 67 in non-Hispanics ($p < 0.001$). A higher proportion of HP were uninsured and in the lowest income quartile compared to NHP across all AML subtypes. HP had statistically significant longer survival across AML subtypes except for tAML. When adjusted for age, sex, Charlson Deyo Comorbidity Index, insurance, chemotherapy, transplant, and income status using a multivariate Cox regression analysis, HP had non-inferior survival to NHP. **Conclusions:** We present the largest study to date in Hispanics with AML. Hispanics presented at younger ages and had worse socioeconomic factors compared to NHP and when adjusted for multiple variables, did not have worse outcomes as reported in prior data. We believe previous studies in HP demonstrating worse prognosis may reflect bias and confounding given smaller patient numbers and are suggestive of disparities in access to health care and present opportunities for improvement. Results from a phase (Ph) 1 clinical study of the all-oral regimen of CC-486 and venetoclax for acute myeloid leukemia (AML). *First Author: Maria Amaya, University of Colorado, Aurora, CO*

Background: Venetoclax (Ven) with azacitidine (Aza) is the standard of care for newly diagnosed AML patients who are unfit for intensive induction chemotherapy. It is well known that this treatment also has activity in the relapsed and refractory (R/R) setting. However, this regimen requires seven consecutive daily SQ or IV doses of Aza each month. The relative inconvenience of this, and its negative impact on quality of life, may lead to its early discontinuation, possibly decreasing the overall efficacy of this regimen. An all-oral regimen may decrease infusion center visits, and potentially increase the efficacy of the regimen due to improved compliance. CC-486 is the oral formulation of Aza that is currently approved for post-induction chemotherapy maintenance in AML. **Methods:** This is a single center open label, Ph 1 study investigating CC-486 and Ven in R/R AML patients. In the dose escalation phase, subjects received CC-486 at one of two cohorts (200 mg PO days 1-14 and 300 mg PO days 1-14). Ven was given at the 400 mg/day PO regimen, for 28 days, after an initial in-patient dose escalation per the standard of care. Using a 3+3 study design for the two cohorts, we aimed to determine the maximum tolerated dose (MTD) of CC-486 in combination with Ven. An expansion cohort is planned for 10 patients treated at the MTD. **Results:** As of February 1, 2023, 8 patients have been accrued. The average age at the time of enrollment was 64, and median prior treatment regimens was 1 (range 1-3). Four patients had received Ven in prior treatments. In cohort 1, there were no DLT events. There have been no DLT events in 5/6 patients enrolled in cohort 2. The most common hematologic toxicities were Gr 3-4 neutropenia (n = 7, 88%), Gr 3-4 anemia (n = 6, 75%), and Gr 3-4 thrombocytopenia (n = 4, 50%). The most common non-hematologic toxicities were Gr 1-2 nausea (n = 4, 50%), Gr 1-2 fatigue (n = 2, 25%), and Gr 1-2 diarrhea (n = 2, 25%). Best responses were complete remission (CR) (n = 2, 25%), partial remission (PR) (n = 1, 13%), and stable disease (SD) (n = 2, 25%). Three patients proceeded to an allogeneic stem cell transplant. **Conclusions:** CC-486 and Ven is an all-oral regimen being investigated for the treatment of R/R AML. Our Ph 1 dose escalation thus far has demonstrated a favorable safety profile for this regimen. Full Ph 1 findings and the MTD will be presented at the meeting. Responses have been seen in both dose cohorts, and patients have been bridged to hematopoietic stem cell transplant. Clinical trial information: NCT05287568. Research Sponsor: Bristol Myers Squibb.

Comparison of next-generation sequencing and flow cytometry in detecting minimal residual disease in adult acute lymphoid leukemia: Evaluating clinical outcomes in a single-center study. *First Author: Vinay Nittur, University of Southern California, Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Detection of measurable residual disease (MRD) is an important biomarker to direct treatment for adult patients with acute lymphoblastic leukemia (ALL). Currently, multiparameter flow cytometry (MFC) is standard of care and can detect residual leukemia cells in 1 out of 100,000 cells (1×10^{-5}). Routine use of next-generation sequencing (NGS) assays with higher levels of sensitivity may improve disease-free survival and overall survival in adult ALL patients. The clonoSEQ MRD assay (Adaptive Biotechnologies Corporation, USA) can detect MRD at a sensitivity of 1×10^{-6} . In this study, we compare the detection of MRD by clonoSEQ assay and MFC in adult ALL patients at a single institution. **Methods:** We performed a retrospective study evaluating 92 adult patients with B- or T-ALL admitted to Norris Comprehensive Cancer Center between 2014 and 2022. Patients were excluded if they did not achieve complete remission (N=9) or if they presented with prior relapse (N=27). Median time to first complete remission (CR1) was 2.38 months. Among our cohort (N=56 patients), all patients underwent pre-treatment bone marrow sampling which was used for Clonoseq assay. 52 patients had contemporaneous MFC which was used for comparative analysis. MRD on MFC was defined as residual leukemia cells at a sensitivity of 1×10^{-5} . MRD on Clonoseq assay was evaluated at 1×10^{-6} ; residual cells under this limit were considered MRD-. **Results:** Demographics are summarized in the table. Median time to follow-up from MRD assessment was 18.0 months. 10 patients relapsed (17.9%), 3 patients died (5.4%), and 20 patients (35.7%) underwent allogeneic transplant during first remission. Among 52 patients analyzed by both MFC and NGS at CR, 26 (50%) were concordantly MRD- by NGS and NGF, 13 (25%) were discordantly MRD- by NGF but MRD+ by NGS, and 13 (25%) concordantly MRD+ by NGS and NGF. Residual cell levels between NGS and NGF were strongly correlated (R-Squared = 0.6744, $p < 0.001$), however, MRD status was significantly different between NGS and NGF ($p < 0.001$ using Fisher's Exact Test). This difference was likely driven by disparities in the limits of detection between both methods. **Conclusions:** Assessment of MRD using the clonoSEQ assay over a standard MFC-based approach adds crucial prognostic information among adult ALL patients who achieved CR. Research Sponsor: None.

Clinical outcomes of patients with newly diagnosed acute myeloid leukemia receiving treatment in a safety-net hospital system. *First Author: Jason Lu, Baylor College of Medicine, Houston, TX*

Background: Standard induction therapy for acute myeloid leukemia (AML) results in 5-year overall survival (OS) rates of 30-45%. Further risk stratification and novel therapeutic options have improved 5-year OS rates to 75-80% in certain subgroups. Despite these advances, many patients lack proper socioeconomic resources, leading to limited access to new therapies, clinical trials, and hematopoietic cell transplantation (HCT), which remains the only curative therapy for AML. Many of these patients receive care within publicly funded 'safety net' institutions designed to serve all individuals, regardless of ability to pay, insurance status, or immigration status. Outcomes of historically underserved patients with AML treated within a large county hospital system remain unknown. **Methods:** This retrospective cohort analysis evaluated clinical outcomes of patients aged ≥ 18 years with newly diagnosed AML (ND-AML) treated in the Harris County Health System, Houston, TX, from January 2005 to July 2019. **Results:** One hundred ninety-two patients with ND-AML were included (de novo AML [n = 140], secondary AML [n = 45], and therapy-related AML [n = 7]). Median age was 52 years (range: 19-89) at diagnosis, and 102 (52.3%) were male. Most patients identified as Hispanic (n = 110). Sixty-two percent of patients were uninsured or indigent, receiving care under the county's financial assistance programs. The majority had adverse risk 84 (44.3%), while 78 were intermediate (40.6%), and 26 favorable risk (13.5%). Standard induction therapy was administered in 172 (88%) of patients. Cytarabine and Anthracycline (7+3) based regimens were most commonly used (72.8%). 192 patients were evaluable for response. 139 (72.4%) achieved composite complete remission (CR/CRi) and 41 (21.4%) had primary refractory disease. For those who achieved CR after first or second induction, the median duration of CR was 16.7 months. with 25 (13.7%) ultimately receiving HCT. Common reasons for not receiving HCT included lack of insurance (19.2%) or non-citizen status (23.1%) (n = 77). 82 of the 139 patients who achieved CR relapsed. After a median follow up of 16 months, five-year OS rates were 20.7% from our entire cohort of patients. **Conclusions:** In this cohort of patients treated in a safety-net system, median OS and EFS were lower than reported outcomes in the past decade. In addition, only 13.7% received HCT, one of the only curative treatments for AML. Some barriers included inability to refer to transplant center due to lack of financial support or immigration status. Addressing socioeconomic and institutional barriers to AML therapy and HCT will advance care for disadvantaged patients, thereby improving outcomes of patients AML. Research Sponsor: None.

Clinical and molecular characteristics of patients with AML with an exceptional response to ivosidenib. *First Author: Justin M. Watts, University of Miami, Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Ivosidenib (IVO) was approved based on a CR/CRh rate of 31.8% in IDH1 mutant (IDH1m) R/R AML; median duration of CR/CRh (DOR) was 8.2 months (mo). The purpose of this study is to elucidate the clinical and molecular characteristics of exceptional responders to single agent IVO. **Methods:** We analyzed all patients (pts) with IDH1m R/R AML who received IVO 500mg QD on the phase 1 dose escalation/expansion study and had a DOR of ≥ 12 mo. **Results:** Of 179 pts who received IVO 500 mg QD, 57 (31.8%) achieved a CR/CRh. Of these, 20 (35.1%) had a DOR ≥ 12 mo. After excluding 7 pts who went to HSCT, 13 (22.8% of responders, 7.3% of cohort) had DOR ≥ 12 mo (exceptional response) and 8 (14% of responders, 4.5% of cohort) had DOR > 24 mo. The 13 exceptional responders all achieved CR as best response, and median DOR was 42.6 mo. Median OS was not reached; estimated OS at 48 mo was 67.1%. Median EFS was 44.4 mo. Reasons for discontinuing treatment included relapse (n=4), adverse event unrelated to IVO (n=3), and patient (pt) decision (n=3). Three pts remain on treatment. All pts who relapsed had DOR between 1-2 years; none of the 8 pts with DOR > 2 years relapsed. Baseline characteristics are in the table. The most common co-mutations were DNMT3A, ASXL1, SRSF2, and JAK2 (3 each, 23%). Five pts (39%) had a splicing factor mutation. No pts had FLT3 or RTK pathway mutations other than JAK2. Only 1 pt with NPM1 had an exceptional response, and 1 pt had TP53 (VAF 3.6%). Six pts (46%) had an abnormal karyotype, 6 normal (46%), and 1 missing (8%). Most pts had intermediate-risk cytogenetics (10 pts, 77%), 2 poor-risk, and 1 missing. The median IDH1 VAF was 25% (range 10-50%). The median number of co-mutations was 1 (range 0-6). Having 0-1 co-mutations was associated with a longer response. Eleven pts (85%) had an IDH1 R132C mutation; 1 each (7.7%) had R132H and R132L mutations. Mutation clearance of IDH1 was noted in 8 pts (61.5%). **Conclusions:** A subset of pts with IDH1m R/R AML have prolonged CR on single agent IVO without HSCT (22.8% of CR/CRh responders) and no pts in CR for > 2 years (14% of CR/CRh responders) relapsed. A low mutational burden, lack of RTK pathway mutations and canonical AML drivers, and co-occurrence of mutations associated with clonal hematopoiesis appear to be associated with exceptional response. Clinical trial information: NCT02074839. Research Sponsor: Agios Pharmaceuticals, Inc; Institut de Recherches Internationales Servier.

Evaluation of cardiac failure and recovery in acute myelogenous leukemia. *First Author: Matthew Wu, University of Washington/Fred Hutchinson Cancer Center, Seattle, WA*

Background: Cardiac failure causes significant comorbidity and death in acute myeloid leukemia (AML) patients, with incidence estimated at 10-15% (Neuendorf N Blood Adv. 2020). We sought to describe the post-treatment cardiac experience in AML survivors including factors associated with onset, persistence, and outcome of cardiac dysfunction during and following treatment. **Methods:** 86 patients with AML or other high-grade myeloid neoplasms treated with induction chemotherapy with or without allogeneic hematopoietic cell transplant were identified at the University of Washington/Fred Hutchinson Cancer Center from 1/2000-1/2022. All patients sustained cardiac dysfunction, defined as left ventricular ejection function (LVEF) decline of 10% with absolute LVEF below 50% during chemotherapy. A multivariable analysis was performed to compare those who recovered (LVEF recovery) and those who did not (LVEF non-recovery), examining baseline health factors, disease risk (ELN 2017), time to dysfunction and recovery, most probable cause of cardiac dysfunction based on cardiologist evaluation, and goal-directed medical therapy (GDMT) use and dosage. **Results:** 48% (41 out of 86) failed to recover following LVEF decline. This cohort tended to be older, male, and had more ASCVD risk factors ($p < 0.05$). Neither the choice of chemotherapy regimen ($p = 0.43$) nor the cumulative anthracycline dose ($p = 0.44$) was significantly different between the LVEF recovery and non-recovery groups. Onset of cardiac dysfunction tended to occur later in the LVEF recovery cohort (median 72 vs. 48.5 days, $p = 0.660$). In subjects who recovered, the median time to recovery was 87 days (range 2-268 days). When chemotherapy was identified as the probable cause, it was associated with greater likelihood of eventual recovery ($p = 0.014$), whereas ischemic coronary etiology was associated with non-recovery ($p = 0.005$). Failing to recover from cardiac dysfunction correlated with shorter survival (median 229 vs 650 days, $p = 0.005$). Multivariable analysis is shown in the Table below. Importantly, the use of GDMT with higher doses of renin-angiotensin inhibitor medications (RAASi) were associated with higher probability of recovery (not shown, $p < 0.05$). **Conclusions:** The present study demonstrates cardiac recovery occurring in over half of AML patients who experienced cardiac dysfunction during their chemotherapy. Recovery was more common in patients whose cardiac dysfunction is precipitated by chemotherapy and in patients who received GDMT with aggressive use of RAASi. Since cardiac recovery was associated with improved survival, next steps include establishing a cardiac monitoring algorithm to initiate early and aggressive GDMT. Research Sponsor: None.

A step toward genomic equity: Mutational profiling of patients with myeloid neoplasm in the largest minority-serving hospital in metropolitan Chicago. *First Author: Maha AT Elsebaie, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL*

Background: Information on genomic landscape of myeloid neoplasms comes from large studies of patients with predominantly European ancestry. Minority-serving hospitals offer unique opportunities to study ethnically diverse populations. **Methods:** In this retrospective study at the Stroger Hospital of Cook County, we included patients ≥ 18 years old with myeloid neoplasms or premalignant conditions who underwent mutational profiling via next generation sequencing (NGS). We utilized two commercially available myeloid panels: “FoundationOneHeme” (406 gene panel) and “Tempus” (648 gene panel). Patient demographics were collected, including self-reported race/ethnicity. We compared data distribution using Kruskal-Wallis, Pearson’s χ^2 , or Fisher’s exact tests. Overall survival (OS) probabilities were compared using the log-rank test. **Results:** Ninety-four patients underwent NGS between 04/01/2020 and 12/31/2022, including 45 females (47.9%). 38 patients (40.4%) identified as Black, 28 (29.8%) as White, and 28 (29.8%) as Other (10.6% Asian, 9.6% Mexican/South American, and 9.6% undetermined). 30 patients (32%) identified as Hispanic and 64 (68%) as Non-Hispanic. Diagnoses included Acute myeloid leukemia (AML, 32%), Myelodysplastic syndromes (MDS, 13%), MDS/MPN overlap syndrome (7%), and Clonal Hematopoiesis of Indeterminate Potential (7%). Eighty-eight patients had at least one pathogenic variant and harbored 259 mutations in 74 genes. Commonly mutated genes were ASXL1 (23%), JAK2 (17%), DNMT3A (14%), and TET2 (13%). Non-White patients were more likely to have IDH2 mutations (5% Black vs. 0% White vs. 14% Other races, $p = 0.011$). Mutation count didn’t differ between racial $p = 0.525$ or ethnic groups $p = 0.345$. AML & MDS patients were more likely to have TET2, RUNX1, TP53, and IDH2 mutations. In addition, 24% of AML & MDS patients had mutated ASXL1. TET2, SRSF2, and RUNX1 mutations were common among MDS/MPN patients (Table). AML & MDS patients had poor OS, but OS didn’t differ between racial/ethnic groups. **Conclusions:** Premalignant mutations (e.g., ASXL1, TET2) predominated in our patients and tended to co-occur, increasing the overall mutational burden. Non-White patients were more likely to have IDH2 mutations. Adverse markers were common among AML & MDS patients, likely contributing to their dismal survival. Studies inclusive of ethnically diverse patients are needed to accurately translate genetic findings into clinical practice. This report from a large, minority-serving hospital represents a step toward promoting genomic and healthcare equity. Research Sponsor: None.

Distribution of mutations by diagnosis.				
	AML & MDS	MDS/MPN	MPN	p-value
ASXL1 ^{Mut}	10	3	8	0.483
TET2 ^{Mut}	5	3	3	0.040
SRSF2 ^{Mut}	5	5	1	0.001
RUNX1 ^{Mut}	6	2	0	0.009
TP53 ^{Mut}	8	0	0	0.011
IDH2 ^{Mut}	6	0	0	0.035
FLT3 ^{Mut}	5	0	0	0.131

Analysis of short-term efficacy and safety of mitoxantrone hydrochloride liposome regimen therapy in adult acute myeloid leukemia. *First Author: Jun Ma, Department of Hematology & Oncology, Harbin Institute of Hematology & Oncology, Harbin, China*

Background: Acute myeloid leukemia (AML) is highly heterogeneous, and more than half of patients (pts) will experience refractory or relapse, with poor prognosis. Currently, chemotherapy and hematopoietic stem cell transplantation (HSCT) are the main treatments for AML. Mitoxantrone is a synthetic anthracenedione anti-cancer drug that is effective in lymphoma, leukemia, and other solid tumors. Mitoxantrone hydrochloride liposome (PLM60) is the first approved mitoxantrone nano-drug, which has shown favorable pharmacokinetic characteristics and significantly prolong the survival time of animals compared with the same dose of mitoxantrone (Li 2008). However, there is still a lack of systematic reports about the real-world application of PLM60 in AML. **Methods:** We performed a multicenter retrospective analysis of 82 pts with newly diagnosed AML and relapsed/refractory (R/R) AML, who received at least one cycle of PLM60 regimen between January 2022 and November 2022. Pts aged 18 years and above with confirmed diagnosis of AML according to the 2016-revised WHO criteria were eligible for inclusion, except acute promyelocytic leukemia (APL). The median dose of PLM60 in the regimen was 20.0 (range 10.3–31.6) mg/m². Efficacy was assessed by composite complete remission (CRc) rate and overall response rate (ORR), and logistic regression analysis was performed to analyze factors affecting the curative effect. Adverse events were assessed by Common Terminology Criteria for Adverse Events (CTCAE) version 5.0. **Results:** 82 pts were enrolled with a median age of 50.5 (range 20-83) years. There were 71 cases of de novo AML and 11 cases of secondary AML. Targeted sequencing was performed on 86.6% of pts (71/82). FLT3 was the most commonly mutated gene found in 22.5% (16/71), followed by ASXL1 mutated in 12.7%, NPM1 in 11.3%, and TP53 in 11.3%. 4.9% (4/82) of pts underwent HSCT. Among the 25 newly diagnosed pts, CRc rate was 72.0% (18/25) and ORR was 92.0% (23/25). Among the 57 R/R pts, CRc rate was 24.6% (14/57) and ORR was 40.4% (23/57). The courses of induction failure (OR= 16.617, P= 0.026), and the duration of the first complete remission (CR1) (OR= 20.647, P= 0.007) were independent influencing factors of the efficacy. Common grade 3/4 AEs included decreased neutrophil count (84.1%), thrombocytopenia (76.8%), anemia (73.2%), febrile neutropenia (47.6%), pulmonary infection (11.0%) and upper respiratory tract infection (2.4%). The overall safety was acceptable and controllable. **Conclusions:** The PLM60 regimen had an encouraging efficacy and showed a manageable safety profile with the most adverse events being hematologic toxicities. Association of intensive chemotherapy with the rate of pathogenic driver mutation clearance in acute myeloid leukemia. *First Author: Ruby Maini, Ochsner Clinic Foundation, New Orleans, LA*

Background: Identification of pathogenic molecular mutations (PMM) as drivers in the development of acute myeloid leukemia (AML) and in initial prognostic assessment has become clinical practice. Persistence of PMM in a morphologic leukemia free state is correlated with high risk of relapse and poor prognosis. Therapy for induction of remission and elimination of all markers of residual disease remains controversial, especially with the addition of venetoclax to hypomethylating agents (HMA). Here we compare the rates of PMM clearance between intensive chemotherapy (IC) and less intensive chemotherapy (LIC) regimens. Secondary, we assessed differences in ethnicity between white and black patients (pts). **Methods:** Retrospective study from a leukemia treatment center in Louisiana. De-identified pt records from 2018-2022 assessed for demographics: race, age, sex and diagnosis: AML, ELN 2017 staging, and mortality by IC vs. LIC regimen. IC included anthracycline and cytarabine containing regimens. LIC included HMA, with or without venetoclax. Chi-Squared analysis preformed, threshold for significance at $p < 0.05$. **Results:** 408 pts with non-M3 AML who underwent treatment, 180(44.1%) were female, 91(22.3%) were black, 303(74.3%) were white, 273(66.9%) received IC while 135(33.1%) received LIC. NGS found a total of 280 pre-treatment PMM. Among 217 pts who received treatment, the rate of mutation clearance with IC was 55.2%, compared with 50.8% LIC ($p = 0.55$). Stratifying by race, black pts had a twofold mutation clearance compared to white pts OR = 1.76, 95% CI (0.91 – 3.44). Similar proportions of pts received LIC vs IC among both white (74.1% vs 74.4%) and black (22.2% vs 22.3%). There was no statistically significant difference for overall survival on chemotherapy regimen intensity ($p = 0.1991$), race ($p = 0.2736$), or gender ($p = 0.6912$). **Conclusions:** In our study, PMM clearance was similar between IC and LIC inductions. Although these findings are from a single center, the ability to clear driver mutations at a similar rate to IC may offer a significant advantage of LIC with venetoclax. Mutation clearance is often used as a surrogate marker for residual disease, it may be reasonably inferred that these regimens serve as suitable induction regimens for pts who may be considered for allogeneic stem cell transplantation. Blacks make up a greater proportion of the population in Louisiana (~33%) as compared to the national average (~13%). Often underrepresented in prospective clinical trials, blacks made up 22.7% of subjects providing increased insight to clinical responses. No difference in mortality based on race and a trend toward greater mutational clearance in blacks. Emphasizing the importance of standardizing care in treatment centers and the need for greater representation in prospective clinical trials to understand better how differences in race may impact treatment outcomes. Comparison of characteristics and prognostic impact of *FUS-ERG* and *AML1-MTG16* fusion genes in adult AML patients: A retrospective study from 1988 to 2022 with a medical database. *First Author: Ziyue Zhou, Zhejiang University, Hangzhou, Zhejiang, China*

Background: *AML1-MTG16* and *FUS-ERG* are two rare fusion genes in acute myeloid leukemia (AML). Their clinical characteristics and factors influencing prognosis have been summarized in a cohort of pediatric patients, but no systematic review is approached in adult. **Methods:** We retrospectively analyzed the clinical data of adult AML patients with *AML1-MTG16* or *FUS-ERG* fusion genes, who were reported on Mitelman Database, PubMed and China national knowledge infrastructure (CNKI) from 1988 to 2022 or have received treatment in the First Affiliated Hospital, Zhejiang University School of Medical, and compared them with patients with *RUNX1-RUNX1T1*, exploring their clinical features and prognosis. **Results:** 314 patients were totally included for analysis. In comparison of *RUNX1-RUNX1T1* group ($n = 209$), *FUS-ERG*-positive patients ($n = 108$) significantly exhibited a younger onset age (34.5y vs. 41y), higher WBC count ($16.7 \times 10^9/L$ vs. $10.4 \times 10^9/L$), higher recurrence rate (61.8% vs. 30.4%), and a worse response to chemotherapy (complete remission rate: 71.6% vs. 91.8%), while patients with *AML1-MTG16* ($n = 24$) presented primarily as the secondary AML (83.3%) with a significantly elder age (56y vs. 41y). The *FUS-ERG* patients had a worse median overall survival (OS) of 13 months (95%CI: 11.6-14.4, $P < 0.01$) and a worse median disease free survival (DFS) of 7.5 months (95%CI: 6.5-8.5, $P < 0.05$) than control group, which also occurred in those had *AML1-MTG16* gene with a median OS of 18.5 months (95%CI: 12.4-24.6, $P < 0.01$) and a median DFS of 14 months (95%CI: 3.7-24.3, $P = 0.10$). As shown in the table below, CR after induction chemotherapy, hematopoietic stem cell transplantation (HSCT), trisomy, monosomy and age of patients were associated with the prognosis of *FUS-ERG* group. Unlike pediatric patients, the adult *AML1-MTG16* patients did not perform a better outcome (OS: HR = 0.90, $P = 0.83$; DFS: HR = 0.54, $P = 0.34$) in contrast with *FUS-ERG* patients. **Conclusions:** The retrospective study summarized the clinical characteristics of *AML1-MTG16* and *FUS-ERG*, identifying their distinctions on multiple aspects such as prior disease, recurrence rate, response to chemotherapy and cytogenetics. *AML1-MTG16* exhibited extremely bad prognosis like *FUS-ERG* in adult population, which varied from the results in pediatric cohort. Several factors including age, CR after induction chemotherapy, HSCT, trisomy and monosomy were relevant to the prognosis of *FUS-ERG*. Research Sponsor: Natural Science Foundation of Zhejiang Province, China (Y23H080018); Special fund for international cooperation of Zhejiang University (2-2050205-22-688(10)); Key research and development program of Zhejiang Province, China (No. 2022C03005).

Multivariate analysis of survival parameters in *FUS-ERG* group.

Prognostic variable	OS		DFS	
	HR [95%CI]	P	HR [95%CI]	P
Age > 60	3.67 [1.42-9.46]	0.01	3.77 [0.78-18.28]	0.10
CR attain	0.28 [0.14-0.59]	< 0.01	0.87 [0.33-2.28]	0.78
HSCT	0.18 [0.09-0.36]	< 0.01	0.32 [0.14-0.75]	0.01
Monosomy	2.26 [1.04-4.90]	0.04	3.15 [0.87-11.42]	0.08

Predictors of early port infection in adult patients with acute myeloid leukemia. *First Author: Hyndavi Kandala, University of Alabama at Birmingham, Birmingham, AL*

Background: The most concerning complications following port placement are infection and thrombosis. Early infections in patients with hematological malignancies are reported at 2-5% post-placement. However, data specific to patients with Acute Myeloid Leukemia (AML) is sparse. Here, we report infection rates within 30 days of placement and factors associated with increased risk of infection in patients with AML. **Methods:** We retrospectively reviewed charts of patients ≥ 18 years with AML who had ports placed between January 2019 to September 2022 at our institution. Baseline and peri-placement characteristics were collected. Port infection was defined as at least one of the following: 1) site infection, 2) gram-positive bacteremia, or 3) bacteremia that was documented by Infectious Disease consultants as a port source. Infections were classified as very early (< 7 days) and early (7-30 days). Variables were compared in each group by using Pearson's chi-square test. **Results:** A total of 101 ports were placed in 98 patients with AML. The median age at placement was 64 years and 58% of patients were female. A total of 14 (13.9%) port infections were identified; 5 (35.7%) were very early and 9 (64.2%) were early infections. The median time to infection was 15 days (range 1-25 days). 5 (35.7%) patients had site-only infections, 6 (42.8%) had isolated bacteremia, and 3 (21.4%) had both. 13 (93%) patients were hospitalized, and 1 patient died from infectious complications. 8 (57%) of infected ports were removed. 57 patients were on regimen-specific prophylactic antibiotics at the time of placement, of whom 12 developed an infection (21%). The infection rate was 10% vs 23% ($p = 0.1$) in patients with ANC $\geq 500/\mu L$ and ANC $< 500/\mu L$ respectively at 1 week after port placement, with no difference based on ANC at the time of placement. The infection rate was 21.9% vs. 6.5% in patients with platelets $< 100 \times 10^3/\mu L$ and $\geq 100 \times 10^3/\mu L$ ($p = 0.01$) at the time of placement; 28% vs. 8.6% in patients with albumin < 3.5 g/L and ≥ 3.5 g/L ($p = 0.02$). The infection rate was numerically higher in Venetoclax-based regimens (19%) compared with cytarabine-based regimens (8%) ($p = 0.06$). Rates of infection were similar among inpatient and outpatient placements (14%). 5/53 patients (9.4%) were in complete remission (CR), 3/29 (10.3%) of newly diagnosed, and 6/19 (31.5%) relapsed/refractory (R/R) AML patients developed an infection ($p = 0.02$). **Conclusions:** In our single-institution study, a higher-than-expected port infection rate of 14% was seen in patients with AML. Platelets $\leq 100 \times 10^3/\mu L$ and albumin < 3.5 g/L at the time of placement, Venetoclax-based regimens, and R/R state were associated with significantly higher rates of infection. Interestingly ANC at the time of placement was not associated with an increased infection rate. Strategies to prevent early infections in these high-risk patients are much needed. An analysis of a first-in-human study of NEXI-001 donor-derived antigen-specific CD8+ T-cell treatment of relapsed AML after allogeneic hematopoietic cell transplantation (HCT). *First Author: Monzr M. Al Malki, City of Hope, Duarte, CA*

Background: NEXI-001 is a non-genetically engineered donor-derived cellular therapy product consisting of $> 90\%$ CD3+/CD4- T cells that includes significant numbers of CD8+ T cells that are of early memory subtypes and target 5 specific HLA A2.01-restricted peptides from the WT1, PRAME, and Cyclin A1 antigens that are commonly expressed on AML blasts and leukemic stem cells. **Methods:** AML patients who relapse after allogeneic HCT have a high unmet medical need. These patients have a poor prognosis (2-year survival rate $< 10\%$) and few treatment options. Currently 11 patients have completed the 4-week dose-limiting toxicity (DLT) period in the 3+3 design of the dose-escalation stage of this NEXI-001 phase I trial. The following doses of NEXI-001 T cells were administered during the DLT period: Cohort 1, 4 patients received an infusion of 50M (million) to 100M T cells; Cohort 2, 4 patients received an infusion of 200M T cells; and Cohort 3, 3 patients received infusions of 200M T cells on Days 1, 8, and 15. **Results:** The NEXI-001 antigen-specific T cells were found to persist and expand in peripheral blood, traffic to bone marrow, and maintain a less differentiated immunophenotype in blood and bone marrow for ≥ 3 months. No DLTs have occurred. NEXI-001-related adverse events have included grade 2 cytokine release syndrome (2), grade 1 diarrhea (2), grade 2 orthostatic hypotension (1), and a grade 3 GVHD of the gut in week 3 of the first NEXI-001 cycle that resolved within 72 hours with corticosteroid treatment. Clinical activity consisting of the following have occurred in patients within each cohort; neutrophil and platelet count recovery resulting in decreased transfusions and decreases in blasts in peripheral blood and bone marrow. A patient who achieved an MRD- remission following bridging therapy and then was administered a single infusion of 200M NEXI-001 T cells has continued to remain in CR at 6 months of follow-up. A patient in Cohort 3 who relapsed after alloHCT with extramedullary disease manifested by a pleural effusion has achieved a 45% decrease of the symptomatic moderate effusion at baseline to an asymptomatic small effusion after the administration of three 200M NEXI-001 T cells on Days 1, 8, and 15 of the first 4-week cycle. The patient remains asymptomatic at 3 months of follow-up with no detectable AML blasts in peripheral blood or bone marrow and a stable small effusion. A PET scan of the chest showed no areas of increased uptake. **Conclusions:** Early results indicate that the antigen-specific NEXI-001 T cells have the potential to enhance GvL effects and is tolerated with easily manageable side effects. Greater clinical activity has been observed with increased doses of the NEXI-001 T cells. The trial remains ongoing, and the data support an Expansion Cohort of the study that will allow for a more complete assessment of clinical activity. Clinical trial information: NCT04284228. Research Sponsor: NexImmune, Inc.

Real-world (RW) use of venetoclax (VEN) in patients (pts) with acute myeloid leukemia (AML) in a US RWE database (COTA). *First Author: Amer Methqal Zeidan, Department of Internal Medicine, Yale School of Medicine and Yale Cancer Center, Yale University, New Haven, CT*

Background: VEN + hypomethylating agents (HMAs)/low-dose cytarabine was approved for the treatment (tx) of pts with AML who are ≥ 75 y or ineligible for intensive chemotherapy (CT) in 11/2018. To understand the use, safety, and efficacy of VEN in clinical practice, the COTA AML database, using pt-level curated electronic health record data from centers across the US, was analyzed. **Methods:** This is a retrospective, descriptive analysis of deidentified secondary data from the COTA AML database in the US. Data was abstracted for adults diagnosed with AML who initiated first-line (1L) tx on or after 01/01/2018 and received ≥ 1 VEN tx at any point. Pts with no diagnosis date or with concurrent primary malignancies were excluded. Follow-up was until the last recorded event (last visit or death). The study period for this analysis was 01/2018 to 09/2022. **Results:** Of 3836 pts with AML in the database, 1163 pts initiated 1L tx in or after 2018; of these, 636 received ≥ 1 VEN tx at any point. See Table for baseline demographic data. Most VEN-treated pts were seen by community healthcare providers (407/636, 64%). Genetic/molecular data were limited. Of the most frequently tested mutations, the most common were *TP53* (129/461, 28%), *RUNX1* (109/444, 25%), *TET2* (101/414, 24%), *ASXL1* (92/417, 22%), and *DNMT3A* (91/424, 22%). Of pts who received VEN, 47% (299/636) received 1L VEN, and the majority (269/636, 42%) received VEN + HMAs. For pts with tx prior to VEN (pretreated), 262/337 (78%) were previously treated with CT. 1L pts were more often treated in community centers than pretreated pts (73% vs 56%), had more comorbidities (56% vs 40%), and *TP53* positivity (19% vs 10%) at baseline. Of 284 VEN-treated pts with available response data, 180 (63%) had a complete response (CR). Median OS (mOS) of VEN-treated pts was 14.4 mo from 1L tx initiation (de novo AML, 17 mo; secondary AML, 14 mo). mOS from diagnosis was 14 mo for newly diagnosed and 18 mo for pretreated pts. Toxicity was the main cause of dose reduction and discontinuation. Median duration of VEN tx was 78 d. Dose reduction was reported in ~30% of VEN-treated pts. Of VEN-treated pts, 53% (338/636) discontinued at least 1 VEN regimen, with a median time to discontinuation of 49.5 d. **Conclusions:** This study provides an overview of the RW use of VEN in pts with AML in the US since its approval in 11/2018. Despite the study period starting earlier than VEN approval, almost half of pts with AML who initiated tx after 2018 received 1L VEN. The RW CR rate in VEN-treated pts with available data was 63%, but over half of VEN-treated pts had VEN tx discontinuation. Research Sponsor: Novartis Pharmaceuticals Corporation.

Characteristic	All pts N=3836	VEN-treated N=636
Male, n (%)	2045 (53)	347 (55)
Age at diagnosis, y, median (range)	65 (52-74)	71 (62-78)
Comorbidity, n (%)	1439 (38)	303 (48)
Initiated 1L tx on or after 2018, n (%)	1163 (30)	636 (100)

Capped F10, a novel DNA directed fluoropyrimidine, in TP53 mutated acute myeloid leukemia (AML). *First Author: Timothy S. Pardee, Comprehensive Cancer Center of Atrium Health Wake Forest Baptist, Winston Salem, NC*

Background: Acute myeloid leukemia (AML) is an aggressive malignancy characterized by resistance to treatment and poor outcomes. One of the most devastating mutations in AML involves loss of the tumor suppressor TP53. AML harboring this loss carries a dismal prognosis and there is a clear need for new approaches. **Methods:** To identify new therapeutics, a TP53 null and WT isogenic cell line pair was generated using CRISPR/CAS9 using a murine AML cell line. Clonal isolates were obtained and loss of detectable TP53 was confirmed by Western Blotting. A high throughput screen of currently FDA approved anticancer agents was performed. **Results:** When agents were ranked by equal cytotoxicity against TP53 null and WT AML cells 20% (6/30) of the top 30 agents targeted the folate/thymidylate synthase axis. This suggests that thymidylate synthase (TS) is a vulnerability in TP53 null AML cells. To confirm TS as a target in TP53 null AML an additional murine AML TP53 null/WT cell line pair was generated using CRISPR/CAS9. When these cell lines were treated with doxorubicin the TP53 null cells were significantly more resistant ($p \leq 0.001$ at 10nM). Capped F10 (CF10) is a second generation fluoropyrimidine oligonucleotide that has been shown to be a highly potent inhibitor of TS. In contrast to doxorubicin, CF10 treatment resulted in significant cell death when dosed in the low picomolar range with minimal differences between the null and WT cell lines ($p = 0.31$ at 50pM). To extend this result TP53 WT or null cells were injected into syngeneic recipients and upon engraftment mice were treated with CF10 at 300mg/kg twice weekly. CF10 provided a significant survival benefit in the TP53 null but not WT injected mice consistent with CF10 having activity against TP53 null AML ($p = 0.035$ vs 0.13). To confirm a TP53 independent mechanism, competition assays were performed with CAS9 expressing AML cells partially infected with a vector expressing an sgRNA targeting TP53 and a GFP reporter. When the mixed population was treated with the IC₉₀ concentration of 5-fluorouracil there was a highly significant increase in GFP+ cells indicating a TP53 mediated cell death ($p < 0.001$). In contrast when cells were treated with the IC₉₀ concentration of CF10 there was a non-significant increase in GFP+ population ($p = 0.074$) consistent with a mainly TP53 independent mechanism. Fluoropyrimidine based therapy can be myelo-suppressive especially in patients with low dihydropyrimidine dehydrogenase (DPD) activity. To assess the tolerability of CF10, healthy WAG/RAJ rats were treated with the DPD inhibitor ethynyl uracil at 2mg/kg alone or in combination with either 141 mg/kg CF10 or the molar equivalent of 50 mg/kg 5-fluorouracil (5-FU) and weight determined. In contrast to 5-FU, CF10 treated animals did not have a significant change in weight compared to controls. **Conclusions:** Taken together these data suggest that CF10 is a promising new agent for TP53 null AML. Research Sponsor: Comprehensive Cancer Center of Atrium Health Wake Forest Baptist.

Preliminary results of a phase 1, first-in-human study of INA03, an anti-CD71 antibody-drug conjugate, in patients with relapsed or refractory (R/R) acute leukemias. *First Author: Sylvain Garciaz, Institut Paoli-Calmettes, Aix-Marseille University, Marseille, France*

Background: R/R acute leukemias (AL) represent major therapeutic challenges. Several reports have highlighted the role of iron metabolism in various proliferative tumor models including AL including the over-expression of the transferrin receptor (TfR1/CD71). Our strategy is thus to harness CD71 overexpression to specifically target cytotoxic agents to leukemic cells. INA03 is an antibody drug conjugate (ADC) constituted of a humanized monoclonal IgG₄ against CD71 and the microtubule disrupting agent monomethyl auristatin E (MMAE). We herein report the preliminary safety and efficacy data of INA03 from a phase 1/2 trial in patients (pts) with R/R AL (NCT03957915). **Methods:** INA03 is given as 30 minutes IV infusion on days 1 (Loading dose (LD)) followed by maintenance injections on D15 for cycle 1 and on D1 and D15 of cycle 2 and beyond. Eligibility criteria are: R/R AL after at least one line of treatment including high dose chemotherapy and/or Vidaza and Venetoclax, AlloSCT > 18y, with FEV₂ > 50%, Creatinine Clearance > 30ml/min, normal liver function, ECOG < 2. The study design is based on a continuous reassessment method and includes 2 parts: a LD Titration study (Part 1, completed), followed by a Dose Escalation Part 2. During Part 1, sequential cohorts of 2 pts were included to receive ascending LD of INA03 followed by subsequent fixed dose of INA03 to deal with a potential sink effect related to the high expression of CD71 in normal erythroblasts. During Part 2, sequential cohorts of 3 pts received escalating doses of INA03 Q2 weeks in 28-day cycles. The objectives were to establish the MTD for subsequent administration and both safety/tolerability and anti-leukemic activity. **Results:** With a cutoff date of January 18, 2023, 22 pts across 8 cohorts were included in the study. The median age was 73 (range: 39 – 83), 20 (91%) pts had AML and two (9%) had ALL. Three (13.6%) pts had a prior allo-SCT and 12 (54.5%) had prior VEN exposure. Pts received escalating doses of INA03 of 0.02 mg/kg to 2 mg/kg. MMAE pharmacokinetics (PK) appears dose-proportional with a small accumulation after repeated IV, while INA03 PK exhibits target-mediated drug disposition without accumulation. No DLT was observed among the 18 DLT-evaluable pts, up to the highest dose of 2 mg/kg. No grade 2-4 TEAEs were observed. One related grade 1 TEAE (hyperkalemia/phosphatemia) was reported. Transient decrease of reticulocyte count and erythroblasts percentage were observed at 0.5 mg/kg and above. Blasts reductions were seen in 3/18 evaluable pts at dose > 1 mg/kg including two partial responses. **Conclusions:** INA03 is well tolerated up to the dose of 2 mg/kg with some efficacy signals in R/R AL. The trial continues to accrue patients. Clinical trial information: NCT03957915. Research Sponsor: Institut Paoli Calmettes; Inatherys.

Superior outcomes after allogeneic stem cell transplantation (SCT) among patients (Pts) ≥ 60 years (yrs) treated with cladribine (CLAD), low dose cytarabine (LDAC) plus venetoclax (Ven) for newly diagnosed acute myeloid leukemia (AML). *First Author: Jayastu Senapati, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: CLAD/LDAC/VEN alternating with AZA-VEN has shown promising outcomes in older pts with AML (*Kadia, JCO Nov 2022*). Improved disease control and preserved performance status achieved with CLAD/LDAC/VEN treatment, may translate into superior post-SCT outcomes. **Methods:** We compared outcomes of pts ≥ 60 yrs of age treated on the phase II study of CLAD-LDAC-VEN who underwent SCT in 1st remission (CR1) to a retrospective cohort of pts ≥ 60 yrs treated with hypomethylating agent (HMA)-VEN based or intensive (INT) therapy who underwent SCT in CR1 between 2013-2022. Relapse free survival (RFS) was from response to relapse/death & overall survival (OS) from start of therapy to death. **Results:** 35 pts treated with CLAD-LDAC-VEN were compared to 42 pts treated with INT & 40 pts with HMA-VEN therapy for remission induction prior to SCT at our center (Table). The median age of pts in the low-intensity arms were similar (68 yrs), but lower on the INT arm (62 yrs). More pts post INT therapy received a myeloablative conditioning (MAC). At a median follow up of 17+ months (m) for CLAD-LDAC-VEN arm, 59 m for INT arm, and 30 m for HMA arm, the median RFS (NR vs. 50 m vs. 20 m respectively, $p < 0.01$) and OS (NR vs. 58 m vs. 32 m respectively, $p < 0.01$) was superior for the CLAD-LDAC-VEN arm. 3-yr cumulative incidence of relapse & NRM (as competing events) were both significantly lower with CLAD-LDAC-VEN (4% and 7%) compared to INT (17% and 23%) or HMA-VEN (41% and 27%) therapy. **Conclusions:** Older pts with AML proceeding to SCT after CLAD-LDAC-VEN therapy had significantly improved survival, characterized by significantly lower rates of NRM and relapse compared to HMA-VEN or INT therapies. Larger studies and longer follow up is needed to confirm its benefit. Research Sponsor: None.

Treatment outcomes in adults with newly diagnosed B-cell acute lymphoblastic leukemia: A comparison between pediatric-inspired regimens and HyperCVAD at a Hispanic-serving cancer center. *First Author: Shawn Patrick Griffin, Department of Clinical Pharmacy Practice, School of Pharmacy & Pharmaceutical Sciences, University of California, Irvine, Irvine, CA*

Background: It is unknown if HyperCVAD is more favorable than pediatric-inspired regimens (PIRs) among adult Hispanic patients with newly diagnosed B-cell acute lymphoblastic leukemia. This analysis aims to determine the interaction of Hispanic ethnicity and treatment regimen on outcomes. **Methods:** Records of adults (≥ 18 years) treated with a PIR or HyperCVAD from January 2011 to November 2022 at our institution were reviewed. Patients were excluded if they received treatment modifications in a clinical trial or were lost to follow-up prior to 6 months. The primary endpoint was event-free survival (EFS) comprised of relapse, death, secondary malignancy, or failure to achieve complete remission. Secondary endpoints included overall survival (OS). Ph+ disease was not grouped into the poor-risk category. **Results:** 100 patients were included. Median age was 39 years, 57% were male, and 61% self-identified as Hispanic. 48 were included in the PIR and 52 in the HyperCVAD groups. 37 in the PIR group received CALGB 10403. There was no difference in race, ethnicity, rituximab use, WBC, LDH, bone marrow blast %, presence of CNS disease at diagnosis, or poor-risk genetics (Table) between the PIR and HyperCVAD groups. However, a lower rate of Ph+ disease (8.3% vs 58%) and younger median age (31 years vs 49 years) was observed in the PIR group. Allogeneic stem cell transplantation (ASCT) was pursued in 48% of PIR and 37% of HyperCVAD-treated patients. EFS at 5-years was lower among patients receiving a PIR compared to HyperCVAD (28% vs 41%; hazard ratio [HR], 1.89; $P = .022$). After censoring for ASCT there was no change ($P = .03$). Treatment group was the only significant predictor for EFS although a treatment-by-subgroup interaction ($P < .10$) with Hispanic ethnicity was found. OS at 5-years was 61% in PIR and 64% in HyperCVAD-treated patients (HR, 1.54; $P = .25$). In multivariable Cox regression analysis, Hispanic ethnicity (HR, 2.56; $P = .041$) and male sex (HR, 2.62; $P = .027$) were predictors for worse OS. Hispanic patients demonstrated worse EFS with a PIR compared to HyperCVAD (HR, 2.52; $P = .008$), which remained significant when evaluating only Ph- patients (HR, 2.20; $P = .048$). Non-Hispanics did not experience the same difference in EFS (HR, 0.88; $P = .81$). **Conclusions:** Treatment with a PIR resulted in worse EFS over HyperCVAD in adult Hispanic ALL patients. Future studies focusing on regimen intensity, adherence, and toxicities are needed to explore potential causes for this disparity. Research Sponsor: None.

Early in vivo generation of V γ 9V δ 2 T-cells after haploidentical stem cell transplant with post-transplant cyclophosphamide: Updated results of a monocentric phase 1 study. *First Author: Maxime Jullien, CHU de Nantes, Service d'hématologie Clinique, Nantes, France*

Background: The presence of donor V γ 9V δ 2 T-cells after haploidentical hematopoietic stem cell transplant (haplo-HSCT) has been associated with improved disease-free survival. These cells, that kill tumor cells in a non-MHC restricted manner and do not induce graft-versus-host disease (GVHD) can be generated by stimulation with bisphosphonate zoledronic acid (ZA), in combination with interleukin-2 (IL-2). **Methods:** A prospective monocentric phase 1 dose-escalating study aimed at demonstrating the possibility to generate V γ 9V δ 2 T-cells in vivo after haplo-HSCT with post-transplant cyclophosphamide (PTCY). A 3x3 protocol was designed to determine the maximum tolerated dose (MTD) of early administration of increasing low-doses of IL-2 in combination with a fixed dose of ZA, starting the first Monday after day+15 post-transplant. A single dose of 4 mg IV ZA was administered, followed, by subcutaneous injections of IL-2, 5 days/week, for 4 consecutive weeks. Three IL-2 doses were tested: 2, 4 and 6 million U/infusion. Main inclusion criteria were patients (pts) between 18-70 years old with a hematological disease eligible for haplo-SCT using a Baltimore-based conditioning, no HLA-matched sibling or unrelated donor, no contraindication to ZA nor IL-2 and informed consent. MTD was defined by the dose just below that which yielded 2/3 or 2/6 dose limiting toxicities (DLT), including severe or recurrent acute GVHD. V γ 9V δ 2 T-cells monitoring was performed in multiparameter flow cytometry on blood samples collected before conditioning, on the day of the first ZA and IL-2 injection, once a week+3 for 4 weeks and at day +70 post-graft. The protocol was registered at ClinicalTrials.gov as NCT03862833. **Results:** Twenty-six pts were included between April 2019 and September 2022 (including 7 controls). Three pts withdrew their consents in the experimental group, and 16 pts were treated with ZA and IL-2 (level 1 n = 7 including 1 not evaluable for DLT, level 2 n = 3, level 3 n = 6). First injections occurred at a median of 20 days after Day 0 (range: 17-21). One, 0 and 1 DLT and 4, 2, 2 acute GVHD (all grade II-III) were documented, and MTD was not reached. V γ 9V δ 2 T cells were clearly detectable in both controls and treated pts before conditioning. The median highest value (0.6x10⁶/L, range: 0.0-3.2) was observed at a median of 12 days (8-12) after first infusion of ZA+IL-2. A significantly higher proportion of V γ 9V δ 2 T cells was observed at days +22 and +29 in treated pts compared to controls. At the date of the submission, 3 relapse/progression occurred in treated pts, and 10 are alive in CR. Median OS is not reached. **Conclusions:** Early in vivo generation of V γ 9V δ 2 T cells is possible after haplo-SCT with PTCY by using a combination of ZA and repeated IL-2 infusions. The DMT has not been reached. This study lays the groundwork for future phase 2/3 studies. Clinical trial information: NCT03862833. Research Sponsor: Nantes University Hospital (public funds).

Effect of disease status prior to T-cell depleted allogeneic stem cell transplantation on relapse-free and overall survival in patients with adverse-risk acute myeloid leukemia (AML). *First Author: Alexandra Ewa Rojek, Section of Hematology/Oncology, Department of Medicine, University of Chicago, Chicago, IL*

Background: Patients (pts) with adverse risk AML experience poor long term disease control. Some of these pts can be rescued with allogeneic stem cell transplantation (SCT). Adverse risk was defined by high risk cytogenetic and molecular markers (2017 European Leukemia Network criteria) and by disease status prior to SCT. We investigated outcomes of pts receiving *in vivo* T-cell depleted allogeneic SCT (TCD-SCT) at our center. **Methods:** We retrospectively analyzed 200 adverse-risk AML pts who received TCD-SCT from 2002-19. Pts were categorized into groups: untreated first relapse at SCT, primary induction failure with active disease at SCT, resistant to first induction but achieving morphologic complete remission (CR) by SCT, and induction sensitive CR with high-risk disease by ELN criteria. Outcomes were evaluated by 1-year (yr) and 3-yr relapse-free survival (RFS), overall survival (OS), and non-relapse mortality (NRM), and compared with log-rank tests of significance. **Results:** Baseline pt characteristics included a median age of 54 years (IQR, 44-61) with 62 (31%) pts older than 60, and 81 (41%) with HCT-CI score 3 or greater. All pts underwent *in vivo* TCD with alemtuzumab or ATG; 153 (77%) received reduced-intensity conditioning; 142 (71%) had 8/8 or 7/8 matched donors. Fourteen (7%) pts developed grade III-IV acute graft versus host disease (GVHD), and 25 (13%) developed chronic GVHD. With a median follow up of 14.3 months, cumulative incidence of relapse was 59% and NRM was 27%. Outcomes are summarized in the table. There was a statistically significant difference between categorized groups by RFS ($p < 0.01$) and OS ($p < 0.01$). **Conclusions:** We conclude that among adverse-risk AML pts, those in CR at time of TCD-SCT have superior survival outcomes to those with active disease. For those in CR at TCD-SCT, prior resistance to frontline induction was associated with inferior survival, suggesting that AML biology, treatment sensitivity, and remission status are important factors for TCD-SCT outcomes. The inferior outcomes observed for those with primary refractory disease suggest that while TCD-SCT can be effective with acceptable NRM, more work is needed to identify which pts can benefit from future transplant strategies. Better post-SCT therapy is needed to prevent relapses. Research Sponsor: None.

Myeloablative fractionated busulfan-based conditioning regimen in patients with AML and MDS: Results of a randomized clinical trial comparing 2 fractionation schedules. *First Author: Uday R. Popat, Department of Stem Cell Transplantation & Cellular Therapy, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Hematopoietic stem cell transplantation (HSCT) cures leukemias, but comes at a cost of higher toxicity and non-relapse mortality (NRM). We previously showed that fractionating the busulfan (Bu) dose and starting it on day -13 instead of day -6, leads to lower toxicity and permits delivery of a myeloablative regimen, even to older patients. We designed a single institution randomized trial to validate the concept of fractionation and to test the hypothesis that further fractionation by starting chemotherapy on day -20 further reduces toxicity and lowers NRM without increasing relapse risk. **Methods:** Patients with AML or MDS, 18 to 70 years old, with a matched related or unrelated donor were eligible if they had adequate organ function. Patients were randomized to one of two arms: The shorter arm consisted of outpatient Bu 80mg/m² on days -13 and -12, while the longer arm consisted of outpatient Bu 80mg/m² on days -20 and -13. The rest of the regimen and GVHD prophylaxis were similar in both arms: On days -6 to -3, fludarabine 10mg/m², cladribine 10mg/m² and Bu dosed to achieve total Bu exposure of 20,000 $\pm$ 12% μ Mol-min for the whole course, including outpatient doses. Additionally, the last 33 patients received venetoclax from days -22 to -3 in both arms. The GVHD prophylaxis was tacrolimus and mini-methotrexate in the first 29 patients and tacrolimus and cyclophosphamide in the remainder. The only difference between the two arms was if busulfan was started on day -20 or not. **Results:** A total of 116 patients were randomized, 59 to the shorter day -13 arm and 57 to the longer day -20 arm. Median age was 59 in the day -13 arm and 57 in the -20 arm. 70.7% had AML. 41.4% were transplanted in first complete remission. The characteristics of the two groups were well-balanced. The median follow-up in the 67 surviving patients was 48.9 months. More patients in the day -13 group experienced grade ≥ 3 toxicities than in the day -20 group (93.2% vs. 73.7%, $p = 0.005$). The difference in toxicity led to a reduction of the 3-year NRM (19% vs. 7%, $p = 0.067$). There was no difference in relapse rate ($p = 0.99$) (Table). **Conclusions:** Further fractionating busulfan and moving just one dose of busulfan 1 week earlier reduces toxicities and may lower NRM, without increasing relapse rate. Clinical trial information: NCT02250937. Research Sponsor: n/a.

Financial toxicity and quality of life in patients undergoing bone marrow transplant evaluation: A single center analysis. *First Author: S. M. Qasim Hussaini, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins Hospital, Baltimore, MD*

Background: The impact of pre-transplant financial toxicity on quality of life (QOL) outcomes following bone marrow transplant (BMT) is unknown. We investigated the prevalence of financial toxicity in a population undergoing evaluation for BMT and its impact on post-transplant clinical and health-related QOL outcomes. **Methods:** This is a cross-sectional study in patients undergoing evaluation for allogeneic BMT between 1/1/2018 and 9/23/2020 at a large academic medical center. Financial health at baseline was measured via the comprehensive score for financial toxicity (COST) survey. The cohort was divided into three groups: none, mild, and moderate-high financial toxicity. QOL was measured using Functional Assessment of Cancer Therapy (FACT)-based questionnaires at multiple timepoints. Multivariate logistic regression analysis evaluated factors associated with financial toxicity. Kaplan-Meier curves and log-rank tests evaluated overall survival and non-relapse survival. **Results:** Of 245 patients evaluated for BMT, 176 (71.8%) completed both questionnaires with 63.1% male, 72.2% white, and median age 57 years. Common diagnoses were myelodysplastic syndrome (39.2%), leukemia (38.1%), and lymphoma (13.6%). Overall, 83 (47.2%) patients reported no financial toxicity, 51 (29.0%) mild, and 42 (23.9%) with moderate-high financial toxicity at initial evaluation for BMT. Compared to those with no financial toxicity, those with mild or moderate-high financial toxicity reported significantly reduced spending on leisure, food/clothing, used all or a portion of savings, borrowed money or accumulated debt using a credit card, and did not fill a prescription due to costs ($p < 0.0001$ for all). In patients with baseline moderate-high financial toxicity, FACT-BMT scores were lower at 6 months (126 none vs 122 mild vs 92 moderate-high; $p = 0.0007$) and 1 year (133 none vs 117 mild vs 112 moderate-high; $p = 0.0075$) following BMT. Older age (> 62) (OR 0.4; 95% CI [0.17 – 0.94], $p = 0.03$) and income equal or greater than \$60,000 (OR 0.16; 95% CI [0.07 – 0.36], $p < 0.001$) were associated with lower odds of financial toxicity. No association was noted between financial toxicity and selection for BMT, overall survival, or non-relapse mortality. **Conclusions:** Financial toxicity was highly correlated with patient-reported changes in behavior affecting their daily activities and transplant care, with notable impact on QOL following transplant for up to 1 year. Early interventions by physician and social work-led teams may benefit patients who are at risk for financial toxicity. Research Sponsor: Supported by the American Society for Hematology Research Scholar Award and P30-AG028716-13 Mini#6.

Report of a chronic myeloid leukemia registry in a low-and middle-income setting. *First Author: Nicolas Anthony Othieno-Abinya, Nairobi Hospital Cancer Centre, Nairobi, Kenya*

Background: Treatment of chronic myeloid leukaemia (CML) in Kenya has been supported since the year 2002 by a collaboration between the Max Foundation and Novartis Pharmaceuticals in the Glivec International Patient Assistance Program (GIPAP). In November 2020 this was transitioned to Max Access Solutions (MAS) that brought in the Ministry of Health as a partner. A broad range of BCR-ABL tyrosine kinase inhibitors are available. We wanted to describe epidemiology, treatment and outcome of CML in the country. **Methods:** Patients' records were reviewed and data entered in a database. Key variables included age, sex, BMI, diet, disease phase at diagnosis, treatment, and outcome. Continuous variables were summarized using mean (standard deviation) or median (interquartile range). Categorical variables were summarized using counts and percentages. Bivariate comparisons of treatment outcome were done using chi-square or Fisher's exact test. Analysis of variance (ANOVA) or Kruskal-Wallis test was used for continuous variables. **Results:** 1347 patients-males 748 (55.5%), females 599 (44.5%). Mean age was 44.5 years. Seventy (9.0%) were underweight, 88 (11.4%) obese. Mean body surface area (BSA) was 1.75m². Chronic phase cases were 1177 (96.2%), accelerated phase 46 (3.8%), blastic phase 1 (0.1%). Mean bone marrow blast count was 5.25%, BCR-ABL/ABL was 63.7%, haemoglobin 10.8g/dl, total wbc count 225 x 10⁹/litre, platelets 392.5 x 10⁹/litre. Imatinib was administered upfront to 1319 patients (99.8%). Two hundred and six (15.3%) were switched to second line; 100 (48.8%) to dasatinib, 50 (24.4%) to bosutinib. Transformation was registered in 26 cases (1.9%) - accelerated in 13 (72.2%), blastic in 5 (27.8%), 4 (80.0%) being myeloid and 1 (20%) lymphoblastic. Those alive are 1151 (85.4%) and 185 (13.7%) lost to follow-up. Deaths were recorded in 11 (0.8%). Those with lower BSA were more likely to die ($p = 0.01$). **Conclusions:** CML in Kenya occurs at a younger age-group with a slight male preponderance. With availability of a range of BCR-ABL tyrosine kinase inhibitors, treatment outcome is close to what is documented in high-income settings. Research Sponsor: Novartis Kenya Limited.

Longitudinal, prospective cardiovascular and metabolic risk in treatment-naive patients with chronic myeloid leukemia in chronic phase (CML-CP) starting tyrosine kinase inhibitor (TKI) therapy in a real-world setting. *First Author: Javid J. Moslehi, University of California San Francisco, San Francisco, CA*

Background: Multiple TKIs used in the treatment (tx) of CML have been associated with the development of cardiovascular/metabolic (CV/Met) comorbidities, yet no study to date has prospectively and systematically assessed CV/Met parameters after TKI initiation. CA180-653 (NCT03045120) is a non-interventional, prospective, real-world study characterizing the effects of TKIs (dasatinib [DAS], imatinib [IM], nilotinib [NIL], and bosutinib [BOS]) on CV/Met risk factors in patients (pts) with CML-CP in routine care. Baseline CV/Met risks were previously reported (Mauro, GCOS 2019). Here, we report data from the final 2-year follow-up. **Methods:** Adult pts with newly diagnosed CML-CP due to start tx with DAS, IM, NIL, or BOS were enrolled; the BOS cohort was not analyzed independently due to small sample size. Pts were followed for 24 mo. Blood/urine samples, CV/Met assessments, coronary calcium scoring, echocardiography, and cytogenetic/molecular response assessments were collected at routine office visits at predetermined timepoints. The primary endpoint was change in CV/Met risk from baseline. **Results:** At the end of follow-up, 118 pts were enrolled; 49 received DAS, 47 IM, 16 NIL, and 6 BOS. Of these, 83 (70.3%) pts completed the study and 35 (29.7%) discontinued; the most common reason for discontinuation was withdrawal of consent ($n = 19$). No pts died from CML. At baseline, median age was 57 (range, 20–97) y; 59.3% of pts were male and 83.9% were White. Sixty-two (52.5%) pts had CV/Met risk factors at baseline, including hypertension ($n = 45/62$; 72.6%), hyperlipidemia ($n = 33/62$; 53.2%), diabetes ($n = 19/62$; 30.6%), and arrhythmia ($n = 10/62$; 16.1%). Over the study period, 1 (3.4%) patient receiving DAS and 2 (6.9%) receiving IM developed coronary artery calcification; 2 (9.1%) pts receiving IM developed pericardial effusion. Median left ventricular ejection fraction on 2D echocardiogram was normal for all TKIs at baseline (65.4% [range, 27–81]) and end of study (65.4% [range, 40–80]). Systolic and diastolic blood pressure increased from baseline only in pts who received NIL. Blood glucose levels increased from baseline for DAS, IM, and NIL (median: 1.9, 4.9, and 5.8 mg/dL, respectively), and low-density lipoprotein levels decreased from baseline in all 3 cohorts (median: 72.7, 52.1, and 56.3 U/L, respectively); data from the NIL group were limited by the small sample size. There was 1 death from myocardial infarction related to NIL. **Conclusions:** These findings suggest more than half of pts with CML-CP have CV/Met risk factors at baseline. At end of study, there was indication of CV/Met effects based on TKI selection. This highlights the importance of appropriate TKI selection based on pt comorbidity characteristics, along with close monitoring and management of CV/Met risks throughout tx. Clinical trial information: NCT03045120. Research Sponsor: Bristol Myers Squibb.

Mortality rate and social disparity trends with tyrosine kinase inhibitory availability in chronic myelogenous leukemia: An analysis in the US from 1999 to 2020. *First Author: Tony Varughese, Hackensack University Medical Center, Hackensack, NJ*

Background: We analyzed CML mortality from 1999 to 2020 in the US in relation to FDA approval of tyrosine kinase inhibitors (TKIs). These agents were introduced in the 2000s, revolutionizing the treatment of CML and providing a paradigm for targeted therapy in oncology. Starting with imatinib in 2001, followed by dasatinib (2006), nilotinib (2007), and bosutinib (2012). TKIs have increased tolerability and efficacy for the treatment of CML as compared to previous treatment modalities. We investigated age-adjusted mortality rates (AAMR) and annual percent change (APC) in this population in relation to TKI approval. **Methods:** Using the CDC WONDER database, we examined mortality trends from 1999 to 2020 for CML in the US. AAMRs were calculated per 100,000 people and stratified by sex, race/ethnicity, and census region. AAMR groups were listed as pre-TKI era and 1 year post-FDA approval of different TKI agents. We computed the APC trends for the respective stratification with Joinpoint, a regression analysis program. **Results:** Between 1999 and 2020 there were 35,268 deaths from CML. In 1999, overall AAMR initially was 0.8, which improved to 0.5 by 2020 with a respective APC of -2.5%. In our subgroup analysis there was a consistent and significant decrease in AAMR since the introduction of Imatinib in 2001. With additional TKI releases, AAMR continued to decline in all subgroups. APC for mortality rates was similar between all subgroups [-2.0 to -2.8%] indicating a similar benefit regardless of subgroup. Male AAMR was consistently higher than female AAMR. Black and white patients (0.5, 2020) have a 2.5x higher AAMR (0.2, 2020) compared to Asian patients. Census region did not show a significant difference between each other. **Conclusions:** Since the FDA approval of imatinib in 2001 and the subsequent release of TKIs there has been a significant impact on reducing AAMR for patients with CML. The decline was seen in sex, race, and census region. The APCs were similar between all subgroups indicating a consistent improvement in survival. Possible etiologies of disparities in AAMR for males in comparison to females and for black and white patients in comparison to Asian patients include gender and race-associated gene polymorphisms possibly inducing differences in drug metabolism. Further gender and race specific pharmacokinetic studies would be useful to further elucidate etiology of the disparity and may lead to changes in TKI dosing strategies. Research Sponsor: None.

External validation of the Molecular International Prognostic Scoring System (IPSS-M) for myelodysplastic syndromes. *First Author: Brian Chernak, Columbia University Irving Medical Center, New York, NY*

Background: Myelodysplastic Syndromes (MDS) comprise a group of clonal diseases characterized by dysplastic hematopoietic progenitor cells, leading to cytopenias and in select cases transformation to acute myeloid leukemia (AML). In June 2022 the Molecular International Prognostic Scoring System (IPSS-M) was developed to build on the traditional IPSS-R and is reported to be prognostic even with incomplete molecular data. We aimed to validate this scoring system with an external dataset, and utilize a patient population which typically does not contain complete molecular testing at diagnosis. **Methods:** This single center study at a tertiary medical center in New York, NY was conducted as an external validation of the IPSS-M. Patients with MDS who had documented peripheral blood counts, bone marrow biopsies, and cytogenetic data were identified in the institutional tissue bank. After eliminating repetitive patient samples, 405 patient entries, collected between July 7, 2010 and March 29, 2022 were included in this study. 392 patients had previously been categorized by IPSS-R score. 332 patients had at least one subsequent follow-up event. 94 patients had bone marrow biopsies that were peri-diagnostic (within 12 months of diagnosis). **Results:** Patients in the entire cohort had a median age of 74 years (range, 30-96). The median follow-up duration was 1.5 years (range 0.0-9.9 years). Nearly all patients had at least partial molecular diagnostic data. Other than PRPF8 mutations (0%), all other mutations included in the IPSS-M scoring system were tested in a subset of the study population. The most common mutations in the patient population were SF3B1 (20.4%), ASXL1 (17.6%), and SRSF2 (15.9%); 12.2% of patients had the del5q cytogenetic abnormality, and 5.6% were found to have at least one TP53 mutation; 2.7% were TP53 (multi-hit). 29% of all patients were up-staged from IPSS-R to IPSS-M score, while 12% were down-staged. At the time of study evaluation, there were 84 events; 61.3% of patients were alive at the time of analysis. The median overall survival was 3.6 years (25-75% range: 2.75-5.50 years). When limited to patients with peri-diagnostic bone marrow biopsies, there were statistically significant differences in overall survival between IPSS-M categories ($p < 0.000001$) as well as IPSS-R categories ($p < 0.00001$). There was no statistical difference in survival between IPSS-M categories ($p = 0.6$) or IPSS-R categories ($p = 0.2$) if scores were calculated at any time point in the patient's disease course. **Conclusions:** This study validates the utility of both the IPSS-M and the IPSS-R scoring systems, and notably retains important risk stratification with incomplete diagnostic data. Importantly, the scoring systems are not effectively prognostic as the disease progresses, and thus should only be utilized at or near the time of diagnosis. Research Sponsor: None.

Methylation-based prediction of myelodysplastic syndrome survival outcomes. *First Author: Alvin Shi, GRAIL, LLC, a subsidiary of Illumina, Inc., currently held separate from Illumina, Inc., under the terms of the Interim Measures Order of the European Commission dated 29 October 2021, Menlo Park, CA*

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of myeloid malignancies associated with a myriad of deleterious outcomes and a 5-year relative survival of 37%. MDS risk stratification is key for optimal treatment decisions. DNA methylation is associated with MDS biology due to frequent somatic mutations in genes (i.e. TET2, DNMT3A, IDH1, IDH2, and WT1) that affect DNA methylation. We hypothesized that methylation-based markers may help stratify risk and improve IPSS-R (the Revised International Prognostic Scoring System). Here, we evaluated the potential of both Bone Marrow (BM) Whole-genome Bisulfite Sequencing (WGBS) and Serum-based Targeted Methylation (TM) Sequencing to predict survival of MDS patients. **Methods:** We conducted paired BM WGBS and Serum-based TM sequencing on a cohort of 127 patients with MDS (N = 104) and secondary AML (N = 23) treated at the Columbia University Medical Center. We categorized patients based on an overall survival of > 3 ("long", N = 50) or < 3 years ("short", N = 77). We then identified differentially methylated regions (DMRs) differing between long and short survivor groups, and analyzed the biological pathways and functions enriched in these regions. To assess survival association, we trained a random forest classifier on principal components ("methylation classifier") on the methylation fractions from a subset of 96 Serum and 98 BM MDS patient samples to predict long vs. short survival, and compared this against a logistic regression IPSS-R model. We optimized the hyperparameters and assessed classifier performance using six-fold nested cross-validation. Finally, we conducted a multivariable cox regression with predicted scores from the methylation classifier, IPSS-R scores (recalculated at sample collection), age, and gender. **Results:** We identified a total of 7,742 DMRs in the BM WGBS and 14,093 DMRs in the Serum TM as significantly different between long and short survivor groups. Signaling pathways for calcium, cAMP, MAPK, Rap1, and PI3K-Akt were significantly enriched in DMRs. We also identified a previously-reported CpG island hypermethylation signature associated with AML progression in BM and Serum. The methylation classifier achieved a comparable AUROC compared to IPSS-R logistic regression for both BM WGBS (0.80 vs 0.78) and Serum TM (0.77 vs 0.73) samples. Multivariable Cox regression demonstrated that both predicted scores from the methylation classifier (Serum $p = 0.002$; BM $p = 0.016$) and IPSS-R scores (Serum $p = 0.003$; BM $p = 0.004$) are significant predictors of survival. **Conclusions:** We demonstrated methylation-based sequencing represents a promising new tool for MDS patient risk stratification. As IPSS-R relies on bone marrow aspirates, the Serum-based TM assay offers a less-invasive method for MDS risk stratification. Hematologic and transfusion outcomes in patients (pts) with lower-risk myelodysplastic syndromes (LR-MDS) receiving luspatercept: Real-world assessment in the community practice setting. *First Author: Sudipto Mukherjee, Cleveland Clinic, Cleveland, OH*

Background: Erythropoiesis-stimulating agents (ESAs) are used as first-line (1L) treatment (tx) for the management of symptomatic anemia in LR-MDS. Luspatercept is approved for pts with LR-MDS with ring sideroblasts (RS) who experience ESA failure and are transfusion dependent. We assessed clinical outcomes of pts with LR-MDS with RS, or MDS/myelodysplastic neoplasms with RS and thrombocytosis, treated with luspatercept in US community practices. **Methods:** This retrospective, observational cohort study used physician-abstracted chart data from community oncology clinics and included adults diagnosed with LR-MDS (including Very low- to Intermediate-risk IPSS-R status) on/after Jan 1, 2015 who received luspatercept for ≥ 3 months (mos) with ≥ 3 mos of follow-up. Transfusion burden (TB) was defined by number of sessions (ses) received in the 8 weeks (wks) prior to luspatercept tx (baseline) and the lowest number for any consecutive period ≥ 8 wks during wks 1–24 of tx: transfusion independent (TI); low TB (LTB), 1–3 ses; and moderate TB (MTB), 4–5 ses. **Results:** Of 253 pts, 219 (87%) had 1 tx prior to luspatercept tx and 31 (12%) received ≥ 2 . ESAs were used as 1L tx in 210 pts (83%). Median follow-up was 5.7 mos. The most common reason for discontinuing initial MDS tx among patients who received ≥ 1 tx prior to luspatercept was lack of anemia improvement (133/250). At baseline, 21 (8%) pts were TI, 208 (82%) had LTB, and 24 (10%) MTB. Median duration of luspatercept tx was 10.8 mos. During wks 1–24, 20/21 (95%) pts remained TI and 201/232 (87%) pts with LTB/MTB at baseline achieved TI for ≥ 8 wks. The Table shows changes in median hemoglobin (Hb), absolute neutrophil count (ANC), and platelet (plt) count. **Conclusions:** Most pts with LR-MDS received 1L ESAs and over half discontinued the first tx prior to luspatercept due to lack of anemia improvement, highlighting the need for alternative options to improve clinical outcomes. Consistent with data from the MEDALIST trial, 87% of pts with LTB/MTB who received luspatercept achieved TI for ≥ 8 wks, supporting its clinical benefit in routine clinical practice. Research Sponsor: Bristol Myers Squibb.

Outcome of TP53-mutated CCUS and the risk of progression to myeloid neoplasms. *First Author: Syed Naseem Shah, Mayo Clinic, Rochester, MN*

Background: TP53-mutated ($TP53^{mut}$) myeloid neoplasms (MN) are aggressive leukemia with poor survival. A subset of $TP53^{mut}$ MN is preceded by $TP53^{mut}$ CCUS that is conventionally considered to be high-risk premalignant condition, though evidence supporting the notion is lacking. We studied outcomes of $TP53^{mut}$ CCUS compared to $TP53$ wild-type ($TP53^{wt}$) CCUS. **Methods:** Mayo Clinic Molecular Hematology Database (N=7593) was queried to identify patients (pts) harboring pathogenic variant(s) in exons 4–11 of the $TP53$ gene with $\geq 2\%$ variance allele frequency (VAF). CCUS was defined using the 5th edition of the WHO Classification for MN. **Results:** Of 457 pts with $TP53^{mut}$, 29 (5.9%) had $TP53^{mut}$ CCUS. The median age at diagnosis was 67 years, 17 (59%) were female, and 20 (69%) had received cytotoxic therapies. One and ≥ 2 $TP53^{mut}$ were seen in 26 (89.6%) and 3 (10.3%) pts, respectively. Median $TP53^{mut}$ VAF was 9% (range 3–42), 3 had $TP53^{mut}$ VAF $\geq 20\%$, and 4 (14%) had non-MDS defining cytogenetic anomalies. Of 16 pts with available follow up evaluation (median interval 22 months, Table), 3 (10.3%) progressed to $TP53^{mut}$ MN at 5, 13, and 14 months from diagnosis. We next compared outcomes of $TP53^{mut}$ CCUS to $TP53^{wt}$ CCUS (n=138). The proportion of pts developing MN was not different between $TP53^{mut}$ and $TP53^{wt}$ CCUS (18.1 vs 10.3%, $P = .42$). Progression free survival of $TP53^{mut}$ CCUS was comparable to $TP53^{wt}$ CCUS at 1- (77 vs 83%), 2- (67 vs 67%), and 5-years (67 vs 59%, $P = .9$). Similarly, overall survival of $TP53^{mut}$ vs $TP53^{wt}$ CCUS at 1- (81 vs 89%), 2- (76 vs 76%), and 5-years (76 vs 67%) was comparable ($P = .94$). **Conclusions:** In contrast to the prevalent notion, $TP53^{mut}$ was not associated with a higher risk of MN progression or mortality compared to $TP53^{wt}$ CCUS. Majority of $TP53^{mut}$ clones showed remarkable stability over years. Research Sponsor: None.

Defining the immune microenvironment in myelodysplastic syndrome and acute myeloid leukemia using machine learning. *First Author: Maher Albitar, Genomic Testing Cooperative, Irvine, CA*

Background: Changes in the bone marrow microenvironment are believed to play a major role in the biology of Myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML). To study the bone marrow microenvironment (BME) in MDS and AML and to compare it with normal BME, we studied the expression profile of 43 immune biomarkers and evaluated the differences in the BME between AML and MDS and compared it to that of normal BME. These 43 immune biomarkers included B- and T-cell markers, cytokines and chemokines. **Methods:** RNA was extracted from fresh bone marrow aspiration samples from 626 patients with AML, 564 patients with MDS, and 1449 individuals having bone marrow without any mutations or having low level mutations determined to be CHIP (clonal hematopoiesis of indeterminate potential) and considered normal. RNA levels of 42 immune biomarkers were quantified using next generation sequencing. Using a machine learning algorithm, we first selected the relative genes that distinguish between two classes using K-fold cross-validation (K = 12). The selected genes were used to predict one class from the other using random forest classifier. Samples were divided into a training set (67%) and testing set (33%) for each classification. **Results:** The random forest showed that MDS can easily be distinguished from normal using the expression of 15 genes (CYFIP2, CXCR4, IL1RAP, CD58, CD36, CD19, PAX5, CD79B, ID1, IL8, CD44, IL1R1, CD79A, IL21R, and CD74). The AUC for distinguishing MDS from normal was 0.996 in the training set and 0.931 (95% CI: 0.912-0.949) in the testing set. Distinguishing between AML and normal was also robust and achievable using the expression of only 10 genes (CYFIP2, IL1R1, CXCR4, IL8, IL21R, CD44, CD28, CD79A, and IL7R, and CD8A). The AUC for the training set was 0.994 and 0.972 (95% CI: 0.961-0.983) for the testing set. Eight of these 10 markers were shared with MDS algorithm. Only CD28 and IL7R were specifically needed for AML classification. Distinguishing between MDS and AML was achievable with high reliability with AUC of 0.994 (95% CI: 0.992-0.997) in training set and 0.924 (95% CI: 0.896-0.952) in testing set. Only 10 biomarkers were used for distinguishing MDS from AML, nine of which (IL1R1, CYFIP2, CD44, IL1RAP, CXCR4, IL21R, CD74, IL8, and CD36) were used in distinguishing MDS from normal. The only unique biomarker was CD28. Comparing levels of these biomarkers, most of which showed highest level in normal BM, significantly lower level in MDS but the level was even significantly lower in AML (deeper reduction) than in MDS. **Conclusions:** This data suggests that the BME is significantly different in MDS from AML and both are different from normal. Few immune biomarkers play major role in defining each BME. However, relative increase or decrease between these immune biomarkers dictate the uniqueness of each microenvironment. Research Sponsor: Genomic Testing Cooperative.

Jaktinib in patients (pts) with myelofibrosis (MF) who were refractory to or relapsed after ruxolitinib: A single-arm, open-label, multicenter, phase 2 study. *First Author: Jie Jin, Department of Hematology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: Currently, ruxolitinib is the only marketed Janus kinase inhibitor (JAKi) for pts with MF in China, which demonstrated symptomatic and splenic benefit with increased cytopenias. However, at least 50% of pts develop resistance or intolerance to ruxolitinib in the long-term follow up, for whom life expectancy is largely reduced. There are few therapeutic options after ruxolitinib failure. Jaktinib, an oral novel JAK and AVCR1 inhibitor showed promising activity in Jaki-naïve pts with intermediate or high risk MF with mild side effects. Here we present the results of jaktinib in MF pts who were refractory or relapsed to prior ruxolitinib therapy. **Methods:** Pts who had primary or post-ET/PV MF and were previously treated with ruxolitinib for at least 3 months and with either inadequate efficacy response (defined as < 10% spleen volume reduction [SVR] by MRI/CT or < 30% decrease in spleen size by palpation from baseline) or spleen regrowth to < 10% SVR or < 30% decrease in spleen size from baseline following an initial response were recruited to receive jaktinib 100 mg twice daily. The primary endpoint was the proportion of pts with SVR ≥ 35% from baseline (SVR35) at week (wk) 24, measured by MRI/CT images and assessed by Independent Review Committee. Secondary endpoints included the best spleen response rate (defined as achieving SVR35 at any time), the proportion of pts with ≥ 50% reduction in MPN Symptom Assessment Form Total Symptom Score (MPN-SAF TSS), improvement of anemia and safety. **Results:** A total of 34 pts were enrolled. The median duration of previous ruxolitinib treatment was 18.6 months (range 3.4-70.1). The median baseline TSS was 19.5 (range 1-55), hemoglobin (Hb) was 101.5 g/L (range 61-149), and platelets was 159×10⁹/L (range 66-951). 11 pts (32.4%) achieved SVR35 at wk 24. The best spleen response rate was 38.2% (13/34). The median time to achieve the first SVR35 was 8.1 weeks, and the median duration of response was not reached. At wk 24, 13 pts (46.4%) achieved a ≥ 50% improvement in TSS from baseline. Of 16 transfusion-independent pts with Hb ≤ 100 g/L at baseline, 8 (50.0%) had a ≥20 g/L Hb increase by wk 24. Of 6 pts who required RBC transfusion at baseline, 2 had a 50% decrease in RBC infusion by wk 24. The median jaktinib exposure time was 231 days (range 96-371). 23 pts (67.6%) had one or more grade ≥3 treatment emergent adverse events (TEAEs). The most common grade ≥3 TEAEs were anemia (32.4%, n = 11), thrombocytopenia (32.4%, n = 11), leukocytosis (20.6%, n = 7) and leukopenia (11.8%, n = 4). Treatment discontinuation due to TEAEs occurred in 2 pts (5.9%). A dose reduction or temporary interruption due to TEAEs were reported in 9 pts (26.5%). **Conclusions:** MF pts who were refractory/relapsed to ruxolitinib attained substantial spleen response, and reduction in MF-related symptom burden with jaktinib, which could be a new option for MF pts who have failed ruxolitinib. Clinical trial information: NCT04851535. Research Sponsor: Suzhou Zelgen Biopharmaceuticals Co, Ltd.

Jaktinib in patients (pts) with myelofibrosis (MF) who were intolerant to ruxolitinib (RUX): An open-label, single-arm phase 2b study. *First Author: Yi Zhang, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China*

Background: As the first approved Janus kinase inhibitor (JAKi) for pts with symptomatic MF, RUX showed superiority in spleen volume reduction with increased anemia and thrombocytopenia. However, there are few treatment options after RUX intolerance. Jaktinib, an oral novel JAK and AVCR1 inhibitor showed promising efficacy in Jaki-naïve pts with intermediate or high risk MF with mild side effects. Here we present the results of MF pts who were intolerant to RUX and received jaktinib 100 mg bid from a phase 2b study. **Methods:** Pts who had primary or post-ET/PV MF and were previously treated with RUX for ≥28 days who either required RBC transfusions or required more frequent transfusions on RUX, or had grade 3/4 anemia, thrombocytopenia or hematoma when receiving RUX, and with palpable spleen ≥5 cm were included. The primary endpoint was the proportion of pts with spleen volume reduction of ≥ 35% from baseline (SVR35) at week (wk) 24, assessed centrally on the basis of MRI/CT images. Secondary endpoints included the best spleen response rate (defined as achieving SVR35 at any time), the proportion of pts with ≥ 50% reduction in MPN Symptom Assessment Form Total Symptom Score (MPN-SAF TSS), anemia response, safety, etc. **Results:** A total of 45 patients received jaktinib 100 mg bid. The full analysis set (FAS) for efficacy included 44 pts who had completed the 24-week treatments and evaluations or terminated prior to wk 24, and excluded one pt because of incorrect diagnosis of MF. The median baseline TSS was 9.5, hemoglobin (Hb) was 79.5 g/L, and platelets was 132.5×10⁹/L. While on RUX, 21 pts (48%) required RBC transfusion and all pts experienced those grade 3 hematological toxicities. In FAS, the SVR35 rate at wk 24 was 43% (19/44). Over the study phase, the best spleen response rate was 55% (24/44). The median time to achieve the first SVR35 was 12 weeks. Response was maintained in 80% pts for at least 24 weeks and median duration was not reached. At wk 24, 62% of the evaluable pts achieved a ≥ 50% improvement in TSS from baseline. Of 31 pts with baseline Hb ≤ 100 g/L, 13 (42%) had a ≥20 g/L Hb increase. Of 19 pts who required RBC transfusion at baseline, 11 (58%) had a 50% decrease in RBC infusion frequency. Of 9 transfusion-dependent pts at baseline, one became transfusion-independent. In the safety set (n = 45), the median jaktinib exposure time was 280 days. The most common grade ≥3 TEAEs were anemia (31%), thrombocytopenia (22%), pneumonia (18%), neutropenia (16%) and leukopenia (16%). Treatment discontinuation due to TEAEs occurred in five pts (11%). A dose reduction or temporary interruption due to TEAEs were reported in 12 pts (27%). **Conclusions:** Jaktinib demonstrated promising activities in MF pts who was intolerant to RUX by substantially reducing spleen volume, ameliorating MF-related symptom burdens, and elevating Hb levels. Jaktinib could be a viable treatment for MF pts with anemia in this setting. Clinical trial information: NCT04217993. Research Sponsor: Suzhou Zelgen Biopharmaceuticals Co, Ltd.

Selinexor (SEL) plus ruxolitinib (RUX) in JAK inhibitor (JAKi) treatment-naïve patients with myelofibrosis: Updated results from XPORT-MF-034. *First Author: Haris Ali, City of Hope, Duarte, CA*

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm associated with splenomegaly, high symptom burden, and poor prognosis. Activity has been shown with the combination of SEL + the JAKi RUX in preclinical studies. Specific subgroups with lower response rates to RUX monotherapy, such as males vs females (25% vs 59%) and those with a lower (≤15 mg vs 20 mg) RUX starting dose (22-27% vs 43%), highlight unmet need in specific groups (grps). **Methods:** XPORT-MF-034 is a Phase 1/2, open-label study evaluating safety and efficacy of SEL at 40 mg and 60 mg once-weekly plus RUX per standard of care in 28-day cycles. Assessments included safety, spleen/symptom response, survival, and hemoglobin levels. The primary analysis population included those who had baseline assessment and were treated to at least Week 24 (W24) or discontinued before W24. Two pts with baseline total symptom score (TSS) = 0 were excluded from analysis of TSS reduction of ≥50% (TSS50). **Results:** As of Dec 21, 2022, 10 participants received 40 mg and 14 participants received 60 mg SEL; 22 of the 24 pts enrolled had reached at least W24 and were included in the efficacy analysis. The median duration of treatment was 28 wks overall, 33 wks for 60 mg and 22.5 wks for 40 mg grps. Most common adverse events (AEs) by dose (60/40 mg) were nausea (79%/70%); majority grade 1-2), anemia (79%/50%), and fatigue (57%/60%). Most common Grade ≥3 AEs were anemia (50%/40%), thrombocytopenia (29%/10%), and neutropenia (7%/20%). AEs were reversible with dose modifications. Two patients discontinued treatment due to treatment-related AEs (thrombocytopenia and neuropathy); 3 deaths have occurred in the study, none related to SEL. Overall, 64% (14/22) achieved SVR35 at W24, with 79% [11/14] vs 38% [3/8], in the 60 mg vs 40 mg grp, respectively. The 60 mg grp achieved a deeper median SVR response vs the 40 mg grp at W24 (49% vs 31%). At W24, TSS50 was achieved by 45% (9/20) overall, 58% [7/12] of the 60 mg, and 25% [2/8] of the 40 mg grp. Among 11 pts with baseline hemoglobin < 10 g/dL, median hemoglobin decreased by 0.5 g/dL from baseline to W12 and increased by 0.8 g/dL from baseline to W24. Similar efficacy was observed across all subgrps with 60 mg. Reduction of variant allele frequency from baseline to W24 was > 10% in 50% (4/8) and > 20% in 25% (2/8) of evaluable pts for 60 mg grp. **Conclusions:** Encouraging activity with 60mg SEL + RUX combination were observed in TSS50, SVR and hemoglobin levels overall, as well as in key subgroups including males, in pts started on low dose RUX (≤15 mg), and pts with larger baselines spleen size. Updated data will be available for presentation. Clinical trial information: NCT04562389. Research Sponsor: Karyopharm Therapeutics.

Effects of ruxolitinib and magrolimab on calreticulin in myelofibrosis CD34+ cells in vitro: Proof of concept for combination therapy. *First Author: Ciro Roberto Rinaldi, University of Lincoln, Lincoln, United Kingdom*

Background: In solid tumours, calreticulin (CALR) overexpression produces a pro-phagocytic signal and is counteracted by concomitant expression of anti-phagocytic CD47, reflecting an apoptosis vs survival mechanism. We have previously found that CD47, not CALR, is overexpressed on the membrane of patients with MPN. Anti-CD47 Magrolimab, is currently being evaluated in clinical trials in AML, MDS but have yet to be tested, either in monotherapy or in combination in MF. **Methods:** Mononuclear cells were collected by Ficoll separation from bone marrow of 6 MF patients and from 2 controls. CD34+ cells and monocytes were purified using Dynabeads kits from ThermoFisher. Cells expression of CALR and CD47 was measured by flow cytometry, before and after incubation with ruxolitinib (Jak inhibitor) alone and in combination with magrolimab. Cells survival was calculated after combining CD34 with monocytes. Informed Consent was obtained for all samples collected. **Results:** CD47 membrane expression was 57% in untreated MF cells compared to 12% in the control samples and CALR membrane expression was 51.8% in untreated MF cell compared to 12.5% in the control samples. After incubation with ruxolitinib, MF CD34+ cell survival decreased to 98.2%. Following Incubation with magrolimab alone, MF CD34+ cells show no changes in survival (100% alive). The combination of ruxolitinib and magrolimab reduced slightly the MF CD34+ cell survival to 92%. A substantial membrane overexpression of CALR was observed in MF CD34+ cells when incubated with Ruxo and Magrolimab, 74.1%, vs Ruxo alone 52.6%, Magrolimab alone 53.4% and in untreated (51.8%). Interestingly, in the healthy controls, the exposure to combination therapy did not cause the same degree of CALR overexpression (20.7% vs 12.5%), indicating a much stronger pro-phagocytic effect following magrolimab/ruxolitinib combo in MF cancer cells. **Conclusions:** In vitro, treatment with ruxolitinib or ruxolitinib plus magrolimab, slightly reduce the overall cell survival rate in CD34+ MF samples, comparing with no significant changes in single agent magrolimab. However, the combination of Ruxolitinib and Magrolimab significantly increases CALR membrane expression comparing with Ruxo or Magrolimab alone, signalling a much stronger pro-phagocytic message in MF cells comparing with controls. The induced CALR over-expression, could stimulate a stronger immune response in vivo, where the presence of macrophages would allow removal of CALR rich cells and potentiate the cytoreductive activity towards MF clone. These data support the rational of combining Ruxolitinib with Magrolimab in the next clinical trial stage in myelofibrosis. Research Sponsor: Gilead.

Impact of transfusion burden on health-related quality of life (HRQOL) and functioning in patients (pts) with myelofibrosis (MF): Post hoc analysis of SIMPLIFY-1 (S1) and -2 (S2). *First Author: Ruben A. Mesa, Wake Forest University School of Medicine, Winston-Salem, NC*

Background: MF is associated with substantial symptom burden that can negatively impact pt quality of life (QOL). Transfusions may reduce anaemia-associated symptoms, but can be burdensome and carry complications that may affect social, emotional, and general health; thus, QOL may be further negatively affected in transfusion-dependent (TD) pts. To characterize the relationship between transfusion burden and pt-reported outcomes (PROs), we report an exploratory post hoc analysis of the phase 3 S1 and S2 trials of the JAK1/JAK2/ACVR1 inhibitor momelotinib (MMB) in pts with MF. **Methods:** The pooled analysis set comprised both arms of the intent-to-treat populations of S1 (JAK inhibitor naive, MMB vs ruxolitinib [RUX]; N = 432) and S2 (JAK inhibitor exposed, MMB vs best available therapy [88% RUX]; N = 156). Transfusion independent (TI): no transfusions and hemoglobin (Hb) ≥ 8 g/dL in 12 wk; TD: ≥ 4 units transfused or Hb < 8 g/dL in 8 wk; transfusion requiring (TR): not meeting TI or TD criteria. PRO assessment: SF-36v2 (physical functioning [PF], role-physical [RP], general health [GH], vitality [VT], social functioning [SF], and mental health [MH]) domains; norm-based scores (NBS) range from 11.6 to 70.4 based on domain). PROs by transfusion status were described over the 24-wk randomized period. **Results:** SF-36v2 NBS were available from 503/588 pts in the pooled analysis set at baseline (BL); mean NBS in all domains were lower than the general population mean per the SF-36v2 Manual (50; SD, 10): PF, 39.6; RP, 39.0; GH, 39.8; VT, 43.6; SF, 43.2; MH, 46.3. Within the pooled analysis set, mean NBS in all domains at BL and week 24 (W24) were lower in TD vs TI pts. Among BL TD pts (n = 150) at W24, 75 remained TD (TD-TD), 40 became TI (TD-TI), 21 became TR, and 14 had no data. Pts who became TI experienced greater improvement (positive mean change from BL) in most domains vs pts who remained TD (Table). **Conclusions:** Among pts with MF in S1 and S2, TD pts had lower functioning and HRQOL than TI pts across SF-36v2 domains, suggesting that transfusion dependence has detrimental effects on multiple aspects of QOL. Among BL TD pts, those who became TI at W24 had greater improvement across most domains than those who remained TD, with mean changes for TD-TI pts near or above the minimally important difference (2 or 3, based on domain) for groups with low BL NBS. These analyses highlight transfusion dependence as a key pt-centered outcome and support further research into the impact of transfusions on QOL in MF. Clinical trial information: NCT01969838; NCT02101268. Research Sponsor: GSK plc.

SF-36v2 NBS, mean (SD)	BL TD (n = 150)	W24 TD-TI (n = 40)	W24 TD-TD (n = 75)	Mean change from BL at W24 (TD-TI vs TD-TD)

Indirect treatment comparison (ITC) of momelotinib (MMB) vs fedratinib (FED) safety in patients (pts) with myelofibrosis (MF). *First Author: Lucia Masarova, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: JAK inhibitors (JAKi) are a mainstay of MF treatment, with proven ability to improve symptoms and spleen volume for most pts; although safety profiles vary, some approved JAKi have associated hematologic toxicity. The JAK1/JAK2/ACVR1 inhibitor MMB has shown consistent benefit in improving anemia, symptoms, and spleen volume in pts with MF. Clinical trials have directly compared MMB with ruxolitinib, with MMB showing a more favorable hematologic toxicity profile. However, there are limited data comparing MMB vs other JAKi such as FED. We performed an ITC of safety outcomes between MMB and FED in pts with MF. **Methods:** A matching-adjusted indirect comparison (MAIC) was undertaken to compare outcomes from phase 2 and/or 3 MMB and FED trials. Adverse events (AEs) occurring in $> 10\%$ of a treatment arm over 24 weeks were evaluated; primary outcomes were grade 3/4 anemia and thrombocytopenia. Separate analyses were performed in JAKi-naive (SIMPLIFY-1 [S1] vs JAKARTa) and JAKi-experienced (pooled SIMPLIFY-2 [S2], MOMENTUM vs JAKARTa2) pts. Evaluable outcomes were limited by published aggregate data, so not all were feasible to compare. MAIC involved reweighting MMB pt data by matching baseline characteristics prioritized by expert clinical input (DIPSS/IPSS, Total Symptom Score, platelet counts, spleen volume/length, and/or hemoglobin levels) between trial arms, and determining odds ratios (ORs), risk ratios, and risk differences (RDs) between outcomes in resulting balanced populations. As nonrandomized groups were compared, results may be biased due to unmeasured/residual confounding, despite adjusting for prognostic factors/effect modifiers. **Results:** Effective MMB sample sizes after adjustment were 151.1 JAKi-naive and 79.4 JAKi-experienced pts. Risk of any or grade 3/4 anemia, diarrhea, nausea, and serious AEs leading to dose reductions were statistically less likely with MMB vs FED in both populations; any or grade 3/4 thrombocytopenia was also less likely with MMB vs FED, significantly so in JAKi-naive pts. Odds/risk of other outcomes assessed varied in significance (key OR/RD results presented in the Table). No identified outcomes were statistically less likely with FED. **Conclusions:** MMB showed a favorable safety profile vs FED in both JAKi-naive and experienced pts, including a significantly lower risk of key hematologic AEs, diarrhea, and nausea over 24 weeks. Clinical trial information: NCT04173494; NCT01969838; NCT02101268; NCT01523171; NCT01437787. Research Sponsor: GSK plc.

Longitudinal assessment of cardiac involvement in Erdheim-Chester disease using cardiac magnetic resonance imaging. *First Author: Levi-Dan Azoulay, Hôpital Pitié-Salpêtrière, Paris, France*

Background: Erdheim-Chester disease (ECD) is a rare multi-systemic non-Langerhans cell histiocytosis that affects the heart in nearly half of patients. Atrial infiltration and pericardial effusion are the hallmarks of cardiac involvement and can lead to clinical complications (conduction disorders, coronary artery stenosis, tamponade, constrictive pericarditis). Evolution under treatment is poorly studied. We aimed to investigate the evolution of cardiac involvement in ECD using cardiac magnetic resonance (CMR) imaging. **Methods:** All ECD patients with a CMR imaging disclosing a cardiac involvement and who underwent at least one follow-up CMR imaging between 2005 and 2020 at a French tertiary center were retrospectively included. First and last CMR imaging were compared. Multivariable analysis was performed to search for independent predictors of cardiac involvement resolution. Variables were included in the model if their P-value was < 0.1 on univariable analysis. **Results:** Overall, 46 patients were included. Median age at first imaging was 63 years [53-69]. Median delay between the first and the last imaging was 4 years [2-7]. *BRAF*^{V600E} mutation was present in 43 patients (94%). Patients received a median of 2 [1-3] treatments. All patients (100%) had cardiac involvement at baseline. Right atrio-ventricular sulcus (RAVS) was infiltrated in 38 patients (83%) and was the main cardiac feature. Overall, complete regression was observed in 6 patients (13%), partial regression in 26 patients (56%), stable imaging in 12 patients (26%), and worsening in 2 patients (5%). In patients with RAVS infiltration, complete regression was observed in 5 patients (16%) and partial regression was seen 22 patients (58%) regression. On univariable analysis, patients with regression of their infiltration had a lower rate of death (16% versus 64%, $P = 0.002$), a higher rate of atrial infiltration late gadolinium enhancement (LGE) (97% versus 71%, $P = 0.01$), a higher rate of hydronephrosis (50% versus 14%, $P = 0.03$) and a lower rate of interferon prescription (69% versus 100%, $P = 0.02$). A similar rate of vemurafenib use was observed in both groups (69% versus 54%, $P = 0.3$). On multivariable analysis, death remained significantly associated with follow-up imaging status ($\beta = -2.3$ $P = 0.01$), while atrial infiltration LGE ($\beta = 2.7$, $P = 0.06$), hydronephrosis ($\beta = 1.6$, $P = 0.1$) and treatment with interferon ($\beta = -1.6$, $P = 1$) were no longer significantly associated with imaging status. **Conclusions:** Partial or complete resolution of cardiac involvement was observed in 69% of patients with ECD and was significantly associated with a lower rate of death on multivariable analysis. Consistency of pacritinib for spleen and symptom reduction in patients with myelofibrosis regardless of cytopenias. *First Author: Prithviraj Bose, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In patients with myelofibrosis (MF), JAK inhibitor therapy can improve both splenomegaly and disease symptoms. Unfortunately, dosing – and thus efficacy – of available current JAK1/2 inhibitors is frequently limited in patients with cytopenic MF due to drug-induced exacerbation of cytopenias. Pacritinib is a novel JAK1-sparing inhibitor of JAK2/IRAK1/ACVR1 that has been studied at full dose in patients with MF regardless of cytopenias. Here, we present data on spleen and symptom benefit in pacritinib-treated patients across the cytopenic spectrum, stratified by both baseline platelet (PLT) count and hemoglobin (HB) level. **Methods:** Evaluable patients treated with pacritinib in the PERSIST-1 and PERSIST-2 studies were analyzed, stratified by baseline PLT (<100, ≥100x10⁹/L) and HB (<8, 8 to <10, ≥10 g/dL). Groups were analyzed for depth of spleen volume response (SVR), modified total symptom score (TSS) response, patient global impression of change (PGIC), and dose intensity. **Results:** Of 276 patients evaluable for spleen response, median age was 67 years, 51.5% had grade 3 fibrosis, 70% had primary MF, and 16% had prior JAK2 inhibitor exposure. Median dose intensity was >99.7% for the duration of the study across PLT and HB subgroups. Overall, 80% of patients had ≥10% SVR (SVR-10), 75.5% had TSS-10, and 78% reported that their symptoms were improved at week 24. Week 24 spleen reduction occurred consistently across PLT and HB strata, with 84-93% and 86-90% of patients respectively (Table). SVR-35 occurred in 23-25% of patients across PLT strata and in 21-28% of patients across HB strata. Symptom response was also consistent across strata, though TSS-50 occurred at highest rates (62.5%) in patients with HB <8 g/dL. There was no diminution in symptom burden reduction in patients with thrombocytopenia (Table). Across all subgroups, at least three-quarters of patients reported symptoms were “improved” at week 24. **Conclusions:** Pacritinib demonstrates consistent efficacy for spleen and symptom response in patients with MF regardless of blood counts. This consistent effect may be related to pacritinib’s unique kinome profile and its ability to be delivered at full dose in patients regardless of cytopenias. Clinical trial information: NCT01773187, NCT02055781. Research Sponsor: CTI BioPharma Corp.

Outcomes of patients with a myeloproliferative neoplasm and atrial fibrillation. *First Author: Orly Leiva, New York University Grossman School of Medicine, New York, NY*

Background: Patients with myeloproliferative neoplasms (MPN), including essential thrombocythemia (ET), polycythemia vera (PV), and primary myelofibrosis (PMF), are associated with increased risk of cardiovascular (CV) disease including arterial thrombosis (AT). Atrial fibrillation (AF) is also associated with increased risk of AT and often co-exists with MPN. However, thrombotic and bleeding outcomes in patients with MPN compared with those without have not been thoroughly investigated. **Methods:** Patients aged ≥ 18 years with a hospital admission for AF with and without a history of MPN in 2017 and 2018 were identified using the National Readmission Database. Primary outcomes were 30-day (D) and 90-D any-cause, AT-related (including stroke, myocardial infarction, arterial thromboembolism), and bleeding-related readmissions. Propensity score weighting (PSW) was performed in order to adjust for imbalances between MPN and non-MPN patients. PSW Cox proportional hazards was performed to estimate risk of 90-D readmission in patients with MPN compared with patients without. **Results:** A total of 468,094 patients with AF were identified with 1,617 patients having a history of MPN. CHA₂DS₂-VASC (mean 3.8 vs 3.7) and HAS-BLED scores (mean 2.4 vs 2.3), risk scores for AT and bleeding in AF, were similar between MPN and non-MPN patients. After PSW Cox proportional hazards, patients with MPN had an increased risk of 30-D all-cause (HR 1.72, 95% CI 1.70 – 1.74), AT (HR 1.45, 95% CI 1.38 – 1.53), and bleeding (HR 2.21, 95% CI 2.01 – 2.44) re-admissions. MPN patients had an increased risk of 90-day any cause (HR 1.38, 95% CI 1.37 – 1.40) and bleeding (HR 1.76, 95% CI 1.65 – 1.88) but not AT (HR 1.03, 95% CI 0.99 – 1.08) readmissions. **Conclusions:** Among patients admitted for AF, MPN is associated with increased risk of 30-D and 90-D any-cause and bleeding readmissions and 30-D AT readmissions despite similar CHA₂DS₂-VASC and HAS-BLED risk scores. Further studies are needed to identify risk factors for bleeding and AT in patients with MPN and AF and improve on current risk scores, which do not include MPN status. Research Sponsor: None.

Bromodomain and extra-terminal (BET) inhibitor INCB057643 (LIMBER-103) in patients (pts) with relapsed or refractory myelofibrosis (R/R MF) and other advanced myeloid neoplasms: A phase 1 study. *First Author: Justin M. Watts, Sylvester Cancer Center, University of Miami, Miami, FL*

Background: BET proteins are epigenetic readers that regulate expression of critical onco-proteins involved in the pathophysiology of hematologic malignancies, including MF. INCB057643 is a small-molecule BET inhibitor evaluated as monotherapy and in combination with ruxolitinib (RUX) in pts with advanced malignancies in 2 previous phase 1/2 clinical trials. **Methods:** This ongoing phase 1, 3+3 dose-escalation/expansion study (NCT04279847) evaluates safety and tolerability of INCB057643 (4 mg once daily [qd]; escalation up to 12 mg qd) in pts aged ≥18 years as (1) monotherapy (part 1) in R/R MF, myelodysplastic syndromes (MDS), or MDS/myeloproliferative neoplasm (MPN) overlap syndromes (MDS/MPN) or (2) added to RUX (part 2) in pts with MF and suboptimal response to RUX. The primary endpoint is safety and tolerability, including identification of dose-limiting toxicities (DLTs). **Results:** 13 pts have been treated in part 1 (4 mg, n=6; 8 mg, n=4; 10 mg, n=1; 12 mg, n=2), and 3 pts received 4 mg + RUX in part 2 (overall age range, 50–79 years; men, n=9; study treatment duration range, 15–314 days). 12 pts had MF, and 4 had MDS/MPN. All 6 pts in the 4-mg cohort discontinued treatment (3 for progressive disease [PD]; MF, n=2; MDS/MPN, n=1); 1 pt with MF in the 12-mg cohort discontinued for thrombocytopenia. The other 9 pts remain on treatment. Thrombocytopenia was the most common treatment-emergent adverse event (TEAE; n=9; Table) and the only TEAE leading to discontinuation (n=3). Grade ≥3 TEAEs occurring in ≥1 pt were thrombocytopenia (n=4), anemia (n=3), and hypokalemia (n=2). There were 8 serious AEs across 4 pts, with only COVID-19 occurring in >1 pt (n=2); all but one (pneumonia) were considered unrelated to study treatment. There were 2 DLTs (thrombocytopenia [MDS/MPN pt] and hyperbilirubinemia [MF pt]; both 12-mg cohort) and 2 deaths (both 4-mg cohort due to PD [MF, n=1; MDS/MPN, n=1]). **Conclusions:** Treatment with INCB057643 monotherapy (4 and 8 mg qd) and in combination (4 mg qd) with RUX was generally well tolerated in this pt population. The 12-mg qd monotherapy dose was not tolerated and caused 2 DLTs. There were no treatment-related fatal events. Dose finding in part 1 is ongoing with 10 mg qd, after which a recommended phase 2 dose will be declared. Combination dose escalation is also ongoing. Preliminary efficacy including spleen size and symptoms will be available for presentation. Clinical trial information: NCT04279847. Research Sponsor: Incyte Corporation.

Clinical outcomes by SF3B1 mutation status in patients (pts) with lower-risk myelodysplastic syndrome (LR-MDS) retreated with erythropoiesis-stimulating agents (ESAs). *First Author: Adeola Y. Makinde, Bristol Myers Squibb, Princeton, NJ*

Background: Pts with SF3B1-mutated LR-MDS often have a more favorable prognosis versus those with SF3B1 wildtype. A sizeable number of pts with LR-MDS undergo ESA treatment even after experiencing ESA failure in first line. This study evaluated the outcomes of pts with LR-MDS retreated with ESAs in routine clinical practice, stratified by SF3B1 status. **Methods:** This retrospective cohort study included pts with LR-MDS in the US community setting who initiated ESAs as first-line therapy between January 1, 2016 and June 30, 2019, and were followed through June 30, 2021. Eligible pts discontinued ESAs (treatment gap ≥ 3 wk for epoetin alfa or ≥ 6 wk for darbepoetin alfa) and subsequently reinitiated ESA therapy at least once during follow-up. Ring sideroblasts (RS) ≥ 15% served as a surrogate for pts with unknown SF3B1 mutation status. Outcomes included ESA switches, dose reductions and escalations, ESA failure, and overall survival (OS). Primary ESA failure was defined as no rise in hemoglobin (Hb) ≥ 1.5 g/dL or no decrease in RBC transfusion requirement by 8 wk of treatment. Transfusion-dependent (TD) status was evaluated for pts who were transfusion independent (TI) at baseline. **Results:** A total of 82 pts with LR-MDS and repeat ESA treatment were included. Median age at start of ESA treatment was 79 y (interquartile range [IQR], 72–85). Diagnosis of MDS-RS, MDS with isolated del(5q), MDS with multilineage dysplasia, and MDS with single lineage dysplasia was reported in 30 (36%), 7 (9%), 9 (11%), and 9 (11%) pts, respectively; 27 (33%) had unknown classification. Median follow-up was 26 mo (IQR, 13–38) with 65% failing ESA therapy by 8 wk. Table shows pts’ SF3B1 mutation status, median OS, pts who had an ESA switch, dose reduction or escalation, experienced ESA failure, and pts who were TI at baseline and became TD during follow-up. Results were similar when RS was not used as a surrogate, and when analyses were limited to pts who were treated with ESAs only throughout follow-up. **Conclusions:** In this study of pts with LR-MDS retreated with ESAs, primary ESA failure was high with nearly half of TI pts becoming TD during follow-up. OS was poor regardless of SF3B1 status – 2–4 times lower than the remaining life expectancy for a 79-y-old (108 mo for men; 125 mo for women). Although treatment options were limited during the study period, the high primary failure rate suggests that pts with LR-MDS may benefit from alternatives to ESAs. Research Sponsor: Bristol Myers Squibb.

Outcomes of individuals with clonal hematopoiesis evaluated at a cancer center. *First Author: Kelly Sharon Chien, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Clonal hematopoiesis (CH) refers to the presence of somatic mutations in individuals without overt hematological disorders. CH, including CH of indeterminate potential (CHIP) and clonal cytopenia of undetermined significance (CCUS), is associated with hematologic malignancies and other systemic comorbidities. There are currently no established guidelines regarding the optimal monitoring and management of patients with CH, and the impact of CH in patients with concomitant underlying malignancies remains unknown. **Methods:** Patients seen at a tertiary cancer center with at least 1 somatic mutation detected by next generation sequencing on bone marrow aspirate or peripheral blood between January 2015 and March 2021 were included. Patients with donor-derived CH or any morphologic evidence of a myeloid neoplasm were excluded. **Results:** We evaluated 78 patients—76% had a history of malignancy and 73% had other comorbidities. The mutations most frequently observed were *DNMT3A* (40%), *TET2* (31%), *TP53* (26%), and *ASXL1* (18%). The median overall survival for all patients was not reached (2-year survival rate of 79%). Most deaths were related to primary malignancies (35%), comorbidities (20%), or myeloid neoplasms (20%). Due to concomitant use of antineoplastic therapy and other causes of cytopenia in 19 patients, we further categorized patients into 4 groups: CHIP on treatment (CHIP-T), other CHIP (CHIP-O), CCUS on treatment or with a non-myeloid hematologic malignancy (CCUS-T), and other CCUS (CCUS-O). Transformation to a myeloid neoplasm occurred in 12 patients (15%). The 3-year cumulative incidence of transformation was higher in CCUS-O (24%) and CCUS-T (21%) compared to the CHIP group (6%, $p = 0.48$). On univariate analysis, increasing age, variant allele frequency (VAF) ≥ 0.2 , hemoglobin < 10 g/dL, and any chromosomal abnormalities were associated with higher risk for transformation. By multivariate analysis, transformation was only significantly associated with VAF ≥ 0.2 (hazard ratio (HR) 18.25; 95% confidence interval (CI): 3.59, 92.73; $p = 0.0005$) and hemoglobin < 10 g/dL (HR 15.62; 95% CI: 3.29, 74.05; $p = 0.0005$). **Conclusions:** CH in predominantly cancer patients is associated with cardiovascular disease and transformation to myeloid neoplasms, especially in those with higher mutational burdens and anemia. However, patients die more frequently from their primary malignancy or comorbidities than from a myeloid neoplasm. Close monitoring of hematologic progression and extra-hematologic manifestations of CH is crucial. Further investigation into the identification of individuals at high risk of myeloid transformation and potential early therapeutic interventions for this population is warranted. A randomized, open-label study of the efficacy and safety of galinpepimut-S (GPS) maintenance monotherapy compared to investigator's choice of best available therapy (BAT) in patients with acute myeloid leukemia (AML) who have achieved complete remission (CR) after second-line salvage therapy. *First Author: Omer Hassan Jamy, University of Alabama at Birmingham, Birmingham, AL*

Background: Patients with relapse/refractory (r/r) AML have poor outcomes. Allogeneic stem cell transplantation (allo-SCT) can potentially cure some patients with r/r AML who achieve second CR (CR2). However, barriers to transplantation such as advanced age, poor functional status/comorbidities or lack of donor exist and not all patients are able to proceed to allo-SCT. Therefore, novel strategies to decrease relapse risk in these patients are urgently needed. A National Cancer Institute consensus study on prioritization of cancer antigens ranked the Wilms tumor 1 (WT1) protein as the top immunotherapy target in cancer. WT1 has emerged as an encouraging vaccine target in AML due to its overexpression in leukemic blasts. Maintenance therapy with Galinpepimut-S (GPS), a multivalent heteroclitic WT1 peptide vaccine, has shown promising activity in patients with AML by inducing a strong innate immune response (CD4+/CD8+) against the WT1 antigen and across a broad range of HLA types. **Methods:** This is an open-label, multicenter, randomized, phase III study of GPS vs. BAT in patients with AML in CR2/CRp2 (CR2 with incomplete platelet recovery). BAT may include observation, low dose cytarabine and hypomethylating agents +/- venetoclax. The primary endpoint of the study is overall survival (OS). Secondary endpoints include safety and tolerability of GPS and leukemia-free survival. Exploratory endpoints include WT1-specific immune response dynamics in blood and bone marrow. Approximately 125–140 patients will enroll, in a 1:1 ratio, to provide at least 90% power under an assumed hazard ratio of 0.52, based on median OS of 8.0 m (BAT) and 15.4m (GPS). Randomization will be stratified by duration of CR1 (< 12 m vs. ≥ 12 m), Cytogenetics (poor-risk vs. all other), CR2 vs. CRp2 and measurable residual disease (MRD) after CR2 (MRD- vs. MRD+). Inclusion criteria consists of willing subjects ≥ 18 y with AML within 6m of achieving CR2/CRp2, ineligible for allo-SCT due to any reason, with ≥ 300 lymphocytes/ μ L and with adequate renal and hepatic function. Subjects with central nervous involvement, having received a live vaccine 30d prior to first dose of study drug, having a diagnosis of immunodeficiency, receiving ≥ 10 mg daily of prednisone equivalent (or any other systemic immunosuppressant) for any indication 7d prior to first dose of study drug, hypersensitivity to study agent and with a history of solid organ transplant would be excluded. The clinical trial is actively enrolling, and the registry number is NCT04229979. Clinical trial information: NCT04229979. Research Sponsor: Sella Life Sciences Group.

Poster Session

A phase 1b/2 study of pivekimab sunirine (PVEK, IMG632) in combination with venetoclax/azacitidine or magrolimab for patients with CD123-positive acute myeloid leukemia (AML). *First Author: Naval Guastad Daver, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite improved outcomes with azacitidine (AZA) and venetoclax (VEN) in frontline unfit AML (CR 37% and CR/CRi 66%), long-term survival for these patients remains inadequate (mOS < 15 m, DiNardo NEJM 2020). CD123 is expressed on the majority of AML blasts and leukemic stem cells while minimally expressed on normal hematopoietic stem cells (Kovtun Blood Adv 2018). Pivekimab sunirine (PVEK, IMG632) is an antibody-drug conjugate (ADC) comprising a high-affinity CD123 antibody, cleavable linker, and an indolinobenzodiazepine pseudodimer (IGN) payload. The IGN payload alkylates DNA and causes single strand breaks without crosslinking. IGNs are designed to have high potency against tumor cells, while demonstrating less toxicity to normal marrow progenitors than other DNA-targeting payloads. Clinical data in relapsed/refractory (R/R) AML (Daver ASH 2022) supported the continued clinical exploration of the PVEK+AZA+VEN triplet. The current enrolling dose expansion cohorts (Regimen C; Cohorts 1 and 2) in frontline AML will evaluate antileukemia activity and MRD levels in the combination of PVEK+AZA+VEN. Regimen E will enroll patients with R/R AML to evaluate the safety and antileukemia activity of PVEK in combination with magrolimab. **Methods:** This is an open-label, multicenter, Phase 1b/2 study of PVEK administered in combination regimens in patients with frontline and R/R CD123-positive AML. Patients will receive the established recommended phase 2 dose (RP2D) of PVEK 0.045 mg/kg IV, as a < 30 -minute outpatient infusion. In Regimen C, patients will receive PVEK 0.045 mg/kg IV on D7 + azacitidine 75 mg/m² SC or IV daily on days 1 to 7, and venetoclax up to 400 mg PO daily for at least 14 days (Cohort 1) or for up to 28 days (Cohort 2) in a 28-day cycle. In Regimen E, R/R AML patients will receive PVEK 0.045 mg/kg IV on D1 of the 28-day cycle in combination with magrolimab at 30 mg/kg Q2W, after the standard ramp up schedule. Regimen C will enroll adults with untreated AML, CD123+ by flow cytometry or IHC and no prior HMA treatments. The primary endpoints for Regimen C are composite CR rate, overall response rate (ORR), duration of remission (DOR), MRD levels and key secondary endpoints are safety, PK and immunogenicity. Regimen E will enroll adult patients with relapsed or refractory CD123+ AML with up to 2 prior lines of therapy. The primary endpoint for Regimen E is dose limiting toxicities (DLTs) and key secondary endpoints are safety, antileukemic activity, PK and immunogenicity. The PVEK+AZA+VEN triplet (Regimen C) is currently enrolling frontline unfit patients across sites in France, Germany, Italy, Spain, UK and USA. The PVEK+Magro doublet (Regimen E) is planned to be open for enrollment mid-2023 at sites in the USA. Clinical trial information: NCT04086264. Research Sponsor: ImmunoGen, Inc.

Iadademstat in combination with gilteritinib for patients with mutated FLT3 relapsed/refractory acute myeloid leukemia. *First Author: Amir Tahmasb Fathi, Massachusetts General Hospital, Harvard Medical School, Boston, MA*

Background: Epigenetic dysregulation is a hallmark of acute myeloid leukemia (AML) and is caused by recurrent translocations and/or mutations in chromatin regulators and transcription factors, resulting in myeloid differentiation blockade and leukemic stem cell renewal. Accordingly, about 70% of recurring mutations in AML patients (pts) target regulators of gene expression, underscoring the potential of epigenetic therapies to change the disease natural history. Iadademstat (iada/ORY-1001) is a specific, oral, potent, covalent inhibitor of the epigenetic Lysine-Specific Demethylase 1 (LSD1/KDMA1) enzyme. In preclinical and clinical studies iada decreased leukemic stem cell survival and induced macrophage/monocytic differentiation of blasts. ALICE, a Ph2 study of iada in combination with azacitidine (aza), showed high complete remission (CR/CRi) rates and durable responses in treatment naive, unfit AML pts without exacerbating the toxicity profile of aza (Salamero et al., Oral at ASH 2022). Despite improvements in AML therapy, relapsed and refractory (R/R) cases are frequent and contribute to the death of more than 50% of pts, particularly in those subpopulations with higher risk genetics, the largest of which (up to 30-40% AML pts) harbors fms-like tyrosine kinase 3 mutations (FLT3mut+). Use of the FLT3 inhibitor (FLT3i) gilteritinib as monotherapy for R/R pts resulted in improved outcomes but the duration of remission achieved is transient and often brief (CR rate: 20%; EFS: 2.8 months) per the ADMIRAL Ph3 study (Perl, et al., NEJM 2019). Preclinically, iada has marked synergy with FLT3i, particularly gilteritinib, in FLT3 wild-type and FLT3 mut+ AML cells and in derived cell lines resistant to venetoclax, azacitidine and FLT3is. **Methods:** Adult pts with ECOG 0-2 and FLT3 mut+ R/R AML, after 1 or 2 prior lines of therapy, will be enrolled. In escalation (3+3), up to 18 pts will receive iada at 75 to 150 μ g, orally, in 5 days ON-2 days OFF schedule, with gilteritinib SoC. Up to approximate 14 pts will be expanded from pharmacologically active dose/s (per Project OPTIMUS). Primary endpoints of the study are safety and RP2D determination. Bayesian posterior probability efficacy monitoring will be performed periodically for each dose cohort. Bayesian efficacy futility and early stopping boundary will be applied. Posterior probability criterion (Prob (CR > 0.3) ≥ 0.60) at the end of the study will warrant further research. Safety in expansion will be evaluated continuously with a Bayesian stopping rule. Secondary endpoints include OS, EFS, CR, CR/CRi, ORR, TTR, DoR, and transfusion rate. Exploratory endpoints include PK, PD, MRD and gene mutational analysis. The study will run in 15 US sites. Additional sites will be added for a subsequent Phase 2 randomized controlled double-blinded FRIDA 2 study to assess the efficacy of this combination in R/R FLT3 mut+ AML. Clinical trial information: NCT05546580. Research Sponsor: Oryzon Genomics.

A phase II study of vibecotamab, a CD3-CD123 bispecific T-cell engaging antibody, for MRD-positive AML and MDS after hypomethylating agent failure. First Author: Nicholas James Short, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: CD123 is a marker of leukemic stem cells that is differentially overexpressed in most patients with acute myeloid leukemia (AML), myelodysplastic syndromes (MDS) and chronic myelomonocytic leukemia (CMML). In contrast, CD123 is expressed at negligibly low levels on normal hematopoietic progenitors, making it a potentially promising therapeutic target. Vibecotamab (formally XmAb14045) is a CD3-CD123 bispecific engaging antibody that has established clinical activity in relapsed/refractory AML. In a phase I study, the overall response rate was 14.8% in patients who received vibecotamab at a dose of $\geq 0.75 \mu\text{g/kg}$ (Ravandi F et al. ASH 2020 abstract #460). Response rates were notably higher in those with lower disease burden (bone marrow blasts $\leq 25\%$) where the overall response rate was 25.9%. In light of the activity of vibecotamab in relapsed/refractory low-blast AML, we designed this phase II study to evaluate vibecotamab in other low-blast states, including CD123-positive, MRD-positive AML and in MDS or CMML after failure of hypomethylating agents. **Methods:** This is a two-arm, open-label, phase II study of vibecotamab in patients with AML in first or second morphological remission with detectable MRD at a level of $\geq 0.1\%$ by flow cytometry and in patients with MDS (intermediate or higher-risk by IPSS-R) or CMML (CMML-1 or CMML-2) after failure of hypomethylating agents. CD123 expression $\geq 20\%$ on aberrant myeloid blasts is required for study eligibility. Vibecotamab is given IV in a ramp-up dose schedule on days 1, 3, 5 and 8 of cycle 1, followed by weekly doses of vibecotamab at a dose of $1.7 \mu\text{g/kg}$. Patients may receive up to 4 cycles of vibecotamab in 28-day cycles. The primary objective of the AML MRD cohort is to determine the MRD negativity rate after 4 cycles; the primary objective of the MDS/CMML cohort is to determine the response rate (CR + mCR + PR + HI + clinical benefit) after 4 cycles. The target MRD response in the AML MRD cohort is 50%, and the target response rate in the MDS/CMML cohort is 30%. Secondary endpoints include remission duration, duration of MRD response (AML MRD arm), CR rate (MDS/CMML arm), relapse-free survival, overall survival, and safety. Exploratory endpoints include correlation of clinical outcomes with CD123 expression and the dynamics of CD123 expression at treatment initiation and at the time of relapse. Additional immunological correlates will be performed, including 1.) determination of molecular immune states that predict response or resistance, 2.) functional interrogation of TCR-antigen interactions, and 3.) nomination of leukemic neo-antigens. The planned enrollment is 40 patients (20 in each of the two cohorts). To date, 13 patients have been enrolled (7 in the AML MRD cohort and 6 in the MDS/CMML cohort). The trial is actively accruing at MD Anderson Cancer Center. Clinical trial information: NCT05285813. Research Sponsor: MD Anderson Cancer Center; Xencor.

Phase 1B/2A safety, pharmacokinetics and pharmacodynamics study of foscicliprox alone and in combination with cytarabine in patients with relapsed/refractory acute myeloid leukemia. First Author: Tara L. Lin, Division of Hematologic Malignancies & Cellular Therapeutics, University of Kansas, Kansas City, KS

Background: Foscicliprox (CPX-POM) is a broad-spectrum anticancer agent being developed through a public-private partnership between CicloMed LLC and KU Cancer Center (KUCC). Following intravenous administration, foscicliprox is rapidly and completely metabolized to its active metabolite clidopirox (CPX). Given foscicliprox is a prodrug lacking pharmacologic activity, in vitro mechanistic studies were conducted utilizing CPX as the test article. In collaboration with Notable Labs (Foster City CA), we characterized ex vivo sensitivity to CPX in bone marrow and peripheral blood samples from ten newly diagnosed and relapsed acute myeloid leukemia (AML) patients. Reductions in blast counts were seen in each of the 10 patients studied at clinically relevant concentrations. In vitro experiments in AML cell lines (HL-60 and MV4-11) characterized the mechanism(s) of the anti-leukemia activity of CPX. CPX inhibited proliferation of AML cell lines in a dose- and time-dependent manner with IC50 values ranging from 2.5-4 μM . CPX induced cell cycle arrest in the subG0 phase and CPX-treated cells lost their ability to enter to G0-G1 phase. Moreover, CPX induced early and late phase apoptosis. CPX also activated Caspase 3/7 activity. This preclinical data led to the development of a multi-center Phase 1B/2A clinical proof of concept trial (NCT04956042) in AML patients. **Methods:** Eligible AML patients are adults with primary refractory (two prior regimens) or relapsed AML; ECOG PS 0-2; adequate end organ function. Prior allogeneic stem cell transplant is allowed if patient is more than 100 days post-transplant with no active graft-versus-host disease. CPX-POM is administered as 900 mg/m² once daily as an IV infusion on Days 1 to 5 of each 21-day cycle. Day 8 bone marrow sample is collected for correlative studies. Ex vivo Drug Sensitivity Screening (DSS) will be performed on samples obtained prior to treatment and C1 Days 8 and 21. 14 evaluable patients will be enrolled in Cohort 1a. If disease response is observed in at least 4 of 14 patients, an additional 14 patients will be enrolled in Cohort 1b. During Cohort 1a, patients who do not respond to CPX-POM alone may be switched to the combination of CPX-POM + cytarabine. Patients who respond to the combination treatment may continue until evidence of disease progression. If disease response to CPX-POM alone is not observed in at least 4 of 14 patients in Cohort 1a, the study may be terminated or a Cohort 2a may be initiated using the combination of CPX-POM and cytarabine. The trial is currently open at two sites with 14 patients enrolled and 8 evaluable for the primary endpoint. Clinical trial information: NCT04956042. Research Sponsor: CicloMed LLC.

Poster Session

A phase 1/2 dose escalation study of the BCL-2 inhibitor ZN-d5 and the WEE1 inhibitor azenosertib (ZN-c3) in patients (Pts) with acute myeloid leukemia (AML). First Author: Catherine Choy Smith, Division of Hematology/Oncology, Department of Medicine, Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA

Background: B-cell lymphoma 2 (BCL-2) is an anti-apoptotic protein and pathway inhibition combined with chemotherapy and/or targeted therapeutics has led to significant clinical benefit in pts with AML. Disruption of cell cycle regulation may complement BCL-2 inhibition as many malignant cells are dependent on proteins that regulate cell cycle progression. The cell cycle checkpoint protein, WEE1, is highly expressed in genomically unstable malignancies and inhibition of WEE1 induces tumor cell apoptosis. It has been previously reported that the combination of ZN-d5 (an oral, selective BCL-2 inhibitor) and azenosertib (an oral, highly potent WEE1 inhibitor) synergistically enhance killing of AML cells both *in vitro* and *in vivo*, as well as in TP53-mutated models (Izadi, AACR 2022). Based on this strong pre-clinical rationale, a Phase 1/2 study was designed to evaluate the novel combination of ZN-d5 and azenosertib in pts with relapsed/refractory (R/R) AML. **Methods:** This phase 1/2 open-label study (ZN-d5-004C, NCT05682170) is determining the maximum tolerated dose (MTD), recommended phase 2 dose (RP2D), pharmacokinetics (PK), and clinical activity of ZN-d5 + azenosertib in pts with AML. The phase 1 dose-escalation stage is based on a Bayesian Optimal Interval design. Phase 2 is an open-label expansion to be conducted if supported by safety and efficacy data from the dose-escalation stage. Prior to initiating dose-escalation for the ZN-d5 + azenosertib combination, an azenosertib monotherapy cohort is being enrolled, as it has not been previously administered to pts with hematologic malignancies. For the dose-escalation azenosertib monotherapy (n=15) and ZN-d5 combination (n=40) cohorts, pts must have relapsed/refractory (R/R) disease after ≥ 1 line of AML therapy that may include the BCL-2 inhibitor, venetoclax. In phase 1, an azenosertib monotherapy cohort will be opened prior to investigation of ZN-d5 + azenosertib in combination. In phase 2, ZN-d5 + azenosertib will be given at the RP2D. Alternative dosing schedules may also be investigated based on emerging clinical data. The primary endpoints are adverse events and dose-limiting toxicities. Secondary endpoints include the rate and duration of remission according to the European LeukemiaNet 2017 criteria, including complete remission (CR), CR with incomplete hematologic recovery (CRi), morphologic leukemia-free state (MLFS), partial remission (PR), stable disease, progressive disease, relapse after remission (including molecular relapse), remission rate (CR + CRi), overall response rate (CR + CRi + MLFS + PR), and rate of and time to relapse. Pts will remain on study until disease progression, failure to respond, remission if additional therapy is clinically indicated, withdrawal of consent, loss to follow-up, or death. Clinical trial information: NCT05682170. Research Sponsor: Zentaris Pharmaceuticals.

Phase 1 study of ziftomenib (KO-539) in combination with venetoclax or venetoclax/azacitidine or standard induction cytarabine/daunorubicin (7+3) chemotherapy for the treatment of patients with acute myeloid leukemia. First Author: Amer Methqal Zeidan, Yale University, New Haven, CT

Background: Relapsed or refractory (R/R) acute myeloid leukemia (AML) with nucleophosmin 1-mutations (*NPM1*-m) or *KMT2A*-rearrangement (*KMT2A*-r) represent a high unmet need. Ziftomenib is a potent and selective inhibitor that targets the menin-mixed-lineage leukemia (MLL) lysine(K)-specific methyltransferase 2A (*KMT2A*) interaction driving leukemogenesis in these subtypes. An ongoing Phase 1/2 study (KO-MEN 001) has demonstrated meaningful clinical activity and tolerability with ziftomenib monotherapy in R/R AML. In preclinical testing, ziftomenib combined with venetoclax induced synergistic lethality in *KMT2A*-r and *NPM1*-m human AML cell lines and patient-derived cells. Moreover, treatment with ziftomenib plus venetoclax/azacitidine has induced prolonged durable remissions in mice with *KMT2A*-r AML xenografts. Therefore, administration of ziftomenib in combination with standard-of-care (SOC) therapies may provide additional clinical benefit for patients with newly diagnosed or R/R *NPM1*-m and *KMT2A*-r menin-dependent AML. **Methods:** KOMET-007 (KO-MEN-007, NCT#) is a 2-part dose escalation (Phase 1a) and expansion (Phase 1b) study to evaluate the safety, tolerability, and preliminary antileukemic activity of ziftomenib in combination with non-intensive chemotherapy (NIC) and intensive chemotherapy (IC) in patients with *NPM1*-m and *KMT2A*-r AML. During Phase 1a, the ziftomenib dose will be escalated with standard doses of either venetoclax and azacitidine (zifto/ven/aza) or cytarabine and daunorubicin (zifto/7+3) in defined genetic cohorts (*NPM1*-m and *KMT2A*-r) using a rule-based approach (n = 6 per cohort/dose level) to select ziftomenib doses for expansion/validation in Phase 1b. The Phase 1b portion will also evaluate zifto/ven/aza in newly diagnosed AML (*KMT2A*-r and *NPM1*-m) and zifto/ven in R/R AML (*NPM1*-m only). The overall primary objectives are to establish the minimum biologically effective, dose limiting toxicities, and recommended Phase 2 dose of ziftomenib combined with NIC and IC backbones in each genetically defined cohort. Additional secondary endpoints include preliminary antileukemic efficacy (including MRD-negative responses and number of patients able to transition to subsequent allogeneic stem cell transplant), pharmacokinetic, and pharmacodynamic data. Exploratory end points include biomarkers for efficacy and resistance, pharmacodynamic biomarkers and activity in isolated myeloid sarcoma. Clinical trial information: NCT04067336. Research Sponsor: Kura Oncology, Inc.

A phase 1b study to evaluate the efficacy, safety, and pharmacokinetics of an investigational microbiome therapeutic, SER-155, in adults undergoing hematopoietic stem cell transplantation. *First Author: Doris M. Ponce, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In patients undergoing allogeneic hematopoietic cell transplantation (HCT), loss of gastrointestinal microbial diversity is associated with risk of bloodstream infections (BSI), acute graft-versus-host disease (aGVHD), and death. SER-155 is a rationally designed investigational cultivated microbiome therapeutic, hypothesized to improve clinical outcomes in HCT by restoring colonization resistance to potential pathogens, promoting epithelial barrier integrity, and reducing colonic inflammation. SER-155-001 is a Phase 1b study evaluating the efficacy, safety, and pharmacokinetics (PK) of SER-155 in adults undergoing HCT. **Methods:** This study will enroll approximately 70 subjects ≥ 18 years in an open-label Cohort 1 (n = 10) followed by a double-blind, placebo-controlled Cohort 2 (n = 60) randomized 1:1 to SER-155 or placebo. A variety of conditioning regimens, donor types, and GVHD-prophylaxis regimens are included. Exclusion criteria include history of severe colitis or active inflammatory bowel disease or total colectomy, umbilical cord blood or ex vivo T-cell depletion, exposure to fecal microbiota transplant or any live microbial therapeutic within 3 months prior to screening, and evidence of relapse or progression of hematologic malignancy (minimal residual disease is allowed). Following screening, participants in both cohorts receive 2 treatment courses (one before and one after HCT), each comprised of microbiome conditioning with oral vancomycin or placebo followed by SER-155 or placebo, plus a conditional 3rd treatment course if the subject receives antibiotics. Safety outcomes are followed through 52 weeks post HCT. The primary endpoint is the incidence and severity of adverse events, serious adverse events, and adverse events of special interest. Secondary endpoints include rates of BSI, gastrointestinal infections, aGVHD, febrile neutropenia and overall survival. Microbiome related endpoints include engraftment of SER-155 bacterial strains in the gastrointestinal tract (PK endpoint) and fecal microbiome diversity, composition and metabolites. **Results:** Cohort 1 enrollment is complete, with 13 participants receiving SER-155. In December 2022, the Data and Safety Monitoring Committee supported continuation to Cohort 2 enrollment following review of safety data from Cohort 1. Enrollment in Cohort 2 is underway. **Conclusions:** This Phase 1b study is designed to assess the safety, and clinical efficacy of SER-155 in allogeneic HCT, expanding the clinical experience of microbiome-directed interventions in allogeneic HCT recipients. Clinical trial information: NCT04995653. Research Sponsor: Seres Therapeutics.

ASC2ESCALATE: A US phase 2, single-arm, dose-escalation study of asciminib monotherapy in patients (pts) with chronic myeloid leukemia in chronic phase (CML-CP) previously treated with 1 prior tyrosine kinase inhibitor (TKI). *First Author: Ehab L. Atallah, Medical College of Wisconsin, Milwaukee, WI*

Background: ATP-competitive TKIs extend life expectancy in CML; yet up to 40% of newly diagnosed pts with CML-CP stop first-line (1L) therapy by 5 years due to resistance or intolerance and switch to second-line (2L) therapy. There is also an unmet need to overcome high rates of resistance in 2L. Studies show some pts with resistance achieve responses with higher doses of TKIs, while use of another second-generation (2G) TKI may not clinically benefit pts with resistance to a 2G TKI. Asciminib is the 1st BCR:ABL1 inhibitor that Specifically Targets the ABL Myristoyl Pocket (STAMP), giving it activity against most BCR:ABL1 mutations imparting resistance to ATP-competitive TKIs. Asciminib was 1st approved in the US for patients with CML-CP after ≥ 2 TKIs at 80 mg once daily (QD) and 40 mg twice daily (BID) and CML-CP with the T315I mutation at 200 mg BID. In the phase 3 ASCEMBL study, asciminib 40 mg BID showed superior efficacy vs bosutinib 500 mg QD in pts with CML-CP after ≥ 2 prior TKIs at weeks 24 (major molecular response [MMR], 25.5% vs 13.2%) and 96 (MMR, 37.6% vs 15.8%) and favorable tolerability with > 2 years' follow-up. The phase 1 dose-finding X2101 trial investigated asciminib doses of 80-200 mg QD and 10-200 mg BID; the maximum tolerated dose of asciminib was not reached and no differing safety signals were noted in patients receiving 200 mg BID vs the total treatment population. Here, we describe the phase 2 ASC2ESCALATE trial investigating efficacy and safety of 2L asciminib with dose escalation in pts with CML-CP (NCT05384587). **Methods:** This is a phase 2, open-label, multicenter, single-arm, dose-escalation study in the US. Adults with CML-CP without the T315I mutation with treatment resistance/failure (BCR:ABL1^{IS} > 10% with 6-12 months of 1L treatment or > 1% with > 12 months of 1L treatment) or intolerance (BCR:ABL1^{IS} > 0.1%) with ≥ 6 months of treatment with 1 prior ATP-competitive TKI are eligible. All pts start treatment with asciminib 80 mg QD. For pts not achieving BCR:ABL1^{IS} $\leq 1\%$ at 6 months, dose will be escalated to 200 mg QD if pts do not have grade ≥ 3 or persistent grade 2 toxicity refractory to optimal management. For those without MMR at 12 months, either dose escalation from 80 to 200 mg QD or from 200 mg QD to 200 mg BID will occur or pts can be switched to an investigator's agent of choice and taken off study treatment. Pts achieving MMR at 12 months will continue asciminib at their current dose. Pts continuing to derive clinical benefit from asciminib per investigator assessment may receive post-trial access. Recruitment for this study began August 2022 with an estimated enrollment of 92 pts with CML-CP across ≈ 40 sites. The primary endpoint is MMR at 12 months. Secondary endpoints include additional efficacy outcomes at 3, 6, 18, and 24 months and safety measures. Clinical trial information: NCT05384587. Research Sponsor: Novartis Pharmaceuticals Corporation.

Poster Session

A phase 1, multicenter, open-label, dose-escalation and dose-expansion study to evaluate the safety, tolerability, pharmacokinetics (PK), and efficacy of HS-10382 (TERN-701) in patients (pts) with chronic myeloid leukemia (CML). *First Author: Weiming Li, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Background: There is a need for new treatment options for pts with CML who are intolerant/resistant to currently available BCR-ABL1 ATP-binding site targeted tyrosine kinase inhibitors (TKIs). HS-10382 (TERN-701) is a potent, oral small molecule allosteric inhibitor of BCR-ABL. By binding to the myristoyl site of the BCR-ABL1 protein, HS-10382 (TERN-701) locks BCR-ABL1 into an inactive conformation. This results in a mutation-driven resistance profile different from that of ATP-binding site TKIs, providing potential for both monotherapy and combination therapy with ATP-binding site TKIs. In preliminary nonclinical assays, HS-10382 (TERN-701) was highly potent against wild type BCR-ABL1 as well as most common mutations acquired by pts treated with second generation active site TKIs. This ongoing first-in-human phase 1 study is evaluating HS-10382 (TERN-701) in pts with CML. **Methods:** Eligible adult CML chronic phase (CP) or advanced phase (AP) pts who are resistant or intolerant to prior BCR-ABL1 TKI therapy are enrolled in an open-label Phase 1 study to evaluate the safety, tolerability, PK and efficacy of HS-10382 (TERN-701). This study is being conducted in two parts: Part 1 dose escalation utilizing a rolling six design and Part 2 dose expansion. In the dose escalation stage, CML-CP/AP pts who are resistant or intolerant to prior BCR-ABL1 therapy are being enrolled to determine the maximum tolerated dose (MTD) or maximum applicable dose. Doses selected from the escalation part will be evaluated in the expansion stage in CML-CP pts who are resistant or intolerant to prior BCR-ABL1 TKI therapy and have no T315I mutation. All pts will be carefully followed for adverse events for the duration of study treatment and for 28 days after the last dose of study drug. Pts will be permitted to continue therapy with assessments for progression if the study drug is well-tolerated and the pt has no objective evidence of disease progression. This study is ongoing (enrollment underway for Part 1, dose 3 as of February 2023) with 7 participating study sites in China. Clinical trial information: NCT05367700. Research Sponsor: Jiangsu Hansoh Pharmaceutical Co., Ltd.

A phase 2/3 trial of oral azacitidine (Oral-AZA) in patients (pts) with low- or intermediate-risk myelodysplastic syndromes (MDS). *First Author: Guillermo Garcia-Manero, MD Anderson Cancer Center, Houston, TX*

Background: MDS, a heterogeneous group of clonal myeloid malignancies, are characterized by ineffective hematopoiesis and peripheral blood cytopenias, which can often lead to red blood cell (RBC) transfusion dependence and a risk of progression to acute myeloid leukemia (AML). In early clinical trials, 14- and 21-day (d) dosing regimens of the hypomethylating agent Oral-AZA were well tolerated and induced hematologic improvement (HI) in pts with lower-risk (LR) MDS. In a phase 3 trial, Oral-AZA 300 mg QD for 21d per 28d cycle significantly improved the rate of RBC transfusion independence (TI) and induced durable HI versus placebo (PBO) in patients (pts) with LR-MDS with RBC-transfusion-dependent anemia and thrombocytopenia (Garcia-Manero, et al. *J Clin Oncol* 2021). Grade 3/4 cytopenias were common in the Oral-AZA arm. Given the substantial clinical benefit of Oral-AZA observed in this setting, a new phase 2/3 trial is ongoing to further evaluate the 14d Oral-AZA regimen in pts with International Prognostic Scoring System Revised (IPSS-R)-defined low or intermediate (int)-risk MDS. **Methods:** This ongoing, multicenter, randomized, phase 2/3 trial (CA055-026; NCT05469737) will evaluate the safety and efficacy of Oral-AZA in pts with IPSS-R low- or int-risk MDS. Key eligibility criteria include ≥ 18 years, ECOG performance status score ≤ 2 , and ≥ 1 cytopenia (anemia, thrombocytopenia, or neutropenia). Pts with an absolute neutrophil count < $0.5 \times 10^9/L$ within a week of randomization will be excluded. Informed consent will be obtained from all participants. The phase 2 portion will enroll and randomize ~ 42 pts 1:1 to receive open-label Oral-AZA 200 or 300 mg QD for 14d per 28d cycle, plus best supportive care (BSC), to determine the recommended phase 3 dose (RP3D). The primary endpoints are safety and rate of complete remission (CR) within 6 Tx cycles. The secondary endpoints are overall response rate (ORR), and packed (p) RBC-TI and platelet-TI sustained for 84d in ≤ 6 Tx cycles. ORR includes CR, partial remission (PR), marrow CR, and any HI, per IWG 2006 response criteria. In the phase 3 portion, ~ 188 additional pts will be enrolled and randomized 1:1 to Oral-AZA at the RP3D or PBO for 14d per 28d cycle, plus BSC. Pts in the PBO arm with stable disease at Tx cycle 6 disease assessment or with documented disease progression after ≥ 3 Tx cycles will have the option to cross over into the Oral-AZA arm. The primary endpoint is CR in ≤ 6 Tx cycles. The key secondary endpoint is 84d pRBC-TI. Other secondary endpoints include those described in the phase 2 portion plus overall survival, event-free survival, time to AML progression, iron parameters, health-related quality of life, healthcare resource utilization, and safety parameters. Pts who benefit from Oral-AZA in phase 2 or 3 may continue to receive Tx in an extension phase. Trial recruitment began in December 2022 and is ongoing. Clinical trial information: NCT05469737. Research Sponsor: Bristol-Myers Squibb.

A phase I study of MEK inhibitor selumetinib in combination with azacitidine in patients with higher-risk chronic myeloid neoplasia. *First Author: Gregory Roloff, University of Chicago, Chicago, IL*

Background: Myelodysplastic syndrome (MDS), Philadelphia chromosome-negative myeloproliferative neoplasms (MPNs), and MDS/MPN overlap syndromes present significant clinical challenges for patients deemed transplant ineligible, and who are relapsed or refractory to conventional therapies. RAS-pathway activating mutations in myeloid malignancies are associated with a proliferative phenotype and contribute to disease progression. Cooperation between RAS-dependent signaling and epigenetic dysregulation provides the basis for rationally designed combination studies. Selumetinib (AZD6244) is a potent, selective, orally bioavailable, and non-ATP competitive small molecule inhibitor of MEK1/2, downstream of RAS. **Methods:** This is an investigator-initiated, Phase I, open-label dose-escalation study of selumetinib in combination with azacitidine for patients with higher risk MDS, MDS/MPNs, and myelofibrosis. The trial will enroll patients with high-risk myeloid neoplasms that meet disease-specific criteria for MDS or MPNs and who require treatment. This phase I study follows a 3+3 dose-escalation design, with three planned dose levels across two different cohorts (A and B). The dose of azacitidine (75 mg/m²) will remain stable, with three planned selumetinib dose levels (50 mg, 75 mg, and 100mg, respectively) across the two cohorts. Azacitidine will be given on days 1-7 followed by selumetinib from days 7-21 of 28 day cycles. Cohort A includes subjects with MDS with relapsed/refractory disease requiring therapy and MDS/MPN overlap syndromes; Cohort B includes subjects with myelofibrosis refractory or intolerant to JAK inhibitor therapy or ineligible for ruxolitinib treatment given baseline cytopenias (thrombocytopenia < 50,000/uL, anemia < 9 g/dL, and/or red cell transfusion dependent). The trial has an enrollment goal of 18 to 24 subjects, and treatment will continue indefinitely if the patient continues to derive benefit. Dose escalation will proceed independently within both cohorts. Cohort A is nearing completion of enrollment and cohort B is actively enrolling. The primary objective is to determine the maximum tolerated dose of selumetinib in combination with azacitidine. Select secondary and exploratory objectives include describing the preliminary clinical response rates and observing relationships between the presence of RAS activating mutations, RAS pathway activation, and clinical response. Clinical trial information: NCT03326310. Research Sponsor: AstraZeneca; University of Chicago Personalized Cancer Care Consortium.

Poster Session

A phase I study of ruxolitinib in combination with abemaciclib for patients with primary or post-polycythemia vera/essential thrombocythemia myelofibrosis. *First Author: Jan Philipp Bewersdorf, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients (pts) with myelofibrosis (MF) have a reduced life-expectancy compared to age-matched controls. Several oral Janus Kinase (JAK) inhibitors such as ruxolitinib (RUX) have been approved by the US FDA based on improvements in symptom burden and spleen volume reduction compared to physician's choice of best available therapy. However, duration of response to these agents is generally time-limited and treatment with JAK inhibitors is not considered to have disease-modifying potential. Additionally, median overall survival after RUX discontinuation is only 11-14 months. Thus, novel mechanism-based therapies for pts with disease progression on RUX are needed. JAK2 V617F mutations promote transition from G1 to S-phase of the cell cycle via increased expression of CDC25A, which is also upregulated in primary MPN patient samples. Additional cell cycle regulators such as CDK6 and Cyclin D have also been implicated in MF pathogenesis. Finally, we and others have shown that combination of the CDK4/6 inhibitors and RUX had synergistic effects in murine models of MF (Rampal et al., CCR 2021) providing the preclinical rationale for this trial. **Methods:** This multicenter, phase I dose-escalation trial (NCT05714072) evaluates the safety of RUX + the CDK4/6 inhibitor abemaciclib in pts with primary or secondary MF with intermediate-1/2 or high-risk disease by DIPSS who require treatment and had an inadequate response to RUX. Among the currently FDA-approved CDK4/6 inhibitors, abemaciclib was chosen for combination therapy due to less myelosuppressive effects compared with other CDK4/6 inhibitors. Inadequate response to RUX is defined by (I) palpable splenomegaly ≥ 5 cm below the left costal margin at study entry AND/OR (II) active MPN symptoms, as defined by the presence of one symptom score ≥ 5 or two symptom scores ≥ 3 using the screening MPN-SAF TSS. Following a conventional "3+3" dose-escalation design, pts will be treated with increasing doses of abemaciclib and stable doses of RUX (10mg or 15mg BID). The primary endpoint is to determine the maximum tolerated dose of RUX + abemaciclib. Secondary endpoints include measures of efficacy. Exploratory endpoints include changes in allele fraction of driver mutations, gene expression profiling, and clonal architecture to identify biomarkers of response, mechanisms of resistance, and to assess for any disease-modifying effects of the combination therapy. This trial is open to enrollment at Memorial Sloan Kettering Cancer Center and MD Anderson Cancer Center. Clinical trial information: NCT05714072. Research Sponsor: None.

Poster Session

Phase 1b clinical study of IRAK 1/4 inhibition for low-risk myelodysplastic syndromes refractory/resistant to prior therapies. *First Author: Guillermo Garcia-Manero, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Chronic stimulation of both interleukin-1 receptor (IL-1R) and toll-like receptors (TLRs) in myeloid progenitors is thought to cause a bone marrow proinflammatory environment responsible for persistent cytopenia in patients with low-risk (LR)-MDS. IRAK1 and IRAK4 are serine/threonine kinases that are critical for the downstream signaling of IL-1R and most TLRs resulting in the production of proinflammatory cytokines and NLRP3 inflammasome-driven pyroptosis leading to bone marrow inflammation and cell death. Thus, IRAK1/4 inhibition is a potential target for the treatment of LR-MDS by decreasing inflammation and cell death within the bone marrow allowing the restoration of hematopoiesis. R289 is a prodrug that is converted to the active drug R835 in the gastrointestinal (GI) tract. R835 is a potent and selective inhibitor of IRAK1 and IRAK4 kinases and inhibits TLR and IL-1R-dependent proinflammatory cytokine production in multiple cell types. *In vivo*, R835 blocks TLR4 and IL-1R-dependent systemic cytokine release in mice. The safety and pharmacokinetic properties of R289/R835 were evaluated in a phase 1 healthy volunteer study (Study C-906289-001). R289 was well tolerated with no serious or severe adverse events (AEs) reported. Most AEs were mild and transient; the most common AEs (mild/moderate) were headache and GI disturbance. Overall, the trial supported the advancement of R289 into further studies. An open-label Phase 1b study to determine the tolerability and preliminary efficacy of R289 for patients with LR-MDS refractory to prior therapies is currently enrolling patients. **Methods:** The current study (NCT05308264) includes a dose escalation phase (up to 12 patients) and a dose expansion phase (up to 10 patients). Inclusion criteria for both phases will include patients ≥ 18 years with a definitive diagnosis of LR-MDS. Exclusion criteria will include prior treatment for MDS that concluded <4 weeks prior to study treatment. Dose Escalation Phase: Dose escalation will utilize a 3+3 design to determine the maximum tolerated dose (MTD). R289 tablets can be taken orally with or without food. Dose limiting toxicity (DLT) will be assessed at each dose level. The DLT evaluation period will be 28 days. After completion of the DLT evaluation period, patients who do not experience DLTs may remain on treatment at their respective dose level if they continue to demonstrate clinical benefit without toxicity. Dose Expansion Phase: Up to 10 additional patients with LR-MDS will be enrolled; the primary endpoint of the study will be the safety and tolerability of R289. The secondary endpoints will include an assessment of preliminary efficacy and characterization of the pharmacokinetics of R289. R289 will be administered to all patients at a dose not to exceed the MTD determined in the Dose Escalation Phase. The trial is currently recruiting at 8 US sites. Clinical trial information: NCT05308264. Research Sponsor: Rigel Pharmaceuticals.

Poster Session

Phase 1b, open-label study of add on therapy with CK0804 in participants with myelofibrosis, with suboptimal response to ruxolitinib. *First Author: Lucia Masarova, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Drugs targeting JAK2 inhibition including ruxolitinib have led to significant improvement in quality of life and survival of myelofibrosis (MF) patients, however almost 30% have suboptimal response and disease remains incurable. Novel therapies are urgently needed. In addition to mutation-driven stem cell-derived clonal myeloproliferation, recent data support role of reactive cytokine- and chemokine-driven inflammatory fibrosis that contribute to MF pathogenesis, specifically, abnormal CXCR4/CXCL12 axis can drive disease progression and extra-medullary hematopoiesis. Targeting bone marrow inflammation is emerging as potential therapeutic strategy for MF. Adoptive therapy with allogeneic, cord blood (CB) derived Regulatory T cells (Tregs) have shown to be safe in bone marrow failure patients. CXCR4 enriched CB Tregs (CK0804) show faster egress across transwell membrane in response to SDF1 α and preferential homing to bone marrow, *in vivo*. We hypothesize that multiple infusions of CK0804 may decrease inflammation and improve clinical outcomes in MF. **Methods:** Single arm study consisting of safety run-in of 9 participants followed by expansion cohort of additional 15 participants using 3+3+3 study design. MF patients receiving ruxolitinib therapy > 3 months prior to enrollment with stable dose for at least 8 weeks prior to Day 1, unlikely to benefit from further ruxolitinib monotherapy in opinion of investigator would be eligible. Each participant will receive single infusion of CK0804 at fixed dose of 100 million Treg cells administered every 28 days. Participants will continue their ruxolitinib therapy. Participants with no treatment limiting toxicity (TLT) after 28 days or those with toxicity with clear alternative explanation (e.g. disease progression) or transient (≤ 72 hrs) abnormal laboratory values without associated clinically significant signs or symptoms based on investigator determination will receive up to six 28-day treatment cycles AND 6 months of follow up after last infusion of CK0804. Primary Objective: Determine safety and tolerability of CK0804 as add-on therapy in MF, with suboptimal response to ruxolitinib. Primary endpoint: Safety, tolerability and TLTs of CK0804 as assessed by incidence and severity of AE and SAEs determined by NCI CTCAE Version 5.0. Secondary Objective: Determine efficacy of CK0804 as add-on therapy in MF, with suboptimal response to ruxolitinib. Secondary endpoint: Assessment of overall response rate and its duration, using modified International Working Group Myeloproliferative Neoplasm Research and Treatment and European Leukemia Net consensus report; Rate of anemia response and Rate of spleen response by imaging at and after 24 weeks; Symptom burden assessed using Myeloproliferative Neoplasms Symptom Assessment Form Total Symptom Score scale. Safety data from cohort 1 will be presented. Clinical trial information: NCT05423691. Research Sponsor: Cellenkos Inc.

EXCEED-ET: A single-arm multicenter study to assess the efficacy, safety, and tolerability of ropeginterferon alfa-2b-njft (P1101) in North American adults with essential thrombocythemia. *First Author: Lucia Masarova, MD Anderson Cancer Center, Houston, TX*

Background: Essential thrombocythemia (ET) is a myeloproliferative neoplasm (MPN) characterized by a high platelet count due to an overacting JAK-STAT pathway as a result of the most common mutations in JAK2, CALR and MPL genes. There is a high, unmet clinical need for safe and effective treatment options for patients with ET who require cytoreduction, both naïve and previously exposed to hydroxyurea (HU) or anagrelide (ANA). In addition to blood count control and thrombohemorrhagic risk reduction, treatment for ET should also halt/prevent disease progression to post-ET myelofibrosis. Reduction in variant allele frequency and changes in marrow morphology may lead to the elimination of the malignant clone, and treatment with an interferon may achieve this outcome. Interferons have been used in the treatment of MPNs for over 30 years with well-established improvements in hematological and molecular rates, but interferons are not approved by a regulatory agency for the treatment of ET. The objective of this study is to assess the efficacy of ropeginterferon alfa-2b-njft, a new generation interferon alfa, in adults with ET who live in the US or Canada. **Methods:** This single-arm, open-label study includes a 28-day screening period, a 12-month treatment phase, and a 28-day follow-up period, for a total trial duration of 14 months. An extension phase will supply ropeginterferon alfa-2b-njft to patients deriving benefit for a total of 3 years of treatment. Adults diagnosed with ET according to the WHO 2016 criteria with a platelet count at screening $> 450 \times 10^9/L$, cytoreductive treatment naïve, or with prior use or currently on HU and/or ANA may participate. Prior treatment with an interferon is an exclusion factor. Patients with a history or presence of clinically relevant depression, risk of suicide, or autoimmune disease may not participate. Ropiginterferon alfa-2b-njft will be administered subcutaneously every 2 weeks at the starting dose of 250 mcg (Week 0), 350 mcg (Week 2), and target dose of 500 mcg (Week 4) and remain fixed for the 12-month treatment period. Subjects currently on HU or ANA will follow a pre-specified dose-tapering schedule. All subjects will receive low-dose aspirin unless contraindicated. The primary endpoint is a durable response defined as the proportion of subjects who achieve simultaneous peripheral blood count remission (platelets $\leq 400 \times 10^9/L$ and WBC $< 10 \times 10^9/L$) for at least 80% of bi-weekly measurements consecutively between weeks 32-52, a durable resolution of disease-related symptoms according to the MPN Symptom Assessment Form Total Symptom Score (MPN-SAF TSS), and absence of bleeding or thrombotic events. This study is being sponsored by PharmaEssentia USA. Clinical trial information: NCT05482971. Research Sponsor: PharmaEssentia.

Phase 1 study to determine the safety and efficacy of onvansertib, a novel, oral, PLK1 inhibitor in patients with proliferative chronic myelomonocytic leukemia relapsed/refractory or intolerant to available therapies. *First Author: Kristen McCullough, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Chronic myelomonocytic leukemia (CMML) is a myelodysplastic/myeloproliferative overlap neoplasm (MDS/MPN) that can be further divided into MD (WBC $< 13 \times 10^9/L$) and MP ($\geq 13 \times 10^9/L$) subtypes. MP-CMML is enriched in RAS pathway mutations (*NRAS*, *CBL*, *KRAS*, *PTPN11* and *NFI*), has a shorter median survival (19 vs 36 months), has a higher rate of acute myeloid leukemia (AML) transformation (40% vs 10%) and has a unique transcriptomic and epigenetic composition. These RAS pathway mutations promote selective PLK1 overexpression, a mitotic checkpoint kinase. Given the relative inefficacy of hypomethylating agents (HMA) in MP-CMML and previously demonstrated in vitro and in vivo efficacy data for PLK1 inhibition on MP-CMML with RAS pathway mutations, we designed a phase 1 clinical trial testing the safety of onvansertib, a novel, orally bioavailable, PLK1 inhibitor in relapsed/refractory MP-CMML. **Methods:** This is an investigator-initiated, prospective, open-label, phase I study of onvansertib in MP-CMML relapsed/refractory (RR) or intolerant to existing therapies including HMA and hydroxyurea. The primary endpoint is characterization of safety. Secondary endpoints include efficacy as defined by the 2015 MDS/MPN International Working Group criteria, volumetric spleen response and symptom response via assessment with MPN-SAF-TSS. Inclusion criteria include MP-CMML RR following hydroxyurea or at least 4-cycles of HMA or intolerance of treatment with either, platelets $\geq 20,000/m^3$ and Cockcroft-Gault creatinine clearance $\geq 60 \text{ mL/min/m}^2$. Hydroxyurea may continue for the first 28 days on study. Onvansertib will be given orally on days 1 through 21 of a 28-day cycle with a Bayesian optimal interval design to assess the safety and recommended phase II dose. Exploratory endpoints include targeting efficacy, impact of PLK1 and KMT2A expression and interactions with ASXL1 and TET2 mutations. Twenty-five patients will be enrolled at Mayo Clinic in Minnesota, with enrollment open since November 2022. Clinical trial information: NCT05549661. Research Sponsor: Cardiff Oncology; Benefactor.

Oral Abstract Session

Results of a phase 3 study of IVO vs IO for previously untreated older patients (pts) with chronic lymphocytic leukemia (CLL) and impact of COVID-19 (Alliance). *First Author: Jennifer Ann Woyach, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: The Bruton's tyrosine kinase inhibitor (BTKi) ibrutinib +/- anti-CD20 antibody obinutuzumab (IO) is a standard frontline regimen for older adults with CLL. BTKi alone do not often lead to complete response (CR) or undetectable minimal residual disease (uMRD), thus are given indefinitely. Smaller trials showed that IO plus venetoclax (IVO) can induce uMRD CRs which may allow successful discontinuation. **Methods:** Alliance for Clinical Trials in Oncology A041702 is a multicenter trial designed to evaluate if IVO with response-guided discontinuation of I improves progression free survival (PFS) versus IO with indefinite I in treatment-naïve, older CLL pts. IO is given in standard fashion, and in the IVO arm V is added at C3D1 and continued until C14D28. After 14 cycles, pts undergo response evaluation including CT scans and bone marrow biopsy with central MRD assessment by flow cytometry. Pts in IVO arm with uMRD CR discontinue I; all others continue I until progression or unacceptable toxicity. Eligible pts were age ≥70 years (amended to ≥65). Pts had CrCl ≥ 40 mL/min, bilirubin ≤ 1.5 x ULN, and no other life-limiting intercurrent illness. Pts were stratified based on Rai stage and +/- del17p13.1 by FISH, and randomized 1:1 to IO:IVO. With 431 evaluable pts, the trial had 90% power to detect significant improvement in PFS using a one-sided log-rank test with one-sided type 1 error rate of 2.5%. The Alliance DSBM approved release of data on Nov 4, 2022 after meeting the protocol defined futility threshold at the second planned event-driven interim analysis. Data were locked on December 15, 2022. **Results:** Between January 4, 2019 and July 15, 2022, 465 pts were registered (IO:232, IVO:233). Median age was 74; 67% of pts were men. Rai stage 3-4 was seen in 55% and del17p in 13%. With median follow-up of 14 months, PFS of IO was 87.5% compared to 85% on IVO. Events were observed in 29 pts on IO (4 progressions, 23 deaths, 2 pts started other therapy) and 35 on IVO (7 progressions, 28 deaths). The predefined futility boundary was crossed, with a hazard ratio (HR) of 1.20 (95% CI: 0.73-1.97) in favor of IO. COVID-19 was the leading cause of death in both arms, (11 COVID-19 deaths on IO, 19 on IVO), with 13 and 11 additional deaths from other causes, respectively. Censoring pts with COVID-19 related deaths, PFS HR is 0.82 (95% CI: 0.44-1.53) in favor of IVO. Grade 3+ toxicity and discontinuation in year 1 of therapy were similar between arms. **Conclusions:** This study demonstrates that PFS for IVO is not superior to IO for treatment-naïve older CLL pts in the setting of the COVID-19 pandemic. Study treatment is ongoing, and long-term follow-up will determine if there are advantages to IVO, with special attention to MRD and therapy discontinuation. Support: U10CA180821, U10CA180882, U24 CA196171; <https://acknowledgments.alliancefound.org>. Clinical trial information: NCT03737981. Research Sponsor: U.S. National Institutes of Health.

Oral Abstract Session

Results of MOLTO, a multicenter, open label, phase II clinical trial evaluating venetoclax, atezolizumab and obinutuzumab combination in Richter syndrome. *First Author: Anna Maria Frustaci, Department of Hematology, Niguarda Cancer Center, ASST Grande Ospedale Metropolitano Niguarda, Milano, Italy*

Background: Chemoimmunotherapy is the standard first line of patients (pts) with diffuse large B-cell lymphoma (DLBCL) variant of Richter syndrome (RS). Response rate and duration are unsatisfactory. The biology of RS (high rate of DNA damage response pathway defects, high tumor mutation burden coupled with the expression of the PD1/PDL1 axis) prompts investigation of non-chemo combinations leveraging agents that circumvent TP53 abnormalities and trigger anti tumor immune response. MOLTO is a multicenter international ph 2 study (NCT04082897) evaluating activity and safety of atezolizumab (humanized monoclonal antibody blocking PD-L1), venetoclax (BCL2 inhibitor) and obinutuzumab (anti-CD20 MoAb) combination in untreated DLBCL-RS. **Methods:** Treatment consisted of 35 cycles with obinutuzumab (1000 mg C1-8), atezolizumab (1200 mg C1-18) and venetoclax (400 mg/d C1-35), q21. Primary endpoint was ORR ≥67% at C6. RS diagnosis was centrally revised. RS mutation profile was tested on pre-treatment cell free DNA. Minimal residual disease (MRD) was tested by 12 colors flow cytometry and NGS on peripheral blood mononuclear cells and plasma. **Results:** 28 planned pts were enrolled from Oct 2019 to Oct 2022 (Table). Three were not evaluable for primary endpoint due to G5 infection (n=1) or early withdrawn (n=2). As per intention-to-treat ORR was 67.9% (19/28) thus meeting primary endpoint. CR rate was 28.6%. No clinical characteristics influenced C6-ORR. After a median follow-up of 11.6 mo, 11/19 pts (57.9%) are in continuous remission (8 on active therapy, 2 received allogeneic transplant, 1 discontinued due to MDS) among them, 6 for ≥24 mo. Of the remaining 8 pts, 7 progressed after a median of 14 cycles, 1 died from sepsis at C9 in remission. Median duration of response, PFS and OS were 11.7, 16.2 and 31.6 mo, respectively. Out of the 13 patients who progressed, 4 received a salvage therapy and are alive at a median follow-up of 24.3 mo. Bulky disease and ECOG PS >1 affected PFS. Rate of unmeasurable MRD, impact of mutations and chronic lymphocytic leukemia-RS clonal relation on outcomes will be presented at the meeting. Overall 43 G3-4 adverse events (AE) were recorded in 17 pts (60.7%), mostly hematological (51.2%). Any grade immune-related AEs were reported in 6 pts (G3-4 in 2), none led to discontinuation. No tumor lysis syndrome observed. Infections ≥G3 occurred in 6 pts, including 2 G5. One pt developed MDS. **Conclusions:** Atezolizumab, obinutuzumab and venetoclax combination is active in pts with untreated DLBCL-RS. This regimen led to durable remissions, longer than 2yrs in one third of responders. Clinical trial information: NCT04082897. Research Sponsor: Roche.

Oral Abstract Session

Lisocabtagene maraleucel (liso-cel) in R/R chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL): Primary analysis of TRANSCEND CLL 004. *First Author: Tanya Siddiqi, City of Hope National Medical Center, Duarte, CA*

Background: In patients (pts) with R/R CLL/SLL that progressed on BTKi and failed venetoclax (ven)-based regimens, achieving CR with current treatment is uncommon. New therapies that achieve deep and durable responses are needed. We report the primary analysis of the phase 1/2, single-arm, multicenter TRANSCEND CLL 004 (NCT03331198) study evaluating liso-cel in pts with R/R CLL/SLL. **Methods:** Pts must have received at least 2 prior lines of therapy, including a BTKi. Eligible pts received liso-cel at a target dose of either 50 (DL1) or 100 (DL2) × 10⁶ CAR⁺ T cells. The primary endpoint was rate of CR and CR with incomplete marrow recovery (CRI) by IRC per 2018 iwCLL criteria in the prespecified subset of efficacy-evaluable pts with disease progression on BTKi and ven failure (primary efficacy analysis set [PEAS]) at DL2 (null hypothesis [H₀]: ≤ 5%). Key secondary endpoints were ORR (H₀: ≤ 40%) and rate of undetectable minimal residual disease (uMRD; 10⁻⁴) in blood (H₀: ≤ 5%). **Results:** Of 137 leukapheresed pts, 117 received liso-cel (safety set), 96 (DL1 = 9; DL2 = 87) were efficacy evaluable, and 53 (DL1 = 4; DL2 = 49) were in the PEAS. In the safety set, median (range) age was 65 y (49-82), 83% had high-risk features, median (range) lines of prior therapy was 5 (2-12), and all pts had prior BTKi. Median (range) on-study follow-up was 21.1 mo (0.4-55.6) for the safety set. In the PEAS at DL2, the primary endpoint of CR/CRI rate was met at 18.4% (95% CI, 8.8-32.0; 1-sided P = 0.0006; Table). ORR was 42.9% and was not statistically significant (95% CI, 28.8-57.8; 1-sided P = 0.3931). The uMRD rate was 63.3% in blood and 59.2% in marrow. Median (95% CI) DOR was 35.3 mo (11.01-not reached [NR]) with a median follow-up of 19.7 mo. Median duration of CR/CRI was NR. In the safety set, rate of any-grade CRS was 84.6% (gr 3, 8.5%; no gr 4/5) and neurological events (NE) was 45.3% (gr 3, 17.9%; gr 4, 0.9%; no gr 5); 69.2% received tocilizumab and/or corticosteroids for CRS/NEs. Rate of gr ≥ 3 infections, hypogammaglobulinemia, and prolonged cytopenia was 17.1%, 15.4%, and 53.8%, respectively. One death related to liso-cel was due to hemophagocytic lymphohistiocytosis. Liso-cel exhibited rapid in vivo expansion and was detected by qPCR in blood up to 36 mo after infusion. **Conclusions:** Liso-cel demonstrated durable CR/CRI, high uMRD rates, and a manageable safety profile in pts with heavily pretreated, high-risk R/R CLL/SLL and high unmet need. Clinical trial information: NCT03331198. Research Sponsor: This study was funded by Juno Therapeutics, a Bristol-Myers Squibb Company.

Oral Abstract Session

Golidocitinib in treating refractory or relapsed peripheral T-cell lymphoma: Primary analysis of the multinational pivotal study results (JACKPOT8). *First Author: Qingqing Cai, Sun Yat-sen University Cancer Center (China), Guangzhou, China*

Background: Currently there is no consensus on the treatment of relapsed/refractory (r/r) PTCL, and patient prognosis was poor. Golidocitinib is an orally available, JAK1-selective inhibitor currently being evaluated in a multinational, pivotal study in r/r PTCL (JACKPOT8 Part B, NCT04105010). Here we reported the primary analysis of efficacy and safety results of this study. **Methods:** PTCL patients who had relapsed from or had been refractory/intolerant to ≥ 1 (but ≤ 3) prior systemic therapy(ies) were enrolled to receive golidocitinib at 150 mg once daily until disease progression or pre-defined discontinuation criteria were met. The primary endpoint was CT-based objective response rate (ORR) assessed by an independent review committee (IRC) according to Lugano 2014 classification. The efficacy analysis set included patients whose pathological diagnosis of PTCL had been retrospectively confirmed by a central laboratory and who had at least one measurable lesions at baseline. The safety analysis set included all dosed patients. **Results:** As of November 30, 2022, a total of 104 patients with r/r PTCL were enrolled and dosed with golidocitinib. Baseline characteristics: median age was 58 years old; 64.4% were male; 20.2% had baseline bone marrow involvement. Major subtypes included NOS (46.2%), AITL (15.4%) and ALCL (9.6%). The median prior lines of therapies were two. All of the patients had been treated with chemotherapies, and 48.1% had also been treated with histone deacetylase inhibitors. By the data cut-off (DCO) date, a total of 80 patients had both IRC assessment and central pathology review results available, and thus were included in the efficacy analysis. Among them, 35 patients achieved tumor response (ORR = 43.8%), including 20 patients (25.0%) achieved complete responses. Tumor response was observed in various subtypes, including AITL (56.3%), NOS (45.7%), ALCL (11.1%) and others (44.4%). In patients who relapsed from HDAC inhibitor treatment, 54.8% achieved tumor response. With a median follow-up of 5.5 months for responders, the median duration of response (DoR) has not been reached. Golidocitinib was tolerated in patients with r/r PTCL. By the DCO date, the longest duration on treatment was 15.7 months (still responding). The most common ≥ grade 3 treatment-related adverse events (TRAEs) were hematological in nature, including neutrophil count decreased (26.0%), white blood cell count decreased (25.0%), platelet count decreased (16.3%) and lymphocyte count decreased (16.3%). TRAEs leading to dose interruption, reduction, and discontinuation were 37.5%, 5.8%, and 7.7%, respectively. The majority of TRAEs were reversible or clinically manageable. **Conclusions:** Golidocitinib demonstrated its potential as a novel targeted therapy for the treatment of r/r PTCL. The updated data will be presented at the conference. Clinical trial information: NCT04105010. Research Sponsor: Dizal Pharmaceutical.

Oral Abstract Session

A phase 2 trial of CHOP with anti-CCR4 antibody mogamulizumab for elderly patients with CCR4-positive adult T-cell leukemia/lymphoma. *First Author: Ilseung Choi, Department of Hematology and Cell therapy, National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan*

Background: No standard of care for elderly patients with aggressive adult T-cell leukemia/lymphoma (ATL) has been established yet. We assessed the efficacy of an anti-CCR4 antibody, mogamulizumab (Moga) combined with biweekly cyclophosphamide (CPA), doxorubicin (DXR), vincristine (VCR), and prednisone (PSL) (Moga-CHOP-14) for untreated elderly patients with aggressive ATL. **Methods:** In this phase 2 trial conducted at 21 centers in Japan, untreated CCR4-positive aggressive ATL patients aged 66 years or older and 56-65 years who were not candidates for allogeneic hematopoietic stem cell transplantation (allo-HSCT) received six cycles of Moga-CHOP-14, followed by two cycles of Moga monotherapy. The primary endpoint was 1-year progression-free survival (PFS), defined as the time from enrollment to the progression/relapse of ATL or death due to any cause, whichever occurred first. Secondary endpoints were complete response rate (CR), overall response rate (ORR), overall survival (OS), 1-year event-free survival (EFS), and the incidence of adverse events. The necessary number of patients calculated by setting the threshold 1-year PFS at 16% and the expected 1-year PFS at 31% using the exact method based on binomial distribution under the conditions of one-sided level of significance of 5% ($\alpha = 0.05$) and power of 70% was 43. **Results:** A total of 50 patients were enrolled from October 2015, until September 2020. Among the 48 evaluable patients, the median age was 74 years (interquartile range [IQR], 70-78). ATL subtypes included 31, 9, and 8 patients for the acute, lymphoma, and unfavorable chronic type, respectively. ATL-PI included 9, 31, and 8 patients for high, intermediate, and low risk, respectively. With a median follow-up of 1.6 years (IQR, 0.7-2.4), 1-year PFS was 36.2% (90% confidence interval [CI], 24.9-47.6), and a median PFS was 0.7 years (95% CI, 0.5-1.0). CR and ORR were noted in 64.6% (95%CI, 49.5-77.8), and 91.7% (95% CI, 80.0-97.7), respectively. One-year OS was 66.0% (95% CI, 50.6-77.6) and median OS was 1.6 years (95%CI, 1.1-2.8). One-year EFS was 29.9% (95% CI, 17.6-43.2) and median EFS was 0.5 years (95%CI, 0.4-0.7). The most frequent adverse events grades 3/4, which occurred in > 10% of patients were lymphocytopenia (97.9%), leukopenia (93.8%), neutropenia (89.6%), febrile neutropenia (64.8%), anemia (58.3%), thrombocytopenia (45.8%), infection (27.1%), skin rash (20.8%), and hyperglycemia (20.8%). Relative dose intensity (RDI) was calculated for each drug: the mean RDI for Moga was 82.1%, for CPA 71.7%, for DXR 72.7%, for VCR 72.0%, and for PSL 77.3%. **Conclusions:** This study demonstrated that Moga-CHOP-14 significantly improved PFS in elderly patients with aggressive CCR4-positive ATL who were ineligible for allo-HSCT. Moga-CHOP-14 is now considered for the preferred first-line treatment in those patients. Clinical trial information: jRCTs041180130. Oral Abstract Session

Epcoritamab + R² regimen and responses in high-risk follicular lymphoma, regardless of POD24 status. *First Author: Reid Merryman, Dana-Farber Cancer Institute, Boston, MA*

Background: Follicular lymphoma (FL) is a heterogeneous disease. Early progression after initial treatment (tx) with chemoimmunotherapy (CIT), POD24, occurs in around 20% of patients (pts) and strongly predicts poor outcomes. There is no standard tx approach for high-risk, relapsed or refractory (R/R) FL (high-risk subgroups in Table). Novel options are needed to improve efficacy in pts with high unmet need. Epcoritamab, a subcutaneous (SC) T-cell-engaging bispecific antibody, demonstrated impressive single-agent antitumor activity and a manageable safety profile in R/R FL (Hutchings et al, *Lancet* 2021) and shows promise combined with standards of care. Here we present pooled analyses from cohorts 2a and 2b of the ongoing phase 1/2 EPCORE NHL-2 trial (NCT04663347) of epcoritamab with rituximab + lenalidomide (R²). **Methods:** Pts with R/R CD20⁺ FL received epcoritamab SC + R² for 12 cycles (Cs; 28 d each). Epcoritamab was dosed QW in C1-3, Q2W in C4-9, and Q4W in C≥10 (2a) or QW in C1-2 and Q4W in C≥3 (2b) for ≤2 y. **Results:** As of Oct 31, 2022, 109 R/R FL pts had received epcoritamab 48 mg + R² in 2a and 2b. Median age was 65 y, 56% of pts had FLIPI 3-5, 61% had stage IV disease, and 59% had only 1 prior tx. Most had received alkylating agents (92%) or anthracyclines (62%); 2 had prior CAR T. At a median follow-up of 8.8 mo (range, 1.2-18.5), 82% were still on tx. The most common tx-emergent AEs were: CRS and neutropenia, 48% each; injection-site reactions, 38%; and fatigue, 33%. CRS events were mostly low grade (G; 46% G1-2, 2% G3) and mostly occurred following the first full dose on C1D15; all resolved and none led to discontinuation. ICANS occurred in 2 pts (G1, G2) and resolved. In 101 efficacy-evaluable pts, overall response rate (ORR) was 97%, with complete metabolic response (CMR) in 86%. Notably, pts achieved higher ORR/CMR rates with epcoritamab + R² vs their immediate prior tx line (ORR, 97% vs 85%; CMR, 86% vs 60%). Estimated 6-mo progression-free survival was 93%. In second-line (2L) pts with POD24, ORR/CMR rates were 95%/90% (additional high-risk subgroup data in Table). Additional data with longer follow-up will be presented. **Conclusions:** Epcoritamab + R² showed potent antitumor activity and a manageable safety profile in a large R/R FL population. Encouraging responses were seen in pts with high-risk disease, suggesting epcoritamab SC may abrogate negative effects of high-risk features. A separate POD24 cohort is planned, and epcoritamab + R² is being studied in the phase 3 EPCORE FL-1 trial (NCT05409066). Clinical trial information: NCT04663347. Research Sponsor: This study was funded by Genmab A/S and AbbVie.

Oral Abstract Session

Real-world outcomes of brexucabtagene autoleucel (brexu-cel) for relapsed or refractory (R/R) mantle cell lymphoma (MCL): A CIBMTR subgroup analysis by prior treatment. *First Author: Swetha Kambhampati, City of Hope National Medical Center, Duarte, CA*

Background: Brexu-cel is a CAR T therapy approved for adult patients (pts) with R/R MCL. In a 3-year follow-up of ZUMA-2 (Wang et al., 2022), ORR was 91% (CR 68%). Median DOR, PFS and OS were 28.2, 25.8 and 46.6 mo respectively. Here, we describe real-world outcomes of brexu-cel by receipt of prior BTK inhibitor (BTKi), bendamustine, autoHCT, and 1-2 vs ≥ 3 prior lines of therapy. **Methods:** From 07/2020-08/2022, 397 pts receiving brexu-cel for R/R MCL from 79 US centers were registered in the CIBMTR observational database. In this analysis, 272 were included (median follow-up 6.6 mo; range 0.3-16.5), excluding pts with prior non-HCT cellular therapy (n = 7), missing data on prior treatment, or no follow-up. Descriptive analyses were used for all outcomes. **Results:** Median age was 65.8 years (range 34.1-84.9); pts were mostly male (78%). Prior to infusion, 7% had ECOG PS ≥ 2; 76% had clinically significant comorbidities; 4% had extranodal CNS involvement. At diagnosis, Ki-67 ≥ 30%, Ki-67 ≥ 50% and TP53/17p deletion were seen in 69% (n = 111/160), 44% (n = 70/160) and 19% (n = 29/153) of pts respectively. Pts had a median of 4 lines of prior therapy (range 1-12; 6% as 2L). Prior to leukapheresis, 87% were BTKi-exposed; 54% received bendamustine; 31% were autoHCT recipients. Median time from leukapheresis to infusion was 28 d (IQR 26-34 d), during which 18% received bridging therapy. ORR for all was 89% (CR 78%). At 6 mo, cumulative incidence of relapse/PD was 21%; DOR, PFS and OS were 76%, 73% and 83% respectively. Grade ≥ 3 (ASTCT consensus) CRS and ICANS occurred in 9% and 27% of pts (88% and 62% for any grade). Most CRS (94%) and ICANS (79%) resolved within 3 weeks. Prolonged cytopenia by 30 d occurred in 23% pts. NRM at 100 d and 180 d were 3% and 6% respectively, mainly due to infections. ORR for BTKi-naïve (n = 36) vs -exposed (n = 233) pts was 85% (CR 79%; 6-mo DOR 84%) vs 89% (CR 77%; 6-mo DOR 74%); for pts with (n = 145) vs without (n = 124) prior bendamustine was 88% (CR 75%; 6-mo DOR 75%) vs 89% (CR 80%; 6-mo DOR 77%); for pts with (n = 83) vs without (n = 188) prior autoHCT was 90% (CR 82%; 6-mo DOR 83%) vs 88% (CR 76%; 6-mo DOR 72%). Higher CR rates were seen in pts with brexu-cel as 2/3L (n = 56) vs 4L+ (n = 213) (91% vs 74%; ORR 92% vs 88%; 6-mo DOR 77% vs 75%). Similar safety profiles were seen regardless of prior BTKi or autoHCT. Pts with prior bendamustine had fewer Grade ≥ 3 ICANS (19% vs 36%) but more prolonged cytopenia (29% vs 16%) vs pts without. **Conclusions:** These early findings suggest that real-world outcomes of brexu-cel are consistent regardless of prior BTKi, bendamustine, or autoHCT. Use of brexu-cel in earlier lines may help achieve a higher CR rate. Further studies with longer follow-up are warranted to contextualize response rates in relation to long-term clinical benefits of brexu-cel. Updated data with longer follow-up will be reported at the time of presentation. SK and NA contributed equally. Research Sponsor: Kite, a Gilead Company; NCI grant: National Cancer Institute (CIDR [U24 CA233032]).

Oral Abstract Session

Very long-term follow-up of rituximab maintenance in young patients with mantle cell lymphoma included in the LYMA trial, a LYSA study. *First Author: Cl  mentine Sarkozy, Institut Curie, Saint Cloud, Paris, France*

Background: The phase III LYMA trial demonstrated the efficacy (OS, PFS, EFS) and safety of rituximab maintenance (RM) post autologous stem cell transplant (ASCT) in first line for young patients with mantle cell lymphoma (MCL) (Le Gouill et al, NEJM). Herein, we present the first long-term analysis of the LYMA trial. **Methods:** 299 patients were included in LYMA trial of whom 240 were randomized to receive 3 years of RM (n = 120) or no RM (observation; n = 120). Primary endpoint was 3 years EFS. We updated the outcome of all patients enrolled in this trial. Treatment at relapse and cause of death were collected. **Results:** At the time of the present analysis, the median follow-up is 7 years (0.2-10). The median EFS and PFS were still statistically superior in favor of RM (not reached (NR), versus 5.8 years, p < .0001 for EFS and NR versus 6.1 years for PFS in RM and observation arm respectively). The 7 years estimated EFS and PFS were 76.2% (95% CI 67.4-82.9%) versus 46% (95% CI 36.6-54.9%) and 78.5% (95% CI 69.9-85.0%) versus 47.4% (95% CI 37.9-56.3%), for RM and observation respectively, p < .0001). In the RM arm, 22 patients had died (18.3%) versus 33 (27.5%) in the observation arm with a 7-year OS estimate of 83.2% (95% CI: 74.7-89.0%) and 72.2% (95% CI 62.9%-79.5%) in RM and observation arm, respectively (p = 0.087). Causes of death were not significantly distinct between the 2 groups, lymphoma being the leading cause in both (50% in both arm), with less than 10% of infectious related death. The end of RM was not associated with an increase in the relapse incidence, since in the RM arm, 17/21 (81%) of the progression occurred during the theoretical 3 years of RM and only 19% after the end of RM. On the contrary, in the observation arm, 32/53 (60%) of the progression/relapses occurred during the theoretical 3 years of maintenance part, and 40% after. Salvage treatments were not different between the RM and observation arm, including anti CD20 and BTK inhibitors administered in 75% versus 79% and 10% versus 15% of the relapsing patients in the RM and observation arms, respectively. Post relapse OS was significantly impacted by previous RM, with a median OS-2 of 1.1 years (95%CI 0.7-2.1) for the 21 relapsing patients in the RM arm versus 4.6 years (95%CI 2-NA) for the 53 relapsing patients in the observation arm. Given the timing of relapses in RM arm, this reflects the aggressiveness of early disease progression during RM. **Conclusions:** The benefice in favor of RM in term of EFS (the primary objective), PFS remains after 7 years of FU, but not in OS. The end of RM was not associated with an increase in relapse rate. RM was not associated with an increase in infectious related mortality, making of this strategy a safe standard of care with long term FU. Patients relapsing during RM have a particularly poor outcome and represent an unmet medical need. Clinical trial information: NCT00921414. Research Sponsor: Roche and AMGEN.

Poster Discussion Session

Five-year follow-up update of defined-composition CD19 CAR T-cell therapy for relapsed/refractory CLL. *First Author: Emily C. Liang, Fred Hutchinson Cancer Center, Seattle, WA*

Background: We have described high response rates in patients (pts) with relapsed/refractory (R/R) chronic lymphocytic leukemia (CLL) treated with CD19-targeted CAR T cells. We now report comprehensive analyses of factors associated with duration of response (DOR) with a 68-month median follow-up. **Methods:** We included 49 pts with R/R CLL and/or Richter's transformation (n = 10) treated on a phase I/II clinical trial of defined-composition CD19 CAR T-cell therapy (1:1 ratio of CD8+:CD4+). Response rates were investigator-assessed by 2018 iwCLL criteria. Measurable residual disease (MRD) in bone marrow (BM) was evaluated by multiparameter flow cytometry (MFC) and *IGH* next-generation sequencing (NGS; clonoSEQ assay). CAR T-cell enumeration was assessed by MFC. Serum cytokine concentrations (20 analytes) were measured by Luminex assay. Univariate associations between duration of response (DOR) and patient, disease, CAR T-cell manufacturing, and treatment-related variables were estimated using Cox regression (50+ variables). Association between CAR T-cell in vivo persistence and DOR was modeled with a time-dependent Cox model including blood CAR transgene levels (copies/ μ g genomic DNA). **Results:** Median age was 61 years (IQR, 55-67). Forty-six pts (94%) had complex karyotype and/or 17p deletion; 46 (94%) received cyclophosphamide/fludarabine lymphodepletion. In the response-evaluable cohort (n = 47), median follow-up was 68.3 months (IQR, 54.3-81.6). Overall and complete response rates at day+28 were 70% and 17%, respectively, and the median DOR was 22.2 months (95% CI, 10.7-not reached [NR]). MRD-negativity at day+28 by MFC occurred in 33/47 (70%). In pts with MRD-negativity by MFC and available data, MRD negativity by NGS was seen in 18/29 (62%). In NGS MRD-negative responders, the median DOR was 56.8 months (95% CI, 39.5-NR). In all evaluable patients, the 5-year OS and PFS were 35.5% (95% CI, 24.0%-52.5%) and 21.5% (95% CI, 12.0%-38.5%), respectively. In univariate Cox regression, day+28 MRD-negativity by MFC (HR = 0.03, 95% CI, 0.01-0.18, p < 0.001), day+28 MRD-negativity by NGS (HR = 0.21, 95% CI, 0.07-0.61, p = 0.004), peak CD8+ CAR T-cell expansion (HR = 0.49, 95% CI, 0.24-1.00, p = 0.05), CAR T-cell persistence (HR = 0.71, 95% CI, 0.54-0.91, p = 0.01), and lower peak MIP-1 β (HR = 3.12, 95% CI, 1.13-8.65, p = 0.03) were associated with longer DOR. Peak MIP-1 β remained associated with DOR (HR = 3.83, 95% CI, 1.35-10.9, p = 0.012) in a multivariable model including pre-LD CLL cells in BM, tumor cross-sectional area, peak CD8+ CAR T-cell expansion, and day+28 MRD by MFC. **Conclusions:** CD19 CAR T-cell therapy achieved durable remissions in R/R CLL pts. Day+28 MRD, CAR T-cell peak expansion, and CAR T-cell persistence were strongly associated with DOR. Lower peak serum levels of MIP-1 β , a cytokine known to be produced by CLL cells upon BCR activation, was strongly and independently associated with DOR. Clinical trial information: NCT01865617. Poster Discussion Session

Real-world early outcomes of axicabtagene ciloleucel for relapsed or refractory (R/R) follicular lymphoma (FL). *First Author: Caron Alyce Jacobson, Dana-Farber Cancer Institute, Boston, MA*

Background: Axicabtagene ciloleucel (axi-cel) is an autologous CAR T approved for adult patients (pts) with r/r FL after $\geq$ 2 lines of systemic therapy. In the primary analysis of the pivotal ZUMA-5 trial, 94% of pts who received axi-cel to treat r/r FL achieved an objective response, with a 79% CR rate (Jacobson et al. 2022). Grade $\geq$ 3 cytokine release syndrome (CRS) and neurologic events occurred in 6% and 15% of pts, respectively. Here, we present the real-world outcomes of pts receiving axi-cel for r/r FL, including those who would have been ineligible for ZUMA-5. **Methods:** A total of 230 pts from 72 US centers receiving first axi-cel for r/r FL in the real-world setting between March 2021 and October 2022 were identified from the CIBMTR registry. The following pts were excluded: no consent, prior non-transplant cellular therapy, and FL grade 3b or 3a/3b unspecified. Of the 230 pts, 151 pts had post-infusion assessments and were included in the analysis of outcomes. Effectiveness outcomes were ORR, CR, DOR, PFS and OS. Adverse events included CRS, immune effector cell-associated neurotoxicity syndrome (ICANS) and prolonged cytopenia. **Results:** Of the 230 pts, median age was 62 years and 60% were male. Prior to infusion, 98% had an ECOG performance score of 0-1, 33% had elevated LDH, and 66% were chemo-resistant. Clinically significant comorbidities were present in 74% of the pts. Ninety-two (40%) pts would have been ineligible for ZUMA-5, mainly due to comorbidities. Pts had a median of 4 (range 1-13) lines of prior therapy including 14% who also underwent prior ASCT. Median time from leukapheresis to infusion was 28 days (IQR 26-34). 9% of pts received bridging therapy. Outcomes were analyzed among the 151 pts with follow-up (median 6.2 mo). ORR and CR rates were 93% (95% CI 88-97%) and 84% (95% CI 77-89%), respectively. Estimated PFS and OS at 6 mo were 88% (95% CI 81-92%) and 96% (95% CI 91-98%), respectively. Grade $\geq$ 3 CRS (ASTCT consensus) and ICANS (ASTCT consensus) occurred in 2% (95% CI 0-6%) and 13% (95% CI 8-19%) of pts, respectively. Median cumulative incidence estimates of CRS resolution was 5 days and ICANS resolution was 4 days. Among pts alive at Day 30 (n = 150), 11% experienced prolonged cytopenia (4% neutropenia, 9% thrombocytopenia). PFS and OS at 6 mo were comparable regardless of ZUMA-5 eligibility, while pts eligible for ZUMA-5 had fewer Grade $\geq$ 3 ICANS (10% vs 16%) and more rapid ICANS resolution (92% vs 71% resolved within 2 weeks). Pts aged $\geq$ 65 vs < 65 years had comparable effectiveness and safety profiles. **Conclusions:** This is the first report on axi-cel to treat r/r FL in real-world settings. Despite a broader pt population, early results demonstrate effectiveness and safety profiles consistent with those observed in the ZUMA-5 trial. The intent is to present findings from an updated dataset with longer follow-up at ASCO. Overall, these findings support the continued broad use of axi-cel to treat r/r FL. SAVE (Safe Accelerated Venetoclax Escalation): Initial results of a prospective, phase Ib study of venetoclax with an accelerated dose ramp-up in patients with CLL. *First Author: Jennifer Leigh Crombie, Dana-Farber Cancer Institute, Boston, MA*

Background: Venetoclax (VEN)-based regimens are highly effective for patients (pts) with treatment naive (TN) and relapsed/refractory (R/R) CLL. Despite high rates of undetectable minimal residual disease (uMRD) and durable responses even with time-limited therapy, uptake of VEN in routine clinical practice has been relatively low, in part due to the inconvenient 5-week dose ramp-up used to reduce the risk of tumor lysis syndrome (TLS). Accelerated ramp-up schedules have been evaluated in retrospective studies (Davids et al., AJH, 2022), but prospective studies are lacking. Here we present initial results of SAVE: Safe Accelerated Venetoclax Escalation, a phase Ib study of VEN with an accelerated dose ramp-up in pts with CLL. **Methods:** This is an ongoing phase Ib investigator-sponsored trial for pts with TN and R/R CLL (NCT04843904). Key eligibility include CLL requiring therapy per 2018 iwCLL criteria and adequate renal function. The primary endpoint is the highest risk TLS group that can safely tolerate an accelerated VEN ramp-up. Secondary endpoints include safety and tolerability and rates of ORR/CR/uMRD after 3 months of VEN-based therapy. Patients are treated inpatient with a 5-day daily VEN ramp-up schedule (20-50-100-200-400 mg). TLS labs are monitored pre-dose and at 4, 8, 12, and 24 hours following each dose. Anti-CD20 antibody is given per SOC. At least 5 pts from cohort A (low TLS risk using standard assessment) were required to enroll prior to opening cohort B (medium and high TLS risk). Efficacy is assessed using 2018 iwCLL criteria, toxicity using iwCLL and CTCAE v5, and MRD using central 8-color flow at 10^{-4} . **Results:** As of 2/2/2023, 20 pts have been treated (10 each from cohort A and B) (Table). 19 pts received obinutuzumab with VEN, and 1 pt received VEN monotherapy. All pts completed an accelerated VEN ramp-up without any clinical TLS. One pt with medium TLS risk had lab TLS (phos and uric acid peaked at 8.7 mg/dL) after the first VEN 400 mg dose, which resolved with sevelamer and rasburicase, thereby prolonging the ramp-up to 6 days. Median inpatient time was 6 days (range 5-8). All grade hemo tox: neutropenia (45%; 20% G3/4), thrombocytopenia (35%; 10% G3/4). One pt died 2 months into treatment due to complications of a bowel obstruction unrelated to study treatment. ORR after 3 mo. was 89% in 19 evaluable pts including 2 CRs. Among 19 evaluable patients after 3 mo., 74% and 42% had uMRD in PB and BM, respectively. **Conclusions:** Our early data suggest that an inpatient, accelerated 5-day VEN ramp-up is feasible in CLL, with a low rate of TLS, even among patients with medium or high risk of TLS. The study is currently ongoing. Clinical trial information: NCT04843904. Research Sponsor: Dana-Farber Cancer Institute; U.S. National Institutes of Health.

Long-term safety with ≥ 12 months of pirtobrutinib in relapsed/refractory (R/R) B-cell malignancies. *First Author: Catherine Callaghan Coombs, UCI Health, Orange, CA*

Background: While Bruton tyrosine kinase inhibitors (BTKi) can induce sustained remissions, ongoing response requires continuous treatment and thus long-term safety/tolerability is critical for adherence, maintaining dose intensity, and delivering maximum efficacy. Pirtobrutinib is a highly selective, non-covalent (reversible) BTKi approved by the FDA in January 2023 for R/R mantle cell lymphoma after 2 prior lines of therapy including a BTKi. Pirtobrutinib has demonstrated promising efficacy with low discontinuation and dose reduction rates in patients (pts) with multiple subtypes of R/R B-cell malignancies. However, the long-term safety and tolerability of pirtobrutinib has not yet been reported. Here we report the clinical safety in pts with long-term (≥ 12 months) pirtobrutinib treatment from the phase 1/2 BRUIN trial. **Methods:** Pts with R/R B-cell malignancies who received ≥ 12 months of pirtobrutinib were included. Median time to onset, dose reduction, discontinuation, and cumulative incidence rates were determined for treatment emergent adverse event (TEAE) that occurred in $\geq 20\%$ of pts and select AE of interest associated with BTKi. **Results:** As of 29 July 2022, 773 pts were enrolled, and 326 (42%) pts received treatment for ≥ 12 months. Among these 326 pts, median time on treatment was 19 months (IQR: 16,25), with 231 (71%) remaining on pirtobrutinib. The most common TEAE (all grade, regardless of attribution) in this long-term 326 pt cohort were fatigue (32%), diarrhea (31%), Covid-19 (29%), contusion (26%), cough (25%), and back pain (21%). TEAE leading to dose reduction or discontinuation occurred in 23 (7%) and 11 (3%) pts, respectively. Four (1%) pts discontinued due to a treatment-related AE, and 1 pt had a fatal treatment-related AE (Covid-19 pneumonia). Select AE of interest for the long-term pts are shown in the Table. Comprehensive safety analyses describing the frequency of TEAE over time will be presented. **Conclusions:** Prolonged pirtobrutinib therapy continues to demonstrate a safety profile amenable to long-term administration at the recommended dose without evidence of new or worsening toxicity signals. The safety and tolerability observed in pts on therapy for ≥ 12 months was similar to previously published safety analyses on all pts enrolled regardless of follow-up. Clinical trial information: NCT03740529. Research Sponsor: Loxo@ Lilly.

Select AE of interest associated with BTKi in pts with ≥ 12 months exposure (N = 326).

Response-adapted therapy (tx) with nivolumab plus brentuximab vedotin (nivo + BV) without autologous hematopoietic cell transplantation (auto-HCT) in children, adolescents, and young adults (CAYA) with low-risk relapsed/refractory (R/R) classic Hodgkin lymphoma (cHL): CheckMate 744. *First Author: Paul David Harker-Murray, Children's Wisconsin, Milwaukee, WI*

Background: Outcomes are poor for patients (pts) with cHL who develop R/R disease after first-line (1L) chemotherapy $\pm$ radiotherapy (RT). Salvage tx that attain high event-free survival (EFS) rates and minimize late toxicity by omitting high-dose chemotherapy (HDCT)/auto-HCT are needed. CheckMate 744 (NCT02927769) is the first multicenter phase 2 study evaluating a risk-stratified, response-adapted salvage tx with nivo + BV in CAYA with R/R cHL. In the standard-risk cohort, complete molecular response (CMR) rate before consolidation with HDCT/auto-HCT was 94% (Harker-Murray et al. *Blood* 2022). With highly active salvage tx, pts in low-risk cohort could achieve high EFS without HDCT/auto-HCT; we report data from this cohort. **Methods:** Pts were aged 5–30 y and had ≤ 3 cycles (C) of 1L anthracycline-based systemic tx. Risk stratification was described in Harker-Murray et al. Pts received 4C of nivo + BV induction. Pts with CMR received additional 2C nivo + BV before involved-site radiation therapy (ISRT) consolidation (dose, 30–30.6 Gy). Pts with suboptimal response received 2C BV + bendamustine intensification; pts with CMR proceeded to ISRT consolidation. Primary endpoints: CMR rate (Lugano 2014) any time before ISRT and 3-y EFS rate, both per blinded independent central review (BICR). For CMR and overall response rate (ORR), a 90% confidence interval (CI) was used per statistical plan. **Results:** Among 28 pts treated with nivo + BV, median (range) age was 17 (6–27) y; 64% of pts were aged < 18 y. Most (64%) pts had stage II disease at relapse; 82% had relapse ≥ 12 mo after 1L tx, 2 pts had prior RT. Median (range) follow-up was 31.9 (2.2–55.3) mo. CMR, ORR, 3-y EFS and PFS rates are shown in Table. Median duration of response was not reached; 87% of pts had sustained response at 36 mo' follow-up. Efficacy outcomes were comparable in the pediatric population (CMR per BICR before ISRT, 88.9%; 3-y EFS rate, 78.3%). During induction, 22 (78.6%) pts had treatment-related adverse events (TRAEs; grade 3/4, 25.0% pts; hematologic, < 10% pts; immune-mediated, 21.4%). Serious AEs leading to discontinuation included rash, pyrexia, and acute kidney injury (1 pt each). **Conclusions:** The findings demonstrate that most CAYA with low-risk R/R cHL can be salvaged with chemoimmunotherapy with a favorable toxicity profile, and do not require HDCT/auto-HCT. Clinical trial information: NCT02927769. Research Sponsor: Bristol Myers Squibb.

CMR and ORR per BICR and investigator (INV) in low-risk cohort.

	BICR	INV
Any time before ISRT

Pirtobrutinib in covalent BTK-inhibitor (cBTKi) pre-treated mantle cell lymphoma (MCL): Updated results and subgroup analysis from the phase 1/2 BRUIN study with > 3 years follow-up from start of enrollment. *First Author: Nirav Niranj Shah, Medical College of Wisconsin, Milwaukee, WI*

Background: Pirtobrutinib is a highly selective, non-covalent (reversible) BTKi. Here, we report updated results of pirtobrutinib in patients (pts) with cBTKi pre-treated relapsed/refractory (R/R) MCL and more than 3 years follow-up from start of enrollment. **Methods:** Pts with cBTKi pre-treated R/R MCL received pirtobrutinib monotherapy in a multicenter phase 1/2 BRUIN trial (NCT03740529). Efficacy was assessed in the prespecified primary efficacy cohort that comprised the first 90 enrolled pts who had measurable disease, had received a prior cBTKi, and had no known central nervous system involvement. The primary endpoint was overall response rate (ORR) as assessed by independent review committee. Secondary endpoints included duration of response (DOR) and safety. A data cut of 29 July 2022 was utilized. **Results:** Among MCL pts who received a prior cBTKi (n=90), median age was 70 years (range, 46–87), median prior lines of therapy were 3 (range, 1–8), 82% discontinued a prior cBTKi due to disease progression, and 78% had intermediate/high risk SMPI score. Of samples available, 17/36 (47%) had TP53 mutations and 25/34 (74%) had Ki67 $\geq 30\%$. The ORR was 57% (95% CI, 46–67), including 19% complete responses (n=17) and 38% partial responses (n=34). At a median follow-up time of 13 months, the median DOR among the 51 responding pts was 17.6 months (95% CI, 7.3–27.2). The 12- and 18-month estimated DOR rates were 58% (95% CI, 41–72) and 45% (95% CI, 27–61), respectively. ORR and DOR by subgroups are shown in the Table. The median progression-free survival was 7.4 months (95% CI, 5.3–13.3). The median overall survival was 23.5 months (95% CI, 15.9–NE). In the MCL safety cohort (n=166), the most frequent treatment-emergent adverse events (TEAE) were fatigue (31%), diarrhea (22%), and anemia (17%). The most common Grade ≥ 3 TEAE was neutropenia (15%). Grade ≥ 3 TEAE of hemorrhage (3%) and atrial fibrillation/flutter (2%) were infrequent. Only 5 (3%) pts discontinued due to a treatment-related AE. **Conclusions:** Pirtobrutinib continues to show durable efficacy and a favorable safety profile in heavily pre-treated R/R MCL pts with prior cBTKi therapy. Responses were observed in pts with high-risk disease features including pts with blastoid/pleomorphic variants, elevated Ki67 index, and TP53 mutations. Clinical trial information: NCT03740529. Research Sponsor: Loxo@Lilly.

ORR and DOR in cBTKi pre-treated MCL pts and high-risk subgroups.

	cBTKi pre-treated MCL, n	ORR, % (95% CI)	DOR, median (95% CI)
Overall	90	56.7 (45.8–67.1)	17.6 (7.3–27.2)

Poster Discussion Session

Circulating tumor DNA of classical Hodgkin lymphoma. *First Author: Maria Cristina Piroso, Institute of Oncology Research, Bellinzona, Switzerland*

Background: Classical Hodgkin lymphoma (cHL) is the most common lymphoma in young adults. The morphologic peculiarity that makes cHL unique are the few tumor cells surrounded by a polyclonal inflammatory microenvironment. It is also the cancer with the highest sensitivity to immune checkpoint inhibitors. But why is it so immunogenic and how it escapes the immune control at the same time have only been partially elucidated. Although cure rates of cHL have constantly increased over the years there is still a high need for identification of biomarkers for more precise treatment decisions. The need for enriching tumor cells before assaying has limited cHL biological studies. Patients with cHL have significant amounts of circulating tumor DNA (ctDNA), suggesting an alternative approach for studying this enigmatic tumor. **Methods:** IOSI-EMA003 (NCT03280394) is a prospective, observational, multi-center study of adult patients with previously untreated cHL aiming at: i) identifying subgroups of patients with phenotype- and outcome-associated molecular signatures; ii) testing and validating baseline ctDNA load as a prognostic biomarker; iii) testing if ctDNA can be used for the early identification of chemoresistance. Blood samples were collected at staging and disease response assessment. PET scans were centrally and blindly reviewed. ctDNA was analyzed by using deep targeted and shallow whole genome sequencing to measure ctDNA load, capture mutations and profile ctDNA fragmentation patterns. The composition of the tumor microenvironment of cHL was probed by single cell RNA-seq. **Results:** A total of 215 patients were enrolled. Based on ctDNA fragmentation patterns reflecting chromatin accessibility in the regulatory region of germinal center (GC) B-cell genes, we segregated cHL into two subgroups that we named SNCD (for sub-nucleosomal cDNA) and NCD (for nucleosomal cDNA). We hypothesized that SNCD cHL stems from a cell that is closer to the GC B-cell differentiation stage than NCD cHL. SNCD cHL and NCD cHL differed in many aspects, including activation induced cytidine deaminase (AID)-hypermutation profile, neoantigen load, immune editing mechanism and response to chemotherapy and checkpoint inhibitors. Clinically, SNCD cHL displayed less sensitivity to both chemotherapy and anti-PD1 antibodies. Immune editing of SNCD cHL points loss of MHC-I, recruitment of Treg and upregulation of LAG3 as prominent immune checkpoint. High load of pre-treatment ctDNA nominated high-risk patients more accurately than clinico-radiological features. In addition, persistence of residual ¹⁸FDG avid lesions and measurable ctDNA was a better proof of chemoresistance than the sole persistence of residual ¹⁸FDG avid lesions. **Conclusions:** Our results provide a roadmap for cHL subtyping and molecular classification. We also propose ctDNA as a quantifiable and radiation-free biomarker to be used in clinical trials testing a more personalized treatment approach. Clinical trial information: NCT03280394. Efficacy and safety of pembrolizumab every six weeks in relapsed/refractory classical Hodgkin lymphoma or primary mediastinal B-cell lymphoma: The phase 2 KEYNOTE-B68 trial. *First Author: Andrew Bruce McDonald, Alberts Cellular Therapy, Netcare Pretoria East Hospital, Pretoria, South Africa*

Background: Pembrolizumab (pembro) 200 mg Q3W demonstrated robust antitumor activity and manageable safety in relapsed/refractory (R/R) classical Hodgkin lymphoma (cHL) and R/R primary mediastinal B-cell lymphoma (PMBCL), resulting in FDA approval. Recently, the FDA granted accelerated approval of pembro 400 mg Q6W in all approved indications based on data from solid tumor trials in solid tumors. The global Phase 2 trial (NCT04875195) evaluates the efficacy and safety of pembro 400 mg Q6W in R/R cHL and R/R PMBCL. We present, for the first time, data from 66 patients (pts) with approximately 9 months (mo) of follow up. **Methods:** In this nonrandomized, open-label trial, pts aged ≥ 18 years with PD-1 inhibitor naïve R/R cHL or PMBCL received 400 mg pembro Q6W for ≤ 18 cycles, until progression, unacceptable toxicity, or withdrawal. Eligible pts with cHL must have relapsed or failed to respond after ≥ 1 prior lines of therapy (LOT) or relapsed or failed to respond after ≥ 1 prior multiagent LOT or autologous stem cell transplant (ASCT). Eligible pts with PMBCL must have relapsed or failed to respond after ≥ 2 prior LOT including rituximab and relapsed or failed to respond to or were ineligible for ASCT. The primary endpoint was ORR per Lugano criteria by investigator (Lugano, INV). Secondary endpoints were DOR (Lugano, INV) and safety. Exploratory endpoints were PFS (Lugano, INV) and OS. Data cut-off date was October 18, 2022. **Results:** At data cut-off, 66 pts (60 R/R cHL, 6 R/R PMBCL) were enrolled. Median follow-up (range) was 8.9 mo (1–15.9) for pts with R/R cHL and 10.6 mo (5.1–15.4) with R/R PMBCL. The ORR was 65% (95% CI, 51.6–76.9 [33.3% CR; 31.7% PR]) for pts with R/R cHL, and 50% (95% CI, 11.8–88.2 [33.3% CR; 16.7% PR]) for R/R PMBCL. Drug-related adverse events (AE) occurred in 24 pts (40%) with R/R cHL and 2 pts (33.3%) with R/R PMBCL. Grade ≥ 3 drug-related AEs occurred in 3 pts (5%) with R/R cHL and 1 pt (16.7%) with R/R PMBCL. Immune-mediated AEs occurred in 13 pts (21.7%) with R/R cHL and 1 pt (16.7%) with R/R PMBCL. Grade ≥ 3 immune-mediated AEs occurred in 2 pts (3.3%) with R/R cHL. Antitumor activity is summarized in the Table. **Conclusions:** With approximately 9 mo of follow up, pembro 400 mg Q6W demonstrates robust antitumor activity in pts with R/R cHL and R/R PMBCL. The ORR observed is similar to pembro 200 mg Q3W in R/R cHL and R/R PMBCL. Pembro 400 mg Q6W had no new safety concerns, confirming Q6W dosing in hematologic indications. Clinical trial information: NCT04875195. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Metabolic response rates of epcoritamab + R-CHOP in patients with previously untreated (1L) high-risk diffuse large B-cell lymphoma, including double-hit/triple-hit lymphoma: Updated EPCORE NHL-2 data. *First Author: Lorenzo Falchi, Lymphoma Service, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients (pts) with 1L diffuse large B-cell lymphoma (DLBCL) typically receive rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP); however, around 40% relapse. Complete response rates and long-term outcomes are worse for high-risk pts with International Prognostic Index (IPI) 3–5 or double-hit/triple-hit lymphoma, representing an underserved pt population requiring better curative options. Data from the pivotal study of single-agent epcoritamab, a T-cell-engaging bispecific antibody, demonstrated impressive efficacy and a manageable safety profile (Thieblemont et al, JCO 2022). Preliminary data for epcoritamab + R-CHOP in 1L DLBCL (NCT04663347) showed encouraging efficacy. Here we present results for a larger cohort with longer follow-up. **Methods:** Pts with 1L CD20+ DLBCL and IPI ≥ 3 received subcutaneous epcoritamab (cycle [C] 1–4, QW; C5–6, Q3W) + R-CHOP for 6 Cs (21 d each) followed by epcoritamab monotherapy Q4W (28-d Cs) up to a total of 1 y. **Results:** As of Oct 31, 2022, 47 pts (median age, 64 y) had received epcoritamab 48 mg + R-CHOP with a median follow-up of 11.5 mo (range, 0.8–15.5). All pts had IPI 3–5, 37 (79%) had stage IV disease, and of 25 pts with FISH data available, 11 (44%) had double-hit/triple-hit DLBCL. Median time from diagnosis to first dose was 28 d (range, 3–423). Median dose intensity for R-CHOP was $\geq 95\%$. The most common treatment-emergent AEs (TEAEs) of any grade (G) were neutropenia (64%), anemia (62%), CRS (60%), fatigue (40%), pyrexia (40%), injection-site reactions (38%), and nausea (38%). TEAEs led to epcoritamab discontinuation in 3 pts; 1 pt had a G5 TEAE (COVID-19, unrelated to treatment). CRS was predominantly low grade (57% G1–2, 2% G3) and occurred mostly after the first full dose (C1D15); all cases resolved. One pt experienced G2 ICANS, which resolved. All response-evaluable pts (100%) had a response, and 76% had a complete metabolic response (CMR; Table). Notably, response rates were similar for double-hit/triple-hit pts (CMR rate, 82% [9/11]). The median durations of response, progression-free survival, and overall survival were not reached. Responses were durable; at 9 mo, an estimated 96% of pts with CMR remained in CMR. Updated data will be presented. **Conclusions:** Subcutaneous epcoritamab + R-CHOP induces high CMR rates with a manageable safety profile in pts with 1L high-risk DLBCL, including double-hit/triple-hit pts. These results support the ongoing phase 3 study of epcoritamab + R-CHOP in 1L pts (NCT05578976). Clinical trial information: NCT04663347. Research Sponsor: This study was funded by Genmab A/S and AbbVie.

Poster Discussion Session

Subgroup analysis of elderly patients (pts) with diffuse large B-cell lymphoma (DLBCL) in the phase 3 POLARIX study. *First Author: Bei Hu, Levine Cancer Institute, Charlotte, NC*

Background: In the Phase 3 POLARIX study (NCT03274492), polatuzumab vedotin with rituximab, cyclophosphamide, doxorubicin, and prednisone (Pola-R-CHP) significantly improved progression-free survival (PFS) compared with rituximab, cyclophosphamide, doxorubicin, vincristine and prednisone (R-CHOP), with a similar safety profile in pts aged 18–80 years with previously untreated DLBCL (Tilly et al. 2022). Combination regimens may be associated with higher rates of toxicity in elderly pts. We report the efficacy and safety of Pola-R-CHP vs R-CHOP in pts aged ≥ 70 years enrolled in POLARIX. **Methods:** POLARIX methods were described by Tilly et al. (2022). Pts with previously untreated DLBCL were randomized 1:1 to receive 6 cycles of Pola-R-CHP or R-CHOP, plus 2 cycles of rituximab. This analysis focused on pts aged ≥ 70 years at enrollment. **Results:** Overall, 284 pts were analyzed for efficacy (Pola-R-CHP, n=141; R-CHOP, n=143) and 280 pts were analyzed for safety (Pola-R-CHP, n=137; R-CHOP, n=143). Median age was 74 years (range 70–80), and 69.7% had an International Prognostic Index score of 3–5. Most pts in either arm received all 6 doses of polatuzumab vedotin or vincristine (88.3% and 91.6% in the Pola-R-CHP and R-CHOP arms, respectively). At data cutoff (June 28, 2021; median follow-up: 24.2 months), the risk of progression, relapse or death was lower with Pola-R-CHP vs R-CHOP (hazard ratio [HR] 0.64; 95% confidence interval [CI]: 0.41–0.99) (Table). Death by any cause occurred in 14.2% and 19.6% of pts treated with Pola-R-CHP and R-CHOP, respectively. Overall survival (OS) and disease-free survival (DFS) results are presented in the Table. Safety profiles were generally comparable for Pola-R-CHP vs R-CHOP, including rates of Grade 3–5 adverse events (AEs), Grade 5 AEs, serious AEs, peripheral neuropathy (any grade), neutropenia (Grade 3–4), and infection (Grade 3–4) (Table). **Conclusions:** Pola-R-CHP and R-CHOP demonstrated similar safety profiles in pts aged ≥ 70 years with previously untreated DLBCL. The risk-benefit profile favored Pola-R-CHP vs R-CHOP. Clinical trial information: NCT03274492. Research Sponsor: The POLARIX study (NCT03274492) was sponsored by F. Hoffmann-La Roche Ltd and Genentech, Inc. Third-party editorial assistance was provided by Leen Al-Mohammad, BSC, of Ashfield MedComms, an Inizio company, and was funded by F. Hoffmann-La Roche Ltd.

Poster Discussion Session

Impact of imaging frequency on progression free survival in Alliance clinical trials enrolling patients with untreated follicular lymphoma. *First Author: Sarah C. Rutherford, Weill Cornell Medicine, New York, NY*

Background: With goal of simplifying clinical trials in lymphomas, we reported that bone marrow biopsies are irrelevant for response assessment in most patients (pts) with follicular lymphoma (FL) on trials (Rutherford JCO 2023). We then investigated impact of imaging frequency in FL clinical trials. We hypothesized that progression free survival (PFS) would not be different when imaging is performed less frequently than required by trials. **Methods:** We identified all trials through Alliance for Clinical Trials in Oncology that enrolled untreated pts with FL from 2008–2016. We considered 2 imaging schedules: protocol specified (control) vs relaxed (X) in which response assessments at every other required time point were omitted. For each trial, we estimated PFS using Kaplan Meier methods for the 2 schedules then determined difference in PFS between schedules as % change from control schedule in 2 year (yr) PFS rate. We performed simulation studies to approximate impact of less frequent imaging on PFS estimation using 50901 (low-intermediate risk FL) and 50904 (intermediate-high risk FL, control arm). We assumed exponential distribution for PFS, where rate parameter was calculated based on observed median PFS with uniform censoring distribution. Protocols for 50901 and 50904 mandated imaging every 4 months (mos) for 2 yrs then every 6 mos (SO). We ran 1000 iterations of 100 observations using 3 tumor assessment follow up schedules: every 6 mos for 2 yrs then yearly (S1), every 8 mos for 2 yrs then yearly (S2), or yearly (S3) for simulated progression times. We calculated deviation of PFS using simulated schedules from truth (SO). **Results:** Across 5 FL trials, median percent change of schedule X from control schedule in estimated 2yr PFS was 2.1% (0.0–30.8%) and in estimated 4yr PFS was 0.9% (-8.6–25.7%). Disparate result in 50901 is due to small shift in events with low number of pts at risk for progression. Simulation study results by trial were: for 50901, true median PFS 1.9 yrs and average median PFS for S1, S2, and S3 of 2.05, 2.11, and 2.21 yrs; for 50904 (control arm), true median PFS 4.1 yrs and average median PFS for S1, S2, and S3 of 4.16, 4.12, and 4.05 yrs. **Conclusions:** Our findings support decreased frequency of imaging studies in FL clinical trials, which would improve resource use and decrease pt burden. We plan a larger analysis to confirm results. <https://acknowledgments.alliancefound.org>. Clinical trial information: NCT00553501, NCT01145495, NCT01190449, NCT01286272, NCT01829568. Effectiveness and safety outcomes in patients with EBV⁺ PTLD treated with allogeneic EBV-specific T-cell immunotherapy (tabellecleucel) under an expanded access program (EAP) in Europe. *First Author: Sylvain Choquet, Hôpital de la Pitié-Salpêtrière, Paris, France*

Background: Pts with relapsed or refractory (r/r) EBV⁺ post-transplant lymphoproliferative disease (PTLD) in Europe have had historically poor overall response rates and median overall survival (OS) with no approved treatment options. Tabelecleucel, an off-the-shelf, allogeneic EBV-specific T-cell immunotherapy has shown clinical benefit and favorable safety profile in the treatment of EBV⁺ PTLD failing rituximab ± chemotherapy (Prockop EBMT 2021, ATC 2021, ASH 2022). Its recent European marketing authorization (EMA) represents the first approval of an allogeneic T-cell immunotherapy globally. **Methods:** Atara Bio supported expanded access requests for tabellecleucel in Europe. Here we report updated effectiveness and safety data for r/r EBV⁺ PTLD pts who provided consent for research between Sep 2020 and Dec 2022. **Results:** 74 EAP requests were received from 10 countries for pts with r/r EBV⁺ diseases. 27 EBV⁺ PTLD pts consented to secondary use of data and 24 pts had received ≥1 dose of tabellecleucel, including 4 pts with primary central nervous system (PCNS) PTLD. 16 of 24 (66.7%) PTLD pts achieved a partial (PR) (33.3%) or complete (CR) (33.3%) response, with median time to response (TTR) of 1.0 mo (0.8–2.2). Response rate for PCNS PTLD pts was 75% (1 CR, 2 PR). 1-yr OS Kaplan–Meier (KM) estimate rates were 73.7% (95% CI: 47.3, 88.3) overall, 87.5% in allogeneic hematopoietic stem cell transplant (HCT) and 66.5% in solid organ transplant (SOT), with a median follow-up time of 9.9 (2.4–13.9) and 6.0 (0.7–18.0) mo, respectively. Serious treatment-emergent adverse events (TESAEs) were reported in 7 (29.2%) pts, including 1 fatal event of disease progression. Predefined risks for tabellecleucel were reported in 3 pts; 1 (4.2%) SOT pt had a TESAE of liver transplant rejection (grade 2) and 2 (8.3%) HCT pts had non-serious TEAEs of chronic graft-versus-host disease (grade 1 and 2). No cases of cytokine release syndrome or tumor flare reaction were reported. No AEs were reported as related to tabellecleucel by the treating physician. **Conclusions:** These updated real-world results for pts with r/r EBV⁺ PTLD post-HCT or post-SOT treated in the European EAP continue to reinforce the favorable risk:benefit profile of tabellecleucel and are in line with clinical study data supporting its recent EMA approval. Research Sponsor: None.

Circulating tumor DNA (ctDNA) status and clinical outcomes in patients (pts) with previously untreated diffuse large B-cell lymphoma (DLBCL) in the POLARIX study. *First Author: Alex Francisco Herrera, Department of Hematology and Hematopoietic Cell Transplantation, City of Hope, Duarte, CA*

Background: the POLARIX study, pts with previously untreated DLBCL were randomized to Pola-R-CHP or R-CHOP (NCT03274492; Tilly et al. 2022). We previously validated the prognostic value of ctDNA at baseline and after one cycle of therapy in POLARIX (Herrera et al. 2022); here, we evaluate the relationship between ctDNA clearance and PFS and OS. **Methods:** Pts were included if baseline and longitudinal ctDNA results were available. Plasma ctDNA was measured at baseline, Cycle (C) 5 Day (D) 1, and end of treatment (EOT), with the AVENIO NHL CAPP-Seq assay (Stokowski et al. 2022). ctDNA clearance was determined as previously described (Herrera et al. 2022). PFS and OS according to ctDNA status were reported as landmarked hazard ratios (HR) and 3-yr rates. HRs were adjusted for IPI score (>2), region, bulky disease (>7.5cm), age (>60 years), and cell of origin. **Results:** At baseline, 654 pts had ctDNA results; 494 (76%) and 519 (79%) pts were evaluable at C5D1 and EOT, respectively. Undetectable ctDNA (ctDNA–) was achieved by 57% (152/265) of Pola-R-CHP-treated pts and 59% (135/229) of R-CHOP-treated pts at C5D1 (p=0.79), and by 66% (172/262) of Pola-R-CHP-treated pts and 67% (172/257) of R-CHOP-treated pts at EOT (p=0.83). Achieving ctDNA– was prognostic for PFS and OS in each treatment arm at C5D1 and EOT (Table). Pts in the Pola-R-CHP arm who had complete response (CR) with PET-CT and ctDNA– at EOT had superior PFS and OS compared with pts with CR and detectable ctDNA (ctDNA+) at EOT (PFS HR 0.30, 95% confidence interval [CI]: 0.14–0.66; OS HR 0.20, 95% CI: 0.07–0.60). This was not observed with R-CHOP (PFS HR 0.74, 95% CI: 0.34–1.63; OS HR 1.11, 95% CI: 0.30–4.16). Among pts with CR and ctDNA– at EOT, pts treated with Pola-R-CHP had superior PFS vs R-CHOP (HR 0.41, 95% CI: 0.21–0.82); this was not observed with OS (HR 0.41, 95% CI: 0.14–1.18). There was no statistically significant difference in PFS between treatment arms in pts with CR and ctDNA+ at EOT (PFS HR 1.20, 95% CI: 0.49–2.83). **Conclusions:** Achieving ctDNA– at C5D1 and EOT was prognostic for longer survival. Although no difference was observed in the number of pts with ctDNA– at EOT between arms, pts achieving CR and ctDNA– at EOT had superior PFS in the Pola-R-CHP vs the R-CHOP arm, suggesting deeper molecular responses in pts treated with Pola-R-CHP beyond the detection sensitivity of the assay used in this analysis. A phase 1 study of AT101, a novel anti-CD19 CAR-T cell therapy targeting a membrane-proximal epitope of CD19, in patients with relapsed or refractory B cell non-Hodgkin lymphoma. *First Author: Dok Hyun Yoon, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: All the FDA-approved CD19 CAR-T products are based on FMC63 scFv, which binds to the membrane-distal region of CD19. We developed a novel anti-CD19 antibody clone (1218) that binds to a membrane-proximal epitope of CD19, thereby not competing with FMC63. AT101 is an autologous CAR T cell transduced with a lentiviral vector, including the CD19-CAR with a humanized scFv of 1218, 4-1BB costimulatory, and CD3zeta domain. **Methods:** In this phase 1 trial, patients (n = 3 per dose level; up to n = 18 in total) are treated with AT101 in 3 dose-escalation cohorts based on a standard 3 + 3 design. Each patient received a single intravenous dose of AT101 at dose level (DL) 1 (0.2 × 10⁶ cells/kg), DL2 (1.0 × 10⁶ cells/kg), or DL3 (5.0 × 10⁶ cells/kg). The primary objective is to determine the safety, the maximum tolerated dose (MTD), and the recommended phase 2 dose (RP2D) of AT101. The secondary objective is to evaluate the pharmacokinetics of AT101 and the preliminary efficacy, such as overall response rate (ORR), duration of response (DOR), progression-free survival (PFS), event-free survival (EFS), and overall survival (OS). Key eligibility criteria include patients aged ≥19 with histologically confirmed relapsed or refractory B-cell non-Hodgkin lymphoma (NHL). **Results:** Fourteen patients were enrolled from March 2022 to December 2022, and nine were treated. The median age of treated patients was 61.6 years (ranged from 39 to 84) after a median of 4 prior lines of therapy (range 2–10). Their subtypes of NHL were as follows: diffuse large B cell lymphoma (n = 4), follicular lymphoma (n = 3), mantle cell lymphoma (n = 1), or marginal zone lymphoma (n = 1). The dosing of AT101 at DL1 and DL2 was completed. The dosing at DL3 is ongoing. Across cohorts 1 and 2, no grade 3 or higher cytokine release syndrome (CRS) was reported. Among the first three patients at DL1, one dose-limiting toxicity (DLT) of grade 4 neurotoxicity was observed but resolved in a week without sequelae. No other DLTs were observed in the additional three patients at the DL1 and three at the DL2 cohort. Another one at DL2 experienced grade 1 CRS with grade 1 neurotoxicity. Five patients experienced Grade ≥3 hematologic toxicities. An ORR is 66.7% (4/6) in cohort 1 and 100% (3/3) in cohort 2, including six complete responses (CR, 50.0% [3/6] in cohort 1 and 100% [3/3] in cohort 2). As of February 13, 2023, all six CRs are ongoing, including two patents exceeding six months after the treatments. Updated results will be presented at the meeting, including the cohort of DL3. **Conclusions:** In this phase I study, AT101 was well tolerated at the first two dose levels and showed promising efficacy in relapsed or refractory B-cell NHL patients. The majority of adverse effects were transient and manageable. The administrations of DL3 are currently ongoing, and updated results will be presented at the meeting. Clinical trial information: NCT05338931. Research Sponsor: AbClon Inc.

High complete response rate with TNB-486 in relapsed/refractory follicular lymphoma: Interim results from an ongoing phase 1 study. *First Author: Ranjit Nair, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Follicular lymphoma (FL) is incurable with a relapsing/remitting pattern and decreasing progression-free survival (PFS) interval per recurrence. In the relapsed/refractory (R/R) setting, patients (pts) failing CAR T or CD20 bispecific T-cell engagers (TCE) have few options. TNB-486 is a novel bispecific CD19xCD3 TCE that induces T-cell-mediated cytotoxicity with reduced cytokine release via a low-affinity αCD3 moiety. We present interim data from a phase 1 dose-escalation study of TNB-486 (NCT04594642). **Methods:** Third-line+ R/R FL pts (grade [G] 1–3a) were enrolled (prior CD19 therapy allowed). Escalating fixed TNB-486 doses (0.03–2.4 mg) without priming were evaluated prior to implementing single (day [D] 1) and double priming doses (D1 & 8) prior to target dose (D15). TNB-486 was given IV every 2 weeks in 28-d cycles (C) for up to 2 y. Response was assessed with REC1L 2017 by central image review. Adverse events (AEs) and CRS/ICANS were graded by CTCAE v5.0 and 2019 ASTCT criteria. **Results:** As of Dec 31, 2022, 17 pts received TNB-486 at target doses 0.03–10 mg (median age 68 y [range 33–86]; 53% male; 65% stage III/IV; 25% CD20– disease; median prior lines of therapy [LOT] 3 [range 2–9]). Prior therapies included αCD20 Ab (100%), alkylator (76%), IMiD (47%), CD20 TCE (12%), CD19 CAR T (12%), and ASCT (6%); 53% progressed or started 2nd LOT within 24 mo of initiating 1st LOT (POD24). Median time on study was 7 mo (range 1–22). Eleven pts were response evaluable for efficacy at target doses ≥2.4 mg. Objective response rate (ORR) and complete response (CR) rate were 91% (Table). ORR/CR for pts with CD20– disease, prior CD20 TCE, and POD24 was 100%. One pt progressed at C6 with preserved CD19 expression; all others remain in remission to date. The 6-mo PFS rate was 91%. No G3+ CRS occurred (59% G1, 12% G2). Neurologic events consistent with ICANS were reported in 24%, all G1–2 except 1 with a G3 event (confusion). All CRS/NT were transient, resolving in a median of 1.5 d (range 1–5). G3+ treatment-related AEs in >10% of pts included decreased lymphocytes (35%) and neutropenia (12%). No treatment-related deaths or AEs leading to discontinuation occurred (1 pt died and 1 discontinued due to COVID-19). One pt received double step-up priming dosing to date with no CRS/NT. **Conclusions:** TNB-486 induces high complete remission rates during early phase dose escalation. With limited follow-up, responses appear durable in heavily pretreated FL pts, with a manageable safety profile. Dose escalation is ongoing to identify the RP2D. Clinical trial information: NCT04594642. Research Sponsor: AstraZeneca; TeneoTwo.

Effect of follow-up time on the ability of subcutaneous epcoritamab to induce deep and durable complete remissions in patients with relapsed/refractory large B-cell lymphoma: Updated results from the pivotal EPCORE NHL-1 trial. *First Author: Yasmin Karimi, University of Michigan Comprehensive Cancer Center, Ann Arbor, MI*

Background: Outcomes are poor for patients (pts) with relapsed/refractory (R/R) large B-cell lymphoma (LBCL). Effective treatments (tx) that drive deep, durable responses and long-term benefit are needed. In the pivotal EPCORE NHL-1 trial (NCT03625037), single-agent epcoritamab (epcor) showed high complete response (CR) and MRD-negativity rates, a median duration of response (mDoR) not reached (NR) in pts who achieved CR, and a manageable safety profile as an off-the-shelf, subcutaneous (SC), CD3xCD20 T-cell-engaging bispecific antibody (Thieblemont et al, *JCO* 2022). We present updated results with longer follow-up in a challenging-to-treat population. **Methods:** Pts with R/R CD20⁺ LBCL received SC epcor (step-up priming and intermediate doses followed by 48-mg full doses) in 28-d cycles (Cs): QW, C1–3; Q2W, C4–9; Q4W, C≥10 until PD or unacceptable toxicity. **Results:** As of Nov 18, 2022, of 157 pts (median age, 64 y) with LBCL (including DLBCL [n=139], HGBCL [n=9], PMBCL [n=4], and FL grade 3B [n=5]; 13/99 double/triple-hit by FISH), 36 remain on tx. Pts had a median of 1.6 y from initial diagnosis to first dose and a median of 3 (range, 2–11) prior tx lines; 61% of pts had primary refractory disease, and 39% had prior CAR T, of whom 75% progressed ≤6 mo of tx. Median follow-up was 20 mo (range, 0.3+ to 28.2). Pts received a mean of 9.1 cycles. LBCL overall response and CR rates were 63.1% and 39.5%, respectively, and were consistent for DLBCL (61.9% and 39.6%). The mDoCR was 20.8 mo. Median time to CR was 2.7 mo; 8 pts converted from partial response to CR at ≥36 wk. Median overall survival (mOS) was 18.5 mo (95% CI, 11.7–NR), with an estimated 58% of pts alive at 12 mo. mOS was NR in pts who achieved CR. Additional outcomes for pts with CR are shown in Table. The most common TEAEs of any grade (G) were: CRS 51%, neutropenia 24%, pyrexia 24%, fatigue 23%, nausea 22%, and diarrhea 21%. Nine pts (6%) had G1–2 ICANS, and 1 pt had a G5 event with confounding factors. Fatal TEAEs occurred in 15 pts; 2 were considered related (COVID-19, ICANS). CRS was predominantly low grade (48% G1–2; 3% G3) and occurred following the first full dose (C1D15). One pt discontinued tx due to G1 CRS. Total metabolic tumor volume (TMTV) data will be presented. **Conclusions:** These data with longer follow-up reaffirm single-agent SC epcor induces durable CRs with improved outcomes and a manageable safety profile. No new safety signals were observed in these hard-to-treat pts. These impressive data support the ongoing phase 3 studies evaluating epcor across different lines of tx and in various combinations. Clinical trial information: NCT03625037. Research Sponsor: This study was funded by Genmab A/S and AbbVie.

Preliminary results from a phase I/II study of IMM0306, a CD47 and CD20 bispecific monoclonal antibody-trap, in patients with relapsed or refractory CD20-positive B-cell non-Hodgkin's lymphoma. *First Author: Jianliang Yang, Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China*

Background: IMM0306 is a fusion protein of CD20 monoclonal antibody with the CD47 binding domain of SIRPα on both heavy chains. It has a higher affinity for CD20 than for CD47, thus enabling its preferential and simultaneous binding to CD20 and CD47 on malignant B cells rather than to CD47-positive normal tissues. Here, we report the safety, pharmacokinetics (PK), pharmacodynamics (PD), and efficacy results of the dose escalation stage in a phase I/II study in patients (pts) with relapsed or refractory CD20-positive B-cell non-Hodgkin's lymphoma. **Methods:** This is a first-in-human, open-label, phase I/II study of IMM0306. The ongoing Phase I part (0.04, 0.1, 0.25, 0.5, 0.8, 1.2, 1.6, 2.0 mg/kg, IV) followed an accelerated titration and standard 3+3 design. IMM0306 was administered once per week after a 2-week single-dose period, until disease progression or intolerable toxicity. Dose-limiting toxicity (DLT) was evaluated in the first 28 days. Safety was evaluated per CTCAE 5.0, tumor assessments performed once every 8 weeks, PK and PD were also assessed. **Results:** As of the data cut-off date on Dec 15th, 2022, 42 pts were enrolled. 18 (43%) pts received 3 or more prior lines of therapy, all pts received prior anti-CD20 therapy. No DLTs were observed up to 2.0 mg/kg. The most frequent treatment-related adverse events (TRAEs) were lymphocyte decreased (61.9%), white blood cell (WBC) decreased (61.9%), anemia (59.5%), neutrophil (ANC) decreased (40.5%), platelet (PLT) decreased (40.5%), infusion-related reactions (31.0%). Grade ≥ 3 TRAEs occurred in 30 (71.4%) pts, the most frequent grade ≥ 3 TRAEs were lymphocyte decreased (59.5%), WBC decreased (16.7%), ANC decreased (11.9%). Three treatment-related SAEs were PLT decreased (grade 4), chest pain (grade 2) and diarrhea (grade 3). In 38 response evaluable pts, 2 follicular lymphoma (FL) pts achieved CR, 1 marginal zone lymphoma (MZL) pt and 2 FL pts achieved PR and 13 pts showed SD. 26 pts were treated at doses ≥ 0.8 mg/kg, among whom 11 were FL pts. Of these 11 FL pts, 4 (36%) responded including 2 CR both at 1.2 mg/kg and 2 PR at 1.2 and 1.6 mg/kg respectively. IMM0306 exhibited approximate dose-proportional increase in PK exposure from 0.5 to 2.0 mg/kg and no obvious accumulation was observed after repeated dosing. B-cell counts depleted rapidly at doses ≥ 0.8 mg/kg. Elevated cytokines levels were observed after first dosing of IMM0306, but multiple dosing did not stimulate further cytokine activation. **Conclusions:** IMM0306 was well-tolerated and with a robust preliminary anti-tumor activity especially in pts with R/R FL and MZL. The phase I/II study is ongoing. Clinical trial information: CTR20192612. Research Sponsor: ImmuneOnco Biopharmaceuticals (Shanghai) Inc.

Subgroup analyses of primary refractory (refr) vs early relapsed (rel) large B-cell lymphoma (LBCL) from the TRANSFORM study of isocabtagene maraleucel (liso-cel) vs standard of care (SOC) as second-line (2L) therapy. *First Author: Loretta J. Nastoupil, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The TRANSFORM primary analysis (PA; NCT03575351) confirmed the superior efficacy of liso-cel vs SOC as 2L therapy in patients (pts) with primary refr or early rel LBCL (Abramson et al. *Blood* 2022). Response to first-line (1L) therapy (refr vs rel), which was a study randomization stratification factor, may influence future treatment response. Here, we present results for refr and rel LBCL subgroups from the TRANSFORM PA. **Methods:** TRANSFORM is a randomized phase 3 study of liso-cel vs SOC (salvage chemotherapy [CT] followed by high-dose CT [HDCT]/autologous SCT [ASCT]) in adults ≤ 75 y with LBCL primary refr to or rel ≤ 12 mo after 1L therapy and eligible for HDCT/ASCT. The primary endpoint was event-free survival (EFS); key secondary endpoints were CR rate, PFS, and OS. In this predefined subgroup analysis, refr was SD, PD, PR, or CR with rel < 3 mo after 1L therapy; rel was CR with rel ≥ 3 mo and ≤ 12 mo after 1L therapy. **Results:** 92 pts were randomized to each arm. Most pts in the liso-cel and SOC arms had refr disease (73% and 76%, respectively; rel disease, 27% and 24%). Baseline characteristics in the refr and rel subgroups, respectively, were generally balanced: median LDH (U/L; liso-cel, 228.5 and 225; SOC, 259 and 259); median SPD (cm²; liso-cel, 11 and 12; SOC, 15.5 and 18); high-grade B-cell lymphoma (liso-cel, 27% and 16%; SOC, 27% and 9%); diffuse LBCL not otherwise specified (liso-cel, 58% and 56%; SOC, 49% and 73%). Consistent with the overall study population, EFS, CR rate, and PFS favored liso-cel vs SOC in both subgroups (Table). Safety was also consistent. Grade ≥ 3 cytokine release syndrome (CRS) and neurological events (NE) were low in refr (1% and 4%) and rel (0 and 4%) subgroups, respectively, with no grade 4/5 CRS or NEs. **Conclusions:** In TRANSFORM, liso-cel showed benefits in EFS, PFS, and CR rate vs SOC irrespective of prior response to 1L therapy. As refr LBCL is historically difficult to treat, outcomes for liso-cel in this subgroup are encouraging. Clinical trial information: NCT03575351. Research Sponsor: This study was funded by Celgene, a Bristol-Myers Squibb Company.

Rates of cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) from Center for International Blood and Marrow Transplant Research (CIBMTR) data on US subjects (SUBJ) with lymphoma following chimeric antigen receptor T cell therapy (CAR-T). *First Author: Matthew J. Frigault, Massachusetts General Hospital, Boston, MA*

Background: The engineered T-cell products axicabtagene ciloleucel (axi-cel) and brexucabtagene autoleucel (brexu-cel) are FDA approved for relapsed/refractory diffuse large B-cell lymphoma (DLBCL) and mantle cell lymphoma (MCL), respectively. This study investigated real-world rates of CRS and ICANS following CAR-T. **Methods:** This study analyzed CIBMTR data of US SUBJ receiving axi-cel or brexu-cel for any indication from Oct 2020–Dec 2021 with ≥1 follow-up visit. CRS and ICANS were graded per American Society for Transplantation and Cellular Therapy consensus guidelines. **Results:** 927 SUBJ (median age, 63 y; men, 65%) from 87 centers were analyzed. Most received axi-cel (76%), 83% of whom had DLBCL or transformed follicular lymphoma (tFL); 24% received brexu-cel (MCL). Most SUBJ had Ann Arbor stage III/IV (63%), no active central nervous system disease (84%), and refractory disease at CAR-T infusion (66%). Among all 589 SUBJ with DLBCL/tFL who received axi-cel, 54% achieved complete response, 17% partial response, and 6% stable disease. 89/715 SUBJ with available data received treatment for CRS prevention, mostly tocilizumab alone (80% [71/89]) or in combination (3% [3/89]). Overall, 766 SUBJ (83%) developed CRS (grade ≥3, 64 [8%]; Table). Of the 89 SUBJ who received CRS prevention treatment, 78% developed CRS, with 3% (3/89) having grade ≥3. 77% of SUBJ with CRS received CRS treatment, 97% of whom received tocilizumab (alone or in combination [eg, with corticosteroids]). Most (64%) SUBJ with grade 1 CRS received treatment, 63% of whom received tocilizumab alone. ICANS occurred in 424/876 SUBJ with ICANS data (48%; Table), of whom 205 (48%) had grade ≥3. ICANS treatment was reported and administered to 86% of SUBJ with ICANS, 92% of whom received corticosteroids. **Conclusions:** CRS and ICANS incidence rates were consistent with previously published literature and highlight potential burdens of CAR-T. In addition, the treatment landscape for CRS is changing; SUBJ with grade 1 CRS often received treatment. These data will inform the design of future studies aimed at preventing and treating CAR-T toxicities. Research Sponsor: Incyte Corporation.

AB-101, an allogeneic, non-genetically modified, natural killer (NK) cell therapy, evaluated as monotherapy or in combination with rituximab in R/R non-Hodgkin lymphoma. *First Author: Rashmi Khanal, Fox Chase Cancer Center, Philadelphia, PA*

Background: AB-101 is a non-genetically modified, cord blood-derived, allogeneic, cryopreserved, NK cell therapy for use in combination with monoclonal antibody (mAb) or innate cell engager therapies. AB-101 is being developed to enhance response to mAb therapy through the antibody-dependent cellular cytotoxicity (ADCC) mechanism. Many cancer patients (pts) are unable to mount a robust ADCC response, rendering mAb therapy less effective for these pts. AB-101 has attributes that enhance NK cell activity: Consistent phenotype for tumor engagement and cytotoxicity; Selected killer immunoglobulin-like receptor B (KIR B) haplotype; V/V CD16 polymorphism at F158 for enhanced ADCC. AB-101 outpatient administration provides optimized NK cells to pts, potentially enhancing their anti-tumor activity in combination with mAb that utilize the ADCC mechanism. We have initiated a Ph 1/2 clinical trial evaluating the combination of AB-101 with rituximab (RTX) in pts with R/R NHL of B-cell origin. **Methods:** Two AB-101 dose levels, 1 or 4e9 cells, will be evaluated as monotherapy or combination with RTX. All enrolled pts will receive at least 1 cycle of 4 weekly AB-101 doses, with cyclophosphamide/fludarabine lymphodepletion (LD). Pts receiving the combination may receive up to 4 treatment cycles. **Results:** Dose escalation is ongoing with 17 pts enrolled. Pts were elderly (median of 68 yrs) and heavily pretreated (median of 4 prior lines) with 64% having had prior CD19 CAR-T. Pts had DLBCL (9), FL (5), MCL (2), and LPL/WM (1). 11 monotherapy pts and 6 RTX combination pts were treated at time of abstract. 16 pts received AB-101 at 1e9 cells/dose; 1 pt received 4e9 cells/dose. 4 of 6 combination pts have received > 1 cycle. AB-101 was generally well tolerated. The most common G3+ AEs were LD-related neutropenia and lymphopenia. All AB-101 related AEs were G1/2. ICANs and GVHD, events associated with allogeneic cell therapy, were not reported; Gr 1 CRS occurred in 2 pts and resolved within 24h. SAEs were reported in 9 pts. The most common SAEs were associated with either infections (n = 3) or PD (n = 3) and one related SAE of Gr 1 fever was reported. No pts discontinued treatment due to an AB-101-related AE. ORR for the RTX cohort was 67% (4/6) with a CR rate of 50% (3/6). 3 of 4 responses were observed in pts who failed prior CAR-T therapy. ORR for the monotherapy cohorts was 27% (3/11). **Conclusions:** 4 weekly doses of AB-101 given alone or with RTX appeared to be safe and well tolerated without the serious/severe toxicities associated with CAR-T therapies. Preliminary efficacy of the combination treatment is encouraging. The study is ongoing and continues to enroll the combination cohorts and the 4e9 cells/dose level. Updated safety, efficacy, and exploratory PK/PD/immunogenicity results will be provided during the presentation. Clinical trial information: NCT04673617. Research Sponsor: Artiva Biotherapeutics.

Zilovetamab vedotin (MK 2140) in relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL): Early results from the phase 2 waveLINE-004 study. *First Author: Muhit Ozcan, Ankara University School of Medicine, Ankara, Turkey*

Background: Treatment options are limited for patients (pts) with R/R DLBCL who are not candidates for autologous stem cell transplant (ASCT). ROR1 is an oncofetal protein pathologically expressed in hematologic malignancies including DLBCL. In the phase 1 first-in-human study in hematologic malignancies (waveLINE-001), the ROR1-targeting antibody-drug conjugate zilovetamab vedotin (ZV) showed promising activity and manageable safety in R/R DLBCL. The single-arm, open-label, phase 2 waveLINE-004 study (NCT05144841) is designed to evaluate activity of ZV monotherapy in pts with R/R DLBCL. Early data are reported. **Methods:** Eligible pts were ≥18 y old, had histologically confirmed DLBCL by WHO classification, measurable disease per Lugano 2014 criteria, PET-positive disease, and ECOG PS of 0-2. Pts must have received ≥2 prior lines of therapy (including an alkylating agent, anthracycline, and an anti-CD20 antibody) with progression after or ineligibility for ASCT and CAR T-cell therapy. All pts received ZV 2.5 mg/kg IV Q3W until disease progression, unacceptable toxicity, or withdrawal. Primary end point was ORR per Lugano 2014 criteria. Safety and tolerability was a secondary end point. Safety was evaluated in all pts who received ≥1 dose of treatment; efficacy was reported for pts with ≥3 mo follow-up. **Results:** At data cutoff (Nov 16, 2022), 40 pts enrolled and received ≥1 dose of treatment; 23 (58%) had discontinued and 17 (43%) were ongoing. Median age was 68.0 y, 29 (73%) pts were male, 37 (93%) had an ECOG PS of 0 or 1, 24 (60%) had ≥3 prior lines of therapy, and 10 (25%) received prior ASCT. 11 (28%) pts received prior CAR-T. Median follow-up (range) was 2.6 mo (0.3-7.9) for all pts and 6.0 mo (3.0-7.9) for pts in the efficacy analysis (n = 20). ORR by investigator review was 30% (95% CI, 11.9-54.3), with 2 pts having a CR and 4 a PR; 5 pts had SD (DCR, 55% [95% CI, 31.5-76.9]). Treatment related AEs (TRAES) occurred in 28 (70%) pts, most commonly (≥15%) diarrhea (9 [23%]), anemia (8 [20%]), neutropenia (7 [18%]), neutrophil count decreased (7 [18%]), and alopecia (6 [15%]). Grade 3/4 TRAES occurred in 16 (40%) pts, most commonly (≥10%) neutropenia (7 [18%]), anemia (6 [15%]), and neutrophil count decreased (4 [10%]). Discontinuation due to a TRAE of diabetic ketoacidosis occurred in 1 (3%) pt. Grade 1/2 treatment-related peripheral neuropathy occurred in 6 (15%) pts; no grade 3/4 AEs occurred. Dose reduction due to treatment-related peripheral neuropathy occurred in 3 (8%) pts. No infusion reaction or tumor lysis syndrome due to treatment occurred and no pts died because of TRAES. **Conclusions:** Early results show that ZV had clinically meaningful antitumor activity in pts with R/R DLBCL who progressed after or have been ineligible for ASCT and/or CAR-T. Additionally, the safety profile was manageable and consistent with other monomethyl auristatin E-containing agents. Clinical trial information: NCT05144841. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Systemic VSV-IFNβ-NIS oncolytic virotherapy in patients with relapsed refractory T-cell lymphoma. *First Author: Nabila Nora Bennani, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Oncolytic virotherapy is a novel immunomodulatory therapeutic approach currently under study for relapsed refractory (R/R) hematologic malignancies. The engineered Vesicular Stomatitis Virus VSV-IFNβ-NIS used in this study encodes interferon beta (IFNβ) and sodium iodine symporter (NIS). Virally-encoded IFNβ serves as an index of viral proliferation and enhances host anti-tumor immunity. Herein, we report the updated results of the phase 1 clinical trial NCT03017820 of a one-time administration of systemic VSV-IFNβ-NIS among patients (pts) with R/R multiple myeloma (MM), T cell Lymphoma (TCL) and Acute myeloid Leukemia (AML) with particular focus on the TCL cohort treated at the highest dose level (DL4) without Ruxolitinib. **Methods:** VSV-IFNβ-NIS was administered as a single IV dose following a classical 3+3 phase I trial, starting at 5e9 TCID50 DL1 through 1.7e11 TCID50 DL4. A dose expansion cohort of 8 additional R/R TCL pts was added at DL4 in view of an initial signal of activity. The primary objective was to determine the maximum tolerated dose of VSV-IFNβ-NIS as a single agent. Secondary objectives were determination of safety profile and preliminary efficacy of VSV-IFNβ-NIS. Adverse events (AEs) are reported based on CTCAE V4; cytokine release syndrome (CRS) grading was based on Lee (Blood 2014) criteria. **Results:** To date, a total of 43 pts received VSV-IFNβ-NIS: MM (N=21), TCL (N=21) and AML (N=1). In the TCL cohort: at DL4 Group A (no Ruxolitinib), 12 pts were registered, but only 11 pts were treated (mycosis fungoides (MF) N=3; ALK- ALCL N=1; PTCL-NOS N=2; AITL N=4; Nodal PTCL, TFH N=2; ages 33-79). These pts received a median of 3 lines of therapy (range: 1-5). No dose limiting toxicities were observed. Grades 3 and higher AEs were hematologic with transient lymphopenia (63.6%), neutropenia (36.4%) being the most common. The non-hematologic AEs observed included unique toxicities such as CRS grades 1-2 (81.8%); the transient transaminitis grade 1-2 (36.4%) and grade 3 (27.3%) along with thrombocytopenia grade 1-2 (63.6%) and grade 3 (18.2%) were a reflection of IFNβ toxicity. All the AEs observed were short lived. Responses were seen in pts with PTCL. At DL4, in pts with systemic PTCL (N=9), there were 5 responses including 3 complete responses (CR) with two long-lasting at 24 months, an ongoing 15 month CR, and a 5 month CR, and 2 partial responses (PR) lasting 5 months in one pts and 6 months in the other. **Conclusions:** These updated results of single agent VSV-IFNβ-NIS which include pts with PTCL treated at the highest dose level and a dose expansion cohort demonstrates not only the safety of VSV-IFNβ-NIS but also a strong efficacy signal in pts with PTCL with impressive durable responses. Two expansion cohorts at DL4 have been added (20 additional PTCL, 10 B-cell lymphoma pts) to obtain additional data on tolerability and efficacy and biomarkers of response in these pts. Clinical trial information: NCT03017820. Research Sponsor: U.S. National Institutes of Health; Vyriad.

Efficacy of COVID vaccinations in patients with chronic lymphocytic leukemia. *First Author: Kaitlin Annunzio, The Ohio State University, Columbus, OH*

Background: Chronic lymphocytic leukemia (CLL) is the most prevalent leukemia in the western world. Primarily affecting older patients, CLL increases the risk of infection due to immunosuppression from underlying disease and treatments. With the COVID19 pandemic now in its third year, vaccines remain one of our best protections against infection. However, people with CLL historically have decreased vaccine efficacy; hence protection from the COVID19 vaccines is uncertain. Furthermore, it is unknown if antibodies generated in response to vaccination confer immunity. Therefore, we tested for presence of SARS-CoV-2 antibodies post vaccination to determine if a response was generated and led to a decreased risk of breakthrough infections. **Methods:** We performed a retrospective cohort study of patients with CLL who received at least one COVID19 vaccine. Spike protein antibodies were assessed in a CLIA-approved laboratory. Detectable spike protein antibodies after vaccination were assessed, excluding those detected any time after Cilgavimab-Tixagevimab administration, within 90 days after any monoclonal antibody or convalescent plasma, or after covid infection post vaccine to best capture antibody responses from the vaccine. Logistic regression model was used to assess the odds of antibody development. Fine-Gray model was used to assess risk of breakthrough infections. **Results:** 477 patients were included in this study with median age of 60.4 years. Patients were predominately male (64.8%) and white (97.3%). 70.4% of patients had received at least one treatment for CLL. 45.5% of patients were on CLL treatment at time of vaccination, with the majority (87.6%) of these treated with BTK inhibitors either as monotherapy or with a BCL2 inhibitor or anti CD-20 therapy. Three hundred thirteen (68.2%) of the patients had a detectable antibody after vaccination. Those who received CLL treatment were less likely to have detectable antibody response compared to those not on treatment (OR = 0.19, p < 0.0001). Compared with patients who received Moderna vaccine, Pfizer (OR = 0.15, p < .01) and Janssen (OR = 0.46, p = 0.29) vaccine receivers were less likely to have detectable antibodies. Eighty (17.2%) patients developed COVID19 infection after vaccination, with 5% mortality from COVID19. Those who received Pfizer vaccines had a higher risk of infection (HR = 2.25, p = 0.0016). Regardless of vaccine type, those who had antibodies post vaccination had a decreased risk for infection (HR = 0.38, p < 0.0001). **Conclusions:** Among patients who were vaccinated against COVID19, those who received CLL treatment were less likely to develop antibodies compared to untreated patients, indicating that treatment decreases vaccine efficacy. We show that detectable antibodies after vaccination decrease risk for infection. Moderna appears to have greater efficacy, with more patients having positive antibody titers and a lower risk of developing COVID19. Research Sponsor: None.

Analysis of racial disparities accounting for treatment received in chronic lymphocytic leukemia: A real-world cohort analysis. *First Author: Adam Kittai, Division of Hematology, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Recent population-based studies have shown that Black patients (pts) with CLL have worse overall survival (OS) than White pts with CLL. These studies could not account for the use of modern therapies, CLL prognostic variables, or comorbidity and thus the root cause of this disparity remains unclear. Here, we use the Flatiron Health Database (FHD) to study this disparity, while accounting for disease-specific variables and treatment (tx) received. **Methods:** Retrospective analysis of pts with CLL in the FHD treated between 2002 to 2022 was performed. Pt characteristics such as age at diagnosis (dx), year (yr) of dx, months (mos) from dx to first tx, race, sex, IGHV status, ECOG performance status (PS), and use of small molecule inhibitors at any time (including BTK inhibitors, venetoclax, PI3K inhibitors, and lenalidomide) were collected and analyzed. OS was measured from tx start. Multivariable cox regression (MVA) was used to determine adjusted odds of survival. **Results:** 13646 pts with CLL were identified. Mean age at dx was 65.3 yrs, and mean time from dx to tx was 32.3 mos. 81.2%, 8.4%, and 10.4% of pts were White, Black, or other race, respectively, and 63.2% of pts were male. 61.4% of pts were IGHV unmutated, and 89.1% of pts had a ECOG PS 0/1. 58.7% of pts were treated with a small molecule inhibitor at any point during their tx. After a median follow-up of 5.3 yrs, the median OS was 10.5 yrs (95% CI: 10.2-10.8). Black pts were younger at dx (63.1 vs 65.4), had shorter time to first tx (23.6 mo vs 34 mo), were more likely to be IGHV unmutated than White pts (83% vs 60.1%), and had more small molecule inhibitor use (69% vs 58.5%). These differences were all statistically significant (p <0.01). 90.8% and 89.1% of Black and White pts had an ECOG PS of 0/1, respectively. Median OS for Black pts was 10 yrs (95% CI: 9.1-11.1) vs 10.5 yrs (95% CI: 10.2-10.8) for White pts. On MVA, Black pts had higher risk of death than White pts of the same age despite increased use of small molecule inhibitor (Table). However, the interaction between age and race was also significant, indicating a decreasing disparity between Black and White race as pts aged. Time to first tx, IGHV unmutated status, and ECOG PS were also independently associated with worse OS. **Conclusions:** Black race especially at younger age was independently associated with worse OS despite the use of small molecule inhibitors, IGHV status, and ECOG PS. Patient perspectives on CLL treatment side effects: A sub-analysis of the VOICE survey. *First Author: Constantine Si Lun Tam, Alfred Health, Melbourne, Victoria, VIC, Australia*

Background: Treatment for chronic lymphocytic leukemia (CLL), including chemo-immunotherapy and targeted drugs, is associated with various adverse events. We surveyed patients with CLL about their knowledge and attitudes regarding treatments and “side effects” (SEs), a more widely understood term for adverse events. **Methods:** Clinicians and patient advocacy group representatives developed and distributed a survey from March through December 2022 in 12 countries to patients with CLL who underwent ≥1 line of treatment. The anonymous survey was available via an electronic platform, digital questionnaires (.pdf), or paper forms. This sub-analysis includes items regarding SEs during treatment intervals, although the SEs queried were not comprehensive. **Results:** Treatment SEs had a moderate or high impact on 27%–43% of patients in every domain queried (Table). Most patients (300/370; 81%) discussed SEs with their physicians “always” or “sometimes”, but (117/277) were seeking more information about the benefits and SEs associated with their treatment, primarily via the internet. When asked how they would respond to common SEs, most patients would consult their physician first. Notably, >10% of them would continue treatment normally if they experienced arrhythmias or cardiac problems, and 21% would continue if they developed hypertension (Table). A similar proportion (11%) would continue treatment if they had an infection, while 23% of them would consider stopping treatment without medical advice if they developed skin cancer. **Conclusions:** These results show the impacts of SEs from CLL treatment affect substantial numbers of patients in multiple life areas. The responses suggest that despite patient-physician communication about SEs, there is a need to help patients find reliable information about their treatments online as well. Finally, patients’ willingness to stop or continue treatment in the event of various SEs, including cardiovascular or oncologic events, indicates a critical knowledge gap regarding the risk associated with these events. The real-world data presented herein highlights areas in which improved patient education initiatives could directly improve patient outcomes. Research Sponsor: MphaR; AstraZeneca.

Fixed-duration ibrutinib + venetoclax for first-line treatment of chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL): 4-y follow-up from the FD cohort of the phase 2 CAPTIVATE study. *First Author: Paul M. Barr, Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY*

Background: CAPTIVATE (PCYC-1142) is a multicenter phase 2 study of first-line ibrutinib (I) + venetoclax (V) in CLL/SLL. Follow-up results from the fixed duration (FD) cohort showed 3-y PFS rate of 88% overall and rates ≥80% in patients (pts) with high-risk features (Wierda, ASCO 2022). Here we present updated results from the FD cohort with 4-y follow-up. **Methods:** Pts aged ≥70 y with previously untreated CLL/SLL received 3 cycles of I then 12 cycles of I+V (I 420 mg/d orally; V ramp-up to 400 mg/d orally). Responses were investigator assessed per iwCLL 2008 criteria. Undetectable minimal residual disease (uMRD; <10⁻⁴) was assessed by 8-color flow cytometry. **Results:** 159 pts were enrolled, including pts with high-risk features of unmutated IGHV (uIGHV) (56%) or del(17p) and/or TP53 mutation (17%). Median time on study was 50 mo (range 1–53). At 4 y of follow-up, the best CR rate was 58% and ORR was unchanged at 96%. At 4 y, PFS rate was 79% (95% CI 71–84) and OS rate was 98% (95% CI 94–99). 4 y PFS rates were numerically lower in pts with uIGHV (73%) or del(17p) and/or TP53 mutation (63%), while OS rates remained consistently high (Table). 4 y PFS rates by MRD status 3 mo after stopping treatment (EOT+3) were significantly higher overall in pts with uMRD vs detectable MRD (dMRD) in PB (90% vs. 66%, Table); this difference was minimal at 24 mo (100% vs 91%). Median TTNT was not reached overall (range 1–53 mo); the 4 y rate of freedom from next treatment was 84% (95% CI 77–89). Second malignancies continue to be collected off treatment; 1 AE of prostate cancer occurred during this y of follow-up. To date, 19 pts with PD after completing fixed duration I+V in either the FD cohort or MRD cohort placebo arm initiated retreatment with I. Responses in 17 pts with available data were 1 CR, 13 PR, and 1 each PR with lymphocytosis, SD, and PD. Median time on retreatment was 11 mo (range 0–39). The most common AEs (≥10%) with retreatment were diarrhea (n=3), COVID-19 (n=3), and anemia (n=2). In addition, 4 pts have started I+V retreatment to date. **Conclusions:** Results of the CAPTIVATE study support I+V as an all-oral, once-daily fixed-duration regimen for previously untreated pts with CLL/SLL. With 4 y follow-up, fixed-duration I+V continues to provide deep, durable remissions with clinically meaningful PFS and time off treatment, including in pts with high-risk disease features. New safety findings off-treatment were expectedly negligible, highlighting the benefits of a fixed duration regimen. Promising responses were observed upon retreatment with I in progressing pts. Clinical trial information: NCT02910583. Research Sponsor: Pharmacyclics LLC, an AbbVie Company.

Real-world outcomes by race in patients (pts) with chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL): Final analysis results from the informCLL registry. *First Author: Jacqueline Claudia Barrientos, Mount Sinai Comprehensive Cancer Center, Miami Beach, FL*

Background: informCLL is a large, US-based, prospective, observational registry of pts with CLL/SLL initiating treatment (tx) in the era after approval of ibrutinib (Ibr). Here, we report real-world tx patterns and outcomes by race and line of therapy (LOT) from the final analysis of informCLL. **Methods:** Pts with CLL/SLL who initiated FDA-approved tx were enrolled between 10/2015 and 6/2019. Baseline characteristics, tx patterns, time to next tx (TTNT), OS, and safety are summarized by race (focus on Black and White pts) and LOT (first-line [1L] or relapsed/refractory [R/R], with focus on 1L). **Results:** Of 1459 eligible pts enrolled, 105 were Black (1L, n=58; R/R, n=47), 1323 were White (1L, n=779; R/R, n=544), and 31 were of other races (Asian [n=6], Native American [n=4], other/not reported [n=21]). Relative to White pts, 1L-treated Black pts were younger (median age 65 vs 70 y) and had worse performance status (ECOG status ≥1: 59% vs 50%), more advanced disease (Rai stage III-IV: 55% vs 46%), shorter time from diagnosis to 1L tx (median 7 vs 19 mo), and lower rates of del(17p) among tested pts (6% vs 13%). Across race, Ibr was the most common 1L tx (Black, n=29 [50%]; White, n=346 [44%]) followed by CIT (Black, n=25 [43%]; White, n=331 [42%]). With median follow-up of approximately 32 mo in 1L-treated pts, the estimated rate of freedom from next-line therapy at 36 mo was similar between Black and White pts across all-treated pts and among Ibr-treated subgroups (Table). Estimated 36-mo OS rates in all-treated pts were also similar by race, with a high OS rate observed among Ibr-treated Black pts (97% at 36 mo). In multivariate analyses (MVA) in 1L-treated pts, male gender, poorer ECOG status, and increased comorbidity burden were independent predictors of decreased OS while race was not associated with OS. In 1L Ibr-treated pts, the only factor associated with decreased OS in MVA was longer time from diagnosis to 1L tx. Rates of serious AEs and AEs leading to tx discontinuation appeared similar across race (Table). **Conclusions:** Although historical retrospective studies from the pre-novel agent era have shown poorer clinical outcomes among Black pts with CLL relative to non-Black pts, results from informCLL show similar or potentially improved outcomes, including OS, among 1L Ibr-treated Black pts relative to White pts. These results suggest that access to novel agents such as Ibr may in part overcome historical disparities in clinical outcomes by race in pts with CLL. Clinical trial information: NCT02582879. Research Sponsor: Pharmacyclics LLC, an AbbVie Company.

Real-world (RW) dosing patterns and outcomes among chronic lymphocytic leukemia (CLL) patients (pts) with or without an ibrutinib (IBR) dose adjustment (DA) in first-line (1L). *First Author: Kerry Anne Rogers, Division of Hematology, The Ohio State University, Columbus, OH*

Background: Pts treated for CLL with IBR, a once-daily Bruton's tyrosine kinase inhibitor with dosing flexibility options, may adjust their daily dose to help prevent recurrence or worsening of adverse events, while preserving efficacy. This RW study describes outcomes for CLL pts treated with 1L IBR who did or did not have a DA. **Methods:** Electronic medical records from the Acentrus database (1/1/2016-4/30/2022) were used to identify CLL pts initiated on 1L IBR (index date). The first 6 months post-index were used to identify pts who remained on a starting dose of 420mg/day or with a DA (reducing to a dose lower than 420mg/day; reasons for DA not available). Treatment adherence (measured by proportion of days covered [PDC] and medication possession ratio [MPR]) and time to next treatment (TTNT) were described for patients with and without a DA. Descriptive analyses are reported for all pts and among a subgroup of pts with high cardiovascular (CV) risk, defined as having a pre-existing CV comorbidity or a high CV risk score (CV subgroup). **Results:** 1,171 CLL patients were initiated on 1L IBR at the recommended dose of 420mg/day (Table). Of those, 1,038 (88.6%) remained on 420 mg for ≥ 6 months (mean age=70.2 years, 33.6% female, median follow-up: 30.5 months); 229 (19.6%) had a DA at any time post-index (median time to DA: 5.5 months) and 126 had the DA during the first 6 months (mean age=72.2 years, 42.9% female, median follow-up: 35.1 months). Mean PDC and MPR were descriptively higher in pts with a DA (overall: PDC=0.81, MPR=0.84; CV subgroup: PDC=0.78, MPR=0.81) relative to pts with no DA (overall: PDC=0.70, MPR=0.73; CV subgroup: PDC=0.69, MPR=0.72). Median TTNT was not reached for pts with or without a DA; 12-month Kaplan-Meier (KM) rates were similar for pts with a DA (overall: 89.1%; CV subgroup: 92.7%) and with no DA (overall: 92.5%; CV subgroup: 92.0%). **Conclusions:** Among CLL pts initiating 1L with standard-of-care IBR, 19.6% had a DA. Those with a DA had descriptively higher treatment adherence with no detriment to TTNT, relative to those who maintained 420mg/day starting dose, regardless of baseline CV risk. These findings are consistent with other RW studies and suggest that IBR DA can be an effective treatment strategy that does not negatively affect efficacy while being well-tolerated outside of clinical trials. Research Sponsor: Janssen Scientific Affairs, LLC.

	Overall N=1,171	CV subgroup N=724

A matching-adjusted indirect comparison (MAIC) of the efficacy and safety of acalabrutinib (acala) versus zanubrutinib (zanu) in relapsed or refractory chronic lymphocytic leukemia (RR CLL). *First Author: Adam Kittai, Division of Hematology, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: The BTKi ibrutinib is the standard of care in RR CLL and was compared in head-to-head randomized clinical trials (RCTs) with second-generation BTKi: acala in ELEVATE-RR and zanu in ALPINE. However, major differences in these RCT's populations prevents comparison of acala and zanu. Acala was also assessed in the ASCEND RCT, which had a similar population to ALPINE but a different comparator. Thus, we used unanchored MAIC to compare the efficacy and safety of acala vs zanu using individual patient data (IPD) from ASCEND and published aggregate data from ALPINE. **Methods:** In the unanchored MAIC, acala IPD from ASCEND were weighted to match zanu baseline data from ALPINE. This reduced between-study differences in variables that were prognostic/effect-modifying of progression-free survival (PFS) in an exploratory multivariate cox regression analysis of ASCEND. These included sex, ECOG PS, bulky disease, prior chemoimmunotherapy, del(11p), del(17p), TP53 without del(17p), IGHV status, region, age, prior lines of therapy and Rai stage. An efficacy analysis assessed investigator-assessed PFS (INV PFS) in randomized patients with baseline data (acala, n = 149; zanu, n = 327). Pseudo IPD for INV PFS for zanu were obtained from Kaplan-Meier curves. A safety analysis assessed odds ratios (ORs) of AEs in treated patients with baseline data (acala, n = 148; zanu, n = 324). To allow comparison of the incidence of AEs, an artificial data cut-off (Feb 21, 2020) was imposed for acala to match the zanu median treatment exposure (both 28.4 months). **Results:** After matching, the effective sample size of acala was 99 (66.6%; 65% male; median age 66 years). 12- and 24-month INV PFS are shown below. The MAIC hazard ratio (HR) for INV PFS is similar for acala vs zanu (HR 0.90, 95% CI 0.60–1.36). The risk of having grade ≥ 3 AE (OR 0.66, 95% CI 0.41–1.05), atrial fibrillation (AF; OR 1.32, 95% CI 0.56–3.08), grade ≥ 3 AF/atrial flutter (OR 0.60, 95% CI 0.12–2.89), grade ≥ 3 hemorrhage (OR 0.61, 95% CI 0.19–2.03) or an AE leading to discontinuation (OR 1.14, 95% CI 0.61–2.13) was similar with acala vs zanu. The risk of having a serious AE (OR 0.61, 95% CI 0.39–0.97), hypertension (any grade: OR 0.18, 95% CI 0.09–0.37; grade ≥ 3 : OR 0.22, 95% CI 0.09–0.54), any grade hemorrhage (OR 0.54, 95% CI 0.34–0.87) or an AE leading to dose reduction (OR 0.30, 95% CI 0.14–0.67) was lower with acala vs zanu. **Conclusions:** Acala and zanu have a similar efficacy in patients with RR CLL, while acala has a lower risk of grade ≥ 3 hemorrhage, any grade and grade ≥ 3 hypertension and dose reduction due to AEs vs zanu. Limitations of MAIC analyses mean the results should be viewed as hypothesis-generating. Research Sponsor: AstraZeneca.

Ibrutinib dose modifications for management of cardiac adverse events in patients with B-cell malignancies: Pooled analysis of 10 clinical trials. *First Author: Deborah Marie Stephens, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Continuous therapy with once-daily ibrutinib (Ibr) is associated with long-term PFS in pts with B-cell malignancies. Dose reduction is a potential AE management approach that may optimize treatment outcomes. We evaluated outcomes with dose reductions in Ibr-treated pts with cardiac AEs. **Methods:** Data were pooled for Ibr-treated pts from 10 studies of CLL (n=781), mantle cell lymphoma (MCL; n=250), marginal zone lymphoma (MZL; n=63) or Waldenström macroglobulinemia (WM; n=169). Cardiac AEs, initial and recurrent, were identified by preferred terms within the cardiac disorders system organ class. Recurrence was defined as an AE of same or worse grade, and was measured up to 30 days after last dose of ibrutinib or start of next-line therapy, whichever occurred earlier. **Results:** Overall, 234/1263 pts (19%) had cardiac AEs of any grade. Twelve pts were excluded from the analysis: 9 who had a dose reduction prior to a cardiac AE (0.7%) and 3 who had a fatal cardiac AE with no prior cardiac AE (0.2%). Of the remaining 222 pts with grade 1–4 cardiac AEs, 22 (10%) had Ibr dose reduction to 420 mg (n=3), 280 mg (n=10), or 140 mg (n=9) after a cardiac AE. These pts (n=22) tended to be older (≥ 75 y: 45% vs 29%), less heavily pretreated (≥ 1 prior therapy: 45% vs 73%), and with a lower Ibr discontinuation rate (23% vs 48%) than those without dose reduction (n=200). Recurrence of the same cardiac AEs at the same or worse severity was less frequent in pts with dose reductions, both overall (14% vs 18%) and as serious AEs (5% vs 10%). No pt died due to cardiac AE recurrence. Among pts with cardiac AEs who started with the 420 mg Ibr dose (177/222; excludes 45 patients with MCL or MZL who per label start with 560 mg dose), no cardiac AE recurred at same or worse severity in the subset with dose reductions (Table). PFS was not negatively impacted by dose reduction, both overall (n=22; median PFS not reached [NR], 24-mo PFS: 91%), and in those who started with the 420 mg dose (n=18; median PFS NR; 24-mo PFS, 94%). **Conclusions:** Dose reduction for cardiac AEs may enable pts to continue to benefit from long-term Ibr and mitigate the risk of cardiac AE recurrence or worsening. Clinical trial information: NCT01105247, NCT01236391, NCT01578707, NCT01722487, NCT01611090. Research Sponsor: Pharmacyclics LLC, an AbbVie Company.

Recurrence of cardiac AEs by dose reduction in patients with Ibr 420 mg starting dose.		
Pts with recurrence of same AE at same or worse grade, n/N (%)	With dose reductions (N=18)	Without dose reductions (N=159)
Any grade 1-4 cardiac AE	0/18 (0)	30/159 (19)
Cardiac arrhythmias	0/15 (0)	23/122 (19)
Cardiac failure	0/1 (0)	3/13 (23)
Other cardiac disorders	0/5 (0)	4/41 (10)
Any serious cardiac AE	0/18 (0)	17/159 (11)
Cardiac arrhythmias	0/15 (0)	11/122 (9)
Cardiac failure	0/1 (0)	3/13 (23)
Other cardiac disorders	0/5 (0)	3/41 (7)

Utility of pharmacogenomic testing in predicting intolerance to BTK inhibitors. *First Author: Fahmin Basher, Duke Cancer Institute, Durham, NC*

Background: Oral inhibitors of Bruton's tyrosine kinase (BTKi) are used for a number of B-cell malignancies, including chronic lymphocytic leukemia (CLL), mantle cell lymphoma (MCL), marginal zone lymphoma (MZL) and lymphoplasmacytic lymphoma (LPL). Real-world data has demonstrated that BTKi discontinuation is commonly due to intolerance, but contributing factors are not fully understood. Prior work suggests that cytochrome P450 (CYP) polymorphisms may increase the risk of targeted therapy discontinuation in CLL. We utilized pharmacogenomic (PGx) testing in Veterans treated with BTKi to evaluate the potential contribution of CYP polymorphisms to intolerance and responses to BTKi. **Methods:** We identified Veterans receiving care through the Veterans Administration (VA) who were prescribed a BTKi and underwent testing through the Pharmacogenomic Testing for Veterans (PHASER) program, currently offered at 22 VA facilities. We analyzed factors including time on BTKi therapy, reasons for discontinuation, and use of concomitant medications known to strongly inhibit CYP. Event-free survival (EFS) was defined as time from BTKi initiation to discontinuation. **Results:** Eighty-nine Veterans treated with BTKi who had PGx testing were identified, of which 97% (86) were male and 85% (76) were diagnosed with CLL. Other diagnoses included LPL (4), MCL (3), and MZL (3). Seventy-seven patients (pts) were treated with ibrutinib, nine with acalabrutinib and three with zanubrutinib. Three pts had poor metabolizer genotype (PMG) for CYP2C19 and 25 pts received strong CYP2C19 inhibitors (inh). Thirty-two pts had PMG for CYP2D6, and 12 pts received strong CYP2D6 inh. With a median follow up time of 38.9 months, 25 pts (28%) permanently discontinued due to intolerance and 10 pts (11%) progressed on BTKi therapy. Another 25 pts temporarily discontinued therapy. Median duration of BTKi therapy was 11.0 months for pts discontinuing for intolerance, 23.2 months for pts discontinuing for progression, and 38.5 months for pts not discontinuing therapy. Reasons for intolerance included arrhythmia, bleeding, and infections. EFS due to intolerance or progression was not statistically different between pts who were either CYP2C19 PMG or who received strong CYP2C19 inh, compared to all other pts. Interestingly, EFS due to intolerance alone was statistically different comparing these groups (p = 0.014, median 49.4m vs NR), but EFS due to progression was not (p = 0.76, median 79.6m vs NR). EFS was not significantly different comparing pts who were either receiving strong CYP2D6 inh or were PM to those who were not. **Conclusions:** We found that Veterans who were treated with BTKi and who either took concomitant strong CYP2C19 inh or had a CYP2C19 PMG were more likely to have intolerable side effects of BTKi therapy leading to discontinuation. Our results suggest that evaluating polypharmacy and PGx factors should be considered when prescribing BTKi. Research Sponsor: None.

Brentuximab vedotin + AVD for newly diagnosed classic Hodgkin lymphoma (cHL): Incidence and management of peripheral neuropathy in a multi-institution cohort. First Author: Jackson Bowers, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Background: Brentuximab vedotin (BV) in combination with doxorubicin, vinblastine, and dacarbazine (AVD) is the new standard of care for newly diagnosed stage III/IV cHL. In the pivotal ECHELON-1 trial, peripheral neuropathy (PN) was the most common toxicity, seen in 67% of patients (pts) and leading to discontinuation of BV in 6.6%. However, PN from BV+AVD in cHL has not been studied in a non-trial setting, where clinicians may have different strategies for managing it. **Methods:** We conducted a multi-site, retrospective study to characterize PN in pts who were planned to receive 6 cycles of BV+AVD for newly diagnosed cHL before 9/2022. Data was obtained from medical records and PN was graded retrospectively using CTCAE v5.0 criteria. Multivariable logistic regression was used to assess factors associated with PN. Progression-free survival (PFS) and overall survival (OS) were calculated using the Kaplan Meier method. A Cox proportional hazards model was used to test the effect of discontinuation on PFS. **Results:** 153 pts from 10 US institutions were eligible. Median age was 35 years (range 18-76) with 22% of pts over 60 years old. Thirty-four pts (22%) had at least 1 ineligibility criteria for ECHELON-1, including stage (8% stage I/II), performance status (3% ECOG 3+), preexisting PN (6%), or other comorbidities including HIV and other malignancies (10%). Of advanced stage pts, 41% had IPS 4-7. Median no. BV+AVD cycles was 6 (range 1-6). PN was reported by 80% of pts during treatment; 39% experienced grade (G) 1, 31% G2, and 10% G3. In total, BV was modified in 44% of pts due to PN leading to BV discontinuation in 23% with median no. of doses omitted of 4 (range 1-10), dose reduction in 17% and temporary dose hold in 4%. Vinblastine was modified in 17% of pts due to PN including discontinuation or temporary hold in 10% and dose-reduction in 7%; in 35% of pts with vinblastine modification, BV was continued. None of the factors assessed (age, sex, baseline PN, diabetes mellitus) predicted development of any grade PN. However, higher initial dose of BV in mg (based on weight) was associated with increased risk of grade 2+ PN (OR 1.03, 95% CI 1.01-1.05, $p = 0.002$). With median follow up of 24 months (range 0.33-87), PN resolution was documented in 36% and improvement in 33% at last follow up. Ongoing G2+ PN was present in 13% of pts at last follow up. 2-year PFS for the advanced stage patients was 82.7% (95% CI 0.76-0.90) and OS was 97.4% (95% CI 0.944-1). Discontinuation of BV due to neuropathy did not affect PFS (HR 1.1, 95% CI 0.45-2.5). **Conclusions:** In the non-trial setting, BV+AVD was associated with a high incidence of PN. In our cohort, which includes pts who would not have been eligible for the pivotal ECHELON-1 trial, BV discontinuation rates were higher than previously reported, but 2-year outcomes remain comparable; discontinuation of BV was not associated with inferior PFS. Identifying racial and ethnic disparities in patients diagnosed with mycosis fungoides/Sézary syndrome in the United States: A contemporary SEER analysis. First Author: Maria Elena Fierro, University of Texas Health Science Center at San Antonio, San Antonio, TX

Background: Mycosis fungoides (MF) and Sézary syndrome (SS) are rare cutaneous T-cell lymphomas. In this study, we compare demographics, treatment, and survival patterns in Hispanic (HI) vs. Non-Hispanic (NH) patients diagnosed with MF and SS. **Methods:** Data were analyzed on MF and SS patients in the US reported to SEER 18 database between 2000 and 2018. SEER 18 contains the most comprehensive population-based cancer information in the US, covering approximately 27% of the total US population, and up to 36% of HI. Racial groups analyzed included NH whites, HI whites, blacks, and Asians/Pacific Islanders. Patient characteristics, age-adjusted incidence rate, and survival rate were compared across ethnic groups, HI vs NH. Stratification by age, gender, and stage at diagnosis were considered. Kaplan-Meier and Cox regression analyses were used to compare overall survival (OS) between HI and NH. Multivariate analysis and propensity score matching were performed with adjustment for age, stage, and B-symptoms. **Results:** 8578 patients with MF and 275 patients with SS were identified. Of patients with MF, 11% were HI and 89% were NH; of patients with SS, 12% were HI and 88% were NH. In NH patients with MF, most patients were male (58%); for HI patients with MF, a male predominance was not observed ($p < 0.001$). In patients with SS, most patients were male in both NH and HI (56% NH, 56% HI; $p = 0.989$). In both MF and SS, HI were diagnosed at younger ages compared to NH, 49 y.o vs 60 y.o ($p < 0.001$) and 59 y.o vs 71 y.o ($p = 0.009$) respectively. Most HI and NH with MF and SS did not receive radiotherapy (91% of NH and 92% of HI for MF; 92% of NH and 91% of HI for SS; p values 0.166 and 0.760, respectively). On survival analysis, for patients with MF, the survival probability (SP) at 2, 5, and 10 years for HI vs NH were 94%, 87%, and 77% vs. 91%, 81%, and 69%, respectively. The survival difference observed favored HI ($p < 0.001$). For patients with SS, there was no statistically significant survival difference between HI and NH with 2, 5, and 10 year SP at 65%, 42%, and 17% for HI and 62%, 36%, and 16% for NH, respectively ($p = 0.99$). In patients with SS, the median survival time in years was 3.3 and 3.2 in NH and HI patients, respectively. In patients with MF, the median survival time was not reached. On multivariate analysis, when adjusted for age, those patients with MF and SS who were older than 80 y.o and between 60 to 80 y.o, had worse OS compared to those younger than 60 y.o, with HR 17.6 (95%: 13.8 – 22.3) and 4.2 (95% CI: 3.6 – 5) respectively for MF; and HR 1.8 (95% CI: 0.9 – 3.7) and 1.64 (CI 95% 1 – 2.8) respectively for SS. **Conclusions:** We identified ethnic differences in incidence, age at diagnosis, sex, and survival outcomes in patients with MF and SS. Notably, we identified a survival advantage in patients with MF that favored HI. In patients with SS, there was no ethnic difference in survival. Research Sponsor: None.

Depth of metabolic response at interim PET and survival outcomes among patients with primary refractory and early relapsing diffuse large B-cell lymphoma (DLBCL). First Author: Allison Marie Bock, Mayo Clinic, Rochester, MN

Background: Total metabolic tumor volume (TMTV) and maximum standardized uptake value (SUVmax) may improve upon standard 18F-fluorodeoxyglucose positron emission tomography/computed tomography (PET-CT)-based assessment of advanced DLBCL during treatment. We report the association of TMTV and SUVmax changes at interim PET-CT (PET2) on survival outcomes in patients with primary refractory DLBCL (prDLBCL) and early relapsing DLBCL (erDLBCL). **Methods:** Adult patients with prDLBCL (less than a complete response (CR) or progression by the end of treatment (EOT)) or erDLBCL (CR at EOT with relapse within 12 months) between 2005 and 2019 at Mayo Clinic Rochester were included. The % change (Δ) from baseline to PET2 (after 2 cycles of 1L therapy) of TMTV and SUVmax were measured. A PET segmentation threshold of 1.5 liver mean SUV + two standard deviations with a minimum volume constraint of 0.5 mL was utilized (MIM Software, Inc., Cleveland OH, USA) with manual input as needed. Functional splines analysis determined SUVmax and TMTV threshold for analysis. **Results:** 131 patients had complete PET-CT data (N=79 prDLBCL, N=52 erDLBCL). Baseline median TMTV and SUVmax were 767.4 cm³ (range 0.9-6840.4) and 20.5 (2.0-52.6), respectively. At a median follow up of 77.6 months, 81 patients had died. 2-year OS rate was 53% (95% CI: 42-67) for patients with a PET2 Δ SUVmax decline $\geq 65\%$ compared to 15% (95% CI: 7-29) for patients with a PET2 Δ SUVmax decline $< 65\%$ ($p < 0.001$). prDLBCL had a 2-year OS rate of 48% (95% CI: 31-74) for a Δ SUVmax $\geq 65\%$ compared to 7% (95% CI: 2-21) for a Δ SUVmax $< 65\%$ ($p < 0.001$), which captured 58% of prDLBCL patients (N=46). Two-year OS rate was 43% (95% CI: 34-54) for patients with a Δ TMTV $\geq 75\%$ compared to 5% (95% CI: 1-35) for patients with Δ TMTV $< 75\%$ ($p < 0.001$). All patients with a Δ TMTV $< 75\%$ had prDLBCL. prDLBCL had a 2-year OS rate of 28% (95% CI: 18-44) for a Δ TMTV $\geq 75\%$. The outcomes for Δ SUVmax $< 65\%$ and Δ TMTV $< 75\%$ at PET2 remained significant in a cox regression model adjusted for IPI and bulky disease (> 10 cm)(Table). **Conclusions:** A Δ TMTV decline $< 75\%$ or a Δ SUVmax decline $< 65\%$ at PET2 identified an ultra-high-risk subgroup of DLBCL with particularly poor outcomes, that captured a high percentage of prDLBCL patients, and was significant after adjusting for IPI and bulky baseline disease. These patients may benefit from clinical trials evaluating alternative PET-adapted treatment strategies, but further evaluation among all patients with DLBCL is needed. Research Sponsor: None.

Multivariate analysis of TMTV and SUVmax response at interim PET (PET2) on OS from time of relapse after 1L therapy, adjusted for baseline bulky disease and IPI.

PET2	Overall Survival (OS)		
	2-Year Rate	HR (95% CI)	P-Value
Δ SUVmax $\geq 65\%$	53%	(reference)	< 0.001
Δ SUVmax $< 65\%$	15%	3.58 (2.15-5.97)	
Δ TMTV $\geq 75\%$	43%	(reference)	< 0.001
Δ TMTV $< 75\%$	5%	2.97 (1.69 - 5.20)

Zanubrutinib plus obinutuzumab versus obinutuzumab in patients with relapsed/refractory follicular lymphoma: Updated analysis of the ROSE-WOOD study. First Author: Christopher Flowers, Department of Lymphoma/Myeloma, MD Anderson Cancer Center, Houston, TX

Background: In an early-phase study, the combination of zanubrutinib plus obinutuzumab (ZO) was well tolerated and associated with an early signal of efficacy in patients (pts) with follicular lymphoma (FL) (Tam et al. *Blood Adv* 2020). ROSE-WOOD (NCT03332017) is a phase 2, randomized study designed to assess efficacy and safety of ZO vs obinutuzumab (O) in pts with relapsed/refractory (R/R) FL. Here, we present an updated analysis with a median follow-up of 20.2 mo. **Methods:** Pts with R/R FL (grade 1–3a) who received ≥ 2 lines of therapy including an anti-CD20 antibody and alkylating agent were randomized 2:1 to receive ZO or O. Zanubrutinib was given at 160 mg twice daily until progression or unacceptable toxicity. The primary endpoint was overall response rate (ORR) by independent central review. Secondary endpoints included duration of response (DOR), progression-free survival (PFS), time to next treatment (TTNT), overall survival (OS), and safety. **Results:** A total of 217 pts were randomized (145 for ZO; 72 for O). Median age was 64 years. Of the 217 pts, 114 (52.5%) had a high Follicular Lymphoma International Prognostic Index (FLIPI) score at screening and 123 (56.7%) pts had high tumor burden criteria according to Groupe d'Etude des Lymphomes Folliculaires (GELF) criteria. Median number of prior lines of therapy was 3 (range, 2–11). A total of 114 (52.5%) pts were refractory to rituximab; 214 (98.6%) pts received prior immunochemotherapy. Prior exposure to anticancer drugs included anthracyclines (80.6%), cyclophosphamide (94.0%), and bendamustine (54.8%). ORR was 69.0% (ZO) vs 45.8% (O) ($P = 0.0012$). Complete response rate was 39.3% (ZO) vs 19.4% (O); 18-mo DOR rate was 69.3% (ZO) vs 41.9% (O); median PFS was 28.0 mo (ZO) vs 10.4 mo (O) (hazard ratio [HR], 0.50 [95% CI: 0.33, 0.75]; $P = 0.0007$). Median TTNT was not evaluable for ZO and 12.2 mo for O (HR, 0.34 [95% CI: 0.22, 0.52]; $P < 0.0001$). Estimated OS rate at 24 mo was 77.3% (ZO) and 71.4% (O), with median OS not reached in either arm. Nonhematologic treatment-emergent adverse events of any grade that occurred more frequently for ZO vs O ($> 5\%$ difference) were petechiae (6.3% vs 0%) and herpes zoster infection (6.3% vs 0%); in contrast, pyrexia (13.3% vs 19.7%) and infusion-related reaction (2.8% vs 9.9%) occurred more frequently in pts on O. When adjusted for duration of treatment exposure, incidences of infection and cytopenia were similar, and incidence of all grades of hemorrhage was 2.4 (ZO) vs 1.3 (O) persons per 100 person-months. Two pts in each treatment group reported major hemorrhage. Incidences of atrial fibrillation and hypertension were low and similar in both treatment arms. **Conclusions:** ZO demonstrated meaningful activity and a manageable safety profile in pts with heavily pretreated R/R FL, representing a potential novel therapy. Clinical trial information: NCT03332017. Research Sponsor: BeiGene.

Safety and efficacy of ABR in pts with TN or R/R MCL: Ph Ib trial. *First Author: Tycel Jovelle Phillips, University of Michigan Comprehensive Cancer Center, Ann Arbor, MI*

Background: Acalabrutinib (A) is a next-generation Bruton tyrosine kinase inhibitor approved for relapsed/refractory (R/R) mantle cell lymphoma (MCL). Bendamustine (B) + rituximab (R) is used for treatment-naïve (TN) and R/R MCL. We present updated data on safety and efficacy of ABR in patients (pts) with TN or R/R MCL. **Methods:** Eligible adults received ABR in this phase 1b study (NCT02717624) as follows: ABR for 6 28-d cycles, maintenance A+R for up to 2 y (TN cohort responders), then oral A continuously until progressive disease (PD) or treatment discontinuation due to toxicity (both cohorts). The primary endpoint was safety. Secondary endpoints were overall response rate (ORR), progression-free survival (PFS), and duration of response (DOR), all per Lugano. **Results:** Overall, 38 pts were enrolled (TN, n=18; R/R, n=20) with median age 66 y (range, 47–86). Baseline characteristics were (TN and R/R cohorts, respectively): stage IV disease in 88.9% and 95.0%, high-risk simplified MPI score in 11.1% and 15.0%, bulky disease >5 cm in 16.7% and 30.0% or ≥10 cm in 5.6% and 10.0%, and blastoid morphology in 5.6% and 15.0%; R/R pts had a median of 2 prior lines of therapy. As of the data cutoff date (6/15/22), 6 (33.3%) TN pts and 4 (20.0%) R/R pts were receiving A monotherapy (Table). Most common any-grade AEs were nausea (n=14, 77.8%; TN) and neutropenia (n=11, 55.0%; R/R). Grade 3–4 AEs occurred in 13 (72.2%) TN pts and 17 (85.0%) R/R pts, most commonly neutropenia in both cohorts (n=7, 38.9% [TN]; n=10, 50.0% [R/R]). Serious AEs occurred in 11 (61.1%) TN pts and 13 (65.0%) R/R pts. There were no reports of ventricular tachyarrhythmia. Grade 3 atrial fibrillation occurred in 1 pt outside the safety reporting period and was not related to study treatment. Grade ≥3 major hemorrhage was reported in 2 (11.1%) TN pts and 3 (15.0%) R/R pts. Grade ≥3 hypertension was reported in 3 (16.7%) TN pts and 2 (10.0%) R/R pts. Five TN pts died (AE: pneumonitis, n=1; unknown, n=4) and 6 R/R pts died (AE: COVID and cerebrospinal meningitis, n=2; PD, n=2; unknown, n=2). ORR was 94.4% (n=17) in the TN cohort and 85.0% (n=17) in the R/R cohort, with CR rates of 77.8% (n=14) and 70.0% (n=14), respectively. Median DOR was not estimable (NE) in the TN cohort and 43.5 mo in the R/R cohort. Median PFS and overall survival were NE in the TN cohort (median follow-up 47.6 mo) and 28.6 mo and NE, respectively, in the R/R cohort (median follow-up 20.4 mo). **Conclusions:** Triple-combination ABR was tolerable and effective in pts with TN or R/R MCL. Clinical trial information: NCT02717624. Research Sponsor: AstraZeneca.

Final three-year follow-up analysis of phase I/II study on tirabrutinib in patients with relapsed or refractory primary central nervous system lymphoma. *First Author: Katsunori Asai, Department of Neurosurgery, Osaka International Cancer Institute, Osaka, Japan*

Background: Primary central nervous system lymphoma (PCNSL) is known as an uncommon and extremely aggressive type of non-Hodgkin lymphoma of brain tumors. Tirabrutinib (TIR), a second-generation oral Bruton's tyrosine kinase inhibitor, was approved for the treatment of relapsed or refractory PCNSL (rPCNSL) based on the results of phase I/II study in Japan (Trial registration: JapicCTI-173646) in 2020. **Methods:** In this study, 44 Japanese patients with rPCNSL received TIR QD at doses of 320 mg (n = 20), 480 mg (n = 7), or 480 mg while fasting (480 mg fasted: n = 17). The International PCNSL Collaborative Group criteria were used to assess the primary endpoint, which was the overall response rate (ORR). We previously reported the interim results with 14.9 (range: 1.4–27.7) months of median follow-up in 2020 (Mishima et al., the 25th Society for Neuro-Oncology 2020). The final analysis results with a three-year follow-up are reported here (data cutoff: April 27th, 2022). **Results:** For the entire population, the ORR was 63.6% with 36.4% of complete response, the median duration of response was 9.2 months, the median progression-free survival was 2.9 months, and the median overall survival was not reached (median follow-up: 37.1 months). The most frequent adverse events (AEs) were skin and subcutaneous tissue disorders and blood and lymphatic system disorders at any grade, including rash (36.4%) and neutropenia (27.3%), leukopenia (25.0%), lymphopenia (18.2%), and thrombocytopenia (11.4%). Grade ≥3 AEs were neutropenia (9.1%), leukopenia (9.1%), lymphopenia (6.8%), and erythema multiforme (6.8%). One patient with 480 mg had grade 5 AEs (Pneumocystis jirovecii pneumonia and Interstitial lung disease), while neither new grade 5 AEs nor new safety profiles were observed since the last data cutoff. As of the current data cutoff, 15 and 6 of 44 patients had been receiving TIR for more than one and three years, respectively, and 5 of the 6 patients continued receiving TIR, including 4 patients who were receiving 480 mg fasted. **Conclusions:** In conclusion, TIR showed long-lasting effectiveness in a subset of patients with a tolerable safety profile of rPCNSL. Clinical trial information: JapicCTI-173646. Research Sponsor: ONO PHARMACEUTICAL CO., LTD.

Circulating tumor DNA (ctDNA) by clonoSEQ to monitor residual disease after axicabtagene ciloleucel (axi-cel) in large B-cell lymphoma (LBCL). *First Author: Brodie Miles, Kite, a Gilead Company, Santa Monica, CA*

Background: Most patients (pts) with LBCL respond to axi-cel, but many will eventually experience disease progression (Jacobson et al. JCO. 2020). Monitoring of ctDNA from blood, a minimally invasive diagnostic tool, has been used to assess measurable residual disease (MRD) with prognostic value, including in pts with diffuse LBCL treated with axi-cel in the third line of therapy (3L; Frank et al. JCO. 2019). Here, we explored the value of ctDNA to predict outcomes in LBCL after axi-cel across lines of treatment. **Methods:** Pts with LBCL from ZUMA-12 (Phase 2 axi-cel in 1L), ZUMA-7 (Phase 3 axi-cel or standard of care [SOC] in 2L), and ZUMA-14 (Phase 2 axi-cel + rituximab in 3L) were included. All studies included initial MRD testing ≈30 days post axi-cel infusion. ClonoSEQ MRD assay (limit of detection=0.0001%-0.00001%) was used to define the lymphoma B-cell clonotype in formalin-fixed, paraffin-embedded (FFPE) biopsy tissue prior to axi-cel infusion and to track ctDNA in blood after treatment. Positive predictive value (PPV; MRD+ pts who relapsed or were nonresponders/total MRD+ pts ×100) and negative predictive value (NPV; MRD- pts in ongoing response/total MRD- pts ×100) were assessed at Day 28, Month (Mo) 3, and Mo 5 for 3L; Days 50, 100, 150, Mo 9, and Mo 24 for 2L; and Day 28, Mo 3, and Mo 6 for 1L. **Results:** In 3L, the PPV at Day 28 was 88% (7/8) and NPV was 83% (10/12). NPV remained 83% at Mo 3 (10/12) and increased to 100% (8/8) at Mo 5. Overall, 83% (5/6) of relapsed pts had MRD detected at any time; of those 5, 100% (5/5) had MRD detected at any time prior to or at progression with a median detection of 43 days prior to progression. In 2L, the MRD+ detection rate among evaluable pre-infusion samples was only 69% (11/16). At Day 50, PPV was 100% (7/7) in the SOC arm, whereas it was only 57% (4/7) in the axi-cel arm. PPV increased over time in the axi-cel arm, reaching 100% by Mo 9 (2/2). At Day 50, NPV was 53% (8/15) in the axi-cel arm and 38% (5/13) in the SOC arm. Overall, 47% (9/19) of relapsed pts on the axi-cel arm had MRD detected at any time; of those 9, 78% (7/9) had MRD detected prior to or at progression with a median of 35 days prior to progression. In 1L, most pts (11/14) remained in ongoing response by data cut off. The PPV at Day 28 was 50% (1/2): of the two pts who had detectable MRD at Day 28, one subsequently became MRD negative at Mo 3 yet relapsed just after Mo 3, while the second became negative by Mo 3 and had ongoing response up to Mo 24. The NPV at Day 28 was 88% (7/8). **Conclusions:** The prognostic value of MRD assessment by clonoSEQ varied across lines of therapy in pts with LBCL treated with axi-cel. A relatively high rate of undetectable MRD at baseline in the 2L setting and prior to relapse in the 2L and 1L settings warrants exploration of more sensitive ctDNA monitoring methods. Clinical trial information: NCT03391466 NCT03761056 NCT04002401. Research Sponsor: Kite, a Gilead Company.

Glofitamab + Pola-R-CHP in patients with previously untreated diffuse large B-cell lymphoma (DLBCL): Results from a phase Ib study. *First Author: Michael Dickinson, The Peter MacCallum Cancer Centre, Royal Melbourne Hospital and The University of Melbourne, Melbourne, Vic, VIC, Australia*

Background: Polatuzumab vedotin plus rituximab, cyclophosphamide, doxorubicin and prednisone (Pola-R-CHP) has shown a significant progression-free survival benefit versus R-CHOP as first line (1L) therapy for DLBCL (Tilly et al. 2022). Glofitamab is a bispecific antibody with a novel 2:1 (CD20:CD3) format; bivalency for CD20 on B cells enables combination with anti-CD20 antibodies, including rituximab. Glofitamab monotherapy induced durable responses in patients (pts) with relapsed/refractory DLBCL and its incorporation in the 1L setting may further improve outcomes (Dickinson et al. 2022). We present results from the expansion stage of an ongoing Phase Ib study (NCT03467373) of glofitamab (Glofit) + Pola-R-CHP in pts with 1L DLBCL. **Methods:** Pts received Pola-R-CHP on Day (D) 1 of each 21-day cycle (C; max. 6 cycles) and glofitamab in C2–C6 (C2 step-up dosing [2.5mg CD28, 10mg CD215]; target dose [30mg] C3D8 and onwards). Response was assessed by PET-CT using Lugano criteria (Cheson et al. 2014). Efficacy-evaluable pts were those that reached end of treatment (EOT), progressed or died by data cut-off (EOT population). Cytokine release syndrome (CRS) events were graded by ASTCT criteria (Lee et al. 2019) and other adverse events (AEs) by CTCAE (v4.0). **Results:** As of Nov 14, 2022, 24 pts had enrolled and received study treatment (safety population). Median age was 65 years (range: 32–85), 96% of pts had stage III–IV disease and median IPI score was 3 (IPI 1: 4% [1/24], IPI 2: 33% [8/24], IPI 3: 38% [9/24], IPI 4: 25% [6/24]). Of 24 pts, 17 were efficacy evaluable. After a median follow up of 5.1 (range: 3–8) months, complete metabolic response rate was 76.5% (13/17) and overall response rate was 100% in the EOT population (best overall response). In safety-evaluable pts, Grade (Gr) ≥3 AEs occurred in 15 (63%) pts and Gr ≥3 AEs related to glofitamab in 9 (38%) pts. One Gr 5 AE was reported (acute respiratory distress syndrome, unrelated to study treatment). Serious AEs (SAEs) were reported in 12 (50%) pts and SAEs related to glofitamab in 4 (17%) pts. AEs leading to glofitamab dose interruption occurred in 5 (21%) pts; median dose intensity was 100% for all Glofit + Pola-R-CHP components. Only Gr 1 CRS (n = 3, 13%) was reported, with no treatment or hospitalization required. Neurological AEs (NAEs) occurred in 11 (46%) pts and were mostly Gr 1/2 (10 pts, 42%); one patient had a Gr 3 NAE (hypomania). No NAEs potentially consistent with immune effector cell-associated neurotoxicity syndrome were reported. Neutropenia was reported in 12 (50%) pts (Gr 3, n = 6; Gr 4, n = 6), febrile neutropenia in 2 (8.3%) pts and Gr 3/4 infection in 4 (17%) pts (Gr 3, n = 2; Gr 4, n = 2). **Conclusions:** Early data suggest that Glofit + Pola-R-CHP has promising efficacy and a similar safety profile to Pola-R-CHP and Glofit + R-CHOP for 1L DLBCL treatment. Glofit + Pola-R-CHP dose intensity was maintained in all pts. Updated data will be presented. Clinical trial information: NCT03467373. Research Sponsor: This study was sponsored by F. Hoffmann-La Roche Ltd. Glofitamab monotherapy in pts with relapsed/refractory (R/R) large B-cell lymphoma (LBCL): Extended follow-up and landmark analyses from a pivotal phase II study. *First Author: Lorenzo Falchi, Lymphoma Service, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Glofitamab is a CD3xCD20 bispecific antibody delivered in a fixed course of 12 three-weekly cycles. In a Phase II study (NCT03075696), glofitamab induced high complete response (CR) rates and had manageable toxicity in pts with R/R LBCL (Dickinson et al. 2022). We present an extended follow-up and a landmark analysis to assess the outcomes of pts in CR. **Methods:** Pts with LBCL and ≥ 2 prior therapies received 1000mg obinutuzumab pretreatment 7 days prior to the first glofitamab dose. IV glofitamab was given as step-up doses: 2.5mg on Day (D) 1 of Cycle (C) 1, 10mg on C1D8 and 30mg (target dose) on D1 of C2–12 (21-day cycles). The primary endpoint was independent review committee (IRC)-assessed CR rate. PFS and OS post-hoc analyses were performed in responders (landmark for CR at C3 or end of treatment [EOT]). **Results:** As of Oct 10, 2022, 154 pts had received ≥ 1 dose of study treatment; baseline characteristics were as previously presented. Median number of prior therapies was 3 (range: 2–7); 33% had received prior CAR T-cells and 85% were refractory to their most recent regimen. Median time on study was 20.1 months (range: 0–32). The investigator (INV)-assessed CR rate (BOR) was 38% (40% by IRC) and overall response rate was 59% (52% by IRC). CR rates were consistent in pts with and without prior CAR-Ts (37% vs 39%). After a median follow-up of 18.3 months (range: 0–30) in pts with a CR (BOR), most CRs (39/59; 66%) were ongoing. Median duration of CR (DoCR) was 24.1 months (95% CI: 19.8–NE); an estimated 70% of pts with a CR at any time remained in remission at 18 months. The 18-month OS rate was 41% (95% CI: 32.1–49.3). Landmark analyses at 1 year in pts with a CR pre-C3 (PFS rate: 71%, OS rate: 92%) and in pts with a CR at EOT (PFS rate: 80%, OS rate: 94%) showed that most pts were progression free and alive. In a cohort of 101 pts treated with glofitamab doses below the recommended Phase II dose but ≥ 10 mg with longer median CR follow-up (31 months, range: 1–49), the median DoCR was 30.1 months (95% CI: 5.5–NE) and 55% of pts were still in remission at data cut-off. This further confirms the highly durable responses achieved with glofitamab. CRS (by ASTCT) remained the most common adverse event (AE), occurring in 64% of pts, and was mostly Grade (Gr) 1 (48%) or Gr 2 (12%); Gr 3 (3%) and Gr 4 (1%) events were uncommon. The incidence of AEs and serious AEs was stable compared with earlier analyses, with one new Gr 3 AE (acute kidney injury), one new Gr 2 neurologic AE (agitation) and no new glofitamab-related Gr 5 AEs reported. **Conclusions:** Glofitamab continued to demonstrate durable responses, with most pts in CR at EOT still in remission without new AEs. These data support the potential for favorable long-term outcomes with fixed-duration glofitamab for R/R LBCL. Updated analyses, including a larger population with a median CR follow up of approximately 20 months post-EOT, will be presented. Clinical trial information: NCT03075696. Real-world outcomes with novel therapies in R/R DLBCL. *First Author: Jennifer Leigh Crombie, Dana-Farber Cancer Institute, Boston, MA*

Background: Outcomes have historically been poor for patients with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL). Despite an increase in approved R/R DLBCL treatment options, clinical outcomes of these therapies remain less certain. Novel treatments for R/R DLBCL patients include chimeric antigen receptor T-cell (CAR T) therapy, polatuzumab vedotin plus bendamustine and rituximab (pola-BR), tafasitamab plus lenalidomide (tafa-len), loncastuximab (lonca), and selinexor. The objective of this study was to examine real-world outcomes of these novel therapies. **Methods:** US patient data from the COTA electronic health records database (2010–2021) were used for this retrospective study. Patients had a diagnosis of DLBCL after 1/1/2010, with ≥ 1 prior line of systemic antineoplastic therapy (including an anti-CD20 antibody), and treatment with any of these novel therapies. Patients receiving variations of pola-BR or tafa-len regimens were included. Outcomes included overall response rate (ORR), complete response (CR) rate, median progression-free survival (mPFS), and median overall survival (mOS). Outcomes were also analyzed for those treated with any novel therapy following prior CAR T exposure. **Results:** A total of 175 R/R DLBCL patients were included (median age 63 y, 60.6% male, median of 2 prior therapies); 29.1% had an international prognostic index score ≥ 3 , 61.7% had stage III/IV disease, and 65.7% had primary refractory disease. A total of 73, 69, and 27 patients were treated with CAR T, pola-BR, and tafa-len regimens, respectively. Only 6 patients were treated with lonca and no patients received selinexor. Among 169 patients treated in the 2L+ setting with tafa-len, pola-BR, and CAR T, the CR rate was 11.1%, 18.8%, and 52.1%, respectively (Table). A total of 112 patients were treated in the 3L+ setting with CR rate of 10.0%, 13.5%, and 41.8%, for tafa-len, pola-BR, and CAR T, respectively. Outcomes in the 18% of patients treated with any novel agent following CAR T exposure were ORR of 19.1%, CR of 4.8%, and mPFS and mOS of 1.4 mo and 2.3 mo, respectively. **Conclusions:** Outcomes of pola-BR and tafa-len regimens in the 2L+ and 3L+ R/R DLBCL setting remain suboptimal, with worse outcomes as patients advance through lines of therapy. Outcomes are particularly poor when these agents are used following CAR T therapy. Research Sponsor: This study was funded by Genmab A/S and AbbVie.

A phase 1a/b study of BR101801, a PI3K γ and DNA PK triple inhibitor, in adult patients with advanced hematologic malignancies. *First Author: Bong-Seog Kim, Boryung Corporation., Seoul, South Korea*

Background: BR101801, a triple inhibitor of PI3K γ and DNA PK, inhibits not only the signal affecting cell growth caused by PI3K γ but also efficiently induces cell cycle arrest and apoptosis through inhibition of DNA-PK activation, and finally decreases the stability of oncogenic protein, c-Myc(AACR2020 abstract #655). We initiated a first-in-human study to investigate BR101801 across advanced hematologic malignancies that had relapsed or was refractory to the standard therapies. **Methods:** This is a phase 1, open-label, multi-center, dose escalation (1a), and expansion (1b) study of BR101801 in adult patients with advanced hematologic malignancies including relapsed/refractory (R/R) B-cell lymphoma, CLL/SL, and PTCL (NCT04018248). Dose was escalated at 50, 100, 200 and 325 mg QD. PTCL-NOS, AITL, FTCL and Nodal PTCL with TFH phenotype were included for dose expansion study at 200mg as RP2D. **Results:** 12 patients with advanced hematologic malignancies were enrolled in phase 1a study and treated with 50-325mg of BR101801. The median age was 63 years (range 30-76 years). Histological subtypes include AITL (n = 5, 41.7%), PTCL-NOS (n = 3, 25.0%), DLBCL (n = 2, 16.7%), MZL (n = 1, 8.3%) and MF (n = 1, 8.3%). Of 7 evaluable patients with PTCL (PTCL-NOS and AITL), ORR was 42.9% (95% CI, 9.9-81.6) and CBR was 85.7% (95% CI, 42.1-99.6). In median follow-up duration of 22.5 months, mPFS was 22.2 months (95% CI, 3.6-22.2) and mOS has not yet reached. Duration of response of the 3 responders were 9.2, 14.1+ and 20.7+ months, respectively. Safety was analyzed in 12 patients. 10 patients (83.3%) experienced ≥ 1 ADRs. The most common ($\geq 10\%$) ADRs were Rash (33.3%), ALT increased (33.3%), AST increased (25.0%), and Diarrhea (16.7%). Grade 3 ADRs occurred in 6 patients (50.0%) and those were ALT increased (25.0%), AST increased (16.7%), Rash (16.7%), erythema multiforme (8.3%), and neutropenia (8.3%). All ADRs were manageable and has recovered. There were no Grade 4 or 5 ADRs and no treatment related death observed. DLTs were occurred at 325mg; thus, 200mg QD was determined as the MTD and RP2D. The pharmacokinetics data showed an ideal profile in general. The PK results did not remarkably deviate from the non-clinical studies, and a more thorough interpretation will be performed in phase 1b. In phase 1b study, 7 PTCL patients were enrolled and it is ongoing till enrollment of total 12 patients. **Conclusions:** The results for the phase 1a study evaluated the safety, efficacy results and pharmacokinetic characteristics, 200 mg QD was shown to provide target exposure for clinical efficacy with the tolerable and safe profile. BR101801 showed of antitumor activity, especially in R/R PTCL patients. Hence, the phase 1b study of BR101801 is warranted in R/R PTCL patients and we expect BR101801 would become a promising therapeutic option for these patients. Clinical trial information: NCT04018248. Research Sponsor: Boryung.

Safety and efficacy profile of a very low dose of MC-1-50 for treatment of r/r NHL. *First Author: Shiqi Li, 920th Hospital of Joint Logistics Support Force of People's Liberation Army of China, Kunming, China*

Background: CD19 chimeric antigen receptor (CAR) T cell therapy has shown promising efficacy in the r/r B-NHL. However, many patients fail to respond, or quickly relapse after the initial response. To improve efficacy, we established a novel PrimeCAR platform (PRIMCAR) that shortens the manufacture time to about 2 days and enriches more stem cell-like memory T (T_{scm}) cells in the product. The MC-1-50 CAR-T cells produced by the PRIMCAR platform have exhibited a promising efficacy for B-ALL (Shiqi Li, et al. J Clin Oncol 2022; 40 [suppl 16]. Abstract 7008). Here, we report the preliminary safety and efficacy data of MC-1-50 for r/r B-NHL. **Methods:** In this Phase I/II study (NCT04271410), MC-1-50 CAR T cells were manufactured by the PRIMCAR platform. T cells were infected with a lentiviral vector encoding a humanized CD19 specific scFv following 4-1BB and CD3 ζ cytoplasmic domain. Patients (pts) received single-dose of MC-1-50 at dose ranged 0.5-5 $\times 10^5$ CAR+/kg (Level 1, 0.5 $\times 10^5$ CAR+/kg; Level 2, 3 $\times 10^5$ CAR+/kg; Level 3, 5 $\times 10^5$ CAR+/kg). Pts were pre-conditioned with fludarabine (25-30 mg/m²) and cyclophosphamide (200-300 mg/m²) daily for 3 days. Toxicity was graded by CTCAE, CRS and ICANS were graded by ASTCT criteria. Primary endpoints are the dose-limiting toxicities (DLTs) rate in the first 28 d and safety to determine a recommended Phase II dose (RP2D). **Results:** As of May 2022, thirteen pts with r/r B-NHL were infused with MC-1-50. Disease characteristics and outcomes are shown in the table. No DLTs were reported. 3 pts (23.08%) experienced CRS, including 2 (15.38%) at grade 1, and 1 (7.69%) at grade 2, no ≥ 3 CRS were observed, and no ICANS occurred. A preliminary dose-dependent response was observed. At dose Level 1 (DL1), none of the 3 patients showed a good response. At DL2, two patients showed PR response, and 3 of the 5 patients achieved CR response. At DL3, 5 of 5 patients achieved CR response. These patients with CR response did not experience a relapse during the followed-up (ranging from 5-18 months). CAR-T expansion was observed in all dose levels, although long-term persistence cannot be evaluated yet, 4 of 5 patients in DL2 and 3 of 5 patients in DL3 had detectable CAR expression by qPCR (≥ 50 copy/ug DNA) in the 6-month follow-up. **Conclusions:** The PRIMCAR platform could produce CAR T cells quickly with a high percentage of T_{scm} . Treatment of r/r B-NHL at very low dose resulted in excellent safety profiles while exhibiting a high and durable efficacy. Clinical trial information: NCT04271410. Research Sponsor: ChongQing Precision Biotech Co., Ltd.

Phase II trial of split-dose R-CHOP for older patients with diffuse large B-cell lymphoma (DLBCL). *First Author: Nirav Niranjan Shah, Medical College of Wisconsin, Milwaukee, WI*

Background: Management of elderly DLBCL is limited by age associated comorbid conditions and decreased tolerance of chemotherapy regimens. Many elderly or unfit/frail patients (pts) with DLBCL receive either non-anthracycline based treatment (bx) or attenuated regimens such as Rituximab (R)-miniCHOP which is ~50% dose reduction from standard R-CHOP-21. Split-dose (SD) R-CHOP is an alternative approach where pts receive CHOP at a 50% dose reduction on Days 1 and 15 of each 28-day cycle with full dose Rituximab on Day 1 for 6 cycles. The cumulative dose of SD R-CHOP delivered over each 28 day cycle is equivalent in dose intensity to one cycle of standard R-CHOP-21. **Methods:** This is a Phase II, prospective, open label study conducted through the Wisconsin Oncology Network and included two academic centers (NCT03943901). Older pts aged ≥75 years or 70-74 years plus elevated cumulative illness rating scale for geriatrics score with untreated de-novo or transformed Stage IIX-IV DLBCL were eligible. Treatment consisted of two months (4 doses) of SD R-CHOP with growth factor support followed by interim response assessment with PET/CT and peripheral blood cell-free clonoSEQ minimal residual testing (MRD). Pts with interim PET/CT score of Deauville 1-3 and MRD negativity were offered abbreviated therapy with two additional months of SD-R-CHOP. All others completed 6 cycles. The primary endpoint was end of tx (EOT) complete response (CR) rate. We utilized a Simon 2-stage design with interim analysis requiring at least 8 EOT CR in the first 16 pts (Stage I) to proceed to stage II. **Results:** To date, 14 pts have completed tx. The median age was 81 years (73-88) and 57% (n = 8) were male. Most pts had stage 4 disease (n = 8, 57%). 8 of 14 pts were interim PET/CT negative and 8 of 12 MRD evaluable pts were interim MRD negative. 10/14 (71%) pts achieved EOT CR exceeding our minimal threshold to continue the study early. The remaining 4 pts had progressive disease (PD) either during tx or at EOT evaluation. 6 pts were both interim MRD and PET negative; 5 de-escalated to the abbreviated arm with all achieving CR with no relapses to date. 7 pts (50%) had Grade 3+ non-hematologic toxicities and 4 pts (29%) had Grade 3-4 neutropenia. There were 2 deaths, one from COVID-19 with concurrent PD and the other from PD. Median PFS or OS have not been reached with a median follow-up of 13 months for surviving pts. **Conclusions:** SD-R-CHOP offers older pts with DLBCL equivalent dose intensity as R-CHOP-21 through a fractionated dosing schedule improving tolerability. Prespecified interim efficacy endpoint was met early with 10/14 pts with EOT CR. Interim stratification by MRD and PET/CT allowed de-escalation of tx in early responding pts without compromising efficacy. Clinical trial information: NCT03943901. Research Sponsor: Froedtert Foundation Grant; Adaptive Biotechnology.

Evaluation of outcomes between rituximab-abbs and reference product rituximab in adult patients with newly diagnosed diffuse large B-cell lymphoma in a non-inferiority study. *First Author: Vivian Nguyen, Kaiser Permanente, San Diego, CA*

Background: Rituximab in combination with cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) is the standard of care for diffuse large B-cell lymphoma (DLBCL). However, adding rituximab has increased treatment costs. Thus, development of biosimilars help provide more affordable care. Though rituximab-abbs was studied primarily in the follicular lymphoma population, in 2018 the FDA approved this drug as the first biosimilar for all indications of the reference product based on extrapolation. However, there are no clinical trials studying the effectiveness and safety of rituximab-abbs in DLBCL in the U.S. **Methods:** This is a data-only, non-inferiority study to compare two-year overall survival (OS) and the incidence of serious adverse events (AEs) between rituximab-abbs and its reference product (RP) as R-CHOP among adult patients with newly diagnosed DLBCL, with an index date from December 1, 2018-December 31, 2020. Non-inferiority will have a margin set to the upper limit of 5% for serious AEs, and a lower limit of 5% for OS. To assess for safety, we are following up on AEs until end of patient's Kaiser Permanente (KP) membership, death, six months after last rituximab dose, or December 2022 for all AEs except infusion reactions. For infusion reactions only, the follow up is 1 day. To assess for efficacy, we are following up on OS until end of patient's KP membership, death, December 2022, or two years. **Results:** 535 patients were enrolled; 240 patients received RP rituximab and 295 patients received rituximab-abbs. The median time of follow up was 730 days, or 2 years (range in days, 2.0-730). Complete response was similar in the RP rituximab group and the rituximab-abbs group (70.4% vs. 77.3% respectively, p = 0.07). Additionally, partial response was also similar among the two products (19.2% vs. 16.9%, p = 0.51). The Kaplan-Meier two-year survival curve was also similar between the two products (p = 0.52), demonstrating no difference. Further statistical analysis confirmed the non-inferiority of the biosimilar products for survival. Infusion reaction adverse events (13.8% vs. 11.2%, p = 0.37) and non-infusion adverse events (68.3% vs. 71.2%, p = 0.47) were also similar in the two groups, with a survival curve demonstrating no difference between the two products and data analysis meeting the non-inferiority criteria. **Conclusions:** Rituximab and rituximab-abbs are non-inferior to each other in both efficacy and safety. Long term follow up would be needed to confirm these results. Research Sponsor: None.

Six-year safety and efficacy results from the CHRONOS-1 study of the PI3K inhibitor copanlisib in patients with relapsed or refractory follicular lymphoma. *First Author: Martin H. Dreyling, LMU University Hospital, Munich, Germany*

Background: The efficacy of copanlisib, an intravenous pan-class I phosphatidylinositol 3-kinase (PI3K) inhibitor, was demonstrated in the Phase II CHRONOS-1 study in patients with relapsed or refractory indolent B-cell lymphoma (Dreyling et al. *J Clin Oncol* 2017). Copanlisib was approved by the US Food and Drug Administration in 2017 for the treatment of patients with follicular lymphoma (FL) who have received ≥2 therapies. Here, we describe updated efficacy and safety data from patients with FL at the 6-year follow-up of CHRONOS-1. **Methods:** CHRONOS-1 included patients with relapsed or refractory indolent FL (grades 1-3a) who had received ≥2 lines of therapy. Copanlisib 60 mg was administered via intravenous infusion on days 1, 8, and 15 of a 28-day cycle. Objective tumor response rate (ORR) was assessed by independent radiologic review (Cheson et al. *J Clin Oncol* 2007) as the primary efficacy endpoint. Safety analysis included adverse events graded using CTCAE v4.03. **Results:** 104 patients with FL were treated in CHRONOS-1, of whom 99.0% (n = 103) discontinued treatment at the time of database cut-off on June 30, 2022. 72% of patients (n = 75) received ≥1 line of subsequent systemic anti-cancer therapy during follow-up, with 40% receiving a rituximab-based regimen. At the cut-off, ORR (primary endpoint) was 57.7% (n = 60), with 19.2% (n = 20) of patients achieving a complete response. Median duration of response was 12.2 months (range 1.1-48.1). Median progression-free survival (PFS) was 11.2 months (range 0.2-51.5) with a median follow-up of 20.7 months (95% confidence interval [CI] 11.5, 31.5); PFS rate was 32% at 2 years. Median overall survival was 46.3 months (range 0.7-82.9) with a total of 56 events and a median follow-up of 82.4 months (95% CI 79.3, 84.9); survival rate was 43% at 6 years. Median duration of treatment was 6.0 months (range 0.23-80.9). No patients experienced transformation to aggressive lymphoma (diffuse large B-cell lymphoma). The primary reasons for stopping treatment included radiologic disease progression (42.3%; n = 44) and adverse events not associated with clinical disease progression (29.8%; n = 31). The safety profile was consistent with the reported 2-year follow-up data (Dreyling et al. *Am J Hematol* 2020). The most common treatment-emergent adverse events (all grades/grades 3-4) were infusion-related hyperglycemia (50.0%/39.5%), diarrhea (36.5%/8.7%), hypertension (28.8%/23.1%), pyrexia (27.9%/4.8%), and neutropenia (26.0%/23.0%). **Conclusions:** Copanlisib continued to induce robust response and durable survival in patients with relapsed or refractory indolent FL at 6 years of follow-up. Copanlisib was well tolerated, with no new safety signals and no evidence of malignant transformation. These results further support the long-term use of copanlisib in this patient population. Clinical trial information: NCT01660451. Research Sponsor: Funded by Bayer AG, medical writing support provided by Complete HealthVizion.

First interim analysis of a phase 1 study of zanubrutinib (zanu) plus lenalidomide (len) in patients (pts) with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL). *First Author: Huilai Zhang, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China*

Background: Effective therapies for R/R DLBCL are limited in China, especially for pts ineligible for high-dose therapy/stem cell transplantation (HDT/SCT). Preclinical data suggest synergy of len with zanu, a potent and selective Bruton tyrosine kinase inhibitor approved for various B-cell malignancies. Here, we present interim analysis results of an ongoing phase 1, open-label, dose-escalation/expansion study of zanu + len in R/R DLBCL (NCT04436107). **Methods:** Pts with R/R DLBCL ineligible for HDT/SCT with ≥1 prior line of adequate systemic therapy were enrolled. Dose escalation (part 1): Len 15 mg, 20 mg, or 25 mg orally once daily on days 1-21 of each 28-day cycle. Dose expansion (part 2): Len 25 mg. Zanu 160 mg was given orally twice daily continuously in parts 1 and 2. Primary endpoints were safety and recommended phase 2 dose (RP2D) of len (part 1) and overall response rate (ORR) by investigator based on Lugano classification (part 2). Interim analysis was performed when the 19th pt in part 2 completed first tumor assessment. Pts who received len 25 mg (RP2D) in parts 1 and 2 were analyzed separately. **Results:** As of November 8, 2022, 46 pts were treated and included in interim analysis (27 in part 1; 19 in part 2; 30 at RP2D). Median age was 60 years (range, 29-82), 83% had stage III-IV disease, 37% had refractory disease, 70% had non-germinal center B-cell (non-GCB) like disease; median number of prior systemic therapies was 1 (range, 1-5). Median exposure to zanu and len was 3.9 months (mo) (range 0.4-24.9), median follow-up was 6.6 mo (range 0.5-25.5). ORR was 46% overall (95% CI: 30.9-61.0; complete response [CR]: 24%) and 57% at RP2D (95% CI: 37.4-74.5; CR: 30%). At RP2D, ORR was 61% (95% CI: 38.5-80.3; CR: 35%) for pts with non-GCB disease and 50.0% (95% CI: 11.8-88.2; CR: 17%) for GCB. At RP2D, median duration of response was not reached and 6-mo event-free rate was 59% (95% CI: 23.8-82.8). Median progression-free survival was 5.5 mo (95% CI: 2.8-not estimable) with a 9-mo event-free rate of 37% (95% CI: 17.6-57.4). Overall, 46 (100%) pts experienced ≥1 treatment-emergent adverse event (TEAE). At RP2D, grade ≥3 TEAEs occurred in 60% of pts, most commonly neutrophil count decreased (43%), white blood cell count decreased (23%), and pneumonia (13%). One pt (2%) had febrile neutropenia (grade 3) but recovered within 2 days. TEAEs led to discontinuation of both len and zanu in 2 pts (cardiopulmonary failure unrelated to treatment [part 1, len 20 mg], pulmonary embolism [part 1, len 25 mg]) and discontinuation of len in 2 pts (platelet count decreased [part 1, len 20 mg], rash [part 2]). Two TEAEs leading to death were reported, unrelated to treatment. **Conclusions:** Zanu 160 mg plus len 25 mg combination showed an acceptable safety profile with promising efficacy. Further evaluation of the combination in a larger sample size is planned in future analysis. Clinical trial information: NCT04436107. Research Sponsor: BeiGene.

Poster Session

A phase 1 study evaluating the safety, tolerability, pharmacokinetics, and preliminary antitumor activity of Bcl-2 inhibitor BGB-11417 in adult patients with mature B-cell malignancies. *First Author: Caixia Li, The First Affiliated Hospital of Soochow University, Suzhou, China*

Background: BGB-11417 is a potent and highly selective Bcl-2 inhibitor. Phase 1 study results showing high activity and good tolerability in patients (pts) with mature B-cell malignancies were previously reported (Abstract 2989, ASH 2022). We present here results of BGB-11417 monotherapy in B-cell malignancies with a longer follow up. **Methods:** BGB-11417-102 (NCT04883957) is an ongoing, multicenter, phase 1, open-label, dose-finding study in China. Primary objectives: safety, maximum tolerated dose (MTD), and recommended phase 2 dose (RP2D) of BGB-11417 monotherapy for selected cohorts. Pts with relapsed/refractory (R/R) B-cell malignancies received escalating doses (80, 160, 320, or 640 mg once daily) with weekly or daily ramp-up to intended target dose. Dose-limiting toxicity (DLT) for each cohort was evaluated during ramp-up through day 21 at the intended dose. AEs were reported per CTCAE v5.0 (or Grading Scale for Hematologic Toxicity in chronic lymphocytic leukemia [CLL] Studies). **Results:** As of 1 Oct 2022, 54 pts (34 R/R non-Hodgkin lymphoma [NHL; 20 diffuse large B-cell lymphoma, 7 follicular lymphoma, 4 marginal zone lymphoma, 3 transformed NHL], and 20 R/R CLL/small lymphocytic lymphoma [SLL]) received $\leq$ 640 mg/d. 640mg was the highest dose pre-defined in the study and MTD was not reached. Median (range) values: age, 61 y (31-84); prior lines of systemic therapy, 2 (1-7); follow-up duration, 6.6 m (0.2-13.0). Study discontinuation: 23 pts (22 NHL; 1 CLL/SLL); reasons: 18 progressive disease, 4 withdrew, 1 investigator decision. Tx-emergent AEs (TEAEs): all grades, 92.6%; grade $\geq$ 3, 53.7%. Most common TEAE: all grades, white blood cell count decreased (48.1%); grade $\geq$ 3, neutropenia (25.9%). DLTs occurred in 3 patients at 80 mg/d or 160 mg/d; 14.8% had serious TEAEs and 14.8% had TEAEs leading to drug interruption. No pts had TEAEs leading to death/tx discontinuation or clinical tumor-lysis syndrome events. Of 39 pts available for tumor assessment (27 NHL; 12 CLL/SLL), 5 with NHL and 9 with CLL/SLL achieved responses (NHL: 3 partial responses [PR] at 160 mg/d, 1 PR at 320 mg/d, 1 complete response [CR] at 640 mg/d; CLL/SLL: 2 CR and 2 PR at 80 mg/d, 3 PR at 160 mg/d, 2 PR at 320 mg/d). Nine pts with R/R CLL/SLL (5 at 80mg/d, 4 at 160 mg/d) had minimum residual disease (MRD) assessment; 3 had undetectable MRD with CLL cell/total nucleated cells $< 10^{-4}$ (uMRD4; 1 pt achieved blood and bone marrow aspirate uMRD4 after 4.5 months at 80 mg/d; 2 pts had blood uMRD4 after 7.1 months at 160 mg/d). The monotherapy RP2D for R/R CLL/SLL was 320 mg/d. **Conclusions:** These results demonstrated that BGB-11417 monotherapy was well tolerated at all tested doses up to 640 mg/d, with no dose-dependent toxicity increase. BGB-11417 monotherapy showed promising initial efficacy results in R/R CLL/SLL, with pts achieving responses at lower dose levels. Clinical trial information: NCT04883957. Research Sponsor: BeiGene.

Long-term efficacy and safety of pembrolizumab with R-CHOP as first-line therapy for DLBCL. *First Author: Carrie Ho, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) represents the historical 1st line treatment standard for DLBCL but fails to cure about 1/3 of patients. While generally ineffective in relapsed DLBCL-NOS, checkpoint inhibitors may have greater promise in untreated, immunocompetent patients. We previously reported safety and early efficacy of pembrolizumab plus RCHOP, noting objective responses in 90% of patients (CR 77%) and a 2-year progression-free survival (PFS) of 83%. We now report 5 year follow up of our study. **Methods:** Patients age > 18 with untreated DLBCL or grade 3b follicular lymphoma, intended to receive 6 cycles of R-CHOP, were eligible. Pembrolizumab 200 mg IV with R-CHOP was given in 21-day cycles for 6 cycles. For this updated analysis, progression and survival events, and immune-related toxicities, are reported. Additionally, prognostic factors including tumor PD-L1 expression (Qualtek/Merck) were re-analyzed. **Results:** 30 patients were treated (13/30 with IPI 3-5). Median follow up is now 4.8 years (95% CI, 4.5-5.4). Since our initial report (Smith BJH 2019) we have observed 1 additional relapse (alive after CAR-T therapy) and 2 deaths in remission (1 urothelial carcinoma, 1 respiratory failure in the setting of progressive ILD). 5-year PFS is 71% (CI, 54-94%) and 5-year overall survival 83% (CI, 71-98%). During the study period and at long term follow up, there were 8 total immune-related adverse events (IRAEs) among 7 patients (23%) (Table). Four were treatment-emergent AE (occurred within 90 days of completing treatment): grade 1 hyperthyroidism, grade 2 hyperthyroidism, grade 3 pneumonitis, and grade 3 rash. There were 4 late IRAEs: colitis, paraneoplastic pemphigus, rheumatoid arthritis, and Graves' disease, occurring at 3, 5, 8, and 46 months after completing treatment, respectively. PD-L1 tumor expression was documented in 19 of 23 (83%) tested patients. At long-term follow up, none of the 19 patients who had any PD-L1 expression have relapsed. Two out of the 4 patients with no PD-L1 expression have relapsed. On univariate analysis, PD-L1 H-score > 0 ($p < 0.0001$) was associated with improved PFS. **Conclusions:** At 5 year follow-up, pembrolizumab plus R-CHOP has led to durable responses in most patients with the best outcomes in PDL1-expressing disease. Furthermore, the safety profile was manageable, with a low rate of grade 3 or higher IRAEs (10%) and no consistent pattern of late events. These data support ongoing strategies incorporating PD-1/PDL-1 inhibitors in 1st line DLBCL therapy and confirmation of predictive biomarkers including tumor PD-L1 expression. Clinical trial information: NCT02541565. Research Sponsor: Merck; U.S. National Institutes of Health.

Updated clinical results of first-in-human study of CD19/BCMA dual-targeting fast CAR-T GC012F for patients with relapsed/refractory B-cell non-Hodgkin's lymphoma. *First Author: Xinfeng Chen, Biotherapy Center, the First Affiliated Hospital of Zhengzhou University, Zhengzhou, China*

Background: CD19-directed CAR-T cell therapy has been demonstrated to be a valuable treatment option for relapsed/refractory B-cell non-Hodgkin's lymphoma (r/r B-NHL). It has been shown that 39% to 97% of clinical samples of B-NHL also express BCMA. To further improve safety and efficacy, we have developed a CD19 and BCMA dual-targeting CAR-T, GC012F, manufactured on the novel next-day Fast CAR-T process, for the treatment of r/r B-NHL. The initial 3-patient data of an investigator-initiated trial (ChiCTR2100047061) was reported at EHA 2022 (#2938). Here, we present updated results of this ongoing IIT trial. **Methods:** From October 2021 to January 2023, nine eligible r/r DLBCL pts were enrolled and treated with a single infusion of GC012F in escalating dosing cohorts after a standard lymphodepletion regimen. The primary objectives of this study were safety and tolerability; the secondary were pharmacokinetics and efficacy. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded by ASBMT 2019, adverse effects were evaluated according to CTCAE 5.0. Efficacy assessment of GC012F was referred to the Lugano criteria. Expansion of CAR-T cells and CAR copy numbers were measured by flow cytometry and qPCR, respectively. **Results:** As of data cut-off of January 16th, 2023, with a median of 207 days (range 94-460) of follow-up, all nine pts received single GC012F infusions at dose levels from 3.7×10^4 to 3×10^5 CAR-T/kg, and completed at least 3 months of follow-up. All pt lymphoma samples expressed CD19, and 6 out of 7 expressed BCMA. The median SPD was 2690.81 mm² (408.3-13325.96). Pts received a median of 2 prior lines (range 2-3) of therapy including rituximab and anthracyclines. Two pts received prior auto-HSCT. The ORR in nine pts was 100% (9/9) at month 3, CR rate was 77.8% (7/9) at month 3 and 71.4% (5/7) at month 6, respectively. To date, the longest duration of remission was 14.4 months. No dose-limiting toxicities were observed. One pt had grade 3 CRS over 2 days. No ICANS were observed. Of the 9 treated pts, $\geq$ grade 3 TEAEs were neutropenia (7/9), leukopenia (5/9) and thrombocytopenia (3/9). All TEAEs were resolved after treatment with standard of care and supportive care. The median peak copy number of CAR-T cells in peripheral blood was 71,000 copies/ μ g DNA (range 9263 -185,039), and the median peak time was 14 days (range 9 - 21). CAR-T cells were also detected in tumor biopsies from all five pts tested. **Conclusions:** This first-in-human trial of GC012F for the treatment of r/r B-NHL showed a manageable safety profile and promising clinical responses. The ORR was 100% at M3 with 77.8% (7/9) achieving CR. GC012F CAR-T cells were detectable in the tumor biopsies, indicating the infiltration of CAR-T cells into the tumor lesions. Study with larger cohort and longer follow-up is ongoing. Clinical trial information: ChiCTR2100047061. Research Sponsor: Gracell Biotechnology (Shanghai) Co., LTD.

A multi-institutional prospective cohort study of minimal residual disease in peripheral T-cell lymphoma: Impact of autologous stem cell transplant. *First Author: Nicole C. Foley, Washington University School of Medicine, St. Louis, MO*

Background: Roughly 80% of pts with peripheral T-cell lymphomas (PTCL) respond to CHOP-based therapy but 5-yr survival ranges between 20-40%. The high relapse rate after complete response (CR) suggests more sensitive response assessment, such as minimal residual disease (MRD) testing, could have prognostic or predictive value. Next generation sequencing (NGS) of the T-cell receptor (TCR) can detect a known TCR clonotype at 10^{-5} . In a prospective study, we evaluated the utility of MRD testing via TCR NGS in PTCL (NCT03297697). Here we report results for pts pre- and post-autologous stem cell transplant (ASCT). **Methods:** This investigator-initiated, multi-institutional, prospective cohort study assessed MRD testing by TCR NGS in PTCL. Pts with previously untreated PTCL not otherwise specified (NOS), angioimmunoblastic T-cell lymphoma (AITL), anaplastic large cell lymphoma (ALCL), PTCL with T-follicular helper (TFH) phenotype, or monomorphic epitheliotropic intestinal T-cell lymphoma (MEITL) treated with anthracycline-based curative-intent therapy were eligible. Baseline TCR (TRG or TRB) clonotypes were established from diagnostic tissue or peripheral blood if tissue was not available. TCR clonality was determined positive via the LymphoTrack TRG/TRB Assays – MiSeq (Invivoscribe, San Diego, CA) when top % reads were $\geq 2.5\%$ and $\geq 2\times$ above background. Samples were obtained at diagnosis (pre-treatment), following induction therapy (EOT/pre-ASCT), and serially post-ASCT. **Results:** Of 43 enrolled pts, 19 underwent consolidative ASCT, of which 10 had post-ASCT samples available for MRD testing (Table). Median age at ASCT was 62 years (range: 38-77). Baseline TCR clonotypes were identified in 10/10 pts. At pre-ASCT evaluation, 7/10 pts had detectable TCR MRD ('pos') and 3/10 pts had TCR MRD below the level of detection ('neg'). Of the 3 MRD neg pts pre-ASCT, 2 had CR and 1 had PR by PET-CT. All 7 TCR MRD pos pts pre-ASCT had CR by PET-CT. Of 7 MRD pos pts pre-ASCT, 6 remained MRD pos and 1 became MRD neg post-ASCT. Of the 4 MRD neg pts post-ASCT, none have relapsed at 52, 31, 34, and 31 mo post-ASCT. Of 7 MRD pos pts pre-ASCT, 3 have relapsed following ASCT (at 3, 9, and 29 mo post-ASCT). **Conclusions:** In this cohort of patients with PTCL receiving consolidative ASCT in CR1, all 4 pts with negative TCR MRD post-ASCT remain in remission at median follow up of 32.5 mo post-ASCT. The negative predictive value of TCR NGS MRD post-ASCT should be further evaluated. Clinical trial information: NCT03297697. Research Sponsor: Lymphoma Research Foundation; T-cell Leukemia/Lymphoma Society.

Treatments and outcomes of patients with localized extranodal NK/T-cell lymphoma (ENKL) diagnosed between 2014 and 2021: A cooperative study in Japan. *First Author: Kana Miyazaki, Mie University Graduate School of Medicine, Tsu, Japan*

Background: A previous cooperative study of patients (pts) with ENKL who were diagnosed between 2000 and 2013 in 31 institutes in Japan reported that the most common first-line treatment for localized ENKL was radiotherapy with dexamethasone, etoposide, ifosfamide, and carboplatin (RT-DeVIC) (66%). The 2-year (yr) overall survival (OS) and progression-free survival (PFS) of pts with localized ENKL were 78% and 68%, respectively (JCO 2017). RT-DeVIC has been included as a preferred regimen of combined modality therapy in the NCCN guidelines. The treatments and outcomes of pts with localized ENKL in recent clinical practice are unknown. **Methods:** We conducted a cooperative study (NKEA-Next; UMIN000046300) by hemato-oncologists and radiation oncologists of pts with ENKL who were diagnosed between 2014 and 2021 in 45 institutes in Japan. The results were compared with those from the 2000-2013 cohort (JCO 2017). The primary endpoint was OS of pts with ENKL who received next-generation treatment in 2014-2021 at participating institutes. We analyzed the data of localized ENKL. **Results:** Of 351 pts in the 2014-2021 cohort, 235 (67%) had localized ENKL. First-line therapy was RT-DeVIC in 185 (79%) pts, sequential chemoradiotherapy in 17, RT alone in 15 pts, and chemotherapy alone in 12 pts. Six pts received no treatment due to poor performance status (PS). Only two pts (1%) received anthracycline-containing regimens. With a median follow-up of 3.4 yrs, the 2-yr OS and PFS of localized ENKL were 83% and 75%, respectively. Pts treated with RT-DeVIC showed the following clinical features: median age, 58 yrs (range, 13-82); age > 60 yrs, 45%; stage IIE, 34%; B symptoms present, 27%; elevated serum lactate dehydrogenase, 23%; ECOG PS 2, 4%; and soluble interleukin-2 receptor (sIL-2R) level > upper limit of normal (ULN), 31% (57/183). The complete response rate was 88% among the 179 pts who were evaluated for response. The 2-yr OS and PFS of RT-DeVIC were 87% and 79%, respectively. There was no treatment-related death due to RT-DeVIC. G3/4 mucositis was recorded in 32% (G3, n = 59; G4, n = 0). G3/4 febrile neutropenia occurred in 18% (G3, n = 32; G4, n = 2). sIL-2R > ULN was associated with worse OS ($P < 0.01$). In comparison with pts with localized disease in the 2000-2013 cohort, pts in the 2014-2021 cohort received RT-DeVIC more frequently ($P < .001$). There was no significant difference in OS ($P = 0.24$) or PFS ($P = 0.10$) between the two cohorts. **Conclusions:** RT-DeVIC was more frequently used for first-line treatment of localized ENKL, and its efficacy has been maintained, with 87% 2-yr OS in recent clinical practice in Japan, providing further evidence of RT-DeVIC as a preferred first-line regimen for localized ENKL. No obvious improvement in OS and a reduction in G3 mucositis were observed, suggesting that more efficacious and less toxic regimens need to be introduced.
