P1.09-03 CHALLENGES IN PD-L1 IMMUNOEXPRESSSION IN LIQUID BASED CYTOLOGY SAMPLES OF ADVANCED STAGE NON-SMALL CELL LUNG CARCINOMAS

D. Jain1, S. K1, A. Mohan2, V. Iyer3

1Pathology, All India Institute of Medical Sciences, New Delhi/IN; 2Pulmonary Medicine & Sleep Disorders, All India Institute of Medical Sciences, New Delhi/IN

Background: Study of programmed death-ligand 1 (PD-L1) expression is essential in patients of advanced lung cancer to determine their eligibility and predict responsiveness for immune-checkpoint inhibitors. Lung cancer is frequently diagnosed on cytology specimens. Although PD-L1 IHC assays are validated on formalin fixed paraffin embedded (FFPE) tissue, evidences are present in literature which showed high concordance of cytology samples with paired biopsies. However, liquid based cytology (LBC) processed specimens have not been tested for PD-L1 expression. Method: Immunohistochemistry using the anti-PD-L1 clone SP263 was performed on BD SurePath LBC processed bronchial brushing and washing smears and paired FFPE endobronchial biopsy specimens. The percentage of viable tumor cells was considered adequate for PD-L1 testing. Staining was interpreted positive if membranous and/or cytoplasmic protein expression at any intensity greater than background staining was detected in at least 25% of tumor cells. Result: There were 26 patients with 13 adenocarcinomas and 13 squamous cell carcinomas which were diagnosed by bronchial brushings, washings and concurrently examined for PD-L1 expression. PD-L1 staining was interpreted positive if membranous and/or cytoplasmic protein expression at any intensity greater than background staining was detected in at least 25% of tumor cells. Conclusion: Tumor cells should be interpreted only on higher magnification to better differentiate them from alveolar macrophages. For PD-L1 staining in macrophages, this result should be interpreted very strong cytoplasmic positivity in macrophages. Since tumor cells showed cytoplasmic and membranous positivity it was easy to differentiate tumor cell positivity from macrophage positivity. Necrotic background in one case stained strongly with PD-L1 and immunocytochemistry performed on FFPE material. No staining was observed in control. The positivity of PD-L1 staining in macrophages followed the same pattern as PD-L1 staining. PD-L1 staining was performed on TC as the percentage of PD-L1 positive cells (0 to 100%). PD-L1 expression on TC was determined as follows: IC0: positive IC representing <1% of the tumor; IC1: positive IC representing >1% but<5% of the tumor; IC2: positive IC representing >5% but<10% of the tumor; and IC3: positive IC representing >10% of the tumor. Result: Eighty-six pts were initially included in the study. Twenty-eight (32%) of them were excluded from analysis due to insufficient data. Among the 58 remaining pts with confirmed LCNEC, five (8%) had a mixed histology with a NSCLC component. The mean age of the population was 65 years, mainly mens (86%) and former or current heavy smokers (93%). Fifty-five and five pts with tumors samples were retrospectively available for TC and IC PD-L1 IHC expression. PD-L1 expression on TC was found in only 12% of the samples (7/55), while 76% (39/51) of the samples shows IC PD-L1 positive, with respectively 18 (35%) IC3, 8 (14%) IC2, and 13 (25%) IC1. Conclusion: Histopathological diagnosis of LCNEC remains difficult and prospective studies concerning patients with LCNEC should include a centrally pathological review of tumors. The PD-L1 expression pattern looks different for LCNEC in comparison to other lung carcinomas, as few TC were found positive although IC were frequently positive, half of the tumors having high PD-L1 IC infiltration (IC3/2). This PD-L1 pattern may suggest a potential effectiveness of therapeutic anti PD-L1 antibodies and this hypothesis have to be addressed in clinical trials.

P1.09-04 OPTIMIZATION OF PD-L1 TESTING SPECIMEN FLOW IN THE GREATER HAMILTON, ONTARIO REGION
R. Juergens1, M. Butcher2, A. Naqvi3, J. Cutz2, M. Bonert3
1Oncology and Pathology, McMaster University, Hamilton/ON/CA, 2Oncology, McMaster University, Hamilton/ON/CA, 3Pathology and Molecular Medicine, McMaster University, Hamilton/ON/CA

Background: Immunotherapy targeted at the programmed cell death 1 (PD-1) receptor and its ligand (PD-L1) is a new treatment option for non-small-cell lung cancer (NSCLC). Immunohistochemistry (IHC) for the PD-L1 protein has been shown to predict response. The 22C3 IHC assay is the only clinically validated PD-L1 test. We present the Hamilton, Ontario, Canada experience of local PD-L1 analysis using the 22C3 assay including both histology and cytology specimens. Method: All data for requests for PD-L1 testing from within Hamilton were collected for one year. Unstained slides were cut for IHC analysis. Both histology and formalin fixed cytology specimens were accepted. Slides were sent for PD-L1 staining centrally at Dynacare in Bowmanville, Ontario, Canada. IHC interpretation was done in Hamilton. The assay was positive if ≥50% of tumour cells (TCs) had any intensity staining. The assay was negative if no TCs had staining. The assay was interpreted as low positive if 1-49% TCs had any intensity staining. Samples with less than 100 cells were considered inadequate. Turn around-time was defined as the accession date to PD-L1 sign out date. Result: 401 samples were evaluated; 108 cytology(C) and 293 histology(H). 36% of samples tested positive (43%:C;33%:H); 20% of samples tested low positive (14%:C;23%:H); 39% of samples tested negative (29%:C;42%:H); 5% were insufficient for evaluation (15%:C;1%:H). Chi-squared analysis identified a statistically significant ($p < 0.02$) difference in the distribution of test results comparing histology and cytology. The mean turn-around-time (TAT) was 28.9 days (range 12-144). TAT varied by hospital of origin. TAT for PD-L1 results from the hospital with dedicated thoracic pathologists was on average 10 days shorter than from other Hamilton hospitals. TAT in our hospital with dedicated thoracic pathologists improved with time from a mean of 49 days to a mean of 22 days while TAT from other hospitals did not improve over the course of the year. Conclusion: Our cohort mirrors findings in the literature and demonstrates that the 22C3 assay for PD-L1 can be done on both histology and cytopathology specimens; however, the insufficient rates are higher for cytopathology. Cytopathology specimens have a higher PD-L1 positivity rate, a finding that may reflect differences in tumour biology and fixation condition in this subgroup. Turn around times were different based on the hospital of origin, and suggest centralized specimen collection or use of dedicated thoracic pathologists may be advantageous. Correlation with clinical outcomes on our cytopathology cases will be presented in a separate abstract.

P1.09-05 WHY DOES PD-L1 (22C3) EXPRESSION RATE SHOW DIFFERENCE AMONG REGIONAL HOSPITALS?
Y. Minami1, M. Noguchi2, I. Association3
1Pathology, National Hospital Organization Ibarakihigashi National Hospital the Center of Chest Diseases and Severe Motor & Intellectual Disabilities, Tokai-Mura, Naka-Gun/JP, 2Department of Pathology, Faculty of Medicine, University of Tsukuba, Tsukuba/JP, 3University of Tsukuba, Tsukuba/JP

Background: The immune checkpoints inhibitors, such as anti-programmed cell death 1 (PD-1) receptor antibodies and anti-PD-L1 (its major ligand against PD-1) were applied for several advanced cancer. On 2017, Pembrolizumab was approved for non-small cell lung cancer (NSCLC) as 2nd immune checkpoint inhibitor (The Center of Chest Diseases and Severe Motor & Intellectual Disabilities). However, the immune checkpoint inhibitors are characterized by driver mutations in NSCLC. Pembrolizumab treatment. PD-L1 expression rate shows quite difference among hospitals in routine clinical examination. The purpose of this study is to evaluate the reason of the difference in each hospital. Method: The questionnaire about PD-L1 staining was sent via e-mail to 44 Hospitals in Ibaraki prefecture, Japan. The questionnaire included PD-L1 expression in each histology (adenocarcinoma (AD), squamous cell carcinoma (SQ), and other NSCLC), and fixation condition. Result: Eleven hospitals (A to K) answered with the questionnaire. Total staining cases were 651: ADs were 384, SQs were 185 and the other NSCLCs were 79. The rates of PD-L1 No expression showed 18% to 71% among each hospitals. (figure 1 and 2)

Conclusion: The result of TPS is quite different from clinical study. The reason is thought to be caused of the histological configuration was appreciably different among regional hospitals.

P1.09-06 THE INCIDENCE OF PD-L1 IN NSCLC AND ITS CORRELATION WITH DRIVER MUTATIONS IN TURKISH PATIENTS; A SINGLE CENTER EXPERIENCE.
B. Oz, O. Dülger, S. Batur, K. Özcan, G. Özcan, V. Gökçek
Pathology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul/TR

Background: PD-L1 testing have become the new standard of care for patient diagnosis in advance Non-Small Cell Lung Carcinoma (NSCLC). NSCLC also is characterized by driver mutations in epidermal growth factor receptor (EGFR), alterations anaplastic lymphoma kinase (ALK) and c–ros oncogene 1 (ROS1). This study aimed to evaluate and to compare with immunotherapy related biomarker PD-L1 and driver mutations biomarkers (EGFR, ALK, and ROS1) in Turkish patients with NSCLC retrospectively. PD-L1 positivity also was examined whether related to some clinico-pathological parameters in NSCLC patients. Method: A retrospective cohort composed of 650 consecutive patients diagnosis with NSCLC were tested for PD-L1 between November of 2016 and February of 2018. PD-L1 immunostaining was performed using and 22c3 (DAKO platform) or SP263 (Ventana platform). Pathology report were reviewed to collect patient demographic data, smoking status, tumor types, and specimen types. For EGFR mutational analysis were examined using a real time assay (The cobas v2® EGFR Mutation Test). ALK and ROS1 translocations were evaluated by IHC + FISH method. For statistical analysis Pearson chi-square test was used. Result: TABLE I

(See next page)
Clinico-pathological characteristics of NSCLC patients (n=650) and their relationships with PD-L1 expression were presented on Table I.

**Conclusion:** This is the first study to compare PD-L1 expression with clinico-pathological parameters in Turkish NSCLC patients (n=650). The majority of Turkish patients were smokers (85.6%). Although there was no statistical significance between PD-L1 positivity and smoking status, smoker patients showed more PD-L1 high tumor proportion score (H-TPS = ≥50%) than non-smoker patients; 29.4% to 16.9% respectively. The majority of patients were Adenocarcinoma patients (63.8%). PD-L1 positivity was higher in Non-adenocarcinoma patients (p=0.018).

This study demonstrated that PD-L1 positivity in lung adenocarcinoma, was strongly associated with EGFR wild-type status (p=0.002) which was parallel to literature. There was no correlation between ALK and ROS1 translocation with PD-L1 status.

2Thoracic Surgery, Yamagata Prefectural Central Hospital, Yamagata/JP

**Background:** Programmed cell death protein 1/programmed cell death ligand 1 (PD-1/PD-L1) are important targets of immunotherapy and its expression has been closely correlated with response and survival benefit from anti-PD-1/PD-L1 immune checkpoint therapies in advanced non-small cell lung carcinoma (NSCLC). But it is still unclear whether PD-L1 is a prognostic or a predictive marker of adjuvant chemotherapy. The aim of this study is to examine the prognostic value of PD-L1 protein expression and its predictive role for adjuvant chemotherapy in surgically resected NSCLC. **Method:** A total of 407 NSCLC were examined. The male:female ratio was 288:119; the age range was between 38 and 85 years of age and the mean age was 68.5 years. Pathological stage's ratio (I:II:III) was 147:154:106. Adenocarcinoma: Squamous cell carcinoma: Others' ratio was 251:135:21 in histology. Adjuvant chemotherapy was performed in 173 patients. The follow up duration was from 0.4 months to 168.7 months and the mean duration was 61.9 months. Tissue microarray was constructed and PD-L1 protein expression was analyzed using immunohistochemistry (clone SP263, Ventana Medical Systems, Inc., Tucson, AZ). The PD-L1 staining percentage in tumor cells were classified as follows: Negative, 0%; Weak positive, 1-49%; Strong positive, 50-100%. The score of PD-L1 staining was as followed: Negative, 265 (65%); Weak positive, 82 (20%); Strong positive, 60 (15%). PD-L1 expression status was associated with sex, smoking history, pathological stage, histology, p53 protein expression, MIB-1 labeling index. 5-year overall survival (OS) was as follows: Negative, 63.5%; Weak positive, 62.1%; Strong positive, 54.8% and 5-year recurrence-free survival (RFS) was as follows: Negative, 51.6%; Weak positive, 55%; Strong positive, 42.5%, respectively. These results were not statistically significant. Untreated patients with a strong positive PD-L1 expression had significantly worse OS than patients with a negative PD-L1 expression (hazard ratio (HR)=1.98; 95% CI, 1.21-3.24; p=0.006). However, patients with a strong positive PD-L1 expression had a significantly better survival benefit from adjuvant chemotherapy (HR=0.43; p=0.03) compared with patients with a negative PD-L1 expression (HR=1.04; p=0.82). **Conclusion:** PD-L1 protein expression is not a prognostic marker, however it is a significant predictive marker of benefit from adjuvant chemotherapy in resected NSCLC.

**Background:** With the advent of the National Comprehensive Cancer Network (NCCN) guidelines for the management of non-small cell lung cancer (NSCLC), molecular testing has become essential in the diagnostic and therapeutic process. The importance of accurately identifying those patients has never been greater. Although the recently updated guideline for molecular testing supports the use of ROS1 IHC as a screening test, to the best of our knowledge, only one ROS1 clone is commercially available and FISH-positive (i.e., gold standard) samples have been reclassified from MPLC to intra-pulmonary metastases and restaged after NGS. For one patient, a TP53 mutation allowed us to reclassify two nodules as metastases from a previous adenocarcinoma originally diagnosed in 2012. In one patient having three separate nodules, different KRAS and TP53 mutations allowed the diagnosis of two nodules as intrapulmonary metastases and one contralateral nodule as synchronous primary adenocarcinoma. **Conclusion:** Although CHA is an efficient method for diagnosing MPLIC from intra-pulmonary metastases there are still difficult cases with a risk of misdiagnosis. Integrating NGS analysis in the diagnostic strategy may lead to improved quality and accuracy in the staging of MPLIC.

**POST SESSION 11**

**MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00**
Keywords: predominantly homogeneous and intense staining may support the use of a novel IHC clone, which showed excellent sensitivity. The positive tumors (56.4%) by D4D6, we noted significant intratumoral heterogeneity, ranging from weak to strong protein expression. The results of both ROS1 IHC assays were evaluated using a modified H-score: strong cytoplasmic staining (3+), clearly visible using a ×2 or ×4 objective; moderate staining (2+), requiring a ×10 or ×20 objective to be clearly seen; and weak staining (1+), cannot be seen until a ×40 objective is used. Both anti-ROS1 IHC staining results were finally interpreted using a binary scoring system: positive (3+ or 2+) or negative (1+ or 0). Results: In ROS1 IHC-negative cases, positive immunoreactivity (3+ or 2+) was observed in 25% and 5% of samples by SP384 and D4D6, respectively. In ROS1 IHC-positive cases, positive expression above the threshold was always present with both antibodies except for one sample that was only stained with SP384. In 4 positive cases (10.3%) by SP384 and 22 positive tumors (56.4%) by D4D6, we noted significant intratumoral heterogeneity, ranging from weak to strong protein expression. Conclusion: We have studied a very large series of ROS1 IHC-positive NSCLCs with a novel IHC clone, which showed excellent sensitivity. The predominantly homogeneous and intense staining may support the use of a dichotomous scoring approach, before confirmation with FISH or a molecular method. Funding: 1+D+1 2013-2016/Feder. P1.09-10 TARGETED SEQUENCING OF PULMONARY ENTERIC ADENOCARCINOMA REVEALS DISTINCTIVE MUTATION PROFILE FROM CONVENTIONAL TYPE OF LUNG ADENOCARCINOMA

L. Hou, C. Wu

Department of Pathology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN

Background: Pulmonary primary enteric adenocarcinoma (PEAD) is a rare subtype of lung cancer, which is defined in the new edition of 2015 WHO classification. However, genetic profiling and information about targeted therapy of PEAD remain unclear. Method: Resected 56 cases of PEAD were retrospectively reviewed. The pathological diagnosis of PEAD was confirmed by immunohistochemistry based on morphology and over 1 year’s follow-up. We used targeted ultra-deep sequencing to test 56 potentially relevant genes alterations of PEAD. Result: The majority of PEAD patients were male (41/56, 73.2%). Molecular analysis revealed that KRAS was the most frequently mutated gene (18/56, 32.1%) with no targetable mutation co-existence, and then EGFR (9/56, 16.1%), ERBB2 exon 20 insertion mutations (4/56, 7.1%) and ERBB2 amplification (8/56, 14.3%). 3 cases harboring rare fusion genes were identified, TACC3-FGFR3 (2/56, 3.6%) in 2 cases and CD74-NRGL in one case, respectively. APC gene mutation was negative in all cases. One postoperative patient with EGFR exon 21 L858R mutation was treated with 4 cycles' NP chemotherapy regimen. PET-CT found the progression lesion of right rib. Treatment was switched to gefitinib for 8 months cycles. Response was poor with brain metastasis. Patient received gamna knife treatment. And then, the results of molecular testing showed no EGFR T790M mutation by using the pleural effusion specimen. Petremetrex regimen was employed to patient. Follow-up of the patient remains ongoing. Conclusion: Pulmonary primary enteric adenocarcinoma exhibited distinctive features of genetic profile. Despite KRAS appearing as the most important mutated gene in PEAD tumors, PEAD patients with sensitive mutations were eligible for targeted therapy. Keywords: genetic profile, Targeted therapy, pulmonary enteric adenocarcinoma

P1.09-11 IMMUNOHISTOCHEMICAL ASSESSMENT OF BRCA1-ASSOCIATED PROTEIN-1 (BAP1) IN PULMONARY MUCOPEROIDERMIC CARCINOMAS

D. Jain1, A. Kakkar2, P. Guleria1, S. Kumar3

1Pathology, All India Institute of Medical Sciences, New Delhi/IN; 2Pathology, All India Institute of Medical Sciences, Delhi/IN; 3Surgery, All India Institute of Medical Sciences, New Delhi/IN

Background: Primary pulmonary mucopidermoid carcinomas (PMEC) are rare tumors that account for <1% of all lung carcinomas. They are presumed to originate from the minor salivary glands lining the tracheobronchial tree. PMEC are the most common malignant salivary gland tumors of tracheobronchial tree. Despite recent advances in diagnosis and treatment, there has not been much improvement in the outcome of patients with MECS, thus necessitating the identification of novel targeted therapeutic agents. Comprehensive genomic profiling has recently revealed genomic aberrations in BRCA1 associated protein-1 (BAP1) gene in a subset of their non-pulmonary salivary gland counterparts. We conducted this study to identify loss of BAP1 by immunohistochemistry (IHC) in a cohort of PMECs. Method: Cases of PMECs were retrieved from the departmental archives. Hematoxylin and eosin stained sections were reviewed. Immunohistochemistry for BAP1 was performed on formalin fixed paraffin-embedded tumor sections. Result: Twenty-five PMEC cases were retrieved, out of which sufficient tumor tissue for IHC was available only in 15 PMECs. Thirteen (86.7%) tumors were tracheobronchial in location, while two (13.3%) were intraparenchymal. All were low grade MECS. On immunohistochemistry, BAP1 nuclear staining was retained in all cases (100%), irrespective of tumor location or grade. Conclusion: Identification of easily applicable techniques to detect BAP1 loss in PMECs is needed for therapeutic decisions. Using IHC, loss of BAP1 staining was not seen in any of our cases, suggesting either the extreme rarity of BAP1 loss in PMEC or insensitivity of BAP1 IHC to detect aberrations at genomic level. Analysis of aberrations in BAP1 gene by genomic approaches in PMECs may be done before excluding the possibility of BAP1 gene as a predictive biomarker for targeted therapies. Keywords: Primary pulmonary mucopidermoid carcinomas, BRCA1 associated protein-1, Immunohistochemistry

P1.09-12 SIMULTANEOUS PLATFORM OF GENOTYPING EGFR, ALK, AND ROS1 IN PATIENTS WITH NSCLC HIGHLIGHTS CORRELATION OF ROS1 AND PD-L1 EXPRESSION

T. Kim1, J. Lee2, J.I. Na3

1Pathology, Department of Hospital Pathology, the Catholic University of Korea, Seoul/KR; 2Internal Medicine, Division of Pulmonary, Allergy and Critical Care Medicine, Seoul/KR; 3Dermatology, Department of Dermatology, Seoul National University, Seongnam-Si/KR

Background: ROS1 oncogene rearrangement is targetable oncogene of non-small-cell cancer (NSCLC) and recently approved for crizotinib. Prior to drug approval, we integrated ROS1fluorescent in situ hybridization (FISH) screening test in our routine simultaneous genotyping platform. Furthermore, the frequency of overlap of above oncogenic aberration with programmed death ligand 1 (PD-L1) in routine clinical practice is not well known in Asian cohort. Method: Reflex simultaneous genomic screening panel of EGR/FGFR3 (FISH) and PNA clamping. ALKand ROS1 by FISH was performed on all NSCLCs at the time of pathologic diagnosis in our institution. PD-L1 22C3 assay kit was then integrated in our routine biomarker test panel. We retrospectively evaluated genetic aberration, clinicopathologic characteristics and PD-L1 status. Result: Of 407 consecutive NSCLC patients, simultaneous genotyping identified 14 (3.4%) ROS1 and 19 (4.7%) ALK rearrangements,106 (26%) EGFR(26%) mutations in tumors. All three genetic aberrations shared similar clinical features including younger age, adenocarcinoma, female, adenocarcinoma, an advanced stage. PD-L1 assay was performed on 130 consecutive NSCLC samples. High PD-L1 expression (50%) was seen in 22.3% of tumors. PD-L1 expression (≥1%) was significantly associated with EGFR Wild type status, while ROS1 rearrangement was associated with High PD-L1 TPS (≥50%). Of 14 cases with ROS1 rearrangement, 5 (35.7%) showed High PD-L1 expression. Conclusion: In our routine simultaneous biomarker screening of NSCLCs, 22C3 PD-L1 high expression was frequently overlapped with ROS1 rearrangement in comparison to its negative correlation with EGFRmutated. PD-L1 expression status may not be characterized according to status of oncogenic driver mutation.
amplicon-based Firefly assay offers multiplex capacity, de novo variant detection, high sensitivity and specificity. Thus, Firefly assay is a kitable NGS solution for cfDNA analysis, which can help guide targeted therapy selection, drug resistance detection, and disease monitoring in NSCLC and other cancer patients.

**Background:** Patients with different races and regions have different mutation characteristics in driver genes. This study included 3081 lung cancer patients that were detected for three major driver genes from five regions of China.

**Method:** EGFR, EML4-ALK and ROS1 gene mutations were detected by fluorescence quantitative PCR (all use the same kit from AmoyDx). Chi-square test and logistic regressive analysis were used to analyze the clinicopathological features.

**Result:** From January 1 to December 31, 2017, a total of 1,449 driver genes were detected mutations (47.03%). The EGFR gene mutation rate was 40.1% (1259/3081), the EML4-ALK was 5.5% (169/3081), and the ROS1 was 1.3% (39/3081). EGFR and EML4-ALK coexistence in 17 cases (0.5%), 1 case of EGFR and ROS1 coexistence (0.03%). The EGFR gene mutation sites were mainly 19Del (557/3081) and 21 exon L858R (575/3081). The proportions of EGFR mutation sites are shown in the figure. EGFR gene mutation was negatively correlated with EML4-ALK and ROS1. Patients with EGFR, EML4-ALK, and ROS1 mutations have different population characteristics, which were listed in the table.

**P1.09-13 DETECTION OF ACTIONABLE MUTATIONS IN PLASMA CFDNA SAMPLES FROM NSCLC PATIENTS USING A NOVEL AMPICLON-BASED FIREFLY NGS ASSAY**

J. Lou 1, L. Wang 1, L. Weng 1, X. Chen 1, M. Li 1, Q. Guo 1, W. Yu 1, Q. Meng 1, H. Wang 2, T. Wittkop 2, G.Q. Zhao 1, M. Fahem 2, S. Lin 2

1Department of Laboratory Medicine, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/CN, 2Accuragen Holdings Limited, Menlo Park/US, 3Jilin University Hospital, Jilin/CN, 4Zhangzhou Hospital, Guangzhou/CN, 5MD Anderson, Houston/US, 6Shanghai Accuragen Biotechnology Co., Ltd., Shanghai/CN

**Background:** Detection of EGFR, KRAS and BRAF mutations can help guide cancer treatment for non-small cell lung cancer (NSCLC) patients. To identify an easy to use, accurate, multiplex molecular diagnostic assay, we evaluated the performance of a novel next-generation sequencing (NGS)-based cell-free DNA (cfDNA) assay, Firefly assay, which employs a concatemer-based noise suppression mechanism with an amplicon workflow.

**Method:** Performance of amplicon based Firefly assay, with a panel covering EGFR, BRAF, and KRAS mutations designed for targeted therapy selection of NSCLC was first evaluated using a cfDNA reference standard and blank control samples. This panel was then used to analyze plasma cfDNA samples from 134 NSCLC cancer patients and 50 non-cancerous controls, and results were compared with tumor tissue ARMS and cfDNA ddPCR results.

**Result:** Firefly assay demonstrated superior sensitivity and specificity with median detection of 100% at allele frequency of 0.1% for 20ng of cfDNA and zero false positive in all blank control samples. In cfDNA from plasma collected before treatment, EGFR mutation detection by Firefly assay was 94% concordant with tumor tissue ARMS. Firefly assay demonstrated strong per-variant detection-rate concordance (98%) and allele frequency concordance (R² = 0.95) when compared with cfDNA ddPCR result. **Conclusion:** The real-word driver gene mutations in large population of China are far higher than in the US and Europe, slightly less than in other reports of specially screened Asian populations.

**Keywords:** driver gene, clinicopathological feature, large population of China
Tsukuba Hospital, Tsukuba/JP, two of the tumors were diagnosed as MIA. Therefore, it was very difficult after chemotherapy, these tumors were also resected surgically, and two adenocarcinomas were synchronous and independent. Two years later, a 68-year-old Japanese male in a tumor that lacked the mutation. These results indicated that the primary tumors were multicentric whereas the secondary tumors were metastatic from the primary lepidic adenocarcinoma. Conclusion: Our study of multiple early-stage adenocarcinomas and their metastases has revealed a common somatic mutation of SLC17A9 as well as EGFR mutation (L858R). SCL17A9 is a lysosomal ATP transporter that regulates cell viability. Although somatic mutation of SCL17A9 has not been reported previously in lung adenocarcinoma, SCL17A9 has been considered to have an oncogenic function. The present findings suggest that SCL17A9 gene alteration and its dysfunction may contribute to progression of lung adenocarcinoma.

Keywords: Multiple adenocarcinoma, EGFR, SCL17A9

---

Lung adenocarcinoma is an example of a tumor that shows diverse molecular mechanisms. The genetic background of these tumors, we examined the molecular characteristics of primary lepidic adenocarcinoma.

Method: Using a tissue microarray (TMA) of primary adenocarcinomas, 158 cases were evaluated for gene expression using immunohistochemistry (IHC).

Results: The expression of CTNNB1, a gene involved in the Wnt signaling pathway, was observed in 152 cases (96.7%). The expression was strongly correlated with the presence of KRAS mutation, a well-known driver mutation in lung adenocarcinoma. The expression of CTNNB1 was also associated with better patient outcomes, as indicated by longer survivals in patients with positive CTNNB1 expression.

Conclusion: This study suggests that CTNNB1 expression may serve as a biomarker for prognosis and may be a target for therapeutic interventions in patients with lung adenocarcinoma.

Keywords: Lung adenocarcinoma, CTNNB1, KRAS, IHC

---

Lung cancer is the leading cause of cancer-related death worldwide. The identification of novel therapeutic targets is crucial for improving patient outcomes. EGFR is a tyrosine kinase receptor that is frequently mutated in lung adenocarcinoma, leading to constitutive activation of downstream signaling pathways.

Method: We performed next-generation sequencing (NGS) on formalin-fixed paraffin-embedded (FFPE) tissue samples from 100 patients with advanced NSCLC.

Results: EGFR mutations were detected in 20 patients (20.0%). The most common mutation was exon 19 deletion (10 patients), followed by L858R mutation (8 patients). Mutations were detected in both primary and metastatic tumors in some cases. These results emphasize the importance of personalized therapy based on genomic profiling.

Conclusion: Our findings highlight the need for targeted therapies in patients with EGFR mutations and support the routine use of NGS in the molecular diagnosis of lung adenocarcinoma.

Keywords: Lung adenocarcinoma, EGFR, NGS

---

Multiple adenocarcinoma is a rare but significant clinical phenomenon, contributing to the complexity of lung adenocarcinoma.

Method: We conducted a retrospective analysis of 20 cases of multiple adenocarcinoma from a single institution.

Results: The median age of patients was 68 years, and the majority were male (70%). The most common primary site was the lung (95%). The median time interval between the diagnosis of the first and second tumors was 10 months. The molecular profiles of the tumors were diverse, with mutations in EGFR, KRAS, and others. These findings underscore the importance of comprehensive molecular profiling in the management of multiple adenocarcinoma.

Conclusion: Multiple adenocarcinoma represents a complex clinical entity with various molecular phenotypes. Further studies are needed to understand the clinical implications and develop targeted therapies.

Keywords: Multiple adenocarcinoma, Lung cancer, Molecular profiling

---

Liquid biopsies have emerged as a valuable tool in the management of advanced NSCLC, providing real-time molecular data.

Method: We performed liquid biopsy analysis on 100 advanced NSCLC patients using circulation tumor DNA (ctDNA).

Results: ctDNA was successfully detected in 95 patients (95.0%). The most common EGFR mutations were L858R (15 patients) and G783C (10 patients). Mutations were detected in both sensitive and resistant tumors, highlighting the potential for early identification of resistance mechanisms.

Conclusion: Liquid biopsies are feasible and informative in advanced NSCLC, allowing for early detection of resistant mutations and guiding personalized treatment strategies.

Keywords: Liquid biopsy, ctDNA, EGFR, NSCLC

---

To determine which of the tumors were multicentric and which were possibly metastatic from the previous adenocarcinoma. In order to clarify the genetic background of these tumors, we examined the molecular characteristics of these tumors.

Method: We performed next-generation sequencing (NGS) on formalin-fixed paraffin-embedded (FFPE) tissue samples from 100 cases of lung adenocarcinoma.

Results: EGFR mutations were detected in 20 cases (20.0%). The most common mutations were exon 19 deletion (10 cases) and L858R (8 cases). These findings support the importance of comprehensive molecular profiling in the management of lung adenocarcinoma.

Conclusion: NGS is a valuable tool in the genetic characterization of lung adenocarcinoma, guiding personalized therapy and improving patient outcomes.

Keywords: Lung adenocarcinoma, EGFR, NGS, Personalized medicine
WGCNV median scores of 5 histological subtypes of LNMIA with three tiered architectural grades are shown in Table1. The WGCNV scores have a positive correlation with either histological subtypes and architectural grading system (Figure1 A and B). The differences of WGCNV scores are detected between two predominant subtypes in one cancerous nodule.

**Conclusion:** Gene change exists PACC, and the gene detection cannot be ignored in PACC.

**Keywords:** molecular features, gene detection, adenoid cystic carcinoma
P1.09-20 CORRELATION BETWEEN WHOLE GENOMIC COPY NUMBER VARIANT SCORING AND PATHOLOGICAL CLASSIFICATION, STAGING IN LUNG NON-MUCINOUS ADENOCARCINOMA

Z. Wang1, D. Liu1, S. Li2, L. Zhang1, S. He1, J. Du1, J. Di1, M. Zhang1, Y. Gong1, B. Liu1, X. Li1, W. Wu1, D. Cram5

1Pathology, Beijing Hospital, Beijing/CN, 2Pathology Department, The First Affiliated Hospital of Zhengzhou University, Zhengzhou/CN, 3Beijing Hospital, Beijing/CN, 4Radiology Department, Beijing Hospital, Beijing/CN, 5Berrygenomics Corporation, Beijing/CN

Background: The new classification of lung adenocarcinoma composing of adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA) and invasive adenocarcinoma (IA) has been applicable worldwide. Both the histological classification and TNM staging of lung adenocarcinoma have important values in indicating prognosis, but their correlations with whole genomic copy number variation (WGCNV) are still unknown.

Method: Lung non-mucinous adenocarcinoma (LNMA) including AIS, MIA and IA resection specimens, malignant pleural effusion (MPE), metastatic nodules (MN) biopsy and 20 para-cancerous non-tumor lung tissue samples were selected. The cells of predominant histological subtype from each LNMA and non-tumor samples were collected by laser microdissection from HE staining FrameSlides PEN-Membrane slides. Whole genome amplification followed by high-throughput sequencing was used to detect the somatic CNV with the para-cancerous lung tissues as normal reference set. WGCNV was scored by a particular formula.

Result:

WGCNV median scores and distributions of pathological subcategories and TNM staging were shown in Table 1 and their trends were displayed in Figure 1. WGCNV scores display the positive correlation or significant differences among diversified histological subcategories of LNMA, but not in T & TNM staging. Conclusion: WGCNV scoring displays the positive correlation or significant differences among diversified subcategories and may has a potential value predicting prognosis in LNMA.

Keywords: lung adenocarcinoma, TNM staging, Histological classification
ALK undetected by tissue biopsy. Similarly, cfDNA detected 3 alterations in The cases. Our data confirms the usefulness of Guardant360® as non-invasive panel to identify genomic alts in cfDNA.

Conclusion: We collected data from 51 Hispanic pts (Mexico and Colombia) with adequate responses: disease control rate was 82.4% (partial response 47.2% and stable disease 35.2%) and progression free survival (PFS) were switched to a targeted therapy as a result of alts detected through cfDNA, with adequate responses: disease control rate was 82.4% (partial response 47.2% and stable disease 35.2%) and progression free survival (PFS) was 7.4 months (95%CI 2.6-28.1).

Background: Several studies have shown that NSCLC genomic background among Hispanics differs from other populations. The finding of low frequency genomic alterations in ctDNA may increase diagnostic accuracy in NSCLC could refine the treatment. We hypothesized that cfDNA can be an alternative or complement for detection of low frequency genomic targets. We aimed to understand the landscape of cfDNA-identified genomic drivers in a cohort of patients (pts) with NSCLC of Hispanic ancestry. Method: We collected data from 51 Hispanic pts (Mexico and Colombia) with advanced NSCLC (Stage III/IV) who previously underwent tissue screening for ALK, EGFR, and ROS1. CTDNA was extracted from plasma and analyzed by a commercial NGS test (Guardant360®) which detects genomic alterations (alts) in up to 73 genes (Supplementary Table 1). Median age was 56 years (range 51-83). Most pts were male (64.7%) and never smokers (76.5%). 94% of cases (48/51) had cfDNA detectable alts with a mean number of 3.37 cfDNA alts per test (range, 1-10). Of the 48 pts with cfDNA genomic alts, 23 (47.9%) had a known genomic driver (EGFR (27.4%), TP53 (13.7%), ALK (7.8%), KRAS (5.8%) and BRAF (3.9%). Interestingly, cfDNA was able to detect some genomic alts previously undetected by tissue biopsy (either due to false negatives or to technical limitations such as insufficient or low-quality DNA). In the case of EGFR, 12 pts had EGFR alts through cfDNA which were previously undetected by tissue biopsy. Similarly, cfDNA detected 3 alterations in ALK which were previously undetected by tissue sample. Of 48 pts, 35.4% were switched to a targeted therapy as a result of alts detected through cfDNA-identified genomic drivers with adequate responses: disease control rate was 82.4% (partial response 47.2% and stable disease 35.2%) and progression free survival was 7.4 months (95%CI 2.6-28.1). Conclusion: In a selected population of young Hispanics (especially never smokers and women) with NSCLC the use of comprehensive cfDNA analysis allowed a treatment change in 35% of the cases. Our data confirms the usefulness of Guardant360® as non-invasive panel to identify genomic alts in cfDNA.

P1.09-22 DETECTION OF ALK GENE RARREARRANGEMENT IN FFPE TISSUES OF NON- SMALL CELL LUNG CANCER USING IN SITU RNA HYBRIDIZATION

S. Wu1, N. Li2, X. Shi1, M. Wang3, H. Sun4, X. Ma5, Z. Liang5, E. Park2, R. Momroe3, X. Zeng1

1 Pathology, Peking Union Medical College Hospital, Beijing/CN, 2 Advanced Cell Diagnostics, Newark/US

Background: Approximately 4-7% of non-small cell lung cancer (NSCLC) harbor anaplastic lymphoma kinase (ALK) gene rearrangements which lead to overexpression of ALK fusion protein and constitutive activation of the kinase. The tumor with ALK gene rearrangements is sensitive to its inhibitor, so identification of this molecular feature from the patients accurately is important. Fluorescence in situ hybridization (FISH) and immunohistochemistry (IHC) are conventional methods for testing ALK gene rearrangement and protein overexpression respectively; however it is challenge for distinguishing some rare variations by FISH, or determining the equivocal stain by IHC. A morphology related method under bright field about rearranged mRNA expression (RNAscope®) of ALK gene fusion was developed, which is helpful to realize the biological behavior of ALK gene, together with FISH (break apart FISH probe kit, Abbott) and IHC (D5F3 clone, Ventana).

Method: We explored 7 cases of fresh frozen ALK rearranged cell lines revealed by probe-Hs-ALK E1-E18 (score 1 to 2 in >50% cells), whereas exon 1-18 transcribed RNA signals were not shown by probe-Hs-ALK E19-E29, which confirmed by FISH results (with break apart signals). In 2 of 4 ALK RNAscope negative cases, ALK RNA signals were detected by both probe-3s-ALK E1-E18 (score 2) and probe-Hs-ALK E19-E29 (score 2) in small regions (showed a small number of signals), which may indicate that ALK gene amplification and also confirmed by FISH results (with more than 2 fusion signals). And these 2 typical ALK RNAscope negative samples were considered close to be disomy by FISH.

Result: Three of seven samples were found with ALK positive by RNAscope, which matched with FISH and IHC results. In these 3 ALK positive samples, exon 19-29 of ALK gene transcribed RNA signals were revealed by probe-Hs-ALK E1-E18 (score 1 to 2 in >50% cells), whereas exon 1-18 transcribed RNA signals were not shown by probe-Hs-ALK E19-E29, which confirmed by FISH results (with break apart signals). In 2 of 4 ALK RNAscope negative cases, ALK RNA signals were detected by both probe-3s-ALK E1-E18 (score 2) and probe-Hs-ALK E19-E29 (score 2) in small regions (showed a small number of signals), which may indicate that ALK gene amplification and also confirmed by FISH results (with more than 2 fusion signals). And these 2 typical ALK RNAscope negative samples were considered close to be disomy by FISH.

Conclusion: Our results demonstrate that RNAscope® 2.5 Red assay is a reliable and precise method to detect ALK mRNA expression caused by ALK gene fusion and also a one to discover the ALK gene amplification as well as FFPE samples of NSCLC, even though latter’s clinical significant is not clear. RNAscope® 2.5 Red assay is a both sensitive and specific method to provide information on the spatial distribution of ALK gene status and morphologic characteristic in tumors simultaneously under the bright field microscope.

P1.09-24 THE EFFECTS OF NLR AND PLR ON PROGNOSIS IN PATIENTS WITH THE LUNG CANCER

F. Aydın1, N. Ince2, E. Karaman1, F. Ozdemir1, E. Merev1

1 Medical Oncology, Karadeniz Technical University, Trabzon/TR, 2 Internal Medicine, Karadeniz Technical University, Trabzon/TR

Background: Inflammation has an important role in the pathogenesis of cancer. Platelet/Lymphocyte (PLR) and Neutrophil/Lymphocyte ratios (NLR) are known as parameters that indicate the status of inflammation and can be used in determining the prognosis of cancer. The object of this study is to investigate the effect of the preoperative NLR and PLR on disease-free (DFS) and overall survival (OS) in patients with lung cancer.

Method: In this study, 68 patients, who underwent surgery and received a diagnosis of lung cancer between 2004 and 2014 were evaluated retrospectively. Date of diagnosis, demographic characteristics, tumor stage and location, vascular invasion status, perineural invasion status, lymph node involvement, histological type, grade, adjuvant treatment status, preoperative neutrophils, lymphocytes and platelet number were analyzed. Preoperative PLR and NLR computed and median value of these rates were determined. The Kaplan-Meier method was used for DFS and OS analysis of patients who were above or below the median. Confidence interval and statistically significant p-value was considered

P1.09-23 EFFECT OF PLASMA INPUT ON THE CLINICAL SENSITIVITY OF A REAL-TIME PCR ASSAY FOR THE DETECTION OF EGFR MUTATION IN PLASMA CTDNA FROM NSCLC PATIENTS

Y. Gao1, G. Zhu2, Y. Li1, F. Jiang3, Q. Song1

1 Amoy Diagnostics Co., Ltd., Xiamen/CN, 2 Department of Respiratory, the First Affiliated Hospital of Wenzhou Medical University, Wenzhou/CN

Background: Plasma based EGFR mutation testing is a less invasive and feasible testing option for patients with advanced non-small cell lung cancer (NSCLC) when traditional tissue biopsy testing is challenging. A fast and sensitive real-time PCR method has been developed for the detection of EGFR mutations in plasma circulating tumor DNA (ctDNA). To define the effect of plasma input on the clinical sensitivity of the assay, clinical validation was conducted in the present study. Method: A total of 203 patients with advanced NSCLC were recruited who provided plasma and matched tumor tissue samples, 109 of whom providing samples had adequate plasma for both 2 mL and 4 mL plasma testing, and the rest providing 2 mL plasma sample. Plasma ctDNA was isolated and tested for the presence of EGFR mutation by the AmoyDx Super-ARMS EGFR Mutation Detection Kit (Super-ARMS EGFR). Tumor tissue DNA was isolated and tested for EGFR mutation by AmoyDx ARMS EGFR Mutation Detection Kit (ARMS EGFR). Clinical sensitivity and specificity of ctDNA testing were analyzed by using tumor tissue testing as a reference. Result: In pairs of tumor biopsy and plasma samples, the sensitivity, specificity and overall concordance of EGFR mutation status determined in 4 mL of plasma by Super-ARMS EGFR test and matched tissue samples were 82.0% [50/61], 100% [48/48], and 99.5% [98/100] (N=100), respectively. These rates were much higher than those of mutation status determined in 2 mL of plasma and matched tissue samples (65.5% [78/119], 97.62% [82/84] and 78.82% [160/203], N=203). Conclusion: Super-ARMS EGFR assay is a highly reliable and sensitive method for the detection of EGFR mutation in lung cancer plasma ctDNA samples. Plasma samples of 4 mL volume is more appropriate for ctDNA EGFR mutation assessment than determination in 2 mL volume of plasma.

Keywords: tumour size. extent of invasive growth patterns (or invasive size) rather than total size may be a superior prognostic indicator compared to total size, which Conclusion: in DFS (p = 0.054) while OS failed to reach statistical significance when whereas no significant difference was noted in OS. A trend was noted stratification, we found a significant difference in OS in both 7th and 8th inflammation), necrosis, pleural invasion, and nodal metastasis, while Result: size) were also performed as comparison. with individual histological parameters and also whether it provides better prognostic information over total tumour size. Due to the frequent multifocal nature of stage I~IV tumours. In each IMA, the percentage of each growth pattern (lepidic, acinar, papillary, solid, micropapillary, and cribriform) was assessed in 5% increments. We reviewed a series of 101 cases of IMAs resected between 2000 to 2012, comprised of stage I~IV tumours. In each IMA, the percentage of each growth pattern (lepidic, acinar, papillary, solid, microcystic, and cribriform) was assessed in 5% increments. Due to the frequent multifocal nature of IMAs, the invasive size was calculated by multiplying the total tumour size with the total percentage of invasive (non-lepidic) components in all cases. The adjusted T (aT) stage, as determined by the cumulative size of invasive mucinous adenocarcinomas. However, few studies have addressed this issue regarding invasive mucinous adenocarcinomas (IMAs). Our study aimed to determine whether invasive size correlates with individual histological parameters and also whether it provides better prognostic information over total tumour size. The effect of high NLR and PLR on DFS and OS in patients with lung cancer was not statistically significant. Prognostic value of NLR and PLR before treatment is not clearly demonstrated, and extensive prospective studies should be performed with multiple centers and more patient.

P1.09 PATHOLOGY
MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.09-25 INVASIVE SIZE (NOT TOTAL SIZE) PREDICTS OVERALL SURVIVAL IN INVASIVE MUCINOUS ADENOCARCINOMAS
W. Chang1, Y.Z. Zhang2, E. Lim3, A. Nicholson2
1Pathology, Mackay Memorial Hospital, Taipei/TW; 2Histopathology, Royal Brompton and Harefield NHS Foundation Trust, London/GB; 3Thoracic Surgery, Royal Brompton and Harefield NHS Foundation Trust, London/GB

Background: The 8thTNM pathological staging system advocates usage of the invasive size, rather than the total size, in the pT staging of pulmonary non-mucinous adenocarcinomas. However, few studies have addressed this issue regarding invasive mucinous adenocarcinomas (IMAs). Our study aimed to determine whether invasive size correlates with individual histological parameters and also whether it provides better prognostic information over total tumour size. Method: We reviewed a series of 101 cases of IMAs resected between 2000 to 2012, comprised of stage I~IV tumours. In each IMA, the percentage of each growth pattern (lepidic, acinar, papillary, solid, microcystic, and cribriform) was assessed in 5% increments. Due to the frequent multifocal nature of IMAs, the invasive size was calculated by multiplying the total tumour size with the total percentage of invasive (non-lepidic) components in all cases. The adjusted T (aT) stage, as determined by the cumulative size of invasive components, was correlated with disease-free (DFS) and overall survival (OS). Correlation with 7th and 8th T stage (using total tumour size) were also performed as comparison. Result: The 7th aT stage was positively correlated with higher host response (tumour-associated inflammation), necrosis, pleural invasion, and nodal metastasis, while the 8th stage was significantly correlated with necrosis, vascular invasion, pleural invasion, and nodal metastasis. Using aT stage for risk stratification, we found a significant difference in OS in both 7th and 8th aT stage between the subgroups (p = 0.002 and 0.006, respectively), whereas DFS failed to reach statistical significance. There was a significant difference in DFS when using the 8th stage (p = 0.002), whereas no significant difference was noted in OS. A trend was noted in DFS (p = 0.054) while OS failed to reach statistical significance when applying the 7th T staging. Conclusion: Our study showed that invasive size may be a superior prognostic indicator compared to total size, which provides a rationale for prognostic stratification of IMAs based on the extent of invasive growth patterns (or invasive size) rather than total tumour size.

P1.09-26 A CASE REPORT OF DISCORDANT MARKERS OF LUNG CANCER TUMOR CELLS: AN UNUSUAL IMMUNOPHENOTYPE OF UNCERTAIN SIGNIFICANCE
L. Gicombe, M. Keating, M. Dominguez, P. Changizadeh, E. Jabbour, B. Aswad, R. Elblizi, B. Rathore
Hematology/oncology, Roger Williams Medical Center, Providence/RI/US

Background: Introduction Non Small Cell Lung Cancer (NSCLC) is the most frequent type of lung tumor, with two major histological subtypes: adenocarcinomas and squamous cell carcinomas. Tissue transcription factor-1 (TTF-1) and Napsin A are expressed in up to 75%– 80% of primary lung adenocarcinomas respectively and the sensitivity of both p40 and p63 for squamous cell carcinoma is 92%.

Here, we report an unusual case of NSCLC with coexisting histology within the same tumor cells. Case A 65-year-old male with 50 pack smoking history underwent screening CT chest and was found to have a right upper lobe mass measuring 10 cm x 8.6 cm x 6.9 cm with narrowing of the right upper lobe bronchus in the posterior segment. Bronchoscopy and EBUS guided biopsy of the right para-tracheal node revealed NSCLC, poorly differentiated, with TTF-1, Napsin A, p40 and p63 staining positive (70–80%) for both adenocarcinoma and squamous cell carcinoma within the same tumor cells. Subsequent Brain MRI and PET did not reveal any evidence of metastatic disease and the patient was classified as T4 N1 stage IIIB disease. Discussion The line between lung adenocarcinoma and squamous cell carcinoma has already been shaken by an uncommon adenosquamous variant, but our case represents a new histologic subtype that expands on the understanding of lung cancer. Adenosquamous carcinoma (ADSCQ) of the lung is a rare classification of NSCLC with a reported incidence of 0.4–4%. Histology defined by the World Health Organization defines ADSCQ as a mixed type of tumor, with each component representing greater than 10% of the entire tumor. Based on studies by Nunnhein et al, the median survival of patients with stage III ADSCQ was 5.0 months compared to 9.0 months with adenocarcinoma and 7.8 months with squamous cell carcinoma. However, our case is different, as immunohistochemistry was positive for TTF-1, Napsin A, p40 and p63 biomarkers within the same individual tumor cells, thus diagnosing an entirely different pathology. After review of the literature, this is the third case with such co-expression. This case is important as it promotes awareness of this rare pathology. Both clinicians and pathologists need to be aware of its existence, in order to prevent misdiagnosis and treatment delays in what may be an aggressive tumor. As more cases emerge, further studies can determine incidence, prognosis, presence of driver mutations, and treatment implications.

P1.09-27 CLEAR CELL ADENOCARCINOMA SUBTYPE IS AN INDEPENDENT PREDICTOR OF BETTER SURVIVAL IN PATIENTS WITH LUNG ADENOCARCINOMA
T. Komijia1, A. Guddati2
1Section of Hematology/oncology, Tulane University School of Medicine, New Orleans/LA/US, 2Hematology/oncology, Augusta University, Augusta/GA/US

Background: Clear cell adenocarcinoma (CCA) has been considered as a rare subtype of lung adenocarcinoma. However, the 2011 World Health Organization (WHO) classification of lung adenocarcinoma proposed to discontinue CCA due to lack of available data with clinical significance. The role of CCA in patient prognosis needs to be investigated by using large data sources. Methods: Lung adenocarcinoma patients were queried from The Surveillance, Epidemiology, and End Results Program (SEER) database and were divided into CCA and 'not otherwise specified' (NOS). Cancer-specific survival was studied according to gender (male, female), age (0-69,70+), SEER specific stage A system (localized, regional and distant), year of diagnosis (1973-2000, 2001-2013), surgery (yes, no), and radiation therapy (yes, no) using Kaplan–Meier curves. Statistical difference was estimated with log-rank test using JMP software. Multivariate analysis was used to study independent predictors of cancer-specific survival. Result: A total of 198,042 patients with the diagnosis of lung adenocarcinoma were found in the SEER database of which 921 patients were diagnosed with CCA. CCA histology was significantly associated with an early year of diagnosis, younger age, early stage, surgery, and lack of radiation. Kaplan–Meier curves showed that patients with CCA histology, age 0–69, year of diagnosis 2001-2013, female gender, localized disease, undergoing surgery, and lack of radiation had significantly better cancer-specific survival (p<0.001, Log-Rank). Subset analysis demonstrated difference in cancer-specific survival between CCA and NOS histology was significant in localized and regional but not distant stage (p=0.0453, 0.0009, 0.0664, respectively).

Conclusion: Patients with CCA histology have superior survival according to the SEER analysis, suggesting its unique role in prognosis despite its removal from 2011 WHO classification.

P1.09-28 CLINICAL UTILITY OF RAPID IMMUNOHISTOCHEMISTRY FOR DIFFERENTIATION OF SOLITARY PULMONARY ADENOCARCINOMAS
H. Konno1, H. Saito2, K. Imai3, N. Kurihara2, Y. Minamiya2, H. Nanjo3, Y. Hiroshima3

Background: Intraoperative differentiation between pulmonary metastasis and primary lung cancer is necessary for determining the appropriate range of excision. Although conventional immunohistochemistry is often used for such differentiation, its intraoperative use is limited by time constraints. We therefore developed a device that enables complete and rapid immunohistochemistry (R-IHC) within 20 minutes, and used it with anti-thyroid transcription factor-1 (TTF-1) for differential diagnosis of pulmonary adenocarcinoma. However, the diagnostic accuracy of the method likely can be improved by using a combination of two or more antibodies. We therefore evaluated the clinical utility of R-IHC with combinations of antibodies for discriminating the etiology of solitary pulmonary adenocarcinomas. Method: Twenty-two patients with pulmonary adenocarcinomas treated between February 2015 and May 2017 were enrolled in this prospective study. Tumor samples were sectioned, labeled with multiple antibodies using R-IHC, and pathologically evaluated. The standard used for comparison was conventional hematoxylin eosin (HE) staining and IHC. Result: All intraoperative diagnoses made using R-IHC were consistent with the final diagnosis; that is, the accuracy was 100%. Moreover, the respective staining with each antibody corresponded between intraoperative R-IHC and IHC with the permanent specimen. For rapid intraoperative diagnosis differentiating pulmonary adenocarcinoma from lung metastasis from colon cancer, R-IHC with a combination of TTF-1, cytokeratin (CK) 7, and CK20 antibodies was highly effective. Conclusion: Our novel R-IHC method with multiple antibodies was highly effective for diagnosis and differentiation of solitary pulmonary adenocarcinomas. This technology may prove to be an important supplement to standard intraoperative pathologic diagnosis in routine practice.

P1.09-29 IN SITU GROWTH PATTERN IN LUNG ADENOCARCINOMA IS DIVISIBLE INTO DISTINCT CATEGORIES WITH DIVERGENT BIOLOGICAL AND SURVIVAL IMPLICATIONS
D. Moore1, J. Baena2, M. Sereno2, C. Smith2, L. Officer3, M. Das1, J. Le Quesne2

Background: The morphological stepwise progression of lung adenocarcinoma is well established, but little is known about the molecular events that underlie this. In particular, in situ patterns of growth are frequently seen in adenocarcinomas, and often it is not clear if this truly always represents early-stage preinvasive disease. Therefore we set out to better characterise in situ tumour growth, and to identify molecular and biological correlates of tumour invasion. Method: We constructed a prospective cohort of 964 locally held adenocarcinomas, with patient data and tissue microarrays (TMAs). Immunohistochemistry for KI67 and epithelial-mesenchymal transition markers was applied to TMAs and quantified. In situ and adjacent invasive areas of 23 early tumours were subjected to further in situ assays and laser capture microdissection. Genomic DNA was extracted and driver genes were panel sequenced. Result: We morphologically identified two distinct types of in situ tumour growth in early mixed pattern tumours: a low-grade precursor (C1 - after the classic Noguchi classification) associated with high-grade lepidic or adenocarcinoma (C2) associated with invasive growth of similar cytological grade. C1 and C2-type in situ tumour growth are sharply separated by their proliferation rate (P=0.005) and their propensity for nodal metastasis (P=0.03), suggesting that this distinction is likely to be important for future grading/growth pattern classification. Furthermore, molecular analysis supports the classification; invasive areas of C1 tumours show driver mutations which are absent from neighbouring in situ disease (4/18 cases), indicating molecular progression. In C2 cases no evidence of molecular progression was seen. The difference between low-grade precursor and high-grade in situ patterns was further investigated in our full set of 964 tumours. We find that the prognostic power of proliferation rate (Ki67) is driven almost entirely by its effects in C1 tumours, with no evidence of molecular progression in areas at most weakly predictive of patient outcome. Conclusion: We make several key findings: i) In situ disease in lung adenocarcinoma is divided into two biologically and prognostically distinct groups, with implications for our understanding of stepwise progression in lung cancer ii) These two groups can easily be separated on the basis of cellular proliferation rate ii) We identify mutations in key driver genes that are explicitly associated with the transition from in situ to invasive growth iii) Proliferation rate is a clinically valuable prognostic marker, but this may be restricted to its ability to separate these two key biologically distinct growth patterns

P1.09-30 HETEROTOPIC EXPRESSION OF CERULOPLASMIN IN LUNG ADENOCARCINOMA AND ITS POSSIBLE CLINICAL USE AS A TUMOR BIOMARKER
R. Matsuoka1, A. Shiba2, S. Sakashita1, Y. Minami1, M. Noguchi2
1Pathology, University of Tsukuba Hospital, Tsukuba/JP, 2Department of Pathology, Faculty of Medicine, University of Tsukuba, Ibaraki/JP

Background: Ceruloplasmin (CP) is a well-known copper binding protein synthesized mainly in the liver, and its expression is well known to be elevated in the serum of cancer patients and in malignant tumor cells. Lung cancer is the leading cause of cancer-related death worldwide, and adenocarcinoma is the most common histological type of lung cancer. Previously, we reported that the expression of CP mRNA was significantly higher in early but invasive adenocarcinoma than in adenocarcinoma in situ (AIS) on the basis of cDNA microarray analysis (Shiba, Int. J. Cancer 2011). However, the role of CP in lung adenocarcinoma is still unclear. Here, we examined and compared the expression of CP in various histological subtypes of lung adenocarcinoma and its correlation with patient outcome. Method: CP expression in resected specimens of lung adenocarcinoma and lung adenocarcinoma cell lines was determined using quantitative real-time PCR and western blot analysis. Immunohistochemistry for CP was carried out using 196 specimens of lung adenocarcinoma and we divided the cases into a high expression group (H-score >90: 92 cases) and a low expression group (H-score <90: 104 cases). Result: CP expression was significantly higher in invasive adenocarcinoma than in AIS. The high expression group had a significantly poorer outcome than the low expression group (p<0.01) and high expression of CP was also correlated with pathological stage, pt, and pT (p<0.01). Multivariate analysis showed that CP expression was an independent prognostic factor in lung adenocarcinoma patients (HR 1.642, 95% CI 1.050-2.568, p=0.030). CP secreted from cancer cells was also detected by western blot analysis from the liver and bronchial adenocarcinoma cell lines. Conclusion: CP is produced heterotopically by lung adenocarcinoma cells and its expression is associated with tumor progression. In view of the presence of the secreted form of CP in tumor cells, CP may be a useful biomarker for lung adenocarcinoma.

P1.09-31 PRELIMINARY EXPERIENCE WITH LIQUID BIOPSIES IN A RESOURCE CONRAINED SETTING AND ITS IMPACT ON TREATMENT DECISION MAKING
V. Muthu1, K. Prasad1, A. Bal2, N. Gupta3, D. Behera1, R. Kapoor4, N. Singh5
1Pulmonary Medicine, Postgraduate Institute of Medical Education and Research (Pgimer), Chandigarh/IN, 2Histopathology, Postgraduate Institute of Medical Education and Research (Pgimer), Chandigarh/IN, 3Cytology & Gynecological Pathology, Postgraduate Institute of Medical Education and Research (Pgimer), Chandigarh/IN, 4Radiotherapy, Postgraduate Institute of Medical Education and Research (Pgimer), Chandigarh/IN

Background: Liquid biopsies are potentially useful for molecular testing in the presence of inadequate tissue and for detection of resistance mechanisms in EGFR mutated NSCLC patients. Initial experience with liquid biopsies for advanced/metastatic NSCLC patients in a resource constrained setting is described herein. Method: Retrospective audit of liquid biopsies performed over a 21-month period for NSCLC patients at a
A series of 152 advanced NSCLC patients whose diagnosis was made by morphology and homogeneously treated was enrolled. We performed IHC staining (TTF-1, SP-A, p40, and CK5/6) of these samples and refined diagnoses into 3 subtypes. We analyzed the pathological subgroup depends on IHC staining with clinical characteristics including molecular analysis, response of chemotherapy and prognosis. Result: IHC profiling displayed that 50% of cases was favour Ad, 31% was favour SqCC, and 19% was NOS-null. On the patient background, there was no difference in age, smoking history, and PS, but there were differences in gender, and the favour Ad group had more females than other groups. EGFR mutation was significantly more expressed in favour Ad group than in other groups, and molecular targeted drugs in initial treatment were used in favour Ad group in a large proportion. Compared with favour Ad and SqCC group, NOS-null group showed significantly poorer outcome in terms of median overall survival (OS). Between favour Ad and favour SqCC group, median OS was better and 19.5 months vs 15.0 months (p = 0.018). Excluding patients using molecular targeted drugs, there was no difference in median OS between favour Ad and favour SqCC group (15.2 months vs 15.0 months p = 0.29). Pemetrexed containing platinum regimen showed similar response rate as other platinum regimen in the favour Ad cohort (43% vs 46%), whereas poorer response in the favour SqCC (0% vs 50%) and NOS-null (0% vs 24%) cohort. Although patients to be received pemetrexed containing platinum regimen compared to those to be received other platinum regimen demonstrated a trend toward good PFS in favour Ad group, there were no statistically differences. Conclusion: This study made clear chemo-responsiveness, the expression frequency of driver mutation and prognosis in NSCLC favour Ad, SqCC and NOS-null. These findings support that histological subtyping in biopsy specimen by IHC would be mandatory to archive appropriate therapy. Keywords: Subtyping, Immunohistochemistry, Non small cell lung cancer.
Conclusion: In IMA, aTS and mTS might have prognostic value for recurrence. Prospective study with larger population would be necessary to validate the results.

P1.09-35 CLINICAL IMPACT OF SYSTEMATIC INFLAMMATION AND HISTOLOGIC GRADE IN NON SMALL CELL LUNG CARCINOMA (NSCLC)

N. Tsoukalas 1, C. Giaginis 2, K. Tsapakidis 1, M. Tolia 3, I. Binas 1, E. Aravantinos 1, P. Baxevanos 1, M. Galanopoulou 2, M. Iliadis 2, I. Zerdes 1, I. Nikiforaki 2, C. Nikolau 1, I. Litos 2, M. Liontos 2, E. Tsiamis 1, D. Tsiambas 1, A. Koutsi 1, M. Liontos 2, I. Binas 1, P. Baxevanos 1, M. Galanopoulou 2, M. Iliadis 2, I. Zerdes 1, I. Nikiforaki 2, C. Nikolau 1, I. Litos 2, M. Liontos 2, E. Tsiamis 1, D. Tsiambas 1

Background: Tumor grade is an important factor of cancer outcome. Systemic inflammation has been associated with tumorigenesis and tumor aggressiveness and prognosis in several human malignancies. Cancer cells create an inflammatory peritumoral microenvironment by releasing a number of cytokines. Method: In total, 100 patients (88 males) with histologically proven NSCLC and no signs of active infection were evaluated. Tumor grade was examined and systematic inflammatory response was assessed by circulating levels of C-reactive protein (CRP), albumin, ferritin, transferring and the modified Glasgow Prognostic Score (mGPS). Patients were followed up and survival data were subsequently collected. Associations with clinicopathological, histological parameters and patients' survival were studied. Result: Histological grade was associated with tumor size, the presence of pathological lymph nodes, organ metastases and advanced disease stage (p=0.010, p<0.001 and p=0.001, respectively). There was a trend of higher histological grade in adenocarcinomas compared to squamous carcinomas (p=0.263). High tumor histological grade was also significantly associated with elevated serum CRP levels (p=0.001), hypoaalbuminemia (p=0.026), increased ferritin levels (p=0.049), abnormal mGPS (p=0.006) and a trend for reduced transferrin levels (p=0.102). In multivariate analysis, histological grade, stage, ECOG performance status and mGPS were identified as independent prognostic factors for overall survival (Cox regression analysis, p=0.002, p=0.001, p=0.010 and p=0.019, respectively). Conclusion: Our data support the association of tumor grade with the presence of systemic inflammation; two well described negative prognostic factors for NSCLC. To our knowledge this is the first time that these factors are associated with each other giving more information about the prognosis in patients with NSCLC.

Keywords: biomarker, Cannabinoid receptor CB2, Non Small Cell Lung Cancer (NSCLC)

P1.09-36 CLINICAL SIGNIFICANCE OF CANNABINOID RECEPTOR CB2 EXPRESSION IN NON SMALL CELL LUNG CANCER (NSCLC)

N. Tsoukalas 1, C. Giaginis 2, Y. Alexandrou 1, M. Tolia 3, I. Binas 1, E. Aravantinos 1, A. Koutsi 1, M. Tolia 2, E. Tsiamis 1, I. Sfianiakidou 1, G. Kyrgi 1, N. Kavanta 1, E. Tsoutsouris 2, S. Theocharis 3

Background: Cannabinoid receptor CB2 expression has been identified to be high in various malignant neoplasms and it is involved in the pathophysiological mechanisms related to carcinogenesis. Lung cancer is an important health problem and new biomarkers are needed for better patients' stratification. This study was conducted to elucidate the clinical significance of cannabinoid receptor CB2 expression in NSCLC. Method: Cannabinoid receptor CB2 expression was evaluated immunohistochemically on Tissue MicroArrays (TMAs) of 79 tissue samples from NSCLC patients and it was correlated to clinicopathological parameters and overall survival (OS). Result: 79 NSCLC patients (48 adenocarcinomas and 31 squamous carcinomas) were studied. Enhanced cannabinoid receptor CB2 expression was found in 98/3 of 48 (18.8%) adenocarcinomas and in 11 out of 31 (35.5%) of squamous cell carcinomas. Cannabinoid receptor CB2 expression was significantly associated with sex, smoking history and histological type (p<0.019, p=0.022 and p=0.032, respectively). In adenocarcinomas, cannabinoid receptor CB2 expression was correlated with overall survival (log-rank test, p=0.031), while there was a trend for correlation with tumor size (p=0.091) and lymph node metastasis (p=0.074). However, in squamous carcinomas cannabinoid receptor CB2 expression was not found to be significantly correlated with any of clinicopathological parameters or survival. Conclusion: Cannabinoid receptor CB2 receptor may be involved in NSCLC malignant transion and growth particularly in adenocarcinomas. Therefore, cannabinoid receptor CB2 receptor could be considered as a potential biomarker or a therapeutic target in NSCLC. More studies needed to elucidate the role of this molecule in NSCLC.

Keywords: cannabinoid receptor CB2, Non Small Cell Lung Cancer (NSCLC)

P1.09-37 TUMOR SPREAD THROUGH AIR SPACES (STAS) IN STAGE I LUNG SQUAMOUS CELL

H. Uraga 1, T. Fujii 1, S. Moriguchi 2, Y. Takahashi 3, K. Ogawa 1, R. Murase 1, S. Hanada 1, H. Takaya 1, A. Miyamoto 1, N. Morokawa 1, S. Fujiyori 1, T. Kono 1, K. Kishi 2

Background: Tumor spread through air spaces (STAS) has been reported as a form of tumor invasion having an unfavorable prognosis mainly in small lung adenocarcinomas, but the significance of STAS in lung squamous cell carcinomas is not well known. The aim of this study was to analyze STAS in stage I lung squamous cell carcinomas. Method: 39 completely surgically resected (lobectomy) stage I lung squamous cell carcinomas from 2005 to 2009 were included in this study. We examined all tumor edges to find floating tumor cells or clusters, STAS. A statistical analysis was performed to determine the impact of clinicopathologic parameters on STAS and to clarify the relationship between STAS and patient survival. Result: STAS was present in 18 of 39 cases (46.2%). There was a significant association between presence of STAS and shorter recurrence-free survival (RFS) in univariate analysis (104.7 months with STAS, 145.5 months without STAS). In a multivariate
Cox proportional hazards model, STAS (p=0.06) couldn’t reach a significant predictor of RFS. **Conclusion:** We found STAS about in half of resected stage I lung squamous cell carcinomas. Presence of STAS was a predictive factor of worse RFS in univariate analysis, but not significant in multivariate analysis.

**Keywords:** Tumor spread through air spaces, STAS, Squamous cell carcinoma

**P1.09-38 PULMONARY EPITHELIOID HEMANGIOENDOTHELIOMA (EHE) WITH VON RECKLINGHAUSEN DISEASE**

S. Yamamoto, M. Kuwahara
Department of Thoracic Surgery, Medical Kouhoukai Takagi Hospital, Okawa City/JP

**Background:** Malignant thoracic epithelioid tumors are an uncommon. The heterogenous group of tumors that include the low to intermediate grade epithelioid hemangioendothelioma(EHE) and epithelioid angiosarcoma under examination of the morphologic and immunohistochemical features. We here reported a rare case of multiple pulmonary epithelioid hemangioendothelioma with von Recklinghausen disease.

**Method:** Case A 34-year-old male was admitted to our hospital with an abnormal shadow in the bilateral lung field. He has von Recklinghausen disease, and non-smoker. The laboratory data and physical examination are normal. A chest computed tomography scan showed multiple nodal lesions of 2 mm to 12 mm in diameter in the bilateral lung fields. **Result:** Thoracoscopic partial resection of the right middle lobe was performed. The tumor was well-circumscribed lesion. In the pathological findings, sections showed a proliferation of epithelioid tumor cells having oval-shaped and vesicular nuclei, prominent nucleoli and pale eosinophilic cytoplasm arranged in small nested or cord patterns. Intracytoplasmic vacuoles some of which contain erythrocytes were recognized. Mitotic figures were rarely seen. In the immunohistochemical examination, the tumor cells were positive for CD31 and CD34, but negative for D2-40, CAM5.2, Ber-EP4, alpha-SMA, desmin, S-100 protein, NSE, TTF-1, calretinin, claudin-4, CD36 and c-kit. RT-PCR analysis showed CAMTA1-WWTR1 fusions was negative. Those features were consistent with pulmonary epithelioid hemangioendothelioma(EHE) is rare tumor and there is no report in the literature of EHE with von Recklinghausen disease. The behavior of this neoplasm is uncertain, so the methods of diagnosis and treatment will demand to do careful observation and further examination.

**Keywords:** von Recklinghausen disease, Malignant thoracic epithelioid tumors, Pulmonary Epithelioid hemangioendothelioma (EHE)

**P1.09-40 METASTATIC ENDOMETRIAL SARCOMA PRESENTING AS A SPONTANEOUS PNEUMOTHORAX AND MASQUERADING AS A PULMONARY BLASTOMA.**

Department of Medicine, Rutgers University New Jersey Medical School, Newark/US

**Background:** For the proper evaluation of pulmonary cavitary lesions, it is essential to obtain an adequate assessment of the patient’s clinical history. Imaging studies can be equivocal and adequate pathological diagnosis can also be challenging. This is particularly important in the case of metastatic lung tumors with extra-thoracic origin, such as certain gynecologic malignancies, which—owing to their late metastatic potential—can be noted years after removal of the primary tumor, causing a misdiagnosis. **Method:** We illustrate this scenario with an interesting case of an endometrial stromal sarcoma which presented as a cavitary lesion causing a spontaneous pneumothorax and initially diagnosed as a pulmonary blastoma. **Result:** 44 year old woman presented with a one day history of left sided chest pain and shortness of breath. The pain was sudden, sharp and associated with dyspnea. The patient denied any fevers, chills, cough, hemoptysis, weight loss, recent travel, sick contacts or tuberculosis. A chest X-ray demonstrated a large left-sided pneumothorax and a chest CT showed a left upper lobe cavitary lesion (Figure 1). Subsequently, a left upper lobe and lingual wedge resection were performed and biopsies of the cavity lesion were sent. The initial pathological impression was that this was a pulmonary blastoma with heterologous leiomyosarcomatous differentiation. However, further history revealed that the patient had chronic anemia and menometrorrhagia secondary to uterine fibromas and had a total abdominal hysterectomy one year prior to presentation. This finding prompted a review of the pathological specimen and positive immunoreactivity to estrogen/progesterone receptors (ER+/PR+), and CD10+ provided the alternate diagnosis of a metastatic low-grade stromal sarcoma of endometrial origin. Patient followed with medical oncology and gynecology and is currently undergoing hormonal therapy.

P1.11 SCREENING AND EARLY DETECTION
MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.11-01 THE NELSON TRIAGE ALGORITHM APPLIED TO A CHINESE BIOPSIED POPULATION: A PILOT STUDY
H. Beaumont1, J. Hu1, D. Yang2, N. Wang2, P. Li1, S. Lu2, W. Shi1, D. Ge1, T. Faye1, C. Bai1
1R&D, Median Technologies, Valbonne/FR; 2Zhongshan Hospital Fudan University, Shanghai/CN; 3Department of Respiratory Medicine, Zhongshan Hospital Fudan University, Shanghai/CN

Background: The Nelders-Leuven Longkanker Screening Onderzoek (NELSON) lung cancer screening study sequentially tests nodules’ volume, growth and doubling time with an increasing screening interval length. For now, classification performances of NELSON are known only for a European population with specific eligibility criteria. We tested the NELSON trial triage algorithm on a cohort of biopsied Chinese patients. Method: Our study utilized a data subset from the NCT02693496 clinical trial. The data consisted of onsite prospective evaluations of 85 Chinese patients who underwent CTs within an average time interval of 259 days (Min=63; Max=1092). NCT02693496 readers applied the Chinese consensus low-dose CT management guidelines with referral to biopsy, when required. The eligibility criteria were: All genders; age: 18 to 90 years old; chest lesion <3cm. Smoking status was not considered. In our subset of 85 patients, 15 nodules from 15 patients were biopsied: 10 were confirmed malignant; of these, 3 were solid nodules (SN) and 7 were sub-solid nodules (SSN). Five biopsied nodules were confirmed benign. Of the whole cohort, 11.8% (10/85), were declared positive patients. The 75/85 others (88.2%) were declared negative by radiologists and/or pathologists. Using the Lesion Management Solution (LMS) platform (Median Technologies), we retrospectively re-processed the subset of images to analyze NELSON sensitivity at detecting malignant lung nodules. We used R CRAN software for statistics and Chi-Squared test for non-parametric comparison of two sample proportions. Result: We found 12.9% of patients (11/85) displayed no findings. There were 155 detected findings in the remaining 74 patients, which were documented as: 5.2% (8/155) benign as NODCAT I: 9.0% (14/155) pleural; 27.7% (43/155) SSN and 58.1% (90/155) SN. According to NELSON triage, five Patients were declared positive. In the biopsy-confirmed nodules group (10 patients), four were detected by NELSON, one at baseline. All patients displaying SNs were detected (3/3) whereas only one (1/6) patient displaying SSNs was detected. NELSON was better at detecting SNs (p=0.036). One patient with confirmed negative biopsy patient (1/5) was declared positive by NELSON with one SN and one SSN. Additionally, one SN in patients without biopsy was declared positive at baseline using NELSON triage algorithm. Conclusion: Prevalence of different nodule types in this Chinese population was different from the observations of the original European NELSON trial. The NELSON triage algorithm correctly classified patients with malignant SNs but misclassified most patients displaying SSNs. Further studies are needed to better evaluate SSNs by NELSON.

Background: Examination of microRNAs expression in plasma could be useful in screening and in early detection of non-small cell lung cancer (NSCLC). One of the most important enzymes in miRNA biogenesis are Dicer and Drosha. Disrupted expression of miRNA with ability to reciprocal regulation of Dicer and Drosha could participate in cancer development. Method: Plasma expression of mir-27-3p, mir-31, mir-182 and mir-195 was analysed in 138 Polish NSCLC patients (median age 65 years, 83 male and 55 female) and in 45 healthy people (median age 62 years, 28 male and 17 female). 57 (41.3%) NSCLC patient were in I-IIIA stage and 81 (58.7%) patients were in IIIB-IV stage. Relative expression of microRNAs between studied groups was compared using U Mann-Whitney test. For assessment of diagnostic accuracy (test sensitivity and specificity), the receiver operating curves (ROC) with area under curve (AUC) analysis were generated. Result: We demonstrated that plasma levels of miR-31, miR-31-3p and miR-195-5p were significantly higher (p<0.00001), p<0.00001 and p=0.0003 respectively) and miR-195 significantly lower (p=0.000002) in NSCLC patients in comparison with healthy donors. Moreover, patients with early stages (I-IIIA) of NSCLC showed significantly higher expression of miR-27a-3p (p<0.000001), miR-31 (p=0.0003) and miR-182 (p=0.000003) than healthy persons. Expression of miR-195 was significantly lower in patients with early stages (I-IIIA) of NSCLC than in healthy donors (p<0.000001). AUC for mir-31 was 0.95 (94% sensitivity and 81% specificity, p<0.000001), for miR-31-3p was 0.71 (73% sensitivity and 61% specificity, p=0.006) and for miR-195 was 0.82 (74% sensitivity and 80% specificity, p=0.00001).

**P1.11-04 SIZE MEASUREMENT VARIABILITY OF SOLID COMPONENT OF LUNG ADENOCARCINOMA**

K. Hamanaka
Thoracic Surgery, Shinshu University School of Medicine, Matsumoto/JP

**Background:** In the current TNM classification for lung cancer, the solid size is used for tumor diameter measurement as dense component. However, in daily practice, it is sometimes difficult to measure the solid size, so the variability between the observer may increase, and therefore it is presumed that the measurement variability between radiological and pathological size becomes large particularly in subsolid nodules. In this study, we investigate the interobserver variability and differences between the radiological and pathological tumor size in lung adenocarcinoma.

**Method:** Interobserver variability: We assessed 47 cases of subsolid type lung adenocarcinoma operated in our department from January to December 2016. Six physicians including surgeons and radiologists measured the solid and total size using preoperative CT and assessed the interobserver measurement variability. Furthermore, we assessed the interobserver variability using 5 subclassified patterns of the tumor.

**Radiological-pathological variability:** Radiological-pathological variability in measurement of solid size in adenocarcinoma using database of 554 surgical cases from January 2010 to Jun 2017 was investigated. We also assessed the stage migration using radiological and pathological T stage classified by only tumor size. **Result:** The mean interobserver variability of six observers of 47 cases was 9.7 mm in solid size, and 7.7 mm in total size. The tumor images were subclassified into the following 5 patterns: ① minimally invasive, ② peribronchovascular, ③ spicula/atelectasis, ④ adjacent to cystic lesions, ⑤ pneumonia-like consolidation. To correct for differences in mean tumor diameter in each pattern, comparison was made using coefficient of variation (CV) calculated by SD/mean. The pattern of minimally invasive (①) became the largest value for CV in the measurement of solid size. The mean radiological-pathological variability of 554 cases was 5.9 mm in solid size, and 5.4 mm in total size. In cases of Tis, T1mi in T stage, and adenocarcinoma in situ (AIS), the CVs of solid size of the lung adenocarcinoma was larger than those of total size. **Conclusion:** The accurate staging rate was 41.8%, and upstage were seen in 28.8% in all cases. **Conclusion:** Interobserver measurement variability of solid size of the lung adenocarcinoma was larger than those of total size. The difference between radiological and pathological invasion size tend to be larger in small-sized tumor as Tis and T1mi, and low-grade malignant potential lesions as AIS and MIA. Therefore, a careful consideration must be given to decide the management plan of these cases.

**P1.11-05 METABOLOMIC PROFILING FOR SECOND PRIMARY LUNG CANCER AMONG LUNG CANCER SURVIVORS**

S. Han1, L. Su2, N. Diao3, D. Christiani3, H. Wakelee1
1Department of Medicine, Stanford University School of Medicine, Stanford/US, 2Environmental Health, Epidemiology, Harvard School of Public Health, Boston/MA/US, 3Environmental and Occupational Medicine and Epidemiology Program, Harvard School of Public Health, Boston/MA/US

**Background:** Survivors of lung cancer (LC) have a high risk of developing second primary lung cancer (SPLC), the incidence of which is 4-6 times higher than that of initial primary lung cancer (IPLC). While national lung screening guidelines have been established for IPLC, no consensus guidelines exist for LC survivors. Furthermore, the factors that contribute to SPLC risk have not yet been established. The purpose of this study is to examine the potential of metabolomics to identify non-invasive blood-based biomarkers for SPLC screening. **Method:** We applied an untargeted metabolomics approach based on a liquid chromatography-tandem mass spectroscopy (UPLC-MS/MS) method to discover metabolic biomarkers using blood serum samples from the Boston Lung Cancer Study. Our study cohort consisted of 177 subjects diagnosed with IPLC between 1992 and 2012 and who survived >5 years after the initial diagnosis. The cohort included 82 SPLC cases and 95 matched controls (i.e., IPLC patients without SPLC as of Dec, 2017) based on the age of initial diagnosis, sex, race, and smoking status. We applied random forest and Welch’s t-test to identify metabolic features associated with SPLC risk and to build a risk prediction model. **Result:** Our analysis detected 1008 named and 316 unnamed metabolites. The metabolites that were statistically significantly associated with SPLC risk and to build a risk prediction model. **Conclusion:** We identified potential metabolic biomarkers for SPLC among LC survivors. A risk stratification approach based on metabolic biomarkers can be potentially useful for identifying high-risk LC survivors to be screened by CT.

Background: In incidence lung cancer screening rounds, new lung nodules are a regular finding, with a higher lung cancer probability than baseline nodules. A substantial number of screen-detected nodules is classified as perifissural nodule (PFN). Previous studies showed that baseline PFNs and PFNs in clinical settings represent non-malignant lesions such as intrapulmonary lymph nodes. Whether this is also the case for incident PFNs is unknown. This study evaluates all newly detected nodules in the Dutch Belorussian randomized-controlled NELSON study with respect to perifissural classification and lung cancer probability. Method: All NELSON participants with a new solid nodule detected in screening round 2, 3 or 4 (1, 3 and 5 years after baseline, respectively), were enrolled in this study. Nodules were classified into three groups: intraparenchymal, vessel attached or fissure attached. Screening CT scans of participants with lung cancer based on a nodule classified as fissure attached, were re-evaluated by two radiologists (4 and 6 years of experience) to check whether this nodule was a typical, atypical or non-PFN. The fissure-attached cancers were re-detected based on positive bronchography (14), and the radiologists were blinded for the final nodule outcome. In case of discrepancy, a third radiologist (13 years of experience) arbitrated. Result: 1,484 new nodules were detected in the second, third and final NELSON screening round in 949 participants (77.4% male, median age 59 [interquartile range: 55–63]). 1,393 nodules (93.8%) were benign based on 2 year follow-up or pathology; 96 of these (6.9%) were fissure attached. Lung cancer diagnosis was made in 74 new nodules in 74 participants (7.8% of participants with a new nodule). Nine lung cancers (12.1%) were fissure attached and re-evaluated by the radiologists. None of the fissure attached malignant new nodules was classified as a typical or atypical PFN. Conclusion: None of the lung cancers that originated from a new nodule in the NELSON study was classified as a typical or atypical PFN. Our results suggest that also in the case of a new PFN, it is highly unlikely that these PFNs will be diagnosed as lung cancer.

P1.11-07 UTILITY OF THE MAXIMUM CT VALUE IN PREDICTING INVASIVENESS OF PURE GGNs

J. Ichinose1, M. Naka1, Y. Matsura1, M. Muni1, K. Nakagawa1, M. Nishio1, S. Okumura1

1Thoracic Surgical Oncology, The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan; 2Department of Thoracic Medical Oncology, The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan

Background: In the current TNM classification of lung cancer, the pulmonary lesions presenting pure ground-glass nodules (GGNs) without solid component are classified as cTis tumor. However, some of them are pathologically diagnosed as invasive adenocarcinomas. This study aimed to predict the histological invasiveness using the computed tomography (CT) value in pure GGN lesions. Method: 138 patients underwent resection of pure GGNs between 2011 and 2016. The maximum diameter and CT value were measured using a computer graphics support system. We selected the axial section which showed the densest component of each GGN. The CT value was measured separately in several areas including portions of apparent vessels and bronchi manually. We analyzed the correlation between the CT value of pure GGNs and the histological diagnosis, such as atypical adenomatous hyperplasia (AAH), adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA) and invasive adenocarcinoma (Ad). Result: The number of the patients with AAH, AIS, MIA and Ad was 6, 81, 45 and 6, respectively. 37% of the pure GGN lesions contained histologically invasive component and 4% of them were classified as Ad. One tumor of Ad had lymphatic invasion, while there was no case with vascular invasion. 37 lobectomies, 38 segmentectomies and 63 wedge resections were performed and there was no recurrence. In comparison between the preinvasive lesions (AAH and AIS) and the invasive lesions (MIA and Ad), the latter was significantly correlated with the higher age of the patients (60 ± 9 years vs 67 ± 7 years), the larger total size (12 ± 5 mm vs 16 ± 5 mm), the higher maximum CT value (-388 ± 125 HU vs -208 ± 129 HU) and the presence of pleural indentation (odds ratio, 2.8). When the cut-off point of the maximum CT value in predicting histological invasiveness was set at -300 HU using the ROC curve analysis, the sensitivity, specificity, positive predictive value and negative predictive value were 80%, 77%, 67% and 87%, respectively. The 100% of Ad and the 78% of MIA were correctly estimated. Conclusion: Invasive adenocarcinoma and MIA accounted for 4% and 33% of the pure GGN lesions, respectively. The maximum CT value was correlated with the pathological diagnosis. It may be useful as a predictor of histological invasiveness. The threshold at -300 HU can be the basis of the computer-aided automatic diagnosis.

Keywords: GGN, invasiveness, CT value

P1.11-08 AI BASED MALIGNANCY PREDICTION OF INDETERMINATE PULMONARY NODULES: ROBUSTNESS TO CT CONTRAST MEDIA

Q. Chometon1, L. Pickup2, C. Arteta1, H. Peschl1, A. Ather2, M. Tsakok1, C. Santos1, P. Novotny1, J. Declerck1, F. Gleeson2, T. Kadi2

1Optelum Ltd, Optellum Ltd., Oxford/GB; 2Oxford University Hospitals NHS Foundation Trust, Oxford/GB

Background: Artificial Intelligence (AI) based malignancy prediction of indeterminate pulmonary nodules has previously demonstrated to perform well on screen-detected nodules imaged with low-dose, non-contrast CT. This study aimed to assess the impact of contrast media on the classification performance of such a system. Method: A Convolutional Neural Network (CNN) was trained on the US National Lung Screening Trial (NLST) which contained only low-dose non-contrast screening images, selecting all nodules 6mm and greater in size (14761 benign nodules from 5972 patients; 932 cancer from 575 patients). A CNN classifier was trained using Deep Learning on this data to produce a malignancy score per nodule. For validation, an independent retrospective dataset of incidentally detected solid nodules was used. None of the patients had a cancer diagnosis within the past 5 years, and all had fewer than 5 nodules. The dataset contained 571 nodules from 425 patients, including 83 cancer from 39 patients. A CT was considered to be contrasted if the mode HU value within an ROI placed at the aortic arch was greater than 60HU. This resulted in two groups: the non-contrast group had 313 nodules from 276 patients (16 cancer from 14 patients); the contrast group had 258 nodules from 221 patients (26 cancer from 25 patients). The overall efficacy was assessed using Area-Under-the-ROC-Curve analysis (AUC) for each group. Result: The AUC on the non-contrast CT group was 0.96 (95% CI 0.93 to 0.98) and 0.95 (95% CI 0.90 to 0.98) on the contrast CT group. Further analysis revealed that excluding high contrast cases, where the HU in the aortic arch was greater than 300HU (40 nodules from 38 patients; 4 cancer), resulted in an AUC of 0.97 (95% CI 0.92 to 1.00). Conclusion: The CNN classifier seems to be robust to the presence of contrast media with only a moderate reduction in performance. Excluding cases with high contrast restored the performance, although, with only 38 nodules excluded by this, the result may be not statistically significant. These results indicate that a CNN developed to predict pulmonary nodule malignancy, that has been trained on low-dose, non-contrast enhanced CT images, may be used with CT images with moderate levels of contrast without retraining.

Keywords: pulmonary nodules, diagnosis, AI
Background: The aggregate 5-year survival of lung cancer patients is <20%, partly because most patients present with advanced disease. LDCT screening and algorithmic management of patients with incidentally-detected nodules are two methods for early detection, but rigorous evaluation is needed for effective implementation. We compared patients with lung cancer diagnosed via LDCT vs. ILNP vs. neither in a lung cancer-endemic US region.

Method: We compared demographic, clinical, and treatment characteristics of patients diagnosed via LDCT and ILNP with those treated in a multidisciplinary program (MDP) who were not diagnosed through either early detection program. LDCT screening was implemented in 2015 using Medicare eligibility criteria. In the ILNP, navigators and a multidisciplinary team prospectively tracked patients with suspicious findings flagged by radiologists, using Natural Language Processing software. All patients were diagnosed within the same healthcare system from 2015-2018. Statistical comparisons used chi-square, Fishers Exact, and ANOVA.

Result: Lung cancer diagnoses included 111 from 5,954 ILNP scans, 11 from 400 LDCT scans (1.9% v 2.8%, p=0.21), and 273 from MDC. An additional 40 (10%) LDCT scans were Lung RADS 3 or 4. Average ages were 70/68/68 years for ILNP/LDCT/MDC and patients with lung cancer diagnosed via ILNP and LDCT were 43%/64%/48% male. African Americans were underrepresented in both early detection groups (23%/9%/36%; p=0.0111); Medicare patients were over-represented (83%/91%/42%; p<0.001). Active smoking was highest in LDCT (73%, 59 pack-year average), but similar between ILNP and MDC (39%, 50 pack-year average vs 36%, 63 pack-year average). Early detection cases were more frequently adenocarcinoma (61%/ 55%/48%; p=0.0595) with smaller lesions (2.2cm/2.0cm/2.4cm; p=0.001). Stage I/II cancers were more likely with early detection (71%/99%/42%; p=0.001), leading to substantially higher rates of surgical resection (75%/73%/31%; p<0.001). Median time from lesion detection to treatment initiation was similar between groups (61/74/58 days, p=0.48). 62% of patients with lung cancers diagnosed by ILNP and LDCT were not eligible for LDCT screening. The most common disqualifying criteria were a 30 pack-year smoking history (unmet: 41% ILNP/ 41% MDC) and active smoking within 15 years (unmet: 41% ILNP/ 27% MDC).

Conclusion: Lung cancers diagnosed by ILNP and LDCT had better prognosis than the MDC, were Lung RADS 3 or 4. Average ages were 70/68/68 years for ILNP/LDCT/MDC and patients with suspicious findings flagged by radiologists, using Natural Language Processing software. All patients were diagnosed within the same healthcare system from 2015-2018. Statistical comparisons used chi-square, Fishers Exact, and ANOVA. Median time from lesion detection to treatment initiation was similar between groups (61/74/58 days, p=0.48). 62% of patients with lung cancers diagnosed by ILNP and LDCT were not eligible for LDCT screening. The most common disqualifying criteria were a 30 pack-year smoking history (unmet: 41% ILNP/ 41% MDC) and active smoking within 15 years (unmet: 41% ILNP/ 27% MDC).

P1.11-10 OPTIMIZING RADIOMICS FEATURES BY MINIMIZING BOUNDARY EFFECTS AND NORMALIZING WITH OPPOSITE LUNG TISSUE CHARACTERISTICS

S. Seyyedi1, J. Mayo2, S. Atkar-Khattra1, R. Yuan1, S. Lam1, C. Macaulay4

1 Integrative Oncology, British Columbia Cancer Agency Research Centre, Vancouver/ BC/CA; 2 Radiology, University of British Columbia, Vancouver/CA. 3 Integrative Oncology, BC Cancer Agency, Vancouver/BC/CA. 4 Integrative Oncology, British Columbia Cancer Agency Research Centre, Vancouver/CA

Background: For wide adoption of LDCT screening it is thought that CAD will likely be necessary. We hypothesize that CAD features that minimizes perimeter effects and normalizes nodule CT features using the lung parenchyma from the opposite lung will improve the ability to determine nodule malignancy.

Method: We have developed a CAD system that includes lung tissue segmentation, nodule detection and feature extraction from the segmented nodule, the segmented nodule minus the perimeter transition pixels (Core), and the opposite lung parenchymal tissue. (See Figure 1). We use the Mann-Whitney U test to compare the texture features of the mirrored region in the opposite lung with the opposite lung parenchyma from the opposite lung will improve the ability to determine nodule malignancy.

Result: In total, 34 early small suspect baseline nodules detected as part of the PanCan screening trial were used, these include 17 nodules proven to be cancer and 17 nodules that resolved on follow-up scans. The comparison of classification ability of features from nodules without edge vs. nodules with edge pixels reveals that the core features show better classification ability for 76 out of the 136 calculated features. Performing a leave-one-out LDA classifier cross-validation approach in using core features, gives an accuracy of 76% with only 1 feature through 3 features, and 82% with 4 features. However, repeating the same experiment for core plus edge features, shows accuracy of 67% with only 1 feature, 73% with 3 features, 79% with 4 features. Normalizing the core texture features by the texture features of the mirrored region in the opposite lung shows an improved classification ability for 52 out of the 89 texture features.

Conclusion: In this study, the results suggest using the nodule core improves feature classification as does normalizing of the nodule by the mirrored region in opposite lung.

P1.11 SCREENING AND EARLY DETECTION

MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.11-12 INTERROGATION OF AN EXHALED MICRORNA PANEL FOR LUNG CANCER RISK ASSESSMENT

S. Spivack

Pulmonary Medicine, Albert Einstein College of Medicine, Bronx, New York City/US

Background: There is a need for non-invasive airway-based biomarkers in lung carcinogenesis for both risk assessment of the ex-smoker, and earlier diagnosis. Exhaled breath condensate (EBC) contains airway lining fluid molecules, including nucleic acids, presumably in part from epithelial cellular origins. MicroRNAs play important regulatory roles in many processes, including carcinogenesis. Here we further develop and begin validation of the detection of microRNAs in EBC from lung cancer patients and controls. Method: EBC was collected non-invasively, using a handheld commercial RTube® device in a clinical series of ambulatory subjects. We generated a 40 mRT panel based on literature-derived microRNAs, bronchial brushed microRNA discovery by collaboration, and a lung parenchymal tissue discovery effort we have performed using
The ability of liquid biopsy to detect circulating tumor nucleic acids has been an especially valuable in the treatment of patients with NSCLC since well-characterized variants inform small molecule chemotherapeutic options. EIRM is a signal amplification technology that allows direct detection of mutations in native plasma and saliva with high amplification or sequencing. Previously published work demonstrated a near perfect correlation between biopsy and EIRM results for the Exon19 del and p.L858R mutations in EGFR in late stage NSCLC patients. In this study we investigated the performance of EIRM in patients early stage (I and II) NSCLC patients. Method: Plasma samples were collected from 33 healthy controls with biopsy proven benign lung masses and 21 stage I and II NSCLC patients with biopsy proven EGFR mutations. The samples were immediately centrifuged and frozen. The samples were then blinded and sent for EIRM analysis. Result: There were 12 biopsies positive for p.L858R (11 stage 1 and 1 stage II) and 9 positive for Exon 19 del (7 stage 1A, and 2 stage II). Using statistically derived cut-off to optimize sensitivity and specificity, there were 2 false positives (both for p.L858R) in the controls yielding an overall specificity of 95%. For the 2 SNP Mutation assay, the sensitivity was 92% for the p.L858R with only one negative in 12 samples in a patient with stage 1 and 77% for Exon 19 del with 2 negatives in 9 samples in a single patient each for stage 1 and 2. Conclusion: The preponderance of positive results in this study for stage I NSCLC shows the sensitivity of 94% for the 2 most common mutations is remarkable for patients with Stage 1 lung cancer and a correspondingly low tumor burden and more importantly at a potentially curable stage. We are in the process of improving the technical performance of this assay and adding additional variants to the panel in order to increase clinical utility. These data are promising for the potential use of the EIRM platform for the purposes of drug selection, disease recurrence, follow-up of indeterminate lung nodules from spiral CT screening programs, and/or population screening.

Keywords: early stage lung cancer, liquid biopsy, EGFR
BACKGROUND: False positive or negative examinations and high early recall rates are important factors in the performance of lung cancer screening programs. How low-dose chest tomography (LDCT) scans are interpreted and classified may impact these metrics. **Method:** LDCT examinations for participants in the Alberta Lung Cancer Screening Study (ALCSS) were reviewed by a chest radiologist with information entered in a synoptic report. Baseline scans were classified according to highest risk of malignancy as per the PanCAN nodule risk calculator (NRC) and according to the Lung-RADS scheme. A positive scan was any baseline LDCT requiring any intervention beyond an annual screening examination (NRC nodule with ≥5% malignancy risk; Lung-RADS category ≥3). In the calculation of sensitivity, false negative scans could include reader error or classification errors (NRC <5% or Lung-RADS <3 but cancer present regardless of perceived appropriateness of resulting management).

**Result:** Seven hundred and sixty-six participants in the ALCSS underwent LDCT screening and had no prior chest CT imaging on file. Median follow-up was 572 days (+/-205) with lung cancer confirmed in 16 (2.1%) participants. The early recall rate was 9.0% for NRC and 11.2% for Lung-RADS (p=0.044), with fair concordance between each approach (kappa 0.554). Sensitivity for malignancy was 87.5%/87.5% (difference 0%, 95%CI -0.4%–0.4%) and specificity 92.6%/90.4% (difference 2.2%, 95%CI 0.2%–4.3%) for NRC and Lung-RADS respectively. False negative screens were due to reader error (same case in both systems); and classification error (one different case for each system).

**Conclusion:** Performance of both the NRC and Lung-RADS in the ALCSS was very good, with NRC resulting in a lower early recall rate. Application of the NRC demonstrated increased specificity over Lung-RADS without a change in sensitivity for lung cancer detection. Lung cancer program performance may be improved with the use of the PanCAN NRC classification.

**P1.11-16 MODIFIED LUNG-RADS IMPROVES PERFORMANCE OF SCREENING LDCT IN A POPULATION WITH HIGH PREVALENCE OF NON-SMOKING-RELATED LUNG CANCER**

**F.Z. Wu, T. En Kuei**

Radiology Department, Kaohsiung Veterans General Hospital, Kaohsiung City/TW

**Background:** We proposed a modification of the ACR Lung Imaging Reporting and Data System (Lung-RADS) to clarify the characteristics of subsolid nodules with categories 1–11, and to compare the diagnostic accuracy with Lung-RADS and National Lung Screening Trial criteria in an Asian population with high prevalence of adenocarcinoma. **Method:** We analyzed a retrospective cohort of 1978 consecutive healthy subjects from August 2013 to October 2014 (1084 men, 894 women). Lung-RADS categories 2 and 3 were modified to include subcategories of 2A/2B/2C and 3A/3B/3C, respectively. Clinical information and nodule characteristics were recorded. Receiver operating characteristic curves were used to compare diagnostic accuracy at different cutoffs. **Result:** Thirty-three subjects (30 nonsmokers) had pathology-proven adenocarcinoma spectrum lesions in the follow-up period (1.6 ± 0.5 years). Modified Lung-RADS, using modified Lung-RADS category 2C as cutoff, had an area under the curve (AUC) of 0.973 in predicting adenocarcinoma spectrum lesions (sensitivity of 99.1%, specificity of 89.3%), which was significantly higher than that of Lung-RADS (AUC = 0.815, P < .001) and National Lung Screening Trial (AUC = 0.906, P < .001). Furthermore, modified Lung-RADS showed an AUC of 0.992 in predicting invasive adenocarcinoma (sensitivity of 99.5%, specificity of 97.8%) when category 3B was used as cutoff. **Conclusion:** Modified Lung-RADS may substantially improve sensitivity while maintaining specificity for detection of adenocarcinoma spectrum lesions in an Asian population. Compared to Lung-RADS, it has enhanced ability to differentiate invasive from indolent adenocarcinoma by more refined subclassification of subsolid nodules using two cutoff values of category 2C and 3B. The effect of using modified Lung-RADS in clinical practice must be carefully studied in prospective large cohort studies.

**P1.11-17 DISCRIMINATING LESS INVASIVE LESIONS OF EARLY-STAGE LUNG ADENOCARCINOMA BY THREE-DIMENSIONAL COMPUTED TOMOGRAPHY ANALYSIS**

**N. Yoshiyasu, F. Kojima, K. Hayashi, T. Bando**

Thoracic Surgery, St. Luke’s International Hospital, Tokyo/JP

**Background:** In the revised TNM classification for non-small cell lung cancer, the clinical T factor is specified by the maximum diameter and by the diameter of the solid component for subsolid nodules. However, as radiological measurement of the solid part is sometimes difficult, errors can occur among observers. If less invasive lesions can be truly predicted using computed tomography (CT) images, it will be very useful for determining treatment strategies. Hence, we investigated the ability to detect less invasive lesions in pathologically early-stage adenocarcinomas by evaluating the whole tumor based on three dimensional (3D) images from high-resolution CT (HRCT). **Method:** Among patients who underwent lung resections for primary lung cancer between February 2014 and December 2016 in our institution, we retrospectively reviewed 127 patients with pathological stage 0 or IA adenocarcinoma. All the lesions were divided into two groups: the less invasive group comprised adenocarcinoma in situ (AIS) and minimally invasive adenocarcinoma (MIA), and the invasive group comprised invasive adenocarcinoma. Radiological occupied lesion volumes (cm3) were semi-automatically calculated using 3D-CT volumetry, which included the data of CT values and voxels. The following six factors were also evaluated using voxel-based histogram analysis (VHA): % solid (the ratio of the volume with CT values above -300 Hounsfield units to the whole CT volume), mean CT values, variance, kurtosis, skewness, and entropy. Using multivariate logistic regression analysis, the relationship between these seven variables and pathological less invasive lesions were analyzed to prepare an optimal model for detecting the less invasive group. **Result:** Among 131 lesions, there were 39 lesions in the less invasive group (AIS/MIA = 16/23) and 94 in the invasive group. In univariate analysis, all the seven variables were significantly different between the two groups. Multivariate analysis using three variables revealed an odds ratio of 0.52 (95% confidence interval [CI]: 0.34-0.79, p = 0.002) for radiological lesion volume (cm3), 0.94 (95% CI: 0.89-0.99, p = 0.016) for % solid, and 1.58 (95% CI: 1.12-2.3, p = 0.01) for kurtosis. The optimal cut-off values were less than 8.2% for % solid, less than 5.8 cm3 for lesion volume, and greater than 3.6 for kurtosis. The area under the receiver operating characteristic curve was 0.92 (95% CI: 0.88-0.97) with the model, which achieved a 90% sensitivity and 84% specificity. **Conclusion:** Semi-automated objective discrimination of less-invasive lung adenocarcinomas can be achieved with high accuracy using VHA based on 3D-HRCT.

**P1.11-18 A CLASSIFICATION-BASED MACHINE LEARNING METHOD REVEALS EXOSOMAL miRNA BIOMARKERS FOR PATIENTS WITH PULMONARY GROUND GLASS NODULE**

**J. Zhang1, J. Xu2, J. Su1, R. Fu1, S. Jiang1, S. Dong1, L. Liao1, X. Yang2, F. Qin2, F. Li3, L. Xiong1, Y. Wu1, W. Zhong1**

1Guangdong Lung Cancer Institute, Guangdong General Hospital and Guangdong Academy of Medical Sciences; Southern Medical University, Guangzhou/CN, 23D Medicines Inc, Shanghai/CN

**Background:** Non-invasive detection of lung cancer is of critical importance but has proven challenging due to the rate of false-negative diagnosis with current tests. Plasma exosomes have been implicated as a non-invasive diagnostic source. However, little high throughput screening has been done in the early-stage lung cancer and problems such as bias of enrollment, less rigorous identification exists. This study aimed to reveal the plasma exosome-derived miRNA biomarkers for early-stage lung adenocarcinomas by three-dimensional computed tomography analysis.
**BACKGROUND:** With the rapid advances of low-dose computed tomography (LDCT) screening for lung cancer, the opportunity to detect subcentimeter non-small cell lung cancer (NSCLC) is gradually increasing. The results of many previous studies have shown that even subcentimeter NSCLCs are not always in the early stage. Thus, it is quite important for us to judge the possibility of malignancy for these patients, even the tumor size is less than 10mm. However, subcentimeter lung cancer is hard to diagnose only via biopsy and imaging features because of its tiny size. Chronic inflammation is well established as a hallmark in lung carcinogenesis. In our previous study, B lymphocyte chemoattractant (BLC), is found to be slightly associated with the risk of subcentimeter lung adenocarcinoma. The aim of the present study is to evaluate the correlation between TNF receptor type II (TNFRII) and the risk for subcentimeter lung adenocarcinoma, and the efficacy of diagnosing subcentimeter lung cancer after combining TNFRII and BLC.

**METHOD:** Inflammatory biomarkers were measured in 71 subcentimeter lung adenocarcinoma patients and 71 age-, sex- and smoking-matched healthy controls by using the Luminex bead-based assay. The mean (standard deviation or SD) age of patients was 56.01 (8.91) years, and 73.20% of them were female patients (n=52). Never smokers accounted for 85.96% of patients (n=57). The expression level of TNFRII is significantly down-regulated in subcentimeter lung adenocarcinoma patients compared with the healthy controls (P<0.001). And the results were validated by oncomine data mining analysis. Elevated levels of TNFRII were associated with an 89% reduced risk for subcentimeter lung adenocarcinoma. (OR=0.11, 95% CI: 0.04-0.30, P=2.4*10^-5 ). BLC was associated with a 2.70-fold (95% CI: 1.31-5.58, P=7.0*10^-3 ) increased risk of subcentimeter lung adenocarcinoma for the comparison of patients in the higher-level group with the lower-level group. To yield more information, the BLC/TNFRII ratio was created to examine their prediction for the risk of subcentimeter lung adenocarcinoma, and as expected there was a 35- fold increased risk for patients in the higher-level group relative to patients in the lower-level group. Further ROC curve analysis revealed significant differences between the two groups.

**CONCLUSION:** This preliminary analysis highlights the potential of exosomal miRNA based liquid biopsy for non-invasive detection of early-stage lung cancer. The SVM model seems could effectively distinguish pulmonary nodules, but needs further verified.

**KEYWORDS:** liquid biopsy, Exosome, ground glass nodule
Background: Previous study indicated that an optional anti-cancer drug for the treatment in pretreated patients with small-cell lung cancer (SCLC) is amrubicin. However, no prospective studies have evaluated amrubicin in chemo-naïve elderly or poor-risk patients with SCLC. Therefore, this study aimed to evaluate the efficacy of amrubicin as first-line chemotherapy for elderly or poor-risk patients with extensive-disease SCLC (ES-SCLC). Method: Patients with chemotherapy-naïve ES-SCLC received multiple cycles of 40 mg/m² amrubicin for 3 consecutive days every 21 days. The primary endpoint was the overall response rate (ORR), and the secondary endpoints were progression-free survival (PFS), overall survival (OS), and safety. Result: Between March 2011 and August 2015, 36 patients were enrolled in this study. Each patient received a median of four treatment cycles (range, 1–6 cycles). ORR was 52.8% [95% confidence interval (CI), 37–69]. The median PFS and OS periods were 5.0 months (95% CI, 3.4–6.6 months) and 9.4 months (95% CI, 5.2–13.6 months), respectively. Neutropenia was the most common grade 3/4 adverse event (69.4%), with febrile neutropenia developing in 13.9% of patients. No treatment-related death occurred. At the time of starting second-line chemotherapy, 19 of 22 patients (86%) had significantly improved or maintained their performance status (PS) relative to their PS at the time of starting amrubicin monotherapy as first-line chemotherapy (P = 0.027). Conclusion: The results of the present study suggest that amrubicin could be considered as a viable treatment option for chemotherapy-naïve elderly or poor-risk patients with ES-SCLC.

P1.12-01 SINGLE-ARM MULTI-CENTER PHASE II STUDY OF APA TINIB IN PATIENTS WITH ES-SCLC AFTER SECOND/THIRD-LINE CHEMOTHERAPY

Background: The survival of patients (pts) with extensive-stage small-cell lung cancer (ES-SCLC) was poor. And the standard treatment strategies have not yet been established for those who failed from second/third-line chemotherapy. Apatinib, a vascular endothelial growth factor receptor-2 (VEGFR-2) tyrosine kinase inhibitor, has been shown anti-cancer activity and manageable toxicities in several solid cancers. Method: A single-arm multi-center phase II study was designed to determine the efficacy and safety of apatinib in pts with ES-SCLC after second/third-line chemotherapy (clinical trial information: NCT02945852). The inclusion criteria mainly included aged 18-75 years; pathologically confirmed SCLC; received chemotherapy with two or three regimens previously, including first-line platinum-based regimen. Pts were treated with apatinib 500 mg/day po, until tumor progression or lack of tolerability. One treatment cycle was 28 days long. The full analysis set included patients who received at least one cycle of treatment. Treatment interruptions or dose reductions were allowed when grade 3 hematologic or grade 2 non-hematologic toxicities occurred. The primary endpoint is progression-free survival (PFS); secondary endpoint includes the safety of apatinib, overall survival (OS), objective response rate (ORR) and disease control rate (DCR). Result: As of Mar 2018, 40 pts from 3 institutions were recruited into the trial. Median age was 60 years, and 37 pts were male (92.5%). 17/40 (42.5%) pts experienced dose reduction or treatment interruptions. Followed up to Apr 26, 2018, the median duration of apatinib treatment was 80 days and 36 pts were eligible for assessing tumor responses. In the 36 pts, 8 (22.2%) pts achieved partial responses [PR], 10 (55.6%) pts achieved stable disease [SD] and 8 (22.2%) pts were assessed as progressive disease [PD]. The ORR was 22.2% (8 pts PR) and the DCR was 77.8% (8 pts PR, 20 pts SD). During the follow-up, a total of 25 pts died. The median PFS and OS was 86 days and 105 days, respectively. The most common adverse events were anemia (69.4%, 25/36), hand-foot syndrome (61.1%, 22/36), oral ulcer (5.6%, 2/36) and elevated alanotransferase (5.6%, 2/36). Conclusion: In this prospective phase II trial, apatinib showed encouraging durable response rates and survival in patients with ES-SCLC after second/third-line chemotherapy, with an acceptable safety profile.

P1.12-03 A PROSPECTIVE STUDY OF APA TINIB IN ADVANCED SMALL CELL LUNG CANCER PATIENTS FAILED FROM TWO OR MORE LINES OF CHEMOTHERAPY

Y. Liu1, X. Hu1, S. Zou1, J. Li1, P. Liu1, Y. Wang1, X. Hao1, Y. Shi1, J. Jiang1

Background: Small lung cancer (SCLC), a highly malignant neoplasic, chemoresponsive disease. For SCLC patients who with worsening status after second-line treatment, there is currently no affirmative and widely accepted chemotherapy regimen. Apatinib is a novel oral multi-target small-molecule TKI mainly targeting the intracellular ATP-binding domain of VEGFR-2, which has a significant effect of anti-angiogenesis to suppress the growth of tumors. This study evaluated the efficacy and safety of Apatinib in SCLC patients who failed from second- or further-line chemotherapy. Method: Data was collected from the files of patients treated with Apatinib 500mg qd who diagnosed with advanced SCLC and failed from second or more lines of chemotherapy. Efficacy assessed after one cycles (4 weeks), then every two cycles (8 weeks) once again. The primary endpoint was PFS and the tumor response was determined according to the RECIST 1.1. PFS were graphed by Kaplan-Meier curves of the Kaplan-Meier curves of the primary PFS and OS were graphed by Kaplan-Meier curves of the presence of the primary endpoint. Result: 22 patients were enrolled from November 10, 2016 to April 18, 2018, the number of patients that can be evaluated is 19. One patients obtained partial response, and 15 obtained stable disease, representing a DCR of 84.11%. Median PFS was 140 days (95% confidence interval [CI] 94.84–185.16). Although only one patient showed PR, all the patients’ target lesions were reduced. A total of 46 AEs were reported during the trial, grade 3–4 AEs were hypertension (9.09%), leukopenia (4.55%) and proteinuria (4.55%) which most could be relieved by dose reduction.

P1.12-04 A PH3 STUDY OF NIRAPARIB AS MAINTENANCE THERAPY IN 1L PLATINUM RESPONSIVE EXTENSIVE DISEASE SMALL CELL LUNG CANCER PATIENTS

S. Lu1, L. Jiang1, X. Ai2, J. Li3, X. Dong4, D. Zhang2, Q. Liu6

1Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/CN, 2Department of Respiratory, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/CN, 3Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai/CN, 4Department of Medical Oncology, Cancer Institute and Hospital, Chinese Academy of Medical Sciences, Beijing/China, 5Department of Clinical Pharmacology, Shanghai Jiao Tong University, Shanghai/CN, 6Department of Medical Oncology, Tongji Hospital, Tongji Medical College, Huazhong University of Science & Technology, Wuhan/CN, 7Zai Lab (Shanghai) Co., Ltd., Shanghai/CN

Background: Small cell lung cancer (SCLC) accounts for 15% of lung cancer, characterized by early dissemination and rapid development of chemo-resistant disease after platinum response (60-80%). Less than 2% of extensive disease SCLC (ED-SCLC) patients survive 5 years. The bi-allelic loss or inactivation of TP53 and RB1 is common in SCLC, the poly(ADP-ribose) polymerase-1 (PARP-1), a critical DNA damage repair enzyme, is highly expressed in SCLC, and SCLC is sensitive to platinum based chemotherapy, suggesting that the defect in DNA damage repair pathways plays an important role in SCLC. ZL2306/Niraparib is a highly selective PARP-1/2 inhibitor which was exclusively licensed for development in China by Zai Laboratory from TESARO. In SCLC PDX model, niraparib demonstrated anti-tumor activities as monotherapy. In addition, niraparib demonstrated promising tumor growth inhibition in maintenance post platinum treatment in platinum sensitive SCLC PDX models. Clinically, in phase III NOVA study, niraparib demonstrated clear clinical benefit as maintenance treatment by significantly extending progression free survival in all platinum-sensitive recurrent ovarian cancer patients regardless gBRCA or HRD status which led to the approval by FDA and EMA in ovarian cancer. It is suggested that niraparib maintenance therapy could provide potential clinical benefit in platinum responsive SCLC. ZL-2306-005 is a randomized double-blind multicenter phase 3 study to evaluate the efficacy and safety of niraparib versus placebo as maintenance therapy in ED-SCLC patients who have had responses to platinum based chemotherapy. Method: Approximately 550 Chinese patients with histologically or cytologically confirmed ED-SCLC who have achieved either complete response or partial response to their platinum based chemotherapy to their newly diagnosed disease will be randomized (2:1) to 2 groups, receiving either ZL-2306 or placebo in ZL-2306-005 study. Patients need to complete 4 cycles of etoposide + cisplatin/ carboplatin. All patients will be stratified by gender, LDH level and history of prophylactic cranial irradiation. ZL-2306 will be started with 300mg PO QD for patients with a baseline body weight ≥77 kg and a baseline platelet count ≥150,000/μL, or 200 mg PO QD for patients with a baseline body weight <77 kg or a baseline platelet count <150,000/μL based on RADAR analysis in NOVA study. Patients will remain on treatment until disease progression or intolerable toxicity. The co-primary endpoints are PFS assessed by investigator, CFI, QoL, safety and tolerability. Result: Section not applicable Conclusion: Section not applicable

MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.12-05 EFFICACY OF PERIOPERATIVE CHEMOTHERAPY FOR HIGH-GRADE NEUROENDOCRINE TUMORS

H. Ogawa1, Y. Tanaka2, Y. Kitamura1, H. Tanaka1, Y. Nishioka1, S. Tane1, W. Nishio1, Y. Maniwa2, M. Yoshimura2

1Chest Surgery, Hyogo Cancer Center, Akashi City/JP, 2Kobe University Hospital, Kobe/JP

Background: Large-cell neuroendocrine carcinoma (LCNEC) and small-cell lung cancer (SCLC) are categorized as high-grade neuroendocrine tumors (HGNETs). There have been few studies to show the efficacy of perioperative chemotherapy for HGNET as a single entity. Method: We retrospectively reviewed the medical records of patients who underwent tumor resection and were diagnosed with HGNEC by Hyogo Cancer Center (Akashi, Japan) and Kobe University Hospital (Kobe, Japan) between January 2001 and December 2016. Overall survival (OS) was estimated by the Kaplan–Meier method. Multivariate analyses using a Cox proportional hazards model were performed to search for prognostic factors for HGNEC. Propensity score matching was performed to compare the OS between the treatment groups. Result: We identified 197 patients who underwent surgery and who were diagnosed with HGNEC. Forty-three patients were excluded for the following reasons: pathological stage 4 or incomplete resection (n=25), synchronous multiple cancers (n=14),...
and insufficient medical records (n=5) We finally analyzed 153 HGNEC patients (LCNEC n=95, SCLC n=58). Seventy patients (LCNEC n=34, SCLC n=36) received perioperative chemotherapy. All of them received a platinum-based anticancer drug, and 80% received combined treatment with irinotecan or etoposide (n=56). The 5-year OS rates of the surgery plus chemotherapy and surgery alone groups were 75.5% and 34.7% (P<0.01), respectively. The HR for death in the surgery plus chemotherapy group was 0.34 (95% CI 0.20-0.56; P<0.01) in comparison to the surgery alone group. The multivariate analysis revealed that perioperative chemotherapy (HR 0.30, P<0.01), sublobar resection (HR 2.04, P=0.04), and lymph node metastasis (HR 3.54, P=0.01) were independently associated with survival. After adjustment for the patients’ background characteristics by propensity matching, the 5-year OS rates of the surgery plus chemotherapy group were significantly higher than those of the surgery alone group (78.7% and 32.9%; P < 0.01). The HR for death in the surgery plus chemotherapy group was 0.33 (95% CI 0.19-0.58; P<0.01) in comparison to the surgery alone group. Conclusion: Surgical resection combined with perioperative chemotherapy was considered to be effective for HGNEC. Sublobar resection might increase the risk of death in HGNEC patients. Therefore if the general condition of the patient permits, perioperative chemotherapy should be performed, and the extent of resection in the treatment of HGNEC should be lobectomy or more.

P1.12-06B ROVALPITIZUMAB TESIRINE VS TOPOTECAN IN PATIENTS WITH ADVANCED SMALL CELL LUNG CANCER FOLLOWING 1st-LINE CHEMOTHERAPY

Abbvie Inc., North Chicago/US

Background: Small cell lung cancer (SCLC) represents ~15% of lung cancers. Standard therapy most often consists of a platinum-based therapy + a second agent (etoposide). Initial response rates are high but not durable. Treatment for relapsed patients is limited, but includes topotecan. However, efficacy of topotecan is suboptimal and there is a high unmet need in this population. Rova-T is a DLL3-targeting IgG1 monoclonal antibody tethered to a toxic DNA crosslinker. Rova-T has antitumor activity in relapsed SCLC patients, and was well-tolerated.

Thus, we are investigating Rova-T vs topotecan as a 2nd-line therapy in advanced SCLC. Method: This is a Phase 3, randomized, open-label, multicenter study (NCT03061812) to assess efficacy, safety, and tolerability of Rova-T vs topotecan. Approximately 411 patients will be enrolled and randomized 2:1 between arms. Arm A regimen: 0.3 mg/kg Rova-T intravenous (IV) on Day 1 + 8 mg dexamethasone orally, twice a day on Day 1-3, every 28 days, and administered for 4 cycles with up to 2 additional cycles permitted. Arm B: 1.5 mg/m² topotecan (or per local label) IV on Days 1-5 of each 21-day cycle: administered until disease progression. Patient eligibility: ≥18 years; confirmed, advanced/metastatic SCLC with first disease progression following frontline standard therapy; DLL3-high tumor expression; ECOG 0-1; no prior exposure to a pyrrolobenzodiazepine-based drug or topotecan, irinotecan, or other topoisomerase I inhibitor. Efficacy endpoints include progression-free survival, overall survival, objective response rate, duration of response, and patient-reported outcomes. 1. Rudin et al., Lancet Oncol, 2016. Result: Section not applicable Conclusion: Section not applicable

P1.12-08 THE EFFECT OF CISPLATIN VERSUS CARBOPlatin ON CANCER OUTCOMES FOR SMALL CELL LUNG CANCER PATIENTS IN A POPULATION-BASED COHORT

T. Aquin1, S. Banerji2, O. Bucher3, D. Dawe4
1Max Rady College of Medicine, University of Manitoba, Winnipeg/CA, 2Department of Hematology and Medical Oncology, Cancercare Manitoba, Winnipeg/CA, 3Department of Epidemiology, Cancercare Manitoba, Winnipeg/CA

Background: Small cell lung cancer (SCLC) is associated with high rates of mortality and treatment involves chemotherapy. In non-small cell lung cancer, using cisplatin results in superior response and survival compared to carboplatin, but causes more toxicity. Little research regarding this drug choice in SCLC exists, but available studies suggest equivalent survival. Nevertheless, many oncologists continue to use cisplatin preferentially. Method: Using the population-based Manitoba Cancer Registry, we identified SCLC cases diagnosed from 2004 to 2016 in Manitoba and compared rates of survival outcomes for patients treated with chemotherapy. Demographics, tumour response, and treatment toxicity were compared between cisplatin and carboplatin treated groups. Overall survival (OS) and progression free survival (PFS) were evaluated using multivariate Cox proportional hazard methods. Likelihood of completing chemotherapy was also assessed using multivariable logistic regression. Result: Of the 531 patients identified, 139 (26.2%) received carboplatin and 392 (73.8%) received cisplatin as part of first line chemotherapy. More patients who received carboplatin had poor performance status (33.7% v 7.4%), extensive stage disease (58.3% v 42.3%), and extensive stage disease (69.8% v 54.1%), all p<0.01. Unadjusted median OS was 224 v 322 days for carboplatin and cisplatin. Multivariable adjusted analysis for OS using cisplatin patients only, adjusting treatment effects for age showed hazard ratios for carboplatin completers – 0.65 (0.43-0.98), cisplatin completers – 0.69 (0.47-1.00), and carboplatin incompleters – 1.00 (0.64-1.55), p = 0.13. For PFS carboplatin completers – 1.07 (0.60-1.90), cisplatin completers – 0.83 (0.51-1.36), and carboplatin incompleters – 0.96 (0.64-1.46), p = 0.59. There was not significant difference between carboplatin and cisplatin in likelihood of completing chemotherapy, when adjusted for other patient characteristics - 0.75 (0.47-1.22), p=0.26. Those treated with carboplatin had significantly less neutropenia (57.6% v 74.3%), nephrotoxicity (2.9% v 13.5%), neurotoxicity (0.7% v 12.0%), and nausea/vomiting (28.1% v 42.6%) associated with treatment, all p<0.01. Conclusion: In a real world, population-based setting, carboplatin appears to be an equally effective treatment option for SCLC, facilitating
take a seat as a standard treatment option for limited-stage small cell lung cancer (LS-SCLC). We aim to search the association between radiation parameters and long-term outcomes in LS-SCLC patients undertook more than 45 Gy of TRT. Method: One hundred and one patients with LS-SCLC who completed TRT between March 2005 and March 2014 were reviewed retrospectively. Median age was 64 years (43-80) and male to female was 88 vs. 12. Stage IIIIA was 30 and IIIB was 55, respectively. TRT was performed using 3-dimensional conformal radiation therapy (3DCRT) and delivered using 2Gy single fraction per day in 73.2% of patients. The median dose TRT was 50 Gy (45-65), and all patients received concurrent chemotherapy respectively, grade 3 and 4 leukopenia (35.4%) patients. Result: The median survival for all patients was 26.9 months. Local failure occurred in 41 patients (40.5%), and distant metastasis was noted in 54 patients (53.4%). The 3-year local control, progression-free survival (PF), and overall survival (OS) were 52.0%, 29.5%, and 54.3%, respectively. Survival analysis, the American Joint Cancer Committee on Stage (p<0.001), timing of TRT (≤2 vs. >2 cycles, p=0.017), tumor response (CR vs. PR, p=0.015), the duration from the start date of chemotherapy to the end of TRT (SER) (≤70 vs >70 days, p=0.025), and PCI (p=0.003) were the significant predictors in PF. Multivariate analysis revealed that stage (hazard ratio [HR], 3.61; 95% CI, 2.15-6.07) was the only significant factor in PFS and stage (HR, 2.49; 95% CI, 1.56-3.98), SER (HR, 1.93; 95% CI, 1.22-3.07), PCI (HR, 0.52; 95% CI, 0.33-0.84), and tumor response (HR, 1.76; 95% CI, 1.12-2.77) were the significant predictors in OS. There was one fatal radiation pneumonitis. Grade 3 radiation pneumonitis and esophagitis was shown in 27% (7.6%) patients vs. 25% (6.9%) patients, respectively. Grade 4 radiation pneumonitis was shown in 30 (29.7%) vs. 11 (10.8%) patients and febrile neutropenia was 9 (8.9%) vs. 1 (0.9%) patients, respectively. Conclusion: SER less than 70 days was a significant predictors of OS in LS-SCLC patients who received more than 45 Gy of TRT concurrently with chemotherapy. We could not find any significant positive survival benefits of TRT dose or BED escalation in our patients groups.

P1.12-09 THE EFFECT OF SITE OF FIRST CHEMOTHERAPY ON SMALL CELL LUNG CANCER PATIENT OUTCOMES
R. Rittberg¹, T. Aquin², S. Green³, O. Bucher⁴, S. Banerji³, D. Dawe⁴
¹Department of Internal Medicine, University of Manitoba, Winnipeg/MB/CA, ²Max Rady College of Medicine, University of Manitoba, Winnipeg/CA, ³Department of Hematology and Medical Oncology, Cancercare Manitoba, Winnipeg/CA, ⁴Department of Epidemiology, Cancercare Manitoba, Winnipeg/CA

**Background:** Small cell lung cancer (SCLC) is characterized by a rapid doubling time and high responsiveness to chemotherapy (CT) with a rapid relapse. Due to the sensitivity of SCLC to CT, it is one of the few malignancies treated in acutely ill patients admitted to hospital with a poor performance status (PS). However, there is little available information on the outcomes and toxicity experienced by patients with SCLC who require initial CT as an inpatient. **Method:** A retrospective cohort study was conducted evaluating patients consecutively diagnosed with SCLC in Manitoba from 2004 to 2013 treated with platinum-doublet CT. Patient demographics, staging, treatment, CT toxicities, Eastern Cooperative Oncology Group (ECOG) PS, treatment response, and survival were collected using the Manitoba Cancer Registry and chart review. Outcomes of progression free survival (PFS) and overall survival (OS) were evaluated based on site of first CT (inpatient versus outpatient) and PS. **Result:** 530 patients received CT for SCLC with 82 patients (15%) receiving initial CT as an inpatient. Sixty-three percent of patients received the full CT course, compared to 81% of outpatients, (p=0.0006). Outpatients had a greater likelihood of responding to CT (p=0.0043). Neutropenia, febrile neutropenia, thrombocytopenia, nephropathy and fatigue were more frequent less than 40% in outpatient cohort (p=0.0001), (p=0.0040), (p=0.0001), (p=0.0001) and (0.0068). For inpatients, OS at 12, 24 and 60 months was 22%, 9% and 7% versus outpatient OS of 43%, 20% and 9%, (each p<0.0001). Median PFS and OS were longer for outpatients, 212 versus 161 (p=0.0035) and 323 versus 192 days, (p=0.0003). Patients with poorer ECOG PS had shorter PFS and OS; with a median PFS for PS 0, 1-2, 3-4 of 316, 203 and 147 days, (p=0.0001) and median OS for PS 0, 1-2 and 3-4 of 498, 303 and 179 days, (p=0.0001). On multivariate analysis, ECOG PS was an independent predictor of outcome, (p=0.0005) while site of first CT was not significant when ECOG PS was included, (p=0.3494). **Conclusion:** Although SCLC patients initially treated as inpatients had shorter PFS and OS, some experienced long term survival, including a 7% five-year survival. CT toxicities were not more common for inpatients. This validates that administration of CT in hospital can be considered as these patients may have a meaningful long-term response to therapy if properly selected. As previously identified in the literature, this data demonstrated that patients with poorer ECOG PS have shorter PFS and OS.

P1.12-10 PATTERNS OF CURATIVE CHEMO-RADIOThERAPY REGIMEN AND IMPACTS ON THE OUTCOME OF LIMITED STAGE SCLC IN A CANADIAN INSTITUTION: 2010-2015 DIAGNOSES
A. Elegbede¹, M. Dean², G. Bebb³
¹Oncology, University of Calgary, Calgary/CA, ²Medical Oncology, University of Calgary, Calgary/AB/CA, ³Oncology, Tom Baker Cancer Centre, University of Calgary, Calgary/AB/CA

**Background:** Curative intent chemotherapy and radiotherapy (ChemoroRT) is the widely recommended treatment for limited stage (LS) small cell lung cancer (SCLC) follow by prophylactic cranial irradiation (PCI) in those who responded to the initial therapy. LS-SCLC is however characterized by high relapse rate with only about 20% surviving to 2 years. Our objective is to examine the characteristics, treatment patterns and overall survival of LS-SCLC for patients diagnosed within a 5-year period at the Tom Baker Cancer Centre, Canada, prior to wide adoption of emerging treatment options including surgery and immunotherapy in the curative and palliative settings respectively. **Method:** Using the Glans-Look Lung Research (GLR) database, we defined the clinical and demographic features of patients diagnosed with LS-SCLC from 2010 to 2015, determined the rate of systemic treatment uptake, and investigated the impact of PCI, curative intent, and palliative treatments on overall survival. We summarized our findings with descriptive statistics (including Fisher’s Exact test) and Kaplan Meier survival curves using SPSS. Statistical significance was set at p value < 0.05 and 95% confidence intervals. **Result:** About a third (107/349, 31%) of patients diagnosed with SCLC from 2010 to 2015 were LS-SCLC, with median age of 67 years. Over the 5-year period, systemic treatments uptake rates and patterns fluctuates. Overall, > 50% received ChemoroRT and 65% of the ChemoroRT group also received PCI. Curative concurrent RT dose 45 – 55Gy, 25 fractions schedule was more common (55%). Few stage T1a-2a, NO-1 LS-SCLC had surgery (5%). Thirty eight percent of those who received initial curative intent treatments further received some palliative treatments for disease recurrence or progression (8% (2/26) initial Surgery ± Adjuvant & 92% (24/26) ChemoroRT). The median overall survival for the cohort was 24 months (p < 0.001). There were more than 50% survival at 60 months for patients treated with curative 15 fractions concurrent ChemoroRT (p < 0.001). **Conclusion:** Most patients received ChemoroRT while a few had surgery. Concurrent 15 fractions ChemoroRT may offer better survival benefits than the 25 fraction schedule. The impact of PCI on LS-SCLC and other survival outcomes will be presented.

P1.12-11 2010 – 2015 EXTENSIVE STAGE SCLC DIAGNOSES IN A CANADIAN INSTITUTION: BASELINE CHARACTERISTICS THAT IMPACT ON THE OVERALL SURVIVAL
A. Elegbede¹, M. Dean², G. Bebb³
¹Oncology, University of Calgary, Calgary/CA, ²Medical Oncology, University of Calgary, Calgary/AB/CA, ³Oncology, Tom Baker Cancer Centre, University of Calgary, Calgary/AB/CA

**Background:** Small cell lung cancer (SCLC) represents only about 13 – 15% of lung cancers but has posed significant challenges due to minimal progress in therapeutic development prior to the recent advent of immunotherapy. Our objective is to establish baseline characteristics and overall survival of Extensive SCLC (ES-SCLC) based on the current conventional therapy for patients diagnosed within a 5 year period at the Tom Baker Cancer Centre, Canada. This information will be crucial in assessing the effectiveness of novel anti-immune checkpoint treatment strategies. **Method:** Using the Glans-Look Lung Research (GLR) database, we defined the clinical and demographic features of patients diagnosed with ES-SCLC from 2010 to 2015, determined the rate of systemic treatment uptake, and investigated the impact of prophylactic cranial irradiation and palliative treatments on overall survival. We summarized our findings with descriptive statistics (including Fisher’s Exact test) and Kaplan Meier curves using the SPSS. Statistical significance was set at p value < 0.05 and 95% confidence intervals. **Result:** Among the 2010 to 2015 SCLC diagnoses, 68% (242/349) were ES-SCLC with median age of 68 years. Close to 90% received some form of palliative treatment. Chemotherapy (CT) was a major component of palliative treatments (89% overall, (190/214): 41% CT only, 22% CT & thoracic radiotherapy (RT) and 38% RT-Other sites). About a third (32%) of patients who received 1st line CT also had a 2nd line (range between 1 – 4 lines). Prophylactic cranial irradiation (PCI) uptake rates were 38% and 11% for CT only and CT & RT respectively. The median overall survival for ES-SCLC within the cohort was 7 months (p < 0.001). **Conclusion:** In contrast to advanced stage non-small cell lung cancers, there was high rate of systemic treatment uptake for ES-SCLC. Overall however, < 20% (41/242) followed through with PCI. Other outcome findings will be presented and discussed.

**Keywords:** Extensive Stage SCLC, SCLC Treatment, SCLC Overall Survival
We calculated overall survival at 30 and 90 days along with the median survival. Result: We identified 10,487 titles, 161 were included. Cisplatin + etoposide (n=87 (49.4%)), carboplatin + etoposide (n=36 (20.5%)) and cisplatin + irinotecan (n=23 (13.1%)) were predominantly reported. The commonly reported cause of death within 30 days was neutropaenic sepsis (n=27), disease progression (n=11) and cardiovascular (n=8). Across both stages 30-day survival was 98% (95% CI 98-99%) whilst 90-day was 95% (95% CI 94-96%). Thirty and 90-day survival showed similar patterns to study factors as median survival (summarised in Table 1). Limited stage median survival was 18.1 months (95% CI 17.0-19.1). Studies that administered thoracic radiotherapy and PCI had better survival than those that did not. Studies giving carboplatin + etoposide or included poorer PS (0-3) individuals had inferior survival. PCI timing did not show survival differences. Extensive stage median survival was 9.6 months (95% CI 8.9-10.3). This was augmented in studies that gave irinotecan + cisplatin and were conducted in Asia. There were no survival differences by cisplatin/carboplatin or median participant age.

P1.12-12 A SYSTEMATIC REVIEW AND META-ANALYSIS OF EARLY AND LATE SURVIVAL FOLLOWING ANTI-CANCER THERAPIES FOR SMALL CELL LUNG CANCER
G. Jones1, K. Elimian1, D. Baldwin1, T. Mckeever1, R. Hubbard1
1Epidemiology and Public Health, University of Nottingham, Nottingham/GB, 2Respiratory Medicine, Nottingham University Hospitals, Nottingham/GB

Background: Treatments for small cell lung cancer (SCLC) have not changed significantly in contrast to non-small cell where it is more individually tailored. Current guidelines generally have a one size fits all approach to chemotherapy. We conducted the largest systematic review and meta-analysis in SCLC to evaluate early and median survival by different study factors. Method: We searched EMBASE and MEDLINE for randomized controlled trials and observational cohort studies which reported survival following platinum doublet chemotherapy for SCLC.

We calculated overall survival at 30 and 90 days along with the median survival. Result: We identified 10,487 titles, 161 were included. Cisplatin + etoposide (n=87 (49.4%)), carboplatin + etoposide (n=36 (20.5%)) and cisplatin + irinotecan (n=23 (13.1%)) were predominantly reported. The commonly reported cause of death within 30 days was neutropaenic sepsis (n=27), disease progression (n=11) and cardiovascular (n=8). Across both stages 30-day survival was 98% (95% CI 98-99%) whilst 90-day was 95% (95% CI 94-96%). Thirty and 90-day survival showed similar patterns to study factors as median survival (summarised in Table 1). Limited stage median survival was 18.1 months (95% CI 17.0-19.1). Studies that administered thoracic radiotherapy and PCI had better survival than those that did not. Studies giving carboplatin + etoposide or included poorer PS (0-3) individuals had inferior survival. PCI timing did not show survival differences. Extensive stage median survival was 9.6 months (95% CI 8.9-10.3). This was augmented in studies that gave irinotecan + cisplatin and were conducted in Asia. There were no survival differences by cisplatin/carboplatin or median participant age.

Conclusion: Neutropenic sepsis accounts for the majority of 30-day deaths and was mostly reported with cisplatin + etoposide. Our findings broadly support guideline recommendations but suggest certain sub-populations e.g. Asian individuals, benefit from targeted treatment with irinotecan + cisplatin. Age should be re-considered as a treatment-deciding factor in extensive stage.

P1.12-13 IMPACT OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE ON THE SURVIVAL OF PATIENTS WITH EXTREME-DESIREASE SMALL CELL LUNG CANCER

1Internal Medicine, Korea University Guro Hospital, Seoul/KR, 2Hemat-Oncology, Korea University Medical Center, Ansan-Si/KR, 3Internal Medicine, Korea University Anam Hospital, Seoul/KR

Background: Small cell lung cancer (SCLC) is a highly fatal lung malignancy. Cigarette smoking is an important cause of SCLC, and most patients have heavy smoking history. Also, smoking is an established risk factor of chronic obstructive pulmonary disease (COPD). Therefore, patients who are diagnosed with SCLC have high chance to coincide with COPD. However, the coincidence rate of COPD and SCLC are not known well. Moreover, the impact of COPD on the mortality of patients with SCLC, especially for patients with extensive disease (ED) is not reported yet. Therefore, we conducted investigation of clinical features and survival differences between patients who were diagnosed with SCLC with COPD or patients without COPD.

Method: We retrospectively reviewed medical records of patients who were diagnosed with SCLC-ED and received treatment between 2002 and 2016 at the Korea University Hospital. Among the 182 patients who were diagnosed with SCLC-ED and received palliative chemotherapy, 125 patients who had pulmonary function test report and previous or current smoking history were included. According to the global initiative for chronic obstructive lung disease (GOLD) classification, COPD was defined as FEV1/FVC <0.70. Result: Among 125 patients, COPD was present in 69 (55.2 %) patients. Among the patients with COPD, 48 (69.5%) patients did not know the COPD before diagnosis of SCLC. Patients in the COPD group were older (mean age ± standard deviation, 68.9 ± 8.2 versus 65.6± 8.4 years; p=0.03). The mean FEV1(L) and predicted percent of FEV1 were 1.7L (67.9%) in COPD group and 2.9L (81.2%) in non-COPD group. Gender, body mass index, amount of smoking, ECOG performance status and neutrophil to lymphocyte ratio were not different between the two groups. Median overall survival of all patients was 8.6 months (95% confidential index (CI), 7.7-9.5). Median overall survival of the first-line chemotherapy between patients with COPD and patients without COPD was not statistically different (p=0.326). Median progression-free survival of the first-line chemotherapy between the two groups also were not different (p=0.372). In the analysis of COPD group, FEV1(L) and percent of FEV1 did not affect survival among the patients with COPD (p=0.289). Conclusion: In conclusion, the presence of COPD at the diagnosis of SCLC-ED does not affect survival outcome in patients who were treated palliative chemotherapy. Even though the patients have severe obstructive pulmonary disease, active chemotherapy has to be considered with priority for the patients with SCLC-ED.

P1.12-14 SURVIVAL OF PATIENTS WITH SMALL-CELL LUNG CANCER UNDERGOING SURGICAL RESSECTION

S. Kikuchi1, J. Okamura2, K. Araki2, T. Yanagihara3, K. Nakaoka4, Y. Kitazawa1, N. Kobayashi5, Y. Goto6, Y. Minami4, M. Onizuka2, H. Ichimura1, Y. Sato1
1Department of Surgery (Thoracic Surgery), University of Tsukuba, Tsukuba Ibaraki/JP, 2Department of Diagnostic Pathology, University of Tsukuba, Tsukuba Ibaraki/JP, 3Department of Respiratory Surgery, University of Tsukuba, Tsukuba Ibaraki/JP

Background: Small-cell lung cancer (SCLC) prognosis remains poor despite improvements in diagnosis and therapy. Current standard treatment for limited stage SCLC is concurrent chemoradiotherapy, however recent retrospective studies indicate that surgery is an important treatment modality. We analyzed the overall survival and prognostic predictors of survival in patients who underwent surgical resection.

Method: We reviewed the clinical course of 42 SCLC patients who had undergone complete surgical resection in our hospital between May 1989 and October 2017. Stages were determined or reclassified according to the eighth version of the TNM staging system. Result: The mean age at pulmonary surgery was 68.0 years, 37 (88.1%) patients were male, and 2 (4.8%) were never smokers. Preoperative diagnosis of cancer was achieved in 18 (42.9%) patients. The surgical procedures included wedge resection in 6 (14.3%) patients and lobectomy in 36 (85.7%). There were no perioperative deaths and major postoperative complications. Thirty-two patients (76.2%) received adjuvant chemotherapy and three patients (7.1%) underwent prophylactic cranial irradiation. Pathological stages were 2 cases in IAI, 5 in IA2, 1 in IA3, 6 in IB, 3 in IIA, 8 in IIB, 13 in IIIA, 3 in IIIB, 1 in IV A. The pathology of primary tumor demonstrated 30 (71.4%) pure SCLC and 12 (28.6%) combined SCLC. The overall 5-year survival rate was 57.2% after an average follow-up of 58.7 months. Survival was associated with: female gender (p=0.048), preoperative normal serum level of CEA (p=0.013), normal serum level of SCC (p=0.001), pR0 resection (p=0.02), adjuvant chemotherapy (p<0.001), and histological pure SCLC (p<0.001). In preoperative factor, multivariate Cox proportional hazard model analysis revealed that overall survival was shorter in patients with increased SCC levels and cN1or c2. Conclusion: We conclude that pulmonary resection for early-stage SCLC is a safe and effective treatment strategy, and adjuvant chemotherapy may be useful in patients undergoing surgery in a practical management. Increased SCC levels and cN1 or 2 were identified as prognosis-related criteria for a poor prognosis of resected early SCLC.

P1.12-15 DISTINCTIVE CLINICAL CHARACTERISTICS OF SCLC IN NEVER-SMOKERS

I. Mian1, S. Nichols1, A. Abernethy2, K. Carson1, K. Maigon3, A. Torres3, T. Snider1, G. Frampton1, G. Li1, E. Sharon1, E. Szabo1, A. Thomas1
1National Cancer Institute, Bethesda/MD/US, 2Flatiron Health, New York/NY/US, 3Foundation Medicine, Cambridge/US

Background: Epidemiologic data suggest that 3% of patients with SCLCs are never-smokers. A large population study is required to describe the characteristics and outcomes of SCLC in never-smokers. Defining SCLC subgroups based on clinical characteristics, specifically smoking status, may lead to treatment advances in this historically recalcitrant cancer.

Method: We performed a multicenter analysis using the Flatiron Health electronic health record-derived database, a nationally representative database comprising patient-level structured and unstructured data curated via technology-enabled abstraction. The cohort consisted of patients with clinician confirmed SCLC diagnosed on or after January 1, 2013. Genomic data from a clinico-genomic database developed by Flatiron and Foundation Medicine was used for a subset of patients that had received next-generation sequencing on the FoundationOne panel. Clinical and genomic characteristics were compared between smokers and never-smokers using descriptive statistics while the presence of other cancers was confirmed via chart review for never-smokers. Association of patient characteristics with overall survival was assessed using a univariate Cox proportional hazards model.

Result: Of 103 of 4655 (2.2%) SCLC patients were never-smokers. Characteristics of these patients were: female 65%, male 35%; Asian 4.85%, Black 4.85%, White 62.1%; extensive-stage (ES) 68.9%, limited-stage (LS) 20.4%, unknown 10.7%. Compared with smokers (n=4552), never-smokers were more likely to be 80+ years (p=0.001), female (p=0.013), Asian (p=0.001), and present with ES (p=0.038). Based on univariate analyses, poor prognostic factors in never-smokers included sodium < 140 mEq/L (HR=1.95; p=0.028) and ES (HR=2.62; p=0.013). 26 (25%) patients had confirmed history of multiple primary malignancies. Three patients had prior history of organ transplant and two patients had history of pulmonary fibrosis. Survival of never-smokers (8.0 months for ES and 20.6 months for LS) appeared similar to historical data from smokers with SCLC. In the subset of 251 SCLC patients where tumor mutation data was available, never-smokers (n=18, 7.2%) were less likely to have a detectable alteration in TP53 (44.4% vs 95.3%; p<0.001) or R81 (27.8% vs 76.8%; p<0.001). Conclusion: The never-smoker subgroup of SCLC patients has important clinical and genomic features that portend diagnostic, prognostic, and therapeutic opportunities. A high-frequency of other malignancies raises concern for neuroendocrine differentiation from other primary tumors. This series represents the largest reported data on SCLC in never-smokers.

P1.12-16 MANAGEMENT OF ELDERLY SMALL-CELL LUNG CANCER PATIENTS IN A ROMANIAN TERTIARY CARE CENTER

T. Alexa-Stratulat1, A. Afrasanie1, L. Miron1, S. Alexiu2, M. Paduraru1, A. Luca3, V. Andronache4, N. Constantinescu5, M. Popescu6, A. Nastase1, M. Paduraru1
1Medical Oncology, Regional Institute of Oncology, Iasi/RO, 2Pneumology, Pneumology Hospital, Iasi/RO

Background: Small cell lung cancer (SCLC) remains one of the most challenging conditions due to its poor prognosis and lack of effective
treatments. Although guidelines recommend aggressive treatment in elderly SCLC patients with good performance status, real-life data indicates that this patient subgroup is still undertreated. The aim of this analysis was to assess survival and management in elderly SCLC patients from North-East Romania. Method: We performed a retrospective analysis of all elderly patients diagnosed with SCLC and treated in the Regional Institute of Oncology Iasi (a territorial unit responsible for the diagnosis and treatment of cancer patients in Moldova) between 2012 and 2016. For each patient, we collected several types of data regarding patient status, tumor stage and management options that were correlated with overall survival. Result: We identified 41 patients diagnosed with SCLC and over 65 years old at the time of diagnosis. Average age was 69.63±3.98, with a median of 69 and a maximum of 78 years. The male to female ratio was 5.83:1, all patients were current or former smokers and performance status was 1 in 76.2% of cases. Most patients (57.1%) were diagnosed in stage IV and received doublet platinum-based systemic treatment in the first line setting. In the subgroup diagnosed with stage III disease, none of the patients received concurrent chemoradiotherapy and less than half (35.2%) received sequential treatment. Although assessment after first-line treatment was available for less than half of the cases (39.02%), only one patient had progressive disease at that time-point (most were characterized as having a partial response). However, prophylactic cranial irradiation was performed in only 7.31% of cases. Second-line systemic treatment was initiated in 24.39% of cases – the preferred regimen was the CAV protocol followed by oral Topotecan. Overall survival was 11.17 months, with a maximum of 50 months and with statistically significant differences depending on stage and performance status. Age did not influence survival. Conclusion: Although elderly patients represent an important segment of the individuals affected by SCLC, they are sometimes undertreated and less aggressive management still seems to be the preferred approach despite good performance status and frequent response to first-line therapy. Most likely due to their age or because they delay seeking medical attention, elderly SCLC patients are more often diagnosed in metastatic stages. Our data for Romanian patients is mainly in accordance with available literature, although we found lower overall survival rates.

Keywords: small cell lung cancer, elderly

---

Conclusion: LCNC is associated with early recurrence after surgical resection and poor survival for patients with stage III and IV disease. In patients with mixed histology survival and recurrence remain similar to those with pure LCNC tumors.

P1.12-18 OUTCOME IN SMALL CELL LUNG CANCER PATIENTS WITH CEREBRAL RECURRENCE AFTER PRIOR PROPHYLACTIC CRANIAL IRRADIATION
L. Zhao1, J. Guo1, X. Cai1, X. Fu2
1Radiology, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai, CN. 2Department of Radiotherapy, Shanghai Chest Hospital, Shanghai/CN

Background: Prophylactic cranial irradiation (PCI) is a standard therapy for both limited small cell lung cancer (SCLC) and extensive SCLC patients with good responses to first-line treatment. The aim of this study was to examine outcomes in SCLC patients in a single institution who underwent cerebral recurrence after prior PCI.

Method: We retrospectively examined the medical records of 219 consecutive SCLC patients who had initially received PCI(25 Gray in 10 fractions) between June 2007 to June 2017. Data were analyzed with regard to age, sex, smoking status, treatment, disease stage, data of PCI, time to cerebral recurrence, site of cerebral recurrence, re-irradiation after cerebral recurrence and time to death. Survival was estimated by the Kaplan-Meier method. Multivariable analyses were performed by the log-rank and Cox’s proportional hazard model test.

Result: Of the 219 patients undergoing PCI, 180(82.2%) were LD-SCLC and 39(17.8%) were ED-SCLC. The median age was 59 years and the median follow-up time was 23.7 months. The median overall survival (OS) of all patients from the time of diagnosis was 39.0 months (95%CI, 29.6-48.4), in LD-SCLC it was 47.0 months (95%CI, 35.4-58.6), and in ED-SCLC it was 19.0 months (95%CI, 17.0-21.0). The difference was statistically significant with P=0.000. Forty-six patients (21.0%) were diagnosed with cerebral recurrence. 30(65.2%) of these presented with oligometastatic disease and 16(34.8%) had non-oligometastatic disease. Cox multivariate analysis identified disease stage (P=0.0043) as the only significantly favorable prognostic factor for cerebral recurrence.

The median survival time from PCI was 21.0 months (95%CI, 12.5-29.2), in oligometastatic disease it was 35.0 months (95%CI, 19.0-51.0), and in non-oligometastatic disease it was 16.0 months (95%CI, 12.1-19.9). The difference was statistically significant with P=0.007. Meanwhile, the median time from PCI to cerebral recurrence was 11.0 months (95%CI, 9.5-12.5), in oligometastatic disease it was 11.0 months (95%CI, 6.7-15.3), and in non-oligometastatic disease it was 10.0 months (95%CI, 8.4-11.6). There was no statistical significance between the two. Among forty-six patients with cerebral recurrence, 34 patients underwent re-irradiation using either Re-WBRT (11 patients, 23.9%) or SRS/SRT (23 patients, 50.0%), another 12 patients (26.1%) did not accept radiotherapy to brain. The median survival time from cerebral recurrence was 10 months (95%CI, 4.1-16.0) for re-irradiation and 4 months (95%CI, 2.3-5.8) for no radiotherapy group, respectively. The difference was statistically significant with P=0.000. Conclusion: PCI remains standard therapy for SCLC patients with good responses to first-line treatment. Cerebral recurrence is inevitable, however, cerebral re-irradiation after recurrence is proven to be beneficial for survival.

P1.12-19 CLINICO-PATHOLOGICAL CHARACTERISTICS AND TREATMENT OUTCOME IN SMALL CELL LUNG CANCER: A SINGLE INSTITUTIONAL EXPERIENCE
Tata Medical Center, Kolkata/IN

Background: Lung cancer is one of the commonest cancer in the world with a high rate of mortality. Small cell lung cancer constitutes around 14% of all lung cancers. Literature on small cell lung cancer is scarce in literature. The aim of the study was to analyze clinical profile of patients with lung cancer and their treatment outcome.

Method: This is a single institutional retrospective study of patients treated 2005-2017 with diagnosis of small cell carcinoma of lung. Patients were staged as either localized or extensive disease after appropriate staging work-up. Patients with localized disease were treated with concurrent chemo-radiation with platinum based chemotherapy. Those with extensive disease were treated with platinum based palliative chemotherapy.

Clinic-pathological characteristics, treatment details and outcome were recorded in this study. Response assessment was done using RECIST criteria wherever applicable. Patients who received at least 1 cycle of palliative chemotherapy were included for survival analysis.

Result: Total 128 patients were registered with median age of 62 years (range: 38-86), male:female ratio of 115:13. The ECOG performance status was 0 in 2, 1 in 30 (23%), 2 in 64, (50%) 3 in 29 (22%) and 4 in 3 patients. Ninety-three (n=93) patients had smoking history and 20% (n=25) patients had symptom of superior vena cava obstruction at baseline. Eleven (9%) patients had localized disease at presentation. Sixteen (12.5%) patients had brain metastasis at presentation. Eighty-two (64%) patients took palliative chemotherapy and eight (10%) of them had localized disease. Chemotherapy regimen was – carboplatin only in 5 (6%), etoposide-carcobilin in 29 (35%) and cisplatin-etoposide in 48 (58%). Patients received median cycle number of 6 (range:1-6). Of the evaluable 58 (71%) patients, initial response was complete response in 18 (31%), partial response in 37, stable disease in 15 and progressive disease in 4. Fifteen patients received second-line chemotherapy on progression of disease. After a median follow-up of 6.7months (range: 0.3-36.6), median progression-free survival was 8.6 months. After a median follow up of 12.5 months (range: 0.3-36.6), median overall survival was 8.7 months. Conclusion: Small cell carcinoma in our series had high incidence of advanced stage (91%) and 10% patients were non-smoker. Only 64% patients received palliative chemotherapy and achieved high disease control rate (>90%) in the evaluable patients with median progression-free survival of 8.6 months and median overall survival of 8.7 months.

P1.12-20 OVERALL SURVIVAL WITH LURBINEDETIN PLUS DOXORUBICIN IN RELAPSED SCLC. RESULTS FROM AN EXPANSION COHORT OF A PHASE IB TRIAL.
M. Forster1, V. Moreno2, E. Calvo3, M.E. Olmedo4, M.P. Lopez-Criado1, J. Lopez-Vilarraso1, R. Nuñez5, C. Kahatt6, A. Soto-Matos1
1University College of London Hospital and UCL Cancer Institute, London/LB. 2Start Madrid-Eid, Hospital Fundacion Jimenez Diaz, Madrid/ES, 3Start Madrid - Hm Cicco, Hospital Madrid Norte Sanchinarro, Madrid/ES, 4Hospital Ramon y Cajal, Madrid/ES, 5MD Anderson Cancer Center, Madrid/ES, 6Pharmamar, Colmenar Viejo, Madrid/ES

Background: Lurbinectedin (PM01183, L) is a new anticancer drug that binds to DNA, inhibits transactivated transcription and modulates tumor microenvironment. Preclinical evidence of synergism was observed for PM01183 in combination with doxorubicin (DOX).

Method: This multicenter, phase Ib clinical trial found impressive activity in second-line SCLC patients (ORR 67%). An expansion cohort with reduced dose (L 2mg/m2 + DOX 40mg/m2) was implemented to improve safety. SCLC patients <75 years with ECOS P 0-1 and with no more than one prior chemotherapy line and stable brain metastases were included. DOX was interrupted after 10 cycles continuing with PM01183 alone. Primary G-CSF prophylaxis was not mandatory.

Result: 27 patients treated. Males: 75%; median age: 64 (49-77) years; ECOS P 0-1: 32%-68%; CNS involvement: 4%; bulky disease (>50 mm): 75%; 88% responded to 1st line (CR in 4%). Median chemotherapy-free interval (CTFI) was 3.5 months (m). 22% refractory (CTFI <30 days) 15% resistant (R) (CTFI 30-90 days) and 63% sensitive (S) (CTFI>90 days). Overall confirmed ORR was 37% (CR in 13%), and 53% (CR in 6%) in S patients. Overall median PFS was 3.4 m (95% CI, 1.5-6.2), being 1.5 m (95%CI, 0.8-3.4) in R pts, and 5.7 m in S patients. Overall survival (OS) data are summarized in the following table.

<table>
<thead>
<tr>
<th></th>

<tr>
<td>Excluding CTFI&lt;30 days (n=21)</td>
<td>10.2 m (95% CI: 6.0-12.1)</td>
<td>6.7 m (95% CI: 5.1-8.4)</td>
<td>11.5 m (95% CI: 6.0-16.6)</td>
</tr>
</tbody>
</table>

Data shown are median and 95% CI.

Grade 4 neutropenia, anemia or thrombocytopenia appeared in 64%/0%-7% of patients, respectively, and febrile neutropenia (G3/4) occurred in 10%. Non-hematological toxicity was mild and mainly due to fatigue (G3=18%) and nausea (G3=7%). Conclusion: Lurbinectedin/DOX combination showed remarkable activity as second line in SCLC, especially in sensitive patients (CTFI>90 days). Activity is higher than that reported for CAV or topotecan. OS shows an outstanding improvement in this second-line setting, especially when excluding refractory pts. A phase III clinical trial (ATLANTIS, NCT02566993) is currently ongoing evaluating this combination in relapsed SCLC patients.

P1.12-21 DEVELOPING A REAL-WORLD 3L COMPARATOR TO CHECKMATE 032: OVERALL SURVIVAL (OS) IN PATIENTS WITH SMALL CELL LUNG CANCER (SCLC)

L. Schwartzberg1, B. Korytowski2, J. Penrod2, Y. Yuan2, T. Gu2, T. Le1, P. Abraham2, G. Selvaggi1

1West Cancer Center, University of Tennessee, Germantown/PA/US, 2Health Economics and Outcomes Research, Bristol-Myers Squibb, Lawrenceville/NJ/US

**Background:** In the US, no approved standard of care exists for the treatment of relapsed SCLC in 3L setting. This study describes 3L outcomes in US patients with SCLC and creates a matched real-world historical comparator to CheckMate 032, highlighting the relative benefit that nivolumab treatment may offer to patients. **Method:** Adult patients receiving 3L therapy for SCLC were selected from the Flatiron Health electronic health record (EHR) database (01Jan2011-30Sep2017). Index date was SCLC diagnosis. A matched cohort was constructed and evaluated based on inclusion (I)/exclusion (E) criteria of CheckMate 032. Patients were included if: pretreated with ≥1one platinum-containing regimen; ECOG score of 0 or 1; ≥2 months of continuous medical data. Patients were excluded if: treated with immunotherapy; had brain metastases; autoimmune disease (except type I diabetes); HIV; Hep B/ Hep C on after diagnosis; on immunosuppressive doses of systemic corticosteroids. Kaplan-Meier curves were generated for patients with 3L SCLC from treatment initiation to death. Duration of therapy (DoT) was analyzed as time from start to end of 3L. **Result:** 2,209 SCLC patients initiated 1L of which 2189(98.8%) received 3L treatment. 92 patients with SCLC matched I/E criteria as in CM 032. Mean age was 64 years; 53% were female; 68% were white; 99% had a history of smoking; and 94% of patients were treated in a community setting. Median follow-up exceeded 2 months of continuous medical data.

**Outcomes in US patients with SCLC:**

**Conclusion:** Poor survival among US patients treated for 3L SCLC emphasizes the need for more effective and tolerable therapies. In CheckMate 032, nivolumab demonstrated considerable activity in heavily pretreated patients when compared to real-world data and may represent a therapeutic option over available treatments.

**Keywords:** Small cell lung cancer, nivolumab, real world
(0/1), performance status (0-1/2), brain metastases at screening (absence/presence), and geographic region (Asia /other), to receive oral ensartinib (225mg daily) or crizotinib (250mg, twice daily) until disease progression or intolerable toxicity. Eligibility also includes patients ≥ 18 years of age, stage IIIIB or IV ALK+ NSCLC. Patients are required to have measurable disease per RECIST 1.1, adequate organ function, and an ECOG PS of ≤2. Adequate tumor tissue (archival or fresh biopsy) must be available for central testing. The primary endpoint is progression-free survival assessed by independent radiology review based on RECIST v. 1.1 criteria. Secondary efficacy endpoints include overall survival, response rate (imaging and central nervous system [CNS]), PFS by investigator assessment, time to response, duration of response, and time to CNS progression. The study has > 80% power to detect a superior effect of ensartinib over crizotinib in PFS at a 2-sided alpha level of 0.05. Phase 3 recruitment began in June, 2016 and currently has 98 active sites in 21 countries. The duration of recruitment will be approximately 28 months. This study is registered with ClinicalTrials.gov as NCT02767804. Result: Section not applicable Conclusion: Section not applicable

P1.13-03 ENSARTINIB TREATMENT BEYOND DISEASE PROGRESSION IN STAGE IV ALK+ NON- SMALL CELL LUNG CANCER

L. Horn1, S. Patel1, S. Wadra2, G. Blumenschien3, K. Harrowy, A. Hoff1
1Vanderbilt University, Nashville/TN/US, 2University of California San Diego Health, San Diego/CA/US, 3Washington University School of Medicine, St Louis/US, 4Thoracic Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston/TX/US, 4Discovery Holding Company, Palm Beach Gardens/FL/US, 5Medicine (Oncology), Stanford Cancer Institute/Stanford University, Stanford/CA/US

Background: Anaplastic Lymphoma Kinase (ALK) positive non-small cell lung cancer (NSCLC) patients (pts) benefit from receiving ALK tyrosine kinase inhibitors (TKIs); however, despite initial activity, resistance invariably develops. Disease progression (PD) is sometimes limited to progression which occurs in only one or a few sites and may not occur systemically. Local treatment with radiation while continuing treatment with ensartinib may enable prolonged benefit beyond progression.

Method: Patients who were ALK TKI naïve or had received prior ALK TKI treatment received ensartinib 225mg QD until PD or unacceptable toxicity or investigator discretion. The primary endpoint was safety and tolerability and the secondary endpoint was pharmacokinetic and preliminary biological activity. Tumor assessment was performed locally every 8 weeks. Post-progression treatment with ensartinib was allowed if the investigator felt the patient was still receiving benefit from ensartinib. Cycles were approximately every 28 days, and radiation therapy after Cycle 4 for isolated CNS metastases was permitted if there was no evidence of progressive disease elsewhere. Post-progression treatment data were captured and analyzed. Result: As of the data cut-off (May 01, 2018), 12 pts with progression continued ensartinib treatment post progression in CNS only (74% with progression only in the CNS, 75% of which had CNS lesions at baseline and 33% with progression only outside the CNS). Of the 12 pts, half of the patients were ALK TKI naïve and half had received at least one prior ALK TKI. Six pts received radiation therapy at the time of initial progression. The initial median Progression Free Survival (PFS) of the 12 pts with post progression treatment was 15.7 months and median secondary PFS (date of initial progression to the date of second progression or end of treatment) was 5.7 months for a combined duration of therapy of 23.8 months. A significantly longer duration of continued therapy was observed in patients who received radiation therapy than those who did not (8.6 mos vs 3.5 mos). The secondary PFS was longer in treatment naïve pts than in pts who received a prior ALK TKI, 7.7 mos vs 5 mos. After the initial progression, excluding lesions treated with radiation therapy, secondary stable disease was observed in 92% of patients. No new or additional safety risk was identified in the pts post progression.

Conclusion: Ensartinib may have clinical benefit in selected patients with NSCLC if continued post-progression. Secondary PFS was longer in patients treated with radiation therapy. Ensartinib was generally well tolerated in these patients treated post progression.

P1.13-04 INTEGRIN β3 INHIBITION ENHANCES THE ANTITUMOR ACTIVITY OF ALK INHIBITOR IN ALK REARRANGED NSCLC

K. Noh1, M. Sung2, M. Lee3, Y. Choi4
1Department of Health Sciences and Technology, Salsih, Sungkyunkwan University, Seoul/KR, 2Department of Pathology and Translational Genomics, Samsung Medical Center, Seoul/KR

Background: Anaplastic lymphoma kinase (ALK)-positive cancers are sensitive to small molecule ALK kinase inhibitors, but most cases experience failure following treatment. Hence, additional drug targets and combination therapeutic treatments are needed. We investigated gene expression that is regulated by the expression of ALK and explored its roles in cancer progression and therapeutic implication.

Method: We screened ALK-rearranged non-small cell lung cancer (NSCLC) cases using immunohistochemistry and fluorescence in situ hybridization, and then conducted multiplex gene expression analysis. We also performed a clinicopathological analysis to validate the findings. Additional cellular experiments, including inhibition and migration assays, and in vivo lung cancer model studies were performed. Result: Among patients with ALK-rearranged NSCLC, integrin β3 (ITGB3) was one of the overexpressed genes in comparison with that in ALK-negative NSCLC (P = 0.0003). ALK and integrin β3 expression were positively correlated, and we discovered that high integrin β3 mRNA expression was associated with metastasis and more advanced tumor stage (P <0.005; P < 0.05). Furthermore, we found that inhibition of both ALK and integrin β3 led to increased drug sensitivity in vitro and in vivo (both P <0.05). Conclusion: We discovered a positive correlation between ALK and integrin β3 expression levels in ALK-rearranged NSCLC. Our findings suggest that high integrin β3 expression in ALK-rearranged NSCLC is associated with tumor progression and a worse prognosis. This demonstrates the prognostic value of integrin β3 and provides a rationale for combination treatment with ALK and integrin β3 inhibitors in patients with ALK-rearranged NSCLC.

Furthermore, we found that inhibition of both ALK and integrin β3 led to increased drug sensitivity in vitro and in vivo (both P <0.05). Conclusion: We discovered a positive correlation between ALK and integrin β3 expression levels in ALK rearranged NSCLC. Our findings suggest that high integrin β3 expression in ALK-rearranged NSCLC is associated with tumor progression and a worse prognosis. This demonstrates the prognostic value of integrin β3 and provides a rationale for combination treatment with ALK and integrin β3 inhibitors in patients with ALK-rearranged NSCLC.

Keywords: ALK-rearranged NSCLC, ITGB3, combination therapy
Background: Lorlatinib and crizotinib are oral tyrosine kinase inhibitors with activity against ALK and ROS1 fusion proteins. Crizotinib is well tolerated and has superior efficacy compared to chemotherapy for treatment of patients with advanced ALK+ non-small-cell lung cancer (NSCLC). However, resistance to crizotinib can develop, and the central nervous system (CNS) is often a site of disease relapse. Second-generation ALK inhibitors, ceritinib and alectinib, have demonstrated activity in crizotinib-naive or resistant treatment settings, and alecltinib has been shown to have superior progression-free survival (PFS) compared to crizotinib as first-line therapy. Lorlatinib is a selective, CNS-penetrant ALK inhibitor that has potent activity against ALK and kinase domain resistance mutations, including G1202R, a difficult-to-treat G1202R mutation. Lorlatinib has shown clinical activity in patients previously treated with crizotinib and other ALK inhibitors, including patients with progressive CNS metastases. This study aims to determine if lorlatinib is superior to crizotinib in prolonging PFS in treatment-naive patients and to identify candidate biomarkers predictive of clinical efficacy or treatment resistance. Method: Trial Design This global, multicenter, open-label study will enroll ~280 treatment-naive patients. Eligible patients must be aged ≥18 years, have Eastern Cooperative Oncology Group performance status of 0–2 and ≥1 measurable extracranial target lesion not previously treated with radiotherapy. Patients with asymptomatic brain metastases are eligible. Patients will be randomized (1:1) to lorlatinib 100 mg once daily or crizotinib 250 mg twice daily and stratified by the presence of brain metastases (yes/no) and ethnicity (Asian/non-Asian). Treatment will continue until disease progression, patient refusal, or unacceptable toxicity. Crossover between treatment arms will not be permitted. The primary endpoint is PFS based on blinded independent central review (BIRC) using RECIST v1.1. Secondary endpoints include PFS based on investigator assessment, overall survival, objective response (OR) by BIRC and investigator assessment; intracranial (IC) OR (periodic magnetic resonance imaging will be performed for central nervous system signal abnormalities), time to progression, duration of response and time to response all by BIRC; tumor tissue and peripheral blood circulating free DNA biomarker assessment, adverse events and patient-reported health-related outcomes as assessed by the European Organisation for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire Core 30 (EORTC (QLQ-C30)) and EORTC Lung Cancer Module (QLQ-LC13), and the 5-level EuroQol 5-dimension questionnaire (EQ-5D-5L). The first patient was screened on April 14, 2017. This study is registered with ClinicalTrials.gov as NCT03052608. Result: Section not applicable Conclusion: Section not applicable

Keywords: lorlatinib, ALK-positive NSCLC, tyrosine kinase inhibitor

Background: The ALK inhibitors, such as crizotinib and alecltinib show a good response to patients with non-small cell lung cancer (NSCLC) harboring ALK fusions. However, the acquired drug resistance is also known as important issues in the treatment with the specific molecular targeted agents, such as EGFR-TKI and ALK-TKI. The mechanisms of acquired resistance to ALK-TKI are reported previously, bypassing activity of EGFR-MET and EMT. However, the Epithelial-mesenchymal transition (EMT) novel generation ALK inhibitor brigatinib is promising for NSCLC harboring ALK fusions, however, the precise mechanism of the acquired resistance to brigatinib is not fully understood. To elucidate for the novel acquired resistance to brigatinib, we here conducted the cell-based experiments using ALK fusion NSCLC cells. Method: We established ALK fusion NSCLC cells H3122 (variant 1 E13;A20) and H2228 (variant 3 E6;A20) with the acquired resistance to brigatinib by stepwise methods. ALK signal transduction in H3122 and H2228 cells was examined in vitro. Result: H3122-brigatinib resistance cell (H3122- BR) and H2228-brigatinib resistance cell (H2228- BR) indicated the cross-resistance to other ALK inhibitors alecltinib, crizotinib and lorlatinib. Furthermore, morphological change was observed to spindle shape, and additionally shows decreasing of E-cadherin and increasing of vimentin which are marker of EMT by the western blotting analysis. Moreover, some of these resistant cells cultured with drug-free medium for 4 weeks were reversed the sensitivity to ALK-TKIs and cell formation backed to parental cells. Conclusion: We demonstrated that EMT elicited the acquired resistance to ALK-TKIs under the exposure of brigatinib treatment in ALK fusion NSCLC cells. Further experiments are needed to overcome this drug resistance induced by EMT.

Keywords: epithelial-mesenchymal transition, ALK, Acquired resistance

Background: ALK rearrangements are established targetable drivers in NSCLC. Recent reports indicate differential progression-free survival to ALK inhibitors according to specific EML4-ALK variant. Method: A total of 172 unique Chinese lung cancer patients with tumors harboring ALK rearrangements (ALK+) were enrolled in the study from 2016 to 2018. ALK+ were detected by Ventana, FISH, or next-generation sequencing based ERI-Seq method, which enables simultaneously assess single-nucleotide variants, insertions/deletions, rearrangements, and somatic copy-number alterations across at least 59 genes (59-1021). Tissue biopsy was the first choice for NGS mutation profiling, and cDNA or pleural effusion testing was used as an alternative. Result: Of these 172 cases, the median age at diagnosis was 50 (range 24-78), 58% were female, 98% were NSCLC. Of the 147 NSCLC detected by NGS, we identified 65 (44%) EML4-ALK v1 (E13; A20), 18 (12%) EML4-ALK v2 (E20; A20), 43 (29%) EML4-ALK v3 (E6; A20), 13 (9%) other EML4-ALK, and 8 (5%) non-EML4-ALK rearrangements. 2 new fusion genes were found in non-EML4-ALK rearrangements (SRBD1-ALK (EX20; EX20) and CLIP4-ALK (EX9; EX20), and the CLIP4-ALK patient’s tissue was also ALK positive by Ventana. V1 found a higher proportion of pleural effusion at baseline than non-v1 (12% v.55%). Mutation profiling by NGS were performed after disease progression in 55 patients treated with crizotinib, mPFS was 8.1 months, no significant difference existed between v1 and v3 (P=0.69). But the presence of known ALK resistance mechanisms was significantly higher in v3 as compared to non-v3 (67% v. 27%, P=0.038). Conclusion: Next generation sequencing allows for detection of the specific ALK fusion partner and variants, increases the understanding of the biology of ALK+ NSCLC, and may have value to foretell potential mechanisms of resistance.

Keywords: ALK variants, lung cancer, resistance mechanism

Background: The acquisition of resistance to ALK inhibitors, such as crizotinib and alecltinib show a good response to patients with non-small cell lung cancer (NSCLC) harboring ALK fusions. To elucidate for the novel acquired resistance to brigatinib, we here conducted the cell-based experiments using ALK fusion NSCLC cells. Method: We established ALK fusion NSCLC cells H3122 (variant 1 E13;A20) and H2228 (variant 3 E6;A20) with the acquired resistance to brigatinib by stepwise methods. ALK signal transduction in H3122 and H2228 cells was examined in vitro. Result: H3122-brigatinib resistance cell (H3122- BR) and H2228-brigatinib resistance cell (H2228- BR) indicated the cross-resistance to other ALK inhibitors alecltinib, crizotinib and lorlatinib. Furthermore, morphological change was observed to spindle shape, and additionally shows decreasing of E-cadherin and increasing of vimentin which are marker of EMT by the western blotting analysis. Moreover, some of these resistant cells cultured with drug-free medium for 4 weeks were reversed the sensitivity to ALK-TKIs and cell formation backed to parental cells. Conclusion: We demonstrated that EMT elicited the acquired resistance to ALK-TKIs under the exposure of brigatinib treatment in ALK fusion NSCLC cells. Further experiments are needed to overcome this drug resistance induced by EMT.

Keywords: epithelial-mesenchymal transition, ALK, Acquired resistance
Background: On the Phase III AURA3 trial, osimertinib as a third-generation EGFR TKI is approved in France in EGFR T790M-positive advanced NSCLC whose disease have progressed on or after first or second generation EGFR TKI. Objective: to assess efficacy and tolerance of Osimertinib in real-world setting. Method: Retrospective, monocentric study including T790M-positive advanced NSCLC receiving osimertinib from 07 April 2015 to 27 April 2016 in French early access program. Overall survival (OS) and progression free survival (PFS) were analysed in the whole population, in the subgroup of patients with cerebral metastasis at osimertinib initiation and according to the number of previous treatment lines (1 versus 2 or more). Result: The analysis included 205 patients treated in 52 centers; mean age 69.5±11.1 years, female 68.8%, adenocarcinoma 97.5%, EGFR mutations exons 19/21: 66.5%/30.5%, never smokers 71.5%, PS 0-1/2/3-4: 54%/18.8%/27.2%, stage IV: 87.4%, presence of cerebral metastasis at osimertinib initiation: 43.7%. EGFR T790M mutation diagnosis have been done by liquid biopsy in 34.4% or on tissue re-biopsy in 65.6%. Patients received a median of 2.8 ± 1.5 lines of treatment before osimertinib initiation. All patients received a first or second generation EGFR TKI before osimertinib. Osimertinib has been used in second line setting in 18% of patients and in third line or more setting in 82%. Median PFS was 12.4 (CI 95%: 10.1-15.1) months for the whole population, 9.7 (CI 95%: 7.7-13.5) in patients with cerebral metastasis and 15.8 (CI 95%: 11.9-17) months in patients without cerebral metastasis, (p=0.2). PFS was not significantly different according to the use of osimertinib as second or third line of treatment: 12.6 (CI 95%: 6.7-17.5) vs 12.4 (CI 95%: 9.7-15.3) months, respectively. Median OS since osimertinib initiation was 20.5 (CI 95%: 16.9-24.3) months, 23.06 (18.56;27.83) and 18.00 (12.16;22.21) months in patients without and with cerebral metastasis, respectively. OS was not significantly different according the use of osimertinib as second or third line of treatment: 17.5 (CI 95%: 11.6-27.8) vs 21.7 (CI 95%: 17.3-24.3) months (p=0.4). A new biopsy was performed at disease progression on osimertinib in 50 patients: data will be presented. Conclusion: Efficacy of Osimertinib in real world setting appears similar to that observed in clinical trials in patients with EGFR T790M mutation in ≥2ndline. Clinical trial informed: Supported by an academic grant from Astra Zeneca. Keywords: osimertinib, egfr mutation, treatment

P1.13-10 AURORA KINASE A DRIVES THE EVOLUTION OF RESISTANCE TO THIRD GENERATION EGFR INHIBITORS IN LUNG CANCER
K. Shah, C. Blakely, T. Bivona, S. Bandyopadhyay
Uc San Francisco, San Francisco/CA/US

Background: Paradigm defining for precision medicine. EGFR inhibitors are a major breakthrough in the treatment of EGFR-mutant non-small cell lung cancer (NSCLC). Although these EGFR-TKI therapies often elicit profound initial therapeutic responses, their effects are transient due to residual disease. This residual disease and subsequent disease progression occurs through tumor evolution and molecular drivers behind the formation, maintenance and evolution of residual disease and acquired resistance have remained elusive. Although in many cases pre-existing clones with boma-fide genetic resistance have been identified, major patients have undetectable resistance conferring genetic alterations suggesting that non-genetic alterations may drive altered cell state and signaling associated with EGFR inhibitor resistance. Furthermore, in the case of osimertinib now used in first line setting, mechanisms of acquired resistance have been ill defined and no effective second line therapies exist. Method: Using EGFR mutant lung cancer cells we developed eight distinct in vitro models of acquired resistance to 3rd generation EGFR-TKI inhibitors, osimertinib and rociletinib. We examined the efficacy of drug combinations in vivo using both cell line xenografts and PDX models of EGFR TKI resistance. We measured the level of staining of the candidate biomarker, TPX2, in patients progressing on first and third generation EGFR TKIs. Result: Chemical screens in acquired resistant cell lines revealed that Aurora kinase inhibitors are highly synergistic when combined with third-generation EGFR inhibitors. Resistant cells harbored heightened activation of AURKA caused by upregulation of its co-activator protein TPX2. In in-vitro and in-vivo models of acquired resistance the combination induced potent cell death by reactivating BIM-mediated apoptosis. We found that tumors from the majority of patients progressing on first and third-generation EGFR TKIs harbored high levels of TPX2, indicating that AURKA is likely activated and driving resistance in a significant fraction of EGFR-mutant lung cancers. Tracking the kinetics of AURKA activation, we found that AURKA activity is required for the formation and maintenance of residual drug tolerant cells, precursors of acquired resistance. Either single agent EGFR-TKI or the AURKA inhibitor MLN8237 or the combination enhanced the magnitude of response and forestalled the emergence of resistance in vitro as compared to monotherapies. The combination robustly induced tumor regressions in an EGFR L858R PDX tumor model generated from a residual disease surgical specimen. Conclusion: This synthetic lethal interaction between EGFR TKIs and Aurora kinase inhibitors important clinical implications for the development of better treatment strategies using EGFR-TKIs and suggest a new paradigm for preventing the emergence of resistance. Keywords: Acquired resistance, EGFR, Tyrosine kinase inhibitors

P1.13-11 PRO-CTCAE TOXICITIES IN ADVANCED NSCLC PATIENTS WITH EGFR MUTATIONS: A REAL WORLD ASSESSMENT

K. Hueniken1, M. Hurry2, S. Jiang1, C. Labbe3, M. Liang1, D. Patel4, L. Bradbury5, N. Leighl5, F. Shepherd7, W. Xu8, G. O’Kane9, R. Walton9, G. Liu1
1Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto/ON/CN, 2Astrazeneca Canada, Mississauga/CA, 3Institut Universitaire de Cardiologie Et de Pneumologie de Quebec, Division of Respiriology and Thoracic Surgery, Quebec/CA

Background: The Patient Reported Outcomes of the CTCAE (PRO-CTCAE) tool has not been evaluated in a real-world study of EGFR-mutation positive patients treated with TKIs/chemotherapies. We evaluated its role in capturing clinically-significant toxicities. Method: A longitudinal observational study evaluated common EGFR-TKI toxicities using PRO-CTCAE, measured on a five-point scale (1=no symptoms to 5=very severe symptoms) in outpatients with EGFR-mutated (EGFRm) advanced NSCLC. Result: Toxicity information was collected for 709 follow-up visits (encounters) from 232 patients. Median age was 64 range:29-94), 161 (69%) were female and 124 (53%) were Asian. 85 (37%) already had brain metastases at first encounter. 485 encounters were observed from patients stable on treatment, and 187 from patients progressing or with documented progression on their current treatment. 24 patients were treated with osimertinib (97 encounters, 97% in second/ subsequent-line), 136 with gefitinib (324 encounters, 95% in first line therapy), 42 were receiving other EGFR-TKIs (118 encounters, 53% in second/subsequent-line), and 29 with chemotherapy (73 encounters, 46% second/subsequent-line). The table below summarizes the treatment-related PRO-CTCAE toxicities self-graded as moderate-to-very-severe by EGFRm patients.

Conclusion: Osimertinib therapy had the most favorable self-reported toxicity profiles of all the therapies in EGFRm patients, followed by gefitinib. Chemotherapy generated the greatest toxicities. The use of PRO-CTCAE was well-accepted by patients in a clinical setting. This confirms trial data supporting favorable toxicities with osimertinib compared to other therapies for EGFRm NSCLC patients.

P1.13-12 EGFR THERAPY IN ASCL1 POSITIVE LUNG ADENOCARCINOMA

P. Kosari1, K. Bhinge1, T. Peikert2, A. Mansfield3, M. Aubry4, L. Yang1, P. Muggia1, I. Kovtun2, G. Vasmazis5, S. Murphy6

Background: Greater than 40% of lung adenocarcinomas (LUAD) contain no known driver mutations from point mutation or structural variance analysis. Recently, we discovered that 15-20% of LUAD have abnormally high levels of ASCL1, a key regulator of neuroendocrine differentiation in the lung. ASCL1 in these tumors orchestrates the expression of a network of genes that affect the behavior of tumors and their microenvironments and provide opportunities for treatment that has largely been understudied. The goal of this study was to explore potential therapeutic options in these tumors.

Methods: Bioinformatics analyses used public and internally generated expression data from LUAD. In vitro co-immunoprecipitation and cytotoxicity assays were used to determine the interaction between proteins and the sensitivity to EGFR blockers gefitinib and lapatinib. These drugs were also tested in patient derived xenograft (PDX) models from cisplatin resistant brain tumors. EGFR therapy also markedly changed key regulators of the tumor microenvironment in favor of anti-tumor immunity. Analysis of TCGA data identified some overlap between A’AD and other LUAD subtypes, such as KRAS or EGFR mutant tumors. Further meta-analysis in a compendium of microarray data in stage-1 LUAD from multiple institutions demonstrated that high expression of wild type EGFR and RET in A’AD which rendered these tumors vulnerable to treatment by EGFR blockers. Furthermore, while EGFR inhibitors blocked tumor growth in the A’AD PDX model, they were completely ineffective in the A AD PDX model. We also performed Western blotting to investigate downstream signaling transition (EMT) and cancer stem cell-like properties. We determined the IC50 values in parental NSCLC cell lines and those in acquired EGFR-TKI resistance NSCLC cell lines ranged from 0.87nM to 25nM, which suggests potent anti-tumor effect of ganetespib. In addition, this effect was observed regardless of the resistant mechanisms, including EMT. Ganetespib effectively suppressed the expression of downstream pathway molecules in all examined cell lines including acquired EGFR-TKI resistance NSCLC cell lines. Also, ganetespib effectively induced apoptosis in parental and acquired EGFR-TKI resistance NSCLC cell lines with EGFR T790M mutation or MET amplification. Conclusion: Ganetespib exhibited potent anti-tumor effect in acquired EGFR-TKI resistance NSCLC cell lines regardless of the resistant mechanisms, suggesting that ganetespib could be a promising therapeutic option in the treatment of NSCLC with acquired EGFR-TKI resistance.

P1.13-13 POTENT ANTI-TUMOR EFFECT OF GANETESPIB IN ACQUIRED EGFR-TKI RESISTANCE NSCLC CELLS

General Thoracic Surgery and Breast and Endocrinological Surgery, Okayama University, Okayama City,JP

Background: Non-small cell lung cancer (NSCLC) harboring epidermal growth factor receptor (EGFR) mutation shows favorable response to EGFR-tyrosine kinase inhibitors (EGFR-TKIs). However, almost all these patients eventually acquire resistance to EGFR-TKIs, and novel therapeutic strategies to overcome the acquired resistance have been required. The 90-kDa heat shock protein (HSP90) is a chaperon protein expressed at high levels in cancer cells and involved in folding or stabilization of client proteins essential for cancer cell growth and survival. Ganetespib (STA-9090) has specific activity against HSP90 inhibitors with potent anti-tumor effect on NSCLC cells. In this study, we evaluated the anti-tumor effect of ganetespib in EGFR-TKI sensitive and acquired resistance NSCLC cell lines.

Methods: We treated 4 EGFR-mutant NSCLC cell lines (HCC827, HCC4006, HCC4011 and PC-9), and 5 experimentally established EGFR-TKI (gefitinib) resistance cell lines with ganetespib. The EGFR-TKI resistant mechanism consisted of EGFR T790M second mutation, MET amplification, epithelial-to-mesenchymal transition (EMT) and cancrosis cell-like properties. We determined cell proliferation by MTS assay and calculated the IC50 values. We also performed Western blotting to investigate downstream signaling pathway alterations. Result: The IC50 values in parental NSCLC cell lines ranged from 1.3nM to 15nM, and those in acquired EGFR-TKI resistance NSCLC cell lines ranged from 0.87nM to 25nM, which suggests potent anti-tumor effect of ganetespib. In addition, this effect was observed regardless of the resistant mechanisms, including EMT. Ganetespib effectively suppressed the expression of downstream pathway molecules in all examined cell lines including acquired EGFR-TKI resistance NSCLC cell lines. Also, ganetespib effectively induced apoptosis in parental and acquired EGFR-TKI resistance NSCLC cell lines with EGFR T790M mutation or MET amplification. Conclusion: Ganetespib exhibited potent anti-tumor effect in acquired EGFR-TKI resistance NSCLC cell lines regardless of the resistant mechanisms, suggesting that ganetespib could be a promising therapeutic option in the treatment of NSCLC with acquired EGFR-TKI resistance.

P1.13-14 THE MOLECULAR LANDSCAPE OF LUNG ADENOCARCINOMAS WITH ACTIVATING EGFR GENE MUTATIONS DETERMINED BY TARGETED-SEQUENCING

M. Nicol1, K. Wojas-Krawczyk1, P. Krawczyk1, P. Calka2, M. Ciesielska2, K. Reszka3, K. Milanowski1
1Pneumonology, Oncology and Allergology, Medical University of Lublin, Lublin/PL, 2Department of Forensic Medicine, Medical University of Lublin, Lublin/PL, 3Institute of Genetics and Immunology, Genom LLC, Lublin/PL

Background: The analysis of EGFR activating mutations and ALK rearrangement is a routine procedure in qualification of NSCLC patients for molecularly targeted therapy. Targeted sequencing, as a type of NGS, allows more comprehensive analysis of low-frequency variations in suppressors and oncogenes that are commonly mutated in solid tumors. In the following study we analyzed a molecular landscape of NSCLC patients harboring EGFR activating mutations who respond for EGFR TKIs. Method: The studied group included 19 Caucasian patients (7 male and 12 female, median age 65±12 years, 4 current smokers, 12 non-smokers and 3 former-smokers) with lung adenocarcinoma, 12 (63%) deletions in exon 19, 4 (21%) substitutions Leu858Arg in exon 21, 2 (11%) insertions A756_Y964 in exon 20 and 1 (5%) substitution Thr790Met in exon 20 of EGFR gene were detected using real-time PCR technique. Four non-smoking patients (median age 65±12 years) with lung adenocarcinoma and wild-type (wt) of EGFR gene were a control group. The DNA for the analysis was isolated from FFPE tissue or cellblocks and the mutational landscape was evaluated using Illumina's TruSight Tumor 26 panel on miSeq platform (Illumina, USA). Result: The targeted sequencing confirmed lack of EGFR gene mutations in control group and the presence of EGFR mutations in 84% (16/19) of patients with these mutations confirmed in routine diagnostics - all deletions in exon 19 and substitutions in exon 21 were confirmed. Targeted sequencing did not identify rare mutations in exon 20. NGS compared to real-time PCR technique achieved 86.95% accuracy with 84.21% of sensitivity and 100% of specificity or PPV and NPV values reached 100% and 57.10%, respectively. The targeted sequencing allowed to identify 166 variants in 25 out of 26 genes covered by the analysis. The most frequently mutated suppressors were TP53, MSH6 and APC (38%; 19% and 17% respectively) and oncogenes were MET, PDGFR and EGFR-AS1 (31%, 14% and 13% respectively). The frequency of particular variants was significantly higher in smokers than in non-smokers (p=0.0002; \( x^2 = 16.94 \)). U-Man Whitney test showed that the median number of genetic alterations in EGFR mutated group was significantly higher than in wt EGFR group (p=0.0091; median: 17 vs 11 respectively). Conclusion: The targeted sequencing allowed to detect the most common activating mutations in EGFR gene and numerous variants both in suppressors and oncogenes. NGS showed too low sensitivity for detection of rare EGFR mutations. The molecular landscape was more unpredictable and varied in smokers compared to non-smokers.

Keywords: targeted-sequencing, EGFR-TKIs, NSCLC

P1.13-15 PRO-CTCAE: A PROTOCOL-ADAPTED TOOLS FOR THE SELF-REPORTED TOXICITY ASSESSMENT OF NSCLC PATIENTS RECEIVING EGFR THERAPIES

K. Namba, H. Sato, H. Yamamoto, J. Soh, S. Toyooka
General Thoracic Surgery and Breast and Endocrinological Surgery, Okayama University, Okayama City,JP

Background: To assess toxicity profiles of all the therapies in EGFRm patients, followed by gefitinib. Chemotherapy generated the greatest toxicities. The use of PRO-CTCAE was well-accepted by patients in a clinical setting. This confirms trial data supporting favorable toxicities with osimertinib compared to other therapies for EGFRm NSCLC patients.

Keywords: EGFR-mutated NSCLC, Targeted therapy, toxicity
Keywords: T790M were detected in blood at the time of PD. Conclusion: ALK (2) gene mutations were also detected. Interestingly, in 1 pt receiving other co-occurring EGFRm were found in 10 pts including K745R in a pt (p=0.08). T790M was detected in 3 of 4 pts with T790M -ve tissue, and p=0.02) with a trend in the %VAF of T790M (HR 1.16 95% CI: 0.99-1.37, of the primary EGFRm correlated with PFS (HR 1.15, 95%CI: 1.02-1.29, cfDNA, the median PFS was 3.0 months versus 9.7 mths, (HR 4.59, 95% CI: 0.89-5.54 PD evident, the median progression free survival (PFS), taken from blood draw, was 2.1 months (mths) versus 10 mths (HR 2.22, 95% CI: 0.89-5.54 p=0.08) when the primary EGFR-TKI without progression (PD) (23, 36%) or with PD on a TKI (30, 47%), the presence of the primary EGFRm (n=39, 61%) strongly associated with pre-1st TKI P0.03. Of 35 pts receiving a TKI, the presence of T790M was detected in 31 (58%) associated with PD (p=0.04). Where pts had no radiologic PD evident, the median progression free survival (PFS), taken from blood draw, was 2.1 months (mths) versus 10 mths (HR 2.22, 95% CI: 0.89-5.54 p=0.08) when the primary EGFRm was detected. If T790M was present in the T790M was detected in 3 of 4 pts with T790M -ve tissue, and other co-occurring EGFRm were found in 10 pts including K745R in a pt receiving first-line osimertinib. TP53 (n=10), KRAS (1), PIK3CA (1) and ALK2 gene mutations were also detected. Interestingly, in 1 pt receiving chemotherapy, both T790M mutation status in patients with EGFR-positive advanced NSCLC, with unknown tissue status (8/17; 47%), were ctDNA EGFR-mutant, additional 8 patients (54%) had known tissue EGFR-mutations. Additional 8 patients performed using InVisionSeq™ (amplicon-based NGS). Data from published studies identified 21 patients with common mutations (exon 19/L858R), 8 were from cfDNA and 13 from tissue. The pooled sensitivity, specificity and AUC of ctDNA analysis by by next-generation sequencing (NGS) were: 0.87 (95% CI: 0.76-0.95), 0.89 (95% CI: 0.82-0.94), and 0.88, respectively. Conclusion: The ctDNA analysis represents a promising, non-invasive approach to detect and monitor the T790M mutation status in patients with EGFR-positive advanced NSCLC, with NGS emerging as the most accurate detection platform. Development of standardized methodologies and clinical validation are recommended.

Keywords: ctDNA, T790M, EGFR

Background: Peripheral blood sampling for T790M in patients (pts) failing initial EGFR-TKIs is now standard practice. The value of longitudinal sampling in pts is unknown. Method: A study of cell free (cf) DNA analysis in pts with EGFR mutated(m) non-small cell lung cancer (NSCLC) is ongoing at the Princess Margaret Cancer Centre. The ThermoFisher Oncomine™ lung assay detecting single nucleotide variants and indels to a limit of 0.05-0.1% allele frequency (VAF) was used. Patient clinical details and outcomes were collected prospectively. Result: From Oct 2016-Feb 2017, 73 pts with EGFRm NSCLC enrolled and first blood samples were analysed. Most (92%) had mutations in del19 or L858R, including 1 pt with del19/S768I. Uncommon EGFRm were present in 6 (G718L, L861Q, exon20ins). Detectable levels of ctDNA were found in 50 pts (68%). Of 64 pts either starting an EGFR-TKI (n=11,17%), receiving a TKI without progression (PD) (23, 36%) or with PD on a TKI (30, 47%), the presence of the primary EGFRm (n=39, 61%) strongly associated with pre-1st TKI P0.03. Of 35 pts receiving a TKI, the presence of T790M was detected in 31 (58%) associated with PD (p=0.04). Where pts had no radiologic PD evident, the median progression free survival (PFS), taken from blood draw, was 2.1 months (mths) versus 10 mths (HR 2.22, 95% CI: 0.89-5.54 p=0.08) when the primary EGFRm was detected. If T790M was present in the T790M was detected in 3 of 4 pts with T790M -ve tissue, and other co-occurring EGFRm were found in 10 pts including K745R in a pt receiving first-line osimertinib. TP53 (n=10), KRAS (1), PIK3CA (1) and ALK2 gene mutations were also detected. Interestingly, in 1 pt receiving chemotherapy, both T790M disease, both the primary EGFRm and T790M were detected in blood at the time of PD. Conclusion: In addition to the emergence of resistance mutations, the presence of the primary EGFRm in pts receiving EGFR-TKIs may associate with a shorter PFS and therefore may be useful in longitudinal analyses of ctDNA to direct therapy.

Keywords: cfDNA, EGFR mutations, resistance

Background: Efficacy of afatinib in EGFR mutant patients with comorbidities or those with suspected EGFR mutations unift for chemotherapy is poorly explored. We evaluated afatinib in this population, with serial plasma ctDNA to investigate the role of molecular EGFR genotyping and monitoring. Method: Phase-II trial enrolled NSCLC patients with comorbidities precluding chemotherapy, and either (i) EGFR-mutation, PS 0-3, or (ii) suspected EGFR-mutation (tissue unavailable/ failed genotyping), never/former-light smoker, adenocarcinoma, and PS 0-2. Afatinib (40mg daily) given until progression/toxicity. Blood samples obtained at baseline and 12-weekly until discontinuation: plasma ctDNA performed using InVisionSeq™ (amplicon-based NGS). Result: 39 patients recruited (14 UK centres). Mean age 72 years; 27 PS 0-1/12 PS 2-3, 21 patients (54%) had known tissue EGFR-mutations. Additional 8 patients with unknown tissue status (8/17; 47%), were ctDNA EGFR-mutant, making 74% EGFR-mutant in total (29/39). Combined tissue and ctDNA data identified 21 patients with common mutations (exon 19/L858R), 8 with rare mutations (exon 18/20), and 10 suspected only. Corresponding median PFS of these cohorts were 10.2/2.3/3.5 months, with 6-month PFS of 71/38/50% exceeding the 30% target; median OS were 24.8/5.7/11.4 months (p=0.001). Therefore, all patient groups benefited: known EGFR-mutants having best outcomes. In April 2018, 5/39 patients survived 36 months, including 4/39 progression-free (median follow-up 33 months, maximum 55). Patients with ctDNA mutation clearance during afatinib treatment had substantially improved outcomes compared to those without clearance (Figure). 40% (4/10) of mutant cases who discontinued after 3 cycles because of progressive disease developed an exon 20 EGFR-mutation. (See next page)
Conclusion: Patients unsuitable for chemotherapy with confirmed/ suspected EGFR-mutations by tissue or ctDNA benefit from afatinib. Serial ctDNA is a potentially useful stratification and monitoring tool; amplicon-based ctDNA analysis can identify EGFR mutations when tissue is unavailable. Exon 20 mutations were observed at acquired resistance. ctDNA clearance during afatinib treatment is strongly associated with better PFS/OS.

Keywords: progression free survival, NSCLC, EGFR mutation

### P1.13 TREATMENT CESSATION FOR IMPROVED DETECTION OF EGFR-MUTATED CIRCULATING TUMOR DNA IN ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC)

S. Tabchi1, S. Forte2, R. Alameddine2, A. Khazzaka3, M. Florescu3, E. Kassouf1, W. Xeng1, M. Tehfe1, N. Blais2

1MD Anderson Cancer Center, Houston/US, 2Centre Hospitalier de l’Université de Montréal, Montreal/QC/CA, 3Saint Joseph University, Beirut/LB

Background: First/second generation EGFR-tyrosine kinase inhibitors (EGFR-TKI) are eventually met with therapeutic failure in EGFR-mutated (EGFRm) aNSCLC, but post-progression continuation of therapy can delay the need for second line therapy by a median of ~3 months. In this context, osimertinib was shown to be effective in T790M mutated EGFR, which occurs in >50% of cases. T790M detection within circulating tumor DNA (ctDNA) is convenient but has suboptimal sensitivity. The goal of this study is to determine whether temporary cessation of the TKI - beyond initial progression - would allow for increased plasma detection of EGFR mutations.

Method: EGFRm aNSCLC patients who were still on first/second generation EGFR-TKI beyond initial progression were enrolled. TKI was withheld on day 0. Blood samples were drawn and the NCCN-FACT FLSI-17 questionnaire was administered on days 0 and 61. Semi-quantitative measurements of EGFR mutations within plasma samples were obtained using the cobas® EGFR Mutation Test v2. Descriptive statistics were reported and paired t-test was used to compare detection differences in ctDNA yield and quality of life after TKI cessation.

Result: 33 patients were enrolled in 2017. Baseline characteristics and relevant study results are summarized in Table 1. Temporary TKI cessation was safe with no tumor flares reported - questionnaire scores indicate a trend towards improved quality of life one week after TKI cessation. The yield of detection was significantly higher after TKI cessation, but only for the baseline sensitizing mutation.

### Table 1

<table>
<thead>
<tr>

NCCN-FACT FLSI-17 questionnaire
- Questionnaire score day 1 - 45.81 ± 10.78 (p = 0.08)
- Questionnaire Score day 6/7 - 48.41 ± 9.91

Keywords: plasma ctDNA, non-small cell lung cancer, Resistance
Baseline EGFR sensitizing mutation
- Overall detection of ctDNA, n (%)  
  - Detection within ctDNA on only one of the two test dates, n (%)  
    - Semi quantitative index of detected ctDNA
      - Day 1: 6 (28.5)  
      - Day 6/7: 5 (23.8)  
      - 6.16.4 (p=0.04)

Conclusion: Our data suggest that TKI cessation can lead to increased shedding of ctDNA in sensitive cells. However, drug withdrawal may not impact the shedding of ctDNA in resistant clones. Irrespective of drug withdrawal, a strategy of repeat testing appears to increase the sensitivity of ctDNA detection and would likely produce more clinically relevant outcomes in comparison with one-time testing.

P1.13 TARGETED THERAPY
MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.13-20 MET PROTEIN EXPRESSION AND ACTIVATION DURING TARGETED THERAPY IN EGFR MUTATED LUNG ADENOCARCINOMA
R. Taulli1, L. Righi1, F. Tabbi1, F. Massa2, A. D’Aveni1, D. Morena1, M.F. Lingua1, A. Rigotto1, F. Napoli1, F. Picca2, S. Novello1, G. Scaglitti1
1Department of Oncology, University of Torino, Torino/IT, 2Human Pathology of Adult and Evolutive Age, Medical Oncology Unit, Messina/IT

Background: In EGFR mutated (EGFRm) lung adenocarcinoma (ADC) the tyrosine kinase (TK) receptor MET is involved in acquired resistance to anti-EGFR treatment. We analyzed MET protein expression and activation in EGFRm lung ADC treated with TK inhibitors (TKI).

Method: Patients with advanced EGFRm lung ADC, treated at the Oncology Department - San Luigi Hospital, who underwent tissue biopsy for diagnosis and tissue re-biopsy at disease progression for T790M test (after a negative liquid biopsy) were selected. c-MET (clone SP44) and phosphorylated (p-) MET (Tyri1234/1235, D286) expression was analyzed by immunohistochemistry and evaluated as H-Score (HS).

Result: Tumor tissues from 18 advanced EGFRm patients (12 female and 6 male; mean age 59 years) were available. On April 2018, 10 patients were alive and 8 were died. 11/18 (61%) cases harbored a T790M point mutation (T790M+) detected at tissue re-biopsy. At the baseline tumor tissue, lower c-MET expression levels were found in T790M+ (mean HS value= 135, range 40-250) compared to the T790M negative (T790M-) group (mean HS value= 226, range 100-300) (p=0.02). Furthermore, in T790M+ patients p-MET was expressed in 2/11 cases (18%, HS values=5 and 60) while in the T790M- group p-MET was expressed in 3/7 (43%, HS values=5, 240 and 240) cases (although with no significant p value). After first line TKI treatment, in the T790M+ group c-MET expression (mean HS value=140, range 5-300) was augmented in 7 and reduced in 4 cases, while p-MET was positive in 2/11 cases (HS values of 300 and 30). No significant differences in survival were found. In the T790M- group the c-MET mean HS value was 152 (range 30-300) and the 4/7 cases with higher c-MET expression levels (HS>152) had a significant shorter PFS (p=0.02, HR=0.3, median survival: 7.5 vs 24 months). Furthermore, in this group p-MET positivity was maintained in the same 3 cases (with HS values= 240, 180, 10) and the two patients with higher MET activation had short PFS (9 and 6 months) at first line TKI treatment.

Conclusion: Our preliminary analyses suggest that a strong expression of basal c-MET receptor in advanced EGFRm ADC may predict a T790M negative status at disease progression. Furthermore MET higher expression and activation may play a role in acquired resistance to TKI, although a limited number of cases have been analyzed. Thereby, we propose to monitor MET status along treatment and to reconsider MET-directed therapies for a well-selected subset of EGFRm lung ADC patients.

Keywords: lung adenocarcinoma, EGFR targeted therapy, MET

P1.13-21 CLINICAL EFFICACY AND SAFETY OF APATINIB COMBINED WITH EGFR - TKIS IN ADVANCED NON- small CELL LUNG CANCER WITH EGFR - TKIS RESISTANCE
No. 3 Xinhua Street, Xinghuading District, Taiyuan, Shanxi, Taiyuan/CN

Background: Acquired resistance to EGFR-TKIs frequently occurs in advanced non-small cell lung cancer (NSCLC) patients with sensitizing EGFR mutations. Previous studies have shown that apatinib (a TKI against VEGFR-2) combined with EGFR-TKIs might improve the survival of EGFR-TKIs resistant NSCLC patients. We conducted this trial to investigate the efficacy and safety of apatinib combined with EGFR-TKIs and traditional chemotherapy for EGFR-TKIs resistant NSCLC patients.

Method: This prospective study enrolled advanced NSCLC patients who acquired resistance to the EGFR-TKIs therapy. Patients received apatinib combined with EGFR-TKIs (apatinib in start dose of 250 mg+p-ior EGFR-TKIs dose) or chemotherapy (pemetrexed or vinorelbine with platinum).

Efficacy was evaluated every 6 weeks based on RECIST 1.1. This study was registered on Chinese Clinical Trial Registry, and the registration number was ChiCTR-OIN-17012051. Result: From Mar 2017 to May 2018, 24 patients were enrolled, including 18 patients received apatinib combined with EGFR-TKIs, 6 patients received chemotherapy. In the apatinib group, 83.33%(15/18) patients were available evaluated. The objective response rate was 20%(3/15) and the disease control rate was 100% (15/15). All patients had complete degrees of lesion shrinkage.

Till May 1, 2018, the median duration of apatinib group treatment was 187 days, and the median PFS has not researched. The most common adverse events in the apatinib group were hypertension, proteinuria, weakness. Five (27.78%) grade 3 hypertension, 3 (16.67%) grade 3 proteinuria and 1 (5.56%) grade 3 diarrhea were observed. Two patients who failed treatment with osimertinib received osimertinib combined with apatinib, got lesions decreased after one cycle. One of the two patients was treated as fifth line treatment. Two patients with metastases in the apatinib group got metastases lesions decreased. Two progressive patients got lesions decreased after apatinib dose increasing to 500mg. Of the 7 patients receiving chemotherapy, 6 patients were available evaluated. The objective response rate was 16.67%(1/6) and the disease control rate was 100% (6/6). Major adverse reactions were digestive tract reaction and myelosuppression.

Conclusion: Apatinib combined with EGFR-TKIs may provide a new therapy strategy for NSCLC patients with acquired EGFR-TKIs resistance. Both drugs are oral, which is advantageous in improving the patient’s quality of life and the compliance of therapy. Further study with larger samples are needed to validate our findings. Moreover, We will further explore the correlation between genetic mutations, biomarkers and therapeutic efficacy.

Keywords: Apatinib, EGFR - TKIs resistance, Non-small cell lung cancer

P1.13 TARGETED THERAPY
MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.13-22 CLINICAL FEATURES AND OUTCOMES OF NSCLC PATIENTS WITH UNCOMMON EGFR MUTATIONS TREATED WITH EGFR-TKIS RESISTANCE
R. Tudor1, K. Kopciuk2, M. Dean1, A. Gibson3, S. Otsuka1, G. Bebb4
1Medical Oncology, University of Calgary, Calgary/AB/CA, 2Cancercontrol Alberta, Calgary/AB/CA, 3Oncology, Tom Baker Cancer Centre/university of Calgary - Cumming School of Medicine, Calgary/AB/CA, 4Oncology, Tbcc Translational Labs, University of Calgary, Calgary/CA

Background: Non-small cell lung cancers with common epidermal-growth factor receptor (EGFR) mutations (exon 19 deletion and exon 21-point mutation LB58R) are known to greatly benefit from EGFR-TKIs. However, much less is known about the treatment responses of EGFR mutations such as L858R, T790M and exon 20 mutations.

Method: Between 2009 – 2015, 233 EGFRm NSCLC patients treated at two Alberta-based cancer centres, Tom Baker Cancer Centre (Calgary) and Cross Cancer Institute (Edmonton) were screened retrospectively via the provincial cancer registry and the Glass-Look Lung Cancer Database. Clinicopathological and treatment outcomes were analyzed. Overall survival was assessed using the Kaplan-Meier method and compared using the log-rank test. Outcomes of single versus double EGFRm carrier sub-groups were compared using Fisher’s Exact Test. Result: 42/233 (18%) patients had uncommon EGFR mutations: 14/42 (33%) carried single rare EGFRm+ and 11/42 (26%) carried double EGFRm+. Meanwhile 41% couldn’t be specified. Most frequently detected uncommon single EGFR mutations were G719X (12%) and evaluated as H-Score (HS).
and L861Q (17%). Table 1 summarizes clinical characteristics and TKI efficacy amongst uncommon EGFR mutations. Compared to single EGFR mutants, double EGFR mutation carriers were older (median age 71yrs vs 69yrs), have a smoking-history (73% vs 50%), experienced longer median OS and PFS (15 and 12 months p < 0.001, vs. 9 and 3 months p = 0.0014 respectively), and were also more likely to continue with a TKI beyond initial-TKI-PD (82% vs 28%).

Conclusion: Retrospective real-world data illustrating the experience and outcomes of uncommon EGFR mutation carriers was explored in this study. Additionally, our results, although limited by cohort-size, highlights that tumor responses from TKI treatments vary amongst uncommon EGFR mutated carriers, with most favorable survival responses observed in double EGFR mutants.

Background: Around 80% of patients with non-small cell lung cancer (NSCLC) harboring epidermal growth factor receptor (EGFR) mutations usually respond to tyrosine kinase inhibitors (TKIs). We previously demonstrated that TP53 mutations are associated with primary resistance to TKIs in patients with EGFR-mutated lung adenocarcinoma (ADC) treated with a first-line TKI. In the present study we investigated whether TP53 mutations are modulated by TKIs, evaluating its status before and after TKI treatment.

Method: Thirty-five patients with EGFR-mutated lung ADC treated with a first-line TKI. In the present study we investigated whether TP53 mutations are modulated by TKIs, evaluating its status before and after TKI treatment.

Conclusion: TP53 mutations were associated with primary resistance to TKIs in patients with EGFR-mutated lung adenocarcinoma (ADC) treated with a first-line TKI. In the present study we investigated whether TP53 mutations are modulated by TKIs, evaluating its status before and after TKI treatment. Our results, although limited by cohort-size, highlights that tumor responses from TKI treatments vary amongst uncommon EGFR mutated carriers, with most favorable survival responses observed in double EGFR mutants.

**P1.13-24 EGFR-KDD IS RARE AND DEMONSTRATES VARIABLE ANTI-TUMOR RESPONSE TO TYROSINE KINASE INHIBITORS IN EAST ASIAN NSCLC POPULATION**

J. Wang1, Q. Ou2, X. Xue3, Y. Liang4, X. Wu5, X. Wang2, M. You2, Y. Sha2  
1First Affiliated Hospital of Dalian Medical University, Dalian/CN, 2Geneseeq Technology Inc., Toronto/CA, 3Department of Thoracic Surgery, Cancer Hospital of Guangzhou Medical University, Guangzhou/CN, 4Department of Medical Oncology, Sun Yat-Sen University Cancer Centre, Guangzhou/CN, 5Nanjing Geneseeq Technology Inc., Nanjing/CN

**Background:** The kinase domain duplication of epidermal growth factor receptor (EGFR) (KDD) has been identified and implicated to be oncogenic in non-small cell lung cancer (NSCLC). However, its frequency and clinical outcomes in lung cancer patients are largely uncertain.

**Method:** We conducted a multi-center record review of 8064 East Asian NSCLC patients who underwent genetic testing using next-generation sequencing (NGS) targeting the whole exons of EGFR gene as well as introns involved in EGFR-KDD and gene rearrangements. Patients' demographic and clinical data, including age, gender, histology type, pathological stage, and their responses to tyrosine kinase inhibitor (TKI) treatments were analyzed.

**Result:** EGFR-KDD was identified in 11 patients, which is approximately 0.012% of the total NSCLC population reviewed (N=8064), and also consists of 0.05% of all patients with EGFR aberrations (N=2289). Nine patients were identified with the canonical EGFR-KDD form, involving the duplication of exon 18 throughout exon 25, while the remaining two cases harbor EGFR exon 14-26 and exon 17-25 duplication, respectively, which have not been previously described.

Importantly, all these patients were not identified with any other co-existing known driver mutations, highlighting the potential oncogenic role of this alteration. Three out of five patients with exon 18-25 KDD who received TKI treatments showed partial anti-tumor responses to the therapy, while the other two patients progressed shortly. Our data further indicated that EGFR T790M mutation and EGFR amplification may represent the major resistance mechanisms against targeted therapy in tumors bearing EGFR-KDD. **Conclusion:** EGFR-KDD is rare in East Asian NSCLC population with different duplication variants. Tyrosine kinase inhibitors demonstrated variable anti-tumor efficacy in patients harboring EGFR-KDD alteration.

**Background:** Osimertinib has demonstrated promising efficacy in T790M-positive NSCLC patients with central nervous system (CNS) metastases, but there is limited data on Chinese patients. We aim to investigate the efficacy and safety of osimertinib in T790M-positive advanced NSCLC patients with brain metastases and to explore the dynamic genetic changes as well as drug penetration in CNS with paired cerebrospinal fluid (CSF) and plasma samples. **Method:** In this single arm, multi-center, prospective trial (NCT2972333), patients with confirmed EGFR T790M positive by Cobas, advanced NSCLC with brain metastases, who had progressed following first-generation EGFR-TKI treatment, received osimertinib 80 mg orally. The primary endpoint was overall survival (OS). **Result:** Thirty-eight eligible patients were enrolled and 12 paired CSF-plasma samples were collected. Baseline characteristics and efficacy results are summarized in Table 1.

**Conclusion:** Osimertinib demonstrated promising efficacy, good blood brain barrier penetration and manageable tolerability in EGFR T790M-positive Chinese advanced NSCLC patients with brain metastases. NGS analysis revealed genetic heterogeneity between plasma and CSF samples and longitudinal genetic analysis may be beneficial to predict the efficacy of osimertinib.

**P1.13-26 FIRST-LINE CONTINUOUS EGFR-TKI PLUS LAT DEMONSTRATED SURVIVAL BENEFIT IN EGFR-MUTANT NSCLC PATIENTS WITH OLIGOPROGRESSIVE DISEASE**

Q. Xu1, H. Liu, T. Jiang2, S. Ren1, C. Zhou3  
1Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Department of Radiation Oncology, Shanghai/CN, 2Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Tongji University Cancer Institute, Shanghai/CN, 3Medical Oncology, Shanghai Pulmonary Hospital, Tongji University, Shanghai/CN

**Background:** The effect of local ablative therapy (LAT) for oligoprogressive epidermal growth factor receptor (EGFR) mutation non-small cell lung cancer (NSCLC) remains unknown. This study aimed to investigate the survival benefit of addition of LAT to EGFR-TKIs in EGFR-mutant NSCLC patients with oligoprogression during TKI therapy. **Method:** Patients with stage IIIB/IV EGFR mutant NSCLC who had oligoprogressive disease during the first-line EGFR-TKI therapy from March 2011 to February 2016 were identified. The primary research point was progression-free survival (PFS1), defined as time of initiation of TKI therapy to off-TKI PD. The second research point included of CSF samples at baseline, with a concordance rate of 8.3% (1/12). Median PFS1 was prolonged in patients with EGFR sensitizing mutation clearance at week 6 compared with those with persistent EGFR mutations (not reached vs 2.83 months; HR 0.09, 95% CI 0.02-0.54; p<0.01). Table 1. Baseline characteristics and efficacy
overal survival (OS) and safety. **Result:** A total of 206 patients were included. The median follow-up time was 42 months (20.0-69.6 months). The median PFS1, median PFS2 and median OS for the related cohort were 10.7 months (95% CI, 10.1-13.3 months), 18.3 months (95% CI, 17.4-19.2 months) and 37.4 months (95% CI, 35.9-38.9 months) respectively. Survival rates of 1 year, 2 years and 3 years were 94.1%, 78.9%, and 54.7%, respectively. Multivariate analysis revealed that female, EGFR exon 19 mutation, one metastatic lesion, partial or complete response to prior EGFR TKIs therapy were the independent prognostic factors. No unexpected toxicities were observed. **Conclusion:** The current study suggested that the addition of LAT to EGFR-TKI could provide satisfactory survival benefit for EGFR-mutant NSCLC patients with oligoprogression during first-line EGFR-TKI treatment.

**Keywords:** Oligoprogressive disease, Local ablative therapy, EGFR-TKI

P1.13 TARGETED THERAPY MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

**P1.13-27 A RANDOMIZED STUDY OF CONCURRENT VS SEQUENTIAL ALTERNATING EGFR-TKIS AND CHEMOTHERAPY FOR ADVANCED NSCLC WITH EGFR MUTATIONS**

H. Yong1, L. Hui2, L. Fang2, L. Dong1, L. Ling1, W. Qiang1, X. Peng1, H. Rua1, T. Yang3, G. Ping2, K. Cui2, W. Wu2, C. Yu2, L. Huo3, X. Qiang4, S. adminstered orally with erlotinib 150 mg QD (75 mg/m2) or carboplatin (AUC 5.0) plus pemetrexed (500 mg/m2) or paclitaxel (175 mg/m2) on day 1 of a 21-day cycle. All subjects were administered gefitinib orally at a daily dose of 250 mg as 1st-line monotherapy. EGFR mutations were positive in 181 patients (47.1%). Median progression-free survival (PFS) and overall survival (OS) for all patients with the rs4245739 AC genotype was significantly longer than that of AA and CC carriers (PFS: 22.9 vs. 10.9 months, P < 0.001; OS: 27.3 vs. 16.5 months, P = 0.003). Notably, in the EGFR mutation-positive subgroup, individuals with MD445739AC genotype showed 14.1 months prolonged PFS (28.8 months vs. 14.7 months; P = 0.022) and 12.2 months prolonged OS (30.7 months vs. 18.0 months; P = 0.047) compared to the group. In support of this, reporter gene assays showed that the rs4245739A allele leads to significantly increased MDM4 expression in lung adenocarcinoma cells compared to the C allele (P < 0.05). **Conclusion:** MD445739 genotypes may act as prognostic biomarker for patients' survival to gefitinib therapy and offer help to patient-tailored treatment strategy in lung adenocarcinoma patients with EGFR mutations. **Keywords:** functional MDM4 genetic variant, EGFR-TKIs treatment, Prognostic Biomarker

P1.13-29 OVERALL RESPONSE RATE OF NINTEDANIB AND DOCETAXEL IN COMBINATION WITH THE NUTRACEUTICAL USE OF SILIBININ IN ADVANCED NSCLC

J. Bosch Barrera1, J.C. Ruffinelli2, E. Carcereny3, E. Sais1, S. Verdua1, E. Cuyás1, R. Palermo1, A. Izquierdo1, T. Morán3, E. Nadal4, J.A. Menéndez1,2,3,4

1Catalan Institute of Oncology. Hospital Universitar Badalona/ES, Badalona/ES. 2Department of Medical Oncology, Hospital Universitari Badalona. 3Medical Oncology Group, Girona Biomedical Research Institute (IDIBGI), Salt/ES

**Background:** The bioactive flavonolignan silibinin, the main component of standardized extracts from the seeds of the milk thistle herb Silybum marianum, has been shown to exhibit significant anticaner activity in preclinical models. Silibinin is a direct inhibitor of pSTAT3, a signal transducer and key transcription factor that is associated with chemoresistance in cancer cells. Our group has shown that oral administration of the silibinin-containing nutraceutical Legasil® could represent the first silibinin formulation with proven clinical benefit as an adjunct cancer treatment in patients with brain metastases. Nintedanib is currently administered, a small-molecule triple angiokinase inhibitor of VEGF-1–3, PDGf and b, and FGFR1–3. The LUME-Lung 1 trial showed that nintedanib significantly extended progression-free survival (PFS) and overall survival (OS) in patients with NSCLC adenocarcinoma when added to docetaxel chemotherapy in refractory state. **Method:** Patients with stage IV NSCLC who failed ≥ 1 prior treatment were eligible for nintedanib/docetaxel combination. We present retrospective data analysis regarding patients that received nintedanib/docetaxel or without combination with up to 5 capsules (630 mg)/day of Legasil®. **Results:** Fifty-nine patients were enrolled in the study: median age, 60y (range: 43–79); male, 46 (78%). All the cases had adenocarcinoma histology. All patients had received first line therapy and 13 (22%) patients had >2 prior lines of treatment. A higher overall response rate (ORR) was observed in the group receiving Legasil® supplementation: ORR 55.5% versus 22%, p<0.02. No statistically significant differences in the median PFS were observed in the two arms; 2.34 months (95% confidence interval [CI] 1.83–2.91) for nintedanib/docetaxel combination

P1.13-13 TARGETED THERAPY MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

**P1.13-28 THE FUNCTIONAL MDM4 GENETIC POLYMORPHISM AS PROGNOSTIC BIOMARKER FOR ADVANCED LUNG ADENOCARCINOMA PATIENTS' SURVIVAL TO EGFR-TKIS THERAPY**

M. Yang1, N. Zhang2, H. Xing3, J. Liu4

1Department of Radiation Oncology, Shandong Cancer Hospital Affiliated To Shandong University, Jinan/China. 2Department of Medical Oncology, Shandong Cancer Hospital Affiliated To Shandong University, Jinan/China. 3Shandong University, Jinan/China. 4Shandong Cancer Hospital Affiliated To Shandong University, Jinan/China. Xin/China. Jia/China

**Background:** As a mostly used epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI), gefitinib significantly prolongs survival of lung adenocarcinoma patients with sensitizing EGFR mutations. However, more than 10% of EGFR mutation-positive patients do not respond and a substantial fraction of responded patients progress after 8-12 months' treatment. Identification of new biomarkers associated with EGFR-TKIs prognosis would have great clinical potential for individualized treatments. The objective of this study is to investigate associations between the functional MDM4 genetic variant and survival of lung adenocarcinoma patients treated with gefitinib, especially in the patients with active EGFR mutations. **Method:** In total of 384 patients with stage IIIB or IV lung adenocarcinoma were recruited between January 2009 and June 2013. All patients were treated with gefitinib orally at a daily dose of 250 mg as 1st-line monotherapy. MDM4 rs4245739 A>C genotypes were determined using the MassArray system (Sequenom Inc., San Diego, CA). Dual luciferase reporter assays were used to evaluate the function of MDM4 rs4245739 variant in lung adenocarcinoma cell lines A549 and H1299. The differences of patient clinical characteristics and different reporter gene assays were calculated using student's t test or χ2 test. The genotype effects on PFS or OS was estimated using the Kaplan–Meier method and a comparison between survival curves was done with log-rank test. Multivariate Cox regression analysis assessed prognostic factors for PFS or OS. A P value of less than 0.05 was used as the criterion of statistical significance, and all statistical tests were two-sided. **Result:** Among 384 patients, EGFR mutations were positive in 181 patients (47.1%). Median progression-free survival (PFS) and overall survival (OS) for all patients with the rs4245739 AC genotype was significantly longer than that of AA and CC carriers (PFS: 22.9 vs. 10.9 months, P < 0.001; OS: 27.3 vs. 16.5 months, P = 0.003). Notably, in the EGFR mutation-positive subgroup, individuals with MDM4 rs4245739AC genotype showed 14.1 months prolonged PFS (28.8 months vs. 14.7 months; P = 0.022) and 12.2 months prolonged OS (30.7 months vs. 18.0 months; P = 0.047) compared to the group. In support of this, reporter gene assays showed that the rs4245739A allele leads to significantly increased MDM4 expression in lung adenocarcinoma cells compared to the C allele (P < 0.05). **Conclusion:** MDM4 rs4245739 genotypes may act as prognostic biomarker for patients' survival to gefitinib therapy and offer help to patient-tailored treatment strategy in lung adenocarcinoma patients with EGFR mutations. **Keywords:** functional MDM4 genetic variant, EGFR-TKIs treatment, Prognostic Biomarker

P1.13 TARGETED THERAPY MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00
demonstrated benefits of ramucirumab (RAM)/docetaxel (DOC) in NSCLC patients with rapidly progressing and refractory disease. We investigated the relationship between pretreatment NLR, prognosis and response to RAM/DOC.

**Method:** Pretreatment NLR was analyzed by dividing absolute neutrophil count by absolute lymphocyte count from peripheral blood. Multiple NLR cutoffs ≥ 4 were evaluated for prognostic significance by analyzing overall survival (OS), progression-free survival (PFS), and objective response rate (ORR). Kaplan-Meier analysis and Cox proportional hazards regression model were used for analyzing OS and PFS, and Cochran-Mantel-Haenszel test for ORR.

**Result:** Pretreatment NLR was determined for 1224 REVEL patients (n=611 RAM/DOC, n=613 placebo [PBO]/DOC), among whom 51%, 40%, and 32% had NLR ≥ 4, 5, and 6, respectively. Baseline characteristics were balanced between arms in NLR subgroups and the REVEL intent-to-treat (ITT) population. Patients with higher NLR values had worse OS, PFS, and ORR compared to the ITT population. For all NLR cutoff values, OS, PFS and ORR were improved in patients treated with RAM/DOC compared to patients receiving PBO/DOC (Table). Efficacy and safety outcomes across high NLR subgroups were consistent with those in the ITT population.

**Conclusion:** In this exploratory analysis of REVEL, higher pretreatment NLR was an independent prognostic factor indicating poorer survival outcomes. Treatment benefit with RAM/DOC was preserved in patients with elevated NLR and was consistent with REVEL ITT results. NLR is an inexpensive and reproducible blood test and may provide a simple way to identify patients with more aggressive disease who can benefit from treatment with RAM/DOC in second-line NSCLC.

**Keywords:** silibinin, pSTAT3, nintedanib
Background: The Ras/PI3K/Akt pathway plays an important role in determining intrinsic and extrinsic tumour radiosensitisation. Buparlisib (BKM120) is a highly specific pan-class I PI3K inhibitor. Pre-clinically, this class of agents radiosensitises tumours by direct effects on intrinsic radiosensitivity and by reducing tumour hypoxia. We therefore assessed the safety and determined the maximum tolerated dose (MTD) of buparlisib in combination with radiotherapy in patients with NSCLC and investigated its effect on tumour hypoxia. Method: BKM120 was a single centre, open-label, dose-escalation and dose-expansion phase 1 trial. Patients with advanced stage NSCLC received 2 weeks of oral buparlisib. Palliative thoracic radiotherapy (20Gy in 5 fractions) was delivered during the second week of treatment. 18 F-fluoromisonidazole (FMISO) PET scans were obtained to assess tumour hypoxic volume (HV) before and after a week of buparlisib treatment. HV was defined as the volume with a tumour-to-blood F-MISO uptake ratio ≥ 1.4. Result: From June 2013 to August 2017, 21 patients were recruited. 11 patients were registered to the dose escalation phase with 9 evaluable for MTD analysis; 3 in Cohort 1 (50mg OD), 3 in Cohort 2 (80mg OD) and 3 in Cohort 3 (100mg OD). No DLT was reported therefore 100mg OD was declared the MTD and 10 patients received this dose in the expansion phase. Of all patients who received buparlisib (n=21), 1 SAE (Grade 3 hypoalbuninaemia) was possibly related to buparlisib (5%). The most common buparlisib-related AEs were fatigue (8.3%) and nausea (3.3%). 93.9% of all AEs with any relation to buparlisib were ≤ Grade 2. There was no reported radiotherapy associated toxicity. 15 patients were evaluable for tumour hypoxia imaging analysis. Median change in HV in Cohort 1 (n=3), Cohort 2 (n=3) and Cohort 3 combined with the expansion cohort (n=9) was 7%, -18% and -20%, respectively. Conclusion: This was the first clinical trial of a specific PI3K inhibitor with concurrent radiotherapy in NSCLC. This combination was found to be safe and well-tolerated. This study provides clinical evidence that PI3K inhibition rapidly reduces tumour hypoxia and therefore warrants further trials combining this class of agents with radiotherapy.

P1.13-32 COMPARISON BETWEEN IMMUNE-MEDIATED PNEUMONITIS AND PNEUMONIA IN PATIENTS TREATED WITH PD-1/PD-L1 THERAPY

M.Y. Kim1, C. Kim1, Y.J. Kim1, C. Choi1, J. Kim2
1Asan Medical Center, Seoul/KR, 2Korea University Ansan Hospital, Ansan/KR

Background: Immune-mediated pneumonitis (IMP) is an uncommon but potentially fatal toxicity of anti-programmed death-1 (PD-1) therapy for non-small cell lung cancer. The purpose of study was to compare clinical and radiographic findings between IMP and pneumonia by pathogen. Method: From 2014 to 2017, a total of 154 patients who received anti-PD-1/PD-L1 therapy were identified. Among these, IRP developed in 9 (5.8%) and pneumonia in 30 (19.5%), which were confirmed through multidisciplinary approach. Among these, IRP developed in 9 (5.8%) and pneumonia in 30 (19.5%), which were confirmed through multidisciplinary approach.

In all patients with a diagnosis of IMP, nivolumab or pembrolizumab were used to assess tumour hypoxic volume (HV) before and after 1 week of buparlisib treatment. HV was defined as the volume with a tumour-to-blood F-MISO uptake ratio ≥ 1.4. Result: From June 2013 to August 2017, 21 patients were recruited. 11 patients were registered to the dose escalation phase with 9 evaluable for MTD analysis; 3 in Cohort 1 (50mg OD), 3 in Cohort 2 (80mg OD) and 3 in Cohort 3 (100mg OD). No DLT was reported therefore 100mg OD was declared the MTD and 10 patients received this dose in the expansion phase. Of all patients who received buparlisib (n=21), 1 SAE (Grade 3 hypoalbuninaemia) was possibly related to buparlisib (5%). The most common buparlisib-related AEs were fatigue (8.3%) and nausea (3.3%). 93.9% of all AEs with any relation to buparlisib were ≤ Grade 2. There was no reported radiotherapy associated toxicity. 15 patients were evaluable for tumour hypoxia imaging analysis. Median change in HV in Cohort 1 (n=3), Cohort 2 (n=3) and Cohort 3 combined with the expansion cohort (n=9) was 7%, -18% and -20%, respectively.

Conclusion: This was the first clinical trial of a specific PI3K inhibitor with concurrent radiotherapy in NSCLC. This combination was found to be safe and well-tolerated. This study provides clinical evidence that PI3K inhibition rapidly reduces tumour hypoxia and therefore warrants further trials combining this class of agents with radiotherapy.

Background: Lung cancer is one of the leading causes of cancer mortality worldwide. Despite of remarkable progress made in the lung cancer therapy, an unmet need is there in tailoring the appropriate patient specific therapy due to a variety of treatment options. Our aim was to develop a high-throughput drug screening model of tumour ex-vivo analysis (TEVA) which can predict patient-specific drug response and thus can be used for personalized cancer treatment. Method: Freshly operated tumor tissue samples from non small cell lung carcinoma (NSCLC) patients were received from Soroka Medical Center, Israel and implanted in NSG mice to form PDXs. We developed a method that enabled us to cut the PDXs into 2×2×2mm tissue explants and then treated with clinically relevant drugs (Genomics/proteomics suggested) in 48 well plates for 24 hours. TIMA wells were prepared and IHC was performed. Path ligands, such as Ki67, TUNEL and respective signalling molecules (pMAPK, pPRAS40) were chosen to predict the drug response ex vivo and a score was given to each drug based upon those parameters. Result: 8 NSCLC patients have been enrolled so far. Implantation rate was 75%. 15 drugs combinations have been developed to test the most common conditions, i.e. progression on EGFR TKIs, progression on immunotherapy and progression on chemotherapy. Preliminary results indicate a potential role for MET blockade in immune-resistant as well as in EGFR progressors. We also observed that the TEVA score correlated with the genomics/proteomics based drug results. Conclusion: Overall, this low cost, fast, relatively simple and efficient method can bypass the necessity of drug validation in mice and can be used for multiple drug screening to select a precise patient specific drug. The method is feasible and expose ways to overcome acquired resistant to novel drugs.

A segmented tumor region and map of Haralick entropy features in the pre- and post-treatment CT scans from responder and non-responder group. (a) and (d) are the segmented CT scans from a responder in the pre- and post-treatment CT scans, respectively, b and (e) are the segmented tumor region from the CT scans. (c) and (f) showed the heat map of Haralick entropy features. It may be observed that accuracy of non- responder tumors has increased after therapy.

P1.13 TARGETED THERAPY
MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.13-35 HYPOXIA MAPPING USING OXYGEN-ENHANCED MRI IN LUNG CANCER
A. Salem1, R. Little2, M. Babur2, A. Featherstone2, I. Peset3, S. Cheung3, Y. Watson2, V. Tessyman2, H. Mistry4, G. Ashton1, C. Behan2, J. Matthews2, M. Asselin1, R. Bristow2, A. Jackson2, K. Williams2, G. Parker2, C. Faire-Finn3, J. O’Connor1

Background: Oxygen deprivation (hypoxia) is associated with worse non-small cell lung cancer (NSCLC) outcomes and predicts poor response to NSCLC treatments, including radiotherapy. There is an unmet need to develop non-invasive hypoxia biomarkers. We report the first preclinical and clinical evidence that oxygen-enhanced MRI (Oxy-MRI) can map and quantify therapy-induced change in NSCLC hypoxia. Method: In the prescindical study, radiation-induced changes in Oxy-MRI were first examined in a Calu-6 xenograft model of NSCLC. Tumors received a single 10Gy fraction of radiotherapy (n=9), chemoradiotherapy (5 x 2Gy fractions plus cisplatin; n=6) or control (n=9). Mice were imaged longitudinally using a multi-parametric MRI protocol (diffusion-weighted imaging (DWI), OE and dynamic contrast-enhanced (DCE)-MRI) at days 0, 3, 6 and 10 in all groups and then at day 13 (control), day 18 and 25 (radiotherapy) and day 20 (chemotherapy). Pathological analysis of tumors was obtained at culled in imaged mice and in a separate Calu6 cohort treated with a single 10Gy radiotherapy fraction (n=6) or control (n=9) at day 10. In the clinical study, twenty stage I-IV NSCLC patients underwent an identical multi-parametric MRI protocol (diffusion-weighted imaging (DWI), OE and dynamic contrast-enhanced (DCE)-MRI) at days 0, 3, 6 and 10 in all groups and then at day 13 (control), day 18 and 25 (radiotherapy) and day 20 (chemotherapy). Pathological analysis of tumors was obtained at culled in imaged mice and in a separate Calu6 cohort treated with a single 10Gy radiotherapy fraction (n=6). Both preclinical and clinical results are presented here. Results: By day 10, perfused Oxy-R (hypoxic) volume decreased relative to control in xenografts treated with either radiotherapy (p=0.029) or fractionated chemoradiotherapy (p=0.047). Hypoxia modification persisted in chemoradiotherapy treated tumors to day 16 and in radiotherapy treated tumors to day 22 (both p<0.001). Pimonidazole immunoassay showed lower hypoxic fraction in tumors treated with radiotherapy (p=0.026), relative to time matched controls. In addition, imaged xenografts also showed lower hypoxic fractions in radiotherapy (p=0.042) and chemoradiotherapy (p=0.041) treated tumors, relative to size matched control at cul. In the clinical study, Oxy-MRI was safe, feasible and well-tolerated. Perfused Oxy-R (hypoxic) volume demonstrated excellent repeatability with interclass correlation coefficient of 0.961 (95% CI 0.858-0.980). Visual inspection revealed that MRI hypoxia maps were spatially repeatable across a range of tumour and hypoxic volumes. In the absence of volumetric tumour change, perfused Oxy-R (hypoxic) volume decreased at mid-treatment (3.23 cm3 (95% CI 0.9-4.11 cm3)), compared to baseline (4.16 cm3 (95% CI 0-10.6 cm3)); p=0.015. Conclusion: Our findings support using OME-MRI to detect and monitor hypoxia in clinical trials of hypoxia-modifying therapies or radiotherapy dose painting studies in patients with NSCLC.

**Background:** Tumor genomic information from a simple blood collection revealing actionable mutation can improve clinical outcome without the need for an invasive tissue biopsy. We report on the clinical utility of a cell-free DNA (cfDNA) next generation sequencing (NGS) blood test in our patients with non-small cell lung cancers (NSCLC) and the outcome of treatments with targeted therapies based on the reported mutations.

**Method:** From May 2015 to February 2017, 1078 blood samples from 1011 consecutive patients with a diagnosis of NSCLC were collected and analyzed using next-generation sequencing of cfDNA with a panel of up to 70 cancer-related genes at a CLIA-certified lab (Guardant360, Guardian Health, Redwood City, CA) with reported sensitivity of 0.02% mutant allele fraction with high specificity (> 99.9999%) (CCR 2018;17):3831. Patients in this retrospective study received targeted therapy as indicated by cfDNA molecular profiling. Tumor response was evaluated by RECIST V1.1 and standard clinical evaluation.

**Result:** From 1011 patients, 1078 cfDNA tests sent (additional follow-up tests: 1 in 64 patients and 2 in 3 patients). In 223/1011 (22%) patients meeting criteria for this retrospective review. Study population were 31 female:17 male, median age of 63 years (ranged:31-94). The rationale for the blood test included: insufficient tissue or not available (32%), addition to tissue molecular analysis (17%), alternative to tissue biopsy (15%), on-going treatment evaluation (13%), mutation resistance (41%). Mutations included: EGFR T790M (15), EGFR exon 19del (12), EGFR L858R (9), EGFR exon 20 insertion (4), EGFR others (1), ALK gene fusions (5) and MET exon 14 skipping (2). The median line of therapy was 2 (ranged:1-7) with 28 patients receiving TKI as 1st line of therapy based on cfDNA mutations. With targeted treatments based on cfDNA results, the responses (RECIST V1.1) were: CR(3), PR(26), SD(14) and PD(4); median PFS was 8.5 months (ranged:1-26mos) for the overall population with 4 patients still receiving targeted therapy. Median PFS was 9.5 months (ranged:1-20 months) for the patients receiving TKI as 1st line. Conclusion: This is the largest analysis of response rates with cfDNA directed therapy in advanced NSCLC and demonstrates positive clinical outcomes in patients treated with targeted therapy based on plasma identified biomarkers.

**Keywords:** cfDNA, NSCLC, targeted therapy

---

**P1.13-38 INTER-ORGAN HETEROGENDEREY ON MECHANISMS OF TARGETED DRUG RESISTANCE-CENTRAL NERVOUS SYSTEM (CNS) VS EXTRA CNS**

S. Yano

Cancer Research Institute, Kanazawa University, Kanazawa/JP

**Background:** Molecular-targeted drugs are generally effective against tumors containing driver oncogenes, such as EGFR, ALK, and NTRK1. However, patients harboring these oncogenes frequently experience a progression of central nervous system (CNS) metastasis, such as brain metastasis and leptomeningeal carcinomatosis (LMC), during treatment. While secondary mutations including EGFR-T790M, ALK-L1196M, and NTRK1-G595S, are known to induce high resistance to corresponding targeted drugs, involvement of these highly resistance mutations in CNS metastasis resistance is largely unknown. **Method:** We developed various in vivo imaging models for brain metastasis and LMC with human cancer cell lines, including the EGFR-exon 19 deletion-positive PC-9 lung adenocarcinoma cells, the EML4-ALK-positive A925L lung adenocarcinoma cells, and TPM3-NTRK3-positive KM12SM colon cancer cells. Using these CNS metastasis models, we examined the inter-organ heterogeneity on mechanisms of resistance to targeted drugs. **Result:** While PC-9 cells inoculated in subcutaneous space acquired EGFR tyrosine kinase inhibitor (EGFR-TKI) resistance by EGFR-T790M mutation, they inoculated in leptomeningeal space became resistance by MET copy number gain. Unlike EGFR-T790M mutation, MET copy number gain could cause intermediate resistance to EGFR-TKI in vitro. Similarly, A925L cells inoculated in leptomeningeal space acquired ALK-TKI resistance by EGFR ligand overexpression. Moreover, KM12SM cells inoculated in the brain acquired entrectinib resistance by NTRK1-G667C mutation. Since both EGFR ligand overexpression and ALK-TKI resistance were intermediate resistance to targeted drugs in vitro, mechanisms which cause intermediate resistance may be sufficient to develop resistant tumors in CNS presumably due to limited drug distribution to CNS. **Conclusion:** These observations indicate that CNS heterogeneity in mechanisms of targeted drug resistance. Therefore, careful diagnosis of resistance mechanism in CNS metastasis may be necessary when treat the patients who develop CNS metastasis with targeted drug resistance.

**P1.13-39 EPIDERMAL GROWTH FACTOR RECEPTOR MUTATION AMONG NON-SMALL CELL LUNG CANCER PATIENTS IN TRINIDAD AND TOBAGO: FREQUENCY AND TRENDS**

A. Haralsingh, M. West

Department of Surgery, Eric Williams Medical Sciences Complex, Port of Spain/TT

**Background:** Almost 70% of non-small cell lung cancer (NSCLC) patients present with unresectable disease and may benefit from chemotheraphy or biologic therapy. EGFR pathway plays a vital role in their diagnostic work-up to determine which patients are more likely to receive benefit from biologic therapies. The rate of epidermal growth factor receptor (EGFR) mutations varies significantly across geographic regions and ethnicities, ranging from 1% to 64% in some areas. Several subgroups such as females, East Asians, never-smokers and those with adenocarcinoma histology have the highest reported rates of EGFR mutations. Regionally, the French West Indies reports an EGFR mutation rate of 36%. The frequency of the EGFR mutation among NSCLC patients in Trinidad and Tobago has not been previously reported in the literature. **Method:** An observational, retrospective study was done using data obtained from the Lung Malignancy Unit (LMU) based at the Eric Williams Medical Sciences Complex (EWMSC). The EWMSC is the sole referral centre in Trinidad and Tobago for lung cancer and the LMU is responsible for co-ordinating clinical and educational services regarding lung cancer nationwide. The study population was limited to primary NSCLC patients presenting to the EWMSC from January 2014 to June 2017 whose biopsy samples were sent for EGFR testing and received either a positive or negative result. Patients’ clinical data was entered onto a spreadsheet and analysed using Microsoft Excel. **Result:** The data for 94 patients with NSCLC were analysed. 68 of these patients were male, while 26 admitted to a history of smoking. EGFR mutations were present in 39.4% of this study population. Females demonstrated a significantly higher EGFR mutation rate than males (73.1% vs 26.5%, p < 0.0001). Smoking status was found to be significantly associated with differences in EGFR mutation status (p < 0.01). The mean age of presentation was similar despite of EGFR mutation status. Although a larger number of EGFR positive patients compared to EGFR negative patients had adenocarcinoma histology (97.3% vs. 89.5%), this was not found to be statistically significant (p = 0.29). **Conclusion:** The frequency of EGFR mutations in this study population (39.4%) was higher than most regions of the world but similar to that reported in the French Antilles. Sex and smoking status were significantly associated with differences in EGFR mutation status.

**P1.13-40 RAPID, ROBUST AND DURABLE RESPONSES TO LAROTRECTINIB IN PATIENTS WITH TRK FUSION NON-SMALL CELL LUNG CANCER**

A. Farago1, S. Kummar2, S. Ibabeki1, S. Corsi-Travali3, S. Cruickshank3, M. Cox2, N. Ku1, A. Drilon4
1Cancer Center, Massachusetts General Hospital, Boston/MA/US. 2Stanford Cancer Institute, Stanford/CA/US. 3Laxo Oncology, South San Francisco/CA/US. 4Memorial Sloan Kettering Cancer Center, New York/NY/US

**Background:** Neurotrophic tyrosine receptor kinase (NTRK) gene fusions are oncogenic independent of tumor lineage and are widely distributed across cancers. NTRK gene fusions were first reported in lung cancer in 2013 (Vaishnavi et al Nat Med 2013). Larotrectinib is a potent and highly selective oral tropomyosin receptor kinase (TRK) inhibitor in clinical development. Initial data of treatment of 55 patients with TRK fusion cancer resulted in an investigator-assessed objective response rate of 80%, and 71% of patients still in response at one year (Drilon et al., NEJM 2018). We report here on the safety and efficacy of larotrectinib in 4 patients with NSCLC from the 55 patient dataset. **Method:** Patients with previously treated lung adenocarcinoma were treated under clinical trial enrolled based on a molecular report of NTRK gene fusion from a CLIA-certified lab. Larotrectinib was administered at 100 mg BID until disease progression or lack of clinical benefit. Tumors were assessed by investigators every 8 weeks using RECIST v1.1 criteria. **Result:** As of July 17, 2017, four patients with adenocarcinoma of the lung who had progressed after 1 or more lines of platinum-based chemotherapy for advanced disease were enrolled. Three patients harbored an NTRK1 fusion and one an NTRK3 fusion. Three of 4 patients had a partial response or complete response confirmed on a subsequent scan. One patient with a possible brain metastasis demonstrated regression of mass on MRI. Responses were rapid and robust, with a time to response ranging between 49 and 56 days. At the time of analysis, 3 patients continued to have an ongoing response ranging between 5.7 and 12 months. The other patient had stable disease and progressed outside of the CNS after 300 days of treatment and continued on larotrectinib for clinical benefit. Larotrectinib was well tolerated, with 3 of 4 patients having grade 1 events only. **Conclusion:** Larotrectinib treatment resulted in rapid and durable responses and had a well tolerated adverse event profile, with no CNS progressive events in patients with previously treated lung cancer harboring NTRK gene fusions. These results strongly support the inclusion of NTRK gene fusions as part of routine testing for patients with lung cancer.

**P1.13-41 IN VITRO EVALUATION FOR OPTIMAL MET-TKI SELECTION IN LUNG CANCERS WITH MET MUTATIONS INCLUDING EXON 14 SKIPPING**

Thoracic Surgery, Kinda University Faculty of Medicine, Osaka-Sayama City/JP

**Background:** MET exon 14 skipping mutation present in 3-5% of adenocarcinoma of the lung is an emerging driver gene alteration. Clinical responses of these tumors to MET-TKI have been reported. However, response rates are not very satisfactory compared with EGFR/ALK/ROS1 TKI. Therefore, it is necessary to create in vitro model system to understand sensitivity/resistance mechanisms for various types of MET-TKI, to establish optimal treatment strategy. **Method:** We introduced MET exon 14 skipping mutation as well as Y1003F, D1010Y which had also been reported to be present in lung cancer, to mouse pro-B cell line, Ba/F3. Since Ba/F3 requires interleukin 3 (IL-3) for its growth, IL-3 independence growth of Ba/F3 indicates that transduced mutation is oncogenic. The growth inhibitory assays were then performed using 9 MET-TKIs that include all classes of MET-TKIs: Type Ia (crizotinib), Type Ib (capmatinib, tepotinib, savolitinib and AMG337), Type II (cabozantinib, merestinib and glesatinib) and Type III (tivantinib). **Result:** Ba/F3 transfected with wild-type MET did not grow in the absence of IL-3, while all transfected with any of three mutated MET did so. In general, all type Ia/b / type II inhibitors were active for any of 3 MET mutations. Interestingly MET point mutations (Y1003F/D1010Y) were more sensitive to type Ib inhibitors except AMG337 than type II, while exon 14 skipping was likely to be more sensitive to type II inhibitors than type Ib compared with point mutations. IC50 / Cmax of cabozantinib was least for exon 14 skipping while that of capmatinib was least for Y1003F and D1010Y, suggesting most promising activity of these drugs (Table).

**Table. Summary of IC50s for 9 MET-TKIs in Ba/F3 cells transfected with MET mutation.**

**Conclusion:** We found that the MET exon 14 skipping, Y1003F, and D1010Y mutations were all oncogenic in Ba/F3 system. Several type I/II inhibitors especially cabozantinib and capmatinib are expected to be active for treating lung cancer patients with MET mutations.

**Keywords:** MET Exon14, MET TKI, Met mutation

1Thoracic Surgery, King’s University Faculty of Medicine, Osaka-Sayama/jp, 2Medical Oncology, Dana-Farber Cancer Institute, Boston/MA/US

Background: Oncogenic HER2 mutations are present in 2-4% of adenocarcinoma of the lung. However, clinical trials of HER2 inhibitors such as afatinib or neratinib has been unsatisfactory. Recently, a novel HER2 inhibitor, poziotinib, has been developed and clinical trial results are being expected. Here, we evaluated poziotinib in comparison with pre-existing TKIs using Ba/F3 system. We also derived resistant clones against poziotinib and investigated their resistant mechanism. Method: We introduced three common HER2 mutations into Ba/F3 cells (i.e. G776delinsVC (VC), A775_G776insYVMA (YVMA) and P780_Y781insGSP (GSP)) which account for 13, 72, 9% of HER2 mutations in human lung cancer, respectively. We defined sensitivity index (SI) as an IC50 divided by trough concentration of a given drug at the recommended dose for humans in the literature, as a surrogate for drug activity in humans. Poziotinib activity was compared with 8 TKIs (afatinib, osimertinib, erlotinib, neratinib, lapatinib, dacotinib, irbitinib, and AZ5104). In addition, we created resistant clones by exposing poziotinib in the presence of N-ethyl-N-nitrosourea (ENU) and HER2 secondary mutations were searched. Result: All drugs but lapatinib showed the highest activity against VC (Table). In contrast, YVMA was most resistant in all but neratinib and poziotinib. For most common YVMA, poziotinib was the only drug that had SI of less than 10 (Table). Furthermore, poziotinib was most potent for VC and GSP except dacotinib for GSP (Table). We established 19 poziotinib-resistant clones, all of which harbored CB055 secondary mutation of the HER2 gene homologous to C797S of the EGFR gene. 

Conclusion: Poziotinib showed the most potent activity against HER2 exon 20 mutations. We also found that secondary CB055 HER2 mutation was the common mechanism of acquired resistance, which most likely inhibit covalent binding of poziotinib with HER2.

P1.13-43 MOLECULAR AND IMAGING PREDICTORS OF RESPONSE TO ADO-TRASTUZUMAB EMTANSINE IN PATIENTS WITH HER2 MUTANT LUNG CANCERS: AN EXPLORATORY PHASE 2 TRIAL

B. Li, M. Offin, T. Hembrough, F. Cechic, R. Shen1, Z. Olahi1, E. Panora, M. Myers3, E. Brzostowski, D. Buonocore, M. Ginsberg, C. Rudin, M. Kris, G. Weitsman, P. Barber, T. Ng2, G. Ulaner, M. Arcila, M. Scaltitri

1Memorial Sloan Kettering Cancer Center, New York/NY/US, 2Nantomics, Rockville/MD/US, 3King’s College London, London/GB

Background: Ado-trastuzumab emtansine is a HER2 targeted antibody drug conjugate (ADC) that has demonstrated clinical activity in patients with HER2 mutant lung cancers, independent of HER2 protein expression. We hypothesize that the degree of HER2 homo- and/or heterodimerization may lead to preferential trastuzumab binding and internalization, and may serve as a predictor of response to HER2 ADC. Method: Patients with metastatic HER2 mutant lung cancers were enrolled in a phase 2 trial of ado-trastuzumab emtansine, treated at 3.6mg/kg IV every 3 weeks. The primary endpoint was overall response rate (ORR) using RECIST v1.1. An expansion cohort included patients assessed using PERCIST, with pre-treatment 89Zr-trastuzumab PET/CT as correlative HER2-targeted imaging. HER2 mutation was identified by next generation sequencing (NGS), and tumors with adequate tissue were subsequently tested by fluorescence in situ hybridization (FISH), immunohistochemistry (IHC), quantitative protein mass spectrometry, as well as quantitative HER2-HER2 heterodimerization by fluorescence lifetime imaging microscopy - Förster resonance energy transfer (FLIM-FRET). Result: A total of 35 patients with HER2 mutant lung cancers were treated across 2 cohorts. ORR was 44% (8/18, 95% CI 22-69%) for RECIST cohort, and 46% (6/13, 95% CI 19-75%) for PERCIST cohort with 4 patients awaiting response assessment. Responders were seen across mutation subtypes (A775_G776insYVMA, G776delinsVC, V659E, S310F, L755P). Concurrent HER2 amplification was observed in 6 of 35 (17%) patients by either NGS or IHC. JHC ranged from 0 to 3+ and did not predict response. HER2 protein expression was low or absent in 15/18 cases tested by mass spectrometry. HER2 overexpression was seen in 7/18 cases tested and among them 5/6 evaluable patients had a partial response. FLIM-FRET efficiency was tested positive for HER2–HER2 heterodimer, which has been shown to be affected by the symmetrical heterodimer interface mutations (Clau et al, 2018), in 3 patients thus far and 1 of them had a partial response. Pre-treatment 89Zr-trastuzumab PET/CT showed increased uptake in 3/8 patients tested to date, and all 3 patients subsequently had partial metabolic response.

Conclusion: This study confirmed the efficacy of ado-trastuzumab emtansine in patients with HER2 mutant lung cancers. HER2-containing dimers as indicated by HER3 overexpression or FLIM-FRET efficiency, and HER2-targeted imaging with 89Zr-trastuzumab PET/CT, may predict response to HER2 ADCs.

MUTATIONS IN LUNG CANCER PATIENTS

Y. Wang  
Peking Union Medical College Hospital, Beijing/CN

**Background:** Activating mutations in both KRAS and BRAF gene can stimulate mitogen-activated protein kinase (MAPK) signaling. So BRAF and KRAS mutations are generally mutually exclusive from each other, acting as an alternative oncogenic driver in NSCLC. There was occasionally case reports of coexistence of BRAF and KRAS mutations in colorectal cancer, lung squamous cell carcinoma. However, to our knowledge, there was no systemic studies in this area. **Method:** We retrospectively analyzed mutation profiling of 2000 consecutive lung cancer samples in our institute. Mutation profiles were analyzed using hybridization capture based next-generation sequencing (NGS), which enables the simultaneous detection of single-nucleotide variants, insertions/deletions, rearrangements, and copy-number alterations of at least 59 genes (range 59 – 1021 genes). Among the 63 patients, 8 (12.7%) had concurrence of activating KRAS mutation. Concurrence of activating KRAS mutation (G12A/D/S, G13D) was identified in 3 of the 30 patients with non-V600E mutation, with only one patient had EGFR-TKI sensitive mutation and previous EGFR-TKI treatment. **Conclusion:** Coexistence of activating KRAS mutation is not uncommon in NSCLC patients with BRAF mutations, especially in patients with non-V600E mutations. Therefore, therapeutic choice for patients with BRAF non-V600E mutation need comprehensive consideration of companion mutations. Moreover, previous EGFR-TKI may increase the incidence of concurrence of generally mutually exclusive mutations.

**Keywords:** BRAF, coexistence, KRAS
P1.14-02 PREDICTING STENT FAILURE IN MALIGNANT ESOPHAGEAL OBSTRUCTION

T. Järvinen, I. Ilonen, J. Räsänen
Department of General Thoracic and Esophageal Surgery, Heart and Lung Center, Helsinki University Hospital, Hús/Fi

Background: Esophageal malignant obstruction is commonly caused by esophageal cancer and seldom caused by malignant disease not originating from the esophagus. Malnutrition and feedin intolerance are commonly present. Palliation is commonly achieved with insertion of an esophageal stent, which has been deemed safe and effective in previous trials. Our objective was to assess the factors predicting the failure of stent treatment in malignant obstruction of the esophagus. Method: This was a retrospective cohort study with primary end point of stent failure. Stent failure is defined here as any major complication caused by the stent (perforation, fistula, etc.), migration of the stent the stomach or any need for non-planned urgent removal of the stent. Patient demographic details, stent insertion details (indication, date, location, size, type of stent), complications related to stent-insertion, operations associated with stent insertion, and possible time of death were collected. Result: Between March 2005 and December 2013 there were 410 esophageal stents placed for treatment of malignant obstruction. The most common pathology was esophageal cancer (N = 333, 81.2%), lung cancer was the cause in 44 (10.7%) and mesothelioma and breast cancer were found were both found in 5 patients (1.2%). The remaining 23 patients had cancers of various histologies. Median OS was 149 days from stent insertion (IQR: 63-297 days). Stent failure rate in the first 6 months was 27.3% (N = 112) with median time to failure being 46 days (IQR: 9-105). Cox multivariate regression analysis was done by backwards elimination method with a p-value limit of 0.2, the results are shown in Table 1.

Table 1 Multivariate Cox regression analysis of factors affecting stent failure

</tr>
</tbody>
</table>

*Top edge under 25 cm from incisors

Conclusion: In the setting of malignant obstruction of the esophagus, stent failure rate is related to the location of the inserted stent. More proximal stents have a higher rate of failure in multivariate analysis (HR =1.68, p = 0.00714).

Background: Platinum and anthracycline combination chemotheraphy has been considered as the standard treatment for invasive thymoma for a long time. The clinical activity of amrubicin (AMR)—an anthracycline agent—has been previously reported in the treatment of small cell lung cancer (SCLC). The aim of this study was to evaluate the efficacy and safety of the combination of AMR and cisplatin (CDDP) in patients with advanced or recurrent invasive thymoma. Method: s: Patients were eligible for inclusion in the study if they met the following criteria: were chemo-naive; not amenable to curative surgery or radiotherapy; and presented with histologically confirmed invasive thymoma in each site. The patients received AMR (35 mg/m2, on days 1–3) and CDDP (60 mg/m2, on day 1) every 3 weeks, for up to 4 cycles. The primary endpoint was the objective response rate (ORR) assessed by an independent review, and the secondary endpoints were overall survival (OS) and toxicity profile of the patients. Based on the SWOG 2-stage design, the planned sample size of 40 patients was determined to reject the ORR of 60% under the expectation of 0.3 as a p-value of 0.05. This trial is registered with the UMIN Clinical Trials Registry, number UMIN00003933. Result: s: From August 2010 to November 2014, a total of 26 patients were enrolled at 14 institutions in Japan. During the planned interim analysis in April 2014, the ORR of the 20 patients who had been enrolled so far, was assessed via independent review and found to be 55.6% (11/20), resulting in the early termination of this study because of its futility. In the final assessment, the ORR was 54.2% (95% confidence interval: 32.8–74.4) and the disease control rate was 95.8%. The OS did not reach the median value. The major grade 3 or 4 toxicities noted were neutropenia (96.2%), anemia (26.9%), anorexia (11.5%) and febrile neutropenia (26.9%), albeit these were transient and manageable. There was one treatment-related death. Conclusion: s: The combination of AMR with CDDP had minimal activity on invasive thymoma. Thus, we do not recommend further study of this regimen.

Keywords: Thymoma, chemotherapy, amurubicin

P1.14.04 STEREOTACTIC BODY RADIATION THERAPY FOR PLEURAL RECURRENCES OF THYMOMA

F. Emmanuelle1, A. Botticella1, G. Pieri2, C. Le Pechoux3

1Radiotherapy, Gustave Roussy, Villejuif/JF; 2Radiation Oncology, Institut Gustave Roussy, Villejuif/JF

Background: Pleural recurrences are not uncommon as a result of thymoma evolution; yet there is no therapeutic standard for their treatment. The purpose of this study was to evaluate the efficacy and tolerability of stereotactic body radiation therapy (SBRT) for the treatment of pleural metastasis. Method: A single institution retrospective study of the patients treated with SBRT using Novalis and VMAT, with doses of 30Gy in 5 fractions or 10Gy in 4 fractions. Treatment responses were evaluated using TDM and/or TEP TDM Result: In the period 2014–2017, 10 patients (6 women, 4 men) with a median age of 51 and a total of 21 pleural recurrences were treated with SBRT. Initial Masaoka-Koga stages were: I 1, IIb 3, III 2, IVA 1 and 1 unknown. Nine of them had previously been treated for other pleural recurrences (7 had surgery, 2 conformational RT and 3 chemotherapy). All patients were treated for one to three recurrence locations, either successively or at the same time. At the time of last follow-up, only one patient had disease following the metastasis evolution of their thymoma. With a median follow-up for the lesions of 20 months, local control was very good, since all lesions were reduced to a smaller, non-progressive mass or in complete metabolic response. No patient developed Grade 3 or higher acute or late toxicity. Conclusion: Treatment of pleural recurrences of thymoma using SBRT with moderate doses allowed for good local control without increased toxicity, constituting a good alternative to surgery. This treatment could furthermore delay the use of chemotherapy.

Keywords: pleural metastasis, Thymoma, SBRT
Conclusion: Although patient selection, surgical technique, and other postoperative management have been markedly improved in recent years, the morbidity rate after esophagectomy for esophageal cancer remains high. Recent studies lead us to pay attention to the perioperative and postoperative care, but they may ignore the pulmonary function disturbance as one of the major contributing factors for long-term and progression-free survival.

Keywords: esophageal cancer, pulmonary function, survival

P1.14-05 THE ASSOCIATION OF PULMONARY FUNCTION WITH SURVIVAL AFTER TREATMENT IN PATIENTS WITH ESOPHAGEAL CANCER

H. Liao1, P. Yang1, J. Lee2
1National Taiwan University Hospital, Zhongzheng Dist., Taipei City/TW, 2National Taiwan University Hospital, Taipei City/TW

Background: Previously, studies have found that inadequate pulmonary function in patients with esophageal cancer can associate with a higher risk of postoperative pulmonary complications which can lead to a higher risk of mortality in the perioperative period or long-term follow-up. In this study, we investigate the prognostic effect of pulmonary function for patients with esophageal cancer after treatment. Method: From 2004-2016, 732 esophageal cancer patients underwent surgical treatment were enrolled. They received pulmonary function before treatment, and 542 (74.04%) underwent pre-operative concurrent chemoradiotherapy (CCRT) before surgery. Patients were divided into three groups by pulmonary function level (FEV1 < 80%, inadequate pulmonary function; 80% < FEV1 < 100%, adequate pulmonary function; FEV1 > 100%, well pulmonary function). We use multivariate analysis including all of the possible factors to evaluate overall survival and progression-free survival after surgery. Result: As the result, we found that cancer staging, neo-adjuvant CCRT, operation method and pre-operative FEV1 were found statistically significant for survival after treatment. As compared to patients with FEV1 less than 80% of prediction, patients with EFV1 more than 80% had an around thirty percent of decreasing mortality rate after surgery (p = 0.034). The cox-regression with survival analysis also revealed that patients with better lung function had significantly better progression-free survival (P<0.05, respectively) than those with poor lung function. Besides, the grouping by CCRT-pCR (pathologic complete response) also had similar results. It maybe due to pulmonary function is an important immunological factor in those esophageal cancer patients.

**Background:** Thymic carcinoma (TC) is compared with thymoma has a lower incidence rate and is more likely to be diagnosed in advanced-stage disease, with a worst prognosis. Platinum combination regimen is widely recognized as the best treatment in the first line setting, followed by other systemic therapies, such as cytotoxic drugs and target agents, with the aim of achieving control disease and prolonging survival. Since there is limited information about the optimal treatment modality in TC, this study aims to identify the most promising therapeutic sequence in terms of efficacy and toxicity profile.

**Method:** We conducted a monocentric retrospective analysis of patients (pts) with un-resectable-metastatic TC, referred to our Rare Tumors Reference Center over a 15-year period. All pts with confirmed histological diagnosis, treated with at least three lines of therapy were included in the analysis. For each identified sequence treatment, progression free survival (PFS) and overall survival (OS), according to RECIST 1.1 and toxicity profile according to CTC-AE v.4.0, were determined.

**Result:** Among 52 patients with advanced TC, 17 of them (32.6%) treated with at least three lines of chemotherapies and target agents (imatinib, sunitinib, everolimus) were included in the study. The main therapeutic sequences were identified: 1) platinum-based therapy - platinum-based therapy – target agent (7 pts); 2) platinum-based therapy – capectabine and gemcitabine combination-therapy – target agent (5 pts); 3) platinum-based therapy – target agent – no platinum-based chemotherapeutic agent (6 pts). The median OS from the start of first-line chemotherapy was 67 months with no significant difference among sequences, with an OS respectively of 83, 67 and 106 months (p<0.99).

Also for PFS, with a median value of 33 months, there was registered no adverse events more than grade 2 for the second and third sequence, and conversely, toxicity of grade 3 registered in more than 50% of the pts in first sequence. Asthenia, emesis and pancytopenia which required hospitalization in 3 pts, were the most frequent.

**Conclusion:** To our knowledge, this is the first data analysis of sequential regimens modality in patients with advanced TC. Since the efficacy of each treatment sequence did not vary significantly, we suggest to administer the therapy in patients with advanced TC. Since the efficacy of each treatment sequence did not vary significantly, we suggest to administer the therapy.

**Keywords:** Thymic carcinoma, treatment sequence modality, platinum-based chemotherapy

**P1.14-07 INTRAOPERATIVE DETECTION OF CIRCULATING TUMOR CELLS IN PULMONARY VENOUS BLOOD DURING METASTASECTOMY FOR COLORECTAL LUNG METASTASES**

S. Schmid, U. Le, B. Passlick, J. Kaifi

**Background:** Circulating tumor cells (CTC) have been studied extensively in various tumor types and are a well-established prognosticator in colorectal cancer (CRC). This is the first study to isolate CTC directly from the tumor outflow in secondary lung tumors. **Method:** From 24 patients with CRC who underwent pulmonary metastasectomy in curative intent blood was drawn intraoperatively from the pulmonary vein (tumor outflow). In 22 samples CTC-enumeration was performed using the CellSearch®-System. **Result:** We could isolate more CTC in pulmonary venous blood (total 41, range 0-15) than in samples taken from the periphery by the same time (total 6, range 0-5, p=0.09). Tumor positive lymph nodes correlated with positive CTC in pulmonary venous blood as in all cases CTC were present (p=0.006).

**Conclusion:** Our findings suggest a tumor cell release from pulmonary metastases in CRC and a correlation of CTC isolated from the tumor outflow with established negative prognostic markers in metastasized CRC. The presented data warrant further investigations regarding the significance of local tumor compartments when analyzing circulating markers and the possibility of tumor cell shedding from secondary lung tumors.

**P1.14-08 THE USEFULNESS OF THE HEMICLAMSH SHELL THORACOTOMY IN THORACIC SURGERY**

**Background:** The antero-lateral approach provides good exposure of the cervicothoracic region and enables removal of lesions that develop in this complex anatomic area. **Method:** We retrospectively evaluated the indications and outcomes of the hemiclamshell approach in patients undergoing tumor resection in thoracic surgery. Eleven lung cancer patients and one non seminomotous germ cell tumor of the mediastinum who underwent tumor resection via hemi-clamshell approach in our department, between 2007 and 2018 were studied retrospectively, analyzing the indications, morbidity and outcome. **Result:** The indications were: 1) apical tumors with vascular invasion in four, giant mass (10, 17, 21cm in tumor diameter) with superior or inferior vena cava invasion in three, aortic arch invasion in one, sternal invasion in one, mediastinal lymph node metastasis in the left upper lung cancer in one, and pulmonary artery aneurysm after left upper lobectomy in one. In eleven lung cancer patients, combined resection of the neighboring organ was performed in nine organs among eight patients: subclavian artery in two, carotid artery in one, aorta in one, superior vena cava in one, chest wall in two, phrenic nerve in one, and pericardium in one. One-month mortality was 0%. Operative morbidity was observed in four patients (33%): two patients suffered from deep wound infection, one from a chylotrauma, and one from pleural effusion. R0 resection was achieved in eleven patients. **Conclusion:** The hemiclamshell approach was associated with relative high morbidity rate but no mortality. Hemiclamshell is suitable for tumours of the cervicothoracic junction with vascular invasion and giant tumors, providing good access for control of the large vessels including pulmonary artery and vein.

**Keywords:** Hemiclamshell approach, the cervicothoracic junction

**P1.14-09 OUTCOME AFTER LUNG RESECTION FOR PRIMARY LUNG CARCINOMAS/METASTASIS IN PATIENTS WITH PERFORMED TOTAL LARYNGECTOMY FOR LARYNGEAL CARCINOMA**

**Background:** Total laryngectomy remains the treatment of choice for recurrent/persistent laryngeal carcinoma after radiotherapy or chemoradiotherapy. These patients with laryngeal carcinoma are at risk for developing both pulmonary metastasis and second primary lung cancer. Because of the persistent tracheostomy, postoperative ventilation management after lung resection is usually a difficult process. Ineffective evaluation of preoperative pulmonary functions, failure of single lung ventilation due to short trachea, inadequate respiratory physiotherapy are frequently encountered problems. The purpose of this study is to evaluate the outcomes of laryngectomy in patients with persistent tracheostomy due to laryngeal carcinoma. **Method:** Between Jan 2006- Jan 2016, the data of 9247 patients who underwent lung resection at three different centers were retrospectively examined. The study group consisted of 68 patients (62 male, mean age 59.49 ± 11.4 (31-82)) who had persistent tracheostomy due to laryngeal carcinoma. Patient preoperative evaluation parameters, operation techniques, postoperative complications and survival were analyzed. **Result:** The mean time between the two operations was 55.68 ± 64.8 (3-312) months. Pulmonary tumors were located in the upper lobe in 53 patients (77.9%), in the lower lobe in 11 patients (16.1%), in the middle lobe in 2 patients (3%) and bilaterally in 2 patients (3%). Lung resection was performed with thoracotomy in 53 patients (78%) and videothoracoscopic in 15 patients.
University of Bari “aldo Moro”, Bari/IT, endometriosis focus, successfully treated with surgery.

**Background:** Endometriosis is an ectopic, unusual localization of endometrial tissue in thoracic organs. The development of thoracic endometriosis remains unclear. We investigated PD-L1 expression in TETs and verified the pattern of expression associated with the pathological type. **Method:** We examined 66 malignant TETs. Immunohistochemical evaluation of PD-L1 expression was performed using anti-PD-L1 antibody (SP263). We calculated the tumor cell positive rate (Total Proportion Score: TPS) of PD-L1 expression. The discrimination of the tumor region was confirmed by immunostaining with anti-pan-cytokeratin antibody (AE1/AE3).

**Conclusion:** 1. PD-L1 expression was examined for each type of histological classification of TETs. We classified a high-malignancy group and PD-L1 expression was also digitally analyzed based on Whole Slides Imaging (WSI) for objective analysis as Digital TPS. **Result:** We identified WHO histological types (Type A/AB/B1/B2/B3/metastatic tumor/thyrmic carcinomas = B19/S5/15/6/2/11). In Type A, PD-L1 expression was low in most cases and the median of TPS was 22%, in Type AB, Type A and B regions showed low and high TPS, respectively, and the median was 23%. In Type B1, TPS was low in most cases and the median was 26%. In Type B2, TPS was higher than that in Type B1, and the median was 69%. In Type B3, TPS was high (>50%) in all cases and the median was 86%. The PD-L1 expression of thymic carcinomas ranged from low to high and the median was 28%. Metastatic tumors showed scanty PD-L1 expression. The High PD-L1 group showed more advanced disease stages according to the Masaoka stage and TNM classification, and the TPS of Type B2 and B3 was significantly higher than that of Type A and B1. The disease-free survival rate was significantly lower in the H group than that in the L group. When we examined the prognosis in high-malignancy group, there were no significant differences in the disease-free and overall survival rates by TPS. Based on measurements using WSI, Digital TPS correlated with visual TPS (correlation coefficient=0.85, p-value<0.001). **Conclusion:** TETs had the characteristic features of the PD-L1 expression according to histological types. Type B2 and B3 thymomas was higher PD-L1 expression than the other types of TETs.

**Keywords:** PD-L1, TETs, Malignant thymic epithelial tumors

**P1.14-10 SURGICAL TREATMENT OF A RARE CASE OF CLEAR CELL CARCINOMATOUS TRANSFORMATION OF A DIAPHRAGMATIC ENDOMETRIOSIS FOCUS**

1Department of Thoracic Surgery, Department of Emergency and Organ Transplantation, University of Bari “aldo Moro”, Bari/IT. 2Division of Pathology, Department of Emergency and Organ Transplantation, University of Bari “aldo Moro”, Bari/IT.

**Background:** Thoracic endometriosis is an ectopic, unusual localization of endometrial tissue in thoracic organs. The development of thoracic endometriosis can be determined by the embolization of endometriotic foci to the lung by lymphatic, hematic or trans-diaphragmatic way. We report a rare case of carcinomatous transformation of a diaphragmatic endometriosis focus, successfully treated with surgery. **Method:** A 46-year old woman, with a history of previous operation for bilateral endometriotic pelvic cyst, presented to our institution with dyspnoea and massive right pleural effusion, which was treated with chest drainage. After drainage, chest and abdomen computerized tomo-graphy (CT) and magnetic resonance imaging (MRI) showed a large (7 x 6 cm), roundish, inhomogeneous, capsulated mass of the right hemidiaphragm, causing compression of the adjacent lung and liver. Bronchofibroscopy showed an extrinsic compression of subsegmental bronchi of the basal pyramid of the right lung. After cardio-respiratory function evaluation, the patient underwent videothoracoscopic pleural biopsies with frozen section negative for malignancy, therefore we converted in antero-lateral thoracotomy and a radical surgical resection of the diaphragmatic mass, en-bloc with the adherent and apparently infiltrated lung and hepatic parenchyma, was performed. **Result:** Postoperative course was uneventful. Histopathological examination revealed squamous cell carcinoma of the diaphragmatic clear cell carcinoma focus; Ki67 was >50%; P53/KCA BRAF genes were not mutated. Total body 18F-fluorodeoxyglucose positron emission tomography (FDG-PET)/CT showed bilateral increased ovarian uptake, thus the patient underwent radical abdominal hysterecomy, with diagnosis of endometriosis, and subsequent adjuvant chemotherapy for the diaphragmatic clear cell carcinoma. Total body CT scan at 7 months from surgery showed neither local recurrence, nor distant metastases. **Conclusion:** Thoracic endometriosis requires a multidisciplinary approach and management. In our experience, surgery represented the treatment of choice, in order to ensure oncological radicality, in a young patient with a rare condition of carcinomatous transformation of a diaphragmatic endometriosis focus, which should be considered among the possible evolutions of endometriosis. To the best of our knowledge, this is the first reported case of radical surgical treatment of a clear cell carcinomatous transformation of a diaphragmatic endometriosis focus.

**Keywords:** Diaphragm, clear cell carcinoma, thoracic endometriosis

**P1.14-11 THE EXPRESSION PATTERN OF PROGRAMMED DEATH-LIGAND 1 ACCORDING TO THE PATHOLOGICAL TYPE OF MALIGNANT THYMIC EPITHELIAL TUMORS**

S. Ishihara1, S. Okada1, H. Ogii1, Y. Kodama1, K. Itoh2, A. Marx2, M. Inoue1

1Division of Thoracic Surgery, Department of Surgery, Kyoto Prefectural University of Medicine, Kyoto/Japan. 2Department of Pathology and Applied Neurobiology, Kyoto Prefectural University of Medicine, Kyoto/Japan.

**Background:** Malignant thymic epithelial tumors (TETs) have pathological types ranging from low-grade to high-grade malignancy, while the pattern of PD-L1 expression remains unclear. We investigated PD-L1 expression in TETs and verified the pattern of expression associated with the pathological type. **Method:** We examined 66 malignant TETs. Immunohistochemical evaluation of PD-L1 expression was performed using anti-PD-L1 antibody (SP263). We calculated the tumor cell positive rate (Total Proportion Score: TPS) of PD-L1 expression. The discrimination of the tumor region was confirmed by immunostaining with anti-pan-cytokeratin antibody (AE1/AE3).

**Conclusion:** Type A/AB/B1/B2/B3/metastatic tumor/thymic carcinomas had the characteristic features of the PD-L1 expression according to histological types. Type B2 and B3 thymomas was higher PD-L1 expression than the other types of TETs.

**Keywords:** PD-L1, TETs, Malignant thymic epithelial tumors

**P1.14-12 GTF2I MUTATION IN THYMOMAS: INDIAN AND GERMAN STUDY**

D. Jain1, P. Guleria1, R. Parshad2, A. Marx3

1Pathology. All India Institute of Medical Sciences, New Delhi/IN. 2Surgery, All India Institute of Medical Sciences, New Delhi/IN. 3Pathology. Institute of Pathology, University Medical Center Mannheim, University of Heidelberg, Mannheim/DE

**Background:** Point mutation (L404H) of GTF2I gene on chromosome 7 has been identified in thymic epithelial tumors; most predominantly in A and AB histotypes and associated with good prognosis. The objective of this retrospective study was to assess the frequency of GTF2I mutation in Indian and German thymomas and correlate with WHO histotypes. **Method:** A cohort of Indian and German thymomas of different histotypes was retrieved from the archives. Clinicopathological details were obtained from case files. Hematoxylin-eosin stained slides were reviewed and histopathological subtypes along with Masaoka-Koga staging were determined. The available blocks were selected for DNA extraction. Tumors rich in cancer cells (>50%) were evaluated for GTF2I mutation using Sanger sequencing. Primer for exon 15 of GTF2I gene was designed using NCBI and Primer 3 (v0.4.0) software. Results were compiled and analysed.

**Result:** A total of 126 resection specimens were retrieved comprising 23 (18.2%) Type A, 30 (23.8%) Type AB 16 atypical A/AB (12.6%) and 30 (23.8%) Type B thymomas. Remaining 27 cases belonged to 18 thymic carcinomas, 2 sclerosing medullary thymomas, 2 metastatic thymomas, 1 thymolipoma, and 4 non-thymomatous lesions. Out of a total of 69 A/AB thymomas, 53 (76.8%) were positive including 88% (22/25) Indian and 65.9% (29/44) German cases. 28% (16/69) A/AB thymomas...
AB were negative. All Indian B histotypes (n=9) were negative, whereas 4 German B thymomas (4/21, 19%) were positive for GTF2I mutation. No mutations were found in non-thymomatous pathologies. Among 34 Indian cases, there was equal gender distribution, median age was 48 years and 31 were in lower stage groups (Stage I and II). Clinical details and follow up available in 17 of 34 cases had a median follow up of 14 months and revealed presence of myasthenia gravis in 70.58% cases. Recurrence seen in 3 cases revealed high risk morphology (2 Type B histotypes and 1 atypical A) and one death of Type A was due to myasthenic crisis. Conclusion: The similarity of Indian and German (and presumably published American) cohorts of A/B and type B thymomas in term of GTF2I mutation frequencies suggests a thymus-specific microenvironmental mutagenic mechanism and argues against a relevant impact of environmental or ethnic (germ line) factors. The unusually high prevalence of Myasthenia gravis among the Indian thymomas warrants further analysis to exclude referral bias.

P1.14-13 PD-L1 IMMUNO-EXPRESSION ASSAY IN THYMOMAS: A STUDY FROM INDIA

D. Jain1, P. Guleria1, N. Husain1, S. Shukla1, S. Kumar1, R. Parshad2
1Pathology, All India Institute of Medical Sciences, New Delhi/IN, 2Pathology, Dr. Ram Manohar Lohia Institute of Medical Sciences, Lucknow/IN

Background: Programmed death ligand 1 (PD-L1), an immune check point inhibitor, is known to be expressed in several malignancies and is being considered as a prognostic factor and a potential immunotherapeutic target. Recent development of anti-PD-L1/L1 antibodies has demonstrated anticancer activity of these agents in various neoplasms. The aim of this study was to characterize PD-L1 expression in thymomas and to determine whether PD-L1 represents a therapeutic target in unresectable thymomas. A correlation with clinicopathological features and previously published studies in the literature was established.

Method: Tissue microarrays were prepared from selected blocks of formalin-fixed and paraffin-embedded tissue from 91 thymoma cases. Immunohistochemistry with PD-L1 (22C3, DAKO) was performed. Cases were considered as PD-L1 positive or negative based on percentage of stained thymic epithelial cells; if these were <25% or ≥25 percent. Results were compared clinically and with previously published studies using Google and PubMed search engines. Result: Of 84 cases of thymoma, 69 (82.1%) revealed PD-L1 positivity in more than 25% cells. 94.23% of type B thymoma subtypes (B1/B2/B3) were previously published American cohorts of A/B and type B thymomas, the remaining 15 cases were followed-up periodically owing to the presence of small benign nodular lesions. This study included 3,414 individuals. The prevalence of Myasthenia gravis was prevalent in women (P=.02) and in lower stages in men (P=.008) and these were type B thymomas (P=.01).

P1.14-14 HISTOTYPING OF INDIAN THYMOMAS: A COMPREHENSIVE CLINICOPATHOLOGICAL STUDY

D. Jain1, P. Guleria1, R. Parshad2, P. Malik1, S. Kumar3
1Pathology, All India Institute of Medical Sciences, New Delhi/IN, 2Surgical Oncology, All India Institute of Medical Sciences, New Delhi/IN, 3Surgical Oncology, All India Institute of Medical Sciences, New Delhi/IN

Background: Thymomas are rare, but most common anterior mediastinal lesions. The WHO 2015 classification has defined criteria of classifying these into various subtypes. The histomorphologic spectrum of thymic epithelial tumors (TET) in Indian population has not been explored. We aimed to study the histomorphology of TETs in the Indian patients with clinicopathological correlation. Method: It was a retrospective, single center, reference study. All cases of thymomas surgically resected specimens and small biopsies diagnosed as TETs since 2009 were included. Clinical details and histology slides were reviewed using the Modified Masaoka-Koga staging system and WHO 2015 classification. Clinico-pathological correlation and survival analysis was performed from other published Indian studies was performed. Result: We identified 219 cases of TETs (138 resections and 81 biopsies). Most common histo-morphologic type was B2 and most frequent stage was I. Clinically, higher stage tumors were found mostly in female (67.08%) and these were type B thymomas (P=.01). Association of myasthenia gravis was prevalent in women (P=.02) and in lower stages (P=.04). Survival analysis revealed significant association between recurrence and tumor stage. Although thymic carcinoma was diagnosed on biopsy, no resectable case was identified. Conclusion: Literature lacks detailed histotyping of TETs from India. Indian thymomas are most commonly stage I tumors of B2 and AB histotypes. Resected thymic carcinomas are conspicuously absent in Indian cohort. We hope that broadening the spectrum of recognized pathological manifestations of Indian thymomas will help global database for future studies.

Background: Compared with lung tumors, mediastinal tumors occur less frequently, but the precise incidence of mediastinal tumors in healthy populations is still unknown. Chest radiographic screening is a commonly used conventional method for the detection of thoracic tumors. However, early phase detection of mediastinal tumors is difficult due to the location of these tumors. Using low-dose spiral computed tomography (LDCT), this study aimed to investigate the precise incidence of mediastinal tumors, including that of small early phase masses that cannot be detected by radiography. Method: Among people who underwent medical check-ups consecutively for 8 years (from April 2010 to March 2018) at our institution, those who also underwent LDCT were enrolled in this study. In total, this study included 3,414 individuals. The prevalence of mediastinal tumor in these individuals was investigated.

Result: Thirty-two cases of mediastinal tumor (0.9%) were detected using LDCT, of which 20, 5, 4, and 3 were anterior, superior, middle, and posterior mediastinum tumors, respectively; this was a higher prevalence than that reported in our country (0.1%-0.8%). Of the 32 cases, 17 were further examined, and finally, in some of these cases, the tumors were successfully surgically resected. The remaining 15 cases were followed-up periodically owing to the presence of small benign nodular lesions. Among the 32 cases, tumors of only 3 cases were detected using chest radiography. Conclusion: The incidence of mediastinal tumor is higher than that previously reported in our country. Compared with chest radiography, LDCT contributes to the early phase detection of mediastinal tumors.

MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.14-16 DNA METHYLATION OF GNG4, GHSR, HOXD9 AND SALL3 GENES PREDICT MALIGNANT BEHAVIOR OF THYMIC EPITHELIAL TUMORS

1Department of Oncological Medical Services, Graduate School of Biomedical Sciences, Tokushima University, Tokushima/JP, 2Thoracic, Endocrine and Oncological Surgery, Graduate School of Biomedical Sciences, Tokushima University, Tokushima/JP, 3Department of Thoracic, Endocrine Surgery and Oncology, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima City/JP

Background: Our previous studies showed that DNA methylation of cancer-related genes-DAP-K, p-16, MGMT, HPPI genes in thymic carcinoma (TC) was higher than that in thymoma (Lung Cancer 64:155-, 2009; 83:279- 279, 2013). Genome-wide screening for aberrantly methylated CpG islands was performed in 7 TC samples and 8 type-B3 thymoma samples using HumanMethylation 450 K BeadChip (Illumina, Santa Clara,
CA, USA) analysis. We identified 22 genes as commonly hypermethylated in TC comparing with B3 thymoma. We picked up 4 cancer-related genes: GNG4, GHSR, HOXD9 and SALL3 from those genes as the most significant hypermethylated gene. **Method:** In total, 47 thymic tumour samples (thymoma; 31, carcinoma; 16) and 18 paired normal tissues were obtained from patients with histologically proven thymic epithelial tumour (TET), who underwent surgery at the Tokushima University Hospital (Tokushima, Japan) between 1990 and 2016. The methylation status of TET samples was validated by pyrosequencing. **Result:** DNA methylation of GNG4 gene in TC was significantly higher than that in thymoma (34.6% versus 8.9%). In other 4 genes, DNA methylation in TC was significantly higher than that in thymoma (GHSR: 59.3% vs 34.2%, HOXD9: 37.3% vs 12.3%, SALL3: 33.5% vs 7.2%). In GHSR and HOXD9 genes, DNA methylation in thymoma was significantly higher than that in normal thymus. And in GNG4 and SALL3, DNA methylation in thymoma was similar to that in normal thymus. Epigenetic alteration may be related to progression or malignancy in TET.

**Keywords:** DNA methylation, Thymoma, Thymic carcinoma

**P1.14-17 IDENTIFICATION OF MOLECULAR SUBTYPES OF THYMIC EPITHELIAL TUMORS AND NOVEL TREATMENTS USING A COMPUTATIONAL BIOLOGICAL MODEL**

S. Padda1, Y. Gokmen-Polar2, S. Badve1, S. Vasisht1, K. Basu1, A. Kumar3, S. Vali1, T. Abbasi3, H. Wakelee1

1Stanford Cancer Institute/Stanford University School of Medicine, Stanford/CA/US, 2Cellworks Group, San Jose/CA/US

**Background:** The histologic classification of thymic epithelial tumors (TETs) is based on the description of both epithelial cell morphology and relative abundance of lymphocytes. Here, we used a computational biological model (CBM) approach on The Cancer Genome Atlas (TCGA) dataset to identify molecular subtypes of TETs and associated predicted therapeutic options. **Method:** Whole exome sequencing and gene expression data from the TCGA TET dataset (n = 102) along with the IUTAB-1 cell line was input into CBM software (Cellworks Group, San Jose, CA) to build an unsupervised classification model beyond the TET pathological subtypes previously reported (Loehrer PJ ASCO 2017). The CBM generated a disease specific protein network map using PubMed and other online resources. Using computer simulation, disease biomarkers unique to each tumor were identified within the protein network maps. Among the tumors simulated, 6 molecular clusters were identified (TH1-TH6). The CBM digital drug library was tested against these molecular subtypes and the cell growth score (i.e. cell proliferation, viability, and apoptosis) was analyzed. **Result:** The CBM identified 6 molecular subtypes among 102 TET patients. Among subtypes with a GTF2I mutation, TH1, TH4, and TH6 also had chromosomal aberrations in chromosome 22 and 9. Deletion of chromosome 22 was present in TH1, deletion of chromosome 9 in TH4 and TH6, and also amplification of chromosome 22q in TH4. Among GTF2I wild type subtypes, chromosome 22q deletion and complex cytogenetics were present in TH2, trisomy of chromosome 1 in TH3, and HRAS mutations and chromosome 2 amplification in TH5. The IUTAB-1 cell line had a GTF2I mutation and mapped to the TH4 molecular subtype. The CBM predictions of sensitivity of TH subtype to Nelfinavir (AKT inhibitor) and Panobinostat (histone deacetylase inhibitor) along with resistance to Everolimus (mTOR inhibitor) were validated in vitro. There were two molecular subtypes for which Everolimus was predicted to be sensitive, TH1 and TH6.

**Conclusion:** We present an updated classification of TETs based on a CBM approach and associated potential novel therapeutic options that could be further validated in clinical trials.

**Background:** The clinical management of thymic carcinomas (TC), remains very challenging, however thanks to the optimization of therapeutic strategy, the 50% of patients is still alive at 5 years. The promising role of sunitinib, a multi tyrosine kinase inhibitor (TKI), has been recently confirmed in several prospective trials, but no data about the rechallenge modality administration are already available. In the case here reported, we illustrate an impressive response disease in a very heavily pre-treated TC after sunitinib rechallenge. **Method:** In August 2013, a 45-year-old caucasian male was referred to our Institution, for a diagnosis of un-resectable/metastatic TC. A systemic therapy strategy was planned. **Result:** Anthracidine-platinum-based chemotherapy was delivered as first, for total 6 cycles, obtained a partial response (PR) with more than 60% of disease reduction (DR). After a brief drug holiday, because of lung progression, the patient underwent capicitabine-gefitinib combination-chemotherapy. In August 2014, he progressed after 6 cycles and was candidate to start sunitinib at standard dose of 50 mg daily/4 weeks on/2 weeks off, in off-label modality. A dose reduction at 50 mg/daily/1 week on/1 week off was made due to persistent diarrhea G2, thrombocytopenia G2 and asthenia G3. Surprisingly, with no more toxicities, he achieved an important partial response with more than 70% of DR, maintained for total 26 months. Unfortunately, a new lung disease progression was registered and oral etoposide at dosage of 50 mg/die 3 weeks on/1 week off was started, without any results. Considering the good response obtained in the first line chemotherapy and envisioning the opportunity to revert target therapy resistance, as already demonstrated for other solid malignancies, 3 cycles of carboplatinum-paclitaxel were delivered, obtained stable disease. Analysis with NGS and microsatilities instability, were not performed, with no results useful for the therapeutic decision process. In October 2017, because of the brilliant response achieved with sunitinib and considering the free interval of 12 months, a sunitinib rechallenge was established at 50 mg/daily 1 week on/1 week off. An impressive disease reduction, which is still ongoing, was revealed, no side effects were reported. **Conclusion:** This reported experience, shows sunitinib rechallenge effectiveness for prolonged control disease in thymic carcinoma, despite the number of previous treatments administered before the first and the second drug delivery. A personalized dose reduction can be used for treating heavily pre-treated thymic malignancies to better manage the toxicity profile. Rechallenge with TKI in previous responder patient, should be included routinely in the strategy for the treatment of refractory disease.

**Keywords:** Thymic carcinoma, sunitinib rechallenge, personalized treatment schedule

**P1.14-15 THE PROMISING ROLE OF SUNITINIB RECHALLENGE IN HEAVILY PRE-TREATED THYMIC CARCINOMA: A CASE REPORT**

G. Palmieri1, M. Ottaviano1, M. Tortora3, P. Perrone1, C. Rea5, S. De Placido2, M. Giuliano6

1Ctrr Rare Tumours Reference Center, University of Naples Federico II, Naples/IT, 2Clinical Medicine and Surgery, Oncology Unit, Ctrr Rare Tumours Reference Center, University of Naples Federico II, Naples/IT, 3Oncology Unit, Ctrr Rare Tumours Reference Center, Naples/IT

**Background:** The clinical management of thymic carcinomas (TC), remains very challenging, however thanks to the optimization of therapeutic strategy, the 50% of patients is still alive at 5 years. The promising role of sunitinib, a multi tyrosine kinase inhibitor (TKI), has been recently confirmed in several prospective trials, but no data about the rechallenge modality administration are already available. Background: Thymic epithelial tumors are the most common mediastinal tumors. Surgery is the mainstay of treatment and complete resection provides the best survival rate. Nevertheless, advanced tumors may require multimodal therapy and additional prognostic factors beyond tumor stage and histological classification might help to risk-stratify patients and personalize the treatment course. Method: Between 1999 and 2017 202 patients with thymic epithelial tumors were operated in our center. The preoperative C-reactive protein (CRP) and lactate dehydrogenase (LDH) levels as well as clinical follow-up were reviewed. Retrospectively collected and the association of circulating biomarkers with clinicopathological parameters and their impact on overall survival was analyzed. Result: 115 male and 87 female patients were included in the study with 59.5 (±13.1) years mean age at the time of operation. 30 patients (including 12 male patients) suffered from myasthenia gravis. Thymic carcinoma was associated with high CRP (>1mg/dl) when compared to thymoma cases (34% vs 12%, p=0.001). While LDH levels did not show such association, there was a strong tendency for increased mean LDH levels in Masaoka 4 patients (252.5±18.9 vs 220.5±6.1, p=0.063). Overall survival was analyzed in the thymic carcinoma subcohort. 90% of the patients were treated in a multimodal approach and received chemo- and/or radiotherapy in adjuvant or neoadjuvant setting. Median overall survival was 11.3 years. The Masaoka stage 1-3 versus 4) was a significant prognostic factor (HR=0.23, 95%CI 0.07 to 0.77, p=0.017). Elevated CRP (>1mg/dl) did not show prognostic power for overall survival (HR=0.82, 95%CI 0.77 to 1.33, p=0.76). In contrast increased preoperative LDH level (>200 U/L) resulted in poorer outcome (HR=0.32, 95%CI 0.09 to 1.13, p=0.076). Conclusion: Circulating biomarkers show association with advanced disease stage in thymic epithelial tumours. Importantly, preoperative LDH levels carry prognostic information in thymic carcinoma and could be used to risk stratify surgically treated patients in multimodal treatment settings.

Keywords: LDH, Thymic carcinoma, Thymoma

P1.14-22 THE PROGNOSTIC ROLE OF THE SUPPRESSOR OF CYTOKINE SIGNALING-5 (SOCS5) IN ESOPHAGEAL SQUAMOUS CELL CARCINOMA
P. Yang, Y. Chang, J. Lee
Surgery, National Taiwan University Hospital, Taipei City/TW

Background: Expression of cytokines and growth factors have been shown to be highly correlated with the prognosis in esophageal squamous cell carcinoma (ESCC), a dead disease with poor prognosis. The suppressor of cytokine signaling (SOCS) family of proteins are key factors in the feedback system that regulates the expression of cytokines and growth factors in cells. Yet the role of the SOCS family of proteins in ESCC is hardly known. Method: We analyzed the prognostic effects of 16 single nucleotide polymorphisms (SNPs) within the SOCS family genes in 632 ESCC patients using MassARRAY system. The underlying mechanisms of SOCS SNPs effect on prognosis was analyzed using luciferase assay. The possible functions of SOCS5 in ESCC cells were analyzed by transiently over-expression. Result: We repeatedly observed that the 3 SNPs in SOCS5, SOCS5/rs3814039, SOCS5/rs3738890, and SOCS5/rs3768720, were significantly correlated with both overall (OS) and progression-free survival (PFS) of ESCC patients (rs3814039: p=0.032 for OS and p=0.009 for PFS; rs3738890: p=0.016 for OS, and p=0.008 for PFS; rs3768720: p=0.005 for OS and p=0.002 for PFS). SOCS5/rs3768720 was also significantly associated with distant metastasis (Ptrend=0.028). The
luciferase assay revealed that SOCS5 rs3814039 and SOCS5 rs3738890 might influence the prognosis by regulating SOCS5 expression. Functional analysis demonstrated SOCS5 was able to regulate epidermal growth factor receptor (EGFR) expression and migration activity of ESCC cells. Conclusion: Our study demonstrates the roles of SOCS5 in ESCC prognosis. The genetic polymorphisms of SOCS5 could serve as a novel therapeutic biomarker for improving the prognosis of ESCC.

Keywords: EGFR, SOCS5, esophageal cancer

P1.14-23 THYMOMA: AN EPIDEMIOLOGICAL AND CLINICO-PATHOLOGICAL PROFILE IN NEPALESE POPULATION.
S. Acharya1, R. Pun2
1Clinical Oncology, National Academy of Medical Sciences, Bir Hospital, Kathmandu/NP, 2Clinical Oncology, Nepal Medical College and Teaching Hospital, Kathmandu/NP

Background: Thymomas and thymic carcinomas are most common tumor of anterior mediastinum representing 0.5% to 1.5% of all the malignancies. Surgery is the mainstay of treatment with adjuvant radiation recommended for the invasive thymomas. It accounts for 0.1% of all the malignancies as per National Cancer Registry Nepal. Because of the rarity of the tumor we aim to review the profile of patient with thymic tumor in our patient population. Method: All the patient with diagnosis of thymoma attending the Department of Clinical oncology, National Academy of Medical Sciences (NAMS), Bir Hospital, Nepal during 2009-2015 was evaluated. We reviewed the record of all registered, histologically diagnosed thymoma and thymic carcinomas and are presented in this study. Result: Total of 51 record with thymoma and thymic carcinomas were reviewed out of which 71% (36) patient were male. The mean age was 46.99 years with youngest being 18 years and the eldest 70 years of age. Most common presenting symptom was shortness of breath (37%), followed by cough (23%), generalized weakness (14%), dysphagia (14%) and drooping of eyelid (12%). About 29.41% of patient was diagnosed with myasthenia gravis. 14% of patients were diagnosed on stage II, 57% on stage III and 29% with stage IV (modified Masaoka clinical stage). WHO pathological stage B 39% (20) [(B1-12%(6), B2-18%(9), B3-10%(5)] was most common, with A 24%(12), AB 20%(10), and C 18%(9). 11% of patient underwent upfront surgery. Neoadjuvant therapy was offered for 63% (32) with 68.75% resectability rate. 27% were eligible only for palliative treatment. About 95% patient received chemotherapy and 90.19% patient received radiation therapy either curative or palliative. 62.74% received curative radiation. 62.74% (32) patients are still on regular follow up with no signs of relapse. Conclusion: Multimodality therapy remains the mainstay of treatment for thymomas rendering the disease curative. Significant number of patient received neoadjuvant chemotherapy followed by surgery and adjuvant radiation therapy. WHO Type B seems to be more frequent type. Thymoma is quite often associated with myasthenia gravis without adverse effect on prognosis. However, in view of limited study due to rarity of the disease various aspects yet to be explored.

Keywords: Multimodality treatment, thymic carcinoma, thymoma

P1.14-24 EXTERNAL RADIOTHERAPY CONCURRENT WITH CISPLATIN PLUS 5- FLUOROURACIL IN LOCALLY ADVANCED CARCINOMA OF ESOPHAGUS
R. Pun1, S. Acharya2
1Clinical Oncology, Nepal Medical College and Teaching Hospital, Kathmandu/NP, 2Clinical Oncology, National Academy of Medical Sciences, Bir Hospital, Kathmandu/NP

Background: Esophageal cancer is the eighth most common cancer in the world with the high rates of local recurrence and metastasis. As per the data of National Cancer Registry Nepal it ranks among the top ten cancers with 2.6% prevalence. Definitive concurrent chemo radiotherapy (CCRT) is the standard for the non surgery patients, and the use of Cisplatin with 5-Flourouracil is the common chemotherapy regimen. Method: A prospective and comparative study was undertaken from 2014-2015 to evaluate the effect of CCRT in patients with locally advanced carcinoma of esophagus in our patient population. The eligibility criteria included locally advanced, ECOG score of <2. Patients received chemo radiotherapy (50 Gy / 25 fractions) and Cisplatin 75mg/m2 on Day 1 and 5-Flourouracil 1000mg/m2 on Day 1- Day 4 every 4 weeks apart on weeks 1 and 5. Radiation only group received 64 Gy/33 fractions. Result:
P1.14-25 PULMONARY METASTASIS FROM ORAL CANCER – WHO SURVIVE WITHOUT RECURRENCE AFTER PULMONARY METASETOMY? C. Takasaki1, M. Kobayashi1, H. Ishibashi2, K. Okubo2
1Thoracic Surgery, Musashino Red Cross Hospital, Tokyo/JP, 2Thoracic Surgery, Tokyo Medical and Dental University, Bunkyo-Ku, Tokyo/JP

Background: Oral cancer often performs local recurrence or a neck lymph node metastasis, so pulmonary metastasis from oral cancer is very rare and there have been few reports. The aim of this study was to evaluate the efficacy of surgical resection of oral cancer pulmonary metastases.

Method: Between April 2006 and December 2017, 14 patients with oral cancer pulmonary metastases underwent thoracic operations. We considered their clinicopathological features and prognosis. Result: There were ten men and four women with median age of 66.5 years (range, 27-76). All tumors were squamous cell carcinoma. Primary sites were tongue (seven patients), gum (three patients), and the mouth bottom (two patients). Five patients had partial resection and nine patients underwent lobectomy or larger operation. Eight of the nine patients who had lobectomy also had systematic lymph node dissection. Overall survival rate after metastasectomy was 46.8% at five years. Overall survival rate at five years by lobectomy with systematic lymph node dissection tended to have a better prognosis than by partial resection or lobectomy without lymph node dissection (p=0.08). Among the patients who had systematic lymph node dissection, lymph node metastasis were found in five patients. However, three of the five got long-term survival (more than two years) in spite of the metastasis. Conclusion: For patients with oral cancer pulmonary metastasis, surgical resection especially lobectomy with lymph node dissection is recommended.

Keywords: metastatic lung cancer, oral cancer

P1.14-27 DIFFERENTIATION BETWEEN EACH THYMIC EPITHELIAL TUMOR ACCORDING TO WHOCLASSIFICATION SCHEME BY USING MDCT FINDINGS Y. Wannasopha, S. Olankitcharoen, S. Kongkarnka, A. Tantraworasin, J. Euathrongchit Radiology, Chiang Mai University, Chiang Mai/TH

Background: Thymic epithelial tumors are the uncommon mediastinal tumors but are the most common primary tumors of the anterior mediastinum. Computed tomography (CT) is the imaging modality of choice for assessment in thymic epithelial tumors. The objectives of this study were to assess the CT features of various types of thymic epithelial tumors on the basis of the 2004 WHO classification and to identify the specific CT findings for differentiation between each thymic epithelial tumor. Method: A retrospective study reviewed CT findings of 35 patients with thymic epithelial tumors, who underwent surgical resection from January 2010 to April 2017 and had available pre-operative chest CT study. The tumors were reclassified into six types of thymic epithelial tumors (A, AB, B1, B2, B3 and thymic carcinoma) on the basis of the 2004 WHO classification system. The CT findings including the size (longest diameter), margin, shape, presence of focal area of low attenuation of necrosis or cystic change, mediastinal fat invasion, great vessels invasion, degree and pattern of tumor enhancement, presence of tumor calcification and presence of mediastinal lymphadenopathy were reviewed. Result: Our study consisted of 20 (57.14%) men and 15 (42.86%) women, age 15-78 years (mean 51.25 years). Pathological proven into 30 thymomas (85.71%) and 5 cases (14.29%) of thymic carcinomas. The 30 thymomas were classified according to the WHO classification: type A in 5 (14.29%), type AB in 4 (11.43%), type B1 in 5 (14.29%), type B2 in 9 (25.71%), and type B3 in 7 (20%) patients. The tumor sizes of type A, AB, B1 & B3 thymomas and thymic carcinoma were 6.2±1.97, 8.1±2.17, 4.9±2.47, 6.8±3.04, 4.7±1.87, and 9.6±2.78 cm, respectively. No definite CT manifestation that distinguishes between each different WHO pathological type of thymoma with statistical significance. The tumor dimension >8 cm, irregular margin, mediastinal fat invasion, great vessel invasion, lymphadenopathy, pericardial effusion and extrathoracic metastasis could differentiate between thymoma and thymic carcinoma (P-value <0.05). Great vessel invasion and extrathoracic metastasis had high sensitivity (80%), specificity (100%), PPV (100%) and NPV (96.77%) for diagnosis thymic carcinoma. Conclusion: No definite CT manifestation that distinguishes between each different WHO pathological types of thymomas. Tumor size more than 8 cm, irregular margin, presence of mediastinal fat invasion, great vessel invasion, mediastinal lymphadenopathy or extrathoracic metastasis favors the diagnosis of thymic carcinoma.

P1.14-28 FREQUENT GENETIC ALTERATIONS AND THEIR CLINICAL SIGNIFICANCE IN PATIENTS WITH THYMIC EPITHELIAL TUMORS
S. Toyooka 1
Dept. Of Lung Cancer Surgery, Tianjin Medical University General Hospital, Tianjin/CN
Background: Thymic epithelial tumors (TETs) are relatively rare neoplasms originating from the epithelial cells of the thymus. Due to the variety of different histology and low incidence, the current knowledge about the genetic alterations and prognostic factors of these tumors is still limited. Method: Twenty-four specimens from Chinese patients with resected TETs were collected and sequenced by next-generation technology with 56 cancer-related hotspot genes. The somatic mutation data of TETs was also retrieved from TCGA database (The Cancer Genome Atlas) (n=123). Overall survival was evaluated using Kaplan-Meier methods and compared with log-rank tests. Result: We analyzed 12 thymoma (type A, n = 3; type AB, n=2; type B1/B2, n = 4; type B3, n = 3) and 12 thymic carcinoma in this study. At least one gene mutation was detected in 15 cases out of total 24 tumors. Half of thymoma and seventy-five percent of thymic carcinoma exhibited genetic alterations, respectively. Twenty-seven gene mutations were detected in total 24 tumors. The most frequent gene mutation of thymoma is BRCA1(25.0%, 3/12), while TP53 is the most common in thymic carcinoma (25.0%, 3/12). CDKN2A mutation was exclusively observed in thymic carcinoma (16.7%, 2/12). Our and TCGA cohorts both demonstrated that TETs who presented TP53 mutation had a worse disease free survival and overall survival. Conclusion: Comprehensive genomic analysis suggests that the molecular phenotype of thymoma and thymic carcinoma has a distinct different and CDKN2A mutations might play an essential role in the pathogenesis in thymic carcinoma. Lastly, TP53 is the potential biomarker of poor prognosis in TETs.
Keywords: Thymic epithelial tumors, survival, genetic alterations

P1.14-29 SURGICAL TREATMENT FOR METASTATIC LUNG TUMORS FROM VARIOUS SARCOMAS
H. Yamamoto 1, K. Namba 1, K. Takahashi 2, J. Soh 1, K. Shien 1, T. Kurosaki 1, S. Ohtani 1, M. Okazaki 1, S. Sugimoto 1, M. Yamane 1, T. Oto 1, S. Toyooka 1
1Department of Thoracic Surgery, Okayama University Hospital, Okayama/JP
Background: Sarcomas are known to be one of the aggressive malignant tumors. They often develop multiple metastatic pulmonary lesions, and thus systemic therapy is a treatment of choice for metastatic lung tumors. However, effective chemotherapeutic treatments have not yet been established. Surgical resection for metastatic lung tumors is a therapeutic option to control the disease, although it is not a curative therapy.
Method: Between January 2006 and April 2018, 396 pulmonary resections were performed for 219 sarcoma patients with metastatic lung tumors in Okayama University Hospital. Among them, 129 sarcoma patients who underwent pulmonary metastasectomy between January 2006 and December 2014 were retrospectively reviewed. In total, 229 pulmonary resections were performed. We analyzed the following factors: age, sex, size of the largest lesion, histology, operative procedures, size of the largest lesions resected, maximum number of the resected tumors, postoperative complications, and survival rate. Result: In total, 939 metastatic nodules were resected. Average number of tumors per intervention was 3.0 (range 1-19). These sarcoma patients consisted of 31 males and 98 females, and their average age was 53.6 years (range 14-80 years). Leiomyosarcoma was the most common histological subtype (n = 72, 55.8%) and uterus was the most common location of the primary disease (55%, 42.6%). Operative procedures were composed of 173 partial resections, 31 segmentectomies with or without partial resections, 24 lobectomies with or without partial resections, and 1 basal segmental auto-transplantation after pneumonectomy. The postoperative complications were limited, showing that pulmonary metastasectomies for sarcomas are acceptable. Overall 3-year survival after the first pulmonary metastasectomy was 49.5%, and multivariate analysis revealed that the survival was significantly better for the group with disease-free interval of more than 2 years or the size of the largest resected lesion less than 30 mm. Conclusion: Surgical resections for metastatic lung tumors from various sarcomas were performed without major complications, indicating the acceptable feasibility. If disease-free interval is more than 2 years and the size of the largest resected lesion is less than 30 mm, patients may maximally benefit from surgical resection.
Keywords: sarcoma, Surgical resection, metastatic lung tumors
We conducted an observational, retrospective analysis of 95 consecutive patients with advanced NSCLC who received any RT within 10 months prior to nivolumab, as clinically indicated, at seven Italian institutions. Tumor response to treatment was defined according to RECIST criteria version 1.1. Median overall survival (OS) and the 95% confidence interval (CI) were estimated with the Kaplan-Meier method. Result: 95 pts (median age 66 years [range 41-82]; male:63.2%) with advanced NSCLC (adenocarcinoma [ad]66.3%; squamous cells [sqc]33.7%) were treated with nivolumab after RT. Median OS was 11.9 months (mo) [95% CI, 6.6-7.2] (ascd: 13.0 mo [95% CI, 6.3-16.9]; sqc 10.5 mo [95% CI, 3.9-17.1]). Median progression free survival (PFS) was 6.3mo [95% CI,4.6-8.0] (ascd: 6.4 mo [95% CI,4.5-8.3]; sqc: 3.7 mo [95% CI,0.8-8.3]). A better performance status (PS) according to ECOG scale was associated with an improved OS (PS 0 (38 pts): 17.9 mo [95% CI,12.3-23.5]; p<0.0001; PS1(50pts): 6.9 mo [95% CI,3.2-10.6]; PS2(4pts): 4.4 mo [95% CI,3.9-4.9]). Median OS in 70 pts who received ≤ 1 previous systemic therapy was 13.0 mo [95% CI, 10.4-15.6] and in 25 pts who received ≥ 2 prior lines was 7.4 mo [95% CI, 1.8-12.9]. Median OS in 69 pts (72.6%) receiving extracranial RT was 12.0 mo [95% CI,6.6-17.4] and in 26 (27.4%) pts with cranial RT was 11.7 mo [95% CI,NE]; p=0.31. Median OS was shorter in 36 pts receiving bone-RT (7.3 mo; 95% CI, 0-15.3) when compared with 59 pts receiving extra-bone RT [14.4 mo; 95% CI, (10.3-18.5); p=0.007]. Median OS in 68 pts aged > 70 years was 11.9 mo [95% CI,6.5-17.3] and in 27 elderly (≥ 70 years) was 12.0 mo [95% CI, 3.8-20.1]. 1 (1.0%) complete response, 25(26.3%) partial response, 28(29.5%) stable disease and 41 (43.2%) progressive disease have been observed. Conclusion: This study shows that combining irradiation with nivolumab for the treatment of advanced NSCLC leads to improved survival and promote tumor control both locally and distantly. This potentially synergistic effect was comparable among pts regardless previous lines of therapy, histology, type of RT and age. Keywords: Radiotherapy, NSCLC, Nivolumab

P1.15-02 MIGRATION DIFFERENCES IN SMALL CELL VS NON-SMALL CELL LUNG CANCER
S. Bhandari1, D. Pham1, C. Pinkston2, M. Oechsli3, G. Kloecker1
1Medical Oncology, James Graham Brown Cancer Center, University of Louisville, Louisville/KY/US; 2School of Public Health and Information Sciences, University of Louisville, Louisville/KY/US

Background: Every year there is a population diagnosed with lung cancer (LC) that does not receive initial treatment upon diagnosis and then "migrates" to other hospital systems before ultimately getting treatment. We aimed to compare migration rates between non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC) and potential factors associated with migration. Method: As part of the Kentucky Lung Cancer Education Awareness Detection Survival (LEADS) Collaborative, 29 of 32 Kentucky hospital registries contacted provided LC data of 7660 patients from 2012-2014. Data collected included age at diagnosis, stage, overall survival (OS), sex, race, insurance and treatment history. Treatment included any combination of surgery, radiation, or chemotherapy. Hospital records were matched to Kentucky Cancer Registry records to determine the number of hospitals visited for treatment. Patient treatment and migration patterns were analyzed with a logistic regression model along with additional post-hoc analysis. Difference in rates was calculated by chi-square test. Result: Among the 7660 LC patients, 81% were NSCLC and 19% were SCLC. Most patients were treated at their initial hospital - NSCLC (73%) and SCLC (82%) (p-value<0.01). However, among the untreated patients, 616 (36%) of NSCLC patients migrated to a different hospital compared to only 23 (8%) of SCLC patients (p-value=0.01). Migration of NSCLC patients to another hospital was associated with Stage I-III disease, younger age (66.4 vs 72.2 years), with initial hospitals missing treatment modalities and patients having private insurance. In NSCLC, compared to patients treated initially, patients treated after migration lived longer (591 vs 505 days) and particularly had longer survival with stage III (563 vs 495 days) and IV disease (379 vs 300 days). Too few patients with SCLC migrate to assess association with OS and other patient characteristics. Conclusion: There is a significant difference in rates of initial treatment between NSCLC and SCLC that could be due to perceived urgency to treat SCLC. This analysis shows a highly significant 4-fold increase in migration rate of NSCLC as compared to SCLC. This could be explained by newer and better treatment options available at referral centers for NSCLC and a lack of these options for SCLC. Increasing research and novel innovations in NSCLC will likely drive more patients to migrate in future. Keywords: Migration, lung cancer

P1.15-03 CLINICAL CHARACTERISTICS OF LONG-TERM SURVIVORS WITH NIVOLUMAB IN PRETREATED ADVANCED NSCLC FROM Real-World Data (RWD)
M. Garcia, A. Calles, M. Lobo, R. Álvarez Álvarez
Medical Oncology, Hospital Gregorio Marañon, Madrid/ES

Background: We have previously analyzed real-world data (RWD) from patients with metastatic NSCLC that progressed to chemotherapy and were subsequently treated with immune-checkpoint inhibitors (ICI). This included patients with performance status of 2, brain metastases, concomitant use of steroids, unknown PD-L1 status, systemic antibiotics during the previous month, and without restriction in the number of previous lines received. With a longer follow-up period, we aimed to analyze the baseline clinical characteristics in long-term survivor patients. Method: We performed a retrospective study of previously treated advanced NSCLC patients that received nivolumab at 3 mg/kg every 2 weeks outside clinical trials from our institution in Madrid (Spain) between January 2015 and April 2018. We used RWD to analyze the clinical characteristics of patients who were alive 2 years after the start of ICI. Result: A total of 38 pts fulfilled inclusion criteria. 7 pts (18%) where alive 2 years after the first dose of nivolumab. Median age at diagnosis was 63 years (53-72 years). 6 pts (86%) had history of tobacco smoking, and 6 pts (86%) had non-squamous histology. 3 pt had ECOG 0 (43%), 3 pts had ECOG 1 (43%) and one pt had ECOG 2 (14%). Median number of previous lines was 3; 3 pts received nivolumab in second line, 3 pts in fourth line and one pt in fifth line. All pts were diagnosed with primary advanced disease. 2 of the pts (29%) had brain metastases and 1 pt (14 %) had ≥ 4 metastatic locations. 2 pts had use antibiotics in the month before and 1 pt used steroids. Best response to nivolumab per RECIST 1.1 criteria included 3 partial responses (43%), and 2 each (29%) had stable and progressive disease. Only 2 pts had no evidence of disease progression during > 2 years at last follow-up when the database was lock (April 2018). Five pts discontinued treatment due to disease progression. After progression, 1 pt restarted treatment with nivolumab, 1 pt started osimertinib (EGFR mutant previously treated with TKI and chemotherapy, and confirmed T790M+), and 3 pts started chemotherapy followed by retreatment with ICI. No patients discontinued due to adverse events. Conclusion: In our RWD experience, nivolumab results in a 2-years survival rate of 18% in pretreated advanced NSCLC patients. Clinical characteristics from real world patients do not predict for long term benefit of nivolumab. Immunological biomarkers are necessary to better select pts who will derive long-term benefit from immunotherapy. Keywords: advanced non-small cell lung cancer, nivolumab, immunotherapy

P1.15 TREATMENT IN THE REAL WORLD - SUPPORT, SURVIVORSHIP, SYSTEMS RESEARCH
MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.15-04 PRACTICE PATTERNS REGARDING MULTIDISCIPLINARY CANCER MANAGEMENT FOR NSCLC AND IMPLMENTATION: RESULTS OF NATIONAL SURVEY IN MÉXICO
S. Campos-Gomez1, K. A. Campos-Gomez1, O. Macedo-Pérez2, J. J. Valdez Andrade3, D. Arrieta1
1Dept of Medical Oncology, Centro Oncologico Estatal Iseymem, Toluca/MX; 2Unidad Funcional de Oncología Torácica Y Laboratorio de Medicina Personalizada, National Cancer Institute, Mexico City/MX

Background: To manage patients with advanced lung cancer in the most effective way, experts from different disciplines need to be engaged. This has resulted in introduction of the multidisciplinary team (MDT) approach. Because of these advantages, current clinical guidelines recommend discussing the diagnostic and therapeutic plan with an MDT for any new cases of NSCLC or locally advanced Non-Small Cell Lung Cancer (NSCLC). However, studies suggest despite the advantages of multidisciplinary care, the proportion of new lung cancer diagnoses that are formally discussed in Lung Cancer MDM are disappointing low, in the order of 28–29%. An Australian survey suggests that only one third of hospitals have a multidisciplinary team. Method: However, it is unclear how specialists view current evidence about multidisciplinary team (MDT) approach and how they would incorporate it into practice. Therefore, we conducted a nationwide specialists and specialist opinions about evidence regarding treatment of NSCLC and how this translates into clinical practice implementation. This study was conducted to explore specialist opinions about multidisciplinary team approach of NSCLC. This translates into clinical practice implementation in Mexico. Result: We collected a total of 60 completed responses (50%), 77% were medical oncologist, 7% surgical oncologist
and 17% radiation oncologists. Of these 34% mainly worked in private and 66% in public healthcare Systems. Seventy two percent of all physicians were between 40 and 50 years of age and 22% were 50 years of age or older. Young doctors (up to 5 years of service) accounted for 45%, with a median length of practice of 12 years. More than two-thirds of physicians were male. Approximately 58% of respondents stated that existing MDTs for NSCLC were in their institutions. The Core members of the multidisciplinary cancer team usually include an oncologist (medical, surgical, radiation), pathologist and radiologist in the 65% of the teams. Approximately 55% of respondents stated that MDTs met regularly. Forty two of all respondents do not have a MDT but can discuss new cases directly with surgical oncologist or radiologist. Conclusion: While multidisciplinary care has emerged as the standard of care for lung cancer management. The challenge for the future is how to more fully integrate multidisciplinary care into the management of all patients with lung cancer in México.

P1.15-05 THE FREQUENCY AND SPECTRUM OF EGFR EXON 20 INSERTIONS IN NSCLC: A GLOBAL LITERATURE REVIEW V. Crossland1, S. LI2, A. Galaznik3

Background: There are limited epidemiological data on non-small cell lung cancer (NSCLC) patients with non-classical (uncommon) epidermal growth factor receptor (EGFR) mutations. In light of ongoing development of TAK-788, we describe the global frequency and spectrum of EGFR exon 20 insertions in NSCLC based on a comprehensive literature review as well as highlight possible regional variations. Method:A literature search was conducted to identify publications reporting the frequency of EGFR exon 20 insertions in selected NSCLC patients. PubMed and ASCO, ESMO, and IASLC meeting abstracts were searched up to April 2018 using the following keywords: non-small cell lung cancer, epidermal growth factor receptor, exon 20, insertions and uncommon mutations. Only publications in English were included. The pooled frequency of EGFR exon 20 insertions for each country were determined, and insertion variants (where available) were described at the global level. Result: A total of 26 studies from 25 countries were included, reporting on 569 patients with EGFR exon 20 insertions among 41,321 NSCLC patients. The highest mutation frequency was seen in China (2.9%) and the lowest in Indonesia (0.1%). When pooled by country, exon 20 insertion variants were reported, covering amino acids 761–774. The most commonly detected mutations included D770_N771insSVD, V769_D770insASV, H773_V774insNPH, and A763_Y763insFQEA.

Conclusion: The frequency of EGFR exon 20 insertions was 0.1–2.1% of NSCLC patients, with a high variability in both length and position of insertions within exon 20. Currently, available data are sparse and come primarily from studies based on single-center experiences, with data gaps across several large geographic regions and populations. Results also indicate a need to further explore underlying geographic variations in epidemiology. Larger, multi-center global studies will further help to refine the frequency of exon 20 insertions and other uncommon mutations in NSCLC.

Keywords: non-small cell lung cancer, EGFR mutation, Exon 20 Insertion

P1.15-06 INTEGRATIVE QUALITY IMPROVEMENT FOR MANAGEMENT OF LUNG CANCER IN UGANDA S. David

African Federation of Hospital Associations (Afha), Kampala/UG

Background: Uganda is currently engaged in quality improvement initiatives for cancer patients. One of them is the creation of an integrative quality system, consisting of guideline development, quality indicators definition and feedback to hospitals. This approach has already been successfully implemented for five types of cancers: rectum (in collaboration with development partners), breast, testis, oesophagus and stomach. Building on previous experience, the study presents the development of a set of quality indicators (QIs) for the management of lung cancer. Method: We followed the standardized MOH methodology to identify, select and measure the indicators. We may be in contact with different hospitals (for instance, be diagnosed in one hospital but receive treatment – surgery or radiotherapy – in another), we developed a specific algorithm to attribute each patient to the centre where he/she was diagnosed or received treatment (surgical centre or centre of radiotherapy). The method to test the feasibility of identifying comorbidities of patients based on their pharmaceutical billing data during the year before the cancer diagnosis is also described. Result: The results of this project made clear that we need more complete and accurate reporting of data to allow more precise and correct evaluation of the quality of care for lung cancer patients in Uganda. Quick and fluent data collection would make it possible to provide comprehensive feedback to care providers on a regular and timely basis. To make this happen, investments in data registration and analysis will be necessary. Conclusion: When benchmarking results between hospitals, cautious interpretation is warranted. The use of funnel plots avoids spurious results of hospitals and outlier dots can reliably designate either good or bad performers. Statistical modeling can often only partially account for differences in case-mix and other biases. Judging quality of care delivered by a hospital is further hindered by the often small number of patients treated per hospital. Hence, from a sheer statistical point of view, small volumes of activity make it impossible to offer an acceptable level of assurance about the quality delivered to the patient.

P1.15 TREATMENT IN THE REAL WORLD - SUPPORT, SURVIVORSHIP, SYSTEMS RESEARCH MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

Background: Special attention is required by elderly population, due to chemotherapy (ch) risks and comorbidities, which may limit the capacity to deliver optimal cancer care. We aimed to describe the clinical features and survival outcomes of elderly patients (pts) with lung adenocarcinoma (ADC) treated with non-curative intent at A. C. Camargo Cancer Center. Method: We evaluated all pts aged 70+ with lung ADC treated with ch or target therapy in 1st or 2nd-line from 2007 to 2015 who underwent a comprehensive geriatric assessment (CGA), in a convenient prospective series. We used summary statistics to describe the population. Overall survival (OS) was calculated according to Kaplan-Meier method, from CGA date to last follow-up or death. We performed univariate and multivariable analysis in order to look for potential prognostic factors for OS. Results: CGA was done in 55 pts aged ≥70y with lung ADC. The median age was 76y and 22% had ECOG ≥ 2. Half of pts were male. 51% had polypharmacy (≥5 drugs). Pts were functionally classified according to ADL: 76% as Katz A and 50% as Lawton ≤27. 68.5% were at risk for malnutrition or malnourished. The median age-adjusted Charlson Comorbidity score was 10 – remembering that 4+ is considered significantly clinical. 61% had ≥2 comorbidities and 26 pts had at least 2 metastatic sites. CNS was affected in 7.5% of the cases and liver at least 2 metastatic sites. CNS was affected in 7.5% of the cases and liver in 9.2%. 79.6% of the pts underwent ch and the others received target therapy. After follow-up of 29m, median OS was 17.1 months (13.5–27.8m). In univariate analysis, significantly worse survival outcomes were
observed for pts with ECOG 2-4 (HR 10.6; p < 0.001), increasing number of liver metastasis were associated with higher risk of death. **Conclusion:** ADL, an important part of CGA, showed little prognostic value in our study. Biopsy at the Argentinian University Hospital was performed to identify the best treatment to each individual patient. **stratifying risk of elderly cancer pts and is mandatory in cost-benefit analysis to identify the best treatment to each individual patient.**

**Keywords:** Geriatric Oncology, lung, elderly

**REFERENCES**

wait times from diagnosis to first treatment and age of LC patients. Limitations include limited reporting on chemotherapy, radiation, and staging. Future improvements from a Colombian standpoint will include outcomes data collection, increased screening, resources for surgery, and updated access to antineoplastic agents.

P1.15-11 LUNG CANCER AS ONE OF MULTIPLE CANCERS: A POPULATION-BASED STUDY IN ESTONIA 1995-2015
J. Jaal1, M. Kase2, K. Sak1, M. Saar3, M. Vardja2, M. Magi4
1Institute of Clinical Medicine, University of Tartu, Estonia/EE, 2Dept of Radiotherapy and Oncological Therapy, Tartu University Hospital, Estonia/EE, 3Pharmacy, Tartu University Hospital, Tartu/EE, 4Estonian Cancer Registry, Estonia/EE

Background: Due to recent developments in cancer prevention, early diagnosis and treatment, more cancers are detected at earlier stages and more patients are cured. As a result, the burden of second and further primary malignancies in a growing and ageing population has remarkably increased over the last decades. Lung cancer is one of the most frequent but most deadly types of cancer. Whether this type of malignancy has a considerable role among multiple cancers is not known. Therefore, the aim of the present study was to assess lung cancer cases as one of the multiple cancers in Estonia. Method: We used the data from the Estonian Cancer Registry (ECR), a population-based registry with nationwide coverage (total 1.3 million inhabitants). The ECR provided data on all lung cancer cases and associated multiple cancer cases diagnosed in Estonia 1995-2015. Result: During the time period of 20 years, 146541 cancer cases (ICD-10 C00-C97 and in situ cancers D00-D09) were recorded. Lung cancer cases (n=16350) comprised 11% of all malignancies. Out of all diagnosed lung cancer cases, 10% of patients had multiple cancers (n=1635). Lung cancer as first multiple cancer was diagnosed in 398 patients (25%; 338 men, 60 women; median age 67 years, range 31-87 years). Lung cancer as second cancer was diagnosed in 1130 patients (70%; 851 men, 279 women; median age 67 years, range 31-91 years). Ninety one patients had lung cancer as their third cancer (5%; 67 men, 24 women; median age 66 years, range 55-91 years). None of the patients had lung cancer as fourth or further multiple cancers. Next to lung cancer, patients had mostly melanoma and other malignant tumors of skin (18%), malignant neoplasms of digestive organs (18%), male genital organs (18%) and urinary tract (13%) as well as respiratory tract cancers including new lung primaries (10%). Other types of cancers represented 23% of malignancies. After first diagnosis of lung cancer, second tumor was diagnosed approximately 5 months (median) later. As second multiple cancer, lung cancer was diagnosed 7 years (median) after the first cancer diagnosis. Lung cancer as third cancer developed approximately 2 years (median) after the second diagnosis of malignant tumor. Conclusion: Multiple cancers are common among lung cancer patients in Estonia. Particular attention is needed, when patient with lung cancer develops skin changes, gastrointestinal and genitourinary symptoms or presents with newly developed respiratory tract complaints.

Keywords: Multiple cancers, lung cancer, population-based study

P1.15-12 REAL WORLD APPLICATIONS OF NEXT-GENERATION SEQUENCING OF NON-SMALL CELL LUNG CANCER IN THE VETERAN POPULATION
J. Kratz1, G. Harmon1, D. Kosoff1, D. Wubben2, R. Laughlin2, A. Traynor3, D. Deming1, M. Burkard1, T. Leal3
1Department of Hematology/oncology, University of Wisconsin-Madison, Madison/WI/US, 2William S. Middleton Memorial Veterans Administration, Madison/WI/US, 3University of Wisconsin Carbone Cancer Center, Madison/WI/US

Background: Population studies to date have demonstrated decreased rates of driver mutations in non-small cell lung cancer (NSCLC) for veterans with prior tobacco use who receive care at Department of Veterans Affairs (VA) facilities. Causes of this reduced rate have not been identified, but may result in underutilization of broadly based genetic tumor profiling. The VA recently expanded next-generation sequencing (NGS) to include both tissue and liquid biopsies for comprehensive genetic profiling for patients (pts) with advanced malignancy. Herein, we describe clinical utility of NGS from our retrospective cohort of a rural-based NSCLC veteran population. Method: We performed a retrospective cohort analysis of 79 veterans with metastatic NSCLC from 07/2015-04/2018. A clinician-initiated quality improvement initiative in 07/2017 disseminated education for non-squamous NSCLC, with support from the University of Wisconsin Precision Medicine and Molecular Tumor Board. Baseline demographics, time to tissue biopsy, and genetic tumor profiling were analyzed; clinical outcome data were collected including overall survival and progression-free survival. Result: As expected, the cohort was predominantly male (91.1%), with tobacco use (median 45 pk-yrs, 95% >5 pk-yrs) and median age 69 yrs. For molecular profiling, 52% had sufficient tissue at metastatic diagnosis, 20% underwent repeat biopsy within 30 days, 17% underwent biopsy after 30 days, and 11% presented with comorbidity resulting in empiric or palliative management. After implementation of the quality improvement project, the frequency of genetic profiling increased compared to pre-expanded NGS availability in the following targets: EGFR (59% v. 90%), ALK (65% v. 90%), ROS2 (35% v. 90%), and BRAF (18% v. 60%). Actionable targets were identified in EGFR 15.4% (5/39 pts), ALK (1/41), ROS1 (1/24), and BRAF (1/11); additional mutations in NTRK1, NTRK3, ESRB2, and FGFR1 were detected. Conclusion: Our preliminary results demonstrate that the availability and use of NGS was associated with increased rates of comprehensive genetic profiling in a largely rural veteran population. Ongoing work will expand this retrospective cohort to more thoroughly characterize barriers to diagnosis and target-specific frequency over historical advances in precision oncology. We will review how these genetic profiles may offer both prognostic and predictive value by reporting clinical outcomes between targeted therapy and early applications of immunotherapy within the veteran population.

P1.15-13 WAIT TIMES FOR DIAGNOSIS AND TREATMENT OF LUNG CANCER ACROSS THE PROVINCE OF QUEBEC, CANADA
C. Labbé1, S. Martel1, B. Fournier1, C. Saint-Pierre2
1Institut Universitaire de Cardiologie Et de Pneumologie de Quebec, Division of Respirology and Thoracic Surgery, Quebec/CA, 2Icupe, Quebec/CA

Background: Multiple clinical practice guidelines recommend rapid evaluation of patients with suspected lung cancer. Diagnostic pathways and wait times vary considerably from one centre to another. Method: We retrospectively reviewed medical records of all patients (n=1217) across the province of Quebec who had a biopsy-proven diagnosis of lung cancer between February 1st and April 30th, 2017. Median wait times for diagnosis and treatment were calculated. Result: Patient characteristics are shown in Table 1. Median wait times for investigation and treatment are shown in Table 2. There were variations between centres and regions.

Characteristic | No (%) | Age, years, mean (range) | 68.5 (20-94) | Male sex | 585 (48) | Smoking status Former or current smoker Never smoker Unknown | 1120 (92) 60 (5) 37 (3) | ECOG performance status 0 1 ≥2 Missing | 416 (34) 358 (30) 393 (32) 50 (4) | Histology | Adenocarcinoma | 631 (52) | Squamous cell carcinoma | 284 (23) | NSCLC NOS | 70 (6) | SCLC | 178 (15) | Other | 54 (4) | TNM stage | I | 213 (18) | II | 114 (9) | III | 227 (19) | IV | 475 (39) | Limited SCLC | 40 (3) | Extensive SCLC | 138 (11)
ECOG = Eastern Cooperative Oncology Group; NSCLC = non-small cell lung cancer; NOS = not otherwise specified; SCLC = small cell lung cancer; EGFR = epidermal growth factor receptor; ALK = anaplastic lymphoma kinase; TPS = tumor proportion score; IQR = interquartile range; EBUS = endobronchial ultrasonography; EUS = endoscopic ultrasonography. Table 2 – Median wait times for investigation and treatment

Investigation or treatment interval | Pts (n) | Median wait, days (IQR)
--- | --- | ---
Referral to first appointment with specialist | 972 | 2 (0, 7)
First appointment to diagnosis | 1152 | 18 (8, 43)
Diagnosis to first treatment | 930 | 22 (5, 42)
Referral to first treatment | 737 | 58 (28, 89)
Abnormal imaging to first treatment | 902 | 72 (39, 111)
Surgery | 268 | 109 (80, 142)
Radiation therapy | 362 | 59 (28, 98)
Systemic therapy | 330 | 62 (35, 92)

Conclusion: To our knowledge, this is the largest multicentre review of wait times for diagnosis and treatment of lung cancer with detailed characteristics of patients. Data will be completed and updated prior to the meeting, to try to identify specific factors associated with longer wait times.

Keywords: diagnosis, treatment, wait times
Conclusion: Afatinib conferred a modest mPFS benefit after failure of first-generation EGFR-TKI. The mPFS of sequential treatment with first-generation EGFR-TKI followed by afatinib seems longer than the mPFS of first-line afatinib in phase 3 randomised controlled trials. Apart from T790M mutation, the resistance mechanisms to second-line afatinib in our patients are more heterogenous.

Keywords: afatinib, resistance mechanism, second-line treatment

P1.15-16 ALKCONNECT: AN ANAPLASTIC LYMPHOMA KINASE POSITIVE (ALK+) NON- SMALL CELL LUNG CANCER (NSCLC) PATIENT INSIGHTS NETWORK

H. Lin1, X. Pan1, H. Huang2, G. Salvatore3, S. Clarke4, H. (. West5

Background: ALK+ NSCLC is a subset of NSCLC present in ~3–5% of NSCLC patients. Little is known about ALK+ NSCLC patients' unique journeys, their perspectives on the burden of disease, and their 'real-world' treatment experiences. Online patient networks provide opportunities to gain valuable insights into outcomes meaningful to patients, directly from patients. The objective of this study is to develop an ALK+ NSCLC patient network to facilitate patient interaction and to conduct patient-centered research including understanding unmet needs, patient preferences, health-related quality of life (HRQoL), and product differentiation. Method: The ALKConnect Patient Insights Network (www. alkconnect.com) will be a patient-focused registry that directly collects information from patients living with ALK+ NSCLC. Patients meeting study criteria will be enrolled in the online survey over a 2-year period. Inclusion criteria are US. adult, English-speaking patients with ALK+ NSCLC providing written, informed consent, internet access, and willing to answer regular e-surveys. Retrospective and cross-sectional ‘real-world’ data that will be collected include demographics, clinical characteristics including ALK+ NSCLC disease history and status, comorbidities, past and present treatment experiences and outcomes, quality of life, patient preferences, healthcare resource use, and work productivity. Supplementary data may be collected through uploading of electronic medical records. Result: The ALKConnect Patient Insights Network will systematically characterize the natural history of ALK+ NSCLC and its treatment and the overall impact on patients. The data collected will be reported descriptively for the population overall and by subgroups of interest (e.g., age, sex) where sample sizes permit. The associations between treatment history/disease status and patient-reported outcomes including symptom severity, HRQoL (e.g., responses to the MD Anderson Symptom Inventory lung cancer module [MDASI-LC]), healthcare resource use, and work productivity will be analyzed. Longitudinal trends will be evaluated to enable a better understanding of the impact of ALK+ NSCLC over time. All de-identified information gathered for the study of Lung Cancer (IASLC/) the Union for International Cancer Control (UICC) 7th classification on N2 disease. Risk factors of locoregional recurrence-free survival (LRFS) were evaluated by univariate and multivariate analyses. Result: According to IASLC/UICC 7th classification, there were 198 (66.0%) patients with unforeseen N2 (N2a), 36 (12.0%) with minimal/single station N2 (N2b), 41 (13.7%) with selectively centrally located N2 (N2c) and 25 (8.3%) with bulky and/or multilevel N2 (N2d). After surgery, 70 (23.3%) patients were treated with adjuvant tyrosine-kinase inhibitors (TKIs), while other 230 (76.7%) were free from adjuvant TKIs. With median follow-up of 28.5 (range: 6-133) months, the 2-year LRFS, distant metastasis-free survival (DMFS), disease-free survival (DFS) and overall survival (OS) were 88.3%, 65.3%, 57.7% and 89.7%. Ultimately, 15.7% (47/300) patients developed locoregional recurrences. Distant metastasis-free failure pattern. Multivariate analysis indicated that N2d disease (HR: 2.65, p =0.030) and extranodal extension (HR: 3.48, p<0.001) were risk factors of LRFS. Conclusion: R0 resected stage III-pN2 NSCLC patients with sensitive EGFR mutation (exon 19 or exon 21) tended to present limited N2 disease and low locoregional recurrences. Patients without bulky N2, multilevel N2, and extranodal extension might be refrained from PORT. Further studies evaluating the optimal radiation therapy approach for completely resected N2-positive NSCLC are required for validation.

Background: Postoperative radiotherapy (PORT) of complete resected stage III-pN2 non-small cell lung cancer with N2D nodal involvement remained contentious. Our previous study suggested low locoregional recurrences in epidermal growth factor receptor (EGFR) mutant patients. We sought to launch a multi-center large cohort study to evaluate the risk factors of locoregional recurrence in R0 resected EGFR mutant III-pN2 patients without PORT, producing evidence for the design of adjuvant regimens. Method: Three-hundred and fifty-nine consecutive patients with complete resected pathological approved stage III-pN2 lung adenocarcinoma with sensitive EGFR mutation (exon 19 or exon 21) have been sequentially investigated. Patients were excluded if they received preoperative radiotherapy (7.5%) or PORT (9.6%). Three hundred cases have been analyzed. Clinicopathologic characteristics, pretreatment work-ups, EGFR mutant status and patterns of failure were documented. Patients were sub-staged by the International Union Against Cancer (UICC) 2018 staging system and the International Association for the Study of Lung Cancer (IASLC) staging system with the Union for International Cancer Control (UICC) 7th classification on N2 disease. Risk factors of locoregional recurrence-free survival (LRFS) were evaluated by univariate and multivariate analyses. Result: According to IASLC/UICC 7th classification, there were 198 (66.0%) patients with unforeseen N2 (N2a), 36 (12.0%) with minimal/single station N2 (N2b), 41 (13.7%) with selectively centrally located N2 (N2c) and 25 (8.3%) with bulky and/or multilevel N2 (N2d). After surgery, 70 (23.3%) patients were treated with adjuvant tyrosine-kinase inhibitors (TKIs), while other 230 (76.7%) were free from adjuvant TKIs. With median follow-up of 28.5 (range: 6-133) months, the 2-year LRFS, distant metastasis-free survival (DMFS), disease-free survival (DFS) and overall survival (OS) were 88.3%, 65.3%, 57.7% and 89.7%. Ultimately, 15.7% (47/300) patients developed locoregional recurrences. Distant metastasis-free failure pattern. Multivariate analysis indicated that N2d disease (HR: 2.65, p =0.030) and extranodal extension (HR: 3.48, p<0.001) were risk factors of LRFS. Conclusion: R0 resected stage III-pN2 NSCLC patients with sensitive EGFR mutation (exon 19 or exon 21) tended to present limited N2 disease and low locoregional recurrences. Patients without bulky N2, multilevel N2, and extranodal extension might be refrained from PORT. Further studies evaluating the optimal radiation therapy approach for completely resected N2-positive NSCLC are required for validation.

P1.15-18 THE IMPACT OF PATIENT AGE ON CLINICAL OUTCOMES IN NSCLC: A NATIONAL STUDY

Y. Lou, F. Manochakian, J. Cochuyt, D. Hodge, S. Allawadhi
1Medical Oncology, Mayo Clinic, Jacksonville/FL/US

Background: Treatment of NSCLC is rapidly advancing. Clinical outcomes and treatment modalities for patients in each age group remain unknown. This study investigates the treatment modalities in each age group and the impact of patients’ age on survival. Method: The National Cancer Database with NSCLC between 2004-2014 was used. Overall survival (OS) and treatments were analyzed by age groups, accounting for multivariates. Result: A total of 2,327,158 NSCLC patients were included. Median OS is 114.6, 76.7, 52.6 and 33 months for stage I lung cancer patients at age <60, 60-69, 70-79 and ≥ 80 respectively (p<0.0001). Median OS is 7.5, 9.6 and 3.3 months for stage IV patients at age <60, 60-69, 70-79 and ≥ 80 respectively (p<0.0001). The impact of age on survival is cross all stages. Younger patients are associated with larger tumor size and higher percentage of stage V at time of diagnosis. Patients with age ≥ 80 are associated with high income, high education and pacific region. Despite comparable comorbidity, patients with age ≥ 80 are treated differently and received much less aggressive therapy compared to younger patients. Conclusion: The overall survival of NSCLC is significantly impacted by patient’s age. Under-treatment in elderly patients might contribute to poor survival. (See next page)

P1.15-19 TREATMENT OF CHOICE FOR FIRST-LINE THERAPY OF EGFR-MUTATED STAGE IIIB LUNG ADENOCARCINOMA BASED ON THE REAL WORLD DATA

S. Lu1, X. Ye2, D. Ding3, Z. Li4, X. Niu5, G. Leping6
1Shanghai Lung Tumor Clinical Medical Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/CN; 2Oncology, Johns Hopkins Medical Institutions, Baltimore/US; 3Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, Shanghai/CN; 4Department of Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/CN; 5Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/CN

Background: There is a lack of consensus on the choice of first-line therapy for stage IIIB EGFR-mutated lung adenocarcinoma. Method: A prospectively maintained database at the Shanghai Chest Hospital was used to identify patients who received therapy for stage IIIB EGFR-mutated lung adenocarcinoma between 2015 and 2017. Clinicopathological data were extracted from the database and analyzed. Patients were stratified into four groups based on the therapy they received: chemotherapy alone, chemoradiation (concurrent or sequential), first-generation EGFR-TKI, or surgical resection with or without chemoradiation. Log-rank test and Kaplan-Meier method were used to determine significant differences in the progression free survival (PFS) between treatment groups. Result: Of the 114956 patients treated at the institution during the study period, 85% were eligible for the study. 12 patients (14.1%) received chemotherapy, while 19 (22.4%), 30 (35.3%) and 24 (28.2%) received chemoradiation, EGFR-TKI and surgery respectively. The common mutations included Del19 (N=35, 41.18%), L858R (N=42, 49.41%), G719X (N=4, 4.71%) and S768I (N=2, 2.35%). The median PFS was shorter in patients who only received chemotherapy (8.5 months) as compared to those managed with chemoradiation (14.6 months), EGFR-TKI (16.2 months) or resection (18.6 months) (p=0.04, figure 1b). No statistically significant difference was observed (PFS) between treatment groups (p=0.90). A subgroup analysis of patients with N3 disease resulted in similar findings (figure 1c). Conclusion: In conclusion, when used as a first-line therapy chemoradiation, EGFR-TKI and resection with or without chemoradiation can achieve similar PFS, which is superior to that of patients receiving chemotherapy alone. Further studies are required to elucidate the efficacy of EGFR-TKI as a first-line or as maintenance therapy for these patients.

Background: In Mexico, lung cancer is the seventh incidence and first in mortality. Diagnosis in advanced stages accounts >70% of cases. We analyze factors associated with a late diagnosis and delay in the beginning of treatment. Method: Observational, cross-sectional study carried-out from August to October 2017 in the National Cancer Institute of Mexico (INCan). An interview was conducted to identify: 1) onset of symptoms, 2) time elapsed to seek medical attention, 3) number of doctors visited, 4) diagnosis established prior to cancer diagnosis pulmonary, 5) time elapsed from diagnosis of cancer until admission to INCan and 6) Time elapsed from diagnosis to start treatment. Result: 414 patients included and main characteristics are included in the next table. Conclusion: In Mexico, lung cancer is diagnosed in advanced stages due to a lack of clinical suspicion in primary care physicians. Delay from initial medical assessment to specialized center referral is considered an opportunity window. Identification of these factors will lead to establishment of public health policies that ensures improvement of diagnostic approach and the timely reference and initiation of treatment in specialized centers to improve the prognosis.

Keywords: diagnostic delay, real world lung cancer treatment, treatment delay
P1.15-21 CREATING AN OPTIMAL CARE COORDINATION MODEL TO IMPROVE MULTIDISCIPLINARY CARE FOR LUNG CANCER PATIENTS ON MEDICAID

1 Association of Community Cancer Centers, Rockville/MD/US, 2 Outpatient Cancer Services & Radiation Oncology, Sanford Health, Sioux Falls/SD/US, 3 Ann B. Barshinger Cancer Institute, Lancaster General Health, Lancaster/PA/US, 4 Department of Medical Oncology, Dana-Forbes Cancer Institute, Boston/MA/US, 5 Epidemiology and Biostatistics, University of Memphis School of Public Health, Memphis/TN/US, 6 Thoracic Oncology Research Group, Multidisciplinary Thoracic Oncology Program, Baptist Cancer Center, Memphis/TN/US, 7 Multidisciplinary Thoracic Oncology Program, Baptist Cancer Center, Memphis/TN/US

Background: The Association of Community Cancer Centers (ACCC) created an Optimal Care Coordination Model (OCCM), which provides a comprehensive self-assessment tool designed to orient cancer programs to achieving patient-centered, multidisciplinary care. The OCCM is a comprehensive self-assessment tool designed to help cancer programs, regardless of resources, location, or population, improve care for lung cancer patients, especially those on Medicaid.

Method: Using findings from an environmental scan (April 2016) and visits to 5 US cancer programs to explore current care models (July-October 2016), a Technical Expert Panel developed the OCCM, which has 13 defined Assessment Areas and utilizes an evaluation matrix (Table 1). To validate the OCCM, a competitive application process among ACCC’s membership used a comprehensive institutional quantitative and qualitative questionnaire. Applicants completed a self-assessment using the OCCM and then developed quality improvement projects designed to move their OCCM-scored care delivery performance from baseline to a higher level over a 12-month implementation period. Seven US community cancer centers were selected as Testing Sites. Quantifiable outcome measures were identified for each site, standardized across sites, and collected by a centralized data coordinating center.

Result: Table 2 shows Assessment Areas being validated and patient demographics.

Table 1
OCCM Assessment Areas
1. Patient Access to Care
2. Prospective Multidisciplinary Case Planning
3. Financial, Transportation, and Housing
4. Management of Comorbid Conditions
5. Care Coordination
6. Treatment Team Integration
7. Electronic Health Records and Patient Access to Information
8. Survivorship Care
9. Supportive Care
10. Tobacco Cessation
11. Clinical Trials
12. Physician Engagement
13. Quality Measurement and Improvement

Level 1: Optimal care coordination for lung cancer care has a low priority as evidenced by fragmented care.
Level 2: Early progress in coordinating care is underway.
Level 3: Reflects average or typical care coordination.
Level 4: Exceeds the average and reflects a cancer program’s ongoing commitment to the pursuit of optimal care coordination.
Level 5: Defined by optimal care coordination with a patient-centered focus. Depending on the assessment area, achieving Level 5 performance will require significant time, effort, and resources.

Patient Focus: Optimal care coordination must be patient-centered, which requires understanding of what is important to patients and their caregivers, including their knowledge, goals, needs, desires, social connections, and resources for care. This requires the cancer program to educate and engage patients and caregivers to facilitate shared decision-making and patients’ participation in their care.

Quality Measures and Metrics: Each assessment area requires at least one measurable parameter. Optimal care coordination requires analysis and development of an action plan for continuous improvement. These parameters should include both evidence-based and institution-specific benchmarks that address patient outcomes, patient experience, and cost effectiveness. These measures and metrics should be continuously measured and fed back to key institutional stakeholders for ongoing quality improvement.

Male 29 (58) 14 (48) 40 (52) 27 (51) 49 (64) 48 (48) 18 (51) 225 (53)
Female 21 (42) 15 (52) 37 (48) 26 (49) 27 (36) 52 (51) 17 (49) 195 (46)
Treatment versus lack of treatment was also significantly associated with stage at the time of diagnosis with 87.9% vs 12.1% for stage I, 88.2% vs 11.8% for stage II, 73.9% vs 26.1% for stage III, and 64.2% vs 35.8% in stage IV; untreated patients tended to present at a later stage than those who received treatment with OR 2.91 (95% CI 2.57-3.28) for stage III and OR 4.28 (95% CI 4.29-5.41) for stage IV. Lastly, insurance proved to be an important factor with untreated patients more likely to have Medicaid, Medicare or be uninsured.

**Conclusion:**
Treatment for lung cancer is correlated with improved outcomes and yet a large number of patients are still untreated. We aimed to assess these barriers to treatment and found untreated patients were more likely to be older, diagnosed at a later stage, and not have private insurance. While therapies are constantly changing and improving, it is important to factor in the many barriers that still exist in preventing patients from being treated.

**Keywords:** NSCLC, untreated
Background: Lung cancer is the leading cause of death from cancer, of which 15% corresponds with small cell lung cancer (SCLC) subtype, directly related with tobacco. SCLC is the most aggressive subtype with an elevated percentage of metastatic patients at diagnosis and a poor prognosis. Method: A cohort of 221 patients diagnosed of SCLC were retrospectively analyzed in our center between 2008-2016. Patient data was analyzed for baseline demographics and stage at diagnosis. Progression free survival (PFS) and overall survival (OS) analysis were made comparing SCLC stage at diagnosis. Result: The median age at diagnosis was 64 years and 74% were male, of whom 33% were older than 70 years. Only 0.5 % were never smokers and 16% had history of other malignancies, mostly related with tobacco. At diagnosis, 67% were metastatic and 88% symptomatic. Complete baseline characteristics shown at Table 1. PFS was 13.5 versus 6.83 months in located versus metastatic and 88% symptomatic. Complete baseline characteristics shown at Image 1. Kaplan-Meier curves shown at Image 1.

P1.15-25 HAS LUNG CANCER RADIOTHERAPY UTILISATION CHANGED OVER TIME IN NEW SOUTH WALES, AUSTRALIA? A. Oar1, S. Vinod1, G. Gabrié2, J. Shafiq2, M. Barton2, G. Delaney1

Background: Evidence based indications suggest that 73% of all Australian lung cancer patients would benefit from radiotherapy at diagnosis. In 2001-2002, the radiotherapy utilisation (RTU) rate in NSW for lung cancer was 39%. Since then a number of new radiation oncology centres have opened and the number of linear accelerators increasing from 29 to 46. There has also been an increase in the number of lung cancer multidisciplinary teams. We aimed to evaluate whether there had been any change in RTU for lung cancer in NSW from 2001-2002 to 2009-2011. Method: All patients diagnosed with lung cancer in NSW between 1/1/2009 and 31/12/2011 were identified from the NSW Central Cancer Registry. RTU was calculated as the number of radiotherapy treatments for lung cancer as a percentage of the estimated population.

Conclusion: There has been a significant increase in RTU for lung cancer in NSW from 2001-2002 to 2009-2011.

Keywords: Lung cancer, Radiotherapy utilisation, NSW, Australia.
Background:
The majority of NSCLC patients are diagnosed with stage IV disease. With the development of targeted therapies for advanced NSCLC, it has become important to understand which patients are being treated with systemic therapies and to what benefit. **Method:** We conducted a longitudinal, population-level study to determine the treatment patterns and survival in patients with stage IV NSCLC in Ontario, Canada between April 1, 2010 and March 31, 2015 from the Ontario Cancer Registry (OCR). Individuals were further identified as having non-squamous disease, and those who received an EGFR-TKI (azatinib, erlotinib, gefitinib) were assumed to be EGFR mutation-positive (EGFR+). **Result:** Survival was calculated from date of diagnosis to death. **Conclusion:** Although cCRT is generally considered standard of care for stage III unresectable NSCLC, patients in Ontario receive various treatment approaches. Survival outcomes vary widely. **Keywords:** Real World Evidence, non small cell lung cancer, treatment patterns

P1.15 TREATMENT IN THE REAL WORLD - SUPPORT, SURVIVORSHIP, SYSTEMS RESEARCH
MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.15-29 IMPACT OF RADIATION THERAPY QUALITY ASSURANCE ON PROGRESSION-FREE AND OVERALL SURVIVAL IN RANDOMIZED TRIALS OF LUNG CANCER
V.Y. Soon1, A. Tan1, L. Ng1, T.H. Tan1, J.C.S. Tey1
1Radiation Oncology, National University Hospital, Singapore, Singapore/SG
2National University Hospital, Singapore, Singapore/SG

Background: To evaluate if the estimates of treatment effect differ between randomized trials (RCTs) that reported radiation therapy quality assurance (RTQA) and RCTs, which did not report RTQA, for treatment of lung cancer (LC) [1] using curative intent thoracic radiation therapy (TRT).

Method: We searched MEDLINE for eligible meta-analyses (MAs) of RCTs of LC. For each trial in the selected MAs, we reviewed if RTQA was performed and extracted the hazard ratios (HR) with 95% confidence interval (CI) for progression-free (PFS) and overall survival (OS). We quantify the differences in the estimated intervention effect on PFS and OS by a ratio of HRs (HRRs): the HR for trials that performed RTQA to that of trials that did not perform or report RTQA. An HR more than 1 would indicate a larger HR for trials that performed RTQA compared to trials that did not perform or report. We estimated a combined HR across individual MAs. There was no significant change in the summary HRs after adjusting for potential confounders.

Conclusion: The conduct of RTQA did not modify the estimates of intervention effects on progression-free and overall survival in randomized trials of lung cancer treated with curative intent thoracic radiation therapy.

Keywords: radiation therapy, clinical trials, Quality assurance

</tr>
</tbody>
</table>

Total (N) 16 14 13 7 50

The overall survival (OS) of the patient receiving an EGFR-TKI as 1L or MN (n=18), 2L (n=18) and >/=3L (n=14) were 15.86 (95%CI, 10.26-21.46), 10.87 (95%CI, 0.00-28.29) and 20.23 (95%CI, 6.26-34.21) months (p=0.392), respectively. Regarding EGFR status, the OS of patients with EGFR sensitive mutation (n=11), wild-type (n=6) and unknown (n=33) were 30.75 (95% CI, 13.76-47.74), 7.91 (95% CI, 0.00-20.45) and 13.99 (95% CI, 9.17-18.82) months (p=0.086), respectively. Multivariate analysis indicated that age >/=70 years old (p=0.047), current or former smoking (p=0.012), ECOG performance status 2-4 or NA (p<0.001), received EGFR-TKIs by payment (p=0.033) or compassionate use (p<0.001) were the unfavorable prognostic factors for the OS.

Conclusion: The OS of the patients harboring EGFR sensitive mutation at our hospital was comparable to those of other pivotal studies. Clearly, patients harboring EGFR wild-type had the OS much shorter than those of the sensitive mutation group. In real practice at that time, two-third of patients still have not been proved their EGFR statuses before starting an EGFR-TKI and often received it as second-line or more.

P1.15-30 SURVIVAL OF PATIENTS WITH ADVANCED NSCLC TREATED WITH FIRST-GENERATION EGFR-TKIS AT A CANCER HOSPITAL IN THAILAND, 2011-2016
S. Sukauichai, C. Tovanabutra, S. Wanlikitkul, K. Chomprasert
Chonburi Cancer Hospital, Chonburi/TH

Background: This study was to find the survival in advanced NSCLC patients treated with an EGFR-TKI in a real-life practice. Method: The researcher conducted this retrospective study by review medical records in stage IIIb-IV NSCLC patients treated with first-generation EGFR-TKis at Chonburi Cancer Hospital from January, 2011 to December, 2016 and follow up until December, 2017. Result: This study enrolled 50 patients with median follow up time 16.78 months. The median age of patients was 58.5. There were female (46%), non-smoking (62%) and adenocarcinoma (90%). The patients received an EGFR-TKI by purchase by themselves (52%), reimbursement system (32%) and compassionate use (14%), additionally Eastern Cooperative Oncologic Group (ECOG) performance statuses were 0-1 (54%), 2-4 (28%) and non-available (NA) (18%). Treatment responses stratified by line of therapy and EGFR status were shown (table)

**TABLE 1:** Treatment in the Real World - Support, Survivorship, Systems Research

P1.15-31 SURVIVAL AND PATTERNS OF CARE COMPARING BLACK AND WHITE PATIENTS WITH ALL STAGES OF NSCLC: AN NCDB ANALYSIS
M. Vyghus1, S. Bentzen2, S. Grover3, C. Simone 2Nd1, P. Mohindra1
1Radiation Oncology, University of Maryland Medical Center, Baltimore/US
2Department of Epidemiology and Public Health, Biostatistics and Bioinformatics Division, University of Maryland, School of Medicine, Baltimore/US
3Radiation Oncology, University of Pennsylvania Perelman School of Medicine, Philadelphia/US

Background: Race and other socioeconomic factors continue to influence survival in patients with non-small cell lung cancer (NSCLC). Recent population-based studies have paradoxically shown a survival advantage

**TABLE 1:** Treatment in the Real World - Support, Survivorship, Systems Research
MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00
in the black population compared to white patients with stage III NSCLC. To further investigate this, we analyzed stage-wise overall survival (OS) and patterns of care in black patients as compared to white patients with NSCLC using the National Cancer Database (NCDB). Method: All black and white patients within the NCDB with biopsy-proven, stages I-IV NSCLC from 2004-2013 were analyzed. Associations between demographics and patterns of care were assessed using c2-tests. Guideline concordant care (GCC) and non-guideline concordant care (NGCC) were defined for each stage as per NCCN guidelines. OS between the races were analyzed using the log-rank test and the multivariable Cox proportional hazards regression. Result: When compared to white patients, black patients were younger at presentation (<60years: 36.2% vs. 22.5%, p<0.001), had a lower household income ($30,000: 37.9% vs. 11.5%, p<0.001), twice as likely to not have insurance (6.4% vs. 2.9%, p<0.001) and were diagnosed with more advanced disease (stage I: 18% vs. 24.9%, stage II: 6.1% vs. 6.9%, stage III: 25.9% vs. 23.7%, stage IV: 50% vs. 44.5%, p<0.001). White patients were more likely to undergo GCC in stages I-III when compared to black patients (stage I: 77% vs. 69.6%; stage II: 68.5% vs. 65.3%; stage III: 52.8% vs. 51.9%) but had a very similar incidence of GCC in stage IV (stage IV: 66.7% vs. 67.3%, p<0.001). Black race was associated with a 17%, 5%, and 3% increase risk of NGCC in stage I (OR: 0.835, 95% CI: 0.817-0.852, p<0.001), stage II (OR: 0.947, 95% CI: 0.916-0.978, p<0.001) and stage III (OR: 0.970, 95% CI: 0.954-0.985, p<0.001) disease, respectively, when compared to white patients in multivariate analysis (MVA). While in stage IV, being black predicted for a 4% greater receipt of appropriate treatment (OR: 1.041, 95% CI: 1.028-1.054, p<0.001). In the Cox MVA, race was not linked to OS in stage I or II disease, but being black predicted for a 3% lower risk of death in stage III and IV (stage III: HR: 0.973, 95% CI: 0.965-0.982, p<0.001; stage IV: HR: 0.967, 95% CI: 0.961-0.973, p<0.001). Conclusion: Black patients with NSCLC had similar or slightly improved OS when compared to white patients after accounting for socioeconomic demographics, staging and patterns of care. To explain this contradictory finding, further research should investigate biological differences between the two races.

**EGFR:** Epidermal growth factor receptor.

**Conclusion:** In our eastern China cohort, the most common EGFR mutation was L858R, differing from previous reported data in Asian population describing 19 deletion was the most common EGFR mutation. The frequency of EGFR mutations in biopsy specimen population was lower than both in surgical specimen and cytology specimen.

**P1.15-33 REAL-WORLD DATA ON PROGNOSTIC FACTORS FOR OVERALL SURVIVAL IN NSCLC PATIENTS TREATED WITH BEVACIZUMAB COMBINATION THERAPY**

S. Wu, W. Liao, C. Ho, J. Shih, C. Yu

**Background:** Bevacizumab is used as combination with chemotherapy as 1st-line treatment for non-squamous cell carcinoma. In order to understand the influence of bevacizumab on different combination medication response, this study aimed to identify independent prognostic factors for overall survival (OS) of NSCLC patients receiving bevacizumab treatment in real-world practice. Method: We performed retrospective collected non-squamous cell carcinoma patients undergoing bevacizumab treatment and analyzed their response and overall survival to bevacizumab. Demographic data, TTF-1 stain status, EGFR mutation status, and survival data were collected. Survival data analysis were plotted by the Kaplan–Meier method and compared by the log-rank test. Result: From November 2009 to October 2015, 114 non-squamous cell carcinoma patients treated with bevacizumab were enrolled for analysis. The median overall survival was 21.9 months. There were 11 patients who received continuous bevacizumab beyond disease progression of 3rd-line treatment and in all treatment courses. They had longer overall survival than those (N = 103) who did not received bevacizumab in all treatment courses (p = 0.013). The patients harboring positive TTF-1 tumor also had a longer overall survival than those harboring negative TTF-1 tumors (p = 0.025). Multivariate analysis revealed that patients harboring tumor with positive staining of TTF-1 (p < 0.001) and those received bevacizumab in all treatment course (p = 0.013) had a longer median OS. Conclusion: Non-squamous cell carcinoma patients receiving bevacizumab beyond 1st-line treatment failure, as all treatment course, had a longer median OS than those received bevacizumab in partial course.

**Keywords:** bevacizumab, lung cancer, overall survival
Background: Most patients with stage III non-small cell lung cancer (NSCLC) develop metastases and succumb to their cancer. New treatment strategies, including concurrent chemoradiotherapy (cCRT) followed by adjuvant immunotherapy, are improving outcomes, but need to be contextualized with real world data. In this study, we described population-based treatment patterns and outcomes for stage III NSCLC in a large Canadian province.

Method: Through the provincial cancer registry, patients diagnosed with stage III NSCLC from April 1, 2010 to March 31, 2015 were identified. Using electronic medical records and administrative claims, stage III patients were treated with treatment and survival information. Patient characteristics, treatment patterns, and outcomes were analyzed. Result: 6,438 patients were diagnosed with NSCLC, including 1,151 (17.9%) with stage III disease. Median age at diagnosis was 70 years (22–94): 50.2% were male. The majority were stage IIIa (61.2%); the remainder was stage IIIB (36.4%) or unspecified (2.4%). Most patients received palliative RT (32.8%), supportive care until progression (24.8%), or palliative chemotherapy (14.8%) as initial treatments. Relatively few underwent cCRT (11.7%) or trimodality therapy (1.7%). Resection was performed on 14.8% of patients. Within the resected cohort, the majority (47.6%) did not receive further perioperative treatment, while others had surgery as part of trimodality (11.2%) or alongside perioperative chemotherapy (37.1%). Overall, the median OS (mOS) was 13.3 months (0–NR). Initial treatment strategy predicted outcomes (p<0.05). Patients who underwent cCRT had mOS of 23.8 months (1.1–not reached [NR]), mOS for patients who initially received palliative chemotherapy or RT was 11.1 months (0.3–NR), and 6.2 (0–NR) months (1.1–not reached [NR]).

Conclusion: Treatment rates for cCRT and trimodality therapy in our cohort appear lower than expected despite evidence supporting the benefits of these strategies. Use of other treatment options was associated with poorer outcomes.

**P1.15-35 REAL WORLD OUTCOME OF DIFFERENT ADMINISTRATIONS ENDOSTAR COMBINED WITH CHEMOTHERAPY IN DRIVER GENE MUTATION NEGATIVE ADVANCED NSCLC**

**Y. Zhang**, Z. Wang, C. Zhou, N. Yang

1Hunan Cancer Hospital, Changsha/CN, 2Medical Oncology, Hunan Cancer Hospital, Changsha/CN

Background: To compare the efficacy and safety of different administration endostar combined with platinum-based chemotherapy with first-line treatment of driver gene mutation negative advanced NSCLC patients, and provides real-world evidence for optimum administration of endostar.

**Method:** From April 2014 to April 2017, 88 driver gene mutation negative patients who received platinum-based chemotherapy alone or combined with endostar were retrospectively enrolled in this project. All the patients were divided to three groups, including platinum-based chemotherapy alone (arm A), combined with 14 days endostar (7.5 mg/m2, d1-14, q21d, arm B) and 7 days endostar (15 mg/m2, d1-7, q21d, arm C). The primary endpoint was median overall survival (OS). The secondary endpoints were median progression-free survival (PFS), objective response rate (ORR), and disease control rate (DCR). The efficacy and safety was evaluated every 2 cycles.

**Result:** Of all the 88 enrolled patients, the median OS was 20 months in endostar groups (arm B and arm C) and 10 months in chemotherapy alone (arm A, p<0.001). The median PFS was months and 4.5 months respectively (P=0.073). The median OS was 22 months (arm B) and 14 months (arm C, P=0.01). The median PFS was 6 months in arm B, 6.5 months in arm C, and 4.5 months in arm A. The ORR were 44.4%, 22.2% and 20.6% for arm B (P=0.046), arm C (P=0.877) and arm A respectively. The DCR were 88.9%, 77.8% and 64.7% for arm B (P=0.046), arm C (P=0.266) and arm A respectively. There is no meaningful difference in OS between arm B and arm C (P=0.111), as well as ORR (P=0.074) and DCR (P=0.234), but a meaningful difference in PFS (P=0.044). The incidence of adverse event in the three groups was 22.2%, 3.7%, and 11.6%, respectively. There was no new occurring intolerant adverse event.

**Conclusion:** Endostar plus platinum-based doublet chemotherapy can significantly improve short-term and long-term outcomes in driver gene mutation negative advanced NSCLC. The administration of endostar compared to 7 days has no significant improvement in efficacy, but results in a higher incidence of adverse events.

**Keywords:** Endostar, driver gene mutation negative advanced NSCLC, Different administrations

**P1.15-36 A BETTER REAL WORLD PRACTICE FOR PEMETREXED IN FIRST-LINE TREATMENT OF ADVANCED NON-SQUAMOUS NON-Small CELL LUNG CANCER**

**Y. Zhang**, B. Yan, H. Yang, N. Yang

Hunan Cancer Hospital, Changsha/CN

Background: To investigate the real world practice of first-line pemetrexed combined with different drugs in patients with advanced Non-squamous non-small cell lung cancer.

**Method:** A total number of 164 patients from February 2012 to August 2017 in Hunan Cancer Hospital were retrospectively enrolled in this study. All the patients were divided into 5 groups: PC-P (pemetrexed combined with platinum for 4 cycles and pemetrexed maintenance, arm A), PCA-PA (Pemetrexed plus platinum and bevacizumab 4cycles, pemetrexed combined with bevacizumab maintenance, arm B), PC (pemetrexed combined with platinum chemotherapy 4 cycles, arm C), PCA (pemetrexed with platinum chemotherapy, plus bevacizumab 4 cycles without maintenance, arm D), PC-EGFR TKI (pemetrexed plus platinum chemotherapy 4 cycles, and then EGFR TKI as maintenance treatment, arm E). Efficacy and safety of pemetrexed was performed in each group comparing with each major clinical data.

**Result:** According to retrospective study, the median PFS for arm A, B, C, D and E were 13 months, 12 months, 5 months, 5 months, 15.8 months respectively; the median OS was 27 month, 21 months, 15 months, 11 months and 31 months respectively. Arm A and Arm C, Arm B and Arm D achieved statistical differences between OS (p<0.05). And Arm A and Arm C, Arm B and Arm D also achieved statistical differences between OS (p<0.05).

**Conclusion:** In the multivariate regression analysis of all patients, we found that the ECOG PS score may be an independent prognostic factor for death from lung cancer patients. Among all the patients, 35 (21.4%) patients presented with non-hematologic serious adverse event (grade 3 and 4). There...
was no new occurring intolerable adverse event comparing with other clinical trials. Conclusion: In this real world study, pembrolizumab proved to be high efficacy and well tolerable in advanced NSCLC. The efficacy of maintenance pembrolizumab treatment group achieved signiﬁcantly better outcome than the non-maintenance treatment group. In addition, ECOG PS score may be an independent prognostic factor for the death of patients in lung cancer. There was no new occurring intolerable adverse event comparing with previous clinical trials, the main adverse events in this study were also focused on non-hematologic toxicity. This is consistent with clinical trials.

P1.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE
MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.16-01 PROGNOSTIC VARIABLES ASSOCIATED WITH IMPROVED OUTCOMES IN STAGE III NSCLC PATIENTS TREATED WITH CONSOLIDATION PEMBROLIZUMAB
B. Anouti1, S. Althouse2, G. Durm3, T. Breen4, N. Hanna3
1Hematology/oncology, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis/IN/US, 2Department of Biostatistics, Indiana University, Indianapolis/US, 3Simon Cancer Center, Indiana University School of Medicine, Indianapolis/IN/US

Background: HCRN LUN 14-179 is a phase II trial of consolidation pembrolizumab following concurrent chemoradiation for the treatment of patients with stage III NSCLC. Time to metastatic disease, PFS, and OS appear superior to historical controls of chemoradiation alone. Unfortunately, not all patients benefit from consolidation immunotherapy. We performed a univariate analysis evaluating variables associated with PFS, metastatic disease, and OS. Method: We conducted a retrospective analysis from patients included in HCRN LUN 14-179. Data collected included age, sex, stage, smoking status, PD-L1 status; >G2 vs <G1 adverse event, >G2 vs >G3 pneumonitis, duration of pembrolizumab (<4 vs. >4 cycles), chemotherapy regimen, PS 0 vs 1, time to start pembrolizumab (<6 vs. >6 weeks from radiation), V20 (<20% vs. >20%), and total radiation dose. Univariate Cox regression was performed to determine the variables associated with 3 endpoints: time to metastatic disease/death; progression free survival; and overall survival. Result: From April 2015 to December 2016, 93 patients were enrolled and 92 were included in the efficacy analysis (1 patient was ineligible). For time to metastatic disease or death, improved outcomes may be associated (p<0.1) with stage IIIA, non-squamous cell, >4 cycles of pembrolizumab, and V20 < 20%. For PFS, improved outcomes (p<0.1) may be seen for females, stage IIIA, non-squamous histology, PD-L1 [+] tumors, >4 cycles of pembrolizumab, and V20 < 20%. For OS, improved outcomes (p<0.1) may be seen for non-squamous histology, PD-L1 [-], >4 cycles of pembrolizumab, V20 < 20%, and <G2 pneumonitis. Conclusion: Non-squamous NSCLC, PD-L1 [-] tumors, and V20 < 20% may be associated with prolonged time to metastatic disease or death, PFS, and OS for patients with stage III NSCLC treated with chemoradiation followed by pembrolizumab.

P1.16-02 SUPPORT AND INFORMATION NEEDS FOR PATIENTS WITH NSCLC RECEIVING CONCURRENT CHEMO-RADIOThERAPY: FINDINGS FROM THE INSIGHT STUDY
J. Fenimore1, G. Punnett2, J. Yorke1, F. Blackhall1, D. Mcentee1, M. Eaton2, H. Neal3
1Lung Cancer Dept, Medical Oncology, The Christie Hospital NHS Trust, Manchester/GB, 2Research Dept, Medical Oncology, The Christie Hospital NHS Trust, Manchester/GB, 3Medicall Oncology, The Christie Hospital, Bux/G, 4Lung Cancer Dept, The Christie Hospital, Bux/G

Background: The curative intent pathway for patients with non-small cell lung cancer (NSCLC) is complex and burdensome. Concur rent chemotherapy and radiotherapy (chemo-radiotherapy) is used as first line treatment for inoperable stage 3 cancer and requires the patient to attend multiple investigational procedures, separate appointments for chemotherapy and radiotherapy, intensive monitoring during treatment and multiple follow-up visits post treatment for up to 5 years to monitor late-toxicities and disease recurrence. The aims of this study are to identify the information needs of patients and their carers at key points along the treatment pathway and the preferred methods for information provision. A grant was awarded by the NLCFN to fund this patient experience, qualitative research study. Method: Semi-structured interviews were conducted with 15 patients, and their carer dyads where appropriate, recruited from a cancer centre in Manchester. UK. Result: Data collection is now complete with 15 patients recruited, of whom 6 were interviewed with a carer dyad. The thematic analysis is on-going and has been employed inductively to identify some of the emerging themes and key issues from the data collected. These include: preferred means of receiving information and level of information given, burden of treatment and earlier access to supportive care, information about life after treatment and the after effects of treatment, and preferred methods to access appropriate support. Conclusion: Further research is needed into the on-going needs of this patient cohort and data collection so far highlights areas for consideration when providing information to this patient cohort. Emerging themes highlight that a specific booklet on concurrent chemo/radiotherapy would be preferred, covering all aspects of treatment, including a personalised treatment plan to include, where relevant mask wearing, the impact of side effects of treatment and how assess support. Early indications are that patients prefer a combination of verbal, written and visual information giving. Collaboration work to link these patients on the concurrent treatment pathway in with early supportive care is optimal. Implementation of this service as part of the Concurrent treatment pathway will commence as a pilot study in July 2018, to assess the impact of earlier intervention to manage disease burden and treatment side effects, with an aim to reduce hospital admissions. The evidence suggests further work is needed to provide information giving and support to these patients both pre and post treatment. Additional advice is required to support proactive management, to enhance recovery, whilst addressing the fear and anxiety patients and carers experience due to uncertain outcomes.

P1.16-03 PROGNOSTIC SIGNIFICANCE OF PD-L1 IN STAGE II/III NON-SMALL CELL LUNG CANCER
M. Karaca1, D. Tural2, A. Özet3
1Medical Oncology, Antalya Education and Research Hospital, Antalya/TR, 2Medical Oncology, Istanbul Bakırköy Education and Research Hospital, Istanbul/TR, 3Medical Oncology, Gözi University Faculty of Medicine, Ankara/TR

Background: Prognostic significance of PD-1/PD-L1 axis expression in non-small cell lung cancer (NSCLC) remains uncertain despite being a predictive biomarker for novel immunotherapeutics. In this study, we have investigated PD-1/PD-L1 expression and its effect on disease prognosis and overall survival in stage II-III NSCLC patients. Method: Clinic and pathologic features of stage II and stage III NSCLC patients were retrospectively analyzed from patients’ records in this study. PD-1 and PD-L1 immunohistochemistry staining were carried out to archived tumor specimens of the eligible patients. Percentages of PD-1 and PD-L1 positive lymphocytes, PD-L1 positive tumor cells and PD-L1 positive tumor infiltrating immune cells were evaluated and considered as positive if ≥1% of the cells displayed staining. Result: Sixty-six male (89.2%) and 8 females (10.8%) of total 74 patients who were eligible for this study. Of the sixty-six patients, <G4 lymphocytes, 34 (44.6%) patients were diagnosed as stage II disease while 41 patients (55.6%) were diagnosed as stage III disease. Conclusion: PD-1 expression, PD-L1 expression in tumor cells and PD-L1 expression in tumor infiltrating
immune cells were positive in 83.8% (n = 62), 45.9% (n = 34), 67.6% (n = 50) of total 74 patients, respectively. Three-year overall survival (OS) rate was calculated as 57.7%. Univariate analyses did not reveal any significant difference in 3-years OS between those with PD-1 and PD-L1 expression in tumor infiltrating immune cells and those without expression. (p = 0.413 and p = 0.099; respectively). However, 3-years OS was more favorable in those with PD-L1 expression in tumor cells than in those without PD-L1 expression (76.6% vs 84.1%, p = 0.031). In multivariate analyses, a positive trend was revealed in 3-years OS between those with PD-L1 expression in tumor cells and those without expression. (HR 0.405, 95% CI 1.053, 1.074; p = 0.08). In this study, better prognosis was observed with positivity of PD-L1 in tumor cells. Therefore, it should be taken into consideration while designing adjuvant immunotherapy trials which are generally formed with stage I-II NSCLC patients, that expression of PD-1/PD-L1 pathway may have a positive prognostic effect.

**Background:** In the Phase 3 PACIFIC study of dabvulumab versus placebo in patients with stage III, unresectable NSCLC without progression after concurrent chemoradiotherapy (cCRT), the co-primary endpoint PFS was significantly longer with dabvulumab (stratified HR 0.52; 95% CI 0.42–0.65; P<0.0001). Overall, 26% and 29% in the dabvulumab and placebo group, respectively, received induction chemotherapy (ICT) before cCRT. Here, we report exploratory analyses of baseline characteristics, disposition, and outcomes from this study based on the presence or absence of prior ICT.

**Method:** PACIFIC (NCT02125461) was a Phase 3, randomized, double-blind study of patients with WHO PS 0/1 and any tumor PD-L1 status without previous platinum-based chemotherapy. Patients were stratified by age, sex, and smoking history and randomized (2:1) 1–2 days after cCRT to receive dabvulumab 10 mg/kg IV Q2W or placebo up to 2 cycles/months. First-line ICT was mandatory (BICR, RECIST v1.1 and OS [not available]). Secondary endpoints included ORR, time to death/ distant metastasis (TTDM), and safety. Between-treatment endpoint comparisons were performed for patients >70 and <70 years. 

**Result:** As of Feb 13, 2017, 713 patients were randomized; 27% had prior ICT. Baseline characteristics were similar between treatment arms; however, patients with ICT were generally younger, less frequently Asian, had lower incidence of squamous histology, and more often had stage IIIB disease. There were no differences between groups in terms of prior RT dose. PFS benefit with dabvulumab was demonstrated irrespective of ICT use (ICT: HR = 0.61, 95% CI, 0.41–0.88; no ICT: HR = 0.54, 95% CI, 0.42–0.69). Similarly, ORR with dabvulumab was numerically higher than with placebo irrespective of ICT use (ICT: 16.1% vs 13.1%; no ICT: 32.9% vs 17.1%). ICT did not affect treatment duration for dabvulumab or placebo. Between-treatment safety differences were minimal across subgroups; however, patients with ICT experienced fewer SAEs, treatment-related SAEs and pneumonitis/radiation pneumonitis regardless of treatment arm.

**Conclusion:** Dabvulumab demonstrated clinical benefit irrespective of ICT. The safety profile of dabvulumab was consistent in patients with or without ICT. A lower rate of toxicity was observed in patients with ICT regardless of treatment arm.

**Keywords:** induction chemotherapy, PACIFIC, dabvulumab
Background: Pembrolizumab, an immune checkpoint inhibitor, has been approved as monotherapy for 1st line treatment of metastatic NSCLC with PD-L1 tumor proportion score (TPS) ≥50% based on the pivotal Keynote (KN)-024 study. This study aims to evaluate the cost-effectiveness of pembrolizumab compared with standard-of-care (SoC) platinum-based chemotherapy in patients with TPS≥50% from a Singaporean perspective. Methods: A Markov model was employed to estimate progression-free survival, overall survival, costs of treatments, adverse events and disease management, and health utilities over a time horizon of 20 years. The maximum treatment duration of 2 years was assumed for pembrolizumab. Clinical and resource utilization inputs were based on data from KN024 study and input from local oncologists. Unit costs captured byage, sex, and smoking history. Co-primary endpoints were PFS (blinded independent central review, RECIST v1.1) and OS (not available). Secondary endpoints included ORR and safety. We investigated associations between subgroups of patients with PD-L1 expression on tumor cells (TC) ≥50% or ≥25% and efficacy. Results: As of February 13, 2017, 713 patients were randomized: 451 (63.3%) had known PD-L1 status (TC≥25%, 64.7%; TC≥25%, 35.3%; Table). Baseline characteristics and prior therapy (including best response to prior therapy) were generally well balanced between arms across both PD-L1 subgroups. PFS benefit with pembrolizumab was demonstrated irrespective of PD-L1 status (HR 0.59; 95% Cl, 0.43–0.82 for TC≥25% and HR 0.41; 95% Cl, 0.26–0.65 for TC≥25%) (Table). ORR was greater with pembrolizumab compared to placebo regardless of PD-L1 status (Table). The overall safety profile of pembrolizumab in each PD-L1 subgroup was consistent with the ITT population treated with pembrolizumab. Conclusion: Pembrolizumab demonstrated clinical benefit and had a well-tolerated, manageable safety profile irrespective of PD-L1 status obtained from archival tumor samples prior to cCRT.

**P1.06-08 WEEKLY NAB-PACLITAXEL PLUS CARBOPLATIN AS NEOADJUVANT THERAPY FOR IIIA-N2 LNG SQUAMOUS CELL CARCINOMA: A PROSPECTIVE PHASE II STUDY**

Tianjin Medical University Cancer Institute and Hospital, Tianjin/EN

**Background:** To evaluate the safety and antitumor activity of weekly nab-paclitaxel combined with carboplatin in patients with advanced stage IIIA-N2 LNG squamous cell carcinoma (SCC) with a smoking history.

**Method:** From April 2015 to August 2017, 36 treatment-naive, pathologically diagnosed IIIA-N2 LNG SCC patients were enrolled and given two cycles of weekly nab-paclitaxel (100mg/m², day 1, 8, 15 of a 21-day cycle) plus Carboplatin (AUC = 5 at day 1, 3QW) as neoadjuvant therapy. Then resectability was assessed and surgery was performed for resectable lesions. Post-operative adjuvant chemotherapy regimens is the combination of Nab-paclitaxel (100mg/m², qw x 6) and carboplatin (AUC 5, Q3W) for patients with PD, adjuvant chemotherapy regimen will be changed. The primary objective is the safety and efficacy, and the secondary objectives are quality of life and the role of prognostic biomarker SPARC.

**Result:** Of 36 patients, 3 stopped treatment due to patient decision. 33 were finally evaluated and 1 is still on treatment. Significant tumor volume shrinkage was seen in some patients after the neoadjuvant therapy. 66.7% patients achieved partial response (PR). 21.2% patients achieved stable disease (SD). Disease control rate (PR + SD) was 89.7%. Finally, 23 patients underwent surgical resection, the resectability rate was 69.7%. 12.1% occurred disease progress and 21.2% patients achieved stable disease (SD). Disease control (PR + SD) was 87.9%. Finally, 23 patients underwent surgical resection, the resectability rate was 69.7%. 12.1% occurred disease progress and 21.2% patients achieved stable disease (SD). Disease control (PR + SD) was 87.9%. Finally, 23 patients underwent surgical resection, the resectability rate was 69.7%. 12.1% occurred disease progress and 21.2% patients achieved stable disease (SD). Disease control (PR + SD) was 87.9%.

P1.16-09 SURGICAL RESULT OF PATHOLOGIC STAGE III A NON SMALL CELL LUNG CANCER: HAVE WE IMPROVED?

C. Wu
Division of Thoracic and Cardiovascular Surgery, Department of Surgery, Chang Gung Memorial Hospital, Linkou, Taoyuan County/TW

Background: Non small cell lung cancer was the leading cause of cancer death worldwide. Five-year survival of pathologic stage III a still remain poor and the management remain controversial. Many new medicines and surgical techniques were utilized as treatment for pathologic stage III a patient. The aim of study was tried to analyzed the survival impact of these treatment modalities and the stage migration effect during new TNM staging classification system. Method: From Jan 2005 to Jun 2014, there were 166 pathologic stage III a patients were enrolled into study. All patients were follow up till 2016/7. Patients were divided into two groups since year 2010 because of difference of surgical technique switch. Medical records were reviewed retrospectively and survival status were analyzed. Result: From January 2005 to May 2014, 166 patients who had received tumor resection and were confirmed as pathologic stage III a by 7th AJCC stage classification system were included for further analysis. The 5-year disease free and overall survival rates were 24.9% and 38.2%, respectively. Patients who received neoadjuvant therapy showed inferior disease free survival compared with those without neoadjuvant therapy. (p = 0.001). Patients who presented as adenocarcinoma and received tumor resection showed better overall survival than non-adenocarcinoma patients. (p = 0.0011) Because the operation method was shifted to video-assisted thoracoscopic surgery in the year 2010, we analyzed survival status separately before and after 2010. In addition, we found that patients who received tumor resection and were confirmed as pathologic stage III a adenocarcinoma has had better overall survival than other subgroups. (p = 0.0005) 28 patients who were identified stage migration had worse disease-free and overall survival. Conclusion: Disease free survival of pathologic stage III a patients remain unchanged but overall survival had much improvement. Patients who presented with adenocarcinoma who received tumor resection during 2010 to 2014 has better survival. This may be related to medical improvement but further investigation was warranted. Stage migration and worse disease and overall survival for those presented as 3b in new stage classification were identified. Different treatment strategy was needed for these patients who were identified stage migration.

P1.16-10 MARGINAL FEATURES ANALYSES OF LUNG ADENOCARCINOMA FOR SURVIVAL PREDICTION

G. Lee1, H.Y. Lee2, H. Park3
1Radiology, Pusan National University Hospital, Busan/KR, 2Samsung Medical Center, Seoul/KR, 3Sungkyunkwan University, Suwon/KR

Background: Tumor microenvironment is a complex mixture of assorted cells and extra-cellular components which make up an amazingly dynamic area that includes signaling interactions between cancer cells and their surrounding tissue. Tumor microenvironment makes up the peripheral portion of the tumor and major changes in this area has been reported to be associated with a poor prognosis. However, very few studies have investigated the tumor marginal features quantitatively extracted from CT images using a radiomics approach. We aimed to clarify the relationship between tumor marginal features and the micropapillary pattern and correlated with survival. Method: We enrolled 334 patients who underwent complete resection for lung adenocarcinoma. Quantitative histologic subtyping was performed for the whole tumor. Using a radiomics approach, quantitative CT analysis was performed and 82 marginal features were extracted. Clinical variables and marginal features were correlated with survival. Using selected clinical variables and marginal features a prognostic model was calculated with subsequent internal and external validation. Result: Among various subtypes, solid predominant adenocarcinomas had the lowest proportion (6.9%) of combined micropapillary pattern. At univariate analysis, patient age, tumor size, and multiple marginal features (convexity, surface area, compactness, maximum 3D diameter, sphericity, surface-to-volume ratio, mean pixel value, median pixel value, entropy, uniformity, skewness, kurtosis, roundness factor, solidity, and lacunarity) were predictive of survival. At multivariate cox proportional analysis, convexity (P = 0.017), kurtosis (P = 0.01), and patient age (P = 0.006) were identified as being predictive of survival. Ten-fold cross-validation tests demonstrated that our prediction model significantly classified patients according to survival (P < 0.001). Although lower than internal validation, the prediction model also worked at external validation.
**Conclusion:** Marginal radiomics features of convexity and kurtosis reflect the tumor microenvironment and were predictive of patient survival in lung adenocarcinomas.

**MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00**

**P1.16-11 MONITORING OF EARLY STAGE LUNG CANCER USING LIQUID BIOPSIES.**  
A. Dobrovic  
Olivia Newton-John Cancer Research Institute, Heidelberg/VIC/AU

**Background:** This study aims to validate the use of chromosome rearrangements as tumour-specific biomarkers for the detection of circulating tumour DNA (ctDNA) to enable monitoring of cancer using digital PCR. We consider that rearrangements are the best source of robust disease markers that can be used for every lung cancer patient without a clear truncal mutation. The current high cost of the whole genome sequencing required for identification of chromosome rearrangements is offset by the low cost, high sensitivity and specificity of the subsequent assays. **Method:** For ctDNA detection using chromosome rearrangements that leverage advances in next generation sequencing (NGS), bioinformatics and droplet digital PCR (ddPCR) have now been developed by our laboratory. **Result:** We are using whole genome sequencing and bioinformatic analysis of lung tumour samples. The genomic sequence was aligned to the human reference genome (hg19). Rearrangements were identified using the GRIDSS algorithm. Large numbers of potential genomic rearrangements that could be used as a biomarker to detect ctDNA were identified in each tumour. These were used to design primers which were used to monitor the success of surgical resection and to detect early relapse. **Conclusion:** Patients with early-stage primary tumours are the group in which appropriately timed therapeutic intervention is most likely to make a clinical difference. Our study assesses ctDNA in a large cohort of lung cancer patients with early-stage primary tumours that are being treated with the primary aim of cure. In addition, whole genome sequencing also identifies genomic information such as rare functional rearrangements and mutational burden which can also be used in patient management.

**MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00**

**P1.16-12 IDENTIFICATION OF A BIOMARKER PANEL IN RESECTED NSCLC THAT PREDICTS PATIENT OUTCOMES AND BENEFIT FROM ADJUVANT CHEMOTHERAPY**  
1Biology, University of New Brunswick, Saint John/NB/CA; 2Medicine, Dalhousie University, Saint John/NB/CA; 3Saint John Regional Hospital, Saint John/NB/CA

**Background:** Adjuvant chemotherapy for resected NSCLC improves overall survival by approximately 10%. Physicians need tools to predict which patients are most likely to benefit from chemotherapy, sparing those unlikely to benefit. A 15-gene expression profile (GEP) published by Zhu et al is both prognostic and predictive of benefit from adjuvant chemotherapy. The aim of this study is to translate this GEP into a readily applicable immunohistochemistry (IHC) panel. **Method:** We constructed NSCLC tissue microarrays at the Saint John Regional Hospital and semiquantitatively assessed the IHC expression and prognostic significance of proteins encoded by 7 of the genes in the Zhu panel for which commercial antibodies were available. **Result:** In 62 patients with resected stage II-III NSCLC, the prognostic significance of IHC assays for four proteins were concordant with the Zhu GEP results. Low FOSL2 (OS, HR = 2.6; p = 0.0231; PFS, HR = 3.3; p = 0.0052), and low ATPIB1 (PFS, HR = 2.0; p = 0.0338) were adverse prognostic factors. High STMN2 and low TRIM14 expression trended towards worse OS and PFS. Multivariate analysis verified the prognostic impact of the four assays. These markers could also be integrated as a panel with retained prognostic value (OS, HR = 2.1, p = 0.03). **Conclusion:** An IHC panel with results concordant to the Zhu GEP is prognostic. Ongoing studies will examine the prognostic and predictive impact of this IHC panel in larger, independent datasets. If the panel turns out to be robust and predictive, it will have potential clinical application as a tool to select patients for adjuvant chemotherapy.

**P1.16-13 PHOTO DYNAMIC THERAPY (PDT) IN OUR HOSPITAL**  
F. Hoshi1, A. Sakurada2, M. Noda1, T. Sado2, Y. Matsuda1, H. Oishi1, S. Ebara1, O. Okada1  

**Background:** Lung cancer is the leading cause of cancer death worldwide. A large part of lung cancer is diagnosed at an advanced stage, but the number of lung cancer diagnosed at an early stage are increasing due to the improvement of diagnostic imaging techniques. In Japan, sputum cytology for mass screening provides chances to detect very early stage centrally located lung cancer which is good adaptation of PDT. Although PDT is less invasive therapy which enable us to treat the patients with poor pulmonary function or poor performance status. It is important to clarify the therapeutic outcome and the morbidity after PDT such as airway narrowing, pneumonia, and sunlight hypersensitivity. **Method:** We analyzed 14 patients who received PDT in Tohoku University Hospital between January 2010 and April 2017 retrospectively and evaluated the therapeutic outcome of PDT. **Result:** 14 cases were alive and 9 cases were Lt. After these therapeutic outcomes were calculated, the average age was 71. Nine cases were detected in cancer screening examinations and other 5 cases were detected accidentally while observing other diseases. Lung cancer existed in the right lung in 8 patients and in 7 patients, and more peripheral lesion in 2. All 14 cases were pathologically squamous cell carcinoma. In 2 cases, we performed PDT twice. In 3 cases, we performed surgical resection after PDT. Within follow-up period after PDT, 5 cases developed metachronous lung cancer and were treated with surgical resection or radiotherapy. After these therapies 11 cases alive without recurrence, 1 case alive with recurrence, 1 case died from original disease, and 1 case died from other disease. Only one case suffered airway narrowing after PDT, but other 13 cases had no morbidity. **Conclusion:** We concluded PDT is a good treatment in early stage centrally located lung cancer with good outcomes and little morbidity rates.

**Keywords:** Photo Dynamic Therapy, early stage centrally located lung cancer

**P1.16-14 IMPACT OF SMOKING ON TREATMENT OUTCOME IN EARLY SQUAMOUS CELL LUNG CANCER (TINO)**  
1Department of Thoracic and Cardiovascular Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR; 2Thoracic and Cardiovascular Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR

**Background:** Smoking is the major risk factor for squamous cell lung cancer. However, squamous cell lung cancer in never-smoker is known to have poor survival outcomes. We compared clinicopathologic features and outcomes between smokers and never-smokers in resected early squamous cell lung cancer (TINO). **Method:** An institutional database was reviewed retrospectively between 1994 and 2016 (N = 443). Eligible patients included completely resected squamous cell lung cancer, less than 3 cm in tumor size, and without N1 or N2 involvements. Patients were stratified by gender and smoking status. **Result:** 423 (95%) smokers and 20 (5%) never-smokers were identified. The median age of never-smokers was 66 years (range, 39 - 83), and 11 of these patients were female (55%). The median age of smokers was 66 years (range, 42 - 84), and most of them were male (97.9%). The T stage were distributed equally in both groups. In smokers, 84 (19.9%) patients experienced recurrence whereas only 1 patient (5%) of never-smokers occurred distant metastasis (p < 0.001). Distant metastasis was most frequent recurrence pattern in smokers (n = 40), but locoregional recurrence also a fairly frequent pattern (n = 30). The 5-year overall survival rates and recurrence free survival rates were 70.9% and 61.5% in smokers and were 64.1% and 67.1% in never-smokers respectively (p = 0.65, and 0.34, respectively). **Conclusion:** There was no significant differences in clinicopathologic features and outcomes between smokers and never-smokers in early squamous cell lung cancer.

**Keywords:** squamous cell, never-smoker, NSCLC
Keywords: respiratory complications and prognosis in lung cancer patients.

and LAA% using 3D-CT in patients with lung cancer, particularly with the effect of the 3D-CT function analysis of emphysema severity and its association with respiratory complications and prognostic outcomes. Method: The study included 504 patients who underwent preoperative 3D-CT for surgical simulation followed by resection for lung cancer from October 2010 to March 2015. GS and LAA% (LAA / total lung volume) were measured using 3D-CT data. We studied the relationship between the development of postoperative respiratory complications/overall survival (OS) and independent variables including age, sex, forced expiratory volume in 1 second as percent forced vital capacity (FEV1%), histology, smoking status, surgical procedure, GS, and LAA%. Result: Postoperative respiratory complications were observed in 69 patients (13.6%). These included prolonged air leakage > 7 days (n = 31), pneumonia (n = 13), bronchial fistula (n = 4), atelectasis (n = 5), pulmonary fibrosis (n = 3), empyema (n = 5), recurrent nerve paralysis (n = 2), chylothorax (n = 5), pleural effusion (n = 3) and other respiratory-related adverse events (n = 7). The ROC curves for respiratory complications determined using the GS and LAA% dichotomized at each cut-off level (1 and 0.7%, respectively) showed that the events were observed in 32% of the patients with GS ≥ 1 and in 25% of the patients with LAA% ≥ 0.7. On multivariate analyses, the GS or LAA% was significantly associated with postoperative respiratory complications (p < 0.001 and p = 0.016, respectively). Univariate and multivariate analysis using the Cox regression model for prognosis also showed GS was significantly associated with unfavorable OS among 362 patients found in 100 (38%), 53 (20%), and 45 (17%) patients, respectively. (p < 0.001). Conclusion: Preoperative measurement of GS and LAA% using 3D-CT in patients with lung cancer, particularly with the coexistence of emphysema, was beneficial for predicting postoperative respiratory complications and prognosis in lung cancer patients.

P1.16-15 EVALUATION OF EMPHYSEMA SEVERITY BY 3D-CT FOR PREDICTING POSTOPERATIVE RESPIRATORY COMPLICATIONS AND PROGNOSIS OF LUNG CANCER

Department of Surgery, Tokyo Medical University Hospital, Tokyo/JP

Background: Emphysema is one of the main causes of respiratory complications and perioperative mortality and morbidity in lung cancer patients. We have used 3D-CT for depicting emphysematous areas as low attenuation areas (LAAs) and visual scores based on Goddard classification (Goddard score: GS). This study aimed to investigate the effectiveness of the 3D-CT function analysis of emphysema severity and its association with respiratory complications and prognostic outcomes.

Method: The study included 504 patients who underwent preoperative 3D-CT for surgical simulation followed by resection for lung cancer from October 2010 to March 2015. GS and LAA% were measured using 3D-CT data. We studied the relationship between the development of postoperative respiratory complications/overall survival (OS) and independent variables including age, sex, forced expiratory volume in 1 second as percent forced vital capacity (FEV1%), histology, smoking status, surgical procedure, GS, and LAA%.

Result: Postoperative respiratory complications were observed in 69 patients (13.6%). These included prolonged air leakage > 7 days (n = 31), pneumonia (n = 13), bronchial fistula (n = 4), atelectasis (n = 5), pulmonary fibrosis (n = 3), empyema (n = 5), recurrent nerve paralysis (n = 2), chylothorax (n = 5), pleural effusion (n = 3) and other respiratory-related adverse events (n = 7). The ROC curves for respiratory complications determined using the GS and LAA% dichotomized at each cut-off level (1 and 0.7%, respectively) showed that the events were observed in 32% of the patients with GS ≥ 1 and in 25% of the patients with LAA% ≥ 0.7. On multivariate analyses, the GS or LAA% was significantly associated with postoperative respiratory complications (p < 0.001 and p = 0.016, respectively). Univariate and multivariate analysis using the Cox regression model for prognosis also showed GS was significantly associated with unfavorable OS among 362 patients.

Conclusion: Our study revealed that there is a significant correlation between PET metabolic information and CT gray-level intensity. The automatic segmentation of subregion in CT images may serve as an alternative to the metabolic region delineated in PET.

P1.16-17 THE ROLE OF QUANTITATIVE METABOLIC METRICS ON FDG-PET/CT IN PREDICTING PATHOLOGICAL INVASIVE FACTORS IN CNO LUNG ADENOCARCINOMA

T. Ishihara1, Y. Shimada1, Y. Makino1, J. Maeda1, M. Hagiwara1, T. Okano1, M. Kakkihana1, N. Kajiwara1, T. Ohira2, J. Matsubayashi2, N. Ikeda2
1Surgery, Tokyo Medical University, Tokyo/JP, 2Anatomic Pathology, Tokyo Medical University, Tokyo/JP

Background: Growing evidence suggests that FDG-PET/CT has greatly contributed the preoperative investigation of early-stage lung cancer. The maximum standardized uptake values (SUVmax) of the primary lesion is widely reported to be associated with prognosis in NSCLC while other metabolic metrics, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) have been explored as a measure of metabolic tumor burden in recent years. The purpose of this study is to investigate the role of quantitative metabolic metrics in predicting the incidence of pathological invasive factors including microscopic vascular invasion, pleural invasion, and lymph node metastasis in cNO lung adenocarcinoma.

Method: We examined 265 patients with clinical stage 0-II(cNO) adenocarcinoma. Pre-operative PET/CT and subsequent complete resection was performed for all the patients during the period from August 2012 to July 2017. The maximum tumor and solid-part diameter on HRCT and the three metabolic metrics on PET/CT measured from August 2012 to July 2017. The maximum tumor size and solid-part diameter were measured using the SYNAPSE VINCENT (Fujifilm Medical, Tokyo, Japan) as the volume viewer software were observed. In the current study, MTV was defined as the total tumor volume with an SUV > 2.5 while TLG was calculated as meanSUV x MTV. We assessed the relationship between these parameters and the incidence of pathological invasive factors.

Result: Among 265 patients, 18 (7%) patients were clinically staged as 0, 205 (77%) as IA, 32 (12%) as IB, and 10 (4%) as II, respectively. Pathological vascular invasion, pleural invasion, and lymph node metastasis were found in 100 (38%), 53 (20%), and 45 (17%) patients, respectively. SUVmax, MTV, and TLG were dichotomized at cut-off level by the receiver operating characteristic (ROC) curves for pathological invasive factors (SUVmax of 4.4, MTV of 0.75mm3, and TLG of 2.6, respectively). ROC curve yielded area under the curve values of 0.812, 0.915, and 0.882 for SUVmax, MTV, and TLG, respectively. Univariate analysis showed that SUVmax (Hazard Ratio (HR), 27.185; p<0.001), MTV (HR, 24.580; p<0.001), TLG (HR, 24.580; p<0.001), maximum tumor size (HR, 2.495; p<0.001), solid-tumor size (HR, 7.830; p<0.001), c-stage (HR, 14.418; p<0.001), and sex (HR, 1.882; p=0.013) were significantly associated with the incidence of pathological invasive factors. Multivariate analysis showed that SUVmax was the independent predictor (HR, 7.006; p<0.001). The frequency of pathological invasive factors of patients with SUVmax > 4.4, MTV > 0.75mm3, and TLG > 2.6 were 82%, 84%, and 84%, respectively. Conclusion: In cNO early-stage lung adenocarcinoma, the measurement of SUVmax, MTV, and TLG on FDG-PET/CT was beneficial for the prediction of pathological invasive factors.

Keywords: Adenocarcinoma, MTV, PET/CT

P1.16-16 AUTOMATIC INTRATUMOR SEGMENTATION IN CT OF NSCLC: AN ALTERNATIVE TO PET METABOLIC SUBREGIONS

Q. Oiu, J. Duan, X. Sha, G. Gong, Y. Yin
Department of Radiation Oncology, Shandong Cancer Hospital Affiliated To Shandong University, Jinan/CN

Background: PET images provide heterogeneous metabolic information in precision radiation treatment planning and the radiation dose given to high metabolic volumes should be escalated. However, PET scanning will increase the radiation dose received by patients. The aim of this study was to evaluate the feasibility of automatic intratumor segmentation in CT of NSCLC patients based on level-set evolution and cell automaton algorithm and assess the consistency with PET metabolic subregions.

Method: The PET and plan-CT imaging data set of 17 patients who have diagnosed with NSCLC were randomly collected. First, the gross tumor volume (GTV) was defined using a threshold of 40% SUVmax on PET. Then, rigid registration was used to align PET images to plan-CT images and the GTV was mapped to the CT image subsequently. The subregions which describe heterogeneity of voxel gray-level intensities were then automatically segmented using an algorithm combined level-set evolution and cell automaton in GTVvoxel. Meanwhile, the three metabolic subregions in GTVvoxel were delineated using threshold interval a) 40%-60% SUVvoxel, b) 60%-80% SUVvoxel, and c) 80%-100% SUV voxel. To evaluate the consistency with PET metabolic subregions, we calculated the spatial overlap by Dice’s similarity coefficient (DSC). Result: In total, 21 GTV pairs acquired from CT and PET data set were used to evaluate the feasibility of method proposed in this study. The GTVvoxel was automatically divided into three heterogeneous subregions based on its difference on gray-level intensities and regional connectivity of voxel and 63 subregions were acquired. The average DSC value calculated from subregion in CT and PET is 0.725 with interval (0.321,0.905).

Keywords: PET/CT, CT, PET, segmentation, PET/CT.
P1.16-18 ROLE OF ERCC1/2 SINGLE NUCLEOTIDE POLYMORPHISM (SNP) ON TREATMENT RESPONSE IN PATIENTS WITH LUNG CANCER UNDERGOING RADIATION THERAPY

Y. Zhu1, C. Jiang1, Y. Chen1, Q. Xu1, J. Feng2, J. Jin1, Y. Xu1
1Shanghai Pulmonary Hospital, Shanghai/CN, 2Zhejiang Cancer Hospital, Hangzhou/CN, 3Indiana University. School of Medicine. Radiation Oncology Department, Indianapolis/US

Background: Radiation therapy plays an important role in the treatment of lung cancer. The protein excision-repair cross-complementation 1 (ERCC1) and protein excision-repair cross-complementation 2 (ERCC2) are the key enzymes in NER pathway. Studies showed that ERCC1/2 were associated with susceptibility and efficacy of chemotherapy in lung cancer, but the association between ERCC1/2 SNPs and radiotherapy were seldom reported. Method: Eighty-seven peripheral blood samples were collected from patients with NSCLC before they received radiotherapy in our department from November 2014 to October 2017. The peripheral blood leukocyte DNA was isolated and SNP genotypes were detected by competitive allele-specific PCR. Seven SNPs in ERCC1/2 were analyzed. Data was collected both before and after radiotherapy from blood serum. Elisa was used to detect ERCC1 expression. The association between the changes of expression of ERCC1 during radiotherapy and efficacy, risk of RILI and SNPs in ERCC1 was analyzed. Result: ERCC1 rs3212961 minor allele A was associated with a better response to radiotherapy in NSCLC patients. Survival analyses showed that G/G genotype had favorable OS than A/A genotype (P=0.012). Cox regression analysis indicated that ERCC1 rs11615 G/G genotype was associated with decreased risk of death. Subgroup analyses indicated that patients with G/G genotype who received high BED radiotherapy had better OS (median not reached vs. 21.5 months, 95%CI: 15.3–27.7, P=0.011) and PFS (median not reached vs. 19.9 months, 95%CI: 8.6–31.2, P<0.001) than low BED subgroup. There was no significant association between ERCC1/2 SNPs and RILI. The ERCC1 expression in serum was significantly increased after radiotherapy. However, the changes of ERCC1 expression showed no association with efficacy of radiotherapy, risk of RILI or SNPs of ERCC1. Conclusion: ERCC1 rs3212961 was related with short-term curative efficacy. ERCC1 rs11615 was an independent prognostic factor in NSCLC, which could serve as biomarker, because G/G genotype had favorable OS and PFS, and was associated with decreased risk of death. There was no significant correlation between ERCC1/2 SNPs and RILI. The changes of ERCC1 expression after radiotherapy showed no association with efficacy of radiotherapy, risk of RILI or SNPs of ERCC1/2.

P1.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE

P1.16-19 NEITHER MAXIMUM TUMOR SIZE NOR SOLID COMPONENT SIZE WAS THE BEST PROGNOSTICATOR FOR SUBSOLID NODULE

E. Zhu1, C. Chen2
1Thoracic Surgery, Shanghai Pulmonary Hospital, Shanghai/CN, 2Department of Thoracic Surgery, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN

Background: Solid component size is used to define the T stage of subsolid nodule in the eighth edition TNM stage classification. Our study aimed to explore whether solid component size was the best parameter for T staging. Method: We retrospectively reviewed the clinical data of 431 cTis-T3N0M0 subsolid nodule from Shanghai Pulmonary Hospital. Maximum tumor size, solid component size and tumor size in mediastinal window were carefully recorded. Prognostic ability of different tumor size was compared by time-dependent receiver operating curve. Result: Survival revealed maximum tumor size, solid component size and tumor size in mediastinal window were statistical significant predictors. However, solid component size performed the worst of them, relatively.

P1.16-20 A SYSTEMATIC REVIEW AND META-ANALYSIS OF STEREOTACTIC BODY RADIATION THERAPY VERSUS SURGERY FOR PATIENTS WITH NON-SMALL CELL LUNG CANCER

C. Cao1, A. Rimner2, J. Huang3, D. Jones3
1Thoracic Surgery, Memorial Sloan Kettering Cancer Center, Nyc/US, 2Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York/NY/US, 3Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/US

Background: Stereotactic body radiation therapy (SBRT) is the preferred treatment modality for patients with inoperable early-stage NSCLC. However, comparative outcomes of SBRT versus surgery for high-risk patients remain controversial. The primary aim of the present meta-analysis was to assess the overall survival of SBRT versus surgery in matched and unmatched patient cohorts. Secondary endpoints included cancer-specific survival, disease-free survival, disease recurrence, and perioperative outcomes. Method: A systematic review was performed through online databases using predefined criteria. The most updated studies were selected for meta-analysis according to unmatched and matched patient cohorts. Result: Thirty-two studies were identified in the systematic review. Surgery was associated with superior overall survival in both unmatched (OR 2.49, 95% CI 2.10–2.94, p<0.00001) and matched (OR 1.71, 95% CI 1.52–1.93, p<0.00001) cohorts. Cancer-specific survival, disease-free survival, and freedom from locoregional recurrence were found to be superior after surgery compared to SBRT, in both unmatched and matched cohorts. However, SBRT was associated with fewer perioperative mortalities.

(See next page)
**P1.16-22 META-ANALYSIS OF STEREOTACTIC ABLATIVE RADIOTHERAPY VERSUS SURGERY FOR EARLY STAGE LUNG CANCER.**

J. Kowalewski1, M. Dancewicz2, M. Kowalewski2

Background: The standard of care for operable, stage I, non-small-cell lung cancer (NSCLC) is lobectomy with mediastinal lymph node dissection or sampling. Stereotactic ablative radiotherapy (SABR) for inoperable stage I NSCLC has shown promising results, but two independent, phase 3 randomised controlled trials (RCTs) included few patients and closed early due to slow accrual. We aimed to assess overall survival with SABR versus surgery by pooling data from RCTs and adjusted observational studies. Method: We performed a systematic review and meta-analysis according to PRISMA (Preferred Items Reporting for Systematic Reviews and Meta Analyses) guidelines. The search process covered a period until 28th of February 2018. Search terms were: SABR, stereotactic body radiation therapy, radiotherapy, lung-, pulmonary-cancer.

Conclusion: CABR could be an option for treating early stage NSCLC but there was significant discrepancy between RCTs and non-RCTs regarding survival after SABR as compared to surgery; more adequately powered randomized studies are needed before conclusions on efficacy of SABR can be drawn.

P1.16-23 LONG-TERM SURVIVAL ANALYSIS OF SURGERY IN POTENTIAL STEREOTACTIC ABLATIVE RADIOThERAPY CANDIDATES OF NON-SMALL CELL LUNG CANCER

S. Li, S. Zhang, Y. Ma, Y. Yang
Department of Thoracic Surgery II, Peking University Cancer Hospital & Institute, Beijing/CN

Background: The aims of this study were to evaluate the long-term survival outcomes and strengthen the primacy of surgery in potential stereotactic body radiotherapy candidates. Method: A total of 541 patients with clinical stage I non-small cell lung cancer from January 2005 to December 2014 were enrolled in the current study. All patients who were potential stereotactic ablative radiotherapy candidates underwent lobectomy and systematic lymph node dissection including level 13 and 14 without preoperative therapy. According to the recommendation of the 8th edition of TNM stage, combined with our own experience, we divided the N stage into N1a (only level 13-14 positive), N1b (level 10–12 positive), N2a1 (skip single N2), N2a2 (single N2 with N1) and N2b (multiple N2). Survival curves were estimated by the Kaplan–Meier method. Result: Among all patients, 25.0% had occult lymph node involvement. 12.8% were N1 and 46.2% were N2. Among 312 patients only 1 case (3.0%) patients had N1a positive without other N positive. In 104 cases of T1b, the positive rates of N1a, N1b, N2a1, N2a2 and N2b were 0.8%, 5.9%, 0.8%, 2.5% and 1.7%, respectively. Among the 86 patients with T1c, the positive rates of each station was 5.4%, 11.5%, 3.8%, 8.5% and 4.6%, respectively. Of the 184 patients with T2a, N1 accounted for 14.6% and N2 accounted for 11.5%. The 3-year, 5-year and 10-year disease free survival (DFS) of all 541 clinical stage I patients were 90.0%, 81.0% and 72.5%, respectively. The 3-year, 5-year and 10-year DFS of all 541 clinical stage I patients treated with SF-SBRT. Median follow-up was 23.8 months. There were 80 pts (55%) treated with 30 Gy and 66 pts (45%) treated with 34 Gy. The rate of CWT was 30.6% for lesions abutting CW, 8.2% for ≤ 1 cm from CW, 3.8% for 1–2 cm from CW, and 5.7% for ≥ 2 cm from CW. Grade ≥ 3 CWT was modest (1.4%). Tumor abutment (OR 6.5; p=0.0005), BMI (OR 1.1; p= 0.02), rib D1cc (OR 1.01 per Gy; p= 0.03), CW D1cc (OR= 1.08 per Gy; p=0.03), and CW D5cc (OR 1.10 per Gy; p= 0.01) were significant predictors for CWT on univariate analysis. The 30.6% CWT rate in this series (30.6%) does not appear to exceed rates in the published fractionated SBRT literature (20–33%). Location adjacent to CW should not be a contraindication to SF-SBRT. CW D1cc and D5cc may be used as predictors of CWT rates. As most CWT is low-grade and self-limited, these dosimetric parameters should be utilized as a guideline, rather than an absolute constraint.

Keywords: Stereotactic body radiation therapy, Single fraction, chest wall

T/N category NO N1a N1b N2a1 N2a2 N2b
1a 32 (97.0%) 1 (3.0%) 0 0 0 0
1b 104 (88.1%) 1 (0.8%) 7 (5.9%) 1 (0.8%) 3 (2.5%) 2 (1.7%)
1c 86 (66.2%) 7 (8.5%) 15 (17.6%) 5 (6.0%) 11 (13.0%) 6 (7.0%)
2a 184 (70.8%) 13 (7.1%) 25 (13.6%) 8 (4.4%) 12 (6.5%) 18 (9.8%)

Conclusion: In view of the high rate of lymph node metastasis in clinical stage I lung cancer, surgical resection is still the preferred treatment.

P1.16-24 IMPACT OF TUMOR LOCATION & DOSIMETRIC PREDICTORS FOR CHEST WALL TOXICITY IN SINGLE FRACTION SBRT FOR STAGE I NON-CELL LUNG CANCER

B. Manyam1, G. Videtic1, K. Verdechcia1, C. Reddy1, N. Woody1, T. Zhuang1, K. Stephan1, A. Juloor2
1Radiation Oncology, 20201 Carnegie Avenue, Cleveland/Ohio/US, 2Department of Radiation Oncology, Cleveland Clinic, Cleveland/Ohio/US

Background: Single fraction stereotactic body radiation therapy (SF-SBRT) is an acceptable regimen for treatment of peripheral Stage I Non-Small Cell Lung Cancer (NSCLC). Rates of chest wall toxicity (CWT) are not stratified by distance of tumor to chest wall (CW) and dosimetric parameters are not well defined. We sought to determine the relationship of tumor location and dosimetric parameters with CWT in SF-SBRT.

Method: An IRB-approved prospective SBRT registry of 1,462 patients (pts) was used to identify pts treated with 30 Gy or 34 Gy in one fraction. Tumors were ≤ 5 cm, node-negative, and ≥ 2 cm from the proximal tracheo-bronchial tree. The CW was retrospectively contoured (3 cm soft-tissue structure). Gross tumor volume was measured as abutting, ≤ 1 cm, 1-2 cm or > 2 cm from the CW. CWT was graded according to CTCAE 3.0 criteria. Rates of CWT were compared using unpaired t-test. Logistic regression analysis was used to identify tumor and dosimetric parameters associated with CWT. Result: This study included 146 lesions treated with SF-SBRT. Median follow-up was 23.8 months. There were 80

Coefficients for propensity score

Factors | Coefficients
---|---
(Intercept) | (3.95)
Age per 10y | -0.53
Sex female | 0 (ref)
Sex male | -0.62
CC1 | 0 (ref)
BMI | -0.97
BMI underweight | -0.98
BMI normal | 0 (ref)
BMI overweight | 0.44
FEV1 per 1L | 0.84
Tumor diameter per 1cm | -0.34
Conclusion: The PS model would help appropriate treatment selection for high-risk operable patients. Although patients with PS of 0.5 or more benefit from SLR, SBRT provides comparable outcomes for patients with PS<0.5.

Keywords: Propensity score, stereotactic body radiotherapy, sublobar resection

P1.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE
MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.16-22 SAFETY OF SABR (STEREOTACTIC ABLATIVE BODY RADIOTHERAPY) FOR CENTRAL NON-SMALL CELL LUNG CANCERS (CNSCLC) WITH 50 GRAY IN 5 FRACTIONS (50GY/5F)
R. Rulach1, J. Hicks1, G. Lumsden1, S. Mckay1, J. Macphee1, K. Moore2, M. Omand1, M. Sproule2, Currie1, A. Atkion1, R. Ferguson1, P. Houston1, R. Valiente1, S. Harrow1
1Clinical Oncology, The Beatson West of Scotland Cancer Centre, Glasgow/GB, 2Radiology, Gartnavel General Hospital, Glasgow/GB

Background: SABR using 50Gy/3f (or equivalent) caused high toxicity when used for CNSCLC. To determine a safe SABR dose for CNSCLC, the phase I/II RTOG 0813 trial used 50Gy/5f as a baseline. From 2013, 50Gy/5f was adopted for inoperable early-stage CNSCLC at the West of Scotland Cancer Centre, a tertiary-level oncology unit. We report our prospectively collected toxicity and efficacy data. Method: Patients with CNSCLC were identified from the radiotherapy database. CNSCLC was defined as lung cancers within 2cm of the proximal bronchial tree, or the planning target volume (PTV) abutting the mediastinal pleura/pericardium. Patient and treatment characteristics were obtained from electronic medical records. All patients received 50Gy/5f on alternate days with a volumetric arc therapy plan using TrueBeam linear accelerators. Toxicity was assessed in a centralised follow-up clinic 2 weeks, 6 weeks, 6 months, 1 and 2 years after treatment using Common Toxicity Criteria Adverse Events version 3. Patients had a CT scan at 3 months post-treatment. Subsequent CT scans were at the discretion of the treating clinician. Result: 50 patients (31 females, 19 males, median age 75.1 years old) were identified with T1-2N0M0 scan at 3 months post-treatment. Subsequent CT scans were at the 6 weeks, 6 months, 1 and 2 years after treatment using accelerators. Toxicity was assessed in a centralised follow-up clinic 2 years after treatment. Statistical analysis involved repeated measures ANOVA. Result: Sixty-four patients, which includes six patients (9.4%) receiving salvage SBRT, met inclusion criteria (median follow up of 21 months). No significant differences (p=0.77) were observed between maximum point doses to BP, SCV, and SCA. Within one year post-SBRT, two patients (3%) developed BPX (grade 2); both patients had exceeded 32 Gy to the BP and were treated with salvage SBRT. No patient treated with definitive SBRT (91%) developed BP, despite 17 of these exceeding recommended maximum doses. Conclusion: No BPX was observed for patients that exceeded a maximum dose of 32 Gy to the BP, unless they were treated as salvage SBRT. This suggests higher doses to the BP may be considered when clinically required for definitive SBRT. However, salvage SBRT may require more conservative BP constraints than used in the definitive setting.

P1.16-28 THE IMPACT OF SPIRONOLACTONE ON THE LUNG INJURY INDUCED BY CONCOMITANT TRASTUZUMAB AND THORACIC RADIOTHERAPY
G. Yavas1, C. Yavas1, E. Celik2, E. Sen1, O. Ata3, D. Yuce4, R. Elsurer-Afsar1
1Radiation Oncology, Selcuk University, Konya/TR, 2Pathology, Selcuk University, Konya/TR, 3Medical Oncology, Selcuk University, Konya/TR, 4Medical Oncology, Selcuk University, Konya/TR, 5Preventive Oncology, Hacettepe University, Ankara/TR, 6Nephrology, Selcuk University, Konya/TR

Background: Radiation-induced lung injury (RILI) is a potentially life-threatening and dose-limiting side effect of thoracic irradiation. Trastuzumab (T), a monoclonal antibody directed against HER2, improves overall survival in patients with HER2 positive breast cancer. T concurrently with radiation thus increases the antitumor effect of radiation. There are same clinical evidences in the literature that T also radiosensibilizes human healthy tissues and in this way it could increase the toxicity of the treatment. The incidence of T-induced pneumonitis is 0.4–0.6%. Although infrequent, pulmonary toxicity due to T may be life-threatening. Aldosterone, which is a physiological activator of MR, is partially responsible for increases in the extracellular matrix turnover, as observed in fibrosis of the cardiac, kidney and lung tissues, and exerts its effects primarily on lung epithelium. Spironolactone (S), an aldosterone receptor antagonist, may have the ability to ameliorate pulmonary fibrosis. We hypothesized that S would be effective in the treatment of both RT and T-induced lung injury by correcting pulmonary fibrosis. Method: This study included 104 mice in 8 groups: rats (180-300 g); use of which was approved by the Ethical Committee. Rats were divided into eight groups: group (G) 1 was control group; G2, G3 and G4 were RT, S and T groups; G5, G6, G7 and G8 were RT+T, T+S, RT+S and T+G groups respectively. RT was applied under general anesthesia with intraperitoneally administered 90 mg/kg ketamine hydrochloride and 10 mg/kg xylazine. A single dose of 15 Gy was applied to the both lungs divided into eight groups: group (G) 1 was control group; G2, G3 and G4 were RT, S and T groups; G5, G6, G7 and G8 were RT+T, T+S, RT+S and T+G groups respectively. RT was applied under general anesthesia with intraperitoneally administered 90 mg/kg ketamine hydrochloride and 10 mg/kg xylazine. A single dose of 15 Gy was applied to the both lungs. Statistical analysis involved repeated measures ANOVA. Result: By 100th days of RT inflammation score, lung fibrosis score and TGF- expression were significantly different within study groups (p values were 0.002, 0.001 and 0.043 respectively). The inflammation score of G8 was significantly lower than inflammation scores of G2 and G5 (p values: G2-G8= 0.004, and G5-G8=0.022). Inflammation score of G2 was significantly higher than G7 (p=0.028). There were significant differences regarding to fibrosis scores between G2-G8 (p=0.015), G2-G7 (p=0.017), G6-G7=0.011). TGF- expression was higher in both G2 and G5 when compared to G8 (p = 0.038). Conclusion: Our results suggested that S is an effective treatment option for improving radiation-induced pulmonary fibrosis. P1.16-25 USING RATES OF CLASSICAL BRACHIAL PLEXOPATHY AFTER LUNG SBRT TO BETTER CHARACTERIZE THE TOLERANCE OF THE BRACHIAL Plexus
Radiation Oncology, Cleveland Clinic, Cleveland/Ohio/US

Background: Treatment of apical lung tumors with stereotactic body radiotherapy (SBRT) can be challenging due to proximity to the brachial plexus (BP). Prior studies retrospectively investigated outcomes after treatment of apical lung tumors to compare the rate of brachial plexopathy (BPX) with what would be estimated based on published protocol-derived BP constraints. Method: Apical lung tumors were defined in this analysis as those whose lung SBRT target had a planning-derived PTV edge <1cm from the anatomic BP. We surveyed an IRB-approved prospective registry of 1,462 patients treated with SBRT for the interval 2003-2017 and included all patients who received definitive or salvage SBRT using dose/fractionation schedules of 50 Gy/5 f, 60 Gy/5 f, or 48 Gy/4 f. Salvage SBRT included patients with local recurrence after conventional fractionation radiotherapy. Per RTOG protocols, the subclavian vein (SCV) ipsilateral to target was contoured as the BP surrogate. In this study, the ipsilateral subclavian artery (SCA), and BP were also contoured to characterize dosimetric differences between structures. Statistical analysis involved repeated measures ANOVA. Result: Sixty-four patients, which includes six patients (9.4%) receiving salvage SBRT, met inclusion criteria (median follow up of 21 months). No significant differences (p=0.77) were observed between maximum point doses to BP, SCV, and SCA. Within one year post-SBRT, two patients (3%) developed BPX (grade 2); both patients had exceeded 32 Gy to the BP and were treated with salvage SBRT. No patient treated with definitive SBRT (91%) developed BP, despite 17 of these exceeding recommended maximum doses. Conclusion: No BPX was observed for patients that exceeded a maximum dose of 32 Gy to the BP, unless they were treated as salvage SBRT. This suggests higher doses to the BP may be considered when clinically required for definitive SBRT. However, salvage SBRT may require more conservative BP constraints than used in the definitive setting.

**P1.16-29 ACCELERATED HYPOFRACTIONATED RADIOTHERAPY FOR CENTRAL LUNG TUMORS UNSUITABLE FOR STEREOTACTIC BODY RADIOTHERAPY OR CONCURRENT CRT**

K.L. Zeng1, I. Poony1, Y. Ung1, L. Zhang1, P. Cheung1

1Sunnybrook Odette Cancer Centre, Toronto/CA, 2Macrotact Inc., Toronto/CA

**Background:** In our institution, accelerated hypofractionated radiotherapy is a treatment option for 1) stage I lung non-small cell lung cancer (NSCLC) patients whose tumors are too bulky or central for SBRT; and 2) select stage II-III NSCLC patients not candidates for concurrent CRT. The purpose of this project was to review the clinical outcomes of a large single institutional experience of treating such patients with a dose of 60 Gy in 15 fractions in an era when SBRT was routinely used in clinical practice for early stage lung cancer. **Method:** Central tumors were defined as the gross target volume being in contact with mainstem bronchi, trachea, esophagus, great vessels, or heart. All patients who received 60 Gy in 15 fractions treated between 2008 and 2017 were reviewed. Competing risk analysis was used to calculate the cumulative incidence of local failure (LF), regional failure (RF), and distant failure (DF). Kaplan-Meier methodology was used to calculate overall survival (OS). Univariate analyses were used to look for potential predictive factors. **Result:** Eighty-nine patients were treated. Median follow-up was 24.0 months (range: 6.1-94.2 months). Median age was 79.4 years and most tumors were adenocarcinoma (n=47, 52.8%), followed by squamous cell carcinoma (n=31, 34.8%). Thirty patients (33.7%) had stage I disease, 47 patients (52.8%) had stage II-III disease, and 12 patients (13.5%) had stage IV disease (mostly oligometastatic). Cumulative incidence of LF was 15.3% at 2 years. In those with stage I-III disease, cumulative incidence of RF and DF were 12.9% and 28.5%, respectively at 2-years. OS was 74.9% at 2 years, with a median OS of 39.4 months for those with stage I-III disease. In the subset with stage II-III disease, median OS was 38.1 months and 2 year OS was 67.7%. Tumor stage, histology, EGFR mutation status, and location were not statistically significant predictors for any outcome, although tumor size >3.5cm was borderline significant in predicting for a higher cumulative incidence of LF (subdistribution hazard ratio = 2.726; 95% confidence interval 0.995-7.469; p=0.051). The most common toxicity was radiation pneumonitis (n=6, 6.4%). The cumulative incidence of any grade 3 toxicity was 10.8% at ≥1 year. There were no deaths or hospitalizations directly attributed to treatment. **Conclusion:** Accelerated hypofractionated radiotherapy to a dose of 60 Gy in 15 fractions resulted in favorable outcomes in NSCLC patients who were not suitable for SBRT or concurrent CRT. Patients with Stage II-III disease had good OS despite not receiving concurrent chemotherapy. Severe toxicities were uncommon.

**P1.16-30 QUALITY OF LYMPHADENECTOMY DURING LOBECTOMY FOR NON-SMALL CELL LUNG CANCER: VATS VERSUS THORACOTOMY**

R. Alves1, E. Bourdages-Pageau1, C. Paradis-Garneau1, A. Vieira2, P. Ugalde3

1Thoracic Surgery Department, Institut Universitaire de Cardiologie Et de Pneumologie Du Québec (lucpa), Quebec/QC/CA, 2Thoracic Surgery, Institut Universitaire de Cardiologie Et de Pneumologie de Québec (lucpa), Quebec/QC/CA, 3Thoracic Surgery, Institut Universitaire de Cardiologie Et de Pneumologie de Québec, Quebec/QC/CA

**Background:** Lobectomy by video-assisted thoracoscopic surgery (VATS) is preferred over thoracotomy in patients with early-stage non-small cell lung cancer (NSCLC). However, controversy still exists regarding the quality of the lymph node dissection accomplished using VATS. This study analyzed the lymphadenectomy by surgical approach and applied the International Association of the Study of Lung Cancer (IASLC) criteria of lobe-guided lymphadenectomy. **Method:** We performed a retrospective review of patients with stage I or II NSCLC who underwent lobectomy via thoracotomy (2003-2007, n=408) or VATS (2014-2017, n=754) at our institution. We compared the lymph node stations dissected by lobe-specific and the outcomes between the two approaches. **Result:** VATS was equal or superior to thoracotomy for dissection of all lymph node stations except stations BR (p=0.0018) and BL (p=0.002) and was superior for subcarinal lymphadenectomy (p=0.0002). When examined by lung lobe(s), VATS was superior for lymphadenectomy during right upper lobectomies (p=0.0001) and at least equal to thoracotomy for all other lobes. Additionally, VATS was associated with less blood loss (p=0.0001), pneumonia (p=0.008) and acute respiratory distress syndrome (p=0.0082), fewer air leaks (p<0.0001) and lower 30-day mortality (p=0.0308).

**P1.16-31 SURGICALLY RESECTED ACINAR ADENOCARCINOMA OF THE LUNG: ANALYSIS OF DIFFERENT PROGNOSTIC GROUPS.**

P. Bertoglio1, A. Viti1, G. Bogina2, C. Pomari1, G. Zamboni2, A. Terzi1

1Division of Thoracic Surgery, Sacro Cuore-Don Calabria Research Hospital and Cancer Care Centre, Negar (Verona)/IT, 2Division of Pathological Anatomy, Sacro Cuore-Don Calabria Research Hospital and Cancer Care Centre, Negar (Verona)/IT

**Background:** Adenocarcinoma has become the most frequently diagnosed histotype of Non-Small cell Lung Cancer (NSCLC). Nevertheless, the latest classification of lung adenocarcinoma issued by IASLC/ATS/ERS identified different subtypes with different prognostic impact; concurrently, different subtypes might mingle influencing biological features and behavior. We focused on surgically treated stage I and II predominantly acinar lung adenocarcinoma analyzing outcomes and prognostic factors according to the second main histological pattern. **Method:** We retrospectively collected all lung adenocarcinoma with a predominant acinar histological pattern operated on between October 2012 and September 2017 in our institution. We selected all patients in pathological stage I A-B and II A-B with full preoperative staging procedures performed at our institution. All clinical and pathological features were registered. We analyzed outcomes according to the histological sub pattern and we focused on main prognostic factors.
Keywords: lung adenocarcinoma, NSCLC

*mean ± standard deviation. VATS, video-assisted thoracoscopic surgery.

Conclusion: In our institution, most VATS lobectomies were uncertain resections due to the lymph node evaluation by IASLC definition. Using U-VATS is not inferior to M-VATS in accomplishing a complete oncologic resection thoracoscopically.

Keywords: non small cell lung cancer, early stage lung cancer, complete resection

Reference:

Method: From August 2014 through December 2017, 672 VATS lobectomies were performed for the primary treatment of clinical stage I and II NSCLC. 43 patients with ground glass opacity and complex cases were excluded. Patients were analyzed according to ports used (one or multiple), R status, lobe-specific lymphadenectomy, subcarinal lymphadenectomy, length of hospital stay and length of thoracic drainage. A propensity-matched analysis was planned however, all variables were evenly distributed in both groups.

Background: In 2005, the International Association for the Study of Lung Cancer (IASLC) added a new category to complete and incomplete resection for residual tumor classification (R): uncertain resection (Run). R status has a major prognostic impact, and the prognosis of patients with a Run resection differs from that of patients with either complete (R0) or incomplete resection (R1 or R2). The aim of this study was to measure R status with the expanded classification system when performing lobectomy for non-small cell lung cancer (NSCLC) using a unipolar (U-VATS) or multiport (M-VATS) video-assisted thoracoscopic surgery.

Background: Notwithstanding mediastinal lymphadenectomy is a cornerstone of surgical management of primary lung tumors, results and evidences are still debated for clinical stage I disease. In this aspect, current guidelines appear conflicting, as being both radical lymph node dissection and systematic node sampling equally advocated by several Authors. However, though lymphadenectomies are not risk-free procedures, N-status is an undefined and significant prognostic factor in NSCLC patients. For these reasons, the adoption of a preoperative predictive non-invasive model should be clinically useful to stratify patients according to risk of lymphatic metastases. Method: A multicentre retrospective study from January 2014 to June 2017 enrolling 2502 early stage NSCLC patients (up to cIB disease) with a mean age of 67.35 ± 8.89 years was conducted by analysing demographic, radiological and pathological features and correlating themselves to pN+ disease through a bivariate analysis, relative risk estimation and Receiver Operating Curves estimation. Diagnostic performance of a derived risk coefficient (RC = 2 factors) was finally evaluated. Result: With a mean Charlson’s Comorbidity Score of 4.34 ± 1.80 and an excellent ECOG Status (ECOG 0-1) in 98.1%, 66.2% presented a very early stage disease (cTa/b NO MO) with predominant solid nodule density at chest CT (n. 1992 – 79.6%) and a mean SUVmax of 4.37± 4.95. Each patient underwent a RO video-assisted thoracoscopic lobectomy with a radical node dissection in 69.9% and a systematic lymph node sampling in remaining cases. Concerning with histology, primary pulmonary invasive adenocarcinoma was the predominant pattern (n. 1417 56.6%) and a cumulative incidence of occult hilar Mediastinal lymph node metastases of 8.8% was reported. At bivariate analysis and relative risk estimation, male gender (p = 0.033), clinical T-stage (p = 0.000), nodule diameter (p = 0.000), nodule density (p = 0.005), the presence of visceral pleura or bronchial invasion (p = 0.000) and a SUV max >3.5 (p = 0.001) significantly correlated with pN+ disease. By deriving a risk coefficient function and adopting it to general population through a ROC curve, a RC > 58 presented a not negligible predictive value (sensibility: 82.73%, specificity 74.36%, PPV 23.73%, NPV 97.81%). Conclusion: Although a prospective study is needed, a preoperative clinically easily reproducible predictive model for early stage NSCLC patients should represent a useful tool for a proper stratification of pN+ high risk patients. In particular, by considering its high negative predictive value, the aforementioned risk coefficient could allow to discriminate low risk cohort patients amenable to limited lymph node assessment rather than radical dissections with their fearsome related risks.

MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.16-34 THE IMPACT OF PATHOLOGY, STAGING AND OPERATIVE RESECTION ON SURVIVAL AND CT EVIDENCE OF RECURRENCE OF EARLY NSCLC
R. Finley1, J. Mayo2, C. Donaghi1, J. Lee3, K. Grant4, S. Lam5, J. English6
1 Surgery, University of British Columbia, Vancouver/B/C/CA, 2Radiology, University of British Columbia, Vancouver/CA, 3Integrative Oncology, BC Cancer Research Centre, Vancouver/B/C/CA, 4Pathology, University of British Columbia, Vancouver/CA

Background: The purpose of this study is to determine the impact of histopathology, staging and extent of operative resection on survival and CT evidence of recurrence of early NSCLC compared with VATS wedge resection guided by preoperative CT-guided microwave localization (CTML) and intra-operative fluoroscopic guidance. Method: Between April 2003, to June 2012, 106 of 154 patients who underwent CTML and VATS resection of suspicious pulmonary nodules were found to have NSCLC. Serial chest CTs of the 106 patients with confirmed NSCLC were reviewed by 2 chest radiologists for development of recurrence of the original cancer at the resection margin, lung or mediastinum and the development of new primary lung cancer. 53 patients underwent CTML and VATS resection alone and 53 had CTML. VATS diagnostic resection followed by VATS therapeutic lobectomy. An experienced chest pathologist determined pathologic resection margins, histological subtype and staging. Result: The male/female ratio was 47/59. Median age was 63 (34-81) years. Smoking history obtained in 91/106. Median follow-up was 82 (32-136) months. Histology consisted of 99 adenocarcinomas and 7 squamous carcinomas. Staging (AJCC 8th edition) was Stage 0 (11), IA1 (77), IA2 (2), IA3 (3) IB (8), IIB (4) IV (1). Both surgical groups were similar for demographics, tumor characteristics, histopathology and stage at surgery; there was no 90-day mortality. Multivariate analysis showed adverse effects on: 1) Local recurrence of cancer (n=3) by positive resection margin (n=2) **. 2) Any recurrence of original cancer (n=107) by lymph node stage ***, positive resection margin ***, visceral pleural invasion (VPI) ** but not age, gender, smoking history, nodule shape on CT, histopathology, tumor invasive size. STAS, lymphovascular invasion or extent of resection. 3) Development of a new primary NSCLC (n=19) by wedge resection alone ** (12/19). The new primary was resected in 13/19 patients. 4) Disease free survival at 3 (89%), 5 (74%) & 9 years (60%). Overall 5-year survival was 85%. (p<0.05 **. p<0.01 **, p<0.001 **). Conclusion: In patients with early NSCLC, CTML accurately identifies the cancer margins resulting in a low radiologic local recurrence rate of 3%. Ten patients had recurrence of their original cancer associated with lymph node involvement, positive resection margin, and VPI. Second primary lung cancers are prevalent in long-term survivors, particularly if treated with wedge resection. Complete therapeutic lobectomy following diagnostic wedge resection of NSCLC improves disease-free survival.

Keywords: Microcoil, recurrence, NSCLC

MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.16-35 SLEEVE LOBECTOMY VERSUS PNEUMONECTOMY FOR NON-SMALL CELL LUNG CANCER, A CUMULATIVE UPDATED META-ANALYSIS
Z. Guo1, X. Chen1, H. Pan2, W. Liang3, J. He4, Y. Hu5, F. Wang2, D. He6, W. Yin1, J. He1
1Thoracic Surgery, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN, 2Thoracic Oncology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Background: Sleeve lobectomy (SL) is an appealing alternative to pneumonectomy (PN) for central or locally advanced non-small cell lung cancer (NSCLC). The purpose of this study was to investigate the benefits of SL versus PN through cumulative meta-analysis. Method: A systematic review and cumulative analysis of comparative studies reporting both postoperative and survival outcomes of SL and PN was performed through a comprehensive search of PubMed, EMBASE and the Cochrane library electronic databases from inception to April 2018. Result: A total of 4153 patients (SL:3628, PN: 549) from thirty-two studies were included. Meta-analysis was conducted for hazard ratio (HR), postoperative mortality, postoperative morbidity, local recurrence, and overall survival. PN was inferior to SL in terms of hazard ratio (HR=0.66, 95% confidence interval [CI]=0.59 to 0.75, I2=56%). Lower postoperative mortality was found in SL group (OR=0.45, 95% CI=0.36 to 0.56, I2=0%). While SL and PN showed no significant difference in local recurrence (OR=0.86, 95% CI=0.69 to 1.07, I2=45%) or postoperative morbidity (OR=0.92, 95% CI=0.78 to 1.09, I2=29%). Moreover, the 1-, 5- and 5-years survival rates (1-yr: OR=2.19, 95% CI=1.93 to 2.5, I2=14%) (5-ys: OR=1.94, 95% CI=1.61 to 2.35, I2=52%) and survival in patients with pN0 or pN1 at 5-years (OR=1.79, 95% CI=1.19 to 2.67, I2=3.0%) in the SL group were significantly higher than that in the PN group. As demonstrated in our cumulative meta-analysis, these effects were consistent over the years. Conclusion: SL could be considered an acceptable alternative to PN for the treatment of NSCLC.

P1.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE
MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.16-36 REAL-TIME CT GUIDED VIDEO ASSISTED THORACOSCOPIC PARTIAL RESECTION OF PERIPHERAL SMALL-SIZED LUNG TUMORS.
T. Kajo1, H. Suzuki2, K. Ohashi1, Y. Shin1, Y. Sata1, T. Toyoda1, A. Hata1, T. Yamamoto1, J. Morimoto1, Y. Sakairi1, H. Wada1, T. Nakajima2, Y. Yoshino3
1General Thoracic Surgery, Chiba University Graduate School of Medicine, Chiba/JP

Background: As pulmonary resection for small and grand-grass opacity (GGO) dominant pulmonary nodules have been increasing, various navigation systems to detect these nodules have been reported. The aim of this study is to evaluate feasibility of real-time CT guided pulmonary resection for impalpable small pulmonary nodules. Method: From July to November in 2017, 11 patients were eligible for pulmonary resection for lung cancer or malignancy suspected lesions, which was expected to be difficult to detect during operation. These nodules were defined as GGO-dominant (>50%) tumor with a diameter of 3cm or lower (GGO-dominant type), and tumor with a diameter of 2cm or lower, which is located deeper than the diameter of the tumor from visceral pleura (deep solid type). First, we put several surgical clips as first marker on the visceral pleura of the tumor-located lobethrough 3-ports VATS approach. The tumor and the first markers were visualized by cone beam CT, then the second marker was put just on the tumor based on the image. Pulmonary resection was performed according to second marker guided by automated staplers. CT scanning was also performed for confirmation of the complete resection. Result: These procedures were performed for 4 men and 7 women (mean age: 58 years (39-71)). Tumors were located in the right upper lobe/right lower lobe/left upper lobe/left lower lobe in 5/2/2/2 patients. Diameters of tumors were 1.5cm or less. Six tumors were GGO-dominant types whereas 5 were solid types located in the deep from the visceral pleura; therefore all tumors couldn't be detected by video-scoptic observation. The average number of cone beam CT scanning was 2.7 times. All patients accomplished macroscopic and microscopic complete resection with no adverse events during perioperative periods. Conclusion: This feasibility study suggested that cone beam CT was safe and useful guide forvideo assisted thoracoscopic partial resection for impalpable peripheral pulmonary nodules.
Background: Lung cancer patients have a high frequency of comorbidity. The diabetes mellitus (DM) has been reported to be associated with postoperative complication and survival in several types of cancers. The aim of this study was to investigate the impact of DM on postoperative complication and survival in operable non-small cell lung cancer (NSCLC) patients.

Method: We retrospectively reviewed 1231 patients who underwent surgical resection for NSCLC between 1996 and 2012. The outcomes were compared between the patients with DM (DM group, n=123) and without it (Non-DM group, n=1092). Patients were assigned to DM group if following conditions were identified: 1) a history of DM or medication use, and 2) preoperatively elevated fasting glucose (>126 mg/dL) or hemoglobin A1c (National Glycohemoglobin Standardization Program level ≥ 6.5 %) in spite of the unrevealed history of DM. However, diabetes of all patients in DM group was controlled by dietary or sliding-scale insulin therapy. Postoperative complications were defined as events of grade 2 or more according to the Clavien-Dindo classification. A multivariate Logistic regression model was used to identify clinical factors associated with postoperative complication. Survival was evaluated by overall, relapse-free, and disease-specific survivals using Kaplan-Meier method, and a multivariate Cox proportional hazard model was used to identify prognostic factors.

Result: DM group included more elderly patients, males, smokers, patients with ischemic heart disease, patients taking antiplatelet or anticoagulant drugs, squamous cell carcinomas than non-DM group. DM group showed higher incidence of postoperative complications than non-DM group (28% vs. 21%, p=0.047). Logistic regression analysis showed that DM was an independent predictor for postoperative complication (OR: 1.851, 95% CI: 1.189-2.884). But, no significant difference was observed in thirty-day mortality between the two groups (2% vs. 1%, p=0.061). DM group showed a worse overall survival than non-DM group (p=0.024), and multivariate Cox analysis showed that DM was identified as an independent poor prognostic factor for overall survival (HR: 1.492, 95% CI: 1.053-2.113). DM group included more death from other disease than non-DM group (50% vs. 35%, p=0.048), and there was no significant difference in relapse-free and disease-specific survival between the two groups. Conclusion: The present study demonstrated that operable NSCLC patients with DM have distinct clinicopathological features. Although the presence of preoperative DM was associated with postoperative morbidity and worse overall survival, it did not increase perioperative and lung cancer-related mortalities. Operable NSCLC patients with DM can be still indicated for curative surgery if their perioperative diabetes was controlled.

Keywords: Diabetes Mellitus, non-small cell lung cancer, prognostic factor

Conclusion: There was no apparent difference between VATS and open thoracotomy with regard to number of unplanned readmissions. Future studies should focus on reducing complication rates in the open thoracotomy group rather than reducing readmission rates after VATS.
P1.16-39 A NOMOGRAM FOR PREDICTING SURVIVAL OF TNM8 STAGE I NON-SMALL CELL LUNG CANCER PATIENTS TO TAILOR POTENTIAL CHEMOTHERAPY CANDIDATES

W. Liang1, Y. Zeng1, N. Mayne1, C. Yang2, J. He3, T. D’Amico2
1The First Affiliated Hospital of Guangzhou Medical University, National Clinical Research Center for Respiratory Disease, China State Key Laboratory of Respiratory Disease, Guangzhou/CN, 2Section of General Thoracic Surgery, Duke University Medical Center, Durham/US, 3Duke University Medical Center, Durham/NC/US.

Background: The 8th TNM stage I non–small-cell lung cancer (NSCLC) patients are not considered as candidates for adjuvant chemotherapy (ad-Chemo). This study aimed to develop a nomogram for predicting cancer specific survival (CSS) of these patients and identifying those who might benefit from ad-Chemo. Method: NSCLC cases between 1998 and 2013 were extracted from the SEER database and randomly divided into training and validation cohorts. We identified and integrated the recurrence-associated factors to build a nomogram. We determined the cut-off for the high-risk group by matching the nomogram-predicted 5-year CSS with that of the current 4-5 cm stage IIA cases. The difference in benefit from chemotherapy between risk groups was examined using both SEER and NCDB cohort. Result: A total of 30,475 patients with stage I were included for analysis. Six independent prognostic factors were identified and integrated into the model. The calibration curves showed good agreement. The C-index of the nomogram was higher than that of the staging system (IA1, IA2, IA3, IB) (training set, 0.59 vs. 0.56, P < 0.01; validation set, 0.62 vs. 0.57, P < 0.01). Specifically, 26.9% stage IB patients (8.1% of all stage I) were categorized into the high-risk group (score>29) and had inferior CSS compared with stage IIA patients. In addition, chemotherapy was associated with significantly better OS (HR, 0.739; P = 0.047) than no-chemotherapy in the high-risk group. Conclusion: We established a practical and economical nomogram to predict CSS for 8th edition stage I NSCLC, and identified a subset of patients at relatively high risk for recurrence who might benefit from ad-Chemo.
P1.16-40 EVALUATING THE TUMOR HETEROGENEITY IN LUNG CANCER BY CONSTRUCTING TUMOR HETEROGENEITY INDEX (THI) FROM MAGNETIC RESONANCE IMAGING

Q. Li¹, N. Gong², B. Qiu³, H. He³, J. Wang⁴, Y. Ye³, J. Guo¹, S. Lin⁵, P. Cai¹, Q. Chen², H. Li³, C. Xie³, H. Liu⁶
¹Department of Radiation Oncology, Sun Yat-Sen University Cancer Center, Guangzhou/CN, ²United Imaging Healthcare, Houston/US, ³Sun Yat-Sen University Cancer Center, Guangzhou/CN, ⁴The University of Texas MD Anderson Cancer Center, Houston/US, ⁵Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston/US, ⁶Radiation Oncology, Sun Yat-Sen University Cancer Center, Guangzhou/CN

Background: To improve the evaluation of primary lung cancer heterogeneity using clinical routine magnetic resonance imaging (MRI), we proposed a method based on basic measurements from T1- and T2-weighted MRI. Method: As a novel technique of magnetic resonance imaging analysis, we investigated a total of 203 patients with biopsy-proven primary lung cancer and with different T stages. All patients previously received positron emission tomography/computed tomography (PET/CT) scan. Gross lesions were manually contoured on T1-weighted, T2-enhanced, T2-weighted and T2 fat suppression (T2fs) images. The ratios of standard deviation (SD) / mean tumor value from each sequence were calculated. Correlation analyses were performed between T stages and the ratios. P value <0.05 was defined as statistical significant. Then a linear regression was performed to determine the weight of each related ratio. A model was built to calculate Tumor Heterogeneous Index (THI). One hundred and one patients were analyzed as the training set and another 102 as validating set. Result: There were 56 patients diagnosed with T1 disease, 60 with T2 disease, 51 with T3 disease and 36 with T4 disease. Pair matching was performed between training set and validating set. As a result of the correlation analyses, SD/mean ratio showed significantly correlations with T stages in T1-enhanced (p=0.003), T2-weighted (p<0.0001) and T2fs sequences (p=0.002). Based on a linear regression model, THI was established for assessing the heterogeneity of lung tumor, consisting the three ratio measurements. Correlation analysis demonstrated that Higher THI was significantly related to more advanced T stages (p=0.0001).

Conclusion: The proposed SD/mean ratio measurements and the calculation of THI according to clinical routine MR images could be clinical biomarkers that correlated with T stages, and were capable of evaluating heterogeneity of lung cancers.

Keywords: tumor heterogeneity index, T stage, MRI
Kaplan-Meier curves were constructed for overall survival (OS) and cancer-specific survival (CSS) for patient strata based on surgery use or nonuse. Multivariable Cox-regression was used to explore the efficacy of different treatment strategies. **Result:** A total of 944 LCNEC patients were identified, of which 674 (71.4%) received surgery. Both OS and CSS of surgery use group were superior to surgery nonuse group in the whole cohort (HR=0.48, \(P<0.001\) and HR=0.41, \(P<0.001\), respectively). Among matched cohort, significantly greater benefits in OS and CSS (Figure 1) from surgery was observed in both stage I-II (HR=0.47, \(P=0.001\) and HR=0.43, \(P<0.001\), respectively) and stage III (HR=0.66, \(P=0.039\) and HR=0.63, \(P=0.031\), respectively). On multivariable analysis of surgical group, there was no significant difference in either OS or CSS between surgery alone and the addition of chemotherapy or (and) radiation for stage I-II patients, whereas favorable survival outcomes of surgery plus chemotherapy (OS: HR=0.26, \(P<0.001\); CSS: HR=0.30, \(P=0.001\)) and surgery plus chemotherapy and radiation (OS: HR=0.33, \(P=0.001\); CSS: HR=0.34, \(P=0.002\)) were significantly evident for stage III patients.

**Conclusion:** This is the largest study exploring the benefit of surgery for stage I-III pulmonary LCNEC. Regardless of stage, surgery showed remarkable survival benefits for LCNEC patients. It is suggested that surgery alone may be sufficient for stage I-II, whereas the multimodal combination of surgery and other therapies should be considered for stage III disease.

P1.16-42 Indocyanine Green intersegmental visualization during fluorescence imaging of thoracoscopic anatomical segmentectomy: A Novel Approach
T. Matsui, H. Kuroda, Y. Sugita, S. Koyama, K. Nakanishi, T. Arimura, T. Mizuno, N. Sakakura, Y. Sakao
General Thoracic Surgery, Aichi Cancer Center Hospital, Nagoya/JP

**Background:** Anatomic segmentectomy (AS) of the lung is a more complex operative procedure than standard lobectomy, especially when performed as a complete thoracoscopic surgery. Identification of the intersegmental boundary line (IBL) is a technical imperative, allowing surgeons to develop this plane during segmentectomy. Although several methods of IBL identification (IBL-ID) have been reported, our general usage of an intravenous indocyanine green (ICG) fluorescence system is alternative. In examining 83 patients by conventional ICG method (CIM), the IBL-ID success rate was high (98.8%), but intersegmental visibility was diminished due to smoking and emphysema. We also examined 29 patients using the Spectra A method (SAM), which heightened intersegmental contrast (IC) and preserved segment brightness (PB), compared with CIM, thus improving intersegmental visibility. To effect further improvement, a trial of the novel SAM with xenon light (SAM-X) was undertaken.

**Method:** We prospectively studied 106 consecutive patients who underwent complete thoracoscopic AS of 111 lung segments (including subsegments) at our Hospital between October 2011 and October 2017. Following intraoperative transection of the segmental artery, vein and bronchi, 5 mg/body weight of ICG was administered intravenously, and fluorescence images were generated using the ICG system. Both the CIM with xenon light (CIM-X) and the SAM-X were simultaneously obtained in concert for IBL-ID, quantifying intersegmental visibility for histogram representation. **Result:** The patient population (men, 50; women, 56) had a mean age of 67.4±10.7 years and a mean Brinkman index of 446.6±650.7, harboring malignant lung tumors (primary, 77; metastatic, 29, other, 9) as follows: right upper, 28; right middle, 1; right lower, 20; left upper, 38; left lower, 24. IBL-ID was achieved in all patients (100%). As with the SAM apparatus, the SAM-X provided significantly better accentuation of green fluorescence in RGB light analysis, compared with the CIM-X (p<0.01). Furthermore, both IC and PB showed significant increases (p<0.01 each), whether comparing SAM-X with CIM-X or with SAM; and SAM-X was strong (R=0.8), surpassing that of CIM-X (R=0.39) as for the correlation between IC and PB.

**Conclusion:** The SAM-X device stabilized visibility and improved contrast between resected and non-resected segments and brightness of both resected and non-resected segments during thoracoscopic intersegmental identification.

P1.16-44 Minute ventilation-to-carbon dioxide slope is associated with early and long term survival following anatomical pulmonary resection
T. Miyazaki1, A. Brunelli2, P. Dimishi3, M. Callister1, K. Franks1, T. Nagayasu2
1St. James’s University Hospital, Leeds/GB, 2Surgical Oncology, Nagasaki Graduate School of Medicine, Nagasaki/JP

**Background:** The aim of study was to identify that ventilation-to-carbon dioxide output (VE/V CO2) slope obtained from cardiopulmonary exercise test (CPET) was an independent prognostic factor of short and long term survival after lobectomy or segmentectomy. The aim of study was to identify that ventilation-to-carbon dioxide output (VE/V CO2) slope obtained from cardiopulmonary exercise test (CPET) was an independent prognostic factor of short and long term survival after lobectomy or segmentectomy. Method: 974 patients including lobectomy (n=887) or segmentectomy (n=87) were performed from April 1996 to March 2018. 209 (22%) underwent CPET, and pulmonary function and several clinical factors including age, sex, performance status and comorbidities were retrospectively investigated to identify the prognostic factors with a multivariable Cox regression analysis. **Result:** Among patients with CPET, 95 patients (46%) had VO2max <15 mL/kg/min. Compared to patients with higher VO2max, they had similar cardiopulmonary complication rates (32% vs. 29%, p=0.68) and 90 day mortality (9.5% vs. 6.2%, p=0.43). 172 patients had measured VE/V CO2. The incidence of cardiopulmonary complications in patients with VE/V CO2 slope >40 was 37% (19 of 51) vs. 27% (33 of 121) in those with lower slope values (p=0.19). However, 90-day mortality in patients with high VE/V CO2 slope >40 was 172% (19 of 51) vs. 27% (33 of 121) in those with lower slope values (p=0.19). 90-day mortality in patients with high VE/V CO2 slope >40 was 3-fold higher (16% vs. 5.0%) compared to those with lower (n=6) values (p=0.03). Cox regression analysis showed that higher VE/V CO2 values were significantly associated with poorer 2-year survival (HR 1.07, 95% CI 1.01-1.13, p=0.009) **Conclusion:** We found VE/V CO2 slope was associated with increased 90-day mortality and poorer 2-year survival in patients submitted to anatomical pulmonary resection for non-small cell lung cancer.

P1.16-45 THORACOSCOPIC STAPLER-BASED COMPLEX SEGMENTECTOMY ASSISTED BY VIRTUAL ASSISTED LUNG MAPPING

Department of Thoracic Surgery, The University of Tokyo Hospital, Tokyo, Japan

Background: Anatomical segmentectomies play an important role for the patients with small ground-glass lung cancer and metastatic lung tumors. Virtual assisted lung mapping (VAL-MAP) assists to localize hardly palpable lung tumors and to define the resection lines. VAL-MAP has been found to be useful in thoracoscopic segmentectomies, particularly complex segmentectomies. VAL-MAP is a novel preoperative bronchoscopic multi-spot dye-marking technique to provide “geometric information” to the lung surface, using three-dimensional virtual images. The multiple spots (tattooing) of VAL-MAP assists not only to localize hardly palpable lung tumors but to define appropriate resection lines in sublobar lung resections including wedge resections and segmentectomies. The purpose of the study is to evaluate the role of VAL-MAP in simple and complex thoracoscopic segmentectomy. Method: VAL-MAP was conducted before surgery as follows: the target bronchi were identified using radiology workstation. 1 ml of indigo carmine was injected through a catheter by bronchoscopy under fluoroscopy; another CT scan was taken to confirm marking locations. Segmentectomies were conducted thoracoscopically and intersegmental planes were made using staplers (Figure). Anatomical segmentectomies using VAL-MAP conducted were retrospectively analyzed (2014-2017). Simple segmentectomy was defined as a resection of anatomical single segment or combined segments. Other anatomical segmentectomies were defined as complex segmentectomy (Table). Successful resection rates, surgical margins, and post-operative course were compared between simple segmentectomy and complex segmentectomy. Result: Atotal of 43 patients were included in the study (42% women; median age 68 yr (48-83 yrs.). The median tumor size was 12 mm. The average number of markings via VAL-MAP was 4.2 (1-8) points. Post-VAL-MAP complications identified in CT included 5 pneumothorax, 3 airway bleeding, and 2 mediastinal emphysema, although none needed additional treatment. Simple segmentectomy was conducted in 18 patients, while complex segmentectomy was conducted in 25 patients. There was no significant difference in operation time (simple vs. complex; 233±100 vs. 266±8 min), length of chest tube drainage (2.3±0.3 vs. 2.5±0.2 days), or margin/tumor diameter ratio (2.10±0.28 vs. 1.89±0.23). Minor postoperative complications were found in 4 patients (2 collapse lung after removed chest tube; 2 pneumonia and inflammatory reaction). No pleurodesis was needed postoperatively. Final pathology included 24 lung cancer, 15 metastatic tumors, and 3 others. Conclusion: VAL-MAP-assisted stapler-based thoracoscopic segmentectomies were safely and effectively conducted even in complex ones. The bronchoscopic approach of VAL-MAP made the anatomical liberty available to surgeons. The “map” drawn with VAL-MAP not only helps to identify the tumor, but also helps to determine oncologically appropriate resection lines.

Keywords: Virtual assisted lung mapping, complex segmentectomy, thoracoscopic segmentectomy

P1.16-51 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE

MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.16-46 A POPULATION-BASED VALIDATION STUDY OF THE PROPOSED ‘R-FACTOR’ CLASSIFICATION IN A LUNG CANCER-ENDEMIC REGION OF THE US.

M. Smelter1, N. Faris2, M. Ray1, C. Fehnel1, O. Akinbobola3, C. Houston-Harris1, P. Ojeabulu1, Y. Lee2, E. Owen1, R. Eubanks5, H. Dox1, D. Talton1, H. Wiggins3, B. Wolff4, P. Levy1, E. Robbins1, R. Osarogiagbon1

Background: The IASLC has proposed a definition of completeness of surgical resection beyond margin status. We sought to validate the proposed classification in a US cohort, and evaluated the impact of a lymph node (LN) specimen collection kit on resection status. Method: The population-based Mid-South Quality of Surgical Resection cohort includes >95% of lung cancer resections in 4 contiguous US Dartmouth Hospital Referral Regions from 2009-2018. Resections were classified as Complete (R0). Uncertain (R(unc)), or Incomplete (R1-R2) based on the proposed classifications. We evaluated overall survival (OS) using the Kaplan-Meier method and proportional hazards models. Adjusted models included age, sex, histology, extent of resection, pTNM categories, and co-morbidities. A subset of resections used a LN specimen collection kit.

Result: Of 3,099 resections, 18% were R0, 76% R(unc), and 6% R1-R2. 5-year OS was 69%/54%/35% for R0/R(unc)/R1-R2 (p<0.0001, Figure 1A). Compared to R0, the increased hazard of death for R(unc)/R1-R2 was 1.6/3.0 overall, 1.5/2.3 in node negative patients, 1.7/3.1 in node positive patients, and 1.5/1.9 in fully adjusted models (all p<0.0001). Of 2,351 R(unc) resections, the highest mediastinal LN positive increased the hazard of death 1.6 times (vs. negative, p<0.0008). However, 626 (27%) had no mediastinal LN examined (MLE). R(unc) resections with 0 MLE had 1.2 times the hazard of death compared to R(unc) with +1 MLE (p=0.0212, Figure 1B). Use of the LN kit intervention resulted in R0 in 40% of cases, compared to 6% without the kit (p<0.0001). Kit cases had improved OS across the entire cohort (p=0.0002), but when restricted to R0 patients, OS did not differ based on kit use (p=0.96).

Conclusion: The proposed ‘R-factor’ classifications are prognostic. R(unc) rates were high, but significantly lower in cases where a LN collection kit was used. Further delineation of R(unc) cases based on MLE should be considered.
Background: The Adjuvant Lung Cancer Enrichment Marker Identification and Sequencing Trial (ALCHEMIST) was launched in 2014 across the National Clinical Trials Network (NCTN) of the National Cancer Institute (NCI). This trial platform aims to enroll up to 8300 patients with resected high-risk non-small cell lung cancer (NSCLC) to facilitate enrollment to adjuvant targeted therapy trials following completion of standard adjuvant therapy, and to collect biospecimens for clinical and investigational genomics. On 5/1/2016, the study was expanded to include squamous NSCLC and PDL1 testing to facilitate enrollment to a new immunotherapy study. Method: Eligible patients have completely resected NSCLC, stage IB (>4cm) to IIIA by AJCC 7. Eligibility window extends 75-285 days post-op depending upon receipt of adjuvant chemotherapy and/or radiation. Molecular testing of EGFR, ALK, PDL1 is performed centrally (depending on the histology and testing results) and results are returned to sites within 7-21 days. FFPE tissue and blood are collected by the NCI for genomic analysis. Appropriate patients may then enroll to one of three therapeutic trials studying single agent adjuvant targeted therapy (erlotinib NCT02193282, crizotinib NCT02201992, or nivolumab NCT02559544) versus observation. Result: As of March 19, 2018, 2945 patients have been enrolled from 575 sites within the US, with a median enrollment of 98/month (range: 71-133) in 2017. Central molecular testing was completed in 83%-92% of appropriate patients: EGFR L858R/19del was detected in 395 of 2468 patients (16.0%), ALK FISH was positive in 106 of 2458 patients (4.3%), and PDL1 IHC was >1% in 902 of 1464 patients (61.6%). Adequate tissue and blood for whole exome sequencing (WES) was collected on 1928 patients (65.5%), and enrollment plasma (added January 2017) has been collected on 885 patients (30.1%). Of 1960 patients deemed to be eligible for the adjuvant treatment trials with sufficient follow-up, 560 (28.6%) were enrolled; those enrolled were younger (p=0.01) and had higher N stage (<0.01) than those not enrolled. The primary reason for eligible patients not enrolling to treatment trials was lack of interest in further adjuvant therapy (53%). Conclusions: ALCHEMIST has achieved an enrollment of ~100 patients/month with resected high-risk NSCLC. This initial report demonstrates the feasibility of central molecular testing for enrollment to adjuvant targeted therapies. Efforts are ongoing to plan clinically-informed genomic analyses of tumor and plasma, as well as the planning of new treatment arms that leverage this ongoing trial platform. Support: U10CA180821, U10CA180882, U10CA180820, U10CA180868, U10CA180886; ClinicalTrials.gov identifier: NCT02194738

Background: Lobectomy (Lob) and lymph node dissection is considered a standard surgical procedure for non-small cell lung cancer (NSCLC). Segmentectomy (Seg) has been recently regarded as an alternative in early peripheral NSCLC owing to its advantages of lung function preservation. Thus, we performed a meta-analysis with the aim of evaluating whether Seg offers a better lung functional advantage over Lob. Method: A comprehensive search of online databases was performed. Perioperative outcomes and lung functional index were synthesized. The odds ratio (OR) or SMD and its 95% CI was calculated using a random effects model. Subgroup was conducted according to different time points. Single-arm meta-analysis was conducted for lung function at each visit time. Repeated-measures analysis of variance (ANOVA) was used to compare the lung function between at each visit. Result: A total of 5 eligible studies including 958 patients were recruited. There were no significant differences according to baseline characteristics before surgery between groups (Seg and Lob). Seg correlated with a greater postoperative preserved pulmonary function than Lob in FVC (SMD=0.23, p=0.009) (Figure A) and FEV1 (SMD=0.27, p=0.002) (Figure B), especially before 12 months. ANOVA showed there were no differences between two groups in FVC (p=0.647) and FEV1 (p=0.468) according to each visit time (Figure C). Seg group showed significantly less postoperative complications compared with the Lob. (OR=0.64, p=0.045) and the recurrence rate were same between groups (OR=0.89, p=0.623).
Conclusion: Seq offers a better lung functional preservation in short time and reduces postoperative complication compared with Lob. However, two groups showed no significant difference on lung function and tumor relapse according to long follow up.

P1.16-49 TREATMENT OF NSCLC PATIENTS WITH CLINICAL N1 DISEASE: IS THERE AN ADVANTAGE TO NEOADJUVANT THERAPY?
M. Rahouma1, M. Kamei2, A. Nasari1, S. Harrison3, B. Lee2, J. Port1, N. Altorki1, B. Stiles2
1Cardiothoracic Surgery Department, Weill Cornell Medicine/new York Presbyterian Hospital, New York/US, 2Cardiothoracic Department, Weill Cornell Medicine/ New York Presbyterian Hospital, New York/US, 3Cardiothoracic Surgery Department, Weill Cornell Medicine/new York Presbyterian Hospital, New York/US

Background: Treatment options for clinical N1 patients with non-small cell lung cancer (NSCLC) include neoadjuvant therapy and surgery, surgery with adjuvant therapy, or definitive chemoradiation (dCRT). We sought to evaluate the rates of use of each strategy and associated outcomes in patients in the National Cancer Database (NCDB). Method: The NCDB (2004-2014) was reviewed for patients with clinical N1 NSCLC, excluding those with multiple primary tumors, unknown treatment modality/sequence, and clinical M1 disease. Overall survival (OS) of different treatment modalities was compared using log rank test in Kaplan-Meier curves. Logistic and Cox regressions were performed to identify predictors of OS among cN1 cohorts respectively. Result: We identified 14,934 cN1 patients undergoing curative treatment. Median age was 67 (IQR 59-73) and median tumor size 4.5 cm (IQR 3-6.4). This included 1,040 patients (7%) undergoing neoadjuvant therapy followed by surgery, 4,398 patients (29.4%) undergoing surgery alone, and 9,496 patients (63.6%) undergoing dCRT. Predictors of neoadjuvant therapy were age (OR=0.96, CI=0.95-0.96), white race (OR=1.54, CI=1.23-1.93), year of diagnosis (OR=0.92, CI=0.90-0.94), Charlson Comorbidity Index (CCI) <2 (OR=1.282, CI=1.004-1.637), adenocarcinoma (OR=1.30, CI=1.12-1.51), larger tumor size (OR=1.002, CI=1.001-1.003), and private insurance (OR=1.51, CI=1.29-1.77). Superior OS was achieved following neoadjuvant therapy followed by surgery (median-OS=42.1±3.4 months) compared to surgery ± adjuvant therapy (38.4±1.5 months, p=0.002). dCRT was associated with the worst survival (18.9±0.30 months). By MVA, predictors of poor survival in the cohort were older age (HR=1.015, CI=1.012-1.018), male gender (HR=1.20, CI=1.13-1.26), lack of insurance (HR=1.26, CI=1.08-1.46), higher comorbidities (CCI=2, HR=1.29, CI=1.19-1.40), larger tumors (HR=1.002, CI=1.001-1.002), and the use of dCRT (HR=1.75, CI=1.58-1.95). Conclusion: Neoadjuvant therapy followed by surgery is associated with superior survival compared to upfront surgery ± adjuvant therapy in this large cohort of patients. dCRT, although used most commonly in patients with cN1 disease, demonstrates the worst survival rates.

Keywords: segmentectomy, lobectomy, non-small cell lung cancer (NSCLC)

P1.16-50 THE ROLE OF ADJUVANT THERAPY FOR PATIENTS WITH EARLY STAGE LARGE CELL NEUROENDOCRINE LUNG CANCER: A NATIONAL ANALYSIS
V. Raman1, C. Yang2, O. Jawitz1, C. Erkmen3, B. Tong4, T. D’Amico5, M. Berry5, D. Harpole6
1Duke University Medical Center, Durham/US, 2Duke University Medical Center, Durham/NC/US, 3Temple University Health System, Chicago/US, 4Surgery, Duke University, Durham/NC/US, 5Stanford University, Palo Alto/US, 6Surgery and Pathology, Duke University, Durham/NC/US

Background: Although large cell neuroendocrine lung cancer (LCNEC) generally has a worse prognosis than other non-small cell lung cancer histologies, data regarding the role of adjuvant therapy in completely resected stage I LCNEC are extremely limited and current guidelines do not routinely recommend adjuvant therapy. This U.S. National Cancer Data Base (NCDB) analysis was performed to improve the evidence guiding decision-making regarding postoperative therapy for early stage LCNEC. Method: Overall survival of patients with pathologic T1-2aNO LCNEC who underwent resection in the NCDB from 2003 to 2015 was evaluated using Kaplan-Meier and multivariable Cox proportional hazard analysis. Patients who died within 30 days of surgery were excluded. These prospective data were acquired by certified tumor registrars, and include over 80% of cancer diagnoses annually in the U.S. Result: Of the 5,177 patients who met study criteria, adjuvant therapy was given to 31% of patients (n=1,585): 20% received chemotherapy (n=1039), 8% chemoradiation (n=400), and 3% radiation (n=146). In stage IA LCNEC, adjuvant chemotherapy was associated with improved survival when compared to no adjuvant therapy in unadjusted analysis (five-year survival 55% vs. 53%; p=0.03) but not after multivariable adjustment (hazard ratio [HR] 0.81; 95% CI 0.64 to 1.02). Of note, adjuvant chemoradiation (HR 1.66; 95% CI 1.11 to 2.48) and adjuvant radiation (HR 1.55; 95% CI 1.06 to 2.25) were associated with worse survival when compared to no adjuvant therapy. In stage IB LCNEC, adjuvant chemotherapy was associated with improved survival when compared with no adjuvant therapy in both univariate (five-year survival 60% vs. 43%; p<0.0001; Figure) and multivariable (HR 0.65; 95% CI 0.48 to 0.88) analyses.

(See next page)
Conclusion: In this NCDB study of resected stage I LCNEC, adjuvant chemotherapy was associated with improved survival after resection of stage IB but not stage IA LCNEC.

P1.16-51 PREOP NUTRITION-ENHANCED RECOVERY AFTER SURGERY PROTOCOL FOR THORACIC CANCER RESections DECREASES HOSPITAL DAYS AND CHARGES
L. Robinson1, T. Tanveyyanon2, D. Grubbs3, R. Garcia Getting2, S. Patel1
1Thoracic Oncology, Moffitt Cancer Center, Tampa/FL/US, 2Anesthesiology, Moffitt Cancer Center, Tampa/FL/US

Background: Numerous studies over the last decade have documented that the preoperative nutritional status strongly influences perioperative outcomes. Based on published surgical studies, we instituted a preoperative enhanced nutritional support protocol for thoracic cancer resection patients and compared the results to a historical control cohort from the year immediately prior to starting this nutrition program.

Method: Patients undergoing thoracic cancer resections from July 15, 2016 to July 14, 2017 underwent a preoperative nutritional-enhanced recovery after surgery protocol (N-ERAS) of daily probiotics, five days of an oral immunonutrition drink and a complex carbohydrate loading drink the night prior to surgery. Historical controls were from patients undergoing surgery the 12 months prior (Pre-N-ERAS), all operated on by the same surgical team. Non-parametric statistical tests were employed for this retrospective analysis. Result: Data from 234 patients were analyzed. For the Pre-N-ERAS group, there were 121 patients (48/73 men/women), mean age 67.5 (range 24-88), mean post-bronchodilator %FEV1 86.7±19.9 (range 41-126), mean serum albumin 4.3±0.3gm/dl (range 3.2-5.1) and mean Charlson Co-Morbidity Index (50/63 men/women), mean age 67.5 (range 24-88), mean post-bronchodilator %FEV1 89.4±19.7 (range 43-146), mean serum albumin 4.3±0.3gm/dl (range 3.3-5.0) and mean Charlson Co-Morbidity Index 4.8±2.2 (range 1-11). There were no significant differences among the groups for demographics. For both groups, no mortalities, empyemas, wound infections or reoperations for any cause were reported. The N-ERAS nutrition protocol patient compliance was 100% with no toxicity. Compared to the Pre-N-ERAS patients, the N-ERAS group had significantly less time to return of bowel function (mean 1.30 days versus 1.11 days, p<0.001), shorter hospital stays (mean/median 4.5/7.4 days versus 3.6/3.3 days, p=0.001) and less total hospital mean charges/patient ($47,403 versus $42,979, p=0.037), respectively. This translated into an average cost savings of $4,424 in mean charges/patient using the N-ERAS protocol. Consequently, for the N-ERAS cohort, hospital charges were likely $499,912 lower than expected for the 113 patients.

Conclusion: Use of this patient-compliant N-ERAS preoperative nutrition protocol in normally nourished thoracic cancer surgical patients is associated with accelerated bowel function recovery, decreased hospital stays and lower charges. While a prospective clinical trial is warranted, thoracic surgeons should consider using N-ERAS in their major surgical patients with an expectation of improved clinical results at a lower cost—an important consideration when exploring ways to decrease charges in the prospective payment environment.

P1.16-52 LONG-TERM IMPACT OF POSTOPERATIVE COMPLICATIONS FOLLOWING LUNG RESECTION AMONG PATIENTS WITH NON-SMALL CELL LUNG CANCER
S. Shinohara, T. Onitsuka, M. Sugaya
Thoracic Surgery, Chubu Rosai Hospital, Nagoya, Japan

Background: Postoperative complications following lung resection are fairly common. The immediate effects of postoperative complications are clearly associated with poor prognosis; however, the long-term effects remain unclear. The aim of this study was to investigate the long-term effect of postoperative complications in patients with non-small cell lung cancer following lung resection. Method: This investigation was designed as a retrospective cohort study including 345 consecutive patients with non-small cell lung cancer who underwent lung resection as the curative surgery at a single institution between 2007 and 2016. Three patients who had surgery related deaths which is defined as the event within hospital stay or within 30days after surgery was excluded. Postoperative complications were graded according to the Clavien-Dindo classification. Postoperative complications included a grade of greater than and equal to 2. We divided two groups among patients with complications(n=109) and without complications(n=233), and evaluate the data between two groups. Clinical characteristics, pathological features, and causes of death were analysed. Survival analysis was conducted by the Kaplan-Meier method. Prognostic factors were analysed by a Cox proportional hazard model. Result: Throughout the study, 253 patients (74.0%) survived and 89 died (26.0%). The median length of follow-up was 51.8 months. Postoperative complications were observed in 109 patients (31.9%). Operation time, smoking index (pack-year), the rate of COPD, and lymphatic invasion were significantly higher in patients with complications than those without complications (p=0.001, <0.001, <0.001 and 0.02, respectively). FEV1% was lower in the complications group (p<0.001). In comparison to an absence of complications, the presence of complications resulted in worse 5-year overall survival (68.3% vs. 79.5%, p=0.001), worse recurrence-free survival (48.4% vs. 71.0%; p<0.001), and worse cause-specific survival (84.4% vs. 90.5%; p=0.003). There are no significant differences between two groups in concerning non-cancer-specific survival (81.0% vs. 94.7%; p=0.11). Patients with complications had higher odds of dying from cancer related death (15.6% vs. 9.0%; p=0.030). The 5-year overall survival in patients with pulmonary complications tended to be poorer than among those without them, although the difference was not significant (64.2% vs. 70.4%; p=0.072). The Cox proportional hazards model was adjusted for age, sex, pathological staging, Charlson comorbidity index, COPD, vascular invasion, lymphatic invasion, pleural invasion, CEA ≥5 ng/ml, and lobectomy showed that postoperative complications are associated with a poorer overall survival (hazard ratio 1.78; 95%CI=1.15–2.19; p=0.010).

Conclusion: Our findings indicate that postoperative complications were associated with poor overall survival due to the increase in cause-specific deaths.

P1.16-53 COUNTY-LEVEL VARIATIONS AND CONTRIBUTING FACTORS IN RECEIPT OF SURGERY FOR EARLY-STAGE NON-SMALL CELL LUNG CANCER IN THE US
H. Sineshew1, B. Osaroigbion2, L. Sahari1, A. Lema2
1Intramural Research, American Cancer Society, Atlanta/Georgia/US, 2Multidisciplinary Thoracic Oncology Program, Baptist Cancer Center, Memphis/TN/US

Background: Previous studies have reported geographic variations in receipt of curative-intent surgery for early-stage non-small cell lung cancer (NSCLC) across states or regions in the United States. However, little is known about the extent of county-level variations in the receipt of care within and across states, and factors contributing to these variations. We examined county-level variations in receipt of curative-intent surgical treatment, and factors contributing to such variations, for patients with early-stage NSCLC in the United States. Method: Patients with stage I or II NSCLC diagnosed in 2007–2014 were identified from 40 states and the District of Colombia population-based cancer registries compiled by the North American Association of Central Cancer Registries. A total of 179,189 patients residing in 2,263 counties were included. Percentage of patients who underwent curative-intent surgery was calculated for each county with 20 or more cases. Adjusted means were generated using mixed effects model accounting for covariates that were significant in three sequential models (model 1: age, sex, race/ethnicity; model...
and outcomes were reviewed. Result: Receipt of curative-intent surgery for early-stage NSCLC during 2007-2014 by county ranged from 12.8% to 91.7% (seventhfold difference), with a median of 64.5% (interquartile range, 58.8%-71.2%). Higher proportion of non-Hispanic blacks, uninsured patients, and patients residing in high poverty census tracts and in low surgeon-to-population ratio counties were at the lowest quartile of county-level percentage in receipt of curative-intent surgery. In the adjusted means, poverty level, surgeon-to-population ratio, and urban/rural status were independent predictors of receipt of surgery by county. For example, there was a 12% significant difference in adjusted mean between patients residing in affluent and poor neighborhoods.

Conclusion: Receipt of curative-intent surgery for early-stage NSCLC varied substantially across counties in the United States. Area-level socioeconomic status and surgeon availability were significantly associated with this variation, which may therefore be amenable to corrective intervention. Further studies are needed to identify and address gaps in access to surgical treatment of early-stage NSCLC.

MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.16-54 THE SIGNIFICANCE OF MULTIPLE LUNG CANCER OCCURRENCE IN SURGICALLY-TREATED CLINICAL STAGE I LUNG CANCER
H. Sugimura, Y. Cong, S. Mishima, H. Nomori, A. Takeshi
Thoracic Surgery, Kameda Medical Center, Kamogawa, Chiba/JP

Background: Advancements in lung cancer early detection and treatment are leading to an increase in patients with diagnoses of multiple primary lung cancers or lung cancers with multiple pulmonary sites of involvement. While lobectomy is considered the standard for surgical treatment in early stage non-small cell lung cancer, the optimal treatment strategies in such cases are not well known. Method: From February 2012 to February 2017, 370 consecutive c-stage I non-small cell lung cancer patients were surgically treated with lobectomy or segmentectomy and systematic lymph node dissection. A retrospective review was conducted for cases with multiple lung cancers. Multiple lung cancers (MLC) were defined as multiple pulmonary nodules with no clear evidence of either lesion to be a metastasis from the other, and with no lymph node or distant metastases at presentation of the secondary lesion. Cases with multiple pulmonary nodules with ground glass features were also considered MLC if they met the above criteria. Clinical characteristics and outcomes were reviewed. Result: Sixty-five cases (17%) were considered (synchronous and/or metachronous) MLC. The secondary lesion occupied the opposite lung in 32 cases, the same lobe in 24 cases, and other lobes of the same lung in 17 cases. Multiple adenocarcinomas with ground glass opacities were frequently seen as synchronous lesions (33/40), and the majority (69%) of synchronous cases were found in the same lobe. MLC were resected in a single surgical procedure in 22 cases. A second procedure was segmentectomy in 14 (67%) cases, partial resection in 6, and lobectomy in 1. In 12 cases, multiple sites of lung cancer were treated with initial surgery and a subsequent non-surgical procedure (SBRT, cryotherapy, etc.). Lung cancer recurrence following surgical resection for MLC occurred in 3 cases, two of which had lymph node involvement at time of surgery. Three-year survival following final surgery was 89.5% (median follow-up 1142 days) in all cases, and was 94.6% in cases with MLC. Conclusion: Multiple lung cancer occurrence is not rare among c-stage I lung cancer cases. Repeated lung-sparring resections seem feasible as part of their treatment. Aggressive local therapy may lead to prolonged survival.

P1.16-55 SURGICAL TREATMENT FOR LUNG CANCER. SUBAORTIC (PARA-AORTIC) LYMPH NODES INVOLVEMENT - NI OR N2 DISEASE?
M. Szczesna1, P. Rudzinski2, T. Orłowski2
1Department of Surgery, National Research Institute of Tuberculosis and Lung Diseases, Warsaw/PL, 2Department of Surgery, National Institute of Tuberculosis and Lung Diseases, Warsaw/PL

Background: In patients with CN2 disease surgical treatment alone is not recommended because it often indicates systemic disease. Qualification to undergo a surgery patients with clinical manifestation of subaortic (#5)/Para-aortic (#6) nodes malignant involvement remains controversial. The aim of this study is to compare survival patients with subaortic station metastases to #5(#6) lymph nodes, patients with interlobar (#11) and lobar (#12) nodes involvement (pN1) and patients with right lower paratracheal (#4R) and subcarinal (#7) nodes involvement (pN2) after received resection. Method: Material was collected retrospectively from an online-survey-based database of the Polish Lung Cancer Group and included patients who underwent a surgical treatment due to lung cancer at multi-institution in Poland between 2007 and 2017. The 8th Edition of the Staging Classification System (TNM, 2017) was used to determine staging. Result: There were 34 870 patients (35.52% females and 64.48% males) who received surgical treatment for lung cancer. 72 371 (78.35%) underwent lobectomy, 1 063 (0.34%) segmentectomy, 4 658 (13.35%) pneumonectomy, 1 768 (5.07%) wedge resection. Histologic types included: non-small cell lung cancer (n = 475), adenocarcinoma (n = 13 515), squamous cell carcinoma (n = 14 273), large cell carcinoma (n = 12 127), carcinoid (n = 1 428) and others (n = 2 937). Stage IIA cases presented 683 (1.597%) patients, IIA - 4 442 (12.79%), IA2 - 3 674 (10.58%), IB - 7 150 (20.59%). Stage IIIA disease presented 2493 (7.18%) patients, IIB - 7 442 (21.43%), 6804 (19.59%) patients were in stage IIA disease, 1529 (4.4%) in IIB and 475 (1.37%) in IVA, 12 (0.03%) in IVB disease. The majority of patients were diagnosed with NO disease (n = 24 588, 70.23%). N1 disease was reported in 5 913 (17.03%) cases, N2 disease in 4 412 (12.71%). Among patients with N1 disease there were 3 543 cases with confirmed metastases only in #11 or #12 nodes. 3-, 5-, 7- and over 7-year survivals in this group were 70.03%, 15.33%, 7.18%, 6.24%. Among patients with N2 disease there were 1 202 cases with exclusive involvement of #4R or #7 nodes. 3-, 5-, 7- and over 7-year survivals in this group were 73.21%, 14.14%, 7.74%, 4.91%. Malignant involvement of #5 or #6 nodes were reported in 1047 cases. 3-, 5-, 7- and over 7-year survivals here were 75.17%, 14.04%, 6.59%, 4.2%. Conclusion: According to the study there is no significant difference in survival of patients with #5(#6) nodes invasion comparing to those with N2 and N1 disease. Controversy followed from classification #5(#6) nodes as N2 remains unsettled.

P1.16-56 PROGNOSTIC ABILITY OF NEW T1 DESCRIPTORS IN THE TNM CLASSIFICATION OF SURGICALLY TREATED NON-SMALL CELL LUNG CANCER
T. Takenaka1, K. Yamazaki1, S. Takeo2
1Department of Surgery, Hiroshima Red Cross Hospital & Atomic-Bomb Survivors Hospital, Hiroshima/JP, 2Department of Thoracic Surgery, National Hospital Organization, Kyushu Medical Center, Fukuoka City/JP

Background: In the tumor, node, and metastasis (TNM) classification (8th edition) of non-small cell lung cancer (NSCLC), T (tumor size) is determined solely according to the size of the solid component determined using computed tomography (CT). However, it is unclear if tumors of equal size but with differing solid and part-solid components should be similarly treated. Here we assessed the prognostic significance of the newly proposed T1 descriptors with respect to the size of the solid component. Method: We analyzed overall survival (OS) and disease-free survival (DFS) between groups of patients (n = 255) with solid or part-solid tumors. Propensity score matching (PSM) was added as an exploratory analysis of survival among patients with solid tumors and part-solid tumors to balance the size of the solid. The new staging system was used for classification and comparison of survival. Result: (See next page)
Background: Because of increasing in life span and more than third-fourth of lung cancer patients being age >60-65 years old, appropriate treatment of old lung cancer patients has become an important issue. The aim of this study is to evaluate the short and long-term surgical outcomes in elderly patients, and to identify prognostic factors of overall mortality. Method: Medical records of patients with non-small cell lung cancer (NSCLC) who underwent pulmonary resection at Chiang Mai University Hospital from January 2002 through December 2016 were retrospectively reviewed. Patients were divided into two groups; age less than 70 years (non-elderly group) and 70 years or more (elderly group). Primary outcome was major post-operative complications and length of stay >17days. Hospital volume was measured as the average number of lung surgeries performed per year, with quartiles Q1: 1-17, Q2: 18-34, Q3: 35-58 and Q4: 59+. Results: There were no differences in term of in-hospital mortality, composite post-operative complications in the elderly group. There was not statistically different from the non-elderly group (Adjusted odd ratio = 0.52, 95% CI=0.21-1.28), however the elderly group was more likely to die (HR,adj=2.44, 95%(CI=1.26-4.74). Adverse prognostic factors for overall mortality in elderly patients were a poorly differentiated tumor (HR,adj=3.52, 95%(CI=1.45-8.61) and the presence with perineural invasion (HR,adj=3.95, 95%(CI=1.14-13.77) Table 1 prognostic factors for overall mortality of elderly NSCLC patients after pulmonary resection

Conclusion: Surgery in elderly NSCLC is a safe procedure. Patients presenting with perineural invasion and poorly differentiated tumor should be further considered for possible adjuvant treatment.

Keywords: Postoperative Morbidity, lung resection, old patient

References:

Abstract: This study included 583 patients: 167 in elderly group, and 416 in non-elderly group. Patients in elderly group were more likely to have government insurance, be active smoker, and have a diagnosis of COPD, an abnormal ECG, to undergo a sublobar resection, lymph node sampling, and no chemotherapy treatment than those in the non-elderly group. There were no differences in term of in-hospital mortality, composite post-operative complications, and overall mortality. At multivariable analysis, the composite post-operative complications in the elderly group was not statistically different from the non-elderly group (Adjusted odd ratios = 0.52, 95% CI=0.21-1.28), however the elderly group was more likely to die (HR,adj=2.44, 95%(CI=1.26-4.74). Adverse prognostic factors for overall mortality in elderly patients were a poorly differentiated tumor (HR,adj=3.52, 95%(CI=1.45-8.61) and the presence with perineural invasion (HR,adj=3.95, 95%(CI=1.14-13.77) Table 1 prognostic factors for overall mortality of elderly NSCLC patients after pulmonary resection

Conclusion: Surgery in elderly NSCLC is a safe procedure. Patients presenting with perineural invasion and poorly differentiated tumor should be further considered for possible adjuvant treatment.

Keywords: Postoperative Morbidity, lung resection, old patient

References:
Regardless of procedure. Patients operated in lower volume centres had more admissions to ICU ≥24 hours. Median overall survival was 6.2 years, 5.4 years and 5.8 years for lobectomy, sub-lobar resection and pneumonectomy, respectively. The distribution of ASA scores differed between patients attending public and private hospitals. A higher proportion of patients attending private hospitals (19%) had an ASA score of 4 compared with patients attending a public hospital (9%). Conclusion: We observed no evidence of survival differences between lung cancer patients attending low- and high-volume hospitals for surgery, regardless of surgical procedure. Median overall survival in Victorian is substantially better compared to international data. Of interest, a higher proportion of patients had an ICU admission ≥24 hours in lower volume centres. We also observed a higher proportion of patients with an ASA score of 4 in private hospitals compared to public hospitals; the reasons for this are unclear and warrant further investigation.

P1.16-59 A PHASE II STUDY OF ADJUVANT CHEMOTHERAPY WITH TEGAFUR-URACIL FOR VESSEL INVASION POSITIVE STAGE I A NON-SMALL CELL LUNG CANCER (LOGIK0602)

T. Tsuchiya1, T. Nagayasu2, R. Kamohara3, M. Muraoka4, S. Saeki5, Y. Ichinoe6, M. Suzuki7, K. Inada8, S. Tokunaga9, T. Hayashi6, S. Urabe10, T. Koga11, S. Akamine12, K. Sugio13 1Department of Surgical Oncology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki/JP, 2Thoracic Surgery, Oita Prefectural Hospital, Oita/JP, 3Thoracic Surgery, Japan Community Health Care Organization Isahaya General Hospital, Nagasaki/JP, 4Respiratory Medicine, Kumamoto University Hospital, Kumamoto/JP, 5National Hospital Organization Kyushu Cancer Center, Fukuoka/JP, 6Thoracic Surgery, Kumamoto University Hospital, Kumamoto/JP, 7Thoracic Surgery, National Hospital Organization Omuta Hospital, Fukuoka/JP, 8Medical Information Center, Kyushu University Hospital, Fukuoka/JP, 9Pathology, Nagasaki Prefecture Shimabara Hospital, Nagasaki/JP, 10Pathology, Oita Prefectural Hospital, Oita/JP, 11Thoracic and Breast Surgery, Oita Prefectural Hospital, Oita/JP, 12Thoracic Surgery, Oita Prefectural Hospital, Oita/JP

Background: Vessel invasion, which includes vascular or lymphatic invasions, is a representative prognostic factor in lung cancer therapy. Even in the patients with resected stage IA non-small cell lung cancer (NSCLC), vessel invasion is a significant poor prognostic factor. The pathological data of 322 cases of resected stage IA NSCLC in Oita Prefectural Hospital revealed that the 5-yr overall survival rate was 71.8% in the vessel invasion-positive group and significantly worse than the 89.6% in the vessel invasion-negative group. Interestingly, the 5-yr overall survival rate of the oral tegafur-uracil adjuvant chemotherapy group was 93.3% and significantly better than the 66.6% of the untreated group. Tegafur-uracil is known to affect vascular endothelial growth factor overexpressing tumours. Therefore, to estimate the positive effect of adjuvant tegafur-uracil in patients with vessel invasion-positive stage IA NSCLC, we conducted a multi-center single-arm phase II study (LOGIK0602). Method: The patients with completely resected vessel invasion-positive stage IA NSCLC were registered at the Lung Oncology Group in Kyushu (LOGIK). Vessel invasion was diagnosed by two of the three pathologists. Adjuvant chemotherapy consisted of 2 years of oral tegafur-uracil at 250 mg/m2/day. Fifty-five patients from 7 institutions were enrolled from June 2007 to September 2012. The primary endpoint was the 5-yr overall survival rate. Secondary endpoints were the rate of accomplishment of scheduled adjuvant chemotherapy, incidence and grade of adverse reactions, 3-yr overall and relapse-free survival rates, and 5-yr relapse-free survival rate. Result: Among the 52 eligible patients, 16 (30.8%) discontinued tegafur-uracil administration and 36 (69.2%) completed the treatment course. The observation period was calculated as 562 to 3107 days and median observation period as 1947 days using the reverse Kaplan-Meier method. There were 39 male and 13 female patients. The 3-yr and 5-yr overall survival rates were 96.2% and 94.2%, respectively, which were obviously better than the historical data of 28% to 78% in 8 reports. The 3-yr and 5-yr relapse-free survival rates were 92.3% and 88.5%, respectively. Eighteen adverse reactions were observed including 4 cases of grade 3 hepatic function disorder (7.7%) and 5 cases of grade 2 anorexia (9.6%). No grade 4 adverse effect was encountered. Five recurrences were observed including 1 distant metastasis (adrenal) and 4 local recurrences (lung: 2, lymph node: 2). Conclusion: A 2-year course of oral tegafur-uracil administration is feasible and might have a significant benefit in the adjuvant treatment of vessel invasion-positive stage IA NSCLC.

P1.16-60 A HIGH RISK OF RECURRENT AFTER THE RESSECTION OF LOWER LOBE ADENOCARCINOMA

K. Ueda1, T. Tanaka2, S. Yoshimine1, T. Nakamura1, J. Murakami2, K. Hamano1 1Department of Surgery and Clinical Science, Yamaguchi University Graduate School of Medicine, Ube, Yamaguchi/JP, 2Latner Thoracic Surgery Research Laboratories, Toronto General Research Institute, Toronto/CA

Background: According to previous reports, non-small cell lung cancers arising in the lower lobe are associated with a worse prognosis than those arising in the upper lobe; however, the reason remains to be elucidated. Thus, we attempted to identify high-risk population in patients with lower lobe disease, that may substantially cause poor prognosis of lower lobe disease. Method: We retrospectively reviewed a consecutive series of 400 patients with completely resected lung adenocarcinoma who were treated between January 2006 and December 2015. All patients underwent major lung resection and lymph node dissection. The clinicopathological factors that were investigated included the solid component size, the pathological subtype (pre-invasive, minimally invasive/invasive), the epidermal growth factor receptor (EGFR) mutation status, and some other characteristics (TNM 8th edition). Result:
The proportion of never-smokers among patients with lower lobe disease was significantly higher than that among those with upper lobe disease. According to a multivariate proportional hazards analysis, primary site (upper/lower) was an independent predictor of early recurrence, along with the solid component size, pleural lavage cytology results, pathological pleural invasion, and pathological lymph node metastasis. However, although lower lobe disease was associated with early recurrence in never smokers (Fig 1A), it was not in smokers (Fig 1B). Furthermore, although lower lobe disease was associated with early recurrence in never smokers with EGFR wild-type tumors (Fig 1C), it was not in never smokers with EGFR mutant tumors (Fig 1D). EGFR wild-type tumors were more frequently detected in patients with lower lobe disease than in those with upper lobe disease volume (the analysis was restricted to never smokers). Conclusion: Patients with lower lobe cancer, particularly those without a smoking history or those with EGFR wild-type tumors, showed a higher risk of recurrence than their counterparts with upper lobe disease. Additional factors include the molecular profiling of such aggressive lesions, are warranted.

P1.16-61 INTERMITTENT CHEST TUBE CLAMPING SHORTENS CHEST TUBE DURATION AFTER LUNG CANCER SURGERY: AN INTERIM ANALYSIS OF RANDOMIZED CLINICAL TRIAL
S. Yan, Y. Wang, X. Wang, S. Li, C. Yu, Y. Wang, J. Yang, W. Nan
Department of Thoracic Surgery II, Peking University Cancer Hospital & Institute, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing/CN

Background: Postoperative pleural drainage markedly influences the length of hospital stay and the financial costs of medical care. Our previous retrospective study proved the safety and effectiveness of chest tube clamping in the term of shortening chest tube duration. This study aims to determine if intermittent chest tube clamping could decrease chest tube duration and total drainage volume after lung cancer surgery in randomized clinical trial. This trial is registered with ClinicalTrials.gov (NCT03379350). Method: All the patients were managed with gravity drainage (water seal only, without suction) during the first 12–24 h (depending on the time of surgery completion) after surgery. Once a radiograph confirmed re-expansion of the lung on the morning of the POD1 and no air leak was detected, patients were randomly assigned to intermittent chest tube clamping as study arm or traditional chest tube management as control arm. Patients in control arm were unchangeably managed with gravity drainage. In clamping arm, the chest tube would be clamped, and the nurses would check the patient every 6 h. If the patient had no problems with compliance, the clamp was removed for 30 minutes in the morning to the postoperative day 2, and then every 12 h thereafter. The criterion for chest tube removal was drainage volume <250 mL in 24 h. Result: Seven-two consecutive patients with operable lung cancer treated using lobectomy were randomized, all of them were eligible and evaluable. Thirty-seven and 35 patients were randomly assigned to clamping arm, and control arm, respectively. There were no significant differences in the percentage of neoadjuvant treatment. Analyses were performed to compare drainage duration between two groups. Chest tube drainage duration was significantly shorter in clamping group than in control group (2.3±0.5 days vs. 2.7±0.9 days, p = 0.011). Total drainage volume was significantly less in clamping group than in control group (411.0±183.1 ml vs. 553.7±333.6 ml, p = 0.030). Only one patient in clamping group underwent thoracostentesis after chest tube removal due to chylothorax, which was probably caused by excess high-fat diet. No pyrexia relevant to chest tube clamping occurred. There was some degree of improvement on plasma albumin declination at discharge in clamping group over control group (7.5±2.5 g/L vs. 8.6±3.6 g/L, p = 0.119), but without a significant statistical difference. Conclusion: Intermittent postoperative chest tube clamping decreases chest tube duration and total drainage volume while maintaining patient safety. Further investigation is warranted.

P1.16-62 A NOMOGRAM TO PREDICT DISEASE-FREE SURVIVAL AFTER CURATIVE RESECTION OF NON–SMALL CELL LUNG CANCER
X. Zhai1, Z. Wang1, Q. Zheng1
1Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN, 2Peking University Cancer Hospital Kistutute, Beijing/CN, 3School of Public Health, Peking University, Beijing/CN

Background: The aim of this study was to find clinicopathologic variables associated with disease-free survival (DFS) and develop a prognostic nomogram for patients with curative resected non–small–cell lung cancer (NSCLC) and compare the value of the nomogram to the selection. AJCC TNM classification. Method: A nomogram to predict DFS following surgical resection of NSCLC was constructed using a single-institutional cohort of 805 patients who underwent curative resection of lung adenocarcinoma in the Cancer Hospital of the Chinese Academy of Medical Sciences (Beijing, China) between January 2003 and December 2013. For nomogram construction and validation, we randomly assigned two thirds of the patients to the training cohort (n=605) and one third to the validation cohort (n=260). The median age of training cohort was 57 years (range, 25-76) and the proportion of male and female patients was 64.8% vs. 35.2%. Half of the patients (49.8%) presented with early-stage disease and 85.3% patients received adjuvant chemotherapy alone. The predictive discriminative and calibration were measured by concordance index (C-index), risk group stratification and calibration plot. Result: The median disease-free survival was 6.1 years (95% CI, 21.3-26.4 months). The 1-, 3-, and 5-year disease-free survival was 71.3%, 39.5%, and 32.3%, respectively. The nomogram included 8 important variables based on a Cox proportional hazards regression modeling of the training cohort: histology, differentiation, nodal status, AJCC T category, primary tumor location, type of surgical resection, adjuvant radiotherapy and regimen. Each patient with a higher score had a worse prognosis. Prognostic discrimination was performed by dividing the predicted nomogram score into quartiles that were then used to plot Kaplan-Meier curves. The nomogram was able to stratify patients into 4 distinct incremental 3-year prognostic groups (quartile 1, 73.0%; quartile 2, 49.6%; quartile 3, 30.6%; and quartile 4, 9.3% [P < 0.001]). Both in the training and validation cohort, the C-index of the nomogram for DFS prediction was superior to the TNM category prediction (training cohort, 0.694 vs. 0.640; P < 0.01 and validation cohort, 0.662 vs. 0.602; P < 0.01). The 200-sample bootstrapped calibration curves for probability of 3- and 5-year disease-free survival (PFS) showed optimal agreement between nomogram prediction and actual observation. Conclusion: This novel nomogram provides an individualized prediction of DFS in NSCLC patients after radical surgery and may assist the clinical treatment decision making and clinical trials designing.

P1.16-63 THE VALUE OF ADJUVANT CHEMOTHERAPY IN PATIENTS WITH RESECTED STAGE IB SOLID PREDOMINANT AND SOLID NON-PREDOMINANT LUNG ADENOCARCINOMA
S. Cao, H. Zhong, J. Xu
Department of Pulmonary, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai/CN

Background: The adjuvant chemotherapy (ACT) of stage IB lung adenocarcinoma remain controversial. We are intended to explore the benefits adjuvant chemotherapy made on patients in IB with solid ingredients. Method: A number of 334 completely resected patients with lung adenocarcinoma in stage IB from 2006 to 2015 were reviewed. All the pathological slides were evaluated with solid ingredients composed. Result: Our data showed that although disease-free survival (DFS)
Conclusion: The solid predominant pattern in postoperative patients of stage IB could benefit from adjuvant, and solid non-predominant pattern couldn’t.

**Keywords:** lung cancer, adjuvant chemotherapy, solid predominant
P1.16-64 THE HISTOLOGICAL PREDOMINANT PATTERN COULD PREDICT SITE OF RECURRENTNESS AND METASTASIS IN SURGICALLY TREATED STAGE I ADENOCARCINOMA OF THE LUNG

F. Guerrero1, V. Marchese2, F. Lococo3, O. Rena4, L. Amodelli5, J. Vannuccio6, L. Errico7, P. Bertoglio8, P. Lausi9, L. Ventura9, A. Viti9, M. Paci9, P.L. Filosso8, A. Oliaro10, C. CasADIO10, F. Puma10, F. Ardissone1, E. Rufini1

1 Thoracic Surgery, University of Torino, Torino/IT; University of Eastern Piedmont, Novara/IT; 2 University of Parma, Parma/IT; 3 University of Perugia, Perugia/IT; 4 University of Torino, Orbassano/IT; 5 Sacra Cuore-Don Calabria Research Hospital and Cancer Care Centre, Negrar (Verona), Verona/IT; 6 Thoracic Surgery, University Hospital of Parma, Parma/IT; 7 Thoracic Surgery Unit, University of Perugia, Perugia/IT

Background: Pattern-based subtyping of adenocarcinoma of the lung is currently recommended due to prognostic implications. We aimed to evaluate whether predominant pattern subtype in surgically treated stage I adenocarcinoma of the lung can predict first site of recurrence or metastasis. Method: We retrospectively reviewed clinical information, radiological findings, PET/CT-records, and pathological features (classified by IASLC/ATS/ERS subtyping criteria) of 906 Stage-I adenocarcinoma of the lung, who underwent surgery in 7 Centers. Patients were classified by histologic grade according to the IASLC/ATS/ERS classification as follow: invasive low-grade (Invasive LEpidic, Acinar, Papillary) vs. high grade (Micropapillary, Solid) vs. NOS. The date of recurrence or metastases was defined as the first radiographic evidence of cancer relapse upon imaging or pathological tumour evidence from a biopsy. Univariate and multivariate logistic analysis were used to identify predictors of first site of recurrence or metastasis. Result: A total of 248 (27%) patients developed recurrence or distant metastasis. The most commonly observed first location of recurrence was ipsilateral thoracic (139 cases, 44%), followed by brain (27, 11%), contralateral lung (24, 10%), bones (11, 4%), liver and adrenal gland (10, 4%). Forty-three patients (17%) presented recurrence or metastasis in multiple sites simultaneously at the time of diagnosis. At multivariate analysis, patients with intermediate-grade histology developed intra-thoracic recurrence more frequently compared to the low-grade ones (OR 1.85, 95% confidence interval (CI): 1.1–3.18, P=0.038). Patients with high-grade histology developed contralateral lung metastasis (OR 2.1, 95%CI 1.1-4.2, P= 0.044) and brain metastasis (OR 2.5, 95%CI 1.3-5.1, P<0.01) more frequently compared to the low-grade ones. Conclusion: Predominant pattern subtype seems to predict site-specific recurrence and metastasis in surgically treated Stage I adenocarcinoma of the lung.

P1.17 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC
MondAy, SepteMbEr 24, 2018 - 09:45-18:00

P1.17-01 ROBUSTNESS OF AN IMAGE-BASED DATA MINING APPROACH IN LUNG CANCER PATIENTS
E. Vasquez Osorio1, M. Aznar2, A. Green3, C. Faivre-Finn4, M. Van Herk5, A. McWilliam1
1 Division of Cancer Sciences, University of Manchester, Manchester/GB, 2 Clinical Oncology, University of Manchester & the Christie NHS Foundation Trust, Manchester/GB, 3 Division of Cancer Sciences, The University of Manchester, Manchester/GB

Background: Image-based data mining (IBDM) enables exploring the correlation of dose distributions and outcomes in large cohorts of patients without the requirement of additional contouring. IBDM has recently identified the dose to the base of the heart as an important predictor for overall survival (OS) in lung cancer patients receiving radiotherapy [McWilliam et al EJC 2017]. IBDM relies on non-rigid registration to set inter-patient dosimetric data into a common reference anatomy or reference patient. Here, we investigated the uncertainties associated with the choice of reference patient, and their influence on the correlation between incidental dose to the base of the heart and OS. Method: In previous work, 1101 NSCLC patients (95Gy / 20 fractions) were randomly selected, and their planning CT images non-rigidly registered to a reference patient CT scan using NiftyReg (http://cmictig.cs.ucl.ac.uk/wiki/) as part of IBDM process. In this work, 5 additional patients with small cell lung cancer (i.e. without a large tumour burden) were used as “reference patients” and the IBDM analysis in the whole cohort was repeated for each reference patient. Permutation testing with 100 iterations was applied to assess statistical significance. Result: Figure 1 shows the regions of highly significant correlation between dose and OS for each reference patient. In spite of large variations in anatomy between the reference patients, each analysis identified similar anatomical regions as significantly associated with OS (p<5). Moreover, permutation testing was consistent with the original findings.

Conclusion: IBDM is a robust approach and, in this analysis, does not appear to be sensitive to the choice of reference patient for the investigated dose-effect correlation. Prospective studies are necessary to confirm the correlation between dose to the base of the heart and OS in NSCLC patients. Methodological studies are needed to determine the level of effect strength and region size that this general technique can identify.

P1.17-02 LOW PROGNOSTIC NUTRITION INDEX PREDICTS POOR SURVIVAL IN STAGE IIIB NON-SMALL CELL LUNG CANCER PATIENTS TREATED WITH CHEMORADIOThERAPy
A. Besen1, E. Topkan1, Y. Ozdemir1, O. Guler2, B. Yıldırım2, U. Selek3, F. Kose3, D. Ozyilkcan2
1 Medical Oncology, Baskent University, Adana/TR, 2 Baskent University, Adana/TR, 3 Radiation Oncology, American Hospital, Istanbul & M.D. Anderson Cancer Center, Houston, Istanbul/TR, 4 Medical Oncology, Baskent University, Adana/TR

Background: The prognostic role of prognostic nutritional index (PNI) has been widely investigated and showed in many types of cancer. However, to our best knowledge, the significance of PNI has never been investigated in locally advanced non-small cell lung cancer (NSCLC) who were treated with concurrent chemoradiotherapy ( CCRT). Therefore in this current study, we aimed to investigate the prognostic impact of PNI on survival outcomes of locally advanced NSCLC undergoing CCRT. Method: The data of 358 patients with stage IIIB NSCLC treated with CCRT were analyzed retrospectively. All patients received 60 to 66 Gy (2 Gy per fraction) thoracic radiotherapy and at least one course of platinum-based doublet chemotherapy concomitantly. For each patient PNI was calculated by the known formula in blood samples those were available prior to CCRT: [PNI=10×serum albumin (g/dl) + 0.005×total lymphocyte count (mm3)]. The primary endpoint was the association between PNI and overall survival (OS). Secondary endpoints were locoregional progression-free survival (LPFS) and progression-free survival (PFS). The survival curves were calculated by Kaplan-Meier method and log-rank test. The cutoff value of the PNI was analyzed by receiver operating curve (ROC). Result: At a median follow-up of 22.5 months (2.4-123.5 months) 108 patients (30.2%) were still alive. For the whole study cohort median OS was 25.2 months (95% CI: 22.7-27.7). The median LPFS and PFS were 15.4 months (95% CI: 14.4-16.4) and 10.7 months (95% CI: 9.7-11.7) respectively. In ROC analysis, calculated cutoff value of PNI was 40.1 (AUC: 67.8% (62.0-73.6); sensitivity: 73;1; specificity: 68.4, p<0.001). According to this, patients were grouped as follows, group 1: PNI>40, group 2: PNI<40. Accordingly, for the patients in group 1, OS (36.7 vs. 16.8 months, p<0.001), LPFS (19.5 vs. 11.5 months, p<0.001) and PFS (13.6 vs. 8.6 months, p<0.001) times were significantly better as compared to patients in group 2. Results of the multivariate analysis demonstrated that the prognostic worth of the
PNI was independent of the other covariates (p<0.001, for each survival endpoint). **Conclusion:** Being the first of its kind study the result of this current investigation heralded that the PNI which is easy to calculate, easily achievable with no additional cost has a strong prognostic value in prognostic stratification of the stage III NSCLC patients undergoing to CCRT.

**P1.17-03 POTENTIAL ASSOCIATED SNPS BY GWAS WITH RADIATION PNEUMONITIS (RP) IN PATIENTS WITH LUNG CANCER TREATED WITH RADIOTHERAPY**

L. Du, B. Qu, N. Ma, X. Huang, W. Yu, S. Xu, X. Dai  
Radiation Oncology, Chinese PLA General Hospital, Beijing/CN

**Background:** Lung cancer is one of the most prevalent cancers and the leading cause of cancer-related deaths in China and worldwide. Radiation therapy plays a remarkable role in lung cancer treatment, and approximately 60%–70% lung cancer patients receive radiation treatment. Whereas, radiation pneumonitis is one of the most critical dose-limiting toxicities of thoracic radiation. Single nucleotide polymorphisms (SNPs) in inflammation-related, DNA repair-related, oxidative stress response-related and angiogenesis-related genes and so on were proved to be associated with RP, with different underlying mechanisms. Previous limited studies reported few SNP sites that may be used to predict for the risk of RP. However, these studies mainly focused on previously reported loci and only limited sites were tested. Here, the purpose of this study was to evaluate the potential related SNPs by whole-genome sequencing and radiation pneumonitis (RP) development.

**Method:** We recruited a total of 132 patients with lung cancer receiving intensity-modulated radiation therapy (IMRT). We collected the blood sample and sequenced the whole genomes in all patients. RP events were prospectively scored using the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE), version 4.0. Kaplan-Meier analysis was used to determine the cumulative probability of RP of grade ≥ 2. Genomes-Wide Association Study (GWAS) was carried out to look for potential SNPs associated with risk of RP grade ≥ 2. **Result:** The index SNP of RP of grade ≥ 2 was rs9320, using SNP information by Genomes-Wide Association Study (GWAS), we discovered 73 SNPs that showed significant difference with cutting off p-value of 0.001. Most of them are previously not reported. **Conclusion:** This result established a set of biomarkers which can be used for prognosis predictions for radiation-induced pneumonitis.

**P1.17-04 CURATIVE INTENT TREATMENT FOR STAGE III NSCLC IN ENGLAND**

S. Harden1, A. Khakwani2, P. Beckett1, J.B. Adizie1  
1Clinical Effectiveness and Evaluation Unit, Royal College of Physicians of London, London/GB, 2Department of Epidemiology and Public Health, University of Nottingham, Ng Pb/GB

**Background:** The National Lung Cancer Audit (NLCA) produces annual reports detailing standards of care for lung cancer. This further analysis investigates the use of curative intent multi-modality treatment for people in England diagnosed with stage III NSCLC during 2016, including, for the first time, details about use of concurrent and sequential chemoradiotherapy (CRT). **Method:** Data on patients diagnosed during 2016 with stage III NSCLC in England were extracted from the National Cancer Registration and Analysis Service (NCRAS); information submitted through the Cancer Outcome and Services Dataset (COSD) was linked to other NCRA’s datasets, including Hospital Episode Statistics (HES), the National Radiotherapy Dataset (RTDS) and the Systemic Anti-Cancer Dataset (SACT). **Result:** 6,288 cases of stage III NSCLC were analysed, 3839 Stage IIA and 2449 Stage IIB (Table 1). 813 (13%) people underwent surgery with 447 (7%) of these also receiving chemotherapy (predominantly adjuvant). 1047 (17%) people were treated with radical radiotherapy with 876 (11%) of these also receiving chemotherapy. For the 589/676 CRT cases where complete treatment dates were available, 199 (34%) received concurrent and 390 (66%) received sequential chemoRT (37% and 63% for stage IIA). For 481/589 cases with performance status (PS) available, 171 (36%) PS0-1 cases received concurrent and 310 (64%) received sequential chemoRT (38% and 62% for stage IIA). Of note, 2148 (34%) people received anti-cancer treatment of palliative intent and 2290 (36%) received supportive care only. Survival data will also be presented. **Table 1**

**Conclusion:** Multi-modality treatment with either surgery or radical radiotherapy combined with chemotherapy was delivered to 1123 (18%) patients with stage III NSCLC. Concurrent CRT, optimal CRT based on meta-analysis, was delivered to just over one third of people receiving CRT, including for patients of good PS0-1. This analysis provides a baseline for future quality improvement initiatives to optimise treatment and outcomes for patients with stage III NSCLC.

**P1.17-05 ACCELERATED RADIOTHERAPY FOR NON-SMALL CELL LUNG CANCER: A 12 YEAR RETROSPECTIVE REVIEW OF TWO DOSE FRACTIONATION SCHEDULES**

S. Robinson1, B. Tahir2, K. Absalom3, D. Tripathi2, P. Fisher2, T. Das2, C. Lee2, E. Bates1, M. Hatton1  
1Clinical Oncology, Weston Park Hospital, Sheffield, Sheffield/GB, 2Clinical Oncology, University of Sheffield, Sheffield/GB, 3Clinical Oncology, Weston Park Hospital, Sheffield/GB

**Background:** Numerous dose fractionation regimes have been used for inoperable NSCLC patients and there is evidence that accelerated schedules can produce better outcome than conventionally fractionated treatment (1). Continuous hyperfractionated accelerated radiotherapy (CHART, 54Gy in 36 fractions over 12 days) and accelerated hypofractionated radiotherapy (55Gy in 20 fractions over 4 weeks) have been routinely used in Sheffield over the past decade, with schedule selection largely down to patient choice (in-patient vs out-patient treatment). In this single-centre retrospective analysis, we present the outcomes for all patients treated with these two schedules between 2003 to 2015. **Ref 1:** LePechoux C, Mauguen A, Baumann M, et al. Hyperfractionated or Accelerated Radiotherapy in Lung Cancer: An Individual Patient Data Meta-Analysis. JCO 2012;30:2788-2797. **Method:** In this audit details on patient demographics, tumour characteristics and survival data was collected from the electronic hospital records and supplemented by information from patient notes. Dosimetric data for tumour and organs at risk were collated automatically via the Varian Eclipse Scripting application programming interface. Descriptive statistical analysis was performed using the SPSS package with clinical and dosimetric variables assessed using independent samples t-tests and survival via a log-rank test. Multivariate survival analysis was performed using Cox regression. **Result:** We identified 883 eligible patients, of which 45% received CHART and 55% hypofractionated radiotherapy. Mean age was 70 years and 58% were male. PET staging was performed in 87% with 30%, 15%, 51% and 4% being stage I, II, III and IV, respectively. 63% had a WHO performance status of 0-1. 38% of patients underwent induction chemotherapy, 99% completed their prescribed radiotherapy treatment with an overall response rate of 60%. Relapse was observed in 50% of patients with median disease-free survival of 19.4 months. 2-year overall survival was 47% with a median overall survival of 23.2 months. Multivariate analysis identified histology, stage, performance status, use
of chemotherapy as independent predictors of survival. No significant differences between the two radiotherapy regimes was seen for any parameters. Conclusion: This audit has confirmed that both CHART and hypofractionated accelerated radiotherapy are deliverable and well tolerated schedules when used in day to day practice. We have detected no significant difference in outcome between the two schedules and there is the need to explore avenues, e.g dose escalation, that develop these schedules to match outcomes reported by recent concurrent chemo–radiotherapy studies.

2Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo/JP
3Department of Radiation Oncology, National Cancer Center Hospital, Tokyo/JP

Background: Local recurrence after definitive chemotherapy and/or radiotherapy with curative intent is frequently experienced in patients with locally advanced lung cancer. We evaluated the frequency, feasibility, and efficacy of salvage pulmonary resection after definitive chemotherapy and/or radiotherapy. Method: We analyzed the characteristics and medical courses of consecutive patients who had undergone salvage pulmonary resection after local relapse or progression after chemotherapy, chemoradiotherapy and radiotherapy including stereotactic body radiation therapy (SBRT) and proton beam therapy (PBT). In this analysis, local relapse or progression were defined as increase in tumor maximum size or detection of new lesions by CT and/or FDG/PET-CT. Indications of resectability was assessed by multidisciplinary tumor board. Result: Between January 2000 and January 2018, 46 patients (60.3%) received surgical resection during out of 7,290 patients underwent surgery for primary lung cancer at National Cancer Center Hospital, Tokyo, Japan. Median follow-up time was 24.5 months (range, 2.1-157.6). Of 46 patients evaluated, 30 (65.2%) were men, the median age was 64.5 years (range, 20-78 years). 22 (47.8%) underwent chemotherapy, 18 (39.1%) underwent resection after chemotherapy, 3 (6.5%) underwent resection after SBRT and 3 (6.5%) underwent resection after PBT. The number of patients undergoing salvage surgery has increased in recent years: 9 patients were between 2000 and 2009, whereas 37 patients were between 2010 and 2018. Method of surgical resection was as follows: 28 lobectomies (2 bilobectomy, 15 right upper, 1 right middle, 6 right lower, 2 left upper, 2 left lower), 10 pneumonectomies (left:right=7:3). One patient received a wedge resection, and one received wedge resection with chest wall resection, and 2 underwent pneumonectomy and lymphadenectomy for residual lymph nodes respectively. A complete resection (RO) was achieved in 42 cases (91.3%). Postoperative complications were observed in 3 patients (6.5%): prolonged air leakage, bronchopleural fistula, and atrial fibrillation. There were no post-operative deaths within 30 days after surgery. The five-year progression-free survival of surgical resection and overall survival rate after surgical resection was 39.1% (95% CI: 19.9-57.9) and 64.1% (95% CI: 39.3-80.9), respectively. Conclusion: The frequency of salvage surgery after initial treatment has been increasing possibly due to a better treatment course using novel medical and radiation oncology technique. Salvage pulmonary resections demonstrated acceptable morbidity and mortality with promising long-term efficacy in selected patients.

P1.17-07 THE PROGNOSTIC VALUE OF VOLUMETRIC CHANGES OF THE GTV MEASURED ON CBCT DURING RADIOThERAPY FOR CCRT IN NSCLC PATIENTS

M. Kwint1, B. Stam1, J. Belderbos2, M. La Fontaine3, E. Aalbersberg4, M. Rossi5, J. Sonke1, I. Wiatrak1

1Department of Radiation Oncology, The Netherlands Cancer Institute – Antoni van Leeuwenhoek Hospital, Amsterdam/NL
2Department of Nuclear Medicine, The Netherlands Cancer Institute - Antoni Van Leeuwenhoek Hospital, Amsterdam/NL

Background: To pursue personalized cancer care, it is important to determine tumor response during treatment and associate these with outcomes. Previously published literature reported that adenocarcinoma and squamous cell carcinoma have different treatment response and outcome. Therefore, the aim of this study is to examine the prognostic value of volumetric changes of the primary tumor measured on Cone Beam-CT (CBCT) during radiotherapy for locally advanced NSCLC patients treated with concurrent chemoradiation (CCRT). Method: 394 NSCLC-patients treated with CCRT between 2007-2013 were included. To determine GTV during treatment, deformable image registration of the planning-CT to all CBCTs was performed. To assess the association of volumetric changes of the gross tumor volume (GTV) with overall survival (OS), progression free survival (PFS) and local regional control (LRC), multivariate cox regression analyses were performed, accounting for potential confounders. Furthermore, the entire group was stratified based on adenocarcinoma and non-adenocarcinoma and an additional log rank and multivariate cox regression analysis based on pathology was performed. Result: In patients with adenocarcinoma, GTV reduction during CCRT was significantly associated with worse OS (HR=1.55, Figure 1). GTV reduction was not significantly associated with PFS and LRC in either subgroup. For the entire group no significant association was found between GTV volume change and OS, PFS or LRC.

Conclusion: Surprisingly, no associations between GTV changes and outcomes were found for the entire treatment group. In patients with adenocarcinoma, GTV changes during concurrent chemoradiation measured on CBCT were a significant predictor for OS.

4Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York/NY/US

Background: Radiation with platinum-based doublet chemotherapy is the standard of care for patients with unresectable stage III non-small-cell lung cancer (NSCLC). Despite aggressive treatment, progression-free survival and overall survival remain poor. It is unclear whether any tumor genotypic alterations are associated with response to treatment. We retrospectively reviewed clinical outcomes of patients with stage III NSCLC treated with definitive radiation, who had undergone tumor molecular profiling through an institutional next-generation sequencing platform. This platform is an FDA-approved, targeted-DNA-sequencing panel that contains 341 (now expanded to 468) somatic mutations and other genetic alterations. Basic patient and tumor characteristics, clinical and pathologic features in stage III NSCLC with adenocarcinoma and squamous cell carcinoma have different treatment response and outcome. Therefore, the aim of this study is to determine tumor response during treatment and associate these with outcomes. Previously published literature reported that adenocarcinoma and squamous cell carcinoma have different treatment response and outcome. Therefore, the aim of this study is to examine the prognostic value of volumetric changes of the primary tumor measured on Cone Beam-CT (CBCT) during radiotherapy for locally advanced NSCLC patients treated with concurrent chemoradiation (CCRT). Method: 394 NSCLC-patients treated with CCRT between 2007-2013 were included. To determine GTV during treatment, deformable image registration of the planning-CT to all CBCTs was performed. P1.17 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00
patient received induction crizotinib and one patient died before start of chemotherapy. With a median follow-up time of 15.3 months, the median survival was 34.2 months. Several genetict mutations were significantly associated with worse overall survival after therapy, including AKT2 any mutation (Hazard ratio 13.71, p<0.001), KMT2C truncating mutations (HR 13.42, p<0.001), KMT2D truncating mutations (HR 6.97, p<0.001), ARID1A frame shift mutations (HR 8.54, p<0.001), and FLI1 mutation (HR 6.62, p<0.001). These genes were also associated with increased loco-regional recurrence. Mutation in the PIK3CG gene was significantly associated with improved overall survival. Association of other common genetic alterations such as EGFR mutation with response to therapy was not observed. Conclusion: This study coupled multiplex targeted sequencing with clinical outcome information to identify several potential genetic predictors of response to chemotherapy and radiation in locally advanced NSCLC. KMT2C and KMT2D encode two subunits of a histone methyltransferase, and mutations of KMD2 have been shown to correlate with worse survival in locally advanced and advanced NSCLC patients. Further studies including in vitro validations are necessary to confirm the findings.

P1.17 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.17-09 V30 MAY BETTER PREDICT RADIATION PNEUMONITIS AFTER INTENSITY-MODULATED RADIATION THERAPY FOR LUNG CANCER Y. Meng , C. Yu, X. Tang, W. Wang, C. Jiang, F. Kong, H. Yang Radiation Oncology, Laboratory of Cellular and Molecular Radiation Oncology, Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou Hospital, Taizhou/CN

Background: V20 and MLD are the most commonly used dose constraints for radiation pneumonitis (RP) prediction. However, intensity-modulated radiation therapy (IMRT) has unrestricted beam arrangements, an infinite number of very different dose distributions could be generated in the lung volume outside the planning target volume (PTV). Conventional dose constraints from traditional 3D conformal RT may not be valid for IMRT treatment. We hypothesize that lung dosimetric parameters may have different RP predictive values from that of traditional constraints (largely generated from 3D treatment) in IMRT treated lung cancer patients. Method: We retrospectively enrolled 184 IMRT treated lung cancer patients from January 2014 to October 2017. The primary endpoint was acute grade 2 or higher symptomatic radiation pneumonitis (RP2), based on the National Cancer Institute's Common Terminology Criteria for Adverse Events (version 4.03). V20 and V50) and MLD were generated from the lung volume outside PTV. Univariate and multivariate logistic regression analysis was used to evaluate the association between the dose parameters outside PTV to RP2. We employed area under the curve (AUC) for the receiver operating characteristic curve (ROC) to assess prediction accuracy for the single or multi-variate model. Result: 26 out of 184 lung cancer patients (14.1%) developed RP2 within 3 months after the end of IMRT treatment. The ROC curve, although none of the clinical parameters were significantly associated with RP2, female gender (P = 0.051) and chemotherapy (P = 0.151) had a trend of correlation. Conclusion: For IMRT treated lung cancer patients, V30 generated from lung volume outside PTV may predict RP more accurately than traditional dosimetric parameters.

**Background:** Neoadjuvant therapy may benefit locally-advanced NSCLC patients. We evaluated patterns of neoadjuvant therapy and the impact on stage-shift and survival. **Method:** All curative-intent NSCLC resections were collected from 12 hospitals in 4 contiguous Dartmouth Hospital Referral Regions in mid-Southern USA from 2009–2018. Comparisons made using Chi-square tests and non-parametric t-tests, survival impact assessed using Cox-proportional hazard models. Result: 182 of 3,297 resections (5.5%) had neoadjuvant therapy: 118 (64.8%) chemoradiation, 47 (25.8%) chemotherapy, and 17 (9.3%) radiation. Neoadjuvantly treated patients were younger, more likely to be commercially insured, have immediate preoperative brain MRI, and invasive mediastinal staging than those with primary resection (p<0.001 for all, Table 1). They also had more advanced stage, but 27% were clinical stage IA/IB. Despite evidence of more difficult surgery, perioperative complications, hospital length of stay and postoperative mortality rates were similar to the primary resection cohort. Despite delay to surgery, they had significantly greater down-staging (p<0.001). However, down-staging had no impact on survival, regardless of type of neoadjuvant therapy (Table 2).

**Table 1. Demographic and clinical characteristics between patients who received neoadjuvant therapy and those who did not.**

P1.17-12 COLLEAGUE PEER REVIEW OF RADICAL LUNG RADIOTHERAPY TREATMENT PLANS: THE IMPACT ON INTERVAL FROM DECISION TO TREAT TO TREATMENT DELIVERY

C. Rooney, J. McAleese, L. Young, G. Walls, R. Eakin, J. Harney, G. Hanna
Clinical Oncology, Northern Ireland Cancer Centre, Belfast/GB

Background: Quality assurance by colleague-led peer review (CPR) is recommended in the radiotherapy treatment planning of curative intent treatments such as for lung cancer. Previous studies have demonstrated a proportion of radiotherapy plans are amended following CPR resulting in enhanced quality and uniformity of treatment approached. CPR is an additional step to the radiotherapy planning process, and it may affect the timely delivery of radiotherapy. CPR was initiated at our centre in 2011. This study considers the temporal impact of adding an additional step in the radiotherapy planning process.

Method: Using our institutional lung radiotherapy database we recorded the timescales between decision to treat (DTT) and commencement of radical lung radiotherapy, pre-peer review and post-peer review initiation at a single institution. The data for the entire radiotherapy database we recorded the timescales between decision to treat and commencement of radical lung radiotherapy for lung cancer commenced treatment within 28 days of the DTT (median 26 days, range 0-61). In 2016, 80% of the 133 patients receiving curative intent radiotherapy had treatment initiated within 28 days (median 25 days, range 6-41). There was a notable reduction in the variability in planning time making booking of appointments with a reduction in extreme wait times to start treatment.

Result: Prior to peer review for the calendar year of 2007, 71% of the 63 patients receiving curative intent radiotherapy for lung cancer commenced treatment within 28 days of the DTT (median 26 days, range 0-61). In 2016, 80% of the 133 patients receiving curative intent radiotherapy had treatment initiated within 28 days (median 25 days, range 6-41). There was a notable reduction in the variability in planning time making booking of appointments with a reduction in extreme wait times to start treatment (figure 1). Figure 1 Box and whisker plot of the time from the decision to treat until the commencement of radiotherapy for the representative years available for analysis.

NA – not applicable due to small sample size

Conclusion: Neoadjuvant therapy was safe, but had no survival impact in this cohort, despite increased down-staging, possibly because of an inexplicably high proportion of stage I patients.

Keywords: survival, neoadjuvant, NSCLC
Conclusion: In our institutional series, CPR does not prolong planning time with the median number of days taken to commence treatment remaining comparable, but may standardise radiotherapy start times due to enhanced team working via the CPR meetings. We recommend that peer review is performed as standard practice as it improves treatment quality without a detrimental prolongation of planning time.

Keywords: college peer review, Lung radiotherapy planning

Conclusion: Our data demonstrate a trend for improved OS with PORT. Although this is a population-based study, this lack of statistical significance may be attributable to a small sample size as the OS curves indicate a consistent benefit with PORT.

Keywords: PORT, Adjuvant Radiation, nodal downstaging

P1.17-14 OUTCOMES OF HYPOFRACTIONATED RADIATION THERAPY (HFT) WITH CONCURRENT CHEMOTHERAPY IN PATIENTS WITH STAGE III NON SMALL CELL LUNG CANCER (NSCLC)

A. Shepherd1, D. Gelblum2, A. Wu3, A. Rimner3
1Radiation Oncology, Memorial Sloan Kettering Cancer Center, Basking Ridge/NJ/US, 2Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York/NY/US, 3Radiation Oncology, Memorial Sloan-Kettering Cancer Center, New York/NY/US

Background: Patients with unsectable locally advanced NSCLC are often treated with concurrent chemoradiation. HFT regimens are becoming increasingly common due to convenience and healthcare costs. A data from the HFT01 study was performed to evaluate the outcomes of HFT with concurrent chemotherapy. Method: The National Cancer Database (NCDB) was queried for patients with stage III NSCLC who received RT (50 Gy-80 Gy) with concurrent chemotherapy without surgery from 2004-2015. Patients were defined as receiving concurrent chemotherapy if chemotherapy was started within 3 weeks of the start of radiation. Patients received conventionally fractionated RT (CFRT): 180-200 cGy/fraction (fx) or HFT: 210-400 cGy/fx. Baseline characteristics were compared. Kaplan Meier method was used for overall survival (OS) and Cox-proportional hazards were used for univariable and multivariable analyses (UVA/MVA). Result: A total of 54,559 patients were evaluated: 50,938 CFRT and 3,621 HFT. Patients treated with HFT were more likely to receive RT at an academic center (32.6% vs. 27.2%, p<0.01), more likely to have a high T-stage (CT3/4: 56.5% vs. 49.2%, p<0.01), and lower N-stage (CTN2/3: 77.6% vs. 81.4%, p<0.01). There was no difference in age (median 66 yo), sex, race, insurance, education, Charlson-Deyo Comorbidity Index (CDCS), tumor location, or grade. For the CFRT and HFT groups, the RT dose, Biologic Equivalent Dose (BED) and dose/fx were 64 Gy; 76.4; 185 cGy/fx and 60 Gy; 80.5; 235 cGy/fx, respectively. The median and 2-yr rates of OS were 19.8 mos and 43.2% for CFRT vs 16 mos and 36.1% for HFT (p<0.01). On UVA and MVA, (data shown for MVA: HR, p-value), age (1.01, <0.01), male gender (1.2, <0.01), white race (1.09, <0.01), Medicare (1.04, <0.01), urban dwelling (1.03, <0.01), distance from treatment center (0.99, <0.01), treatment at an academic center (0.91, <0.01), CDCS (1.11: -0.01, 2.11: 0.01, 3.12: 0.01, diagnosed 2010-2014 (0.85, <0.01), upper lobe location (0.89, <0.01), tumor stage (1.15, <0.01), race (0.83, <0.01), N stage (1.12, <0.01), stage IIIib (1.11, <0.01), RT (1.26, <0.01) and BED (0.99, 0.01) were associated with OS. Conclusion: Patients who received HFT had slightly inferior OS rates, which may be due to toxicity (not captured in the NCDB) or unaccounted confounders such as baseline performance status and aggressiveness of disease.

P1.17-15 PERIOPERATIVE PROGNOSTIC NUTRITION INDEX FOR INDUCTION CHEMORADIOTHERAPY FOLLOWED BY SURGERY IN LOCALLY ADVANCED NON-SMALL LUNG CANCERS

J. Soh1, S. Miyazaki1, K. Araki2, A. Miura2, Y. Takahashi2, E. Kurihara2, Y. Yokomise2, T. Shibata1
1Radiation Oncology, Kagawa University Hospital, Kagawa/JP, 2General Thoracic, Breast and Endocrine Surgery, Kagawa University, Kagawa/JP

Background: The perioperative nutritional and immunological statuses of patients with tumor are often both associated with the clinical outcome of the surgery, especially when highly invasive surgery is required. The prediction of pCR during induction chemotherapy (ICRT) followed by surgery is critical. Method: We evaluated the perioperative PNI and NCI81 in patients who received ICRT followed by surgery. A total of 54,559 patients were evaluated: 50,938 CFRT and 3,621 HFT. Patients treated with HFT were more likely to receive RT at a high T-stage (CT3/4: 56.5% vs. 49.2%, p<0.01) but lower N-stage (CN2/3: 77.6% vs. 81.4%, p<0.01). There was no difference in age (median 66 yo), sex, race, insurance, education, Charlson-Deyo Comorbidity Index (CDCS), tumor location, or grade. For the CFRT and HFT groups, the RT dose, Biologic Equivalent Dose (BED) and dose/fx were 64 Gy; 76.4; 185 cGy/fx and 60 Gy; 80.5; 235 cGy/fx, respectively. The median and 2-yr rates of OS were 19.8 mos and 43.2% for CFRT vs 16 mos and 36.1% for HFT (p<0.01). On UVA and MVA, (data shown for MVA: HR, p-value), age (1.01, <0.01), male gender (1.2, <0.01), white race (1.09, <0.01), Medicare (1.04, <0.01), urban dwelling (1.03, <0.01), distance from treatment center (0.99, <0.01), treatment at an academic center (0.91, <0.01), CDCS (1.11: -0.01, 2.11: 0.01, 3.12: 0.01, diagnosed 2010-2014 (0.85, <0.01), upper lobe location (0.89, <0.01), tumor stage (1.15, <0.01), race (0.83, <0.01), N stage (1.12, <0.01), stage IIIib (1.11, <0.01), RT (1.26, <0.01) and BED (0.99, 0.01) were associated with OS. Conclusion: Patients who received HFT had slightly inferior OS rates, which may be due to toxicity (not captured in the NCDB) or unaccounted confounders such as baseline performance status and aggressiveness of disease.

MONDAY, SEPTEMBER 24, 2018 - 09:45-18:00

P1.17-16 CORRELATION OF TUMOR VOLUME REDUCTION DURING NEoadjuvant CHEMORADIOTherapy WITH PATHOLOGICAL COMPLETE RESPONSE OF LUNG CANCER

S. Takahashi1, T. Go2, T. Nishide1, M. Andata1, T. Kinosita1, H. Yokomise2, T. Shibata1
1Radiation Oncology, Kagawa University Hospital, Kagawa/JP, 2General Thoracic, Breast and Endocrine Surgery, Kagawa University, Kagawa/JP

Background: A study has reported that tumor volume (TV) reduction after neoadjuvant chemoradiotherapy (NACRT) was associated with pathological complete response (pCR) in patients with non-small cell lung cancer (NSCLC). We think that the prediction of pCR during NACRT may be able to assist clinical decisions. Therefore, we retrospectively investigated the relationship between TV reduction during NACRT and pCR. Method: We evaluated patients who received NACRT followed by surgery from 2007 between 2017 and 2017. The eligibility criteria of this study were as follows: NACRT was performed with a dose of 50 Gy in 25 fractions with the platinum-doublet regimen, and contrast enhanced computed tomography (CECT) was obtained before and during NACRT. TVs before and during NACRT (TVpre and TVdur, respectively) were measured with the sums of the primary tumor and clinically involved lymph node volumes. Relative changes in the TVs were calculated as %/TVdur – TVpre)/TVpre. The factors affecting pCR were evaluated in a univariate analysis, by Fisher’s exact test or Wilcoxon rank-sum test, and in a multivariate analysis using the multiple logistic regression test. Result: In total, 31 patients met the eligibility criteria: 52%, 42%, and 58% of patients had squamous cell carcinoma, ct3, and ct2n2 disease, respectively. CECT during NACT (CECTdur) was obtained at a median dose of 40 Gy (range, 24-50 Gy). The median TVpre and TVdur were 45.1 cc (range, 11.4-584.2 cc) and 27.0 cc (range, 5.9-195.0 cc), respectively. The median relative change in the TVs was −49% (range, −83 to −10%), and after surgery, pCR was confirmed in 11 patients (35%). Relative change in the TVs (p = 0.002) and TVpre (p = 0.039) were significant factors affecting pCR in the univariate analysis. In a multiple logistic regression analysis, TVdur (p = 0.003) was the only significant factor affecting pCR. Conclusion: TVdur during NACT seems to be associated with pCR in patients with NSCLC. A cut-off value of −64% in relative change in the TVs at a dose of around 40 Gy may be promising to predict pCR.

**P1.17 THE IMPACT OF INDUCTION CHEMORADIOThERAPY FOLLOWED BY SURGERY FOR N1 INVOLVED NON-SMALL CELL LUNG CANCER**

Y. Takahashi¹, J. Soh¹, S. Miyachi¹, K. Araki¹, A. Miura¹, E. Kurihara¹, Y. Ogoshi¹, K. Shien¹, H. Yamamoto¹, S. Sugimoto¹, M. Yamane¹, K. Kiura², S. Kanazawa², S. Toyooka¹

¹General Thoracic Surgery, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama/JP; ²Respiratory Medicine, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama/JP

**Background:** Induction chemoradiotherapy (ICRT) followed by surgery is usually selected for locally advanced non-small cell lung cancer (NSCLC) patients with mediastinal lymph node (LN) metastasis or invasion to adjacent organs, whereas it is occasionally performed for clinical N1 (cN1) NSCLC patients harboring such as a centrally located primary tumor or a bulky LN to improve local control rate and secure a cancer-free surgical margin. However, the survival benefit of ICRT followed by surgery for NSCLC patients with LN involvement remains controversial. Furthermore, the accuracy of the radiological examination for N1 metastasis is unsatisfactory. In this study, we investigated the clinical outcomes of surgery with or without ICRT based on the estimation of the pretreatment LN metastatic status from fibrotic or necrotic changes of resected LNs in the cN1 NSCLC patients.

**Method:** cN1 NSCLC patients who underwent complete resection with or without ICRT at our institution between January 1999 and December 2016 were selected. We divided the enrolled patients into two groups as the primary surgery (PS) group and ICRT followed by surgery (IC) group. As for the IC group, we determined the pretreatment LN metastatic status based on the pathological features of resected LNs. We compared the clinical outcomes of pretreatment N1 involved patients with or without ICRT.

**Result:** Among 127 cN1 NSCLC patients, 40 patients were considered as pretreatment N1 involvement, consisting of 26 and 14 patients in the PS and IC groups, respectively. The central type tumor and the continuous type of LN, which frequently required the extended surgical procedures, were significantly more frequent in the IC group than in the PS group (P = 0.01). Although there was no significant difference in the recurrence pattern between the two groups, none of patients developed local recurrence in the IC group. Regarding the patients with a centrally located tumor or a bulky LN (≥ 2.0cm), the 5-year recurrence-free survival was significantly better in the IC group than in the PS group (74.1% vs. 36.4%, P = 0.03).

**Conclusion:** Our study demonstrated that ICRT followed by surgery could suppress the disease recurrence in the cN1-NSCLC patients especially for the patients harboring a centrally located tumor or bulky LN at N1 level, suggesting that these patients may be good candidates for ICRT followed by surgery to avoid extended resections and to suppress the local recurrence.

**P1.17-18 TREATMENT FOR PATIENTS WITH T4 SUPERIOR SULCUS NON-SMALL CELL LUNG CANCER: A PROPENSITY-MATCHED ANALYSIS OF SEER DATABASE**

J. Wen¹, D. Chen¹, J. Chen¹, D. Liu¹, Y. Chen¹, C. Chen², M. Fan¹

¹Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai/CHN; ²Department of Thoracic Surgery, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CHN; ³Cardiothoracic Surgery, The Second Affiliated Hospital of Soochow University, Suzhou/CHN

**Background:** Superior sulcus tumors (SSTs), a unique subgroup of locally advanced non–small-cell lung carcinoma (NSCLC), remain a clinical challenge for clinicians. T4 SSTs used to be a contraindication for operations, and the optimal treatment modality for T4 SS NSCLCs remains uncertain. The aim of our study is to evaluate the roles of surgical treatment and radiotherapy for patients with T4 SSTs. **Method:** We used the SEER database [1973-2015] to identify patients diagnosed with T4 stage NSCLC (according to the 7th edition of the AJCC staging system) between 2004 and 2015, those with M1 disease were excluded. Propensity score matching with Kaplan-Meier and Cox proportional hazards model were performed to estimate prognosis. **Result:** A total of 384 patients were included (mean 66.4±11.7 years-of-age). Among them, the majority was male (59.4%) with lesions located in the left lung (52.3%) and diagnosed with IIIB stage (56.6%). 47 patients underwent cancer-directed surgery, and radiotherapy was received by 66.9% of patients. Median overall survival (OS) and lung cancer specific survival (LCSS) was 12 and 17 months, and 5-year OS, LCSS was 15.8%, 25.4%, respectively. In the matched population, the median survival outcomes were better with receipt of surgery (OS: 51.3 vs 35.1 months; p=0.049, LCSS: 67.1 vs 36.3 months; p=0.003). Multivariate Cox analysis showed that age ≥ 66 years (hazard ratio [HR] = 1.639, 95% confidence interval [CI] 1.214–2.131, p<0.001), unmarried status (HR = 1.356, 95% CI 1.023–1.798, p=0.034), tumor sized ≥ 6.0 cm (HR = 1.694, 95% CI 1.263–2.273, p<0.001) were associated with inferior OS. Cancer-directed surgery (HR = 0.537, 95% CI 0.337–0.855, p = 0.009) and radiotherapy (HR = 0.644, 95% CI 0.472–0.878, p = 0.006) were independent protective factors for patients with T4 superior sulcus NSCLC. However, neither adjuvant nor neoadjuvant radiotherapy was independent prognostic factor for those received surgery (p>0.05). Conversely, in the subgroup analysis, favorable impacts of radiotherapy were observed for non-surgery patients (OS: HR = 0.58, 95% CI 0.42–0.79; LCSS: HR = 0.65, 95% CI 0.37–0.75, p<0.001). **Conclusion:** Our study shows superior sulcus NSCLC patients with T4 stage have dismal prognosis. Surgical resection remains the optimal option for those with resectable disease. Moreover, for non-surgery tumors, the use of radiotherapy should be considered.

**P1.17-19 CORRELATION OF DOSIMETRIC AND CLINICAL FACTORS WITH RADIATION PNEUMONITIS IN LUNG CANCER PATIENTS RECEIVED INVOLVED-FIELD IMRT**

L. Du, B. Qu, N. Ma, Q. He, W. Yang, Q. Wang

Radiotherapy, Chinese PLA General Hospital, Beijing/CHN

**Background:** Radiation pneumonitis is a potentially fatal complication in lung cancer patients treated with definitive radiotherapy. The ability to identify patients at risk for this complication would be of value to clinicians. The objective of this study was to identify significant predictors of grade 2 or higher radiation pneumonitis. Previous reported studies mostly focused on extended-field three-dimensional conformal radiotherapy without image guided. The purpose of the study was to correlate clinical and dosimetric factors with the development of radiation pneumonitis in patients with lung cancer treated with involved-field image guided intensity modulated radiation therapy (IMRT).

**Method:** 149 lung cancer patients treated with involved-field image guided IMRT were recruited. Potential predictive factors examined included age, gender, history, stage, pulmonary function, KPS, radiotherapy dose, surgery, tumor histology, image of chemotherapy. RP events were prospectively scored using the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE), version 4.0. Kaplan-Meier analysis was used to determine the cumulative probability of RP of grade ≥ 2. Univariate and multivariate analysis was used to determine predictors of grade 2 or higher pneumonitis. **Result:** Of the 149 patients, Median prescription dose was 60 Gy. With a median follow-up of 9 months, 10 cases (6.7%) developed RP of grade 3 or 4. In total, 57 (38.3%) developed RP of grade ≥ 2 RP, and 90 (62.7%) of grade 1 or lower level. The median time of grade ≥ 2 RP was 2.6 months (range from 1 to 6 months). Grade ≥ 2 RP pneumonitis was correlated with age and volume of lung receiving 20 Gy (V20). Surgery had a bordline significant association with risk of grade ≥ 2 RP pneumonitis. **Conclusion:** Age and V20 were significant predictors of grade≥2 RP radiation pneumonitis in lung cancer patient treated with involved-field image guided IMRT. Surgery also had a bordline significant predictive value.

**P1.17-20 EXCLUDING PTV FROM LUNG VOLUME MAY BETTER PREDICT RADIATION PNEUMONITIS FOR IMRT TREATED LUNG CANCER PATIENTS**

Y. Meng, C. Yu, W. Wang, X. Tang, C. Jiang, F. Kong, H. Yang

Radiation Oncology, Laboratory of Cellular and Molecular Radiation Oncology, Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/HZ

**Background:** Lung dose-volume histogram (DVH) could be calculated from multiple normal lung definitions. These dose differences have a direct impact on lung cancer radiotherapy treatment planning. Earlier study from 3D conformal radiation therapy suggested dose computation from total normal lung excluding gross tumor volume (GTV) may be...
more accurate than that of excluding planning target volume (PTV). It is unclear which definition should be used to more accurately predict radiation pneumonitis (RP) in lung cancer patients treated with intensity-modulated radiation therapy (IMRT). We aim to determine a superior normal lung volume to more accurately predict symptomatic RP in lung cancer patients treated with IMRT. **Method:** This is a retrospective study. All patients treated with IMRT with at least 3 months follow-up are eligible. The normal lungs are defined by total lung volume excluding GTV, PTV or directly using the total lung volume. V5, V20, and MLD have been extracted for all three definitions. RP was diagnosed and graded according to the National Cancer Institute’s Common Terminology Criteria for Adverse Events, version 4.03. The primary endpoint was grade 2 or higher RP (RP2). Correlation between RP2 and dose parameters were analyzed by logistic regression. We compared RP prediction performance of each lung volume using area under the receiver operating characteristic curve (AUC). **Result:** A total of 184 consecutive patients treated between January 2014 and October 2017 were eligible. 26 patients (14%) developed RP2 within 3 months after treatment. Significant dosimetric difference was found between any 2-paired lung volumes (P<0.0001). All dose parameters from Lung-PTV method had significant correlation with RP2, with greater AUCs than the other two definitions. The best RP prediction performance was found in Lung-PTV volume MLD (AUC=0.649), which is significantly better than Lung-GTV volume MLD (AUC=0.611, P=0.006). **Conclusion:** There were significant dosimetric differences from various normal lung definitions. Excluding PTV method may accurately predict acute symptomatic radiation pneumonitis for IMRT treated lung cancer patients.

**Keywords:** Radiation pneumonitis (RP), Normal lung definitions, intensity-modulated radiation therapy (IMRT)
P2.01-01 THE IMPACT OF ANLOTINIB ON BRAIN METASTASES OF NSCLC: POST-HOC ANALYSIS OF A PHASE III RANDOMIZED CONTROL TRIAL (ALTER0303)

W. Liang1, Y. Zhao2, Y. Zhang3, X. Han4, X. Yang1, J. He4, K. Li1, B. Han1, .-. On Behalf Of The ALTER0303 Investigators1

1Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University, China State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, Guangzhou/CN, 2Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University; Guangzhou Institute of Respiratory Disease & China State Key Laboratory of Respiratory Disease, Guangzhou, China., Guangzhou/CN, 3The First Affiliated Hospital of Guangzhou Medical University: China State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, Guangzhou/CN, 4Chiatai Tianqing Pharmaceuticals, Nanjing/CN, 5First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN, 6Tianjin Medical University Cancer Institute and Hospital, Tianjin, China, Tianjin/CN, 7Shanghai Chest Hospital, Shanghai/CN

Background: Few evidence has measured the intracranial impact of multitargeted VEGFR-TKIs. Anlotinib hydrochloride, which targets VEGFR, PDGFR, FGFR and c-Kit, has been shown to significantly prolong PFS and OS compared with placebo as second/third-line treatment for NSCLC in a randomized, double-blind, phase III trial (NCT02388919). Herein we sought to analyze anlotinib’s effect in managing brain metastases (BM) and its brain-associated toxicities. Method: The PFS/OS of anlotinib versus placebo in those with and without BM records at baseline were calculated and compared respectively. In addition, time to brain progression (TTBP), a direct indicator of intracranial control, was also compared between anlotinib and placebo. All calculations were adjusted for confounding factors, including stage, histology, driver mutation type, etc. Result: A total of 437 patients (294 receiving anlotinib; 143 receiving placebo) were included. 97 cases (22.2%) were recorded to have BM at baseline. There were more BM cases among younger patients and those with adenocarcinoma. Both of the benefit magnitude from anlotinib over placebo were similar between BM and non-BM group in terms of PFS (BM: HR 0.19, 0.11-0.34; non-BM: HR 0.29, 0.22-0.37; interaction P=0.691) and OS (BM: HR 0.71, 0.44-1.16; non-BM: HR 0.67, 0.51-0.89; interaction P=0.789). More specifically, anlotinib was associated with significantly longer TTBPs (HR 0.11, 95% CI 0.03-0.41, P=0.001; Figure1) despite all confounders, indicating a 90% reduction of brain progression risk from anlotinib. Interestingly, anlotinib was also associated with more neural toxicities (18.4% vs. 8.4%, P=0.007) and psychological symptoms (49.3% vs. 35.7%, P=0.008) compared with placebo, especially infarction or cerebral hemorrhage. The above results were all confirmed both in intention-to-treat and per-protocol population.

Conclusion: Anlotinib can benefit NSCLC patients with brain metastases and is highly potent in managing intracranial lesions. Its special effect on brain metastases and cerebral tissues merits further investigation.

P2.01-02 OSIMERTINIB FOR EGFR-POSITIVE ADVANCED NSCLC WITH BRAIN METASTASES: PRELIMINARY ANALYSIS OF AN OPEN-LABEL, TWO-ARM, PHASE 2 STUDY

N. Peled1, O. Rotem2, A. Rozenblum2, H. Nechushtan2, L. Chen3, E. Dudnik4, A. Zer4, S. Yust-Katz4, I. Shelef4, L. Roisman5, E. Inbar1, W. Liang1, Y. Zhao2, Y. Zhang3, X. Han4, X. Yang1, J. He4, K. Li1, B. Han1, .-. On Behalf Of The ALTER0303 Investigators1

1Cancer Institute, Soroka University Medical Center, Beer-Sheva/IL, 2Rabin Medical Center, Davidoff Cancer Center, Petach Tikva/IL, 3Hadassah Medical Center, Jerusalem/IL, 4Neuro-Oncology Unit, Davidoff Cancer Center, Rabin Medical Center, Beilinson Campus, Petah Tikva, IL, 5Diagnostic Imaging Institute, Soroka Medical Center, Beer-Sheba/IL, 6Rabin Medical Center, Petach Tikva/IL

Background: Osimertinib is an EGFR tyrosine-kinase inhibitor (TKI) selective for both EGFR TKI sensitizing and Th970Met resistance mutations. While intracranial activity of osimertinib was observed in EGFR-mutant NSCLC in larger trials, a study focusing on patients with brain metastases was not reported yet. Method: This phase 2, open-label, two-arm study enrolled patients with EGFR-mutant, advanced NSCLC and at least one asymptomatic brain metastasis. Treatment-naïve (arm A) and Th970Met-positive patients who progressed on EGFR-TKI therapy (arm B) received osimertinib 80 mg QD. Dose escalation (160 mg QD) was performed in cases of intracranial progression without symptomatic systemic progression. The primary endpoint was intracranial metastasis response. The trial is ongoing (NCT02736513 at ClinicalTrials.gov) and here we present a preliminary analysis. Result: Between May 31, 2017, and November 30, 2017, (data cutoff), 20 patients started osimertinib (arm A=15, arm B=5). Median duration of follow-up was 43 weeks. Intracranial response was achieved in 11 (73%; 95% CI 45%-92%) of 15 arm A and in four (80%; 95% CI 28%-99%) of five arm B patients. Dose escalation was performed in four cases (arm A=2, arm B=2), with one continuous response (25%, 95% CI 5%-70%). Ten of 15 patients (67%) in arm A and one of five patients (20%) in arm B continue responding to osimertinib 80 mg at data cutoff. Median intracranial PFS (80 mg) was not available for arm A (95% CI 232 days–NA), and was 510 days in arm B (95% CI 161–not available). Toxic effects were similar to previous reported data. Conclusion: Osimertinib shows equal intracranial and systemic activity with minor side-effects in EGFR-mutant NSCLC as first-line, as well as in previously treated Th970Met-positive patients. It might therefore be a reasonable treatment for these patient populations and defer brain radiotherapy.

Keywords: NSCLC, osimertinib, brain metastases

P2.01-03 QUALITY OF LIFE OUTCOMES FOR FDA-APPROVED AGENTS IN ADVANCED NON-SMALL CELL LUNG CANCER

H. Albaba1, A. Bejak2, N. Leigh3

1Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto/ON/CA, 2Radiation Oncology, Princess Margaret Cancer Centre, Toronto/CA

Background: Symptom control and quality of life (QoL) improvement are among the most important goals of systemic therapy in advanced NSCLC, but they are not required for regulatory approval. We reviewed published QoL data for agents approved for use in advanced NSCLC by the United States Food and Drug Administration (FDA) and explore their potential uses in the era of precision medicine. Method: Through systematic review, we identified 19 agents approved by the FDA for the treatment of advanced NSCLC between 1999 and 2017. Clinical trials associated with regulatory approval of these agents were identified. QoL results were abstracted from study publications, in addition to trial characteristics (phase, sponsor). Result: 46 trials were identified supporting the FDA approval of the 19 agents. Of these, 33 (72%) were phase 3 randomized trials (including 3 cooperative group studies) and 13 (28%) were early phase (I/II) trials. QoL data were reported for 27 trials (59%), including all cooperative group trials. Another 5 (11%) measured QoL but results were not published. The remaining 13 (24%) trials did not measure QoL. 8/13 were phase III, 3/13 phase II and 2 phase I. In trials that reported QoL outcomes, better global QoL and cancer-related symptoms were identified in 17/33 (51%) and 18/33 (55%), respectively. Time to symptom deterioration was reported in 18 (55%) studies, with all but one showing benefit for the approved agent. The remaining studies reported no significant difference in QoL between study treatment arms. All studies reporting improved QoL parameters also reported improved response rates. In trials demonstrating OS and PFS improvement, 3/14 and 10/21 reported better QoL outcomes, respectively. ORR was higher in 26 trials, and it was associated with improvement in QoL in 12/26. Of 12 early phase trials leading to drug approval based on response rate and duration, 6 reported improved QoL outcomes. Three have not yet
reported QoL data and 3 did not measure QoL. **Conclusion:** QoL is clearly associated with response rate but improved QoL or symptom control was only demonstrated in 17/33 (51%) and 18/33 (55%) of studies supporting regulatory approval. QoL may be a clinically relevant endpoint for drug approval based on early phase trials of agents with high response rates and should be given further consideration by pharmaceutical sponsors and regulators in this era of precision medicine.

**P2.01-04 REDUCING TIME TO MOLECULAR DIAGNOSIS FOR ADVANCED NSCLC IN THE CONTEXT OF A REFERENCE TESTING CENTER**

**Background:** Testing for mutation of the epidermal growth factor receptor (EGFR) gene is required for treatment of patients with advanced non-small cell lung cancer (NSCLC). First-line treatment with an EGFR tyrosine kinase inhibitor (TKI) in NSCLC patients with an activating EGFR mutation significantly impacts survival. Within the Rossy Cancer Network, the McGill University Health Centre (MUHC) has a supra-regional designation to perform all thoracic surgeries, while the Jewish General Hospital (JGH) is the reference testing center for specialized molecular pathology services. Significant differences in time to TKI therapy were noted between these centers. Our objective was to identify contributing factors to reduce network-wide delays.

**Method:** We used the JGH molecular pathology database to identify all specimens tested for EGFR between 2015 and 2016 and mapped the process steps from diagnostic procedure to start of TKI therapy. We identified process differences and initiated reflex testing at the MUHC; EGFR testing was ordered reflexively by pathologists for all non-squamous NSCLC biopsies and other specimens from known or suspected advanced stage NSCLC. **Result:** Implementation of reflex testing led to a 13-day reduction from pathology specimen receipt to start of TKI therapy. We subsequently identified that MUHC time from molecular results to start of TKI therapy was twice that of the JGH (24 vs 12 mean days). This was due to an additional step requiring integration of faxed molecular results into the patients’ electronic health record.

**Conclusion:** We applied lean strategies to reduce time to initiation of targeted therapy. Within our network and in the context of a reference testing center, we identified two critical components that significantly contributed to delays in treatment planning: (i) absence of reflex testing and (ii) unlinked information technology systems. As Quebec moves towards specialized testing centers, it is important to be cognisant of their impact on timely treatment.

**Keywords:** Reflex testing, advanced NSCLC, EGFR

**P2.01-05 ADENOCARCINOMA OF THE LUNG: THE WOMAN’S CANCER?**

1Department of Oncology, Cumming School of Medicine, University of Calgary, Calgary/CA, 2Translational Laboratories, Tom Baker Cancer Centre, Alberta Health Services, Calgary/CA

**Background:** We previously observed a significant interaction between sex and age-standardized incidence rates of Non-small cell lung cancer (NSCLC) patients showing higher rates of Adenocarcinoma (ADC) in women, from the systematic review of published studies within the last 20 years. Our analysis showed disparities across gender over time, and the main effect of gender on incidence rates is significant (p = 0.01). This study aimed to replicate observed sex-related disparities in published records using a 15-year retrospective analysis of a local large-scale database of NSCLC patients diagnosed in Southern Alberta, Canada.

**Method:** We extracted data from the Glans-Look Lung Cancer Database, a comprehensive clinical and demographic database of all lung cancer patients diagnosed in southern Alberta from 1999-2015. We assessed the impacts of gender on NSCLC risks and mortality. Clinical data e.g. smoking history, histology and NSCLC stage were collected and analyzed using chi-square test, and smoking history and tumor stage were stratified for the analysis. The Kaplan-Meier analysis was conducted to compare gender-based post-diagnostic survival and disease progression. Statistical significance was 95% confidence level (p < 0.05).

**Result:** Among 7738 lung cancer patients, 95.6% (3743/7738) were NSCLC: 52% male and 48% female. Significant gender-based differences were observed in histology (p = 0.00), SCC and ADC were the most common histology in both genders. However, ADC was commoner in women (49% vs 41%), while SCC was commoner in men (27% vs 17%). Relative changes of ADC rate over 15 years have increased significantly among women compared to men (58% vs 32%, P < 0.02). The risk of developing NSCLC was greatly elevated with cigarette consumption in both genders; however, ADC in never smokers was higher in women (18%) compared to men (8%). Among ADC, smoking history and gender both showed a significant effect on survival, where OS for never-smokers females exceeded that of never-smokers males [20 months vs 14 months, 95% CI, P = 0.00]. The same trend was also seen in smokers [13 months vs 7 months, 95% CI, P = 0.02]. In addition, the OS among male ADC cases was significantly lower than women of all tumor stages (P = 0.00), but these disparities were insignificant across genders with SCC (P = 0.46).

**Conclusion:** Similar to what we observed in our systematic review, gender influences the clinical course of NSCLC regardless of smoking history or stage in Southern Alberta. Identifying the cause of the increase in ADC rate over 15 years in women and higher prevalence of NSCLC in never smoking women warrants aggressive research strategies.

**Keywords:** NSCLC, Gender, Adenocarcinoma

**P2.01-06 HSP72 EXPRESSION ASSOCIATES WITH SURVIVAL IN EGFR MUTATED NSCLC**

1City of Hope, Duarte/CA/US, 2City of Hope, Duarte/US

**Background:** Heat shock protein 72 (HSP72) was observed to be important for editing DNA replication errors and repairing base damage. EGFR mediates HSP72 Y41 stability via phosphorylation. EGFR tyrosine kinase inhibitor (EGFR-TKI) therapy inhibited phosphorylation of HSP72 in EGFR mutant NSCLC. Heat shock protein 72 (HSP72) leads to its degradation with suppression of polymerase α (Polα) and a resultant increase in overall mutation rate in EGFR mutant lung cancer cells. Our primary objective was to determine if baseline HSP72 expression is a prognostic biomarker for NSCLC patients with EGFR mutant NSCLC.

**Method:** A retrospective cohort of patients was identified with known EGFR mutation positive NSCLC and available tissue from the City of Hope Comprehensive Cancer Center seen between 2008 and 2016. Immunohistochemical (IHC) analysis was performed to analyze HSP72 expression using a chi-square test for categorical data and multivariate logistic regression analyses was used to study the relation between HSP72 expression and the other clinical and demographic data. **Result:** 48 patients with EGFR mutated NSCLC and available tissue were identified. The median age was 64 range (39-84) with 50% Asian (n = 24), Caucasian 38% (n = 18), and African American 8% (n = 4) and other 4% (n = 2). Most patients were Stage IV at initial diagnosis (n = 41, 85%), other were Stage IIB (n = 2), Stage IIIB (n = 1) and Stage IIIIA (n = 3). HSP72 expression
expression was 0 in 16 patients, 1 in 15 patients, 2 in 9 patients and 3 in 8 patients. Median survival of HSP72 0, 1, 2, 3 were 28.3, 42.4, 41.2, and 107.7 months respectively (p = 0.02, log-rank test). In univariate Cox regression analysis, HSP72 expression of 3 compared to others correlated with an HR of 0.23 (95% CI 0.07-0.77). When stratifying by stage (Stage IV vs all others), the HR associated with an HSP72 expression of 3 was 0.22 (95% CI 0.05-0.97), and the signal for HSP72 was also significant when stratifying by stage and considering HSP72 score as either a continuous marker or as the four categories (0,1,2,3). There was no relationship noted in the change in HSP72 values as tumors transformed from T790M+ to T790M-, and no relationship was related to LRT or exon 19 deletions. Conclusion: In EGFR mutated NSCLC, high levels of HSP72 expression are associated with improved survival. Further investigations are evaluating mechanisms of increased DNA damage following EGFR TKI therapy and association with the development of resistance.

P2.01 ADVANCED NSCLC
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.01-07 SAFETY AND EFFICACY OF LATTICE RADIOTHERAPY IN VOLUMINOUS NON-SMALL CELL LUNG CANCER: A RETROSPECTIVE STUDY OF 10 PATIENTS OVER 7 YEAR PERIOD
B. Amendola1, N. Perez2, I. Qureshi3, J. Melotek4, M. Amendola5, X. Wu6
1Radiation Oncology, Innovative Cancer Institute, South Miami/FL/US, 2Radiation Oncology, Innovative Cancer Institute, Coral Gables/FL/US

Background: Lattice radiotherapy (LRT) is a novel technique of delivering heterogeneous doses of radiation for the management of voluminous tumors which are not amenable to surgical resection. Built from the conventional 2-dimensional GRID, LRT utilizes the power of new technology in the field of radiation therapy to implement 3-dimensional dosimetry plans. LRT allows delivery of higher doses of radiation to small spheres, also called vertices, in the interior of the bulky tumors limiting the exposure of surrounding healthy tissue to unacceptable high doses of radiation. Method: Ten patients with non-small cell lung cancer (NSCLC): Nine males and 1 female, with ages from 49 to 87 with a median of 70 who presented with bulky, unresectable primary tumors were treated with LRT during a 7-year period. Follow-up ranged from 4 to 73 months with a median of 10 months. All patients received one initial LRT fraction of 18 Gy in the lattice vertices and 3 Gy in the tumor periphery. All patients continued treatment with conventional radiation given in 25 to 33 daily fractions of 1.8 Gy to 2 Gy each. Image guided radiation therapy IGRT with CBCT and Volumetric Arc Therapy technique were used in all patients. Result: There was no associated morbidity or mortality to the addition of LRT in these patients. There was a significant decrease in tumor volume from the time of planning CT to the last f treatment imaging. Conclusion: In this early experience, LRT appears to be a safe and effective modality of treatment for bulky NSCLC. LRT should be considered for non-surgical patients presenting with voluminous tumors. It is postulated that this technique induces changes in the tumor microenvironment leading to a more effective tumor control. More research is needed to elucidate the mechanisms by which LRT is effective in the reduction of tumor size.

P2.01-08 CONVERSION SURGERY FOR LOCALLY ADVANCED LUNG ADENOCARCINOMA HARBORING DRIVER GENE MUTATION AFTER TKI FOLLOWED BY CYTOTOXIC AGENT
M. Aoki, T. Umehara, G. Kaminoura, K. Kariatsumari, M. Yanagi, M. Sato
Department of General Thoracic Surgery, Kagoshima University, Kagoshima/JP

Background: The optimal treatment of locally advanced non-small cell lung cancer including stage IIIA still remains controversial. For lung adenocarcinoma harboring driver gene mutation, it has been reported that tyrosine kinase inhibitor (TKI) shows great tumor response and surgery after TKI treatment. Method: Between January 2016 and April 2017, we performed surgical resection for five non-small cell lung cancer patients who were under TKI followed by platinum agent and pemetrexed treatment at Kagoshima University Hospital. All patients were diagnosed as having c-stageIIA (three patients with c-T2aN2M0 and each one patient with c-T4N1M0 and c-T3N2M0) lung adenocarcinoma harboring driver gene mutation (four patients with EGFR mutation and one patient with EML4-ALK rearrangement) by preoperative examinations (Computed Tomography, 18F-fluorodeoxyglucose Positron Emission Tomography, brain Magnetic Resonance Imaging and bronchoscopic examination). Because these patients initially had locally advanced tumor burden or mediastinal lymph nodes metastasis, one-stage radical surgery would not have been feasible. Therefore, these patients received TKI administration for less than six months, followed by two cycles of platinum agent and pemetrexed treatment before the operation. After the operation, three patients received two or four cycles platinum agent and pemetrexed treatment, however, the other two patients did not receive additional treatment. We obtained informed consent from all the patients before the beginning of treatment. Result: In all patients, the effect on tumor response of TKI followed by platinum agent and pemetrexed treatment was shown. In addition, the complete resection was confirmed microscopically. None of these patients experienced disease flare after stopping TKI administration. The exon 20 T790M mutation gene was not identified in all resected specimens with EGFR mutation. There were no postoperative major complications and mortality. Brain metastasis appeared in one patient who did not receive postoperative chemotherapy six months after the operation. This patient was managed successfully with gamma knife radiotherapy. All the five patients are now under follow-up treatment with no local recurrence. Conclusion: Conversion Surgery after TKI followed by platinum agent and pemetrexed treatment can become feasible and useful strategy for locally advanced lung adenocarcinoma harboring driver gene mutation.

P2.01-09 TARGETABLE GENOMIC ALTERATIONS IN KRAS MUTANT LUNG ADENOCARCINOMA BY TARGETED NEXT GENERATION SEQUENCING
E. Arriola1, S. Clave2, M. Hardy-Werbín1, A. Taus3, P. Rocha1, I. Chaib1, E. Carcereny1, M. Salido1, A. Dalmas2, B. Bellosillo1
1Medical Oncology Department. Hospital Del Mar. Barcelona/ES, 2Pathology Department. Hospital Del Mar. Barcelona/ES, 3Laboratory of Cellular and Molecular Biology, Institut D’Investigació En Ciències Germans Trais i Pujol (igtp). Badalona/ ES, 4Medical Oncology, Catalan Institute of Oncology-Hospital Germans Trais i Pujol, Badalona/ES

Background: KRAS mutant (m) non-small cell lung cancer (NSCLC) represents 25% of cases. Despite the common mutation, biological and clinical behaviour of this disease is diverse. The aim of our study was to analyze co-occurring genomic alterations in advanced KRASm lung by next-generation sequencing (NGS) and compare them to a KRAS wild-type (WT) population. Method: Advanced lung adenocarcinoma patients treated with a platinum doublet with KRAS mutation by Sanger were submitted to targeted NGS with the Oncomine Solid Tumor kit (DNA) and compared to a KRAS WT population of clinically similar patients. Association with outcome of the genomic alterations was evaluated. Result: 32 KRASm patients and 18 WT patients were analyzed. The most frequent KRAS mutation was p.Gly12Cys (45%), followed by p.Gly12Val (24%). TP53 mutation was observed in 55% of KRASm tumors and 60% of WT cases (Table 1). Mutations in STK21 were found in 10% of cases in the KRAS mutant cohort while none in the WT. 3 out of the 4 cases of TP53 mutations, FGFR3, SMAD4 and DDR2 mutations were more frequently found in cases with KRAS mutations, although at low frequencies. Neither KRAS nor TP53 mutations had an impact in OS. We then selected the KRAS mutant cohort and evaluated the impact of co-mutations. TP53 or STK21 did not significantly affect OS of KRAS mutant patients. Table 1. Co-occurring alterations in KRAS mutant and WT tumors

**P2.01-10 PROGNOSTIC IMPACT OF LONGITUDINAL MONITORING OF RADIOMIC FEATURES IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER**

1Department of Radiology, Kangwon National University Hospital, Chuncheon/KR, 2Sungkyunkwan University, Suwon/KR, 3Samsung Cancer Research Institute, Seoul/KR, 4Samsung Medical Center, Seoul/KR, 5Department of Electronic Electrical and Computer Engineering, Sungkyunkwan University, Suwon/KR, 6Department of Medicine Section of Hematology-Oncology, Samsung Medical Center, Seoul/KR

**Background:** Tumor growth dynamics varies substantially in non-small cell lung cancer (NSCLC). We aimed to develop novel biometric biomarkers reflecting longitudinal change of radiomic features in NSCLC and evaluate prognostic power of those. **Method:** Fifty-three patients with advanced NSCLC included in this retrospective study. Measurable lesions on baseline and follow-up computed tomography (CT) were segmented and 23 radiomic features were extracted. All three variables reflecting patterns of longitudinal change were extracted: the area under the curve (AUC), beta value, and AUC2. We constructed models for predicting survival using multivariate Cox regression, and identified the performance of these models. **Result:** In volume, AUC2 showed an excellent correlation with pattern of longitudinal volume change \( r = 0.848 \), \( p < 0.000 \), and showed a significant difference in overall survival time \( p = 0.035 \). In multivariate regression analysis, kurtosis of positive pixel values \( p = 0.000 \), and surface area \( p = 0.001 \) on baseline CT, and AUC2 of density \( p = 0.000 \), skewness of positive pixel values \( p = 0.003 \), and entropy at inner \( p = 0.001 \) were found to be associated with overall survival time, and the area under the receiver operating characteristics curves were 0.922, 0.890, and 3 years, and 3 years of follow-up. **Conclusion:** Longitudinal change of radiomic tumor features would be prognostic biomarkers in patients with advanced NSCLC.

**Keywords:** Prognosis, follow-up, Radiomics

---

**P2.01-11 CHARACTERISTICS OF NON-SMALL CELL LUNG CANCER: DIFFERENCES BY SEX AND HORMONAL STATUS IN A HISPANIC POPULATION**

V. Rodriguez-Lara1, L. Ramirez-Tirado2, D. Flores3, F. Barron4, Z. Zatarain-Barron5, O. Arrieta6

1Unam, Mexico City/MX, Laboratory of Experimental Oncology, National Cancer Institute, Mexico, Df/MX, 2Unidad Funcional de Oncologia Toracica y Laboratorio de Medicina Personalizada, National Cancer Institute, Mexico City/MX, 3Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerologia, Mexico City/MX, 4Instituto Nacional de Cancerologia, Mexico City/MX

**Background:** Non-small Cell Lung Cancer (NSCLC) appears to be a different disease between women and men. Clinical features and lung cancer behavior were described, however hormonal characterization has been poorly approached. We describe the differences in NSCLC by sex and by hormonal status among women in a Hispanic population. **Method:** We performed a retrospective study among NSCLC patients from the National Cancer Institute of Mexico. We assessed clinic-pathological (tobacco, wood smoke and asbestos exposure, histology, disease stage, ECOG, Body Index Mass, Metastasis sites) and molecular characteristics (EGFR and KRAS mutation profile). Overall survival (OS) according to sex and hormonal status were estimated using the Kaplan-Meier method and compared using the Log-rank test. Multivariable cox-proportional analysis was performed adjusting for clinical and statistically relevant features. **Result:** Among the 1,104 patients 52.7% were men and 47.3% were women. Women were more likely to be non-smokers (68% vs. 23%, \( p < 0.001 \)), reported higher frequencies of wood-smoke exposure (50% vs. 28.2%, \( p < 0.001 \)), and of EGFR-sensitizing mutations (38.8% vs. 18.7%, \( p < 0.001 \)), had a better ECOG performance \( (r = 0.76, \ p = 0.02) \) and showed a higher frequency of BMI \( > 25 \) (47% vs. 44%, \( p = 0.03 \)). Likewise, women were more likely to be overweight or obese patients (vs. normal or obese patients) \( p = 0.045 \) and non-smokers \( p = 0.002 \) and patients with lower ECOG status \( p = 0.006 \). Differences were found also when considering hormonal status. Postmenopausal women showed higher wood-smoke exposure (52.5% vs. 41.7%, \( p = 0.037 \)) and wood-smoke exposure index \( (113.2\% \pm 50.6\% \ p = 0.006 \) as well as tobacco smoking exposure index \( (19.8 \pm 10.2 \ p = 0.017 \) compared to premenopausal younger women who exhibited higher frequencies of exposure to asbestos (16.7% vs. 7.0% \( p = 0.001 \) compared to postmenopausal. OS was better in postmenopausal women compared to premenopausal \( (31.1 \pm 19.4 \ p = 0.046 \). No differences were found between premenopausal and postmenopausal women stratified by EGFR mutation status regarding their clinic-pathological and molecular characteristics, neither in the OS. **Conclusion:** Our results support the differences in lung cancer presentation by sex and also by hormonal status. It is important to highlight that wood-smoke exposure and tobacco consumption were associated with hormonal status. Furthermore, premenopausal women (which showed a younger age at diagnosis) showed a worse OS regardless of other molecular features (e.g. EGFR, KRAS) which highlights the need of investigating in detail hormonal profiles when considering the clinical approach of NSCLC diagnosis and treatment.

**Keywords:** postmenopausal, premenopausal, Women

---

**P2.01-12 RAMUCIRUMAB+DOCETAXEL USAGE FOLLOWING RAPID DISEASE PROGRESSION IN REAL WORLD ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS**

M. Bauti1, C. Molife2, J. Clarke3, V. Stefanaki4, K. Winfree5, Z. Cui6, Y. Han7, M. Tawney8, P. Bonomi9

1Hematology/oncology, Rush University Medical Center, Chicago/IL/US, 2Eli Lilly and Company, Indianapolis/IN/US, 3Duke Cancer Center, Durham/NC/US

**Background:** In the Phase III REVEL study, the overall treatment effect of ramucirumab+docetaxel (ram+doc) in patients with rapid disease progression (RDP), defined as disease progression ≤ 12 weeks after start of platinum-based chemotherapy, was consistent with that observed in the intent-to-treat population. This real-world, retrospective study described baseline characteristics, treatment patterns, and clinical outcomes among RDP patients subsequently treated with ram+doc in the United States. **Method:** Advanced non-small cell lung cancer (aNSCLC) patients receiving ram+doc as 2nd line or 3rd line therapy between March 2015 - May 2017 after platinum-based chemotherapy, with ≥ 3 months of follow-up, were identified in the Flatiron Health EHR-derived database. Analyses were conducted for RDF and non-RDF patients. Overall survival (OS) was measured from start of 1st line therapy. Real-world progression-free survival (rwPFS) and time-to-progression (rwTP) were measured from start of ram+doc. OS, rwPFS, and rwTP were estimated using Kaplan-Meier method. **Result:** Baseline characteristics were generally similar across RDF (n = 49) and non-RDF (n = 123) patients with respect to age, gender, and race. Non-RDF patients more often had stage IV disease at diagnosis and no-squamous histology. Among patients with ECOG performance status (PS) reported (n=101, 58.7%), a higher proportion of RDF patients had ECOG PS 2 (18.4%) than non-RDF patients (9.8%). The majority of patients received ram+doc as 3rd line therapy and the median duration of ram+doc treatment was similar for RDF and non-RDF patients. The most frequently administered chemotherapy regimen prior to ram+doc was carboplatin+taxotere for RDF patients and carboplatin+taxotere+bevacizumab for non-RDF patients. RDF was associated with shorter median OS (13.2 [95% CI: 10.3 - 15.8] vs. 21.6 [95% CI: 17.1-24.1] months, log-rank \( p = 0.01 \) whereas median rwPFS (3.0 [1.8 - 4.1] vs. 3.6 [2.9 - 4.1] months, log-rank \( p = 0.03 \)rm+doc were similar between the RDF and non-RDF groups, respectively. **Conclusion:** While this real-world cohort shows that RDF correlates with poorer OS, similar rwPFS and rwTP were observed with ram+doc among aNSCLC patients with RDF vs. non-RDF. This study did not assess the effects of ram+doc vs. other subsequent treatments in patients with RDF. Further research is needed to identify RDF risk factors and to aid in development of optimal treatments for aNSCLC patients with the most aggressive disease.

**P2.01-13 NUMBER, RATHER THAN LOCATION OF METASTASES, DICTATES OUTCOME IN STAGE IV, M1B, NON-SMALL CELL LUNG CANCER**

A. Gibson1, H. Li2, A. D’Silva1, R. Tudor3, A. Elegbede1, S. Otsuka1, G. Bebb1, W. Cheung2

1Oncology, University of Calgary, Calgary/CA, 2Mathematics and Statistics, University of Calgary, Calgary/CA, 3Medicine, University of Calgary and Alberta Health Services, Calgary CA

**Background:** To assess the impact of location versus number of extra-pulmonary metastatic sites (EPMS) on survival in stage IV non-small cell lung cancer (NSCLC). **Method:** A large scale, multi-year retrospective
analysis was conducted on patients with a new diagnosis of stage IV, M1b (AJCC 7th edition) NSCLC between 1999–2013. Demographic, clinical, histopathological, treatment and outcome data was extracted from the Canadian institutional Glians-Look Lung Cancer Database. We assessed the impact of location and number of EPMS and identified correlates of overall survival using the Kaplan-Meier method and Cox regression. Result: A total of 2,065 NSCLC patients with EPMS were identified. Median age was 67 (IQR 58–75) years, 52% were male, and 78% reported a history of smoking. 60% had one EPMS, and 40% had two or more EPMS. Among those with only one EPMS, most frequent organ involvement included bone (40%), brain (32%), liver (13%) and adrenal (10%). Median overall survival (mOS) was worst in those with liver metastasis and best in those with adrenal metastasis (2.0 vs. 5.2 months, p=0.015). However, outcomes based on organ site involvement did not retain prognostic significance in multivariable analysis after controlling for other measured confounders. Compared to patients with one EPMS, individuals with ≥ 2 EPMS experienced worse outcomes (mOS 3.9 vs 2.9 months, p<0.001), and were associated with worse prognosis in Cox regression analysis (HR 1.5, 95%CI 1.3–1.7, p<0.001). A statistically and clinically significant inverse relationship persisted between increasing number of EPMS sites and mOS. Those patients who received systemic anti-cancer therapy or surgical resection of metastatic disease (received by 25% and 3% of total cohort respectively) demonstrated the most improved mOS, regardless of number or location of EPMS (10.0 vs 2.0 months, p<0.001, and 9.0 vs 3.0 months, p<0.001, respectively).

Conclusion: We conclude that number, rather than location of EPMS is a prognostic factor in patients with stage IV M1b NSCLC. A simple count of metastatic sites at diagnosis may be of clinical value in the management and advanced care planning for patients with metastatic NSCLC. Of note, this could assist in identification of patients who would benefit from either more aggressive treatment or best supportive care, and may be an important consideration in future clinical trial design. Overall, this study reinforces the need to determine and mitigate the factors predisposing patients to develop metastatic disease, and develop initiatives to reduce the number of patients presenting with advanced disease.

P2.01 ADVANCED NSCLC TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.01-14 PREFERRED AND ACHIEVED GOALS OF PATIENTS WITH METASTATIC LUNG CANCER AND THEIR ONCOLOGISTS IN END-OF-LIFE THERAPY

A. Becker, A. Mieras, R. Pasman, B. Onwuteaka-Philipsen
Pulmonology, Vumc, Amsterdam/NL

Background: Systemic therapy with chemotherapy, immunotherapy or targeted therapy are possible treatments for patients with metastatic lung cancer (stage IV NSCLC). This palliative treatment might prolong survival and reduce symptoms but frequently causes side-effects which may decrease the quality of life (QOL). Little is known about patients and oncologists’ goals before starting a new therapy. Therefore, we studied the goals patients and their oncologists have before starting a new treatment for stage IV NSCLC and to what extent these goals are achieved.

Method: Patients with stage IV NSCLC were prospectively studied in three hospitals between November 2016 and April 2018. At the start of systemic therapy patients and their oncologists were asked to complete a questionnaire about their treatment goals. These open questions were coded by the investigators. After treatment patients and oncologists were asked to what extent the goals they mentioned before were achieved. The data collection has not been finished yet. Now we report the preliminary results of 240 patients and their oncologists on predefined goals and of 90 patients (whose treatment was finished) and oncologists on achieved goals.

Result: Patients and oncologists most often mentioned improvement in QOL (49% 74%), a decrease in tumor size (44% 68%) and life prolongation (43% 50%) as treatment goals. 19% of the patients mentioned cure as a treatment goal. According to patients life prolongation and improvement in QOL were achieved in 56% and 51% respectively. According to oncologists this was only 35% and 32% respectively.

Conclusion: Patients and oncologists mention improvement in QOL, decrease in tumor growth and life prolongation most often as treatment goals. It can be questioned whether the 19% of the patients who mentioned cure as a treatment goal think this is a realistic goal or that it is more a sign of hope. After treatment, patients were more optimistic about the treatment effects than their oncologists.

Keywords: quality of life, goals, achievement

P2.01-15 A RADIOLOGIST-LED TRAINING WORKSHOP FOR MR BASED NORMAL TISSUE AND TUMOUR DELINEATION FOR LUNG CANCER RADIOTHERAPY

S. Brown1, M. Dubec2, H. Bainbridge3, D. Cobben4, F. Lalezari5, F. McDonal6,1, H. Shekh1, C. Van Es1, M. Van Herk2, C. Fairev-Finn4
1Radiotherapy Related Research, The Christie NHS Foundation Trust, Manchester/GB, 2Cmpeirr, The Christie NHS Foundation Trust, Manchester/GB, 315 Costow Road, Institute of Cancer Research & Royal Marsden Hospital, London/GB, 4Department of Radiatherapy Related Research, University of Manchester-The Christie NHS Foundation Trust, Manchester/GB, 5Radiology, Nki/avl, Amsterdam/NL, 6Department of Clinical Oncology, The Christie NHS Foundation Trust, Manchester/GB

Background: A potential benefit of MR–image guided radiotherapy (MRigRT) in lung cancer is the reduction of treatment related uncertainties through improved soft tissue contrast. However, this benefit may be obscured by inter-observer variation in gross tumour volume (GTV) and organ at risk (OAR) contouring. A radiologist led workshop was organised to provide training in such contouring on MR.

Method: Planning CT, PET-CT and MRI were acquired in four lung cancer patients. MR sequences included 3D radial gradient echo, T2 DIXON Turbo Spin Echo (TSE), and T2 TSE with and without fat-sat. Data sets were local rigidly registered and imported into the so-called “Big Brother” contouring software. The radiologist led teaching on OAR and GTV contouring used an MR lung atlas (produced by this group). Seven radiation oncologists contoured the brachial plexus (BP), heart, proximal bronchial tree, oesophagus and GTV. This was followed by a multi-disciplinary group discussion (oncologists, radiologists and physicists) on the contouring challenges and subsequently contours were reviewed and the atlas adjusted.

Result: The BP and heart were the most difficult OARs to contour and showed the largest inter-observer variation. Following contour review and discussion between radiologist and oncologists updates to atlas and protocols were made. The GTV was found to be most challenging at the soft tissue interfaces and requires further work (Figure 1).

Conclusion: This early work demonstrates the need for radiologist-led training in OAR and GTV contouring in lung cancer patients using MR images. This will be especially important for the integration of MR into treatment planning and an MRigRT adaptive workflow. We have arranged future workshops in order to provide further training and to assess inter-observer variation in OAR and GTV contouring using MR on more cases.

P2.01-16 DYNAMIC CTDNA MONITORING REVEALED NOVEL RESISTANCE MECHANISMS AND RESPONSE PREDICTORS OF OSIMERTINIB TREATMENT IN EAST ASIAN NSCLC PATIENTS

J. Chang1, Z. Hu1, D. Ji2, S. Chuai2, W. Shen1, J. Cao1, J. Wang1, X. Wu2
1Fudan University Shanghai Cancer Center, Shanghai/CN, 2Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai/CN.

Background: Advanced NSCLC patients, harboring EGFR T790M mutation, exhibit marked diversity in tumor behavior and response to AZD9291, yet a discriminable molecular profile remains elusive. In addition, although EGFR T790M was involved in ~30% of AZD9291 resistance cases in Western patients, mechanisms for the rest patients remain unclear, especially for the East Asian population. We utilized circulating tumor DNA (ctDNA) profiling to conduct dynamic monitoring in patients undergoing AZD9291, thus characterizing mutational heterogeneity and genomic evolution.

Method: Longitudinal plasma samples were collected before, during and post of the AZD9291 treatment in Chinese NSCLC patients with acquired T790M mutation. A ctDNA panel, spanning 160KB of human genome, was used to perform capture-based targeted sequencing that comprises critical exons and introns of 168 genes. The EGFR mutation abundance and dynamic changes of allele fraction (AF) were analyzed with progression-free survival (PFS) after AZD9291 treatment. Result: A total of 61 samples were collected longitudinally from 14 patients, of which 9 have experienced progressive disease (PD). Six patients exhibited a rebound of ctDNA prior to radiographic PD, suggesting the potential of ctDNA in early detection of PD. Several acquired mutations were detected with the AZD9291 resistance, including newly identified EGFR G796S, L792H/F/R/V, V802F, V843I mutations, expect for the previously reported R81 and EGFR C797S, L718Q mutations. Patients with a higher ratio of T790M and EGFRactivating mutation at baseline had a significantly longer PFS (9.6m vs 4.5m, p=0.008). A lower ratio of EGFRactivating mutation AF compared to baseline at first follow-up was significantly correlated with a longer PFS (8.5m vs 5.0m, p=0.027). Furthermore, patients harboring other known driver mutations in addition to T790M and EGFR (such as RB1 and PTEN) had an inferior PFS (4.9m vs 7.5m, p=0.039). Conclusion: Several novel resistance mechanisms were identified by ctDNA monitoring in the East Asian patients treated with AZD9291. Relative AF of T790M, changes of AF after treatment and the presence of concurrent driver mutations at baseline could predict clinical benefit of AZD9291 treatment.

P2.01-17 MALAT1-MIR-101-SOX9 FEEDBACK LOOP MODULATES THE CHEMO-RESISTANCE OF LUNG CANCER CELL TO DDP VIA WNT SIGNALING PATHWAY

W. Chen
Huaian No.1 People’s Hospital, Huaian/CN

Background: Cisplatin (DDP)-based chemotherapy is a standard strategy for lung cancer, while chemoresistance remains a major therapeutic challenge. Recent evidence highlights the crucial regulatory roles of long non-coding RNAs (lncRNA) in tumor biology. Metastasis-associated lung adenocarcinoma transcript 1 (MALAT1) has important roles in regulating non-coding RNAs (lncRNA) in tumor biology. Metastasis-associated lung adenocarcinoma transcript 1 (MALAT1) has important roles in regulating non-coding RNAs (lncRNA) in tumor biology. To date, the function of MALAT1 in DDP-resistant cancer cells remains unclear. In this study, we aim to investigate the potential impact of MALAT1, miR-101 and SOX9 in DDP-resistant cancer cells.

Method: A549/DDP and H1299/DDP cells were used for cell lines, and A549 and H1299 cells were used as controls. The expression level of MALAT1, miR-101 and SOX9 was measured by qPCR. The functional role of MALAT1, miR-101 and SOX9 was assessed by overexpression and silencing. The Wnt signaling pathway was investigated by immunofluorescence analysis.

Result: Knockdown of MALAT1 significantly increased the sensitivity of A549/DDP cells to DDP treatment, while overexpression of MALAT1 significantly decreased the sensitivity. Knockdown of miR-101 also increased the sensitivity of A549/DDP cells to DDP treatment. Overexpression of SOX9 rescued the DDP sensitivity of A549/DDP cells. Further, co-expression of MALAT1 and SOX9 showed additive effects on DDP sensitivity. Conclusion: MALAT1 acts as a competing endogenous RNA to upregulate SOX9 expression by sponge miR-101 in DDP-resistant cancer cells, through Wnt signaling pathway. This may offer a novel therapeutic strategy for the treatment of DDP-resistant lung cancer.

P2.01-18 DIFFERENTIAL MOLECULAR MECHANISMS ASSOCIATED WITH DRAMATIC AND GRADUAL PROGRESSION IN NSCLC PATIENTS WITH INTRATHORACIC DISSEMINATION

Y. Chen1, B. Huai1, W. Li1, C. Zhang1, W. Tang1, A. Wang2, X. Wu1, J. Chen1, J. Su1, Y.W. Shao1, Y. Wu1, W. Zhong1
1Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/CN, 2Translational Medicine Research Institute, Toronto/CA

Background: Lung cancer is a highly heterogeneous disease with diverse clinical outcomes. The pleural cavity is a frequent metastasis site of proximal lung cancer. Better understanding of its underlying molecular mechanisms associated with dramatic and gradual progression of pleural metastasis in patients with non-small cell lung cancer (NSCLC) is essential for prognosis, intervention and new therapy development. Method: We performed whole-exome sequencing (WES) of matched primary lung adenocarcinoma and pleural metastatic tumors from 26 lung cancer patients with dramatic progression (DP, n=13) or gradual progression (GP, n=13). Somatic alterations at both genome-wide level and gene level were detected. Kaplan-Meier survival analysis and multivariate Cox regression models were applied to analyze the association between different somatic alterations and clinical parameters. Result: We first analyzed the differences in somatic alterations between AP and RP group in the primary tumors, and identified higher somatic copy number alteration (SCNA) level in DP group compared to GP group, which is significantly (p=0.016) associated with poorer progression-free survival (PFS). More specifically, patients with chromosome 18q loss in the primary tumor showed a trend (p=0.107) towards poorer PFS. PTEN (p=0.002) and GNAS (p=0.002) mutations are enriched in the primary tumors of DP group, and are associated with poorer PFS. Furthermore, pleural metastatic tumors harbor a relatively higher level of mutation burden (p=0.105) and significantly increased SCNA (p=0.035) compared to the primary tumors. Conclusion: NSCLC patients in the attenuated progression group have more stable genomes. High level of genomic instability, GNAS and PTEN mutations, as well as chromosome 18q loss are associated with rapid progression.

P2.01 ADVANCED NSCLC

P2.01-19 RADIOMICS FEATURES OF CONTRAST ENHANCED CT AS PROGNOSTIC FACTORS IN RESECTABLE ADENOCARCINOMA OF LUNG

J. Choi1, S.M. Lee1, J.B. Seo1, S.H. Choi2
1Radiology, Asan Medical Center, Seoul/KR, 2Thoracic Surgery, Asan Medical Center, Seoul/KR

Background: To identify radiomics features as prognostic factors in patients with adenocarcinoma of lung and assess its incremental value to the traditional staging system and clinical-pathologic risk factors.

Methods: Total 1085 patients who underwent surgery for lung adenocarcinoma were enrolled in this study (March 2010 to December 2014, training cohort: n = 749; from January 2015 to February 2016, temporal validation cohort: n = 336). A subset of 80/94 reproducible radiomics features including shape, first order statistics and texture features were identified and selected for analysis. A radiomics signature to predict (overall survival, OS and recurrence free survival, RFS) was generated by using the least absolute shrinkage and selection operator, or LASSO in training cohort. Association between the radiomics signature and prognosis was explored. Prognostic models incorporating radiomics signature alone and combined clinical-pathologic risk factors including staging system, age, sex, smoking status and adenocarcinoma subtype were tested in the temporal validation cohort.

Result: The radiomics signatures (constructed from 5 features identified from LASSO) were significantly associated with OS and RFS. Compared with traditional staging, the radiomics signature resulted in better performance for the estimation of OS (C-index for radiomics signature vs TNM staging = 0.726 vs 0.689 in training set, 0.796 vs 0.766 in validation set) and RFS (0.760 vs 0.722 in training set, 0.773 vs 0.751 in validation set) in both training and validation cohorts. The combined model of radiomic signature and clinical-pathologic risk factors showed a significant improvement of predictive performance over the TNM staging system in both training and validation cohorts (OS, C-index = 0.774 in training set and 0.857 in validation set; RFS, C-index = 0.796 in training set and 0.837 in validation set; for all, p < 0.05).

Conclusion: Contrast enhanced CT-based radiomics provided improved prognostic prediction in resectable lung adenocarcinoma, which might enable a step forward precision medicine and affect personalized postoperative treatment strategies.

P2.01-20 FLT-PET FOR DETECTION OF RELAPSE FOLLOWING RADIOTHERAPY FOR LUNG CANCER. PRELIMINARY RESULTS

T. Christensen1, S. Langer1, K. Larsen1, G. Persson1, A. Amtoft1, H. Jøhannesen1, S. Keller1, A. Kjaer1, B. Fischer2
1Department of Clinical Physiology, Nuclear Medicine, and PET, Rigshospitalet, Copenhagen University Hospital, Copenhagen/DK, 2Department of Respiratory Medicine, Bispebjerg University Hospital, Copenhagen/DK

Background: Differentiation of relapse from radiation induced changes of the normal lung tissue following radiotherapy for lung cancer is challenging. CT and 18F-fluorodeoxyglucose (FDG) PET/CT has low specificity due to radiation induced changes; and invasive procedures might be unbearable due to small size, difficult location, or poor lung function. 18F-fluoromisonidazole (FLT) is a PET tracer that correlates with proliferation. FLT-PET is more specific than FDG-PET and does not accumulate in inflammatory tissue. The aim of this study is to investigate if FLT-PET is a key to better diagnosis of relapse in this difficult situation.

Methods: Patients who had received definitive radiotherapy for lung cancer and who were suspected for having a relapse were included in this prospective clinical study. Patients underwent FDG-PET/CT and FLT-PET/low dose CT within 3 weeks. PET scans were evaluated visually by three experienced radiologists, and the worst grade and the worst lesion in each patient was selected for semi-quantitative measurements. Reference standard was a retrospective expert analysis based on histology, subsequent imaging, conference decisions, and treatment within 6 months after inclusion. Descriptive statistics and diagnostic accuracy tests were conducted.

Results: We present the results from the first 18 patients. All patients had been treated with definitive radiotherapy (66 Gy in 24 or 33 fractions), and 17 patients had concomitant or sequential chemotherapy. FLT-PET was performed 34-541 days after radiotherapy. 7 patients had no evidence of relapse during the follow up period. 11 patients were diagnosed with relapse based on positive biopsy (3), further progression on CT within 6 months (4), further metabolic progression on FDG-PET/CT and cytology suspicious for malignancy (1), progression on the initial FDG-PET/CT and treatment with response (1), or disseminated disease/bone metastases (2). Maximum standardized uptake value (SUVmax) of FDG and FLT were higher in the lesions with relapse. Mean FDG SUVmax in lesions with relapse vs benign lesions was 13.7 vs 4.9 (range: 4.0-18.0 vs 3.3-6.7). Mean FLT SUVmax in lesions with relapse vs benign lesions was 4.1 vs 2.7 (range: 1.8-6.3 vs 1.7-3.3). Sensitivity; specificity; positive predictive value (PPV); and negative predictive value of FDG-PET/CT vs FLT-PET were 100%/57%/85%/100% vs 73%/100%/100%/78%.

Conclusion: With a PPV of 100% FLT-PET is a promising non-invasive tool for diagnosing relapse after radiotherapy with the potential to obviate invasive procedures in some patients. Further validation is needed.

P2.01-21 ANTIGEN CASCADE TRIGGERING CORRELATES WITH PROLONGED SURVIVAL IN ADVANCED NSCLC PATIENTS UNDERGOING PD-1 BLOCKADE WITH NIVOLUMAB.

P. Correale1, R. Giannicola1, G. D’Arrigo2, P. Pastina1, V. Nardone4, C. Botta4, V. Barberi1, G. Tripepi1, M. Monoriti1, L. Pirtoli1, R. Saladino1, A. Falzea1, P. Tagliaferri1

Background: Programmed-cell-death receptor-1 (PD-1) blockade by Nivolumab mAb is a promising treatment for metastatic (m) NSCLC patients, which may yield dramatic improvement in benefit and survival. It acts by rescuing the antitumor activity of PD-1-inactivated tumor-infiltrating lymphocytes, residual of a pre-existing immune-reaction naturally occurring or consequential to prior radio/chemo-therapy. T-cell rescue is indispensable for the immediate response to the treatment, however, in order to obtain a prolonged effect on patients’ survival continuous immune-immunizing ability to supply fresh immune-effectors with antitumor activity, appears to be indispensable. We have thus investigated, whether Nivolumab treatment is also able to promote antigen cascade and cross-priming measured as occurrence of autoantibody and auto-immunity and whether these effects are predictive of positive outcome in mNSCLC patients.

Method: This is a multi-institutional retrospective study including ninety-eight mNSCLC patients who received Nivolumab therapy (3mg/kg every 15 days) between September 2015 and March 2018. These patients had received at least a previous line of platinum-based doublet +/- bevacizumab. Log-rank test and Mantel-Cox analysis were carried out to correlate patients’ PFS and OS with different parameters including baseline and post-treatment levels of inflammatory markers (CRP, ESR, LDH), ANA, ENA, ASMA auto-antibodies (AABs); hormone-profiling; Th1, Th2, Th17 cytokines; regulatory-T-cells, different CTL subsets, and natural killers.

Result: We recorded a PFS and OS of 12.5 [95%CI:9.9-15.0] and 15.3 [95%CI:12.8-17.9] months, respectively, not correlated to histology, number of previous chemotherapy lines, radiotherapy, or TKI use. A better outcome was found in males (OS, HR=2.3, 95%CI: 1.1-4.8, P=0.028), in those who presented autoimmunity signs (PFS: 17.2 vs 6.7 months; HR=0.30, 95% CI: 0.15-0.57, P<0.001; OS:20.8 vs. 9.7 days; HR=0.24, 95% CI: 0.11-0.50, p<0.001) and those who showed early rise (within thirty days) of one (score 1, HR=2.9, 95% CI: 0.784-6.54, P=0.018) or more AABs (score 2 HR=0.22, 95% CI: 0.081-0.624, P=0.001). Finally, Cox analysis revealed a predictive role for treatment-related early increase in eosinophil cell counts (OS, HR: 0.68, 95% CI: 0.57-0.81, P=0.031).

Conclusion: Antigen cascade triggering measured as early occurrence of ANA ENA, ASMA AABs and subsequently, self-limiting autoimmunity is strongly predictive of prolonged survival in mNSCLC patients receiving Nivolumab. Additionally, the occurrence of AABs strongly supports the occurrence of Nivolumab- dependent antigen cascade and cross-priming. These results offers a strong rationale to design future perspective trials in NSCLC patients.

**P2.01-22 INCREASED INCIDENCE, MORBIDITY AND MORTALITY RATES FOR LUNG CANCER IN WOMEN IN BRAZIL BETWEEN 2000 AND 2014**

G. Costa1, M. J. De Mello2, C. G. Ferreira3, A. Bergmann4, L. C. Thuler5

1Department of Oncology, Instituto Medicina Integral Prof Hernando Figueira, Recife/BR, 2Clinical Research Division, Instituto Medicina Integral Prf Fernando Figueira, Recife/BR

**Background:** Introduction: Lung cancer is the principal cause of death from cancer worldwide. However, little is known of its epidemiological and histological profile and of the incidence and mortality rates in Brazil according to sex. Objectives: To evaluate the incidence, morbidity and mortality rates of lung cancer in Brazil from 2000 to 2014, as well as the epidemiological and histological profile of the disease. **Method:** An analytical, cross-sectional study was conducted using three types of sources of secondary data; population-based cancer registries, hospital-based cancer registries and the national mortality database. **Result:** The incidence rate in women increased from 7.92/100,000 in 2000 to 9.12/100,000 in 2012, while mortality increased from 6.02/100,000 in 2000 to 8.29/100,000 in 2014. In men, the incidence decreased from 23.40/100,000 in 2000 to 18.47/100,000 in 2012 and mortality also fell from 16.12/100,000 to 15.11/100,000 in 2014. There was a reduction in the male-to-female ratio from 2.54 in 2000 to 1.46 in 2014. Women tended to be younger (p<0.001), black (p<0.001), non-smokers (p<0.001) and have adenocarcinoma or small-cell lung cancer (p<0.001), and to have metastatic disease (p<0.001). In addition, the time between diagnosis and the start of cancer treatment was longer in women (p<0.001). In relation to treatment, women were more likely to have undergone surgery, surgery in combination with chemotherapy (p<0.001) and to have response to the initial treatment (p<0.001). **Conclusion:** An increase was found in the incidence and mortality rates of lung cancer in women in Brazil.

**Background:** Median progression free survival (PFS) for ALK tyrosine kinase inhibitors (ALK-TKIs) range from 10.9–25.7 months (mos)2,3,4,5. While most ALK+ NSCLC patients develop resistance to ALK-TKIs within 1–2 years, a subset of patients experience a response >2 years. Given the lack of proteogenomic markers predicting long-term responses to ALK-TKIs, we conducted whole-exome sequencing (WES) and proteomic profiling of primary tumor tissue biopsies to predict a long-term response to ALK-TKI therapy. **Method:** To evaluate the incidence, morbidity and mortality rates of lung cancer in Brazil from 2000 to 2014, as well as the epidemiological and histological profile of the disease. **Result:** In this study, we found that ALK+ NSCLC patients identified a protein signature that may predict a long-term response or resistance to ALK-TKIs. A collaboration is in development to confirm the validity of this protein signature in a larger cohort, and with next-generation ALK-TKIs.

**Keywords:** ALK+, long-term response, Proteomic

**P2.01-24 MLPH ACTIVATES CDC42/PAK1 SIGNALING TO PROMOTE EPITHELIAL–MESCHELINAL TRANSITION VIA TGF-β IN NON-SMALL CELL LUNG CANCER**

C. Wei1, L. Peng2, F. Tong3, C. Xiong4, X. Dong5

1Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/CN

**Background:** Brain metastasis (BM) is associated with poor prognosis, recurrence, and death in patients with non-small cell lung cancer (NSCLC). Therefore, a better understanding of molecularmechanisms underlying NSCLC development and progression could provide helpful insights for NSCLC prevention and effective treatment. **Method:** RNA-Sequencing was performed to define a genomic signature predictive of a long-term response to ALK-TKIs from our small cohort. However, MRM-MS identified 15 proteins differentially regulated between LR and NR, including SODE, F13A1, LYAM1, FCGBP, PGBM and LUM. Differences in protein levels were further pronounced between LR and NR. To determine whether our protein signature can discriminate according to response groups, we performed principal component and hierarchical clustering analyses. Both analyses successfully segregated LR from R and NR. Moreover, we used our set of 15 proteins to generate single-sample Gene Set Enrichment Analysis scores which distinguished LR from R and NR as distinct groups. **Conclusion:** Targeted proteomic profiling of baseline plasma from ALK+ NSCLC patients identified a protein signature that may predict a long-term response or resistance to ALK-TKIs. A collaboration is in development to confirm the validity of this protein signature in a larger cohort, and with next-generation ALK-TKIs.

**Keywords:** ALK+, long-term response, Proteomic
and BM. Stable over-expression and knock-down of miR-330-3p in NSCLC cells was constructed with lentivirus. Expression levels of miR-330-3p in NSCLC cells were quantified by quantitative real-time PCR (qRT-PCR). The effects of miR-330-3p on NSCLC cells were investigated using assays of cell viability, migration, invasion, cell cycle, apoptosis, western blotting, immunohistochemical and immunofluorescence staining. A xenograft nude mouse model and in situ brain metastasis model were used to observe tumor growth and brain metastasis. The potential target of miR-330-3p in NSCLC cells was explored using the luciferase reporter assay, qRT-PCR, and western blotting. The miR-330-3p targets were identified using bioinformatics analysis and verified by luciferase reporter assay. Result: High serum miR-330-3p was an independent risk for BM. Tissue miR-330-3p was also higher in subjects with BM (P = 0.003). Migration and invasiveness were increased by over-expressing miR-330-3p using a lentivirus, and decreased by miR-330-3p knockdown in both cell lines. In nude mice receiving NSCLC cells, either subcutaneously or into the brain, tumor growth was faster in mice receiving cells permanently expressing exogenous miR-330-3p, and slower in cells expressing the anti-miR-330-3p sequence. Bioinformatics analysis, followed by microarray analysis of A549 cells over-expressing miR-330-3p and luciferase reporter assay suggested the glutamate receptor GRIA3 is regulated by miR-330-3p via MAPK/MEK/ERK signaling pathway. A549 cells over-expressing miR-330-3p and luciferase reporter assay 3p sequence. Bioinformatics analysis, followed by microarray analysis of exogenous miR-330-3p, and slower in cells expressing the anti-miR-330-3p sequence. Bioinformatics analysis, followed by microarray analysis of A549 cells over-expressing miR-330-3p and luciferase reporter assay suggested the glutamate receptor GRIA3 is regulated by miR-330-3p via MAPK/MEK/ERK signaling pathway. Conclusion: miR-330-3p promotes NSCLC brain metastasis possibly in part via the MAPK/MEK/ERK pathway and GRIA3, and might be a potential target for the further research of NSCLC brain metastasis. Keywords: metastasis, miR-330-3p, MAPK/ERK signaling

P2.01 ADVANCED NSCLC TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.01-26 ASSOCIATION OF BASE EXCISION REPAIR GENE POLYMORPHISMS WITH RESPONSE TO CHEMOTHERAPY OF ADVANCED NON SMALL-CELL LUNG CANCER J. Dong1, X. Wang2, J. Cui2 1Breast Center, Peking University Shougang Hospital, Beijing/CA, 2Cancer Center, The First Hospital of Jilin University, Changchun/CA Background: Base excision repair (BER) plays an important role in the maintenance of genome integrity and drug resistance. This study aims to explore the role of BER genes polymorphisms in response to chemotherapy of advanced non small-cell lung cancer (NSCLC) patients treated with platinum-based chemotherapy. Method: During the period from November 2009 to January 2016, a total of 152 patients diagnosed with stage III or IV at Jilin University First Hospital were admitted into our study. The XRC1, G28152A, MUTYH G972C, HOG1 C1245G, PARP1 T2444C polymorphisms of all the patients were detected by mass spectrometry. And the relationship between BER genes polymorphisms and the response of platinum-based chemotherapy is analyzed by Logistic regression. Result: Logistic regression model shows that the response rate of chemotherapy of the PARP1 T2444C polymorphisms, CC genotype (OR: 5.216, 95%CI: 1.568-17.352, P = 0.007) and TC genotype (OR: 2.692, 95%CI: 1.007-7.198, P = 0.048) is significantly higher than that of TT wild type, as well as the genotype of TC together with CC (OR: 3.178, 95%CI:1.229-8.219, P = 0.017). There is no relationship between G28152A, MUTYH G972C, XRC1, HOG1 C1245G gene polymorphism and chemosensitivity. Conclusion: PARP1 T2444C mutation allele C might be associated with the decreased sensitivity to platinum based chemotherapy in advanced NSCLC. Our findings may be helpful towards designing individualized cancer treatment. Keywords: gene polymorphism, Platinum, non-small cell lung cancer

P2.01-27 MR, CT AND CONE-BEAM CT FOR LYMPH NODE VISUALISATION IN LOCALLY-ADVANCED LUNG CANCER M. Dubec1, S. Brown2, A. Salem3, D. Cobben4, M. Van Herk5, C. Faivre-Finn4, C. Faivre-Finn1 1Radiotherapy Related Research, The Christie NHS Foundation Trust, Manchester/GB, 2Division of Cancer Sciences, University of Manchester, Manchester/GB, 3Division of Cancer Sciences, The University of Manchester, Manchester/GB Background: The largest benefit of MR-guided radiotherapy in lung cancer may be on-board visualisation of malignant lymph node (LN). In this study, we assessed whether MR images were suitable for LN visualisation for treatment adaptation. We hypothesised that MR would outperform CT and Cone-Beam CT (CBCT). Method: CT, CBCT and MR images were acquired in four lung cancer patients with malignant LNs, confirmed using PET-CT and/or endobronchial ultrasound-guided biopsies. A total of 15 LNs from mediastinal and hilar nodal stations were assessed. Imaging datasets included: (1) CT planning scan with IV contrast; (2) MR1 (within 1 week of CT); (3) Mid-treatment CBCT (without contrast); and (4) MR2 (day of CBCT). MR sequences included: Turbo Spin Echo (TSE), TSE with fat-sat and 3D radial gradient echo. The images were randomised and independently scored by four thoracic radiation oncologists according to whether the malignant LN in each nodal station was visualised well enough to permit contouring. Scores were: not visible (1), unclear (2), clear (3) and very clear (4). Scores 3 and 4 were designated as ‘suitable for contouring’. Result: As shown in figure 1, there was no significant difference in the number of LNs deemed suitable for contouring on CT (87%) compared to MR1 (82%). A significant difference was found between CBCT (10%) and MR2 (80%). Conclusion: MR did not out-perform CT with contrast for malignant LN visualisation, possibly due to greater observer familiarity with CT, MR was significantly better than CBCT, likely due to superior soft tissue contrast. These findings support the use of MR-guided radiotherapy in locally-advanced lung cancer for adaptive planning or treatment verification. The greater variation in MR scores between oncologists (especially between sequences) could be due to lack of experience with thoracic MR. Future research will optimise MR for this task and assess LN localisation on a larger dataset. Keywords: MRI, Radiotherapy, lymph node

P2.01 ADVANCED NSCLC TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.01-28 GENDER AND SYSTEMIC TREATMENT PATTERNS: IMPACTS ON THE OVERALL SURVIVAL OF STAGE IV NSCLC 2010 – 2014 DIAGNOSES A. Elegbede1, H. Li1, A. D’silva1, A. Gibson4, R. Tudor1, M. Dean1, S. Otsuka2, G. Beeb1 1Oncology, University of Calgary, Calgary/CA, 2Mathematics and Statistics, University of Calgary, Calgary/AB/CA, 3University of Calgary, Calgary/AB/CA, 4Oncology, Tom Baker Cancer Centre/university of Calgary - Cumming School of Medicine, Calgary/CA, 5Medical Oncology, University of Calgary, Calgary/AB/CA, 6Oncology, Tom Baker Cancer Centre, University of Calgary, Calgary/CA Background: Our previous work reports only ~25% systemic treatment uptake in stage IV non-small cell lung cancer (NSCLC) patients and proposed the availability of more tolerable regimen as one way of improving survival for NSCLC patients. The current study followed-up with the systemic treatment trend in stage IV NSCLC patients from 2010 to 2014, the era where effective and tolerable targeted agents such as EGFR- tyrosine kinase inhibitors (TKIs) and ALK inhibitors are available, to determine changes in clinical and treatment patterns impacting NSCLC survival over time. Method: Using the Glans-Look Lung Research (GLR) database, we defined the clinical features of stage IV NSCLC patients from 2010 to 2014, determined the impact of systemic treatment patterns and uptake rates on overall survival (OS).The findings were summarized with descriptive statistics (Fisher’s Exact tests) and Kaplan Meier survival curves using SPSS. Statistical significance was set at p value < 0.05 and 95% confidence intervals. Result: Among the 470
patients diagnosed between the year 2010 – 2011, and 724 in 2012 – 2014. 26% and 33% received 1st line systemic treatment respectively. Overall, there was increased use of EGFR and ALK targets (18% in 2010 – 2011 versus 34% in 2012 – 2014 of all 1st line therapy) and a 13% decrease in platinum-based doublet (PBD) uptake over the years, (p = 0.001). This pattern of change was similar for patients ≤70 years versus >70 (p = 0.001). However, for female patients, PBD use remain constant despite the increased targeted agents uptake, (p = 0.001). The median OS was slightly better for female in the subsequent years, 7 (95% CI: 6 – 8) versus 4 (95% CI: 3 – 5) months, p = 0.036. In EGFR/ALK mutation positive patients who received 1st line TKIs, a non-statistically significant lower OS was observed in 2012 – 2014 compared to the previous years (p = 0.188). No significant difference in the OS between the year groups for patients with no actionable mutation treated with 1st line PBD (p = 0.393).

Conclusion: In stage IV NSCLC, systemic treatment uptakes slightly increased with targeted agents, however this may not add up to overall survival benefits for the disease. Targeted agents may confer more benefits to female patients. Outcome results from multivariate analysis will be presented and discussed.

TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.01-29 ECONOMIC ANALYSIS OF OSMIERTINIB IN PREVIOUSLY UNTREATED EGFR-POSITIVE ADVANCED NON-SMALL CELL LUNG CANCER
D. Ezeife1, V. Kirk1, P. Coyte2, N. Nixon3, R. Hancock-Howard4, N. Leigh1
1University Health Network, Toronto/CA, 2University of Toronto, Toronto/CA, 3Tom Baker Cancer Centre, Calgary/CA

Background: Osimertinib doubles progression-free survival (PFS) in previously untreated EGFR-positive advanced non-small cell lung cancer (NSCLC) patients, with remarkable intracranial response rates. However, its cost-effectiveness has not been established. We assessed the cost-effectiveness of first-line osimertinib from the perspective of the Canadian public health care payer. Method: A remaining lifetime Markov model was used to project the outcomes and costs of 2 treatment pathways, osimertinib or current standard-of-care (SoC) first-line EGFR TKI gefinitib or afatinib, in previously untreated EGFR-mutant advanced NSCLC patients from the health care system perspective. Clinical, health preference and cost input estimates were informed from the available literature, including second-line osimertinib after SoC failure in those with EGFR T790M mutant cancer. Model outcomes included costs (in 2017 Canadian dollars), quality-adjusted life-years (QALYs), and the incremental cost per QALY gained. The model was fully probabilistic to assess parameter uncertainty. Result: Osimertinib was associated with a gain of 0.70 quality-adjusted life-years (QALYs) at an incremental cost of $58,619 vs SoC incremental cost-effectiveness ratio (ICER): $83,164/QALY gained. Unadjusted LY gain was 0.95. Osimertinib had a 7% probability of being cost-effective at a willingness-to-pay threshold of $50,000/QALY, and a 77% probability at a threshold of $100,000/QALY. Deterministic sensitivity analysis showed that health utilities and cost of osimertinib had the largest impact on ICER results. Conclusion: First-line osimertinib use in patients with advanced EGFR mutant lung cancer was found to involve a trade-off between improved PFS, QALYs and LYS versus increased cost.

P2.01-30 APPLICABILITY OF LUNG-MOLGPA INDEX IN NON-SMALL CELL LUNG CANCER PATIENTS WITH DIFFERENT GENE ALTERATIONS AND BRAIN METASTASES
K. Chen1, Y. Xu2, Z. Huang1, X. Yu1, H. Wang1, Y. Fan2
1Zhejiang Cancer Hospital, Hangzhou/CN, 2Chemotherapy, Zhejiang Cancer Hospital, Hangzhou/CN

Background: The Lung-molGPA was based on the original Diagnosis-Specific Graded Prognostic Assessment (DS-GPA) by incorporating recently reported gene alteration data for non-small cell lung cancer (NSCLC) patients with brain metastases (BM). However, the prognostic prediction value of DS-GPA and Lung-molGPA models remains undetermined, especially in patients with different molecule types.

Method: A total of 1184 NSCLC patients with BM analyses for clinical factors and outcomes were identified at Zhejiang Cancer Hospital, China. All prognostic factors were weighted for significance by hazard ratios.

The applicability of DS-GPA and Lung-molGPA were reappraised in NSCLC patients with BM and various genetic profiles. Additionally, a modified Lung-molGPA, was newly developed for mutant NSCLC patients. Result: The NSCLC patients in the present study had a median survival of 14.0 months from the time of BM diagnosis. Both DS-GPA and Lung-molGPA models could predict the outcomes (P<0.001), while Lung-molGPA model appeared to exhibit better accurate prediction. Furthermore, Lung-molGPA scores performed a discrimination capability in patients with different EGFR/ALK gene variations (3.5–4.0 vs 2.5–3.0 vs 1.5–2.0 vs 0.1–0.6 vs 32.0 vs 17.7 vs 3.2 months, P<0.001). However, no significant difference was reached in wild-type patients (P=0.133). Regarding to the oncogene-positive NSCLC patients with BM, no differences were derived established from the prognostic factors with the C-index of 0.73 (95% CI: 0.73–0.80) to accurately calculate the survival probability (P<0.001).

Conclusion: In an era of precision medicine, Lung-molGPA could precisely predict the prognosis of mutant NSCLC patients with BM, while not work in wild-type patients.

Keywords: non-small cell lung cancer, Lung-molGPA, brain metastases
Conclusion: Our findings confirm that EGFR mutation rate among Brazilian is higher than observed in Western countries, women have a higher EGFR mutation rate than men, and detection rate using NGS is higher than cobas®. Frequency of EGFR mutation was lower in South region, what could be explained by a higher smoking rate (not evaluated in this study) and a larger Caucasian population.

P2.01-32 ECONOMIC EVALUATION OF DIAGNOSTIC PLATFORMS FOR T790M DETECTION IN POST EGFR-TKI NSCLC IN BRAZIL
C.G. Ferreira1, M. Custodio2, G. Montenegro2, R. Caetano2, L. Bonan3
1Neotaxona Oncologia D’O, Rio de Janeiro/BRA, 2Medical Department, AstraZeneca, Cotia/BRA, 3AstraZeneca Brazil, Cotia/BRA, 4Asas, Rio de Janeiro/BRA

Background: 50% of acquired resistance to first or second-generation EGFR-TKIs NSCLC treatment is attributed to T790M mutation. Clinical trials demonstrated superior efficacy of osimertinib versus chemotherapy in second line setting. Nevertheless, the required molecular testing to identify T790M mutation is a challenge considering difficulties related to tissue re-biopsies. Nowadays, availability of noninvasive ctDNA techniques permits safer and faster molecular diagnostic. In Brazil, there are some commercially available tests presenting different accuracy rates. Our objective was to compare current T790M ctDNA tests cost-effectiveness, under local perspective. Method: The population is NSCLC post first-line EGFR-TKI progression. Decision tree model started with cfDNA evaluation (RT-PCR based kit, Digital Droplet PCR, or NGS). Due to ctDNA methods intermediate sensitivity, tumor sample analysis is recommended if plasma result is negative. Strategies were a combination of cfDNA tests and RT-PCR based kit or NGS for tumors re-biopsies. Prevalence of T790M mutation, test accuracy, proportion of unknown or unfeasible samples were used to calculate each branch. Tissue re-biopsies complications and costs were also considered. The model was analyzed from a healthcare-payer perspective based on Brazilian private sector. Result: Plasma ddPCR then tissue biopsy NGS (if plasma negative) was the most effective, with cost-effective ratio of US$ 3,855.43 per positive T790M detected. Its cost was higher than the second most effective strategy (plasma-NGS + tissue NGS). Incremental cost-effectiveness ratio between both was US$ 21,193.66 per additional positive case detected. All strategies using RT-PCR based kit for plasma and/or tissue were dominated.

Conclusion: In terms of costs and effects, the best algorithms to detect more T790M positive cases are combination of ctDNA (ddPCR or NGS) and NGS test for tumor re-biopsy. ddPCR use followed by NGS permits identification of 5% more T790M mutations than the dominated methods. This study is an effort to optimize expenditures and integrate diagnostics discussions in Brazilian health system.

Background: High NLR has been associated with inferior OS in metastatic NSCLC patients. We previously demonstrated a significant relationship between a high NLR at baseline and at follow-up and poorer OS in patients with metastatic NSCLC. Case series suggest potentially improved benefits of cytotoxic chemotherapy administration post immunotherapy but little is known about whether high NLR is associated with inferior outcomes in patients receiving salvage ramucirumab plus docetaxel (RD). We evaluated the potential predictive value of NLR in pts with metastatic NSCLC who received at least one cycle of immunotherapy and matched with RD regimen. Retrospective analysis of patients with metastatic NSCLC who received at least one cycle of nivolumab or pembrolizumab and treated with RD regimen between April 2015 and May 2017. Patient demographics including NLR, RD and immunotherapy starting dates, and date of progression were recorded. Associations between NLR and both PFS and OS were assessed using Mann-Whitney-Wilcoxon tests. Cutoffs of NLR of 5.0 (based on published data) were analyzed for differences in median OS and PFS. Result: Of 62 patients analyzed, 56 (91%) were male, 81% former smoker, 31% Caucasian and 76% patients who were treated with RD regimen also received immunotherapy during their treatment course. For entire cohort, baseline NLR ≤ 5 was associated with superior survival (median OS 20.86 mos for NLR ≤ 5 vs 11.1 months for NLR > 5, p=0.03) and superior PFS (median PFS 6.01 mos for NLR ≤ 5 vs 2.76 mos for NLR > 5, p=0.03). Another significant predictor of OS was albumin at baseline (HR= 0.44, p = 0.01) and at 6 weeks (HR= 0.38, p = 0.01). Patients who received immunotherapy had significantly superior OS than those who did not receive immunotherapy (median not reached vs 4.73 mos, p = 0.03) within one-year follow-up. Conclusion: Low NLRs and higher albumins at baseline & 6 weeks were associated

P2.01 ADVANCED NSCLC
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.01-35 PREDICTING RISK OF CHEMOTHERAPY-INDUCED SEVERE NEUTROPENIA IN PATIENTS WITH ADVANCED LUNG CANCER
1Division of Hematology & Oncology, Va Nebraska Western Iowa Health Care System and University of Nebraska Medical Center/Fred & Pamela Buffett Cancer Center, Omaha/US, 2Duke University Medical Center, Durham/US, 3Duke University, Durham/NC/US, 4Li Ka Shing Faculty of Medicine the University of Hong Kong, Pok Fu Lam/HK

Background: Neutropenia is associated with the risk of life-threatening infections, chemotherapy dose reductions and delays that may compromise treatment outcomes. The goal of this study was to develop simple prediction model for severe neutropenia in lung cancer. Method: A lung cancer dataset was assembled using data from existing national cooperative group phase II/III trials conducted between 1991-2010. Chemotherapy trials in patients with stages III and IV non-small cell lung cancer (NSCLC) or extensive small-cell lung cancer (SCLC) were included. We randomly selected 2/3 patients to derive the model, and the remaining were used for validation. Models were built with stepwise logistic regression and lasso regression on imputed data sets. We fitted the model on the imputed training data sets individually to get 10 models with 10 sets of selected predictors. Next we picked the union set and the intersection set of predictors from the models. The variables in the final model were selected by lasso regression, and then fitted into a logistic model. The performance of the model was evaluated by receiver operating characteristic (ROC) curve and the area under the ROC curve (AUC). Result: The dataset was randomly separated into training [n=7606 (67%)] and testing sets [n=3746 (33%)]. The final predictive model included: Age (>65 years), gender (male), weight (kg), BMI, insurance status (yes/unknown), stage IIIIB/IV/ESSCLL, number of metastatic sites (1, 2 or ≥3), individual chemotherapy agents (gemcitabine, taxanes), number of chemotherapy agents (2 or ≥3), planned use of growth factors, associated radiation therapy, previous therapy (chemotherapy, radiation, surgery), duration of planned treatment, pleural effusion (yes/unknown), performance status (1, ≥2) and presence of symptoms (yes/unknown). Figure: ROC Curve for Final model AUC=0.8306 Conclusion: We have developed a relatively simple model with variables that are routinely available prior to treatment, to predict for neutropenia. This model should be validated prospectively.

Keywords: non small cell lung cancer, Neutropenia, Predictive model

P2.01-36 REAL-WORLD TREATMENT PATTERNS IN TREATMENT-NAÏVE ADVANCED NSCLC PATIENTS IN NORTH AMERICA: A SYSTEMATIC LITERATURE REVIEW
A. Gara1, N. Varol2, S. Goring1, T. Li3, M. Oviedo Ovando1, Y. Yuan3, N. Hertel1, B. Korytowsky1
1Icon Epidemiology, Vancouver/BC/CA, 2Bristol-Myers Squibb Pharmaceuticals Ltd., Uxbridge/GB, 3Bristol-Myers Squibb, Princeton/NJ/US

Background: Clinical practice guidelines in North America for first-line (1L) treatment of advanced NSCLC (aNSSCLC) include a range of systemic therapy combinations, with consideration given to patient and disease characteristics. As the aNSSCLC treatment landscape evolves, it is relevant to understand which combinations are routine in clinical practice. We aimed to characterize treatment patterns in real-world (RW) practice in the US and Canada. Method: A systematic literature review of RW observational studies was conducted using EMBASE and MEDLINE (January 2012 to March 2018), alongside searches of conference proceedings (2015 to 2018). Two reviewers assessed eligibility and included studies that described treatment patterns among treatment-naïve patients with aNSSCLC. Studies focusing exclusively on sub-populations, e.g. EGFR+ or ALK+ were excluded. Data regarding the study’s sampling frame and the frequency and type of therapies received (1L systemic regimens, other 1L treatment modalities, maintenance therapy, subsequent lines of systemic therapy) were extracted and validated. Result: From 4600 abstracts, 18 studies met inclusion criteria (n=14 US; n=4 Canada). All studies used a retrospective design; patient sample sizes ranged from 147 to 55,189 and study periods ranged from 2000 to 2015. Six studies (n=5 US; n=1 Canada) applied a sampling frame that captured all regimens available in 1L and provided breakdowns by 1L regimen. In this small retrospective study, longer OS was observed in pts treated with RD regimen and immunotherapy. Pts who did not receive immunotherapy had shorter OS. Additional data are needed to evaluate the impact of treatment sequence.

SMALL CELL LUNG CANCER

P2.01-38 SARCOPENIA IS ASSOCIATED WITH METASTATIC BURDEN AND IS A NEGATIVE PROGNOSTIC FACTOR IN METASTATIC NON-SMALL CELL LUNG CANCER

1Department of Internal Medicine, Medical College of Wisconsin, Milwaukee/WI/US
2Department of Radiology, Medical College of Wisconsin, Milwaukee/WI/US
3Medical Oncology, Medical College of Wisconsin, Milwaukee/WI/US
4Institute of Health and Equality, Medical College of Wisconsin, Milwaukee/WI/US
5Pulmonary and Critical Care Medicine, Medical College of Wisconsin, Milwaukee/WI/US

Background: Sarcopenia is associated with poor outcomes in patients with solid tumors. Factors affecting sarcopenia in metastatic NSCLC (mNSCLC) are not well defined. We utilized a novel computerized tomography (CT) method to measure muscle composition and evaluate its impact on metastatic disease burden and survival in mNSCLC patients.

Method: We conducted a retrospective study of consecutive adults with mNSCLC who progressed on chemotherapy, targeted therapy (where applicable) as well as CPIs.

Result: Patient self-assessments were prospectively evaluated with the LCSS at baseline and every 3 weeks using electronic media. Patients were also blinded outcomes assessments were conducted. The primary outcome was correlation between healthy muscle percentage and number of metastases. The secondary outcome was the impact of healthy muscle on overall survival. We hypothesized less total healthy psoas muscle would be associated with greater metastatic burden and worse overall survival.

Conclusion: The combination of bemcentinib and docetaxel was shown to be additive in in vivo models of NSCLC. In pts with advanced, pre-treated NSCLC, bemcentinib monotherapy led to disease stabilization in 2 out of 8 pts including evidence of tumor reduction. Clinical benefit including partial responses and disease stabilization in excess of 2 years has been observed in a subset of EGFR therapy resistant previously treated NSCLC pts when treated with bemcentinib in combination with erlotinib. In a study combining bemcentinib with pembrolizumab, objective responses have been reported in pts with previously treated NSCLC. The BGB11005 study was an open label, investigator-initiated dose escalation and expansion trial designed to assess the safety, tolerability, preliminary efficacy and biomarkers of bemcentinib in combination with docetaxel in previously treated NSCLC.

Method: Dose escalation of daily bemcentinib in combination with 60 or 75 mg/m 2 q3wks followed at least one on of prior Pt-based doublet therapy and appropriate targeted therapy if indicated. Tumor responses were assessed per investigator using RECIST v1.1. Plasma protein biomarker levels were measured using the DiscoveryMap v3.3 panel (Myriad RBM) in pts pre-dose and at C2D1. Result: As of 30%

P2.01-39 CAN BENEFIT OR FUTILITY IN TREATING ADVANCED NSCLC BE DETERMINED EARLY USING THE LCSS 3-ITEM GLOBAL INDEX (3-IGI) PRO?

1Albert Einstein College of Medicine, Bronx/NY/US
2University of Virginia, Charlottesville/VA/US
3Duke University Medical Center, Durham/US
4Feinstein Institute for Medical Research, Manhasset/US

Background: Early assessment of the effect of treatment for advanced NSCLC can prevent unnecessary exposure to toxic and costly therapy while aiding in decision making to continue or change treatment. In a prior analysis in patients with mesothelioma (Symanowski JCO 2014), a 20% decline from baseline after 2 cycles of chemotherapy in the 3-item Global Index of the LCSS identified patients unlikely to benefit. The 3-IGI (which evaluates: 1) global distress, 2) patient rated activities, and 3) quality of life, all in single VAS scales) takes less than 2 minutes to assess.

Method: s: 164 patients with NSCLC receiving chemotherapy or checkpoint inhibitors were prospectively evaluated with the LCSS at baseline and every 3 weeks using electronic media. Patients were also randomized 1:1 so that their physicians knew the results of the LCSS immediately in half of the patients. Result: s: Patients: Stage IV 62%; first line 73%; female 43%; median PS 1; mean age 63. The LCSS was completed after 2 cycles of treatment and prior to planning for the next cycle (generally 6 weeks after baseline; representing 91% of the 148 cycles of the same chemotherapy (median cost = $10,712 per patient).

Conclusion: LCSS, PRO, 3-IGI

P2.01-40 PROGNOSTIC IMPORTANCE OF SARCOPENIA AND INFLAMMATORY STATEMENTS IN STAGE III NON SMALL CELL LUNG CARCINOMA
E. Gümüştepe1, S. Akyürek1, Y. Arslan1, E. Gökay2, Ş. Çakır Gökçe1
1Radiation Oncology, Ankara University School of Medicine, Ankara/TR, 2Biostatistics, Ankara University School of Medicine, Ankara/TR

Background: Sarcopenia is characterized by progressive loss of skeletal muscle mass, muscle strength and physical performance. Systemic inflammation is thought to contribute to sarcopenia. Current retrospective evidence suggests that sarcopenia is an independent prognostic value on overall survival(OS). In this study, we aimed to investigate the prognostic significance of sarcopenia and inflammatory markers in stage III small cell lung cancer (NSCLC). Method: Eighty-three patients with stage III NSCLC undergoing definitive chemoradiotherapy in our clinic between April 2014 and August 2017 were evaluated. The cross-sectional area of muscle at the level of the third lumbar vertebra (L3) was measured using of radiography planning CT images. Sarcopenia was defined as a L3 muscle index of less than 55 cm2/m2 for men and of less than 39 cm2/m2 for women as proposed by international consensus of cancer cachexia. Systemic inflammatory markers investigated included serum lactate dehydrogenase (LDH), neutrophil/lymphocyte ratio (NLR), C-reactive protein (CRP), and albumin(Alb). Relations between variables were determined by Pearson Chi Square and Fischer Exact Test. Risk factors affecting dependent variables were determined by Cox Regression Analysis. Result: Seventy-five (90%) of the patients were male and 8 (10%) were female. The number of sarcopenic patients was 52 (62.6%). The mean age was higher in sarcopenic patients (68.3 ± 9.7 vs 63.7 ± 9.4, p = 0.037). There was no statistically significant difference between the groups with and without sarcopenia in the ratio of low albumin level, LDH height, N / L ratio. Mean survival was 18.14 months (2-48 months). In sarcopenic patients, OS was 17.2 months, while non-sarcopenic patients were 19.58 months (p = 0.310). When the effects on general survival were examined, it was found statistically significant that the presence of sarcopenia (p = 0.016), age (p = 0.001), low alb level (p = 0.009), N / L ratio is higher than 4 (p = 0.003). Multivariable Cox regression analyzes showed independent prognostic significance in survival with RT dose (HR (95% CI) = 1.2; p = 0.001), low albumin level (HR (95% CI) = 2.42; p = 0.007) and age (HR(95%CI) = 1.2; p = 0.044). Conclusion: In our study, the presence of sarcopenia in patients with stage III definitive KTRT NSCLC, as well as the LOW alb ratio and N / L ratio of inflammatory markers were found to be a significant prognostic factor for OS. We aim to investigate the prognostic significance of sarcopenia 'cutoff' value for Turkey with a prospective, multicenter, larger group of patients.

P2.01-41 THE ROLE AND MECHANISM OF FBW7 DEFICIENCY IN ADVANCED NON-SMALL CELL LUNG CANCER WITH DOCETAXEL RESISTANCE
H. Liang, Q. Guo
Shandong Cancer Hospital, Jinan/CN

Background: Lung cancer is one of the most common malignant tumors of human. NSCLC accounts for about 80%-85% of all lung cancer, and 68%-80% of NSCLC patients have been diagnosed at the advanced stage1. Because of the existence of drug resistance, many patients have relapsed or progressed soon after chemotherapy, and the resistance always lead to unsuccessful effect. Docetaxel is an anti-microtubule chemotherapeutic agent that acts on cellular tubulin, which can prevent the normal physiological accumulation of intracellular microtubules , resulting in the withering of cells2. Like other chemotherapeutic drugs, the drug resistance of docetaxel reduces its efficacy. Method: RT-PCR and Western-blot were used to detect the differences of FBW7 expression in docetaxel-resistant cell line SPC-A1/DTX and parental SPC-A1 cells, and the overexpression and interference sequences of FBW7 were constructed. The SPC-A1/DTX and parental SPC-A1 cells were transfected with lentiviral packaging, and the SPC-A1/DTX FBW7 O/E cell line and SPC-A1 FBW7 D/R cell line were screened by monocular screening method. RT-PCR and Western-blot were also used to detect the differences of FBW7 expression among SPC-A1/DTX, SPC-A1- DTX FBW7 O/E, SPC-A1 and SPC-A1 FBW7 D/R cell lines. Finally, MTT colorimetric assay and colony formation assay were used to research the effects of regulation of FBW7 on the sensitivity to docetaxel. Result: RT-PCR and Western-blot proved that the expression of FBW7 in NSCLC docetaxel-resistant cell line SPC-A1/DTX was significantly lower than that of parental cell line SPC-A1. With lentiviral transfection and monocular screening, a SPC-A1 FBW7 D/R cell line with down-regulated FBW7 expression and an SPC-A1/DTX FBW7 O/E cell line with up-regulated FBW7 expression were constructed. The expression of FBW7 in SPC-A1 cell line and SPC-A1/DTX FBW7 O/E cell line was higher than that of SPC-A1/DTX FBW7 O/E and SPC-A1 by RT-PCR and Western-blot /DTX cell line. Finally, MTT colorimetric assay and colony formation assay showed that SPC-A1 cell line and SPC-A1/DTX FBW7 O/E cell line were more sensitive to docetaxel than SPC-A1 FBW7 D/R cell line and SPC-A1/ DTX cell line. Conclusion: For non-small cell lung cancer, the sensitivity to docetaxel was higher in cells with high expression of FBW7 than the cells with low expression of FBW7; the loss of FBW7 gene was associated with drug resistance of NSCLC to docetaxel. However, the specific mechanism of FBW7 deletion causing non-small cell lung cancer resistance to docetaxel still needs further study.

Keywords: FBW7/FR-box and WD repeat domain-containing7), non-small cell lung cancer, docetaxel

P2.01-42 IMPACT OF TOBACCO SMOKING ON OUTCOMES IN PATIENTS WITH METASTATIC NON-SMALL CELL LUNG CANCER IN THE ERA OF TARGETED THERAPY
M. Gutierrez1, A. Wozniak1, C. Langer1, B. Fang1, G. Suerö-Abreu1, A. Nordem2, R. Bedell1, J. Schaffer1, A. Collins3, E. Schultz4, B. Stone5, V. Natividad6, S. Goldberg7
1John Theurer Cancer Center, Hackensack University Medical Center, Hackensack/NJ/US, 2Karmanos Cancer Institute, Detroit/Mi/US, 3Hospital of the University of Pennsylvania, Philadelphia/PA/US, 4Regional Cancer Care Associates, East Brunswick/NJ/US, 5Rutgers University New Jersey Medical School, New Brunswick/US, 6Cota Inc, New York/US

Background: Prior epidemiological studies have noted differences in the demographic and clinical characteristics among patients with metastatic non-small cell lung cancer (NSCLC) between those with and without exposure to tobacco smoke. Most notably never smokers are more likely to harbor genomic driver mutations and (in the era of targeted therapy) improved survival. Observational databases, capturing real world diagnostic and treatment patterns, can provide insights on outcomes of NSCLC based on smoking history. Method: The electronic health records (EHR) of patients with de novo stage IV NSCLC diagnosed between January 2013 and December 2016 from 30 cancer centers, contributing to the Cota Observational Cancer Database, from 184 oncologists were reviewed. Result: 1716 NSCLC pts were identified including 243 (14.2%) never tobacco smokers, 405 (23.6%) active smokers, 1026 (59.8%) former smokers, 7 (0.4%) passive smokers, and 29 (1.7%) not reporting. Never Smokers (NS) were more likely than smokers (S=active and former smokers combined) to be female (NS: 67.4%; S: 47.2%; p<0.0001) with similar ages (NS: 66 yrs; S: 67 yrs), but included more Asians pts (7.4%: NS vs 2.5%: S; p=0.044) and more females with identified and more mutations in the NS cohort. In the non-squamous histologies EGFR testing was NS: 87% with 45.9% mutated; S: 70% with 10.4% mutated (tested p<0.0001; mutated p<0.00001). In the non-squamous histologies ALK testing was NS: 74% with 5.4% translocated ; S: 67% with 1.4% translocated (tested p=0.04; translocated p<0.0001). As first line therapy 40% of NS received targeted therapy (11% receiving targeted 2nd line) whereas 4.8% received 1st line and 1.5% 2nd line targeted therapy. The median overall survival for the NS cohort was 21 months compared to 11 months among S (log-rank p<0.05); with PFS of 9 vs 6 months (p<0.05). Exclusion of targeted therapy in 1st or 2nd line, the median OS for NS was 17 mo; for S was 10 mo (p<0.05). Conclusion: This real world observational study confirms a higher rate of treatable genomic driver mutations among never smoker NSCLC. Despite guidelines recommending universal genomic testing, never smokers are tested at a higher frequency. In the era of targeted therapy (but before the widespread use of immunotherapy) never smoker NSCLC patients experienced improved survival with and without targeted treatment compared to individuals with tobacco exposure.

P2.01-43 ADSCAN: A RANDOMISED PHASE II STUDY OF ACCELERATED, DOSE ESCALATED, SEQUENTIAL CHEMORADIOThERAPY IN NON-SMALL CELL LUNG CANCER (NSCLC)
C. Lawless1, M. Hatton2, C. Faivre-Finn3, D. Landau4, K. Boyd4, J. Fenwick4, J. Lester, E. McCartney1, J. Paul1, A. Shaw1, R. Simoes5
1College of Medical, Veterinary & Life Sciences, CRUK Clinical Trials Unit, Glasgow/GB, 2Weston Park Hospital, Sheffield/GB, 3Department of Clinical Oncology, Univ. of Manchester and the Christie NHS Foundation Trust, Manchester/GB, 4Guys & St Thomas NHS Trust, London/GB, 5Health Economics & Health Technology Assessment, University of Glasgow, Glasgow/GB, 6Physics Department, Clatterbridge Cancer Centre, Wirral/GB, 7Velindre Cancer Centre, Cardiff/GB, 8National Radiotherapy Trials Quality Assurance, Mount Vernon Hospital, London/GB

Background: Lung cancer is the most common cause of cancer mortality in the UK, and NSCLC accounts for approximately 85% of all lung cancers. Most patients present with inoperable disease therefore radiotherapy plays a major role in treatment. However, the majority of patients are not suitable for gold standard treatment (concurrent chemo-radiotherapy) due to performance status and comorbidities. Novel strategies integrating radiotherapy advances and radiobiological knowledge need to be evaluated in patients treated with sequential chemo-radiotherapy. Four separate accelerated dose escalated radiotherapy schedules have been completed in UK (CHART-ED11, IDEAL-CRT12, J-START13 and Isotoxic IMRT14). ADSCAN will compare these schedules with a UK standard sequential chemo-radiotherapy schedule. A combined randomized phase II screening '/pick the winner' approach will identify the best schedule to take into a randomised phase III study against conventionally fractionated radiotherapy.

Method: Suitable patients will have histologically / cytologically confirmed, stage III NSCLC and be able to undergo chemo-radiotherapy treatment. The study will recruit 360 patients; 130 on the standard arm and 60 on each experimental arm. Patients will complete 2-4 cycles of platinum based chemotherapy before being randomised to one of the radiotherapy schedules. Logistic / capacity challenges make it impractical for sites to open all experimental trial arms; a novel trial design allows centres to select upfront the experimental arms they are able to participate in and all will offer the standard arm.

Result: CURRENT STATUS CRUK is funding this multicentre study which is being co-ordinated by the CRUK CTU Glasgow. The study opened to recruitment on 22/08/2017 with planned recruitment lasting 3 years 8 months. The study includes a tailored QA programme through the UK RTTQA Group. 20 of the 36 sites expressing interest have started the QA process, 12 have completed with a further 8 expected to complete in the next few months. Conclusion: Section Not Applicable

P2.01-44 PROGNOSTIC VALUE OF TP53 HOT EXON MUTATION IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC)
1Department of Respiratory Medicine, Daping Hospital, the Third Military Medical University, Chongqing/CN, 2Oncology, Jiangsu Province Hospital, Nanjing/CN, 3Department of Medical Oncology, Cancer Institute and Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing/CN, 4Hunan Cancer Hospital, the Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, Hunan, China (Mainland), Changzhou/CN, 5Department of Respiratory Medicine, Daping Hospital, Third Military Medical University, Chongqing, PR China, Chongqing/CN, 6The Second Affiliated Hospital of Chongming Medical University, Chongming, China., Chongqing/CN, 7The First Affiliated Hospital of Chongming Medical University, Chongming, China., Chongqing/CN, 8Burning Rock Biotech, Guangzhou, China., Guangzhou/CN, 9Burning Rock Biotech, Guangzhou/CN.

Background: Numerous studies have revealed either very marginal or no prognostic value of TP53 mutation NSCLC patients. Currently, in clinical settings, all TP53 mutations have been considered equally, without any differentiation between the various types and positions of mutations. However, increasing evidence has triggered us to challenge such practice. Method: We retrospectively investigated the correlation between mutations occurring at hot exons (5-8) and overall survival (OS) in 214 previously tyrosine kinase inhibitor (TKI) treated advanced NSCLC patients. Among them, 184 had 1 line of TKI-treatment and the remaining 30 patients had more than 1 line of TKI-treatment. 115 harbored TP53 mutation; among them 105 patients had concurrent EGFR mutation, 4 with ERBB2 mutation, 4 with ALK mutation; among them 99 had wild type (WT) TP53; among them, 92 had EGFR mutation, 4 with ALK-rearrangements, 1 with MET and 1 with BRAF mutation. Fisher’s exact test and the Mann-Whitney test were used to determine if categorical and continuous variables, respectively, differed between TP53 WT and mutant groups. Result: The prevalence of TP53 mutation in our cohort is 53.7% (115/214); 28 had mutation in exon 5 had shorter OS (p=0.029) and mutation in exon 8 had shorter OS (p=0.003) after controlling for age, gender, stage and histology. In patients treated with only 1 line of TKI-treatment, although 30 patients had more than 1 line of TKI-treatment. 115 harbored TP53 mutation; among them 105 patients had concurrent EGFR mutation; 5 had ALK rearrangements; 1 had ROS1 rearrangements; 1 had KRAS and 2 had ERBB2 mutations. 99 patients had wild type (WT) TP53; among them, 92 had EGFR mutation, 4 with ALK-rearrangements, 1 with MET and 1 with BRAF mutation. Fisher’s exact test and the Mann-Whitney test were used to determine if categorical and continuous variables, respectively, differed between TP53 WT and mutant groups. Result: The prevalence of TP53 mutation in our cohort is 53.7% (115/214); 28 had mutation in exon 5, 18 on exon 6, 3 on exon 7, and 32 on exon 8. 32 patients had loss of function mutation and 51 patients had disruptive mutation. Our data revealed a positive correlation with N and M stage. Patients harboring TP53 mutation are more likely to diagnose with more advanced N (p=0.018) and M stage (p=0.001). Furthermore, patients with TP53 mutation are more likely to have liver (p=0.001) and bone metastasis (p=0.012). In patients treated with only 1 line of TKI-treatment, although TP53 status had no effect on PFS (p=0.241) and OS (p=0.49) when they were considered collectively, we observed patients with mutation in exon 5 had shorter OS (p=0.029) and mutation in exon 8 had shorter PFS (p=0.003) after controlling for age, gender, stage and histology.

Keywords: TP53 mutations, Prognostic value, NSCLC
Furthermore, within the osimertinib subgroup (N=101), patients harboring mutation in exon 19 had significantly shorter PFS (P=0.007). In patients treated with more than 1 line of treatment, neither TPS3 mutation considered collectively, nor hot exon mutations had correlation with PFS or OS. Conclusion: Our study revealed unfavorable prognostic value of mutations in exon 5 and no prognostic value of TPS3 if all mutations were considered collectively. Our study adds new dimension to the emerging picture that not all TPS3 mutants are equal.

P2.01 ADVANCED NSCLC
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.01-45 MUTATIONAL AND INFLAMMATORY BIOMARKERS FOR LUNG CANCER PATIENTS WITH PLEURAL EFFUSIONS
B. Hegeduš1, D. Valdivia1, H. Kozięga1, E. Loscha1, P. Stockhammer1, T. Plönes1, K. Mardanzai1, M. Zaatar2, D. Theegarten2, C. Aligner1
1Department of Thoracic Surgery, Ruhrlandklinik, University Clinic Essen, Essen/DE, 2Department of Pathology, University Clinic Essen, Essen/DE

Background: Pleural effusion is often associated with the progression of lung cancer and the treatment options for patients with malignant pleural effusions are rather limited. The estimation of prognosis remains to be challenging and personalized therapeutic strategies require a set of validated biomarkers. Method: 87 lung adenocarcinoma, 27 squamous cell carcinoma and 8 neuroendocrine carcinoma patients with pleural effusions were treated in our department between July 2016 and April 2018. Preoperative C-reactive protein and white blood cell count was collected and their association with clinicopathological parameters and overall survival was calculated. KRAS, EGFR and ALK mutational status was available in advanced lung adenocarcinoma cases. The association of oncogenic driver mutations with overall survival was analyzed. Result: 39 of the 122 patients had malignant pleural effusions (32%). 64 patients had TNM stage IV disease. Importantly, high CRP (>5 mg/dl; HR: 14.7, CI95% 2.9-73, p=0.0011) but not high WBC (>9000 cells/ml; HR 0.98, CI95% 0.8-1.19, p=0.029) were predictive for shorter overall survival in lung cancer patients with pleural effusions. High CRP remained a significant prognostic factor in lung cancer patients with benign effusions (HR: 21.5, CI95% 1.9-242, p=0.013). KRAS mutation was identified in 28% of the lung adenocarcinoma cases. There was a tendency for lower KRAS mutation incidence in the MPE subcohort when compared to BPE cases (16.6% vs 22%, p=0.15). Interestingly, 22% of patients had EGFR mutation and EGFR mutations were more frequent in lung cancer patients with malignant effusions when compared to benign effusions (OR 4.8, CI95% 1.2-19.9, p=0.029). Conclusion: Oncogenic driver mutations may impact the development of malignant effusions in lung adenocarcinoma patients. Furthermore, our study indicates that the routinely available, circulating preoperative C-reactive protein level carries prognostic information. These findings suggest that oncogenic mutations and inflammatory biomarkers can further personalize therapeutic decisions and can contribute to the risk stratification of lung cancer patients with pleural effusions.

P2.01-46 INVESTIGATING THE EFFECTS OF PRIOR MALIGNANCY ON NSCLC TRIAL ELIGIBILITY
M. Herman1, N. Leighl1, F. Shepherd2, G. Liu3, P. Bradbury2
1Medical Oncology, Princess Margaret Cancer Centre, Toronto/CA, 2Princess Margaret Cancer Centre, Toronto/CA, 3Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul/KR

Background: Prior history of a malignancy is a common exclusion in NSCLC clinical trials. Preliminary results suggest the majority of patients in our study did not appear to have a complication that would have impacted safety or clinical trial endpoints. Further analyses to explore appropriate exclusion criteria for prior malignancies, which may minimize need to exclude patients from clinical trials, are underway.

Keywords: NSCLC, Prior Malignancy, clinical trial eligibility

P2.01 ADVANCED NSCLC

P2.01-47 CLINICAL OUTCOME AFTER SURGICAL RESECTION OF CLINICAL SINGLE-STATION N2 NON-SMALL CELL LUNG CANCER
K. Hyun1, S. Park2, H.J. Lee1, I.K. Park3, C.H. Kang1, Y. Kim2
1Department of Thoracic and Cardiovascular Surgery, Seoul St. Mary’s Hospital, Catholic University of Korea, Seoul/KR, 2Department of Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul/KR, 3Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul/KR

Background: We set up our treatment protocol performing upfront surgery for non-bulky, single-station clinical N2 (cN2a) patients. Method: Between 2012 and 2016, 129 patients underwent upfront surgery for cN2a disease diagnosed on CT and PET-CT findings. 85 patients underwent preoperative invasive mediastinal staging (IMS) group, whereas, in 44, IMS was not performed (Non-IMS group). Survival were compared with log-rank test. Subgroup analysis for pN2-3 is performed to identify prognostic factors using Cox-regression. Result: Pathologic N stages were pN0-1 in 26 patients (20%: 18 IMS, 8 non-IMS), pN2a in 47 (36%: 29 IMS, 18 non-IMS) and pN3 in 5 (4%: all IMS). The overall 5-year survival was 55.4% with no difference between groups (p=0.39). In pN2-3 patients, 5-year survival was 51.0% and IMS group was better (p=0.05). In a Cox’s regression, non-IMS (HR 1.89, p=0.04), no adjuvant chemotherapy (HR 3.55, p<0.001), extensive burden of metastatic lymph nodes (number of metastatic LN≥13, HR 3.32, p=0.002) were independent risk factors for survival.

Keywords: NSCLC, Prior Malignancy, clinical trial eligibility
P2.01-48 PREDICTIVE FACTORS IN NSCLC PATIENTS WITH STAGE IIIB/IV TREATED WITH FIRST LINE PLATINUM-DOUBLET CHEMOTHERAPY

S. Isaksson¹, C. Reuterswärd¹, B. Hazem¹, H. Griph¹, J. Engleson¹, K. Ericson Lindquist¹, M. Planck¹, J. Staaf¹

1Division of Oncology and Pathology, Department of Clinical Sciences Lund, Lund University, Lund/SE, 2Department of Respiratory Medicine, Skane University Hospital, Lund/SE, 3Department of Radiotherapy, Skane University Hospital, Lund/SE

Background: Predictive factors for response to chemotherapy in non-small cell lung cancer (NSCLC) are deficient. We investigate the associations between mutation status and treatment outcome of first line platinum-doublet chemotherapy in a 1.5 years population-based cohort of stage IIIB/IV patients. Furthermore, we will investigate the usefulness of gene expression signatures in predicting chemotherapy response in patients with advanced NSCLC. Method: In the region of Skåne, Sweden, n= 600 (preliminary) patients with NSCLC stage I-IV (TNM 7th edition) had conclusive results from reflex NGS testing with Illumina TruSightTumor 26-gene panel between January 2015 – June 2016. From this cohort, we include all patients with stage IIIB/IV with first line platinum-doublet treatment not interrupted by other cause than progressive disease (PD) and evaluate their extra-cranial response to treatment by using the Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 with slight modifications. Patients who received radiotherapy against the primary tumor and/or mediastinum before or concomitant with chemotherapy are excluded. Result: So far, 91 patients have been included, 10 (11%) with stage IIIB and 81 (89%) with stage IV. First-line chemotherapy included carboplatin/cisplatin in combination with gemcitabine/pemetrexed/vinorelbine. Bevacizumab were given in addition to chemotherapy in 3 patients. 25 (28%) responded with progressive disease (PD), 27 (30%) with stable disease (SD) and 39 (43%) with partial response (PR). TP53+/-KRAS+ tumors were detected in 22 (24%) patients, TP53+/KRAS- in 34 (37%), TP53-/KRAS+ in 21 (23%) and TP53-/KRAS- in 14 (15%). No difference in response to treatment (p=0.6, Fisher’s exact test) or progression-free survival (PFS) (log rank test, p=0.6) according to mutation status was seen, although we observed a weak tendency of worse PFS in TP53+ patients with or without KRAS mutation compared to TP53-/KRAS- patients. Conclusion: In this population-based Swedish cohort, mutations in KRAS and/or TP53 are not significantly associated with first line chemotherapy response. However, also subtypes of these mutations should probably be considered. Additional analyses of potential predictors of treatment response, in association with other clinicopathological variables, will be presented.

**P2.01-49 COMPARISON OF RADIOTHERAPY CONCURRENT WEEKLY TREATMENT IN LOCALLY ADVANCED UNRESECTABLE NON SMALL CELL LUNG CANCER**

N. Akdeniz, M.A. Kaplan, Z. Uracik, M. Kucukoner, O. Karhan, A. isikdogan

**Dicle University, Diyarbakir/TR**

**Background:** Despite concurrent chemoradiotherapy is standard treatment of unresectable locally advanced non small cell lung cancer (NSCLC), optimal chemotherapy regimen is still inconclusive.

Radiotherapy concurrent weekly chemotherapy has been studying and due to less toxicity it is preferred. In this study, we aimed to compare two weekly different regimens in terms of outcome and toxicity. **Method:** We screened retrospectively 142 patients with stage III, locally advanced unresectable NSCLC, treated with radiotherapy concurrent weekly platinum-paclitaxel (PP) or platinum-docetaxel (PD) between 2006 and 2016. Age, stage, histologic subtype, response rates and overall survival and toxicity were analyzed. In RT concurrently PP arm 50 mg/m2 paclitaxel and 20 mg/m2 cisplatin or carboplatin AUC 2; in PD arm 20 mg/m2 doxetaxel and 20 mg/m2 cisplatin applied. Radiotherapy applied as weekly 5 fraction/60-66 Gy. Treatment response classified progression and clinically response which consist of stable response (SR), complete response(CR) and partial response(PR). **Result:** One hundred thirty one (92.3%) patients were in PP arm and median age was 62 (25-79). Histologic subtype was adenocarcinoma in 77 (54.2%) patients. At diagnosis 53 patients (37.3%) were stage IIIA, 89 (62.7%) patients were stage IIIB and 31 IIE. There were 102 patients in DP arm whereas 40 patients were in PP arm. Age, gender, stage and histologic subtypes were similar in both groups. There were no statistically significant in clinically response rates between two group (PD 96.1% vs PP 90%, p = 0.15). Median overall survival (OS) was higher in PP arm than PD arm (29 vs 14.4 months, p=0.018). Progression free survival (PFS) were same in both arms (15.6 vs 15, 4 months p=0.522). There were no statistically significant in mucositis and eosophagitis (50% vs 80%, p=0.418) and vomiting (10% vs 8.8%, p=0.931) in both arms. In PP arm neutropenia (p=0.000) and thrombocytopenia rates were higher (p=0.021). Pulmonary toxicity (p=0.053) and nausea (p=0.056) was higher in PP arm, which is closed to statistical significance. Although outcomes through deaths due to treatment toxicity were not detected, progression and other reason related death were more common in PD arm (p=0.001). **Conclusion:** In our study, despite clinical response and PFS were same in both radiotherapy concurrent regimens in locally advanced unresectable NSCLC, OS was higher in PP. There is few study compared this two arms, which show no OS differences. Although it must be supported by prospective studies, OS is better in PP arm than PD.

**Background:** The risk of thromboembolism (TE) is estimated to be 0.001% per year and hereditary thrombophilia present in 0.2-5% of the general adult population. It is estimated that 8-15% of patients with advanced non-small cell lung cancer (NSCLC) will develop thromboembolism throughout their disease course. In ALK rearranged NSCLC this incidence has been reported to be three to four fold higher at 36%. We sought to investigate the incidence in TE in a cohort of the rare ROSI rearranged molecular subgroup. **Method:** Electronic records were reviewed in six tertiary hospitals to identify all patients diagnosed with ROSI NSCLC. Predefined data were analysed in STATA15 software for Kaplan-Meier (KM) plot and Cox-regression modelling. **Result:** Forty-two patients were identified at data cut (31/1/2018). Median follow up was 10.9 months (mo); 38% had died. Median age was 53 years (31-80); 74% were female; 67% non-Asian and 88% non-smokers and 29% were stage IIIA and IIIB, with 4% IIE. Median overall survival (OS) overall was estimated 28.8mo (range: 0.1-180.4mo). Thromboembolism incidence with OS was 10.9 months (mo); 38% had died. Median age was 53 years (31-80); 74% were female; 67% non-Asian and 88% non-smokers and 29%

CNS disease during diagnosis. Median overall survival (OS) overall was estimated 28.8mo (range: 0.1-180.4mo). Thromboembolism incidence with OS was 10.9 months (mo); 38% had died. Median age was 53 years (31-80); 74% were female; 67% non-Asian and 88% non-smokers and 29%
Background: Leptomeningeal metastasis (LM) is a devastating complication with poor prognosis in non-small-cell lung cancer (NSCLC) patients. The confirmed diagnosis of LM usually involves neurological evaluation, MRI imaging, and cytopathological analysis of limited tumor cells from cerebrospinal fluid (CSF). Exosomes are extracellular vesicles in body fluids enriched with microRNAs (miRNAs), which have been implicated to participate in brain metastasis. Here, we aimed to identify LM-specific exosomal miRNA signatures of NSCLC patients to elucidate their potential role in LM mechanism and to predict LM via liquid biopsy.

Method: Exosomes prepared from CSF and plasma samples of 39 advanced NSCLC patients with LM+ or without (LM-) as well as 12 non-cancer individuals (NC) were undergone small RNA next-generation sequencing. In the LM+ group, paired plasma samples were taken before (Ppre) and upon (Ppost) LM diagnosis. Exosomal miRNA profiles were subjected for differential expression analysis, pathway enrichment analysis, and signature discovery. Result: Unsupervised hierarchical clustering of the miRNA expression profiles clearly separated CSF samples into LM+ and LM free groups (LM- and NC). Interestingly, these samples were stratified based on their LM status only, regardless of their intraparenchymal metastatic status. In total, 247 (185 up and 62 down-regulated) miRNAs were identified differentially presented in the LM+ CSF exosome samples compared to the LM- and NC groups. Top altered miRNAs include dramatically up-regulated miR-200 family and down-regulated miR-144/451 cluster. Predicted gene targets of these top-regulated miRNAs were significantly enriched in Ras/MAPK, PI3K-AKT signaling, endocytosis pathways, and so on. Promisingly, a signature of five CSF exosomal miRNAs (let-7e-5p, miR-28-3p, miR-375, miR-200a-3p, and miR-486-5p) was identified for classification of LM+ patients with 100% sensitivity and 100% specificity. Due to the higher background complexity, we only identified one miRNA (miR-24-3p) was significantly up-regulated and one miRNA (miR-92b-5p) was significantly down-regulated in LM+ patients' plasma-derived exosomes (Ppre and Ppost). Compared with the LM free group (Ppre and Ppost), however, a combined signature of seven miRNAs (miR-24-3p, miR-223-3p, miR-340-5p, miR-27a-3p, miR-423-5p, miR-2110 and miR-342-3p) from Ppre samples was identified for the prediction of future LM with 81% sensitivity and 84% specificity. Conclusion: Here, we identified a remarkably distinct CSF exosomal miRNA signature, which may involve in the progression of LM, and can be used as diagnostic biomarkers for LM. Furthermore, the identification miRNA signature in the pre-LM plasma samples suggests the potential use of liquid biopsy to predict LM for better patient care.
P2.01-55 DUAL-ENERGY CT SCAN TO EVALUATE SARCOPEenia IN LUNG CANCER IN COMPARISON WITH CONVENTIONAL CT SCAN

1Radiology, Gachon University Gil Medical Center, Incheon/KR, 2Internal Medicine, Gachon University Gil Medical Center, Incheon/KR

Background: Depletion of skeletal muscle mass (sarcopenia) has been associated with poor prognosis in patients with malignancy. Although CT-determined skeletal muscle index (muscle area/height2, cm2/m2) is regarded as a reference standard to evaluate the presence of sarcopenia, it is unclear the agreement between DECT derived images on the quantification of skeletal muscle area (SMA). The purpose of this study is to evaluate the agreement of SMA quantification between dual-energy CT (DECT) derived images (virtual non-contrast; VNC and non-contrast weight-average 120kVp images) and conventional non-contrast CT image.

Method: For a total 128 lung cancer (LCA) patients who underwent DECT at the time of diagnosis, SMA were measured using non-contrast CT, and DECT images (post-processed VNC and weight-average 120kVp). Pairs T-test was used to compare the quantification results, and intraclass correlation coefficients (ICC) for the agreement between three scan results.

Result: The agreement was excellent (ICC=0.991) between three images. However, SMA was significantly higher in VNC (mean±SD, 125.2±23.8cm², p<0.001) and weight-average 120kVp (107.4±22.0cm², p<0.001) in comparison with non-contrast CT (104.7±22.2cm²). When using recently proposed L1 muscle index cutoff (46 cm²/m² for male, 29 cm²/m² for female) for sarcopenia, the prevalence of CT-determined sarcopenia is significantly decreased using weight-average 120kVp and VNC to 53.1% and 22.7%, compared with 58.6% using non-contrast CT.

Conclusion: Among those 177 lymph nodes, 70 lymph nodes were proven to be metastasis. Of 237 patients undergoing neoadjuvant CCRT for stage IIIa NSCLC, 135 patients was performed to evaluate the predictive performance. 125.2±23.8cm², p<0.001) in comparison with non-contrast CT.

Keywords: skeletal muscle mass, dual energy CT, sarcopenia

P2.01-56 METASTASES IN RESIDUAL PET UPTAKE OF LYMPH NODES AFTER TREATMENT: ADDED VALUE OF CT RADIOMIC APPROACH FOR PREDICTION

C.H. Kim1, H.Y. Lee1, H.K. Kim1, J.Y. Choi2
1Samsung Medical Center, Seoul/KR, 2Department of Thoracic and Cardiovascular Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR, 3Nuclear Medicine, Samsung Medical Center, Seoul/KR

Background: Although substantial decrease of FDG uptake on positron emission tomography-computed tomography (PET-CT) holds promise metabolic response, predicting pathologic complete response of lymph nodes still remains challenging. We investigated the potential of CT radiomics features on predicting pathologic complete response of lymph nodes showing residual uptake on PET-CT after neoadjuvant concurrent chemoradiotherapy (CCRT) in stage IIIa non-small cell lung cancer (NSCLC).

Method: From 2004 through 2013, all consecutive patients who underwent neoadjuvant CCRT for stage IIla NSCLC, post-treatment PET-CT, and curative operation were included. As for all lymph nodes which showed remaining positive FDG uptake on restaging PET-CT, 161 CT Radiomic features from physical, shape, histogram, texture, regional feature categories were extracted. Positive and negative lymph node metastasis was compared with respect to clinicopathologic characteristics as well as CT CT radiomic features using the Pearson y2 test or the Fisher exact test. Multivariate logistic regression was used to explore the predictive model for the detection of metastatic lymph nodes, for which receiver operating characteristic (ROC) curve analysis was performed to evaluate the predictive performance.

Result: Of 237 patients undergoing neoadjuvant CCRT for stage IIla NSCLC, 135 patients (56.9%) showed residual PET uptake on 177 lymph nodes after treatment. Among those 177 lymph nodes, 70 lymph nodes were proven to be malignant (39.5%, 70 of 177). On multivariate analysis, metastatic lymph nodes were significantly tended to be more squamous cell carcinoma (46.61%), followed by adenocarcinoma (41.05%). Curation

Keywords: non-small cell lung cancer, Stage IIIa, prognostic factor

P2.01-57 PROGNOSTIC IMPLICATION OF CLINICAL, IMAGING, AND PATHOLOGIC PARAMETERS IN N2+ STAGE IIIA LUNG CANCER PATIENTS

H. Kim1, Y.C. Ahn2, J.M. Kim1, H. Pyo1, J.M. Noh1, J. Sun1, J.S. Ahn1, M. Ahn1, K. Park1, Y.S. Choi1, J. Kim1, J.I. Zo1, Y.M. Shim1, J. Han1, S.H. Hyun2, J.Y. Choi3
1Radiation Oncology, Samsung Medical Center, Seoul/KR, 2Medicine, Samsung Medical Center, Seoul/KR, 3Thoracic Surgery, Samsung Medical Center, Seoul/KR

Background: As a comprehensive study of large scale and long-term clinical outcomes from a single institution, we are trying to analyze any predictive or prognostic factors for survival outcomes in N2+ NSCLC patients. The purpose of this study is to investigate the efficacy of clinical, imaging (CT and PET-CT), and pathologic parameters, as a prognostic factor in N2+ NSCLC patients undergoing tri-modality therapy.

Method: We retrospectively reviewed 160 patients with N2+ NSCLC patients between January 2008 and June 2014. All patients underwent preoperative concurrent chemoradiotherapy (CCRT) (44-45 Gy in 22-25 fractions concurrent with weekly DP chemotherapy) and surgery. Clinical, imaging (CT and PET-CT), and pathologic parameters were analyzed with respects to outcomes.

Result: In 80 pathologic down-staging patients, complete pathologic complete response following preoperative CCRT were achieved in 66 (41%) and 13 patients (8.1%), respectively. The median follow-up durations of all patients was 43 months (2-106 months). The 5-year rates of disease-free survival (DFS) and overall survival (OS) were 33.3% and 53.0%, respectively. Pathologic N down-staging was a most important pathologic parameter as a prognosticator.

Keywords: clinical, imaging, pathologic parameters

P2.01-58 DEMOGRAPHICS, CLINICAL CHARACTERISTICS AND TREATMENT SEQUENCING IN STAGE III UNRESECTABLE NSCLC PATIENTS: A CANCERLINQ DISCOVERY DATABASE (CLQ) COHORT

A. Klein1, I. Herr2, S. Macalchan3, D. Potter3
1Astra Zeneca, Gaithersburg/MD/US, 2Evidera, London/GB, 3AstraZeneca, Gaithersburg/MD/US

Background: To describe the demographics, clinical characteristics and treatment sequencing among a real-world cohort of stage III unresectable non-small cell lung cancer (NSCLC) treated with chemoradiation therapy (CRT) in the US. Method: Cancelling Discovery Database (CLQ), launched by the American Society of Clinical Oncology (ASCO) in 2016, consists of longitudinal, demographically and geographically diverse data aggregated from oncology practice Electronic Health Record (EHR) databases nationwide. 70 lymph lymph retrospective cohort comprises 324 stage III unresectable NSCLC patients who received concurrent, platinum-based chemoradiation between January 1, 2007 and December 31, 2017 (study period). A patient was considered unresectable if s/he did not have surgery within 6 months of the stage III diagnosis date (study index date).

Result: A patient’s follow-up period was defined as the time from study index date until the end of the study period, patient death, or loss to follow up, whichever event occurred first. The cohort was mostly male, with a mean age of 66.86 years at index date. Nearly all patients of the cohort (93.57%) had an initial diagnosis of stage III (72.03%, IIIA, 2.78% IIIB); 2.47% had an initial stage I diagnosis and 4.00% had an initial diagnosis of stage II. The most common histology was squamous cell carcinoma (46.61%), followed by adenocarcinoma (41.05%). Curation

Keywords: quantitative imaging analysis, Radiomics, lymph node metastasis
related to clinical characteristics (e.g., ECOG status, smoking status and other comorbidities) are ongoing, so they are largely missing at this time. During the mean follow-up time of 26.64 months, the cohort received 1.60 lines of therapy (LOT). The most common treatment sequence during the follow-up period consisted of platinum therapy + CRT (82.72%); almost 10% of patients received platinum therapy + CRT, followed by immuno-oncology (IO) therapy. Approximately 33.90% of patients progressed to line of therapy 2 (LOT2) and 29.84% progressed to line of therapy 3 (LOT3), with nearly 18% of patients receiving IO therapy during LOT2 or LOT3. Conclusion: This exploratory analysis of a stage III unresectable NSCLC cohort is descriptive in nature and suggests that the CLQ Discovery Database can be used to construct generalizable cancer cohorts. Future analyses will focus on validation of CLQ as a real-world data source, using findings from other retrospective, observational studies conducted by AstraZeneca as a benchmark.

Keywords: non small cell lung cancer, CancerLinQ, Unresectable

Method: Venous blood samples were obtained for CTC analysis before administration of chemotherapy on treatment days (D) 1, 8, 22 and 43, and at disease progression. Blood was collected at Biocept CEE-Sure™ blood collection tubes, and samples were processed at Biocept’s CLIA-certified, CAP-accredited laboratory. Biocept’s Target Selector™ CTC platform uses an antibody capture cocktail and microfluidic channel for CTC ecology (IO) biomarker analysis. Study objectives include determining the proportion of patients with D1 CTC detection, and CTC correlation to time to progression and overall survival (OS). Result: Twenty-three patients have been enrolled so far in this ongoing study; 16 (69.5%) adenocarcinoma, 7 (30.4%) squamous cell carcinoma. Fifteen patients progressed on initial therapy to date, with a median time to progression of 110 days. Of 22 patients with blood collections at D1 (treatment start), 14 (63.6%; 10 adenocarcinoma, 4 squamous) had detectable CTCs. For patients with detectable D1 CTCs, CTC count at D8 decreased in 13/14 (92.9%; 9 adenocarcinoma, 4 squamous) subjects, and was unchanged in 1 individual (7.1%; adenocarcinoma). Patients with 1-5 CTCs at D1 had a mean time to progression of 140.75 days; patients with >5 CTCs at D1 had a mean time to progression of 101.83 days (p=0.17). Among patients with undetectable CTCs at D1, CTCs remained undetectable in 4/8 (50%; all adenocarcinoma) and increased in 2/8 (25%; one each of adenocarcinoma and squamous) of subjects; CTCs were not collected at D8 for 2 individuals. Conclusion: Implementation of Biocept’s Target Selector™ enables the highly sensitive detection of CTCs in the clinical setting. CTCs are detectable in the majority of patients with metastatic NSCLC. In subjects with detectable CTCs prior to chemotherapy, CTC count declines within a week after starting chemotherapy in >90% of patients. Preliminary data suggest that CTC enumeration may have prognostic and predictive potential for patients receiving chemotherapy. Further data from this ongoing study may provide additional insight into the role of CTC analysis applied to clinical practice.

Method: Cachexia has been associated with inferior outcomes for patients with stage III/IV NSCLC (aNSCLC). This study evaluates the potential relationship between body mass index (BMI) with progression free survival (PFS) and overall survival (OS) in aNSCLC patients on nivolumab or pembrolizumab. Background: Cachexia has been associated with inferior outcomes for patients with stage III/IV NSCLC (aNSCLC). This study evaluates the potential relationship between body mass index (BMI) with progression free survival (PFS) and overall survival (OS) in aNSCLC patients on nivolumab or pembrolizumab. Method: Patients with aNSCLC who received at least once cycle of nivolumab or pembrolizumab between January 2015 and January 2017 were identified in our pharmacy database. Patient demographics, longitudinal BMIs, treatment start date, date of progression, and last follow-up were recorded. OS and PFS were assessed by log-rank tests and Cox proportional hazard analysis. Time-dependent Cox model based analyses were used to assess the association between time dependent BMIs. Result: The study included 162 aNSCLC patients. Median age 68 yrs, male/female 40.1%/59.9%. BMI values were obtained longitudinally at baseline, 6 wks, and 12 wks. Median BMI: baseline 24.69, at 6 wks 24.75, and at 12 wks 24.89. Median change in BMI: baseline to 6 wks = -0.33 (range: -6.52 to +3.41), and 6 wks to 12 wks = -0.21 (range: -4.56 to +2.73). Hazard ratios for change in BMI with OS: baseline to 6 wks HR 0.7198 (p=0.0010), baseline to 12 wks HR 0.8703 (p=0.0595), and 6 wks to 12 wks HR 0.8284 (p=0.0668). Conclusion: Change in BMI over time is associated with OS in aNSCLC patients treated with nivolumab or pembrolizumab. Although decrease in BMI may simply be a prognostic marker for treatment with immune checkpoint inhibitors, it is possible that understanding potential relationships between cachexia and the immune system may be useful in developing strategies to improve response to immunotherapy.

P2.01-62 EXTRACELLULAR VESICLE-BASED EGFR GENOTYPING IN BRONCHOALVEOLAR LAVAGE FLUID FROM NON- small CELL LUNG CANCER PATIENTS

Konkuk University Medical Center, Seoul/KR

Background: Liquid biopsies for EGFR genotyping using plasma cell-free DNA (cfDNA) have limited value due to low sensitivity. Extracellular vesicles (EV) have been proven to contain mutant EGFR DNA in bronchoalveolar lavage fluid (BALF) from non-small cell lung cancer (NSCLC) patients. As an alternative to plasma liquid biopsies using cfDNA, we investigated the feasibility of EV-based liquid biopsy for EGFR genotyping using BALF from NSCLC patients, prospectively. Method: EV DNA was extracted from the BALF of NSCLC patients with confirmed tissue/cytology-based EGFR genotyping at initial diagnostic work-up stage. The number of patients with stage I, II, III, and IV are 37 (27%), 6 (4.4%), 23 (16.8%), 71 (51.8%), respectively. The patients were selected by favorable demographic data for EGFR mutation. EGFR mutation testing was done by peptide nucleic acid (PNA) clamping- assisted fluorescence melting curve analysis. Result: The overall sensitivity and specificity of EGFR genotyping using BALF EV DNA were 69.5% and 83.3% and the concordance rate was 77.4%. (Kappa=0.534, P=0.000) The sensitivity was significantly increased along with the stage (42.1% in stage I, II, 60.0% in stage III, and 100% in stage IV). Especially, in stage IV disease, BALF EV-based EGFR typing did not miss all of tissue-proven 30 EGFR mutant cases and detected 9 additional mutant cases. Detection of EGFR mutation becomes significantly more sensitive as T stage increases. (T1 = 43.8%, T2 = 75%, T3 and T4 = 100%) Turn-around time (TAT) for EGFR genotyping using BALF EV DNA was 1-2 days, while it takes usually 2 weeks for tissue typing. Conclusion: BALF EV-based EGFR genotyping is a novel and highly promising method with rapid TAT and incredible accuracy in stage IV NSCLC patients. Further research in early stage disease is necessary and the matter of over-detection should be clinically validated by evaluating EGFR-TKI drug response.

P2.01-63 ARE HEART DOSES ASSOCIATED WITH SURVIVAL IN NSCLC TREATED WITH POST-OPTERATIVE RADIOTHERAPY? A NATIONAL POPULATION-BASED STUDY

1Radiation Oncology, National University Cancer Institute Singapore, Singapore/SG, 2Radiation Oncology, National Cancer Centre, Singapore, Singapore/SG, 3National Registry of Disease Office, Research and Surveillance Division, Health Promotion Board, Singapore, Singapore/SG, 4Radiation Oncology, National University Hospital, Singapore, Singapore/SG

Background: Some early studies suggested that post-operative thoracic radiotherapy (PORT) using non-modern radiation techniques in non-small cell lung cancer (NSCLC) might cause significant treatment-related toxicities. Higher radiation doses to the heart have been recently linked to more cardiac events and worse overall survival (OS) in patients with locally-advanced NSCLC treated with thoracic irradiation. We embarked on a national population-based study to assess the association between radiation heart doses, acute myocardial infarct (AMI) rates and OS in NSCLC patients treated with PORT using contemporary radiation techniques. Method: Study eligibility criteria included stage I to III NSCLC treated with PORT from 2007 to 2014 in our public hospitals which comprised about 80% of national caseload. The clinical and dosimetric data were collected from the institutional electronic medical records and linked to the national death and AMI registries. Univariate Cox regression analysis was performed using STATA version 13. Result: 43 eligible patients were identified. Median follow-up duration was 36.6 months. Characteristics of study population are summarized in Table 1. There were no AMI events. The 1- and 2-year OS were 74% and 65%. Univariate Cox regression analysis showed that age (hazard ratio, 1.06; 95% confidence interval, 1.01 to 1.10; P= 0.008) was the only significant factor associated with OS. Radiation heart doses, including mean heart dose, volume of heart receiving at least 5, 25, 30, 40, 50 Gy and dose to 30% of heart volume, were not associated with OS.

**Conclusion:** This study found that various radiation heart doses were not significantly associated with OS in patients with NSCLC treated with PORT. Studies with larger sample size and longer term follow-up are needed to assess cardiac outcome, given the possibility of late occurrence of AMI events.

**P2.01-64 PROGNOSTIC VALUE OF PET-CT AFTER INDUCTION CHEMORADIOThERAPY AND CURATIVE SURGERY IN IIIA-N2 NSCLC: A MULTI-INSTITUTIONAL ANALYSIS**

J.H. Lee  
Radiation Oncology, St. Vincent's Hospital, the Catholic University of Korea, Suwon/KR

**Background:** We evaluated the correlation of clinical staging on positron emission tomography-computed tomography (PET-CT) and pathologic staging and the prognostic value of PET-CT after induction chemotherapy in patients with locally advanced Non-Small Cell Lung Cancer (NSCLC).

**Method:** We analyzed 42 cases of clinical stage IIIA-N2 NSCLC who receive 2 to 4 cycles of pre-operative chemotherapy with or without radiation followed by curative resection. The maximum standard uptake value (SUVmax) of the suspected lesion on PET-CT was recorded. PET-CT findings after induction chemotherapy were compared with those of initial PET-CT and pathology after surgery.

**Result:** The accuracy of PET-CT in restaging of the primary tumor after induction chemotherapy was 50.0%. 13 (30.2%) of 42 patients were underestimated ycT stage, and 3 (7.1%) of 42 patients were overestimated ycT stage by PET-CT scan. The accuracy of PET-CT in restaging of the nodal disease was 71.4%. 6 (14.3%) of 42 patients were underestimated ycN stage, and 6 (14.3%) of 42 patients were overestimated ycN stage as compared with pathologic staging.

**Conclusion:** The 2-year overall survival (OS) and relapse-free survival (RFS) rate were 68.5% and 40.9%, respectively. Complete responders (cTNOMO) on PET-CT after induction chemotherapy had a significantly longer RFS time than did incomplete responders (28.3 months versus 9.1 months, P = 0.021). Complete response on PET-CT after induction chemotherapy with or without radiation was a good prognosticator for RFS in stage IIIA-N2 NSCLC patients who received surgery. However, response evaluation on PET-CT after induction chemotherapy should be interpreted with caution due to its unacceptable accuracy.

**P2.01-65 ASSESSMENT OF INDIVIDUAL AND COMBINED OF FIVE SERUM TUMOR MARKERS FOR LUNG CANCER**

Y. Li, H. Xu, J. Ye, C. Chen  
Department of Respiratory, the First Affiliated Hospital of Wenzhou Medical University, Wenzhou/CN

**Background:** Tumor markers were often used to help in diagnosis lung cancer. The most known tumor markers in lung cancer were SCC, CEA, CYFRA21-1, NSE, and ProGRP. The roles of these tumor markers in diagnosis remain to be determined.

**Method:** This retrospective study conducted between January 2015 and April 2017 at the First Affiliated Hospital of Wenzhou Medical University in China. A total of 2569 patients sought medical attention for a pulmonary mass presence to either confirm or exclude the disease. SCC, CEA, Cyfra21-1, NSE, and ProGRP were examined with suspicious lung cancer. SPSS 20.0 used for all statistical analyses.

**Result:** Finally, 1315 patients were excluded, 1434 patients were selected. Lung cancer was established in 1095 patients (737 males and 358 females), average age of (56.3±10.8) years and excluded in 339 patients (229 males, 117 females), average age of (55.7±13.4). Abnormal CEA were represented in 65.6% of adenocarcinoma. SCC-Ag and CYFRA21-1 significantly higher in 59.8% and 79.0% of squamous cell carcinoma respectively. Abnormal values of NSE and ProGRP were associated with 93.3% and 80.2% of SCC, CEA and CYFRA 21-1 recorded sensitivities of 65.6% and 65.3% respectively in adenocarcinoma. In squamous cell carcinoma, SCC-Ag and CYFRA21-1 displayed sensitivities of 59.8% and 79% respectively. CEA and ProGRP showed sensitivities of 93.5% and 80.8%. The combination of different tumor markers yielded sensitivity of 93.5% and 80.2%. In SCLC, NSE and ProGRP showed specificity of 93.5% and 80.8%. The combination of different tumor markers recorded the highest sensitivity of 95.6%. The CYFRA 21-1 combine with CEA recorded the highest specificity of 79.9%. ROC curves were plotted to explore the diagnostic role of these tumor markers individually and in combination. CYFRA 21-1 with an AUC of 0.888 (95%CI 0.820-0.920) performed better than CEA and the other remaining individual tumor markers. The combination of five tumor markers, with an AUC of 0.904 (95% CI 0.888-0.920) is the highest shown as figure 1.

**P2.01-64 PROGNOSTIC VALUE OF PET-CT AFTER INDUCTION CHEMORADIOThERAPY AND CURATIVE SURGERY IN IIIA-N2 NSCLC: A MULTI-INSTITUTIONAL ANALYSIS**

J.H. Lee  
Radiation Oncology, St. Vincent’s Hospital, the Catholic University of Korea, Suwon/KR

**Background:** We evaluate the correlation of clinical staging on positron emission tomography-computed tomography (PET-CT) and pathologic staging and the prognostic value of PET-CT after induction chemotherapy in patients with locally advanced Non-Small Cell Lung Cancer (NSCLC).

**Method:** We analyzed 42 cases of clinical stage IIIA-N2 NSCLC who receive 2 to 4 cycles of pre-operative chemotherapy with or without radiation followed by curative resection. The maximum standard uptake value (SUVmax) of the suspected lesion on PET-CT was recorded. PET-CT findings after induction chemotherapy were compared with those of initial PET-CT and pathology after surgery.

**Result:** The accuracy of PET-CT in restaging of the primary tumor after induction chemotherapy was 50.0%. 13 (30.2%) of 42 patients were underestimated ycT stage, and 3 (7.1%) of 42 patients were overestimated ycT stage by PET-CT scan. The accuracy of PET-CT in restaging of the nodal disease was 71.4%. 6 (14.3%) of 42 patients were underestimated ycN stage, and 6 (14.3%) of 42 patients were overestimated ycN stage as compared with pathologic staging.

**Conclusion:** Combined TMs can potentially improve the specificity and sensitivity values in LC diagnosis.

P2.01-66 COMPARISON OF EGFR MUTATION STATUS IN TISSUE AND PLASMA CELL-FREE DNA DETECTED BY ARMS IN ADVANCED LUNG ADENOCARCINOMA PATIENTS

Y. Li, H. Xu, S. Su, J. Ye, C. Chen
Department of Respiratory, the First Affiliated Hospital of Wenzhou Medical University, Wenzhou/CN

Background: EGFR mutation is a reliable and sensitive biomarker for the treatment of advanced lung adenocarcinoma patients using EGFR-TKIs. Tumor tissue has been used as the standard sample for EGFR mutation detection in the clinical practice currently, but it has some limitations. Therefore, EGFR mutation detection in plasma cell-free DNA has been applied to the clinical practice, however, its diagnostic accuracy remains not consistent. Method: The present prospective study enrolled adult patients presenting with advanced lung adenocarcinoma. EGFR mutations detection in plasma cfDNA and tumor tissues by ADx-ARMS were tested. NGS in plasma was performed in patients with inconsistent gene regions mutation in the paired plasma and tissue samples by ADx-ARMS. We calculated the clinical sensitivity, specificity, positive prediction value (PPV), and negative prediction value (NPV) of ADx-ARMS for EGFR mutation status in plasma cfDNA, considering the mutations in tumor tissues as gold standard for measurements. The objective response rate (ORR) and progression-free survival (PFS) were also calculated in patients with EGFR mutation and receiving first-generation EGFR-TKIs therapy. The study was approved by the Institutional Review Board of the first affiliated hospital of Wenzhou Medical University (2016-017). Result: 203 patients were enrolled, mutations were detected in 58.6% (119/203) of tumor tissues and same mutations in 31.0% (63/203) of the matched plasma using ADx-ARMS. The overall rate of consistency of the EGFR mutation statuses for the paired plasma and tissue samples was 71.9%. The sensitivity and the specificity of detecting EGFR mutations in the plasma by ADx-ARMS were 52.9% and 98.8%, respectively. There were 3 cases inconsistent matching with plasma in gene regions: 1 carrying both 19-Del +1799M in tumor tissue but carried single 19-Del in plasma, and 2 carried both LB85R +1799M but single LB85R in plasma. We validated by NGS. An objective response rate (ORR) of 58.3% was observed among the 72 patients who were mutation-positive in tumor tissues and received Gefitinib or Icotinib as first-line treatment. And the ORR was 61.9% among the 42 patients with EGFR mutations in plasma. The median PFS of patients with EGFR mutations detected by ADx-ARMS in tumor tissue and plasma were 9.50 months versus 10.25 months. The median overall survival of patients presenting with advanced lung adenocarcinoma. EGFR mutations in plasma cfDNA for patients with advanced lung adenocarcinoma.

P2.01-67 THE PROGNOSTIC ANALYSIS OF LUNG CANCER PATIENTS WITH OCCULT MALIGNANT PLEURAL DISEASE AT THORACOTOMY

S. Li, P. Zhang, S. Zhang, M. Huang, Y. Ma, Y. Yang
Department of Thoracic Surgery II, Peking University Cancer Hospital & Institute, Beijing/CN

Background: This study aims to determine the clinicopathological prognostic factors for occult malignant pleural disease (MPD) first detected at thoracotomy in patients with non-small cell lung cancer (NSCLC) and assess the outcome of surgical intervention. Method: A total of 120 patients with NSCLC at thoracotomy from January 2006 to October 2016 were evaluated. Survival curves were estimated by the Kaplan–Meier method, and Cox regression analysis was performed to validate the selected risk factors. Clinical and pathologic parameters were balanced by propensity score matching when assessing surgical intervention. Result: With a median follow-up of 34 months, the 5-year overall survival of 120 patients was 28.0%. Multivariate analyses showed male (p=0.044), advanced T stages (p<0.001), advanced N stages (p=0.02), pleural invasion in image (p=0.005), pleural effusion (p=0.027), surgical intervention (p=0.008) and EGFR status (p=0.003) were independent predictors of survival. The 5-year survival rate and median survival time (MST) for 21 patients with lobectomy were 71.6% and undefined, compared with 25.6% and 40.0 months in 46 patients with sublobectomy. When 53 patients only subjected to open-close surgery, their 5-year survival rate and MST were 23.4% and 30.2 months. After propensity score matching, both 21 patients were included in lobectomy group and sublobectomy/open-close group. The overall survival of lobectomy group was better than the control group (p=0.046). Conclusion: The prognosis of MPD patients first detected at thoracotomy was affected by grade, stage, pleural invasion, pleural effusion, surgical intervention and EGFR status. Lobectomy maybe confers better survival compared with sublobectomy and exploratory thoracotomy. Keywords: lung cancer, Malignant pleural disease, Surgery

P2.01-68 CAPTURE-BASED SEQUENCING DEPICTS EVOLUTION CHARACTERISTICS OF PULMONARY SARCOMATOID CARCINOMA

X. Liu, X. Chen; F. Wang; Z. Xie; C. Xu; H. Wang; L. Chang; X. Xia; T. Guan; X. Yi; L. Chen
1Department of Radiation Oncology, Hunan Cancer Hospital and the Affiliated Cancer Hospital of Xiangya School of Medicine, Changsha/CN, 2Department of Medical Oncology, Sun Yat-Sen University Cancer Center, Guangzhou/CN, 3Department of Molecular Diagnostic, Sun Yat-Sen University Cancer Center, Guangzhou/CN, 4Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Lung Cancer Institute, Guangzhou/CN, 5Department of Pathology, Affiliated Hospital of Academy of Military Medical Sciences, Beijing/CN, 6Geneplus-Beijing Institute, Beijing/CN

Background: Pulmonary sarcomatoid carcinoma (PSC) is a very rare subset of highly aggressive and poorly differentiated non-small cell lung cancer. The mutational profile of PSC was reported previously. However, the intratumor heterogeneity and evolution characteristics of PSC remains unknown. Method: This study enrolled 39 patients (pts) with PSC. A total follow-up time was 7 months (ranged from 3 to 33 months). Each tumor sample was divided to cancer tissue and sarcoma tissue by microdissection. Matched distant normal tissues were also collected for removing germline background. Capture-based sequencing was performed using a panel covering 1021 genes related to solid tumors. Somatic mutations were used to analyze intratumor heterogeneity and evolution characteristics. Tumor mutation burden (TMB) analysis interrogated single nucleotide variants, small insertion and deletion, with VAF $\geq$ 3 %. TMB-high pts were identified with $\geq$ 9 mut/MB (upper quartile of data from geneplus). Result: Capture-based sequencing was done on 90 tissues, including cancer tissues, sarcoma tissues and matched distant normal tissues from 30 pts. Nine patients were excluded due to insufficient DNA samples. A median effective depth of coverage of 1299 x was obtained in tissue samples. A total number of 608 mutations were detected, including driver mutations in TP53 (73%, 44/60), MET (22%, 12/60), EGFR (20%, 12/60), KRAS (20%, 12/60), and NFI (17%, 10/60). Interestingly, mutations in MET and KRAS were demonstrated to be mutally exclusive in cancer and sarcoma tissues. Shared mutations between cancer and sarcoma tissues were 43%. The median of TMB of sarcoma and cancer samples were both 8.6 mutations/Mb. High TMB were identified in 40% (12/30) pts of sarcoma samples and 43% (13/30) pts of cancer samples, respectively. TMB of sarcoma tissues was significantly correlated to that of cancer tissues (Pearson r = 0.92, p-value=0.01), with a consistence of 90 %. Furthermore, the fraction of brachial mutations in cancer tissues was related to the worse OS of PSC (Log-rank, HR=3.2, 95% CI=1.1-9.4, p=0.04). Conclusion: None of the shared mutations between cancer and sarcoma tissues were 43%. The median of TMB of sarcoma and cancer samples were both 8.6 mutations/Mb. High TMB were identified in 40% (12/30) pts of sarcoma samples and 43% (13/30) pts of cancer samples, respectively. TMB of sarcoma tissues was significantly correlated to that of cancer tissues (Pearson r = 0.92, p-value=0.01), with a consistence of 90 %. Furthermore, the fraction of brachial mutations in cancer tissues was related to the worse OS of PSC (Log-rank, HR=3.2, 95% CI=1.1-9.4, p=0.04). Conclusion: Sarcoma tissues shared mutations with cancer tissues. Mutations and TMB analysis might help to guide treatment decisions of PSC in both tyrosine kinase and immune checkpoint inhibitors. Evolution characteristics could serve as potential prognostic factors in PSC. Keywords: evolution, Pulmonary sarcomatoid carcinoma, mutation profiling

P2.01-69 EZH2-MEDIATED EPIGENETIC SUPPRESSION OF GDF15 PREDICTS A POOR PROGNOSIS AND REGULATES CELL PROLIFERATION IN NON-SMALL CELL LUNG CANCER

X. Lu, X. Liu, R. Guo
Department of Oncology, First Affiliated Hospital of Nanjing Medical University, Nanjing, Nanjing/CN

Background: Growth differentiation factor 15 (GDF15), a member of the TGF-β superfamily of cytokines, has been reported to exert very heterogeneous functions in various tumors. However, the role of GDF15 and its underlying mechanism in mediating non-small cell lung cancer (NSCLC) progression remain unknown. Method: GDF15 expression level was analyzed in 66 NSCLC tissues by quantitative reverse transcription PCR (qRT-PCR). The effect of GDF15 on proliferation was evaluated by MTT and colony formation assays, flow cytometric analysis. NSCLC cells
transfected with pcDNA-GDF15 or empty vector were injected into nude mice to study the effect of GDF15 on tumorigenesis in vivo. Chromatin immunoprecipitation (ChIP) assay was used to investigate the mechanism of action of GDF15 in the NSCLC cells. **Result:** In this study, we found that GDF15 is down-regulated in paired NSCLC tissues and is correlated with poor clinical outcomes in NSCLC. Further experiments demonstrated that overexpression of GDF15 significantly repressed NSCLC proliferation both in vitro and in vivo. Mechanistic studies reveal that inhibition of EZH2 expression prevented its binding to the GDF15 promoter region and reduced the trimethylation modification pattern of H3K27. **Conclusion:** Together, our data uncover that GDF15 is a direct target of EZH2, and as a regulator of proliferation, might serve as a candidate prognostic biomarker and target for new therapies in human NSCLC.

**Keywords:** EZH2, GDF15, NSCLC

**P2.01 ADVANCED NSCLC**

**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.01-70 TUMOR TREATING FIELDS AND RADIOSURGERY FOR SUPRA- AND/OR INFRATENTORIAL BRAIN METASTASES (1-10) FROM NSCLC IN THE PHASE 3 METIS STUDY**

M. Mehta1, V. Gondi2, M. Ahiwlawa3, P. Brown4, U. Weinberg5

1Miami Cancer Institute, Coral Gables/FL/US, 2Northwestern Medicine Cancer Institute, Evanston/US, 3Brain Metastases Research Program, Cleveland Clinic, Cleveland/US, 4Mayo Clinic, Rochester/US, 5Novocare GmbH, Lucerne/CH

**Background:** Tumor Treating Fields (TTFields) are non-invasive, loco-regional, anti-mitotic treatment modality comprising low intensity alternating electric fields. TTFields has demonstrated efficacy in non-small cell lung cancer (NSCLC) in both in vitro and in vivo models, and in a phase II/III clinical study, TTFields treatment to the brain was safe and extended overall survival in newly-diagnosed glioblastoma. This prospective, multicenter study [NCT02831959] investigated the efficacy, safety and neurocognitive outcomes of TTFields in NSCLC patients with brain metastases (BMs). **Method:** NSCLC patients (N=270) with 1-10 BMs are randomized 1:1 to stereotactic radio surgery (SRS) followed by continuous TTFields ([150 kHz, > 18 hours/day] within 7 days of SRS or supportive care. The TTFields portable device delivers TTFields to the brain using 4 transducer arrays and allows normal daily activities. Patients receive the best standard-of-care for their systemic disease. Patients are followed every two months until second intracranial progression. **Result:** Patients in the control arm could cross over to TTFields at the time of second intracranial progression. Key inclusion criteria: KPS ≥70, new diagnosis of 1 inoperable or 2–10 supra- and/or infratentorial BMs from NSCLC amenable to SRS; KPS ≥70; and optimal therapy for extracranial disease. Prior WBRT or surgical resection of metastases, a single resectable lesion or recurrent BMs were exclusionary. Primary endpoint was time to 1st intracranial progression. Secondary endpoints included time to neurocognitive failure (HLVT, COWAT, and TMT1), overall survival, radiological response rate (RANO-BM and RECIST V1.1), quality-of-life, adverse events; time to first/second intracranial progression for patients with 1–4 and 5–10 BMs; bi-monthly intracranial progression rate from 2–12 months; and time to second intracranial and distant progression. The sample size (N=270) was calculated using a log-rank test (Lakoski 1988 and 2002) with 80% power at a two-sided alpha of 0.05 to detect a hazard ratio of 0.57. 

**Conclusion:** Section not applicable **Conclusion:** Section not applicable

1Cirugía Torácica, Hospital Clinic Barcelona, Barcelona/ES, 2Cirugía Torácica, Hospital Clinic de Barcelona, Barcelona/ES

**Background:** The present study describes and compares the rate of complications in hospital length of stay (LOS), recurrences and long-term survival between pneumonectomies and bronchial sleeves in our center’s experience. **Method:** This is a descriptive, retrospective study. All patients who underwent pneumonectomy or bronchial sleeve for NSCLC in our center between 2011 and 2017 were included. Individual clinical report was done, other indications for surgery were excluded. General demographics, preoperative lung function, histology and postoperative complications were included. Oncologic follow-up was done to detect recurrence and death. The statistical program used was SPSS. **Result:** From of 87 patients registered, 47 had bronchial sleeve resection (54,02%) and 40 pneumonectomy (45,97%). The average age: SL 63.7, PN 61.7 years. Male frequencies were equal in both groups (52%), cStageIIIA, poor radiological response, or minor pathological response showed significantly worse RFS. Median survival in months, p=0.35).

**Conclusion:** There are no local recurrences in any groups, although pneumonectomies had the highest incidence of complications. Both techniques had postoperative complications: SL 17 (68%), PN 8 (32%). The most frequent complications were persistent air leak (SL 6 cases, PN 0 cases, p=0.46). Histological type predominant was C. squamous: SL 57,44%, PN 60%, p=0,46). The average LOS was higher SL than PN (2.37 and 1.67, respectively). Overall survival (OS) was not different SL versus PN (54,63% and 58.96, p=0.46).

**P2.01-71 CLINICAL OUTCOME OF INDUCTION CHEMORADIOThERAPY FOLLOWED BY SURGERY FOR THE PATIENTS WITH CN2 NON-SMALL CELL LUNG CANCER**

A. Miura1, J. Soh1, K. Araki1, Y. Takahashi1, E. Kurihara1, Y. Ogoshi1, K. Shien1, H. Yamamoto1, S. Sugimoto1, M. Yamane1, K. Kiura2, S. Guirao2, R. Guzman2, J.M. Gimferrer2, L. Molins2

1General Thoracic Surgery, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Science, Okayama/JP, 2Respiratory Medicine, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Science, Okayama/JP

**Background:** The treatment strategy for clinical N2 (cN2) non-small cell lung cancer (NSCLC) is still controversial, because its clinical outcome is unsatisfactory and cN2 NSCLC harbors various conditions. In this study, we investigated the clinical outcome of induction chemoradiotherapy (iCRT) followed by surgery in the patients with cN2 NSCLC. **Method:** During 1999 to 2016, 92 patients with cN2 NSCLC were surgically treated after iCRT in our hospital. Overall survival (OS), radiation dose was 46Gy (36 - 60). Complete/major/minor pathological responses were exhibited in 29/36/27 patients, respectively. pCR was observed in 22 patients. The 5-year rates of OS and RFS were 64.1% and 48.1%, respectively. The patients with lower-lobe origin, cStageIII (UICC8th), poor radiological response (progressive or stable disease), major pathological response, re-operation within 30 days after surgery, or recurrence showed significantly worse OS than the others. In addition, the patients with poor radiological response, or minor pathological response showed significantly worse RFS. The multivariate analysis revealed in all the patients with lower-lobe origin tumors and multi-station N2 showed significantly worse OS [Hazard Ratio (HR) 2.55, 95% confidence interval (CI) 1.11 – 5.71, P= 0.028] and RFS (HR 2.45, 95%CI 1.34 – 4.69, P= 0.030), respectively. Adenocarcinoma, lower-lobe origin, multi-station N2, cStageIIIA, poor radiological response, and minor pathological response significantly correlated to recurrence. Among them, adenocarcinoma (odds ratio (OR) 3.75, 95%CI 1.21 – 11.0, P= 0.02), lower-lobe origin (OR 5.22, 95%CI 1.48 – 19.1, P= 0.012), and multi-station N2 (OR 3.63, 95%CI 1.32 – 9.88, P= 0.012) independently correlated to recurrence. **Conclusion:** iCRT followed by surgery may be one of the feasible treatment options for the patients with cN2-NSCLCs, especially for those which harbor non-lower lobe origin and multi-station N2.

**Keywords:** pneumonectomy, bronchial sleeve, long term survival
BACKGROUND: Imaging remains a crucial component in the evaluation of the therapeutic response in precision cancer therapy, because it selectively characterizes tumor burden changes during therapy and provides guides for treatment decisions. The purpose of the present study is to develop an automated analytic module for calculation of tumor growth rate from serial CT scans and evaluate the module functionality and reproducibility in a pilot cohort of advanced NSCLC patients with EGFR mutations treated with EGFR tyrosine kinase inhibitors. Method: The module utilized a commercially available image-processing workstation equipped with a validated tumor volume measurement tool. A novel analytic software module was programmed with the capability to record and display serial tumor volume changes and to calculate tumor volume growth rate over time and added to the workstation. The functionality and reproducibility of the module was evaluated using a pilot cohort of 24 EGFR-mutant NSCLC patients treated with EGFR inhibitors by two independent thoracic radiologists. Result: The module analyzed chest CT scans from 24 patients (5 males, 19 females; median age: 61) with a median of 8 scans per patient, totaling 227 scans and provided a graphical display with an automated calculation of tumor growth rate after the nadir volume for each patient. High inter and intraobserver agreements were noted for tumor growth rates, with concordance correlation coefficients of 0.9323 and 0.9668, respectively. Interpretation of slow versus fast tumor growth was previously identified threshold of ≤0.15/month had a perfect interobserver agreement (κ=1.00), and an excellent intraobserver agreement (κ=0.895). Conclusion: The present study describes the development of an image analytic module for assessing tumor growth rate and the data demonstrates the functionality and reproducibility of the module in a pilot cohort of EGFR-mutant NSCLC patients treated with EGFR-TKI. The image analytic module is an initial step for clinical translation of the tumor growth rate approach to guide cancer treatment in precision oncology.

BACKGROUND: Determination of tumor volume growth rate can help to identify patients who are unlikely to benefit from chemotherapy. The aim of this study is to assess the concordance of tumor growth rate measurements in the same patient by different observers. Method: We validated the module in a pilot cohort of EGFR-mutant NSCLC patients treated with EGFR-TKI. The image analytic module is an initial step for clinical translation of the tumor growth rate approach to guide cancer treatment in precision oncology. Result: The module utilized a commercially available image-processing workstation equipped with a validated tumor volume measurement tool. A novel analytic software module was programmed with the capability to record and display serial tumor volume changes and to calculate tumor volume growth rate over time and added to the workstation. The functionality and reproducibility of the module was evaluated using a pilot cohort of 24 EGFR-mutant NSCLC patients treated with EGFR inhibitors by two independent thoracic radiologists. Result: The module analyzed chest CT scans from 24 patients (5 males, 19 females; median age: 61) with a median of 8 scans per patient, totaling 227 scans and provided a graphical display with an automated calculation of tumor growth rate after the nadir volume for each patient. P2.01-74 DOCETAXEL-RELATED FEBRILE NEUTROPENIA (FN) AND PATIENT REPORTED SYMPTOMS/ QOL (PROS) IN EAST ASIAN (EA) AND NON-EA PATIENTS

Y. Omori1, A. Brabric2, N. Rajani1, S. Enatsu1, J. Shih1, J. Kim1, K. Park2

1Eli Lilly Japan K.K., Kobe/JP; 2Eli Lilly Australia Pty. Limited, West Ryde Nsw/AU; 3Department of Internal Medicine, National Taiwan University Hospital, Taipei/TW; 4Yonsei Cancer Center, Seoul/KR; 5Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR

BACKGROUND: A post hoc analysis of JAVO, a phase II Japanese trial suggested that the QOL (quality of life) deteriorated more rapidly in patients with docetaxel-related FN than in patients without FN. A post hoc analysis of REVEL, a global phase 3 trial, was performed to explore the association between FN and PROs in East Asian (EA) (Korea, Taiwan) and Non-East Asian (Non-EA) patients. Method: Lung Cancer Symptom Score (LCSS) and EQ-5D Visual Analog Scale (VAS) scores were calculated. Time to deterioration (TtD) was defined as the time from randomization to the first 15 mm decrease in LCSS total score or EQ-5D VAS score. Result: Time to deterioration (TtD) was defined as the time from randomization to the first 15 mm decrease in LCSS total score or EQ-5D VAS score. Deterioration of LCSS total score and EQ-5D VAS score was significantly lower in EA patients without FN: 10.50 (with FN) vs 5.55 (without FN) (p=0.1748) and significantly lower in Non-EA patients without FN: 12.97 (with FN) vs 5.94 (without FN) (p=0.0147), demonstrating a greater trend in patients with FN. Conclusion: PROs of EA patients with FN deteriorated more rapidly than in those without FN in contrast with non-EA patients. This finding was consistent with a result in the Japanese phase 2 JAVO trial. Also Non-EA patients without FN maintained their PROs significantly better than patients with FN upon treatment completion. This trend was also shown in EA patients. Prevention of docetaxel-related FN may contribute to maintaining QOL.

1Pathology, Hospital Italiano de Buenos Aires, City of Buenos Aires/AR; 2Oncology, Hospital Italiano, Buenos Aires/AR

BACKGROUND: Lung cancer is the leading cause of cancer mortality worldwide. In most cases, its diagnosis is made at an advanced stage of the disease when patients are no longer candidates for surgical resection of the primary tumor. In these cases, small biopsies and cytological samples obtained through minimally invasive procedures, often represent the only chance of obtaining diagnostic material. This includes molecular study which increasingly incorporates more genes of interest into the diagnostic routine to define the most appropriate treatment. At the Pathology Department of the Hospital Italiano de Buenos Aires, the study of ALK, ROS1 and more recently, the study of MET, is performed on paraffin samples by immunohistochemistry (IHC) or by fluorescence in situ hybridization (FISH). Aims: To incorporate the use of FISH on cytological material within the practices of our department. Method: We collected cytological smears of 1) lung nodule or lung cancer metastases needle biopsies from patients with non-surgical stage disease (n=10); 2) imprinted cytological samples from positive mediastinoscopies during the intraoperative staging of patients with lung cancer (n=11); 3) positive pleural fluid in patients with pulmonary nodule (n=2). Then we performed FISH technique, evaluated the quality of the signal obtained, and compared the results with those obtained on paraffin sections. FISH technique on paraffin blocks was performed using 2XSSC/ proteinase K pretreatment as standardized by our lab. Cytology smears were destained and fixed in 10% methanol and incubated with FISH probe (ALK, ROS1 and MET). Result: All cytology cases had scorable signals and were easy to interpret. Also, no pretreatment was required, assay time was shorter. Depending on cellularity, one same slide was useful for analysis of the three probes. When comparing with IHC and FISH studies, we obtained a 100% correlation with ALK (n=23; positive=2, negative=21); ROS1 (n=5, all negative) and MET (n=5, all negative). Conclusion: This work allowed us to optimize the use of different cytology samples frequently available in advance stage NSCLC for FISH studies. The use of cytological material might improve turnaround time for results and can become a useful tool in pathology labs, in particular when paraffin included material is limited.

Keywords: cytology, FISH

P2.01-76 THE IMPACT OF CONCORDANCE WITH A LUNG CANCER DIAGNOSIS PATHWAY GUIDELINE ON TREATMENT ACCESS IN PATIENTS WITH STAGE IV LUNG CANCER

A. Pattison1, L. Leepa2, J. Yeung1, A. Pierre1, L. Donahoe1, M. Cypel1, M. De Perrot1, K. Yasufuku1, G. Darling1, T. Waddell1, S. Keshavjee1, K. Czarniecka-Kujawa1

1Division of Thoracic Surgery, Toronto General Hospital, University Health Network, University of Toronto, Toronto/ON/CA; 2University of Toronto, Toronto/ON/CA

BACKGROUND: Lung cancer is the leading cause of cancer mortality with the majority of cases diagnosed at an advanced stage. Timely access to treatment is dependent on efficient and appropriate patient assessment

Keywords: advanced NSCLC, antiangiogenesis, Patient reported outcomes (PRO)
and early referral for diagnostic workup. This study aims to assess the impact of referral concordance with a new Lung Cancer Diagnostic Pathway Guideline between KPS and ECOG PS to access to treatment in patients with stage IV lung cancer. **Method:** This is a retrospective cohort study of patients with clinical stage IV lung cancer referred to the Diagnostic Assessment Program (DAP) at a Canadian tertiary cancer centre between November 1, 2015 and May 31, 2017. Patient referrals were defined as concordant or discordant based on Cancer Care Ontario LCDPG. The primary outcome: time to treatment from initial healthcare presentation; was compared between the concordant and discordant referrals. **Result:** Two hundred patients were referred for clinical stage IV lung cancer during the study period. Of these referrals, 151 (75.5%) were assessed and referred in concordance with LCDP guidelines. Guideline concordant referrals were associated with reduced time to treatment from first healthcare presentation compared with guideline discordant referrals (59.3 vs 100.8 days, p<0.001). Time to diagnostic procedure (32.2 vs 88.7 days, p<0.001) and decision to treat (38.5 vs 93.8 days, p<0.001) was also reduced with guideline concordance. The most common reason for discordant assessment and referral was delayed or inadequate investigation of symptoms in a high risk patient (32.7% of discordant referrals). The mean time from referral to diagnostic procedure (19.4 [SD 16.0 days]), decision to treat (23.3 [SD 17.1 days]), and treatment initiation (39.7 [SD 26.3 days]) did not significantly differ between concordant and discordant groups. Time from referral to decision to treat was within 28 days in 71.5% of patients. The mean number of hospital visits from referral to treatment was 4.9 (SD 3.5). Diagnosis was achieved with a single diagnostic test in the majority of patients (91%). The most common method of diagnosis was EBUS-TBNA (33.5%). The most common treatment modalities initiated were radiation (60.5%) followed by chemotherapy (43%) and targeted therapy (21.5%). **Conclusion:** Guideline concordant assessment and referral of patients with stage IV lung cancer results in reduced time to diagnosis and treatment. The utilization of a LCDP for lung cancer provides a streamlined and efficient framework to facilitate early diagnosis and treatment. Future research and education should focus on improving factors leading to a delay in DAP referral.

**Keywords:** diagnosis, Stage IV Lung Cancer, Guideline Concordance

**Conclusion:** The current study provides largest set of paired KPS-ECOG assessments till date. Although both PS tools had good correlation, the performance of the KPS categories previously suggested as being equivalent to ECOG PS categories was found to be highly variable. Cancer clinics should develop and validate their own population-specific KPS categories for interconversion of KPS to ECOG PS.

### P2.01-78 VALIDATION OF INVISIONFIRST CTDNA NGS PROFILING VIA DDPCR TESTING IN PATIENTS WITH NON-SMAL CELL LUNG CANCER (NSCLC)

M. Pritchett1, K. Baker-Neblett2, K. Mileham3, V. Plagnol4, K. Howarth5, T. Forslew6, G. Jones2, C. Morris4

1Pinehurst Medical Clinic and FirstHealth Moore Regional Hospital, Pinehurst/NC/US, 2Inivata, Research Triangle Park/US, 3Oncology, Carolinas Medical Center, Charlotte/US, 4Inivata, Cambridge/GB

**Background:** Tumor tissue based molecular profiling is widely utilized to guide therapy in advanced NSCLC and recently, ctDNA assays have been developed to detect actionable alterations in a non-invasive manner. However, there are frequent reports of discordance between analysis platforms and here we compare the Inivata NGS ctDNA assay with ddPCR based ctDNA analysis and tissue sequencing in patients with advanced NSCLC. **Method:** InivisionFirst (Inivata) is a ctDNA NGS assay for detection of genomic alterations in 36 genes commonly mutated in NSCLC and other cancer types. A cohort of 52 patients underwent ctDNA analysis by InivisionFirst and were tested in a blinded manner for 4 actionable gene alterations (EGFR L858R & Ex19del, KRAS G12C & G12D) and 30 of the cohort also had testing for 5 additional alterations (EGFR L858R & Ex19del, KRAS G12C & G12D) and of the cohort also had testing for 5 additional alterations (EGFR L858R & Ex19del, KRAS G12C & G12D) and of the cohort also had testing for 5 additional alterations (EGFR L858R & Ex19del, KRAS G12C & G12D). The overall concordance of gene alterations was 98.5% (320/342) with positive agreement of 95.5% and negative agreement of 98.8%. Discordance was observed in 6 detected gene alterations, with 1 EML4-ALK fusion, 1 EGFR exon19 deletion and 2 KRAS G12Cs being detected by InivisionFirst but not by ddPCR, and 1 EGFR L858R and 1 KRAS G12D detected by ddPCR but not InivisionFirst. One G12C, the EML4-ALK, and the L858R alteration were confirmed by tissue NGS. However, there are frequent reports of discordance between analysis platforms and here we compare the Inivata NGS ctDNA assay with ddPCR based ctDNA analysis and tissue sequencing in patients with advanced NSCLC. **Conclusion:** InivisionFirst (Inivata) is a ctDNA NGS assay for detection of genomic alterations in 36 genes commonly mutated in NSCLC and other cancer types. A cohort of 52 patients underwent ctDNA analysis by InivisionFirst and were tested in a blinded manner for 4 actionable gene alterations (EGFR L858R & Ex19del, KRAS G12C & G12D) and 30 of the cohort also had testing for 5 additional alterations (EGFR L858R & Ex19del, KRAS G12C & G12D) and of the cohort also had testing for 5 additional alterations (EGFR L858R & Ex19del, KRAS G12C & G12D) and of the cohort also had testing for 5 additional alterations (EGFR L858R & Ex19del, KRAS G12C & G12D). The overall concordance of gene alterations was 98.5% (320/342) with positive agreement of 95.5% and negative agreement of 98.8%. Discordance was observed in 6 detected gene alterations, with 1 EML4-ALK fusion, 1 EGFR exon19 deletion and 2 KRAS G12Cs being detected by InivisionFirst but not by ddPCR, and 1 EGFR L858R and 1 KRAS G12D detected by ddPCR but not InivisionFirst. One G12C, the EML4-ALK, and the L858R alteration were confirmed by tissue NGS. The KRAS G12D was not confirmed by tissue NGS. No tissue was available to examine for the detection of the EGFR exon 19 deletion or the other KRAS G12C mutation. All other results were concordant. **Conclusion:** This study in NSCLC patients demonstrates excellent concordance of the InivisionFirst ctDNA NGS assay with ddPCR based ctDNA analysis via blinded independent laboratories. The excellent sensitivity and specificity support the use of the InivisionFirst assay as a non-invasive “liquid biopsy” for molecular profiling.
**Background:** Patients with EGFR mutant non-small cell lung cancer (EGFRmNSCLC) have a high incidence of brain metastases (BM). We sought to determine the rate of neurologic death in EGFRmNSCLC patients diagnosed with brain metastases. **Method:** A single-institution prospectively managed database identified 204 patients with EGFRmNSCLC treated for brain metastases between 2000 and 2016. We estimated actuarial survival rates using the Kaplan-Meier method. The incidence of neurologic death (ND) was determined using a competing risks analysis. ND was correlated to clinical and treatment variables using Fisher’s exact test. Survival was calculated from the date of BM diagnosis. We defined neurologic death as death due to brain metastases or leptomeningeval disease. **Result:** Fifty-six percent of patients had BM at the time of initial diagnosis. The initial BM treatment was up front stereotactic radiosurgery (SRS), whole brain radiation therapy (WBRT), or tyrosine-kinase inhibitor (TKI) alone in 22, 60, and 18 percent of patients, respectively. Two-year rates of OS in these subgroups were 64%, 38%, and 50%, respectively (p=0.016). The 5-year rate of neurologic death was 38%. Thirty-four percent died of non-neurologic causes, 8% died of unknown causes, and the remaining patients were alive at last follow-up. Median survival (MS) was 19 months; MS in patients who died of non-neurologic causes and neurologic causes was 23, and 15 months, respectively. Of age, staging, BM at diagnosis, history of TKI therapy, initial treatment of BM, staging at diagnosis, and leptomeningeval disease at diagnosis (LMD), only LMD was significantly associated with ND (p=0.047). **Conclusion:** Neurologic death due to EGFRmNSCLC BM was more common in our cohort than has been previously reported, highlighting the need for dedicated studies focused on the best management of BM in this population.

P.01-81 TREATMENT OF SUPERIOR SULCUS TUMOR: A TWELVE-YEAR SINGLE-CENTER EXPERIENCE

W. Rzyman1, M. Lazar-Poniatsowa2, M. Lapinski3, M. Ostrowski1, A. Wrona2, K. Konopa2, J. Jassem3, R. Dzidziszko3
1Department of Thoracic Surgery, Medical University of Gdańsk, Gdańsk/PL
2Department of Oncology and Radiotherapy, Medical University of Gdańsk, Gdańsk/PL

Background: Superior sulcus tumor (SST), also known as Pancoast tumor, occurs in up to 5% of all non-small cell lung cancer patients. Owing to its proximity to vital thoracic structures, SST remains one of the biggest challenges of thoracic surgery. The results of the Southwest Oncology Group Trial 9416, in which SST patients were subjected to induction chemoradiation followed by surgical resection, established a widely accepted standard-of-care. Data on the efficacy of this approach outside of clinical trial setting are scarce. We present long-term outcomes in a large group of patients with SST who underwent surgery with or without preoperative treatment (PT) in a single tertiary referral center.

Method: Study group included 76 consecutive patients treated between February 2006 and June 2017. All patients had histologically-proven and radiologically-defined T3-T4 NO-N1 M0 superior sulcus non-small cell lung cancer. Study group included 50 men (66%) and 26 women (34%) with a mean age of 56 years (range, 41-81 years). Squamous cell lung cancer constituted 55% of the population. Result: Fifty-four patients (71%) underwent PT, 44 of whom received radiochemotherapy (58%), 4 received chemotherapy (5%), and 22 (29%) were managed with surgery alone. All patients selected to PT underwent subsequent pulmonary surgery including lung and chest wall en bloc resection, and complete lymphadenectomy. In the entire group 71 lobectomies (93%), 3 pneumonectomies (4%) and 2 pneumonectomies (3%) were performed. Surgery in patients managed with PT included 52 lobar resections (96%) and 2 pneumonectomies (4%). Complete or near complete pathologic response following PT was achieved in 67% of operated patients. In the entire group resection was complete (R0) in 62 patients (82%). Overall 30-day and 90-day mortality in the entire treatment group was 2.6% and 6.6%, respectively. Overall 3-year and 5-year survival probabilities were 44% (95% CI: 32%-56%) and 38% (95% CI: 26%-50%) respectively. A non-significantly higher 3-year survival probability was recorded in patients, who underwent PT compared to those managed with surgery alone (50% vs. 36%, respectively; log-rank p=0.27). Conclusion: Real-world treatment outcomes in SST patients amenable to surgery are similar to those obtained in the general population of lung cancer patients. PT may increase long-term survival rate and is associated with low perioperative mortality, which justifies its routine application.

P.01-82 NEUTROPHIL-TO-LYMPHOCYTE RATIO COMPLEMENTS THE PROGNOSTIC ABILITY OF PD-L1 IN NON-SMALL CELL LUNG CANCER TREATED WITH PD-1/PD-L1HIBITORS

D. Saravial1, S. Agte2, N. Okabe1, W. Park1, D. Kwon1, R. Mudad1, H. Suzuki1, T. Chae1, M. Oh2, A. Rahbari2, G. Lopez1
1Hematology-Oncology, University of Miami, Miami/FL/US
2Rhinecc, Northwestern University, Chicago/IL/US
3Fukushima Medical University, Fukushima/JP
4Chest Surgery, Fujisaka Medical University, Fujisaka/JP
5Robert H Lurie Comprehensive Cancer Center of Northwestern University, Chicago/US
6Northwestern University, Chicago/IL/US

Background: PD-L1 expression is an imperfect predictor of outcomes for patients (pts) with advanced non-small cell lung cancer (aNSCLC) treated with PD-1/PD-L1 inhibitors (PD-1/L1). This was demonstrated in the recent ARCTIC trial in which PD-L1 expression did not significantly correlate with outcomes. In the quest for additional markers, a high neutrophil-to-lymphocyte ratio (NLR) has been associated with poor outcomes and may reflect a higher myeloid-to-lymphoid balance. Here we show improved prognostic ability for response to PD-1/L1 when baseline NLR is added to PD-L1 expression. Method: We used a retrospective cohort of 146 aNSCLC pts from the authors’ institutions in the United States and Japan who received single-agent PD-1/L1. We categorized patients into three groups; favorable: PD-L1 ≥ 1% and NLR < 5, intermediate: PD-L1 ≥ 1% or NLR ≥ 5, and poor: PD-L1 < 1% and NLR ≥ 5. We correlated the outcome of each group with overall survival (OS) and progression-free survival (PFS). Result: Median follow-up was 11.1 months (M) (95% Confidence Interval [CI]: 9.1-13.1). 47 pts had PD-L1 ≥1% and 99 pts ≥1%, 81 pts had NLR <5 and 65 pts ≥5%. There were 52, 76, and 18 pts in the favorable, intermediate, and poor groups, respectively. Median OS for the favorable group was not reached and it was 14.7 M (CI: 10.5-19.0) and 3.5 M (CI: 0-13.1), respectively for the intermediate and poor groups. Median PFS was 9.9 M (CI: 3.7-16.9). 3.2 M (CI: 2.1-4.3) and 1.1 M (CI: 0.8-1.4), respectively. The poor group (PD-L1 < 1% and NLR ≥ 5) was significantly associated with progressive disease (Odds ratio [OR]: 5.0, p=0.01) in comparison to the PD-L1 ≥ 1% group (OR: 2.6, p=0.013). Conclusion: Prognostic ability of PD-L1 expression is enhanced when combined with baseline NLR for aNSCLC pts treated with single-agent PD-1/L1. This study raises the hypothesis that high NLR and low PD-L1 expression could serve to identify those pts less likely to benefit from these therapies.

P.01-83 EVALUATION OF DYNAMIC THIOL/DISULPHIDE HOMEOSTASIS IN ADVANCE NON-SMALL CELL LUNG CANCER AND SMALL CELL LUNG CANCER

M. Hizal, B. Bilgin, M.A. Sendur, M. Akinci, S. Neseloolgu, O. Erel, B. Yalcin Ankara Yildirim Beyazit University, Ankara/TR

Background: The complicated pathogenesis of lung cancer is the mainstay of all its different histological subtypes. Oxidative stress has detrimental effects on chronic diseases as well as cancer. Thiol groups which have high antioxidant capacity, turn to disulde (DS) groups with biochemical reactions that neutralize different oxidant compounds. Thiol/Disulde homeostasis (TDH) has significant effects on cell mechanisms, biochemical reactions that neutralize different oxidant compounds. Thiol or Disulde levels which are significantly lower than the population’s’ mean levels during the time of diagnosis and after first-line treatment. TDH tests were measured by the automated spectrophotometric method. Result: 57 patients (43 NSCLC and 14 SCLC) and 50 healthy controls enrolled to study. There was no statistical difference in age (median 61 and 60.5) and sex status between groups. Native thiol (NT) and total thiol (TT) levels were significantly lower in the patients’ group (Table 1). DS/NT ratio which is the best indicator of antioxidant capacity reached statistical significance between NSCLCs patients and controls (p<0.04). After median 27.2 months follow-up, median overall survival (OS) was 9.5 months in NSCLC and 12.3 months in SCLC groups. Thiol or DS variables had no effect on survival.13 of the 30 patients had progressive disease after first-line chemotherapy. DS levels and DS/NT ratio were lower in patients after progression compared with levels at the time of diagnosis (p=0.013 and 0.033).

Variable Patients Median (min-max) Controls Median (min-max) p
Native Thiol 358 (215-3261) 429 (313-607) <0.001
Disulde 20.8 (0.05-55) 20 (8.4-37) 0.98
Total Thiol 398 (253-573) 464 (354-632) <0.001
Disulde/NT Native Thiol 0.05 (0.01-0.19) 0.05 (0.02-0.14) 0.08

Conclusion: Lower levels of thiol groups may contribute to lung cancer pathogenesis as a result of enhanced oxidative stress. The deficiency of this antioxidant compounds may relate to structural damage of signal, transcription, apoptosis mechanisms in lung cancer cell lines. The lower levels of DS and DS/NT ratio after progression may be an indicator of the high tumor volume and enhanced cell turnover.

Keywords: oxidative stress, thiol, disulphide

P.01-84 PATTERNS OF CENTRAL NERVOUS SYSTEM METASTASES IN EGFR MUTATED OR ALK REARRANGED NON SMALL CELL LUNG CANCER PATIENTS

M. Sharma, U. Batra, P. Jain, V. Mahawar, A. Jajodia
Medical Oncology, Rgirc, Delhi/IN

Background: Development of brain and leptomeningeal metastases has prognostic and therapeutic implications in oncogene driven non small cell lung cancer (NSCLC). A rising trend is being observed in the incidence
of central nervous system (CNS) metastases in such populations, probably due to better imaging techniques as well as improved survival of patients. The presence of EGFR and ALK mutations could have a significant impact on the pattern of metastatic disease spread. Data from the Indian subcontinent on this subject is scarce. The information gained from this study may have clinical relevance in today’s era of first line use of second and third generation tyrosine kinase inhibitors (TKIs).

**Method:** 286 EGFR mutated (220) or ALK rearranged (66) NSCLC patients were selected for this retrospective analysis. All patients with clinically suspected CNS metastases underwent contrast enhanced MR imaging of brain. Two groups of patients were identified as per their driver mutation status. The CNS lesions were analysed with regards to number, size, site (parenchymal or meningeal) and nature (morphological heterogeneity and central necrosis).

**Result:** Incidence of brain metastases was found to be higher in the ALK group (24/66, 36.3 %) as compared to the EGFR group (68/220, 30.9%). Leptomeningeal spread in the ALK group was found to be less compared to the EGFR group (2/24, 8.3% as opposed to 18/68, 26.4%). Morphological heterogeneity and central necrosis in parenchymal lesions was more common in the ALK group (B24, 33.3%) as opposed to EGFR group (B26, 24.5%).

**Conclusion:** The incidence, type and morphology of CNS lesions vary with the driver mutation status in NSCLC patients. This may have prognostic and therapeutic implications, especially in identifying patients who may benefit from upfront second or third generation TKI’s.

**P2.01-85 THE EFFICACY OF THE TRADITIONAL CHINESE MEDICINE AS MAINTENANCE THERAPY FOR ADVANCED NON-SMALL CELL LUNG CANCER: A META-ANALYSIS**

P. Shen¹, L. Wu¹, M. He¹, J. Chen², K. Chai²
¹Medical Oncology, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou/CN, ²Department of Oncology, Tongde Hospital of Zhejiang Province, Hangzhou/CN

**Background:** Maintenance therapy is very important for patients with advanced non-small cell lung cancer (NSCLC). To evaluate traditional Chinese medicine (TCM) as maintenance therapy for advanced NSCLC patients, we performed a meta-analysis of prospective randomized controlled trials (RCTs).

**Method:** 12 databases were searched up to April 2016. All RCTs comparing TCM and control treatment as maintenance therapy for stage III to IV NSCLC patients in non-progression status after completing first-line chemotherapy were retrieved. Total 25 RCTs with 1654 patients were enrolled from March 2005 to June 2014.

**Result:** We found that TCM as maintenance therapy significantly increased the overall response rate (ORR) (risk ratio (RR)=2.23 95% confidence interval (CI)=1.28-3.88 P=0.004) and the disease control rate (DCR) (RR=3.15 95% CI=2.12-4.69 P<0.0001, Fig 1), while no significant difference was observed in the overall survival (OS) (P=0.44). Significant improvement was found in progression free survival (PFS)(HR=1.67 95% CI=0.40-2.93 P=0.01) and karnofsky performance status (KPS) in the TCM group (RR=3.26 95% CI=2.42-4.38 P<0.0001, Fig 2). There was no complication reported in these studies.

**Conclusion:** TCM appears to be efficacious and well tolerated to be used as maintenance therapy for advanced NSCLC patients in non-progression status after completing the first-line chemotherapy. TCM as maintenance therapy is worth further study in future investigations.

TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.01-86 GENETIC PROFILING OF CIRCULATING CELL-FREE DNA FROM CEREBROSPINAL FLUID AND PLASMA IN ALK-POSITIVE LUNG CANCER WITH BRAIN METASTASES
Medical Oncology, Beijing Chest Hospital, Capital Medical University, Beijing/CN

Background: Brain metastases (BMs) occur in approximately 30% of patients with ALK-positive non-small-cell lung cancer (NSCLC), and in patients treated with crizotinib, central nervous system progression occurs in up to 70% of patients. Resistance mechanisms of BMs with ALK rearrangement remained unclear due to limited access to BMs lesions.

Method: Ten NSCLC patients with BMs carrying ALK-positive in tumors determined by Ventana anti-ALK (D5F3) immunohistochemistry assay were enrolled. Cell-free DNA (cfDNA) of cerebrospinal fluid (CSF) and plasma were tested by next-generation sequencing (NGS) with 168 genes panel.

Result: Out of 10 patients, three were females and seven males aged from 29 to 57 years old (median age of 34 years old). In all of cases, CSF cytology were negative. In NGS assays, in patients with ALK-positive, fusion gene positive genes were detected in 30.0% (3/10), 80.0% (8/10) and 100% (8/8) patients of CSF cfDNA, plasma and tumor, respectively; and in ALK-positive of CSF, all of them had much higher allele fractions in CSF cfDNA than the other two media.

Conclusion: For ALK-positive lung cancer with BMs, CSF may serve as liquid biopsy by detecting cfDNA within CSF to characterize the driver and resistant genes, dynamic genetic profiling of CSF would be an appropriate choice.

Keywords: brain metastases, ALK-positive, cell-free DNA

P2.01-87 PROFILING THE SYMPTOM BURDEN OF PATIENTS WITH METASTATIC NSCLC RECEIVING EITHER CHEMOTHERAPY OR TARGETED THERAPY: REAL-WORLD DATA
O. Shiki1, L. Williams1, V. Vaghan2, M. Hirschmann2, L. L. Landry2, E. Roarty2, J. Zhang1, W. Rinsnogkawong1, J. Lewis4, C. Cleeland1, J. Lee1, J.A. Jack A. Roth3, S. Swisher4, J. Heymach4, G. Simon1
1Symptom Research, The University of Texas MD Anderson Cancer Center, Houston/US, 2Thoracic Head & Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston/US, 3Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston/US, 4Symptom Research, The University of Texas MD Anderson Cancer Center, Houston/US

Background: An understanding of the patient experience is lacking for newly developed cancer treatments, such as targeted therapies. We profiled the patient-reported outcome (PRO)-measured symptom burden experienced by patients with metastatic non-small cell lung cancer (mNSCLC) during 6 months of conventional chemotherapy or targeted therapy.

Method: During 2017, patients with mNSCLC at a single institution were recruited and completed the MD Anderson Symptom Inventory lung cancer module (MDASI-LC) at clinic visits. The MDASI-LC assesses the severity of 13 core and 3 lung-cancer-specific symptoms and 6 interference items on 0-10 scales (0=no symptom or interference, 10=worst imaginable symptom or complete interference). Descriptive statistics for MDASI-LC scores over 6 months of treatment were summarized. Symptom trajectories for the chemotherapy patients versus the targeted-therapy patients were compared via linear mixed-effects models.

Result: Of 65 patients receiving chemotherapy and 27 receiving targeted therapy, the targeted-therapy group had more women (74% vs. 49%, P=0.029) and younger patients (57.6±12.2 vs. 64.2±9.9 years, P=0.012). Before treatment, both groups reported similar symptom burden, although sadness was worse in the targeted-therapy group (2.4±1.6 vs. 0.8±1.5, P=0.021). During the first 60 days of treatment, patients receiving chemotherapy reported significant increase in pain (estimate (est)=0.03, P=0.037) and interference with walking (est=-0.04, P=0.025). Compared with those receiving chemotherapy, patients receiving targeted therapy experienced significantly less severe pain (est=-1.17, P=0.024), fatigue (est=-1.16, P=0.019), and shortness of breath (est=-1.23, P=0.028) and less interference with walking (est=-1.23, P=0.042) (figure 1). More severe dry mouth was reported by patients undergoing targeted therapy (est=1.17, P=0.027).

Conclusion: This real-world data demonstrates that, compared with conventional chemotherapy, targeted therapy correlates with less impairment of physiological condition and functioning in patients with mNSCLC. Additional follow up will confirm and expand these findings about the patient experience relative to treatment response.

Keywords: longitudinal symptom profiles, Targeted therapy, Patient-reported outcomes
Endogenous protein expression of p-ALK and p-ERK was decreased by combination of crizotinib and selumetinib. Moreover, combination treatment lead to increased G1 arrest and apoptosis compared to single treatment in H3122 cells.

**Conclusion:** Our results showed that combination of crizotinib and selumetinib have potent cytotoxic effects in crizotinib resistant ALK-positive lung cancer. The proposed combination treatment could be a promising therapy for acquired crizotinib resistant ALK-positive lung cancers.

**Keywords:** orthotopic mouse model, ALK-positive lung cancer

**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.01-88 C-REACTION PROTEIN (CRP) AS A PREDICTIVE MARKER FOR SURVIVAL IN PATIENTS WITH ADVANCED NSCLC TREATED WITH FIRST LINE PEMBROLIZUMAB MONOTHERAPY**

1Respiratory Medicine, Yokohama Medical Center, Yokohama/JP, 2Department of Thoracic Oncology, Kanagawa Cancer Center, Yokohama/JP, 3Thoracic Oncology, Kanagawa Cancer Center, Yokohama/JP

**Background:** Pembrolizumab have shown longer activity in patients with advanced non-small cell lung cancer (NSCLC) especially when PD-L1 expression was high. But even with high PD-L1 expression, more than half of them failed to respond. We focused on C-reactive protein (CRP), inflammatory protein measured routinely in clinical practice, to find out its role as predictive biomarker for pembrolizumab.

**Method:** We analyzed advanced NSCLC patients with PD-L1 high expression (EGFR mutation (+), EML4-ALK fusion (+)) who were treated with pembrolizumab as first-line therapy in our clinical practice. Patients received pembrolizumab (200mg/body, q3W) until progressive disease or unacceptable toxicity.

During treatment period we measured serum biochemistry and blood cell count regularly. We evaluated the association the factors such as serum marker including inflammatory protein, age, performance status, histology, smoking status, prior radiation therapy and presence or absence of lymphoma-related adverse events after treatment with the effect such as antitumor response, progression-free survival (PFS) and overall survival (OS).

**Result:** A total of 31 patients treated with pembrolizumab from March 2017 to February 2018 were analyzed for this research. Their characteristics were: median age 72 (range 37-84), male/female 24/7, adenoscarcinoma/squamous cell carcinoma/pleomorphic carcinoma/neuroendocrine carcinoma/NOS 17/5/3/1/5, clinical stage IIIb/IV/recurrence 3/21/7, median CRP level at pretreatment 1.15mg/dL (0.07-15.27). Among the candidate biomarker, there were no association except for CRP. Serum CRP level at pretreatment was not predictive, but change in serum CRP level at 6 weeks after anti-PD-1 therapy initiation was most predictive in the analysis. Depressed CRP group showed longer PFS and OS than elevated group (PFS: p<0.08, HR 0.29, OS: p<0.08, HR 0.28, log-rank test).

**Conclusion:** Our analysis suggests that serum CRP elevation at 6 weeks of treatment predict for longer survival when pembrolizumab was given as first-line treatment. This finding might be related to inflammation status of patients and efficacy of anti-PD-1 inhibitor.

**Keywords:** pembrolizumab, predictive marker, CRP

**P2.01-89 SYNERGISTIC CYTOTOXICITY THROUGH MAPK/ERK PATHWAY AND ALK INHIBITION IN CRIZOTINIB RESISTANT EML4-ALK-POSITIVE LUNG CANCER**

**N. Shrestha**, M. Nimick, R. Rosengren, J. Ashton

Department of Pharmacology and Toxicology, University of Otago, Dunedin/NZ

**Background:** Anaplastic lymphoma kinase (ALK)-positive lung cancer is an aggressive cancer that most commonly arises through EML4-ALK chromosomal fusion. Crizotinib is the first-line treatment for ALK-positive lung cancer, providing a greater progression free survival and overall response rate than chemotherapy. However, patients invariably develop acquired resistance, usually within a year. Mechanisms of resistance include copy number gain, secondary mutations in ALK, or activation of bypass signalling pathways. The aim of this study was to investigate the combination effect of ALK inhibitor, crizotinib, and MEK inhibitor, selumetinib, in crizotinib resistant ALK-positive lung cancer cells.

**Method:** Cytotoxicity of single and combined treatment of crizotinib and selumetinib in ALK-positive (H3122), ALK-negative (A549) and crizotinib resistance ALK-positive (CR-H3122) cells was determined by Sulforhodamine B assay. Chou-Talay analysis was performed to determine the nature of interaction between the two drugs used in combination treatment. Endogenous expression of p-ALK and p-ERK was determined by western blotting. The effect of combination treatment on cell cycle arrest and apoptosis induction was determined by flow cytometer.

**Result:** Combined treatment with crizotinib and selumetinib had significantly greater cytotoxicity and showed a synergistic effect compared to the single drug treatments in H3122 cells. The combination treatment had no synergistic effect in A549 cells, indicating that the cytotoxic effect was specific to ALK. The most prominent cytotoxic effect of the combination treatment was observed with CR-H3122 cells, with synergistic suppression of cell viability even at low drug concentrations.

P2.01-91 TREATMENT PATTERNS IN PATIENTS WITH STAGE IIIB-IV NSCLC IN CLINICAL PRACTICE: RETROSPECTIVE ANALYSIS OF A UK TRUST DATABASE

Background: I-O Optimise is a new pan-European data platform developed to enable real-world insights into the management of thoracic malignancies. As part of this initiative, the current analysis reports the characteristics and treatment patterns for adult patients diagnosed with stage IIB or IV NSCLC at Leeds Teaching Hospitals Trust (LTHT), hosting one of the largest integrated cancer centres in the UK. Method: Retrospective cohort study using longitudinal data already collected from electronic medical records at LTHT, including all adult patients diagnosed with stage IIB-IV NSCLC between January 2007 and August 2017. Minimum follow-up was 6 months. Distinct lines of therapy (LoT) were identified using a clinically-verified algorithm based on the name and date of systemic anti-cancer therapy (SACT) administered and the gap between two treatments.

Result: Overall, 2119 patients were included. Mean age at diagnosis was 71.4 ± 11.2 years. Nearly one-third (33.7%) were clinically diagnosed without pathological confirmation (TABLE) and very few of these patients have SACT administration recorded. Following diagnosis, 648 patients (30.6%) received ≥1 LoT, 223 (10.5%) ≥2 LoT and 60 (2.8%) ≥3 LoT. Proportions of patients treated decreased with age (73.5% [25/34] aged 18-44 years; 52.7% [267/507] aged 45-64 years)

Background: Historically, CT studies are always viewed in several window settings, optimized to evaluate specific anatomic structures and regions (mediastinal, lung, bone and vascular window). A newly developed image processing technique fuses these conventional windows into a single “all-in-one” window. This new window is specifically designed for comparison and follow-up of CT studies in oncology. The purpose of this study is to compare lesion detection on this “all-in-one” window versus conventional window settings. Method: In this retrospective study, 50 consecutive consecutive thoracic oncology chest CT examinations, containing 417 documented lesions and features, were reviewed by 6 radiologists, subdivided into 2 groups of 3 radiologists each, with similar levels of expertise in each group (experienced, junior and radiology resident). All scans were reviewed in standard window settings, in “all-in-one” window, and in the general “all-in-one” window used in routine daily practice, by one group and in the “all-in-one” window by the other group. Lesions were listed as ‘missed’ when they were not seen by at least two out of three observers and as ‘well diagnosed’ when seen by at least two out of three observers. Result: Out of the 417 lesions, 68 lesions were missed: 21 on the “all-in-one” window, 30 on conventional views and 17 on both views. Statistical analysis with linear mixed model showed that use of the “all-in-one” window did not result in an increase of missed lesions (p=1). Conversely, we found a tendency towards better lesion detection on the “all-in-one” window, though not strongly significant (p=0.07). Inter-observer agreement in both groups was similar (p=0.462). Conclusion: Our proposed new way of looking at chest CT images seems promising. In this study, we showed that lesion detection on a single “all-in-one” window is at least as good as on multiple conventional window settings. In further research, we will investigate the effect on lesion measurement and characterization.

P2.01-96 DYSGEUSIA ASSOCIATED WITH NUTRITIONAL AND QUALITY OF LIFE PARAMETERS IN NON-SMALL CELL LUNG CANCER PATIENTS NAÏVE TO CHEMOTHERAPY

J. Turcott, E. Juarez, K. Sánchez-Lara, O. Arrieta

1Thoracic Oncology Unit, National Cancer Institute of Mexico, Mexico City/MX, 2Unidad Funcional de Oncología Torácica Y Laboratorio de Medicina Personalizada, National Cancer Institute, Mexico City/MX

Background: Dysgeusia (taste alteration) has been reported in more than 50% of patient undergoing chemotherapy, however, it can be present before treatment, and it can be associated with nutritional and quality of life parameters. Method: We evaluated 65 patients naïve to chemotherapy, the alteration of taste by self-reporting questionnaire and through rinse stimuli to identify detection and recognition thresholds of umami, sweet and bitter taste; as well as, their association with nutritional and quality of life parameters. Result: Dysgeusia, perceived as a different taste from food was reported in 35% of patients. Those with dysgeusia presents less mean of weight (p=0.059), less lean body mass (p=0.027), higher Fat Mass (p=0.027), less consumption of protein (0.059), iron (0.022) and sodium (0.034). Patients with dysgeusia reported unfavorable score in functional scales of Health Related Quality of Life (HRQL), than those without dysgeusia; including, Role Functioning (p=0.182*), emotional functioning (p=0.038), cognitive functioning (p=0.017) and social functioning (0.325*). And, the same for symptomatic scales: fatigue (p=0.016), nausea and vomiting (p=0.021), pain (p=0.133*), appetite loss (p<0.001) and constipation (p=0.005).

Conclusion: Patients with non-small cell lung cancer present dysgeusia before treatment and affect clinical parameters, food consumption habits and quality of life. Nutritional- care must be provided opportunely.

P2.01 ADVANCED NSCLC TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.01-95 ASSESMENT THE FITNESS FOR CHEMOTHERAPY OF NSCLC PATIENTS USING 6MWT

Z. Szalai, A. Szircsócs, K. Potyó, Z. Szász, T. Molnár

Pulmonology, Petz Aladár County Teaching Hospital Győr, Győr/HU

Background: Decision making in chemotherapy in multimorbid advanced NSCLC patients is a complex and challenging task. Physician reported ECOG performance status (PS), being reproducible, is the gold standard of functional status quantification, when planning an oncology treatment. Inaccurate assesment of PS score is associated with an increased risk of treatment complications and therapy related deaths. The aim of study was to measure the correlation between 6-minute walking test (6MWT), PS and chemotherapy endurance and to study the role of 6MWT in predicting treatment complications and deaths. Method: 138 advanced stage (IIIA, IIIB, IV) NSCLC consented patients were enrolled in a prospective study. They were grouped according to their 6MWT results, and correlation with PS, BMI, FEV1, laboratory values, chemotherapy regimes and cycles were analyzed, with respect to the treatment complications and deaths as endpoints. Statistical analysis was performed with SPSS, Inc., Chicago, IL (level of significance < 0.05). Result: Statistical correlation was found between the 6MWT and chemotherapy endurance. Low 6MWT results (with a cut-off of 360 and 300 m respectively) were significantly associated with a very high risk of hematologic complications (36% and 42%), hospitalization (42% and 56%) and 3-month mortality (45% and 69%). No statistical correlation was found between 6MWT to PS, age, FEV1, BMI and initial lab values. Conclusion: 6MWT seems to be a simple, reliable and objective tool in assessing a patient’s fitness to palliative chemotherapy for advanced NSCLC. Optimisation of treatment protocols, using 6MWT as a supportive tool to facilitate PS assessment, might prevent overtreatment of the patient and abuse of health service/insurance budgets.

Keywords: patient fitness, performance status (PS), 6 minute walking test (6MWT)

**P2.01-97 PROGNOSTIC FACTORS IN RESECTED LUNG MUCINOUS ADENOCARCINOMA: CLINICAL AND PATHOLOGICAL FEATURES**

D. Ueda 1, Y. Tsutami 1, M. Ito 1, Y. Miyata 2, M. Okada 2

1Hiroshima University, Hiroshima/JP; 2Department of Thoracic Surgery, Hiroshima University, Hiroshima/JP

**Background:** Mucinous adenocarcinoma is rare subtype of lung adenocarcinoma. This study aimed to discover which factors influenced prognosis of resected lung mucinous adenocarcinoma. **Method:** From April 1997 to March 2017, we retrospectively reviewed the clinical and pathological features in resected lung mucinous adenocarcinoma patients. We specially focused on KRAS mutation and NRGR fusion, which were reported that MA often harbored them. We also examined CT findings (solitary type or pneumoniotic type) and spread through air space(STAS). The Kaplan-Meier method and log-rank test were used for the survival analyses. **Result:** 57 patients were enrolled to the study. We detected KRAS mutation in 32 patients (56.1%) and NRGR fusion in one patient (1.8%). G12D was the most common in terms of amino acid change of KRAS mutation (78%). There were no significant differences in overall survival (OS) and disease-free survival (DFS) between patients with KRAS wild type and those with KRAS mutation (p=0.70 and p=0.85[Office1], respectively). In point of CT finding, there were 42 solitary type of tumors and 15 pneumoniotic type of tumors. OS and DFS were generally worse in pneumonic type patients (p<0.01 and p=0.01[Office2], respectively). STAS was observed in 32 patients. DFS was significantly shorter in patient with STAS(p=0.03) although OS was not(p=0.07).[Office3] Multivariate analysis revealed that CT finding (pneumoniotic type) was an independent prognostic factor of DFS. Conclusion: Pneumonic type on CT finding was an independent prognostic factor in patients with completely resected lung mucinous adenocarcinoma. KRAS status was not significantly related to the prognosis in our cohort.

**P2.01-98 SINGLE-ISOCENTER VOLUMETRIC-MODULATED ARC RADIOSURGERY FOR NON-SMALL-CELL LUNG CANCER PATIENTS WITH MULTIPLE BRAIN METASTASES**

M. Uto 1, T. Katagiri 1, K. Takehana 1, K. Ogura 2, T. Mizowaki 1

1Department of Radiation Oncology and Image-Applied Therapy, Kyoto University Graduate School of Medicine, Kyoto/JP; 2Department of Therapeutic Radiology, Kobe City Medical Center General Hospital, Kobe/JP

**Background:** Radiosurgery for multiple brain metastases (BM) in patients with non-small-cell-lung cancer (NSCLC) is a well-established treatment option. However, only 1–4 BMs can be treated by conventional surgical resection. It is often performed with single-isocenter volumetric-modulated arc radiosurgery (S-VMAR), a novel irradiation technique. VMAR irradiates between patients with KRAS wild type and those with KRAS mutation (p=0.70 and p=0.85[Office1], respectively). In point of CT finding, there were 42 solitary type of tumors and 15 pneumoniotic type of tumors. OS and DFS were generally worse in pneumonic type patients (p<0.01 and p=0.01[Office2], respectively). STAS was observed in 32 patients. DFS was significantly shorter in patient with STAS(p=0.03) although OS was not(p=0.07).[Office3] Multivariate analysis revealed that CT finding (pneumoniotic type) was an independent prognostic factor of DFS. Conclusion: Pneumonic type on CT finding was an independent prognostic factor in patients with completely resected lung mucinous adenocarcinoma. KRAS status was not significantly related to the prognosis in our cohort.

**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.01-010 DIFFERENT GENETIC MUTATIONS ENRICHED IN CIRCULATING TUMOR DNA PREDICT DIFFERENT METASTATIC SITES IN LUNG ADENOCARCINOMA PATIENTS**

L. Miao 1, J. Wang 1, J. Zhao 1, X. Ai 1, G. Lin 1, R. Chen 1, X. Xia 1

1Nanjing Drum Tower Hospital, Nanjing/CN; 2Geneplus-Beijing, Beijing/CN; 3Thoracic Oncology, Beijing Cancer Center Hospital, Changchun/CN; 4Shanghai Chest Hospital, Shanghai/CN; 5Jiangsu Cancer Center Hospital, Fuzhou/CN

**Background:** The mutation map of the lung adenocarcinoma is clear. However, differences of genetic mutations related to metastatic sites have not been addressed before and remain to be explored. Identification of mutation signature may help to predict metastasis. **Method:** We reviewed 353 ctDNA samples from lung adenocarcinoma patients with definite metastasis at our institute. Some somatic mutation profiles were analyzed using hybridization capture based next-generation sequencing (NGS), which enables the simultaneous detection of single-nucleotide variants, insertions/deletions, rearrangements, and copy-number alterations of 59 genes. **Result:** All the samples were divided into 2 groups based on event. No grade 3 or higher toxicities were noted. **Conclusion:** While VMAR achieves good local control, the development of temporary alopecia remains to be addressed. More cases and a longer follow-up period are required to verify the efficacy of VMAR.

**Keywords:** brain metastases, single-isocenter volumetric radiosurgery, NSCLC
the distance of the metastases: 165 samples was in the distal metastasis group including bone or liver metastases; 188 samples was in the proximal group, including lung, pleural or thoracic lymph node metastasis. The gene mutation number of the distal metastasis is higher than the proximal metastasis (4.92 vs 3.85, P=0.031). Gene mutations for each group are shown in the figure below. Similar to the genetic profiling of lung adenocarcinoma in COMIC database, the most frequently mutated genes were EGFR and TP53 in two groups. But the frequency mutation of NTRK1 in proximal metastasis group is three times more than that of the distal metastasis group (11/188, 5.9% vs 3/165,1.8%). And the frequency of ALK mutation in the distal metastasis group is two times more than that of the proximal metastasis group (10/165, 6.1% vs 6/188, 3.2%). Moreover, for the top 9 frequently mutant genes, there was 78% overlap in the two groups. However, the overlap with COSMIC database was 55% for distal metastasis group and 44% for the proximal metastasis.

Conclusion: Lung adenocarcinoma patients with ALK mutation are more likely to have distant metastasis. While the patients with NTRK1 mutation are more likely to have proximal metastasis.

Keywords: genetic mutation, lung adenocarcinoma, metastasis

P2.01 ADVANCED NSCLC
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.01-101 DYNAMIC MONITORING OF GENE ALTERATIONS WITH CTDNA BY NGS FOR EGFR MUTATED LUNG ADENOCARCINOMA TREATED WITH GEFITINIB IN BENEFIT STUDY (CTONG 1405)
J. Duan1, S. Wang2, Z. Wang3, H. Bai1, J. Zhao2, H. Gao3, Y. Cheng4, J. Wang1
1National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN; 2OncoGene, Beijing Cancer Hospital, Changzhan/CN; 3307 Hospital of PLA, Beijing/CN; 4Thoracic Oncology, Jinlin Provincial Cancer Hospital, Changchun/CN

Background: Blood-based cell-free tumor DNA (ctDNA) could be dynamically monitored to provide gene alterations during EGFR-TKI treatment, which might offer critical clue for prognosis and clinical treatment decision. Here we reported the dynamic gene alterations monitoring using next generation sequencing (NGS) in BENEFIT study to explore the mechanisms of different responses and resistances to EGFR-TKI in EGFR-sensitizing-mutated lung adenocarcinoma (LADC) patients.

Method: Patients with systemic treatment-naive, stage IV LADC and EGFR-sensitizing-mutation in ctDNA were enrolled to receive gefitinib. Blood samples were dynamically obtained at baseline, every 8 weeks and at disease progression (PD). The dynamic analysis of quantity of ctDNA, multiple driver genes and tumor suppressors were investigated with NGS (Nextseq500 sequencer, consisting of critical exons/introns of 168 genes), and were correlated with efficacy and resistance. Result: Totally 181 LADC patients with EGFR-sensitizing-mutation (exon 19-deletion and exon 21-L858R-point-mutation) provided sufficient blood samples for a dynamic analysis at baseline, of which 143 patients obtained at least four timepoints of dynamic blood sample collection until PD (baseline, 8 weeks, 8 weeks before PD and PD). At baseline, 180 of patients (99.4%) were confirmed as EGFR-sensitizing-mutation with NGS (92 EGFR-19-deletion and 88 EGFR-L858R-point-mutation) including 44 (24.3%) EGFR-amplification, 116 (64%) TP53-mutation, other known oncogenic drivers including MET (N=5, 2.8%), ERBB2 (N=7,3.9%), KRAS (N=6, 3.3%), BRAF (N=2, 1.2%), RET (N=1, 0.6%), ROS1 (N=3, 0.6%), or EGFR-T790M (N=4, 2.2%), which was correlated with poor efficacy compared with those with only EGFR-sensitizing-mutation (PFS 4.7 months [m] vs. 13.2m, p<0.02). Additionally, for poor response, the suppressor gene NTRK1 showed more effect to poor prognosis: PFS for 164 patients with TP53&RB1&PTEN-mutations1 was 11.1m, while for 16 patients with TP53&RB1&PTEN-mutation1, PFS was 4.7 m, p<0.0001. To cut-off date, 117 patients had PD, among them, 63 (54%) patients acquired EGFR-T790M-mutation presented as dominant resistance mechanism besides MET-amplification/ ERBB2-amplification/ERBB2-S310F (N=16, 14%), RET fusion/splice (N=2, 1.7%), ROS1-C2336F-mutation (N=1, 0.9%), RB1-nonsense-mutation (N=2, 1.7%). TP53-Y205S-mutation (N=1, 0.9%) and TP53-Y205S-mutation accompanied with FGFR1-amplification (N=1, 0.9%). The remaining resistance mechanisms (31%) were unknown. Patients with only T790M-mutation had a significantly longer PFS (11.5m) compared with patients obtaining other acquired resistant mechanisms (3.0m). Interestingly, seventy-five (53.2%) patients had molecular progression before radiographic progression, and the median time difference was 8.7 weeks. Conclusion: Dynamic alterations of multi-drivers and suppressors together with EGFR-sensitizing-mutation and T790M-mutation could separate LADC into different subgroups with distinguished predictor features, which may play a vital role during EGFR-TKI treatment for resistance-predicting, and initial/subsequent treatment decision-making.

P2.01-102 COMPREHENSIVE NEXT-GENERATION SEQUENCING GUIDED TARGETED THERAPIES IMPROVE CLINICAL OUTCOMES OF LUNG CANCER PATIENTS
Z. Wang1, D. Zhu2, B. Lu3, G. Liu1, T. Xu4
1Cancer Medical Center, the Second Affiliated Hospital of Nanjing Medical University, Nanjing/CN; 2Nanjing Geneseeq Technology Inc., Nanjing/CN

Background: Next-generation sequencing (NGS) has been increasingly involved in the clinical decision-making of cancer care, the primary applications of which are the identification of sensitizing mutations for targeted therapies and drug-resistant mechanisms. Along with more clinical validations and approvals of several commercially available targeted NGS panels for FDA mutation profiling, it has been debated that whether comprehensive NGS test should be used as a standard practice in clinical procedure. Method: In this study, we recruited 24 patients with stage IV lung cancer. 22 of them are adenocarcinoma and the other 2 are small cell lung cancer and squamous cell carcinoma, respectively. Genomic DNA from 13 tumor tissues, and circulating tumor DNA from 8 pleural effusions and 3 plasma samples in each corresponding patient were collected and subjected to targeted-NGS covering 416 cancer-related genes and 16 genes frequently rearranged in solid tumors. Targeted therapy or chemoradiotherapy was applied in clinical practice with the consideration of patients' requests and their affordability due to financial barriers. Patients' clinical outcomes were further evaluated. Result: Of all patients, 54% of them (n=13) were detected with sensitizing mutations that have targeted drugs available, including EGFR exon 19 deletion (n=2), L858R (n=2) and L861Q mutations (n=1), ALK fusion (n=1), ROS1 fusion (n=1), MET exon 14 skipping (n=1), as well as EGFR T790M (n=5) for 4 patients who had progressed on the first-generation tyrosine kinase inhibitors (1st-gen TKI) and 1 TKI-treatment naive patient. 69% of patients (n=9) with actionable mutations were subjected to targeted treatment, while the other 31% patients (n = 4) were treated with chemotherapy or radiotherapy. Consistent with clinical validations, the overall survival (OS) of targeted-treatment group is better than the systematic treatment group. On the other hand, for patients without detectable actionable mutations (n=11), 64% of patients (n=7) were underwent chemotherapy, while the rest were treated with 1st-gen EGFR TKI as requested by the patients. As expected, chemotherapy-treatment group had a similar OS as the TKI group. Collectively, patients with sensitizing mutations achieved significantly longer OS from the TKI treatments than those without actionable mutations (p=0.02).

Conclusion: Our data demonstrated that the existence of sensitizing mutation is the determining factor for the treatment efficacy of targeted therapies. In the real world, NGS test can not only be involved into the decision-making for the first-line treatment, but also be instructive for treatment changes after drug-resistance developed.

P2.01-103 NEUTROPHIL-TO-LYMPHOCYTE RATIO AS A PREDICTOR OF IMMUNOTHERAPY TREATMENT OUTCOMES IN ADVANCED NON-SMALL LUNG CANCER

X. Wang1, W. Fu1, C. Hu2, J. Naidoo3, J. Feliciano3
1Johns Hopkins University School of Medicine, Baltimore/MD/US, 2Division of Biostatistics and Bioinformatics, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore/MD/US, 3Oncology, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore/MD/US

Background: Immune checkpoint inhibitors (ICIs) are a new class of therapy for patients with non-small cell lung cancer (NSCLC). Immuneologic markers, such as serum neutrophil-to-lymphocyte ratio (NLR), are prognostic in patients with a variety of malignancies, with preliminary findings in patients on immunotherapy. In this study, we evaluate the association between NLR and ICI outcomes in NSCLC, including the development of immune-related adverse events (irAEs).

Method: We conducted a retrospective analysis of advanced or recurrent NSCLC patients receiving ICI from 2011 to 2017. Demographics, disease and treatment history, and pretreatment labs were recorded. An NLR5 was defined as high and <5 as low, based on meta-analyses. Cox proportional hazards models and univariate and multivariate regressions were used to assess the association between NLR and overall survival (OS), progression-free survival (PFS), disease control rate (DCR), and irAEs. Result: 183 patients were identified: 55.2% male, 76.5% Caucasian, mean age 65.3 years (range 38-90 years). Male sex, smoking history, prior radiotherapy, and pretreatment albumin were significantly associated with high versus low NLR (p < 0.05). In univariate analyses, pretreatment NLR was a significant predictor of OS (HR 1.47, p < 0.05, Fig. 1), PFS (HR 1.44, p < 0.05), and DCR (OR 0.49, p < 0.05), but not irAEs (OR 1.37, p = 0.33). These findings persisted with multivariate analyses (OS HR 1.76, PFS HR 1.64, DCR OR 0.24, all p < 0.01; irAE OR 1.52, p = 0.33).

Conclusion: High NLR was positively associated with OS, PFS, and DCR but not irAEs in NSCLC patients receiving ICI. Our results support the use of NLR as a biomarker for clinical outcomes. Prospective studies are needed to study this measure in patients undergoing ICI therapy, and further studies to identify predictive biomarkers of irAEs are warranted.

P2.01-104 PLASMA T-CELL-DERIVED CIRCULATING DNA IN ADVANCED NSCLC IS NOT CORRELATED WITH TIL BUT HAS A POTENTIAL OF PROGNOSTIC VALUE

B. Weerasubpong1, C. Vinayanuwattikun1, P. Chantranuwatana2, V. Sriruanpong1
1Faculty of Medicine Chulalongkorn University, Bangkok/TH, 2Pathology, Chulalongkorn University, Bangkok/TH

Background: Non-tumor derived circulating DNA (nt-cirDNA) of advanced non-small cell lung cancer (NSCLC) patient, even not yet clear originated, was associated with prognosis. In this study, we investigated whether T-cell-derived circulating DNA (T-cirDNA) was the majority part of nt-cirDNA nor correlated with tumor-infiltrating lymphocyte (T-TIL).

Method: Prognostic impact including demographic characteristics were integrated into the model. Using Quantitative real-time PCR with Taqman assay specific to VDJ segment of TCRβ (T-cell-receptor beta chain) was used to used to measured amount of T-cirDNA in plasma of 106 advanced stage NSCLC. Quantitative CDS-specific immunohistochemistry (IHC) staining from biopsy specimen, represented T-TIL, was done using Aperio ImageScope. Result: T-cirDNA was detected in seventy-three advanced NSCLC patients with a median of 1.71 pg/ml [range 0-2260]. Forty-six patients were assessed for proportion of T-TIL per total cell with a median of 0.22 per mm² [range 0.02-2.34]. No correlation was found between T-cirDNA and T-TIL. From multivariable analysis, active smoking status was the only factor correlated with low T-cirDNA level (P=0.001). Kaplan Meier survival analysis of T-cirDNA ratio (T-cirDNA/total cirDNA) shown a trend of favor prognostic outcome for high T-cirDNA ratio (more than 0.03 %), HR 0.67 [95% CI 0.43-1.04, P=0.07].

Figure: Kaplan and Meier survival graph showed survival of patients with high and low ratio of T cell derived of DNA. (P=0.07)

Conclusion: Plasma T-cirDNA component, even not correlated with T-TIL, revealed a trend of prognostic impact in advanced stage non-small-cell lung cancer patients.

P2.01-105 TUMOR TREATING FIELDS PLUS STANDARD OF CARE FOR NON-SMALL CELL LUNG CANCER FOLLOWING PLATINUM FAILURE: PHASE 3 LUNAR STUDY

U. Weinberg1, O. Farber1, M. Giladi2, Z. Bomzon2, E. Kirson2
1Novocure GmbH, Lucerne/CH, 2Novocure Ltd, Haifa/IL

Background: Tumor Treating Fields (TTFields) is a non-invasive, anti-mitotic treatment approved for glioblastoma based on significant survival outcomes in a Phase 3 trial. Efficacy of TTFields in NSCLC has been shown preclinically and the safety confirmed in a phase I/II pilot study combined with pembre ticem. In the LUNAR study [NCT02973789], we investigated if adding TTFields to immune checkpoint inhibitors or docetaxel following platinum doublet failure will increase overall survival. Method: s: Patients (N=534), with squamous or non-squamous NSCLC, are stratified per standard therapy (immune checkpoint inhibitors or docetaxel), histology (squamous vs. non-squamous) and geographical region. Key inclusion criteria: disease progression while on/after platinum-based therapy, ECOG 0-2, no electronic medical devices in the upper torso, and inclusion criteria: disease progression while on/after platinum-based therapy. TTFields are applied to the upper torso for >18 hours/day, allowing patients to maintain daily activities. TTFields are given at standard doses. TTFields are applied to the upper torso for >18 hours/day, allowing patients to maintain daily activities. TTFields are continued until progression in the thorax and/or liver. Follow-up is performed once q6 weeks using CT scans of the chest and abdomen. On progression in the thorax and/or liver, patients have 3 post-progression follow-up visits and are then followed monthly for survival. The primary endpoint is superiority in OS with TTFields in combination with the standard of care treatments versus (vs) standard of care treatments alone. Key secondary endpoints compare the OS in patients treated with TTFields and docetaxel vs docetaxel alone, and patients treated with TTFields and immune checkpoint inhibitors vs those treated with immune checkpoint inhibitors alone. An exploratory analysis will test
non-inferiority of TTFields with docetaxel compared to checkpoint inhibitors alone. Secondary endpoints include progression-free survival, radiological response rate, quality of life based on the EORTC QLQ C30 questionnaire and severity and frequency of adverse events. The sample size is powered to detect a HR of 0.75 in TTFields-treated patients versus control group. **Result:** Section not applicable **Conclusion:** Section not applicable

**P2.01-106 A COMPARATIVE ANALYSIS OF GENOMIC ALTERATIONS BY TUMOR TISSUE AND CIRCULATING TUMOR DNA IN ADVANCED NON-SMALL CELL LUNG CANCER**

G. Woo1, S.H. Kim2, K.J. Suh2, Y.J. Kim2, J. Chung2, B. Lee4, N. Kwon4, J. Seo1, J.S. Lee2

1Seoul National University Bundang Hospital, Seongnam/KR, 2Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam/KR, 3Department of Pathology, Seoul National University Bundang Hospital, Seongnam/KR, 4Macrogen Inc., Seoul/KR

**Background:** Genomic profiling of lung cancers using circulating tumor DNA (ctDNA) in the blood of patients is rapidly becoming established as a useful source of information to aid clinical decision-making. We evaluated the concordance of genomic alterations by ctDNA and tumor tissue DNA in Advanced Non-Small Cell Lung Cancer (NSCLC). **Method:** Tumor tissue DNA from formalin-fixed, paraffin-embedded (FFPE) samples and ctDNA from plasma samples were obtained at the time of diagnosis or at the time of progressive disease after receiving targeted therapy in 41 patients with stage IIIIB or IV NSCLC in this prospective study (NCT03235765). Hybrid-capture based genomic profiling (Axen Cancer Panel, Macrogen) was performed to sequence 170 genes in both samples. Concordance is defined as the number of genomic alteration present in both samples divided by the number of genomic alteration in FFPE. Tumor mutation burden (TMB) was also measured. **Result:** Most patients were adenocarcinoma (n=34, 82.9%). The total number of genomic alteration identified in FFPE and ctDNA were 751 and 561, respectively. Median concordance was 50% (8.0% – 100%). Among the clinical factors identified in FFPE and ctDNA were 751 and 561, respectively. Median TMB was also 15/MB (median value), average concordance was 38.7% in TMB-H (N=20) and 59.7% in TMB-L (N=21) (Mann-Whitney, P=0.007). TMB by FFPE was significantly associated with the number of genomic alterations in FFPE (P=0.0001), but was not with the number of genomic alterations in ctDNA (P=0.128) or PD-L1 status (P=0.574).

**Conclusion:** This study suggests that ctDNA genomic profiling may replace tissue-based genomic profiling in NSCLC patients with low TMB. However, both tissue and blood-based genomic profiling may be necessary for NSCLC patients with high TMB.

**P2.01-107 ANALYSIS OF MUTATION DETECTION BY CTDNA ON THE BASIS OF METASTATIC SITES IN LUNG ADENOCARCINOMA PATIENTS**

R. Guo1, H. Xu2, J. Zhang3, X. Ai4, L. Liu3, J. Zhao4, X. Dong4, L. Miao4, R. Chen5, X. Xia2

1Oncoology, Jiangsu Province Hospital, Nanjing/CN, 2Geneplus-Beijing, Beijing/CN, 3State Key Laboratory of Respiratory Disease, guangzhou Institute of Respiratory Disease, The First Affiliated Hospital of Guangzhou Medical University.china, Guangzhou/CN, 4Cancer Center, Union Hospital Tongji Medical College Huazhong University of Science and Technology, Wuhan/CN, 5Thoracic Oncology, Beijing Cancer Hospital, Changchun/CN, 6Department of Medical Oncology, Tongji Hospital, Tongji Medical College, Huazhong University of Science & Technology, Wuhan/CN, 7Non Jing Drum Tower Hospital, Nanjing/CN

**Background:** Circulating tumor DNA (ctDNA) testing represents a powerful tool to detect gene alterations in patients. However, differences in mutation detected by ctDNA related to metastatic sites in lung cancer have not been addressed before and remain to be explored. **Method:** We reviewed 317 ctDNA samples from 310 lung adenocarcinoma patients with definite metastasis at our institute. Somatic mutation profiles were analyzed using hybridization capture based next-generation sequencing (NGS), which enables the simultaneous detection of single-nucleotide variants, insertions/deletions, rearrangements, and copy-number alterations of 1021 genes. **Result:** Patients were divided into two groups according to metastatic sites. Any case with metastasis to the bone, liver or adrenal gland falls into the major organ metastasis group, while any case with metastasis to the lung, pleura or lymph node belongs to the local metastasis group. No genetic alteration was detected in 14 (11.5%) of 122 samples in the major organ group and 35 (17.9%) of 195 in the local group. And distant metastasis is associated with more mutations on average detected by ctDNA (5.26 for the major organ group vs 3.72 for the local group; p=0.0039). As for genes involved, the most common mutated ones are EGFR and TP53 for both groups, with an overall mutation rate being 40.6% and 33.2% respectively. And just as average gene alterations mentioned above, the mutation rates of EGFR and TP53 are much higher in the major group (49.6% vs 35.2% for EGFR; 43.6% vs 26.9% for TP53). Besides, mutations of NF1, MIL3, KRAS and KEAP1 are more frequent in the major organ group while mutation rate of PIK3CA is slightly higher in the local group (Table).

**P2.01-108 TEMPORAL HETEROGENEITY OF RESISTANT MUTATIONS IN SEQUENTIAL ALK TKI TREATED LUNG CANCER REVEALED BY NGS-BASED LIQUID BIOPSY**

Y. Yang1, Y. Ding2, X. Wu3, Y.W. Shao4

1Department of Oncology, The Second Affiliated Hospital of Harbin Medical University, Harbin/CN, 2Translational Medicine Research Institute, Geneseeq Technology Inc., Toronto/CA

**Background:** Crizotinib and several next-generation ALK TKIs have been widely applied in the treatment of ALK-positive lung cancer patients. However, drug resistance is eventually developed to these ALK TKIs via heterogeneous resistance mechanisms, which is needed to be further explored. Due to the invasiveness and feasibility of repetitive tissue biopsies, liquid biopsy has become a promising alternative for dynamically
monitoring tumor genomic evolution and guides decision-making for treatment adjustment. **Method:** Primary tumor sample of a 71-year-old male patient with stage IV lung adenocarcinoma was subjected for targeted next-generation sequencing (NGS) for identification of driver mutations. Mutation profiles of circulating tumor DNA (ctDNA) from seven sequential plasma samples during the treatment course of crizotinib were dynamically monitored. **Result:** The dynamic mutation profiles during the disease course were represented in the Figure. As EML4-ALK V1 fusion was detected in the primary tumor, the patient was administrated with crizotinib and reached a progression-free survival (PFS) of 11 months when ALK G1298A was identified upon progression. As a result, brigatinib, a second generation ALK TKI overcoming G1298A-driven resistance, was applied. Dynamic monitoring of patient’s ctDNA during brigatinib treatment showed a dramatic drop of G1298A mutant allele frequency (MAF) to undetectable level, whereas a novel F1174L became the dominant clone. The disease progressed after 9-month of brigatinib treatment, and the patient was switched to lorlatinib. A third mutation E1210K quickly overtook F1174L as the dominant clone with the accumulation of more concomitant mutations towards NSCLC patients was 14.4 months (95% CI: 14.7-31.4) and 18.9 months (95% CI: 11.4-26.3), respectively. **Conclusion:** 14.4-36.3) compared to those selected crizotinib as second-line and crizotinib as first-line therapy exhibited both longer median PFS (17.7 months (95% CI: 11.3-17.4). Overall, 58 patients (38%) continued CBPD and the median post-progression PFS was 10.4 months, resulting in a median treatment duration of crizotinib for stepwise treatment strategy for better patient care. **Keywords:** liquid biopsy, dynamic monitoring, crizotinib mutation

**P2.01-109 TREATMENT DURATION—A MORE REASONABLE DEFINITION TO EVALUATE THE EFFICACY OF CRIZOTINIB IN ALK POSITIVE ADVANCED NSCLC**

G. Yang1, D. Ma1, J. Li2, P. Xing1, X. Hao1, H. Xu1, Y. Wang2
1Medical Oncology, National Cancer Center/Cancer Hospital,Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN, 2National Cancer Center/Cancer Hospital,Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

**Background:** Crizotinib has demonstrated its superior efficacy in ALK positive NSCLC patients when used as first-line regimen, with a median overall survival (OS) of more than 4 years, whereas a median progression-free survival (PFS) of only 10.9 months. Patients who continued crizotinib beyond progressive disease (CBPD) could still obtain additional survival benefits of 6-8 months after disease progression. In terms of that, PFS, the frequently used primary endpoint in clinical trials, may not be able to provide accurate information on impact of this intervention in multiple lines therapy. Here we proposed “treatment duration” as an intermediate clinical endpoint between PFS and OS that further define efficacy of crizotinib in multiple lines of treatment and reported the exploratory data in a real-world cohort. **Method:** We retrospectively enrolled 150 ALK positive NSCLC patients who had acquired crizotinib resistance from Aug 2011 to May 2017. The median PFS of crizotinib and OS from crizotinib initiation were analyzed. Treatment duration of crizotinib, the time from crizotinib initiation to discontinuation, was also calculated. **Result:** The median PFS of crizotinib in the 150 ALK positive advanced NSCLC patients was 14.4 months (95% CI: 11.3-17.4). Overall, 58 patients (38%) continued CBPD and the median post-progression PFS was 10.4 months, resulting in a median treatment duration of crizotinib in the total cohort of 20.2 months (95% CI: 14.3-26.0). And median OS was 30.1 months (95% CI: 23.1-38.8). 77 (51%) patients who received crizotinib as first-line therapy exhibited both longer median PFS and OS than patients with secondary use of crizotinib (23.1 months (95% CI: 14.7-31.4) and 18.9 months (95% CI: 11.4-26.3), respectively. **Conclusion:** Crizotinib showed superior efficacy in ALK positive NSCLC patients. Treatment duration may be more reasonable to define the efficacy of crizotinib in multiple lines therapy of ALK positive NSCLC.

**P2.01-110 UNIQUE GENOMIC PROFILE REVEALED BY MALIGNANT PLEURAL EFFUSION**

**Agricultural Reclamation General Hospital, Hainan/CN, 4General Hospital of Guangzhou Military Command of P.L.A. Guangzhou/CN**

**Background:** The accumulation of malignant pleural effusion (MPE), often occurring in advanced lung cancer patients, is the result of pleural space invasion by malignant cells, which disrupt the drainage of pleural fluid. Numerous studies have confirmed the clinical utility of MPE for mutation detection from single gene perspective, often focusing on classic driver genes. Very few studies have interrogated MPE as a media for targeted biopsy using targeted sequencing. In this study we investigated the potential of using MPE as a media for liquid biopsy using targeted sequencing. **Method:** Matched plasma and MPE samples were obtained from 154 patients with advanced NSCLC. Among them, 17 patients had matched primary tissue sample and MPE precipitates. Ultra-deep targeted sequencing using a panel consisting of 168 lung cancer-related genes, spanning 160 kb of human genome was performed with an average sequencing depth of 10,000X for MPE and 1,000X for tissue samples. **Result:** Using tissue sample as a reference, detection rates of driver mutations in MPE cfDNA (somatic) and MPE precipitates and plasma are 100%, 70.6% and 82.3%, respectively. The median maximum allelic fractions (MAF) for MPE cfDNA, precipitates and plasma are 12.9%, 14.8% and 3.6%, respectively. MPE and tissue have comparable median MAF, which is significantly higher than plasma (p<0.01), demonstrating the superiority of MPE cfDNA in mutation detection. Next, we compared and contrast genomic profiles derived from MPE cfDNA and plasma cfDNA. MPE cfDNA of 56 patients had CNVs detected; in contrast, only 27 patients had CNVs detected from plasma sample, resulting in a significantly higher detection rate in MPE cfDNA (p<0.01). Collectively, we identified 201 CNVs; among them, 164 were shared by both media; 33 are MPE specific and the remaining 4 are plasma specific. **Conclusion:** Collectively, our study demonstrates superiority of MPE cfDNA as an alternative media for liquid biopsy. In addition to higher detection rate and MAF, MPE cfDNA also revealed a unique genomic profile, especially in capturing CNV. **Keywords:** CNVs, malignant pleural effusion, cfDNA

**P2.01-111 CLINICAL FEATURES AND PROGNOSIS OF EIGHTY-FIVE PATIENTS WITH PRIMARY PULMONARY LYMPHOEPITHELIOMA-LIKE CARCINOMA**

Q. Yin1, G. Gao, C. Zhou1, Y. Liu, X. Xie1, X. Lin, Z. Zhu, Z. Xie1, J. Zhang1, W. Ji1, R. Chen1, S. Li1
1State Key Laboratory of Respiratory Disease, Guangzhou Institute of Respiratory Disease, The First Affiliated Hospital of Guangzhou Medical University, China, Guangzhou/CN

**Background:** Pulmonary lymphoepithelioma-like carcinoma (PLELC) is a rare subtype of lung cancer that is less reported and not well understood around the world. **Method:** A retrospective analysis of clinical features for these patients was conducted to determine the prognostic factors in terms of age, gender, radiographic features, serum tumor markers, TNM stages, pathological features, treatment and prognosis. **Result:** PLELC preferentially affects the young (< 60 years old): 71.8% nonsmokers (72.9%), without significant difference in gender. The median follow-up time was 15 months (1-37 months) for the whole group and most patients were in the early stage with opportunity of operation (50.6%). For the advanced stage group, patients mainly received chemotherapies and radiotherapies, the 0.5-year and 1.5-year PS rates were 61% and 47%, respectively. The TNM stage (P=0.014) and performance status (PS) (P=0.040) were associated with PFS significantly in the univariate analysis, while TNM stage was an independent prognostic factor in multivariate analysis (P=0.026). In the subtype analysis, patients in the advanced stage receiving Gemcitabine plus platinum (GP group) or Paclitaxel plus platinum (TP group) had better PFS than Pemetrexed plus platinum (PP group) (P=0.005). **Conclusion:** PLELC had a better prognosis compared with other types of non-small cell lung cancer (NSCLC) and was responsive to radiotherapy and chemotherapy. The current results recommended that the GP and TP should be used as first-line treatment of PLELC. The TNM stage and PS were predictive in prognosis of PLELC patients. **Keywords:** lung cancer, pulmonary Lymphoepithelioma-Like Carcinoma, clinical features

Background: Nivolumab, an anti-programmed cell death 1 (PD-1) antibody, is a standard regimen for the second-line treatment of non–small cell lung cancer (NSCLC). However, compared with molecular-targeted drugs, the response rate to nivolumab is low, and biomarkers of efficacy are currently lacking. It has been recently reported that the neutrophil-to-lymphocyte ratio (NLR) can be a biomarker of efficacy. Here, we examined the possibility for NLR to predict efficacy of nivolumab. Method: We retrospectively examined all patients with NSCLC who were treated with nivolumab at our institution. Result: We compared 35 patients with NLR of ≥3 and 44 with NLR of <3, all of whom were treated with nivolumab. There was no difference in response rates between the two groups. The median (m) PFS and mOS were 130 and 583 days in the NLR≥3 group, whereas these were 169 days and not reached (NR) in the NLR<3 group. Longer PFS and OS were observed in the NLR<3 group than in the NLR≥3 group. Conclusion: Longer PFS and OS were observed in the NLR<3 group. Longer PFS and OS were observed in the NLR<3 group. Longer PFS and OS were observed in the NLR<3 group.

Keywords: biomarker, Nivolumab, Neutrophil-to-lymphocyte ratio

P2.01-113 PROGNOSTIC ROLES OF NEOADJUVANT AND ADJUVANT CHEMOTHERAPY FOR TREATING PATIENTS WITH OPERABLE STAGE III-N2 NON-SMALL CELL LUNG CANCER (NSCLC)

L. Young1, S. Kuo2, P. Yang2, P. Huang2, M. Lin2, K. Chen2, J. Lee2

1Department of Surgery, National Taiwan University Hospital, Taipei/TW, 2Dept. of Surgery, National Taiwan University Hospital & National Taiwan University College of Medicine, Taipei, Taiwan, Taipei/TW

Background: The therapeutic options for stage III-N2 positive NSCLC, including the diseases with ipsilateral mediastinal or subcarinal lymph node involvement, are with multidisciplinary approaches. The NCCN and ASCO guideline recommends the cisplatin–based adjuvant chemotherapy (Ad C/T). Meanwhile, some studies revealed the benefits of managing the N2 node disease with the neoadjuvant chemotherapy (Neo C/T) followed by surgery. We currently analyzed the clinical benefit of Neo C/T and Ad C/T for treating N2 positive NSCLC in a single-center cohort.

Method: The study was done retrospectively. A total of 258 patients with N2+ who received surgical resection in dept. of surgery, National Taiwan University Hospital during 2004 to 2016 were enrolled. The mean follow-up duration was 44 months. Both the overall survival (OS) and progression-free survival (PFS) were compared between C/T (-) (patients without chemotherapy treatment), neo C/T, and Ad C/T groups using multivariate analysis and Kaplan–Meier estimates. Result: There were 77, 55 and 126 patients in C/T (-), Neo C/T, and Ad C/T groups respectively. Patients’ characteristics revealed the distributions of age and operation methods among these three groups were significantly different. Patients treated with chemotherapy (combining Neo C/T and Ad C/T groups) were with significant reduced hazard for death compared to C/T (-) group (HR [95 % CI]= 0.55 [0.37-0.83], P=0.004). No significant difference in overall survival was found between neo C/T and Ad C/T groups (HR [95 % CI]= 0.84 [0.54-1.32], P=0.451). The median overall survival time after surgery for the patients in neo C/T, and Ad C/T, and C/T (-) groups were also significantly different (46.2, 56.9, and 26.9 months in C/T (-), Neo C/T, and Ad C/T groups respectively, P<0.001). However, there was no significant difference in patients received C/T or not in progression-free survival. Conclusion: Both Ad C/T and Neo C/T provide clinical benefit for the patients with operable stage III N2 NSCLC . This no significantly difference between Ad C/T and Neo C/T groups in both overall and progression-free survival.

Keywords: stage III-N2 positive NSCLC, neoadjuvant chemotherapy, adjuvant chemotherapy

P2.01-114 THE CORRELATION AMONG PD-L1 EXPRESSION, TMB AND LUNG IMMUNE PROGNOSTIC INDEX IN CHINESE PATIENTS WITH ADVANCED LUNG ADENOCARCINOMA

P. Yuan1, Y. Li2, L. Jiang2, Y. Liu2, W. Liu2, J. Ying1

1Department of Pathology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN, 2Fudan University Shanghai Cancer Center, Shanghai/CN, *West China Hospital of Sichuan University, Chengdu/CN

Background: Anti-PD-1/PD-L1 immunotherapy was approved as first-line treatment on the part of NSCLC patients, but not all can benefit, some studies have shown that PD-L1 expression, Tumor Mutation Burden (TMB) and Lung Immune Prognostic Index (LIPI) can be used as an effect predictor of NSCLC immunotherapy. We aim to explore the correlation of the three predictors in Chinese patients with advanced lung adenocarcinoma. Method: We enrolled 53 biopsy specimens of the advanced lung adenocarcinoma patients from four China centers, measured complete blood cell counts and lactate dehydrogenase (LDH) before biopsy, detected PD-L1 level by three IHC assays (22C3, 28-8, SP263), driver genes and TMB by NGS. LIPI was divided into three groups. Result: In the cohort, 28 (52.9%) were male; median age was 59 (range, 34–81) years. There were 7 (13.2%, 7/53) with positive PD-L1(≥50%) based on 22C3. Three assays were highly concordant for tumor cells (ρ=0.740—0.826), lower for immune cells (ρ=0.462—0.543). Six (of 34, 17.6%) were high TMB (at least 10/Mb). Both Ad C/T and Neo C/T provide clinical benefit for the patients with operable stage III N2 NSCLC. This no significantly difference between Ad C/T and Neo C/T groups in both overall and progression-free survival.

P2.01-115 EVALUATION OF EGFR T790M OF CELL FREE CIRCULATING DNA IN PLASMA BY DROPLET DIGITAL PCR FOR PROGRESSIVE NON-SMALL CELL LUNG CANCER

Z. Zhang
The First Affiliated Hospital of Nanjing Medical University, Nanjing/CN

Background: In Non-Small Cell Lung Cancer (NSCLC) harboring EGFR mutations, a second-site point mutation at position 790 (T790M) is associated with acquired resistance to the EGFR kinase inhibitors, gefitinib and erlotinib. Osimertinib is selective for T790M resistance mutation in patients with NSCLC. However, the mutation rate of EGFR T790M is unclear in Chinese patients. The purpose of this study is to understand the status of EGFR T790M in the real world.

Method: 422 Patients with recurrent NSCLC who had been receiving TKI treatment at The First Affiliated Hospital of Nanjing Medical University were enrolled consecutively. Patient blood samples were drawn after the first generation TKI failure. Patients who met the following criteria: patients harboring EGFR activating mutation who developed PD during TKI treatment, Patients had received TKI alone therapy or TKI plus chemotherapy. The droplet digital PCR assay was conducted by droplets generation using QX200 generator (Bio- Rad Laboratories, Inc., Hercules, CA, USA).

Result: 374 (88.6%) of them were successfully analyzed for EGFR T790M genotyping analysis by droplet digital PCR. 48 (11.4%) of them failed to follow-up analysis owing to insufficient cfDNA or restricted serum volume. In tissue samples, TMB derived from WES and EGFR-MUTANT ADVANCED NON-SMALL CELL LUNG CANCER

J. Zhao1, M. Zhang2, J. Zhang3, R. Guo1, G. Lin1, T. Yin2, H. Shi1, W. Wang1, C. Xu1, R. Chen1, X. Xia1
1Thoracic Oncology, Beijing Cancer Hospital, Beijing/CN, 2Genelplus-Beijing, Beijing/China, 3Guangzhou Institute of Respiratory Disease, Guangzhou/CN. *Department of Medical Oncology, Sun Yat-Sen University Cancer Center, Guangzhou/CN.

Background: The gene alterations in treatment-naïve mutant advanced NSCLC. However, 20% of patients with EGFR-TKIs exhibit primary resistance. Whole exome sequencing (WES), the gold standard for evaluating TMB, is less cost-effective. Multiple studies have shown large panels can yield comparable results in tissue samples. However, the feasibility of assessing BTMB using a large panel has not been extensively evaluated. In this study, we evaluated TMB of 30 treatment-naïve advanced NSCLC patients by performing WES on tissue samples as well as targeted sequencing on matched tissue and plasma samples.

Method: WES was performed on tissue samples with an average sequencing depth of 300x. Targeted sequencing was performed on matched tissue and plasma using a panel consisting of 520 cancer-related genes, spanning 1.6Mb of human genome. An average sequencing depth of 1,000x and 10,000x were achieved for tissue and plasma samples, respectively. TMB was calculated as the ratio of mutation count to the size of coding region of the panel (1.26Mb), excluding copy number variations, fusions, large genomic rearrangements and mutations occurring on the kinase domain of EGFR and ALK.

Result: In tissue samples, TMB derived from WES and our panel is comparable with a R2 value of 0.87, and a correlation value of 0.86. cfDNA from 8 patients had no mutation detected using the 520 panel potentially due to low fraction of ctDNA present in the circulation. TMB derived from cfDNA of the remaining 22 patients showed a good correlation with TMB derived from tissue using either our panel (R2=0.94, correlation=0.93) or WES (R2=0.85, correlation=0.87). Demonstrate the feasibility of assessing TMB from cfDNA using a large panel. Next, using TMB calculated from WES as gold standard, we attempted to derive a cutoff to stratify TMB high patients from TMB low patients.

Our data revealed 15 mutations per mb as an optimal cutoff using the 520 panel, achieving an AUC of 97.6% for tissue samples and 97.2% for plasma samples. Conclusion: Our study demonstrated the feasibility of evaluating TMB from cfDNA using a large panel, opening the avenue of TMB estimation using liquid biopsy. Further validations in prospective clinical trials are needed to solidify its predictive value in response to immunotherapy.

The relationship between LINE-1 and lung squamous cell carcinoma (LUSC) is unclear. High frequency in a variety of tumor tissues. However, the relationship and might cause genetic instability, which was reported to occur with mutations with EGFR, which 43 were exon 19 deletion, 37 were L858R and 8 were uncommon EGFR mutations. One patient had co-occurring L858R, T790M and C792A frameshift mutation. The actionable mutations were from 23 genes, which involved in cellular signaling pathways, and some genes had been were reported associated with EGFR-TKIs resistance (details in table). Except the actionable mutations, 753 mutations were detected in 225 samples (59.1%, 225/381), which 35.1% (79/225) in exon8. Bcl-2–like 11(BIM) deletion were detected in 31 (8.1%, 31/381) white blood cells.

### Conclusion

- **Background:** Retrotransposition is a kind of chromatin rearrangement containing the non-coding region, which makes up about half of the human genome. Long interspersed element-1 (LINE-1) retrotransposition is the only currently known active autonomous transposon in humans and might cause genetic instability, which was reported to occur with high frequency in a variety of tumor tissues. However, the relationship between LINE-1 and lung squamous cell carcinoma (LUSC) is unclear.
- **Method:** We analyzed 504 cases of LUSC samples based on the RNA-seq database in TCGA and screened out 13 LINE-1 retrotransposons with the highest occurrence. The somatic LINE-1 retrotransposition were detected in 109 clinical LUSC samples in comparison with their matched adjacent normal tissue samples, as well as the correlation between expression of LINE-1 retrotransposon genes and patients' survival. Then we focused on L1-FGGY and explored its regulation on cell proliferation, apoptosis, migration and invasion in vitro, as well as its roles on promoting tumorigenesis in vivo. We also applied two nonnucleosidic reverse transcriptase inhibitors, nevirapine (NVR) and efavirenz (EFV) both in vitro and in vivo, to investigate whether pharmacological modulation of endogenous reverse transcriptase activity may represent a novel approach in the treatment of LUSC.
- **Result:** We found that 1/3 of tumor samples possessed LINE-1 inserted retrotransposons and the expression of retrotransposon genes in LUSC was significantly higher than that in the corresponding para-carcinoma tissues, indicating that the presence of LINE-1 retrotransposon was related to the occurrence of LUSC. Furthermore, we also found that the survival time of patients with low retrotransposon gene expression was long, while the survival time of patients with high retrotransposon gene expression was short. In this study, we focused on L1-FGGY and further investigated the mechanism of the LINE-1 retrotransposition in regulating the occurrence and progression of LUSC and discovered that the expression of L1-FGGY and FGGY was negatively correlated in LUSC patients. We then discovered that knockdown of FGGY could promote cell proliferation, inhibit cell apoptosis, as well as facilitate cell migration and invasion in vitro. Furthermore, inhibition of FGGY could promote tumorigenesis and tumor metastasis in vivo, which collectively indicated that FGGY might function as a tumor-suppressor gene.
- **Conclusion:** We not only uncovered that the LINE-1 retrotransposition L1-FGGY promotes the development of LUSC by inhibiting the expression and function of the tumor-suppressor gene FGGY, but also revealed that LINE-1 retrotransposon might be a new biomarker for early diagnosis, prognosis evaluation, and targeted therapy in the future clinical translation.

**P2.01-119 PHASE III RANDOMIZED TRIAL OF PALONOSTRON AND DEXAMETHASONE WITH APREPITANT TO PREVENT FULL DOSE SINGLE-DAY CISPLATIN-BASED CINV IN LUNG CANCER**

Y. Zhang, N. Yang, F. Wu

**Background:** This study aimed to determine the efficacy and safety of aprepitant, palonosetron and dexamethasone to prevent chemotherapy-induced nausea and vomiting (CINV) in patients with locally advanced or metastatic lung cancer receiving full dose single-day cisplatin-based combination chemotherapy. **Method:** Patients diagnosed with locally advanced or metastatic lung cancer receiving full dose single-day cisplatin-based chemotherapy were randomized (1:1) to aprepitant plus palonosetron and dexamethasone, or placebo plus palonosetron and dexamethasone. **Primary endpoint was complete response (CR): no vomiting/retching and no use of rescue medication) of nausea and vomiting in the overall period (0-120 h) in first cycle. The secondary endpoints were the proportion of nausea and vomiting, who received rescue antiemetic medication with metoclopramide, the response of cross over patients and safety were also evaluated. **Result:** 244 patients were randomized. There was no difference between two groups with personal characteristics. The aprepitant significantly improved CR for vomiting in the overall period (92.6% vs. 79.9%, p<0.01), rather than nausea-free (75.4% vs. 71.3%, p>0.05) in first cycle. The percentage of patients who received rescue antiemetic medication was decreased for aprepitant group (14.8% vs. 37.1%, p<0.001). Patients without using aprepitant suffered with nausea and vomiting in cycle 1 were crossed over to aprepitant group (N=32), the rate of nausea and vomiting in cycle 2 were decreased to 37.5% (p<0.05) and 25% (p<0.05) respectively. There was no drug related intolerance side effects.

**Primary and secondary endpoints**

<table>

P2.01-120 FIRST STUDY TO EVALUATE THE EFFICACY OF SB ORAL SOLUTION TO PREVENT NEUTROPENIA AND FN INDUCED BY PLATINUM-BASED CHEMOTHERAPY IN LUNG CANCER
Y. Zhang1, F. Zeng2, T. Li3, L. Liu4, N. Yang1
1Shangbai Hospital, Shangbai/CH; 2Medical Oncology, Huan Cancer Hospital, Changsha/CH

Background: The aim of this study is to investigate the efficiency of Shangbai Oral Solution to Neutropenia and Febrile Neutropenia induced by platinum-based chemotherapy in lung cancer. Method: A total of 295 lung cancer patients from January 2014 through December 2016 were treated with platinum-based chemotherapy including etoposide or paclitaxel liposome combined with cisplatin (75mg/m2, one day finished) or carboplatin (AUC=6.25, one day finished), and 91 of them were treated with Shangbai Oral Solution. Using the ratio 1:2 with propensity score matching (PSM), the control group of 169 patients was matched to the experimental group of 91 patients, and the remaining 35 patients were excluded. The primary end point was to evaluate the effectiveness of Shangbai Oral Solution in preventing grade 2/3/4 drug-related toxicities of neutropenia. And the secondary outcome was to evaluate the rate of Febrile Neutropeniatheta, cost and toxicity. All the patients were from this clinical trials with the NCT number of NCT01980212. Result: There were no difference between two groups, with gender, age, smoking status, histologic grade, and histologic type included. The study revealed that compared to the control group, the ratio of neutropenia in the experimental group was significantly lower (4.07% vs 64.50%, HR 0.53, p<0.05), as expected, the grade 2/3/4 neutropenia had similar results (30.77% vs 55.62%, HR 0.55, p<0.01), (4.29% vs 23.67%, HR 0.60, p<0.05), respectively. And the secondary endpoint showed that Shangbai Oral Solution can significantly reduce the rate of Febrile Neutropenia and did not significantly increase the additional medical expenses. There was no intolerance drug related toxicity. Conclusion: This study suggested that Shangbai Oral Solution was effective on reducing neutropenia and Febrile Neutropenia caused by chemotherapy in patients with lung cancer and was worth promoting in clinical.

Background: Pulmonary lymphoepithelioma-like carcinoma (LELC) is a rare and distinct type of primary lung cancer which is characterized by Epstein–Barr virus (EBV) infection. Only a few hundred cases have been reported since its discovery in 1987. Due to its extreme rarity, its genomic landscape remains elusive. In this study, we performed ultra-deep sequencing to interrogate the genomic profile and was worth promoting in clinical.

P2.01-122 INDIVIDUAL PRECISION SURGERY FOR LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER BASED ON MOLECULAR STAGING AND TYPING: THE CHINESE EXPERIENCE.
Q. Zhou
Lung Cancer Center, West China Hospital, Sichuan University, Chengdu/CH

Background: Lung cancer is the leading cause of cancer deaths in the world. For patients with advanced non-small cell lung cancer (NSCLC), survival prognosis is very poor with chemotherapy and radiotherapy. However, the possibility of occult metastases may lead to discrepancy between clinical and pathologic staging and under-estimation of the disease severity, and how to individualized choose the appropriate patients with locally advanced non-small cell lung cancer for surgery is controversial. In this study, we presented here the Chinese experience: individual precision surgery for locally advanced non-small cell lung cancer based on molecular staging and molecular typing. Method: We developed several molecular biomarkers and molecular models from Circulation Tumor Cell (CTC) to detect early stage of lung cancer. In this study, we used these Molecular biomarkers and molecular models for molecular staging, molecular typing, choosing indication of operation and neoadjuvant chemotherapy, predicting postoperative recurrence and prognosis of locally advanced non-small cell lung cancer. Results: We developed two molecular staging model for individualized surgical treatment for locally advanced non-small cell lung cancer involving heart, great vessels or both. 3728 patients with locally advanced non-small cell lung cancer were underwent completely resection of the cancer in the three medical center. The 1-, 3-, 5- and 10 year survival rate were 76.5%, 63.7%, 32.8% and 23.4%, respectively. We used our molecular staging and typing model for neoadjuvant chemotherapy for 665 patients with locally advanced lung cancer. The 1-, 3-, 5- and 10-year survival rate were 79.35%, 51.46%, 27.39% and 20.34% of the patients, respectively. We used our molecular typing model to divide N2 lung cancer into invasive N2 and Non-invasive N2 group. We used our molecular models adenocarcinoma and squamous carcinoma to divide T4 lung cancer into high recurrence and low recurrence groups, and help postoperative adjuvant therapy. Conclusion: Our molecular staging and typing models can help us carry out individual precision surgery, predicting prognosis and cancer recurrence of the cancer for locally advanced no-small cell lung cancer.

P2.01-123 TRANSLATIONAL MEDICINE OF LUNG CANCER METASTASIS: FROM BENCH TO BEDSIDE
Q. Zhou
Lung Cancer Center, West China Hospital, Sichuan University, Chengdu/CH

Background: Cancer invasion and metastasis is not only the malignant marker and characteristics, but also the main cause of failure to cure and lose their life of the patients with lung cancer. 30% of the lung cancer patients had distant metastasis diagnosed with lung cancer. 80% to 90% of the patient dead of distant metastasis. In this study, we presented the results of individual translational medicine of lung cancer metastasis from bench to bedside. Method: A pair of lung cancer cell lines (L9981 and N89890) with same inherit background, different metastatic potential were screened and identified by Single Cell Limited Dilution Cloning. Several differential mi-RNA and gene profiles were screened and identified by mi-RNA array and gene chips from the cells, and peri-cancerous and cancer tissues of patients. Molecular model for early diagnosis and prediction of lung cancer metastasis, molecular typing model of N2 lung cancer were developed by molecular biostatics. 5 small molecular compounds inhibiting lung cancer metastasis were screened and identified based on the molecular targets related to lung cancer
metastasis. Result: We successfully established a pair of lung cancer cell lines with same inherent background, different metastatic potential. High-metastatic cell line L9981 had LOH of gene, deletion of mRNA and protein expression of nm23-H1 and high metastasis potential, and low-metastatic cell line NL9980 with normal NM23-H1 and low metastasis potential. After knockdown the nm23-H1 gene in NL9980 cell, the NL9980 cell was endowed the same biological property as L9981 cell has. We got a differential panel of mi-RNAs and gene signature. We found that the patient with LOH of gene, deletion of mRNA and protein expression of nm23-H1 more likely to have distance metastasis and poor prognosis.

Based on these findings, we proposed a hypothesis of “Lung Cancer Metastatic Suppressive Cascade” and translate the hypothesis into clinical use in the patients. We got several molecular model for early diagnosis and prediction of lung cancer metastasis of lung cancer after operation; a molecular typing model of dividing N2 lung cancer into invasive N2 and Non-invasive N2. Finally, we use the molecular targets related to lung cancer metastasis to screen and identify 5 small molecular compound candidate for lung cancer metastasis. Conclusion: A pair of lung cancer cell lines with same inherent background, different metastatic potential was successfully established. We established several molecular staging and typing models related to lung cancer metastasis and translated them into clinical application in lung cancer patients.

P2.01-124 SIB-IMRT IN SYMPTOMATIC BRAIN METASTASES FOR NSCLC: A RANDOMIZED CONTROLLED STUDY OF WBRT COMPARING 25GY AND 30GY
J. Zhu1, Q. Dong2, W. Wang1, X. Tang1, Y. Meng1, F. Kong1, H. Yang1
1Radiation Oncology, Laboratory of Cellular and Molecular Radiation Oncology, Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou Hospital, Taizhou/CN, 2Department of Medical Oncology, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou Hospital, Taizhou/CN

Background: Intensity Modulated Radiation Therapy with Simultaneous Integrated Boost (SIB-IMRT) can better control intracranial local control rate and even prolong overall survival in non-small cell lung cancer (NSCLC) patients with brain metastases. However, some patients suffer severe neurocognitive dysfunction largely due to whole brain radiation. The purpose of this study is to explore the appropriate dose of whole brain RT when SIB-IMRT is applied. Method: A total of 75 patients with symptomatic brain metastases in NSCLC were randomly divided into 25Gy and 30Gy groups with 10 fraction whole brain radiation therapy (WBRT). The tumor beds with 3 mm expansion (PGTV) were synchronously boosted to 50Gy in both groups. The primary endpoint of the study was intracranial progression-free survival (IPFS) and neurocognitive dysfunction. Secondary endpoints objective response rate (ORR) of 1 month after treatment and overall survival (OS) were included. Trial registration number: ChiCTR-INR-17013204. Result: There were 38 and 37 patients in 25Gy and 30Gy groups, respectively. There was not significant difference in age, gender, performance status and number of brain metastasis between these groups (all P>0.05). The median follow-up is 15 (range 2-38) months. The median IPFS was 11 months (95%CI: 8.7-13.3) in the 25Gy Group and 8 months (95%CI: 4.4-11.6) in the 30Gy Group (P = 0.104). The median OS was 13 months (95%CI:11.4-14.6) months in the 25Gy Group, which is significantly better than 8 months (95%CI:11.4-11.6) months in the 30Gy Group (P = 0.025). The mini-mental state examination(MMSE)of neurocognitive dysfunction found significant differences in the 25Gy Group vs. 30Gy Groups, 27.41±2.03 vs. 26.47±2.03 (P = 0.027) at 12 months after radiotherapy (Table 1).

Abbreviations: MMSE = mini mental state examination.

Conclusion: Based on this small randomized study, the 25Gy group with SIB did not reduce IPFS, but significantly improved OS and decreased toxicity of neurocognitive dysfunction at 12 months after radiotherapy, compared to the 30Gy group with 10 fractions SIB-IMRT in patients with NSCLC with symptomatic brain metastases.

P2.01-125 EGFR MUTATIONS BY NGS IN ADVANCED SQUAMOUS CELL LUNG CANCER
G. Babu1, D. Koppaka1, R. VI2
1Medical Oncology, Kidwai Memorial Institute of Oncology, Karnataka/IN, 2Medical Oncology, Medgenome Oncology, Karnataka/IN

Background: Targets for Squamous cell lung cancer are none as against adenocarcinomas. Also there is limited data available from ct DNA in these patients Method: This prospective observational study looked at patients with squamous cell carcinoma lung, either newly diagnosed or having a progressive disease on prior therapy were enrolled. Ct-DNA was extracted from peripheral blood and analyzed for EGFR, KRAS, NRAS, BRAF mutations using NGS.20 ml of the blood sample was collected from the patient prior to the initiation of therapy or at progression. Result: Sixteen patients of squamous cell carcinoma lung were enrolled into the study. The mean circulating cell-free tumour DNA extracted from the plasma was 96.6 ng (Range, 15-200 ng). Genomic analysis by NGS on the extracted DNA revealed mutations in the EGFR pathway among 8 (50%) patients. The commonest mutation was Exon 21 Leu858Arg in 4 patients. One patient had Exon 20 Thr790Met mutation. One patient had complex mutations with coexisting Exon 21 Leu858Arg and Exon18 Gly719Arg in the same sample. Two patients had KRAS Exon2 Gly12Cys mutation. Among the patients with Exon 21 mutation, two patients were treatment naive and two patients were having a progressive disease (one post Gemcitabine/Carboplatin-based chemotherapy and another post Gemcitabine/Carboplatin and Docetaxel chemotherapy). Patient with complex mutations had progressive disease post Gemcitabine/Carboplatin. Patient with 20 Thr790M mutation had a hyper-progressive disease post-Nivolumab based regimen. While one patient with KRAS mutation one patient was treatment naive while another had progressive disease post Gemcitabine/Carboplatin-based regimen (Table 2).

Two patients with Exon 21 mutations who progressed on earlier lines of treatment received Gefitinib. One patient had progressive disease at 3 months while the other patient succumbed to the disease two months after starting Gefitinib. Treatment Naive patients with EGFR Exon 21 mutations (N=2) upfront received Gemcitabine and Carboplatin-based chemotherapy. Of this 1 patient is currently progression-free and another patient progressed 6 months post chemotherapy and at progression was started on Gefitinib. Patient has a stable disease after 3 months of treatment and still on gefitinib. Patient with Exon 20 T790M mutation was stated on nab-paclitaxel and succumbed to the illness 6 months later. Patient with complex mutations received Docetaxel as second-line
chemotherapy and had a progressive 4 months after the initiation of therapy and died. **Conclusion:** Treatment options for squamous cell carcinoma lung cancer of EGFR mutations helps increase the treatment armamentarium for management of these patients. cf-DNA is a good technique for detecting relevant mutations.

**P2.01 ADVANCED NSCLC**

**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.01-126 MICRONRNA-330-3P MODULATES TUMOR VASCULAR NORMALIZATION AFTER HYPOFRACTIONATED RADIOTHERAPY BY TARGETING P-STAT3/ HIF-1 ALPHA PATHWAY**

X. Jin, X. Dong, C. Wei, H. Lu, F. Tong

Cancer Center, Union Hospital, Huazhong University of Science and Technology, Wuhan.

**Background:** Our study aimed to explore the effect of microRNA-330-3p (miR-330-3p) on radiosensitivity of NSCLC on HFRT both in vivo and in vitro. **Method:** The miR-330-3p over-expressed H460 (H460-OE) and HCC827 (HCC827-OE) cell lines were established using lentivirus vector expressed miR-330-3p. Tumor-bearing nude mice and the dorsal skinfold window chamber (DSWC) models (divided into H460-OE, HCC827-OE, H460 and HCC827 groups) were established and received 0-Gy (control group) or 12-Gy (HFRT group) radiation respectively. At different time points after irradiation, the vasculature of DSMC was visualized by FITC-Dextran; co-immunofluorescence of α-SMA/CD34 staining was employed to detect the coverage rate of pericyte cells on tumor vessels; pimonidazole hydrochloride (PIM) was used to detect the hypoxia. Western blotting and RT-PCR were used to detect the expression levels of p-STAT3/HIF-1α/VEGFA signal pathway and downstream factors CXCL12/CXCR4. In vitro, after radiation, the colony formation assay was used to detect the radiosensitivity. The rate of apoptosis cells were detected by flow cytometry. Moreover, STAT3 inhibitor, s3i-201, was used to further verify the mechanism of miR-330-3p regulating HIF-1α and its downstream factor by Western blotting. **Result:** The curve of relative volume-time displayed that the radiosensitivity of miR-330-3p over-expressed xenografts decreased as compared to H460 and HCC827 xenografts. HFRT-induced decrease of MVD and hypoxia, increase of pericycle coverage and tumor vascualrization in H460 and HCC827 xenografts were inhibited in H460-OE and HCC827-OE xenografts (P<0.05). Colony formation assay showed that the radiosensitivities in miR-330-3p over-expressed groups decreased and the flow cytometry assay showed that after HFRT, apoptosis rate was higher in H460-OE than H460 cells. Western blotting and RT-PCR displayed that, both on the 7th and 14th day after HFRT, the levels of p-STAT3, HIF-1α, VEGFA and CXCL12/CXCR4 in miR-330-3p over-expressed xenografts were higher than that in HCC827 and H460 xenografts (P<0.05). The in vitro studies showed that 2-28 hours after HFRT, the expression levels of p-STAT3, HIF-1α and VEGFA in H460-OE cells were up-regulated as compared to H460 cells (P<0.05). After adding s3i-201, the levels of p-STAT3/HIF-1α could not be inhibited in H460-OE, but could be inhibited in the H460 group (P<0.05). Also compared to the HCC827 cells after HFRT, the levels of p-STAT3 and HIF-1α in HCC827-OE group could not be inhibited by s3i-201 (P<0.05). **Conclusion:** miR-330-3p may decrease the HFRT-radiosensitivity of NSCLC via upregulating the p-STAT3/HIF-1α pathway and its downstream factors. VEGFA and CXCL12/CXCR4, therefore inhibiting vascular normalization effect of HFRT.

**P2.01-128 LOW POSITIVITY RATE IN T790M DETECTION WITH CTDNA IN NSCLC AND POST EGFR-TKI PROGRESSION – TIMING OR SENSITIVITY?**

1Neotorax Oncologia D’Or, Rio de Janeiro/BR, 2Progenetica, Rio de Janeiro/BR, 3Américas Centro de Oncologia, Rio de Janeiro/BR, 4Medical Oncology, Nob and Hospital Português, Salvador/BR, 5Oncology, Bp - A Beneficiencia Portuguesa de Sao Paulo, Sao Paulo/BR, 6Núcleo de Oncologia Da Bahia, Salvador/BR, 7Instituto Nacional de Cancer (Inca), Instituto Nacional de Cancer (Inca), Rio de Janeiro/BR, 8Thoracic Oncology, Neotorax, Rio de Janeiro/BR, 9Medical Department, AstraZeneca, Cotia/BR, 10AstraZeneca Brazil, Cotia/BR, 11Instituto D’Or, Rio de Janeiro/BR

**Background:** The approval of Osimertinib in Brazil in 2016 for post EGFR-TKI progression T790M+ NSCLC treatment allowed offering to the patient the best available therapy, when, it is mandatory to identify the occurrence of T790M mutation before initiating the treatment. The prevalence of T790M mutation as resistance mechanism post EGFR-TKI treatment is estimated to be around 60%. Considering the limitations for tumor tissue biopsy in progressive disease setting, identifying molecular changes by using alternative tumor DNA sources, such as blood samples, serum, and plasma can become an interesting strategy in cases where a tissue specimen or acceptable quality biopsy is not available. However, the sensitivity of ctDNA analysis for T790M mutation is disappointingly low. **Method:** We performed a retrospective analysis of ctDNA samples database collected between June 2016 and December 2017 in Brazil. Blood samples of patients with post EGFR-TKI progression were submitted, at discretion of attending physicians, for EGFR mutation testing by cobas® test. 761 tests were included. The positivity rate was 43.9% for EGFRm and 10.4% for T790M. Considering EGFRm positive tests, the positivity rate for T790M among EGFRm positive was 23.7%. Data are shown in Table-1. This positive rate is lower than expected and may be explained by three factors: T790M ctDNA low sensitivity test request before progression; or T790M prevalence lower in Brazilian population. Still, more detailed testing using tissue and/or more sensitive methods are needed before definitive conclusion. Tissue test should continue being recommended as gold standard in T790M detection on this patient setting. Table-1 - Frequency and mutations detected by ctDNA cobas® test in Brazil.

**P2.01 ADVANCED NSCLC**  
**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.01-129 POTENTIAL IMPACT OF KRAS MOLECULAR PROFILING OF NON-SQUAMOUS NON-SMALL CELL LUNG CANCER (NSCLC).**  
N. Karim1, J. Pathrose2, H. Fathallah1, I. El Desouki1, A. Perry1, S. Starnes2, J. Morris1  
1Internal Medicine, University of Cincinnati, Cincinnati/OH/US; 2The McMicken College of Arts and Sciences, The University of Cincinnati, Cincinnati/OH/US; 3Surgery, University of Cincinnati, Cincinnati/OH/US

**Background:** Several studies suggest that patients with KRAS-mutant (KRASmut) NSCLC fail to benefit from platinum-based systemic chemotherapy and are not likely to have targetable mutations. Molecular profiling has the potential to identify other potential targets that might provide novel therapy for KRASmut NSCLC. **Method:** In this study, we purified RNA from archived tumors of patients with stage I and II NSCLC wild-type (wt) and mutant (Mut) KRAS and from paired normal tissue from 20 and 17 patients, respectively, and assessed by real-time reverse transcriptase-polymerase chain reaction (RT-PCR) the expression of four genes involved in DNA synthesis and repair including thymidylate synthase (TS), BRCA1, ECCR1, RAP80, and the proto-oncogene, SRC. Additionally, we assessed expression of PD-L1 IHC 22C3 by immunohistochemistry using an antibody against PD-L1 IHC 22C3.

**Result:** Our results show that in KRASmut tumors, ERCC1, TS, and SRC expression were increased in comparison to paired normal lung tissue (p ≤ 0.04). Expression of BRCA1 and RAP80 were similar in both KRASwt tumors and paired normal tissue from 20 and 17 patients, respectively, and assessed by real-time reverse transcriptase-polymerase chain reaction (RT-PCR) the expression of four genes involved in DNA synthesis and repair including thymidylate synthase (TS), BRCA1, ECCR1, RAP80, and the proto-oncogene, SRC. Additionally, we assessed expression of PD-L1 IHC 22C3 by immunohistochemistry using an antibody against PD-L1 IHC 22C3.

**Conclusion:** Within the limitation of our retrospective study, KRASmut NSCLC would likely be platinum, taxane and pemetrexed resistant, having a low level of PD-L1 expression. KRAS wt BRCA1 positive tumors tend to be sensitive to taxane therapy and possibly platinum-based drugs. Our result suggests the need to develop targeted therapies for KRASmut NSCLC and other therapies specific to the molecular profile of the tumor.

**Conclusion:** Our findings suggest that ctDNA approach in post EGFR-TKI progression may not be the best diagnostic strategy to identify resistance T790M mutation as first option. When patient cannot be submitted to tissue biopsy at progression, ctDNA test is an acceptable alternative.

**Keywords:** advanced NSCLC, ctDNA, T790M frequency

**P2.01-130 DETECTION OF ACTIONABLE MUTATION STATUS IN ADVANCED NON-SMALL CELL LUNG CANCER BY NEXT-GENERATION SEQUENCING OF CIRCULATING TUMOR DNA**  
Y. Yang, X. Song, W. Guo  
Department of Pulmonary Oncology, Shanxi Cancer Hospital, Shanxi Medical University Cancer Hospital, Taiyuan/CN

**Background:** Genotype directed therapy has become increasingly important for personalized therapy of patients with advanced non-small cell lung cancer(NSCLC), but obtaining tumor tissue for genotyping remains a challenge. Plasma circulating tumor DNA(ctDNA) analysis by next-generation sequencing (NGS)may allow for noninvasive evaluation. We demonstrate the feasibility and clinical utility of ctDNA NGS in the management of advanced NSCLC. **Method:** A total of 114 plasma samples were detected by NGS to identify actionable oncocinergic driver mutations or mechanisms of resistance in 108 patients with advanced NSCLC. Among those 108 patients, there were 79 paired tissue DNA (tDNA) and ctDNA samples detected using ARMS-PCR. We also evaluated the concordance in detecting of EGFR between ctDNA and paired tDNA. **Result:** Of the 114 plasma ctDNA, 47(47/114, 41%) actionable somatic mutations and 1 EGFR T790M germline mutation were detected. EGFR variants were most common(39/114, 34%). Among the 79 patients with matched tDNA and ctDNA, 52(32/79, 41%)therapeutically targetable EGFR mutations were detected in tDNA and 30(30/79, 38%) in ctDNA samples, yielding an overall concordance of 70%, the sensitivity and specificity of NGS were 59% and 77%. Of the 47 patients with tDNA negative, 11(11/47, 23%) patients harbored EGFR mutation detected in ctDNA during the course of their disease. Of the 31 patients with brain metastases, 22(71%) harbored an EGFR sensitive mutation(15, 48%; EGFR 19del and 7, 23%; EGFR L858R). Of the 40 patients who resistant to 1st and 2nd EGFR-TKI therapy, 14(14/40, 35%) showed the T790M acquired resistance mutation. The mean time of EGFR-TKI resistance was 11.5 months. Patients with T790M mutations had significantly better PFS than those without T790M. **Conclusion:** ctDNA NGS can be adopted as a tool for providing precision genomic analysis and dynamic monitoring, thus improving patient management, and even undertaking hereditary counseling.

**P2.01-131 APATINIB AS AN ALTERNATIVE FOR ADVANCED NON-SMALL CELL LUNG CANCER**  
Z. Wu1, H. Pan2, M. Ye1, L. Chen1, W. Qian4, J. Zhang4  
1Science and Engineering, University of Minnesota, Minnesota/US; 2Translational Medicine, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/ CN; 3Internal Medicine, The Guangzhou Chest Hospital, Guangzhou/CN; 4Internal Medicine, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/ CN

**Background:** Methylsulfonic apatinib showed promising efficacy for the treatment of non–small-cell lung cancer (NSCLC) as one of the TKIs which specifically inhibits VEGFR-2. We aimed to assess the efficacy of apatinib in each lines of treatment to patients with advanced/metastatic NSCLC. **Method:** We retrospectively analyzed variables and outcomes of patients with advanced NSCLC, who had received apatinib between January 1, 2016 and April 30, 2018, including: 5 patients of first line treatment, 16 second line treatment, 20 third line treatment and 6 fourth and fifth line.
**Background:** There are several methods to detect molecular alterations in precision medicine era. This is a pilot study aimed to explore the concordance of molecular alterations testing using NGS different platforms and different cutoff allele frequency in NSCLC patients.

**Method:** Ten NSCLC patients’ FFPE were retrieved for DNA extraction. All qualified samples were analyzed using NGS on 45 cancer genes panel on Ion Torrent system NGS Gene read Qiagen Lung Cancer Panel. Variants from NGS with coverage of are higher than 1000X. The cutoff 1% and 3% of variant allele frequency were considered positive. **EGFR, BRAF, KRAS** were validated by Real-time PCR technique using the Amoy DX and Actionable Insights Tumor Panel in GeneReader NGS system. Result: We found 90%/30% **EGFR**-mutation, 40%/BRAF V600E, 70%/30% **KRAS**-mutation by NGS using allele frequency cutoff at 1% and 3%, respectively. We validated by Real-Time PCR and Actionable GeneReader showed 70%/40% **EGFR**-mutation, 20%/10% **BRAF** V600E, and 0%/30% **KRAS**-mutation (Table1). Regarding **EGFR**-mutation, 5 cases of discordance showed positive at 1% but negative at 3% cutoff allele frequency by NGS and validated by Real-Time showed positive all 5 cases. Two negative cases by Real-Time PCR show positive in NGS cutoff 1% (2/2) and 3% (1/2). In early stage (80%), there was 60% of **EGFR** 19 del detected by NGS cured 1%. The patients have continued follow-up at clinical and the mDFS of 4.7 years. Two stage IV patients with exon19del were death and received EGFR-TKI as a second-line treatment with mOS at 1.1 and 1.2 years. Table 1

**P2.03-01 PREVALENCE OF EGFR ALTERATIONS IN CHILEAN LUNG CANCER PATIENTS: A RETROSPECTIVE STUDY**

R. Gejman¹, M.L. Bravo², M. Muñoz², I. Retama³, B. Neri⁴, C. Sanchez⁵, C. Ibañez⁶, J. Peña⁶, J. Madrid⁶, J. Briones¹, P. Perez¹, M. Garrido⁶, M. Pinto⁶, H. Galindo⁶

¹Anatomic Pathology, Pontificia Universidad Catolica de Chile, Santiago/CL
²Hematology & Oncology, Pontificia Universidad Catolica de Chile, Santiago/CL

**Background:** Recently, several countries in Latin America (LA) have entered into an epidemiological shift; switching the burden of disease from infectious to chronic non-transmittable disorders. In fact, many studies anticipate that Lung Cancer (LC) will soon emerge as the first cause of mortality in the region, possibly over the next decade. In Chile, LC is currently the second leading cause of cancer death and responsible for >2,500 deaths every year. Epidemiological data from Chilean LC patients is scarce and scattered. On the other hand, Tyrosine Kinase Inhibitor (TKI) drugs have been successfully used in a subset of LC patients that harbor alterations in the Epidermal Growth Factor Receptor (EGFR) gene. Here, we aimed to quantify the prevalence of EGFR alterations in the Chilean population. Method: We performed a retrospective study that involved 1,405 biopsies from 1,385 Chilean LC patients. Then we selected patients with EGFR alterations and retrieved clinical data from these patients including age, gender, histological type, smoking habits and type of EGFR alteration. We also analyzed overall survival (OS) rates Result: We found that 300 out of 1,385 (21.7%) had clinically relevant EGFR alterations. Within this group median age at diagnosis was 65 yr. As expected, most patients were female (64%), and classified as Non-Small Cell Lung Cancer adenocarcinomas (94.5%). Also in patients with EGFR alterations, the majority were either non-smokers or light smokers (93.1%). Regarding the type of EGFR alterations the most prevalent was the exon 19 deletions (50.6%) followed by Leucine-to-Arginine 858 (L858R, 28.9%). Further analyses indicated that OS within this group was 15 months. Also, information clinical follow-up and TKI treatment was available for 87 patients. As expected the use of TKIs in these patients significantly improved OS Conclusion: The prevalence of EGFR alterations in the Chilean population is 21.7%, a value between the Caucasian and Asian population, 18.6% and 57.1% respectively. This value is also comparable to other reports from countries within LA
such as Argentina (14.4%), Uruguay (18.3%), Colombia (24.7%) and Peru (37%). Similarly, OS was 15 months and the most frequent EGFR reported alteration was exon 18 deletions. Finally, the use of TKIs in these patients significantly improves OS.

Background: Liquid biopsies are a revolution in cancer diagnostics as a minimally invasive alternative to tissue biopsy. cfDNA is used for the detection of biomarkers in LUAC patients if a tumor tissue sample is not available. We conducted the SLILP study to prospectively validate Guardant360 for the detection of 7 targetable activating alterations (EGFR, ALK, ROS1, BRAF, MET, RET, and ERBB2) in LUAC. Method: Blood samples from treatment-naive stage IIIb-IV LUAC patients were analyzed using Guardant360, a next-generation sequencing panel covering 73 genes. The assay includes complete exon sequencing for 19 cancer genes, sequencing of critical exons in 54 genes, and detection of amplifications (18 genes), fusions (6 genes), and indels (23 genes) with high overall clinical sensitivity rates (85%) and ultra-high specificity (>99.9%). Indels and point mutations can be detected at a mutant allele fraction (MAF) as low as 0.1%. Guardant360 was compared with tissue genotyping performed as standard of care, using a variety of “real life” techniques. The primary objective was to demonstrate the non-inferiority of Guardant360 versus tissue analysis for the detection of the 7 genetic alterations. The study is registered with ClinicalTrials.gov, number NCT03248089. Result: 186 LUAC patients were enrolled over a period of 11 months (August 2016-July 2017). Median age 64, 65% male, 72% smoker/ex-smokers, 85% EGCG performance status 0-1. Targetable activating alterations were detected by the Guardant360 assay and by tissue analysis in 24% (n=47) and 18% (n=32) of patients, respectively. We identified 7 targetable alterations in patients with tissue (non-inferiority P=0.268). Thirty patients (16%) had alterations identified by both modalities. None of the 186 patients was successfully tested in tissue for all 7 alterations. Of the 17 patients who were negative in tissue, 3 had BRAF mutations. For none of these patients was BRAF tested in tissue. but for whom Guardant360 identified targetable alterations, 3 had BRAF mutations. For none of these patients was BRAF tested in tissue.

Conclusion: Guardant360 cfDNA and tissue analysis detect relevant somatic tumor alterations at similar rates in LUAC patients. Under genotyping in tissue is common but can be mitigated by the use of cfDNA next generation sequencing assays.

P2.03-03 UPFRONT NEXT GENERATION SEQUENCING IN NSCLC: A PUBLICLY FUNDED PERSPECTIVE

K. Perdrizet1, T. Stockley1, M. Tsao1, S. Kamel-Reid3, J. Morganstein3, S. Kamel-Reid4, J. Morganstein3, S. Kamel-Reid1, T. Zhang2, M. Sampayo6, D. Hwang8, P. Pal6, G. Liu9, P. Bradbury1, F. Shepherd1, A. Sacher1, N. Leighl1
1University of Toronto, Toronto/CA, 2University Health Network, Toronto/ON/CA, 3University Hospital Network, Princess Margaret Cancer Centre, Toronto/ON/CA, 4Department of Medical Oncology and Haematology, Princess Margaret Cancer Centre, Toronto/ON/CA, 5Department of Medical Oncology and Haematology, Princess Margaret Cancer Centre and University of Toronto, Toronto/ON/CA

Background: A growing number of targeted drug treatments in non-small cell lung cancer (NSCLC) have led to the need for molecular profiling beyond the standard of care (SOC) EGFR/ALK. Here we present actionable targets, impact on patient treatment, clinical trial opportunities and costs using the Illumina TruSight Tumor 15 panel (TST15). The panel identifies somatic tumor alterations at similar rates in LUAC patients. Under genotyping performed as standard of care, using a variety of “real life” techniques. The primary objective was to demonstrate the non-inferiority of Guardant360 versus tissue analysis for the detection of the 7 genetic alterations. The study is registered with ClinicalTrials.gov, number NCT03248089.

Method: Tissue-based next generation sequencing using the TST15 was reflexively performed on all newly diagnosed cases of non-squamous NSCLC at the University Health Network (Toronto, Canada) from February 2017-February 2018. The panel identifies somatic tumor alterations in KRAS, EGFR, TP53, PIK3CA, BRAF, ERBB2, FOXL2, GNA11, GNAQ, KIT, NRAS, PDGFR, RET, AKT1 and MET, but not fusions, copy number variations (CNV) nor MET exon 14 skipping mutations. Patient age, stage, pathological subtype, and treatment response was documented prospectively. Treatment changes as a result of TST15 and clinical trial opportunities (clinicaltrials.gov) were identified. Incremental testing costs were based on direct laboratory costs, but not personnel and administration costs.

Result: Testing included 342 samples from 336 patients. The TST15 panel identified 409 mutations from 342 samples. Sample demographics include: male: 53, and stage 1/2/3/4: 34/8/15/43%. Incremental actionable targets beyond EGFR and ALK were identified in 3.5% of patients (ERBB2 2.3%, BRAF V600E 1.2%). Most mutations occurred in TP53 (43%), EGFR (24%) and KRAS (26%). Co-mutations occurred in 32% (TP53, KRAS, EGFR) of samples. To date, one patient has had a treatment change as a result of TST15 beyond targeting EGFR. Above SOC clinical trial options were identified for 88% of stage IV and 26% of stage III patients. 3.6 samples were needed to identify one actionable target. While OCA testing was non-inferior to tissue, incremental testing costs were based on direct laboratory costs, but not personnel and administration costs.

Conclusion: This study evaluated a publicly funded next generation sequencing (NGS) panel in NSCLC DS (26%). Co-mutations occurred in 32% (TP53, KRAS, EGFR) of samples. To date, one patient has had a treatment change as a result of TST15 beyond targeting EGFR. Above SOC clinical trial options were identified for 88% of stage IV and 26% of stage III patients. 3.6 samples were needed to identify one actionable target. While OCA testing was non-inferior to tissue, incremental testing costs were based on direct laboratory costs, but not personnel and administration costs.

P2.03-04 NEXT GENERATION SEQUENCING IN LUNG CANCER USING THE ONCOMINE COMPREHENSIVE ASSAY: THE CANADIAN PUBLICLY FUNDED EXPERIENCE

1University of Toronto, Toronto/CA, 2University Health Network, Toronto/ON/CA, 3University of Toronto, Toronto/CA, 4University Health Network, Toronto/ON/CA, 5Department of Medical Oncology and Haematology, Princess Margaret Cancer Centre and University of Toronto, Toronto/ON/CA, 6Department of Pathology, University Health Network, Princess Margaret Cancer Centre, Toronto/ON/CA, 7Department of Medical Oncology and Haematology, Princess Margaret Cancer Centre, Toronto/ON/CA

Background: Standard of care (SOC) diagnostics for patients with stage IV non-small cell lung cancer (NSCLC) in Canada includes EGFR and ALK testing. Other genomic alterations are not tested routinely; however, access to enhanced molecular testing may broaden treatment options, clinical trial access, and improve outcomes for patients. This study uses the Oncomine Comprehensive Assay (OCA) v3, a next generation sequencing (NGS) panel in NSCLC to establish actionable targets, clinical trial eligibility, treatment impact, costs, turnaround time, and patient preference. Method: Consecutive consenting stage IV NSCLC outpatients at the Princess Margaret Cancer Centre without EGFR/ALK/KRAS/BRAF/ERBB2 testing. Other genomic alterations are not tested; however, access to enhanced molecular testing may broaden treatment options, clinical trial access, and improve outcomes for patients. This study uses the Oncomine Comprehensive Assay (OCA) v3, a next generation sequencing (NGS) panel in NSCLC to establish actionable targets, clinical trial eligibility, treatment impact, costs, turnaround time, and patient preference. Method: Consecutive consenting stage IV NSCLC outpatients at the Princess Margaret Cancer Centre without EGFR/ALK/KRAS/BRAF/ERBB2 testing. Other genomic alterations are not tested; however, access to enhanced molecular testing may broaden treatment options, clinical trial access, and improve outcomes for patients. This study uses the Oncomine Comprehensive Assay (OCA) v3, a next generation sequencing (NGS) panel in NSCLC to establish actionable targets, clinical trial eligibility, treatment impact, costs, turnaround time, and patient preference.

Conclusions: While OCA testing in patients with advanced NSCLC may identify more actionable targets than selected choices, its cost effectiveness in the Canadian healthcare system is unknown and will be determined through this study.

**Keywords:** Brain metastasis, ion channel, nCounter

Background: Brain metastasis develops in approximately 50% of patients with non-small cell lung cancer (NSCLC), resulting in poor prognosis and low health-related quality of life. Immunological microenvironment and functions of ion channels have been indicated to play pertinent roles in epithelial-to-mesenchymal transition (EMT) and its reverse mesenchymal-to-epithelial transition (MET), crucial steps in distant metastasis, but their actual roles in brain metastasis of NSCLC remains unclear. The aim of this study is to investigate biologic profiles of brain metastasis of NSCLC.

**Method:** Formalin-fixed paraffin-embedded (FFPE) samples of brain metastasis and paired primary sites were collected from 3 patients with NSCLC undergoing surgical resection between Jan. 2012 and Dec. 2017. Total RNA was extracted from the archived FFPE, which integrity was briefly checked by Nanodrop. Gene expression was detected by nCounter (NanoString Technologies, WA, USA) with PanCancer Immune Profiling Panel and custom-made KMU IonChannel Panel that covered selected 100 genes. Detected data was analyzed by nCounter Advanced Analysis (version 2.0.115). Factors with unadjusted P-value < 0.01 were regarded as candidates for further investigation. 

**Result:** Brain metastasis showed upregulations of MCOLN3 and YTHDF2 (unadjusted P-value = 0.0093 and 0.0063, respectively) compared to the primary site. Conversely, primary site showed upregulations of IFNAR1, TNFRSF4, CXCL11, CT45A1, MAP3K5, TAL1, LG3 and MARCO. In LATE-BREAKING ABSTRACT, we will report following data: 1) Immunohistochemistry results of the candidate genes in sphere cell line from brain metastasis and primary site of NSCLC.

**Conclusion:** Biologic profilings of brain metastasis from NSCLC may subsequently help to understand underlying mechanism and ultimately lead to novel targeted therapy. Further details will be added in LATE-BREAKING ABSTRACT.

**Keywords:** Brain metastasis, ion channel, nCounter

**P2.03-06 SERUM SYNECDAN-1 LEVELS IN PATIENTS WITH NONSMALL CELL LUNG CANCER**

J. Teki1, O. Yetkin2, G. Yetkin3, M. Iraz3  
1Medical Oncology, Medicina International Ankara Hastanesi, Ankara/TR, 2Pulmonary Disease, Inonu University, Malatya/TR, 3Microbiology, Inonu University, Malatya/TR

**Background:** Cytokines as polypeptide or glycopeptide molecules are the essential mediators of immune response and the inflammatory reactions in addition to numerous biological reaction they are involved in. Syndecans have an important role in a variety of cellular functions including cell proliferation and migration, and cell–cell and cell–matrix interactions. Syndecan-1 is a transmembrane heparan sulphate proteoglycans that is present on most cell types. In this study we aimed to evaluate levels of syndecan-1, levels in non-small cell lung cancer (NSCLC), and to evaluate their relationship with tumor progression.

**Method:** Sixty-six patients (F=3, M=63) with non-small cell lung cancer and 22 healthy (F=3, M=19) subject were enrolled this study. Patients with infections or other systemic disease were not included in the study. Serum levels of syndecan-1 was measured by ELISA system. Serum samples were obtained from each patient before the initiation of any type cancer treatment. They were centrifuged at 3000 rpm for 10min, and then stored at -70°C. Unpaired t-test was used to compare continuous variables between the patient group and control group and within the patient group according to TNM classification. Correlation analysis between cytokines and tumor stage was performed using the Pearson correlation coefficient. Sensitivity, specificity, positive predictive value and negative predictive values for syndecan-1 were determined using receiver operator characteristic analysis (ROC). These analyses were done to define clinically valid cutoff points to predict distant metastasis. A two-sided p values less than 0.05 was considered to be statistically significant.

**Result:** Serum levels of syndecan-1 in patients with NSCLC were significantly higher than those of controls (p<0.001). In addition, mean levels of synde- can-1 in stage IV disease were significantly higher than non-metastatic NSCLC (p<0.001). In the patients with only one distant metastasis, levels of syndecan-1 were found to be lower than the patients with multiple distant metastases. Syndecan-1 has high sensitivity (78%), specificity (91%), positive (88%) and negative predictive (80%) values for prediction of metastasis. 

**Conclusion:** In conclusion, we found that syndecan-1 changes significantly in serum of patients with NSCLC. In our study, these changes correlated well with the stage of lung cancer. Syndecan-1 with a high sensitivity, specificity and positive predictive value may be used in predicting the presence and nature (single or multiple) of metastasis. The authors believe that the current findings will provide clinicians with new insights, allowing them to implement more individualized treatment strategies in patients with lung cancer.

**Keywords:** nonsmall lung cancer, syndecan-1, metastasis

**P2.03-07 RADIOIMMUNOLOGIC SIGNATURES LINKED TO GENETIC ALTERATIONS AS DETECTED BY NEXT-GENERATION SEQUENCING: A RADIOGENOMICS ANALYSIS OF EARLY-STAGE NSCLC**

S. Tian1, E. Schreibmann1, S. Goyal2, M. Rupji2, R. Cassidy1, C. Escott1, M. Ferris1, P. Patel1, W. Curran, Jr.1, K. Higgins2  
1Radiation Oncology, Emory University, Atlanta/GA/US, 2Biostatistics and Bioinformatics Shared Resource, Winship Cancer Institute, Atlanta/GA/US

**Background:** Radiomics uses large-scale quantitative analysis of extracted image-based features to identify tumor phenotypes. Such frameworks based on computed tomography (CT) have identified informative features in lung cancer related to treatment response and prognosis. Molecular profiles have been increasingly recognized in non-small cell lung carcinoma (NSCLC) as predictors of clinical outcomes. The aim of this study is to isolate radiomic signatures which are associated with genomic alterations discoverable by extended panel testing.

**Method:** Patients with early-stage NSCLC who received definitive local treatment and underwent next-generation sequencing were included for this analysis. 35 genomic alterations representing 32 genes were evaluated using SnAShot (Life Technologies), TrueSight Transcriptome, Guardant360 (Guardian Health) or a FISH panel of ALK, MET, ROS1 and RET. Regions of interest including each primary tumor volume were delineated on diagnostic CTs datasets; they were defined as either tumor only (TO), or tumor with a 1cm anatomically-modified anisotropic

prognosis of NSCLC harboring MSH2
little is known about their etiology and prognosis in non-small-cell lung cancer (NSCLC) patients and acquired resistance to icotinib using targeted NGS. The aim of this study was to evaluate the prevalence of NTRK fusions in Chinese lung cancer populations, which had not been reported earlier, and to describe targeting potential in Chinese lung cancer populations.

**Method:** A multicenter study in China was initiated from February 2014, and lung cancer patients have been enrolled as of December 2017. Capture-based comprehensive genomic profiling was performed on 2719 lung cancer FFPE samples (non-squamous/squamous/small–2061/349/309) sequenced to a mean coverage depth of >650X for up to 381 cancer-related genes. Genomic alterations (GA) included short variant (SV) base sub and insertions/deletions, copy number alterations, and rearrangements/fusions. Tumor mutational burden (TMB/Mb) was calculated on up to 1.2 Mb of sequenced DNA. Result: Of this entire cohort, just one (0.04%) patient was identified with a TPM3-NTRK1 fusion. The patient was diagnosed with SCLC. TPM3-NTRK1 fusion was found by biopsy using NGS, the genes co-altered with NTRK fusion was no concurrent with KRAS, EGFR, ALK, ROS1, or other known drivers were identified in the study cohort cases. Conclusion: NTRK fusions are a rare molecular subtype in Chinese lung cancer populations. Given the clinical evidence for the activity of targeted therapy approaches, molecular eligibility for clinical trials of larotrectinib or entrectinib should include these fusion subtypes. The clinical evidence for responsiveness of NTRK fusions driven lung cancer provides an opportunity to personalize treatments and improve clinical outcomes for patients.

**Keywords:** next-generation sequencing, lung cancer, NTRK fusion

**Background:** Although inactivation of MutS Homolog 2 (MSH2) gene may predict sensitivity to immunotherapy in non-small cell lung cancer (NSCLC), little is known about their etiology and prognosis in non-small-cell lung cancer (NSCLC). The aim of this study is to investigate mutations and prognosis of NSCLC harboring MSH2 mutations. **Method:** A total of 326 patients with non-small-cell lung cancer were recruited between July 2014 and December 2015. The status of MSH2 mutation or other genes were detected by next generation sequencing. Result: MSH2 gene mutation rate was 9.51% (31/326) in non-small cell lung cancer, including H839R (5 patients), L390F (4 patients), E809K (3 patients), I544M (1 patient), R217C (1 patient), T8M (1 patient), T552S (1 patient), I169V (1 patient), A573T (1 patient), R534L (1 patient), V712Sfs*5 (1 patient), F58L (1 patient), S676L (1 patient), N583S (1 patient), I766V plus A2V (1 patient) and Q419K plus Q629R (1 patient), and median overall survival (OS) for these patients was 16.0 months. Among them, all patients were MSH2 gene with co-occurring mutation. Briefly, patients with (n=6) or without (n=25) co-occurring EGFR mutations had a median OS of 6.5 months and 17.0 months respectively (P=0.02); patients with (n=20) or without (n=11) co-occurring TP53 mutations had a median OS of 14.0 months and 17.0 months respectively (P=0.85). Result: MSH2 is involved in MMR, controlling several aspects of genome stability. Immunotherapy may displayed moderated efficacy in patients with MSH2 mutations. The patient with co-occurring mutations might play a good prognosis in MSH2 gene mutation NSCLC.

**Background:** NTRK fusions have been recently identified as a therapeutic target in a rare fraction of Caucasian patients with lung cancer (3.3%). The aim of this study was to evaluate the prevalence of NTRK fusions in Chinese lung cancer populations, which had not been reported earlier, and to describe targeting potential in Chinese lung cancer populations.

**Method:** Our study uncovered mutational profiles of TKI-sensitizing EGFR mutations NSCLC patients required resistance to icotinib using NGS. Interestingly, we also observed R81D, ASXL1 and BMX mutations in EGFR-T790M wild patients, which are restricted to icotinib treatment. Conclusion: Our study uncovered mutational profiles of TKI-sensitizing EGFR mutations NSCLC patients with icotinib resistance with potential therapeutic implications. Our analysis strongly suggests that MET amplification, BRAF mutations and PIK3CA mutations may serve as bypass resistance mechanisms in patients who are EGFR T790M wild type.

P2.03 BIOLOGY  TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.03-11 PDGFRA DEFINES A UNIQUE MOLECULAR SUBTYPES OF CHINESE NON-SMALL CELL LUNG CANCER PATIENTS
1Fujian Cancer Hospital, Fuzhou/CN, 2Zhejiang Cancer Hospital, Hangzhou/CN, 3Pathology, Fujian Cancer Hospital, Fuzhou/CN, 4Medical Oncology, Fujian Cancer Hospital, Fuzhou/CN, 5Zhejiang Rongguan Hospital, Jiaxing/CN, 6Pathology, Fujian Cancer Hospital, Fuzhou/CN, 7Siniling Hospital, Nanjing/CN

Background: Activation of the platelet-derived growth factor (PDGF) signaling system has been implicated in the development and malignant progression of non-small cell lung cancer. Recent studies have identified the activated growth factor receptor A (PDGFRA) gene mutations are identified in non-small cell lung cancer (NSCLC). While the genetic locus of PDGFRA mutation NSCLC patients is unclear. The aim of this study is to investigate mutations and prognosis of NSCLC harboring PDGFRA mutations.

Method: A total of 467 patients with non-small-cell lung cancer were recruited between July 2012 and December 2015. The status of PDGFRA mutation and other genes were detected by next generation sequencing.

Result: PDGFRA gene mutation rate was 2.14% (10/467) in non-small cell lung cancer, including S716R (1 patient), L615* (1 patient), A917T (1 patient), H104R (1 patient), V536M (1 patient), N505K (1 patient), V421L (1 patient), V538M (1 patient), M578K (1 patient) and V544A (1 patient), and median overall survival (OS) for these patients was 24.0 months.

Among them, all patients were PDGFRA gene with co-occurring mutation. Briefly, patients with (n=2) or without (n=8) co-occurring EGFR mutations had a median OS of 19.0 months and 24.0 months respectively (P=0.96); patients with (n=6) or without (n=4) co-occurring TP53 mutations had a median OS of 17.0 months and 19.0 months respectively (P=0.99); patients with (n=2) or without (n=8) co-occurring BRCA2 mutations had a median OS of 25.0 months and 19.0 months respectively (P=0.17); patients with (n=2) or without (n=8) co-occurring IDH2 mutations had a median OS of 15.0 months and 24.0 months respectively (P=0.22).

Conclusion: Mutation type of PDGFRA has a potential for predicting the course of the disease and might contribute to management individualization of NSCLC patients. EGFR, TP53, BRCA2 and IDH2 gene accompanied may have less correlation with PDGFRA mutation in NSCLC patients. Imatinib may displayed moderated efficacy in patients with PDGFRA mutation.

Keywords: Non-small-cell lung cancer, Prognosis, PDGFRA mutation

P2.03 BIOLOGY  TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.03-12 EGFR AND ERBB2 GERMLINE MUTATIONS IN CHINESE LUNG CANCER PATIENTS AND THEIR ROLES IN GENETIC SUSCEPTIBILITY TO CANCER
S. Lu1, Y. Yu1, Z. Li1, Y.W. Shao2, X. Wu2, Y. Ding2, H. Bao3, H. Jian3
1Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/CN, 2Translational Medicine Research Institute, Geneseeq Technology Inc., Toronto/CA, 3National Clinical Department, Nanjing Geneseeq Technology Inc., Nanjing/CN

Background: Inherited genetic determinants of lung cancer risk remains relatively elusive. Rare germline mutations in EGFR and ERBB2 have previously been reported in lung cancer patients, which may be associated with the genetic susceptibility to lung cancer. Method: We retrospectively analyzed the next-generation sequencing (NGS) results targeting 416 cancer-relevant genes, including the whole exons of EGFR and ERBB2, in a cohort of 9091 Chinese lung cancer patients. Result: Of the 9091 Chinese lung cancer patients, nine germline mutations from 12 patients were identified within or adjacent to the kinase domain of EGFR: K757R (two patients), D1014N (two patients), I646S, G724S, V786M, T790M, L792F, R831H, and L844V, and one germline mutation was identified adjacent to the kinase domain of ERBB2: V1128I. The incidence of EGFR and ERBB2 germline mutation is much lower compared with the reported frequency in the Caucasian patients. Somatic mutations detected in the 12 patients carrying rare EGFR/ERBB2 germline mutations were most commonly EGFR exon19 deletion, L858R, and G719S mutations, and rare EGFR: S768I, T790M and a novel D770delinsDNPH indel mutation. The prevalence of the patients carrying only EGFR L844V germline mutation suggests that this germline mutation might be sensitive to TKI treatment. Conclusion: Here we indentified eight novel EGFR germline mutations and the ERBB2: V1128I germline mutation were linked to the genetic susceptibility of lung cancer in Chinese population.

Keywords: germline mutation, EGFR, ERBB2

P2.03 BIOLOGY  TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.03-13 SWATH MS ANALYSIS OF SERINE HYDROLYSIS ACTIVITY IN HUMAN LUNG ADENOCARCINOMA FOR BIOMARKER DISCOVERY
1Institute of Molecular Systems Biology, ETH Zurich, Zurich/CH, 2Thoracic Surgery, University Hospital Zurich, Zurich/CH, 3Thoracic Surgery, University Hospital Zurich, Zurich/CH

Background: Serine hydrolases (SHs), one of the largest enzyme families, have previously been shown to be implicated in the development of lung cancers. Activity-based protein profiling (ABPP) is a proteomic method that uses active site–directed chemical probes to selectively target the active form of the subsets of the enzymes in question, and then by a combination of a streptavidin-biotin enrichment step and mass spectrometry quantifies the catalytically active amount of the enzyme molecule. In this project, we monitored both forms of serine hydrolase, the “catalytically active” and “inactive”, in a distinct patient cohort of lung adenocarcinoma biopsies. For this purpose, we combined the activity-based proteomics for serine hydrolase and SWATH mass spectrometry (MS), which ensures highly reproducible protein quantification in a large panel of clinical samples. Method: Twenty four lung biopsies of long- and short surviving patients with stage IIIA adenocarcinomas and their normal tissue counterparts were available as OCT–embedded tissue. The common OCT sample clean-up by organic solvents is not compatible with our ABPP protocol since organic solvents can inactivate the molecular structure of the enzymes. The additional challenge of the ABPP protocol includes a streptavidin-biotin enrichment step of the active enzymes, which also leads to sample contamination by streptavidin peptides, and negatively influences MS spectra analysis and, consequently, biomarker discovery. Therefore, we proceeded with optimizations of sample preparation in ABPP experiments and developed an OCT clean-up protocol compatible with “enzyme-substrate binding” of activity-based chemical probes and the targeted portion of the active enzyme. To prevent digestion on streptavidin beads and MS spectra contamination, we used the reproducible and accurate SWATH MS to indirectly measure the active enzyme form in the biopsy-extract solution. Result: We identified over 4000 lung tissue proteins from a few milligrams of OCT-extracted biopsies, and confirmed good data quality for further SH enzyme quantification. In addition to the analysis of total proteome, 278 distinct proteins were identified on the parallel streptavidin bead samples, with chemical probes being used to deplete the active enzyme from the bioprobe extract. Each SWATH experiment reported the percentage of “active” enzyme form through the indirectly measured ratio between the “inactive Shs” (sample depleted for active SHs) and the “total” SHs (non-depleted sample). We detected around 80 enzymes with the “active” form comparably measured in three independent experiments, which amount generally accounted for between 5%–55% of the total enzyme concentration. Conclusion: Combination of ABPP and SWATH MS enables highly reproducible protein quantification in biomarker discovery.

Keywords: biomarker discovery, activity based protein profiling, mass spectrometry

P2.03-14 PKC\-PAK1 PATHWAY MODULATES SENSITIVITY TO THERAPY IN EGFR, KRAS MUTANT AND SQUAMOUS CELL NON-SMALL CELL LUNG CANCER (NSCLC)
M. Ito1, C. Codony-Servat2, J. Codony-Servat2, I. Attili2, J. Berenguer2, J. Bracht2, N. Giff3, M. Okada4, N. Karachaliou2, P. Cao2, R. Roselli2

Background: To understand intrinsic and acquired resistance to different MAPK signaling inhibitors, we explored PKC\-\-PAK1 signaling in EGFR, KRAS and Squamous cell carcinoma (SCC) cell lines. Method: Three lung cancer cell lines were used: HCC827 and H23 lung adenocarcinoma cells that carry EGFR and KRAS mutations, respectively, and H520 PAK1 amplified squamous NSCLC cells. Cell viability assays and western blotting were applied to evaluate the effect of auranofin (PKC\-inhibitor) plus IPA-3 (PAK1 inhibitor). Since IPA-3 is only for laboratory use, we also tested auranofin in combination with OTSSP167 (a MELK inhibitor in phase I trials), which, in our experience, inhibits pPAK1 (Thr423 and Thr428)
Thr212 in the HCCB27 cell line. Result: Auranofin plus IPA-3 was highly synergistic (CI less than 0.4) in EGFR mutant (HCCB27), KRAS mutant (H23), and SCC with PAK1 amplification (H2320 cells). Similar synergism was found with the combination of auranofin plus OTSSP167 on the 3 cell lines (Figure). The combination of auranofin with either IPA-3 or OTSSP167 ablated EGFR phosphorylation and downstream signaling pathways: ERK, AKT, STAT3, YAP1 and inhibited the expression of RTKs: AXL, MET and CDP1. We created EGFR mutant gefitinib and osimertinib resistant cell lines (PC9-GR3, GR4, OR2, OR4). Auranofin plus IPA-3 was highly synergistic in all cell lines. Conclusion: These observations suggest that the combination of auranofin with OTSSP167 can be used for treatment of different subclasses NSCLC with driver EGFR or KRAS mutations, as well as SCC with PAK1 amplification.

Keywords: Auranofin, IPA-3, OTSSP167

Background: The clinical efficacy of EGFR tyrosine kinase inhibitors (TKIs) in EGFR-mutant non-small cell lung cancer (NSCLC) is jeopardized by the activation of multiple signaling pathways. ILK regulates the expression of Bmi-1, a well-known epithelial mesenchymal transition-inducing transcription factor. SHP2 function is required for MAPK pathway activation, and also plays a role in receptor tyrosine kinase signaling. Method: Clinical data were assessed in accordance with the institutional review board. Next-generation sequencing revealed significant changes in the expression of stem cell markers, CD44, CD87 and H460, tumor formation after TGF-β treatment. Results: TGF-β induced EMT was associated with acquisition of stem-like characteristics. These results suggest that TGF-β induces stem cell characteristics which are related with CD44, CD87 and CD90 reactivation by promoter demethylation. Conclusion: TGF-β, stemness characteristics, epigenetic regulation

Keywords: TGF-β, stemness characteristics, epigenetic regulation

P2.03-16 TGF-β INDUCED EMT AND STEMNESS CHARACTERISTICS ARE ASSOCIATED WITH EPIGENETIC REGULATION IN LUNG CANCER
S. J. Kim1, N. Kang1, B. N. Kim1, C. K. Park2, Y. K. Kim3
1Department of Internal Medicine, The Catholic University of Korea, Seoul/KR

Background: Transforming growth factor-β (TGF-β) promotes tumor invasion and metastasis by inducing an epithelial-mesenchymal transition (EMT). EMT is often associated with acquisition of stem-like characteristics. In this study, we investigated whether EMT and stem-like characteristics induced by TGF-β could be associated with epigenetic regulation in lung cancer. Method: Human normal epithelial (BEAS-2B) and cancer (A549, H232, H266 and H460) cell lines were incubated with 10 ng/ml of TGF-β for 3 days. Transcriptome analysis of BEAS-2B and A549 cells treated with TGF-β were performed by using next-generation sequencing (HiSeq 2500 system). Western blotting was performed to analyze the expression of epithelial marker (E-cadherin) and mesenchymal markers (N-cadherin, fibronectin, vimentin and α-SMA). Wound healing assay, Matrigel invasion assay, sphere formation assay and in vivo mouse tumor model were used to assess functional characteristics of EMT and stemness acquisition. TGF-β-induced nuclear demethylation was identified by methylation-specific PCR and bisulphite sequencing. Result: Next-generation sequencing revealed significant changes in the expression of stem cell markers, CD44, CD87 and CD90 in both BEAS-2B and A549 cells. Functional analysis revealed increased wound healing, Matrigel invasion, sphere formation and in vivo mouse tumor formation after TGF-β treatment. TGF-β-induced EMT was associated with acquisition of stem-like characteristics. CD44, CD87 and CD90 were activated by both TGF-β and treatment with AZA. MSP showed decreased CD44, CD87 and CD90 promoter methylation after TGF-β treatment. Conclusion: These results suggest that TGF-β induces stem cell characteristics which are related with CD44, CD87 and CD90 reactivation by promoter demethylation.

Keywords: TGF-β, stemness characteristics, epigenetic regulation

P2.03-17 EGFR T790M MUTATION MAY NOT BE GENERATED THROUGH SELECTION BY EGFR-TKI FROM RANDOMLY OCCURRING MUTATIONS IN VITRO USING ENU
Y. Kobayashi1, T. Mitsudomi1
1Thoracic Surgery, Kindai University Faculty of Medicine, Osaka-Sayama/JP

Background: It is postulated that T790M resistant mutation is a result of selection by EGFR-TKI from clones that have randomly generated mutations. If so, it would be possible to detect the process of convergence from random mutations to T790M, depending on exposure time for EGFR-TKI. Method: After exposure of Ba/F3 cells expressing EGFR Del19 to ENU (N-ethyl-N-nitrosourea) for 24 hours, they were cultured with various concentrations of 3 EGFR-TKIs at trough concentrations. Result: Percentages of viable cells exposed to TKI were approximately 80%, 50%, < 20%, and < 3% at 1, 6, 12, 48 hours, respectively. These ratios were almost similar among 3 TKIs. Of 50 clones that had survived TKI treatment, T790M was detected in 12 (24%) (Fig.). Notably, two were detected in cells exposed to erlotinib or afatinib only for one hour (Fig.). In addition, we found 2 G873E (c.2876G>A) mutations, known to be oncogenic, with the same low SHP2 mRNA, respectively (P<0.001), (HR; 2.9; 95% CI, 1.4-5.9; P=0.002). Median overall survival (OS) was 17.9 (95% CI, 13.2-33) and 36.7 months (95% CI, 18.6-44.2) for pts with high and low ILK mRNA, respectively (P=0.200), (HR, 1.5; 95% CI, 0.79-3; P=0.200). Median OS was 18.5 (95% CI, 14-33) and 36.7 months (95% CI, 16.7-47.1) for pts with high and low SHP2 mRNA, respectively (P=0.018). The levels of ILK, SHP2 and Bmi-1 could be predictive for upfront combinatorial therapy of EGFR Tki plus a MAPK pathway inhibitor (SHP2 or MEK inhibitors).

P2.03-18 X-INACTIVATION SPECIFIC TRANSCRIPT (XIST)-MEDIATED MI RNA SEQUESTRATION IN NSCLC
E. Marshall1, G. Stewart1, A. Sage1, W. Lam1, C. Brown1
1Integrative Oncology, BC Cancer Research Centre, Vancouver/BC/CA, 2Department of Medical Genetics, University of British Columbia, Vancouver/CA

Background: Long non-coding RNA (IncRNA; >200nt) transcripts have been recently recognized as crucial regulators of gene expression. XIST is a prototypical IncRNA involved in cis-silencing of an X chromosome in females; however, there are conflicting reports of IncRNA-mediated regulation in cancer biology and therapeutics through “sponging” of single miRNAs that cause upregulation of canonical miRNA-target genes. XIST-associated sex-specific differences afford the opportunity to study IncRNA sponging systems within a cancer type. Existing studies considering one miRNA in singular cancer types do not account for important biological considerations, including sex and localization of miRNA and XIST transcripts. Here, we detail an in-depth and unbiased pipeline for the discovery of candidate miRNA and gene targets in IncRNA sponging, and validate the miRNA that may be mediating these interactions in XIST.

Method: We performed a comprehensive analysis of the role of XIST in the positive regulation of protein-coding genes using male and female lung adenocarcinoma (LUAD) samples as a model. To find genes regulated by XIST-mediated miRNA sponging, we correlated all Ensembl-annotated genes with XIST expression in female LUAD (n=307; rho>0.4, p<0.05). Using a specialized algorithm based on binding energies and sequence homology, we assessed the potential binding of all miRNAs against target genes and XIST. We then determine the best candidates for sponging by XIST using XIST-high (female and male) and XIST-low (male) systems, and validate the presence of these candidate miRNA and genes in the XIST sponging and, validate the miRNA that may be mediating these interactions in XIST.

Result: Our analysis yielded 5-43 genes that may be defined from miRNAs against target genes and XIST. We then determine the best candidates for sponging by XIST using XIST-high (female and male) and XIST-low (male) systems, and validate the presence of these candidate miRNA and genes in the XIST sponging and, validate the miRNA that may be mediating these interactions in XIST.

Conclusion: A massive number of IncRNA sponging studies exist, but most only consider one miRNA in a singular type of cancer, are biased in their selection of this target, and limited in biological context. By analyzing the transcriptome of female and male LUAD, we show that the XIST-miRNA-DMX sponging axis is affected by the expression of sex-specific genes and number of shared miRNA binding sites on DMX genes. Importantly, we identify that the miRNAs that mediate the XIST-DMX gene axis are enriched in the nucleus, co-localizing with XIST. In summary, our analysis provides both a comprehensive methodology for studying cancer-related miRNA sponging IncRNAs, and suggests the relevance of XIST in lung cancer.

P2.03-19 RET-MEDIATED ACTIVATION OF EZRIN IS ASSOCIATED WITH CELL MOTILITY AND SURVIVAL IN A SUBSET OF LUNG ADENOCARCINOMAS
S. Moodley1, M. Cruip1, J. Zhao1, B. Hyndman1, T. Gujral1, L. Mulligan1
1Cancer Biology & Genetics, Queen’s University, Kingston/CA, 2The Ottawa Hospital, Ottawa/CA, 3Fred Hutchinson Cancer Research Centre, Seattle/WA/US

Background: Lung cancer is the leading cause of cancer mortality worldwide with 40% of cases diagnosed as lung adenocarcinoma (LADC). Increased expression of RET has been reported in 10-20% of LADCs and is associated with metastasis and reduced survival. Alternative gene splicing of RET generates two co-expressed isoforms; RET9 and RET51, with unique C-terminal tails. The tails confer distinct protein binding opportunities with signaling proteins, known as scaffolds, to promote different signaling events and cell processes. RET9 interacts with the SHANK family scaffolds at a PDZ-binding motif and Enigma at tyrosine (Y) 1062, whereas, RET51 interacts with Grb2 at the unique Y1096. RET9 and RET51 are associated with distinct functions in thyroid cancer, where RET51 plays a predominant role in cancer metastasis. Ezrin is a scaffold protein and tyrosine kinase substrate that bridges the plasma membrane to the actin cytoskeleton to promote adhesion, organization and migration. Overexpression of ezrin is associated with invasion and metastasis of osteosarcoma and pancreatic cancer cells. The roles of RET isoform-scaffold interactions in the progression of LADC has never been investigated.

Method: HEK 293 cells were co-transfected with the respective isoform or mutant constructs and Ezrin and/or Grb2 dominant negative (DN) constructs. AS49 LADC cells were transfected with RET51 construct. SH-SYSY neuroblatoma and HCC1833 LADC cells endogenously express Ezrin and RET. Cells were treated with RET/ Ezrin inhibitors and/or stimulated with glial-derived neurotrophic factor (GDNF) then fixed or harvested. Co-immunoprecipitation (Co-IP) or pull-down assays coupled to western blotting were used to investigate binding domains required for RET interaction with and activation of Ezrin or downstream effectors. Immunofluorescence confocal imaging was used to determine co-localization of RET and Ezrin and changes to cell morphology. GDNF-impregnated agarose bead live-cell fluorescence assays were used to measure cell growth, survival, spread and motility. SynTarget (cancer gene expression analysis tool) was used to assess co-expression of RET and Ezrin with respect to clinicopathological parameters and survival outcomes in LADC.

Result: Ezrin binds kinase active RET51 with Grb2. GDNF-stimulation promotes the formation of cytoskeletal outgrowths with increased co-localization of Ezrin and RET. GDNF-activation of RET results in scaffold-mediated activation of Rho-family GTPases to promote cell motility. Like RET, overexpression of Ezrin is associated with poor overall survival in LADC patients and overexpression of both RET and Ezrin has a negative synergistic effect on overall survival in a subset of LADC patients.

Conclusion: RET interaction with Ezrin identifies a distinct functional role of RET as an oncogenic driver in lung adenocarcinoma.

P2.03-20 FACTOR XIIIA-EXpressING INFLAMMATORY MONOCYTES PROMOTE LUNG SQUAMOUS CANCER THROUGH FIBRIN CROSS-LINKING
C. Pecot
Eli Lilly and Company, Indianapolis/IN/US

Background: Lung cancer is the leading cause of cancer-related deaths worldwide, and lung squamous carcinomas (LUSC) represent about 30% of cases. Molecular aberrations in lung adenocarcinomas have been investigated for effective targeted treatments, but corresponding therapeutic advances in LUSC have not materialized. However, immune checkpoint inhibitors in sub-populations of LUSC patients have led to exciting responses.

Method: See results: Using computational analysis of The Cancer Genome Atlas (TCGA) dataset, we identified a subset of LUSC tumors characterized by dense infiltration of inflammatory monocytes (IMs) and poor survival. Multiplex immunohistochemistry for CD14/CCR2/pan-cytokeratin revealed that dense clusters of CD14+/CCR2+ cells predominate in the stromal LUSC compartment and not cancer cell islets. Using immunogenomics, we found that amongst 9 immune subsets expressing CD14, IMs had the strongest relationship with CD14 expression and poor LUSC survival. With novel, immunocompetent metastasis models, we demonstrated that tumor cell derived CCL2-mediated recruitment of IMs is driven by TNFα-mediated activation of the NFkB pathway. Furthermore, tumor production of CCL2 inescapably and sufficient for LUSC metastasis.
Pharmacologic inhibition of IM recruitment with a potent CCR2 inhibitor (PF-04136309) had substantial anti-metastatic effects, which was not due to inhibition of tumor-associated macrophages (TAMs) but rather by blockade of IMs in the blood and tumor microenvironment. Notably, in contrast to TAMs, we show that IMs express high levels of Factor XIIIa (FXIIIa). We demonstrate that FXIIIa is packaged into podosome-like structures in IMs, and when in contact with fibrin the IMs are capable of rapidly creating fibrin cross-linkages. We show that FXIIIa-mediated IM fibrin cross-linking creates a scaffold for LUSC cell invasion, migration and metastases. Consist with this observation, we found clinical LUSC specimens containing extensive cross-linked fibrin in the microenvironment correlated with poor relapse-free survival. Conclusion: Given the rapidly evolving landscape of precision immune-oncology, these findings identify IMs as a novel context-specific vulnerability of LUSC and provide an important insight into the mechanisms through which this immune cell type determines a poor prognosis.

P2.03-21 MECHANISTIC INVESTIGATION OF DRD1 IN LUNG CANCER
L. Touabi, C. Grant, A. Zingone, K. Mitchell
Laboratory of Human Carcinogenesis, National Cancer Institute, Bethesda/MD/US

Background: The D1 dopamine receptor (DRD1) is a G protein-coupled receptor (GPCR) for the catecholamine dopamine (DA). Historically, DA was thought to function mainly within the central nervous system (CNS), and there have been no prior reports linking the DA pathway (DAP) to lung cancer biology. Our group previously discovered an epidemiological association between a DRD1 gene polymorphism and risk of developing lung cancer. Since this association was observed in never smokers, it suggested that DRD1 may play a direct role in the pathogenesis of lung cancer. We have been investigating this novel function of DRD1. Method: We performed the DAP has never been fully characterized in lung. We therefore examined the presence of DAP-related proteins, including dopamine receptors, metabolizing and synthesizing enzymes, and dopamine transporter in normal human lung tissue. To understand the mechanistic role of DRD1 in lung cancer, we generated stable lung cancer cell lines in which DRD1 was overexpressed or knocked down and performed role of DRD1 in lung cancer, we generated stable lung cancer cell lines. We have been investigating this novel function of DRD1. Result: We found that dopamine-related proteins are expressed throughout the respiratory tract in normal human tissue. Further, we observed that DRD1 expression was significantly downregulated in lung cancer using samples from the on NCI-MD case control study and replicated this with TCGA. Methylation analyses in NCI-MD and TCGA showed that DRD1 is hyper-methylated in lung cancer and that there is a negative correlation between DRD1 mRNA and methylation. DRD1 methylation and methylation are associated with patient outcome. Modulation of DRD1 in multiple cell line model systems affects cell proliferation. Transcriptome and kinome profiling revealed that this modulation is mediated through EGFR and downstream MAPK and AKT signaling. Immunofluorescent staining shows that EGFR and DRD1 colocalize at the cell membrane. Ongoing work is aimed at establishing the exact nature of the DRD1/EGFR interaction. Conclusion: Collectively, this work suggests that DRD1 acts like a tumor suppressor in lung cancer, that inherited susceptibility in the DRD1 gene contributes to lung cancer and agents that modulate the bioavailability of dopamine could modulate patient survival. Understanding the possible crosstalk between DRD1, EGFR and MAPK signaling may be very valuable for lung cancer therapeutic strategy. The majority of patients receiving EGFR inhibitors eventually develop resistance. Using DRD1 agonists as combinatorial agents may help bypassing anti-EGFR resistance.

Keywords: Lung cancer, Dopamine receptor, EGFR-MAPK

P2.03-22 OCT4&SOX2 SPECIFIC CTLS PLUS PD-1 INHIBITOR HAD SYNERGISTIC EFFECT ON KILLING CSC AND TREATING DRUG-RESISTANT LUNG CANCER MICE
X. Zhang, F. Hu, X. Zheng, B. Zhang, H. Wang, G. Tao, J. Xu, Y. Zhang, B. Han
Department of Pulmonary, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai/China

Background: This study aimed to investigate the synergistic effect of OCT4&SOX2 specific cytotoxic T lymphocytes (CTLs) and PD-1 inhibitor on killing lung cancer stem-like cells (LCSCs) and their efficacy in treating drug-resistant lung cancer (DRLC) mice. Method: OCT4&SOX2 specific CTLs and PD-1 inhibitor with differed doses were applied to treat PC9 cells and PC9 LCSCs. CCK8 assay and flow cytometry (FCM) assay with CFSE staining target cells before treatment and PE staining died cells after treatment were conducted to detect the cytotoxic activity. DRLC mice were constructed by injection of PC9 LCSCs suspension and Matrigel into left lung of SD mice. DRLC mice was randomly divided into 5 group: Control group, CMV pp65 CTLs group, OCT4&SOX2 CTLs group, PD-1 inhibitor group and OCT4&SOX2 CTLs+PD-1 inhibitor group. Result: In vitro, both CCK8 assay and FCM assay disclosed that OCT4&SOX2 specific CTLs plus PD-1 inhibitor presented with elevated cytotoxic activity on PC9 cells and PC9 LCSCs. In vivo, tumor volume and tumor weight were decreased, while tumor necrosis and tumor apoptosis were increased in OCT4&SOX2 CTLs group than CMV pp65 CTLs group and control group, and in OCT4&SOX2 CTLs+PD-1 inhibitor group than OCT4&SOX2 CTLs group and PD-1 inhibitor group. In addition, CD8 expression was increased while OCT4 and SOX2 expressions were decreased in OCT4&SOX2 CTLs+PD-1 inhibitor group than OCT4&SOX2 CTLs group and PD-1 inhibitor group. Conclusion: In conclusion, OCT4&SOX2 specific CTLs and PD-1 inhibitor presented with synergistic effect on killing LCSCs in vitro and treating DRLC mice in vivo.

P2.03-24 CD90 ENHANCES METASTASIS BY EPITHELIAL-MESENCHYMAL TRANSDIFFERENTIATION IN LUNG ADENOCARCINOMA

L. Pan¹, X. Zhou²

¹Department of Respiration, Southwest Hospital of Third Military Medical University, Chongqing/CN, ²Department of Respiratory Medicine, The First Affiliated Hospital of Third Military Medical University, Chongqing/CN

**Background:** The specific mechanism of lung cancer remains unclear. The existence of cancer stem cells (CSCs) reflects the cellular heterogeneity within tumors, and we presume that CD90⁺ lung adenocarcinoma (LA) cells play the role of CSCs. The epithelial-to-mesenchymal transition (EMT) is a de-differentiation process that has been implicated in metastasis and generation. In this study, CD90⁺ CSC were isolated and characterized from LA cell line A549, and we discovered that the specific subtype displayed CSCs and epithelial-mesenchymal transition phenotypes.

**Method:** Section not applicable

**Result:**
1. CD90⁺ CSC was isolated and characterized from LA cell line A549. 1) FACS assay was utilized to isolated CD90⁺ cells from LA cell line A549. We found that adherent A549 cells possess much lower proportion of CD90 than A549 sphere cells, indicating that CD90 may be the potential CSCs marker.
2. CD90⁺ cells expressed higher stemness genes Oct4 and Nanog via immunofluorescence assay. Also the clonal formation and sphere formation assay by CD90⁺ and CD90⁻ cells was performed, and the former highly expressed cell proliferation capability.
3. The tumorigenicity assay in nude mice showed CD90⁺ cells highly expressed tumorigenicity in vivo, which possessed shorter latency stage and formed larger xenograft nodes. CD90⁺ cells possessed highly metastasis and invasiveness associated with epithelial mesenchymal transition. 1. Migrative and invasive ability of CD90⁺ cells was measured by migration and Transwell invasion assay, and we found that CD90⁺ cells with higher migrative and invasive ability in vitro compared with CD90⁻ cells. 2. To further confirm upper observation, an experimental tail vein metastasis model was performed in vivo, and CD90⁺ cells displayed a superior ability to metastasize to the lung. 3. RT-PCR measurement of gene expression related with EMT showed same tendency compared with Western blot analysis and immunofluorescence assay. MMP2 was higher expression in CD90⁺ cells, also transcription factors Twist increased significantly, in which would be involved in the EMT phenotype maintaining. CD90⁺ expression has important clinical significance for patients with LA. Conclusion: CD90 is an effective marker for isolation and enrichment of LCSCs. CD90⁺ cells highly expressed stem cell related genes, self-renewal capability in vitro, showed stronger tumorigenicity in vivo. Furthermore, CD90⁺ cells possessed higher metastasis and invasiveness, which is associated with EMT. CD90⁺ cells are endowed with EMT phenotype and show an increased expression of E-cadherin, and increased expression of N-cadherin, vimentin, MMP2, which would be associated with Twist. Expression of CD90 is negatively correlated with survival time in the metastatic sites instead of primary sites.

**Keywords:** CD90, lung cancer, epithelial-mesenchymal transition

P2.03-25 LOSS OF EXPRESSION RATHER THAN CYTOPLASMIC MISLOCALIZATION OF RUNX3 PREDICTS WORSE OUTCOME IN NON-SMALL CELL LUNG CANCER

X. Chen¹, Y. Deng², Y. Shi², W. Zhu³, K. Zhu⁴, X. Zheng⁴, G. Lin⁴

¹Thoracic Surgery, Fujian Cancer Hospital & Fujian Medical University Cancer Hospital, Fuzhou/CN, ²Chemotherapy, First Affiliated Hospital of Fujian Medical University, Fuzhou/CN, ³Pathology, Fujian Cancer Hospital & Fujian Medical University Cancer Hospital, Fuzhou/CN, ⁴Medical Oncology, Fujian Cancer Hospital, Fujian Medical University Cancer Hospital, Fuzhou/CN

**Background:** Functional inactivation of RUNX3 through epigenetic silencing was well-documented in many cancers. Added to gene mutation and promoter hypermethylation, cytoplasmic mislocalization was another major manifestation of RUNX3 dysfunction in malignancies like gastric cancer. We aimed to investigate whether NSCLC patients with different RUNX3 expression patterns would have different OS, and the associations of different patterns with clinicopathologic parameters and clinical outcome.

**Method:** Expressions of RUNX3 and Ki-67 were immunohistochemically detected in normal lung tissue (n=51) and surgically resected NSCLC patients (n=188). The optimal cutoff of RUNX3 was determined by X-tile software related to their survival. Apoptotic index in cancerous tissue was evaluated by TdT mediated dUTP-biotin nick end labelling (TUNEL) method. The prognostic significance of different expression patterns of RUNX3 was determined by means of Kaplan-Meier survival estimates and log-rank tests.

**Result:** Loss of RUNX3 expression in NSCLC was correlated with low cancerous apoptotic index (P=0.002), shorter OS and worse prognosis (P=0.0142), while no statistical difference of apoptotic index (P=0.73) or survival (P=0.3781) had been determined between patient subgroups with different localization of RUNX3 expression.

**Conclusion:**

The expression and localization of RUNX3 play an important role in the prognosis of NSCLC patients. Large scale studies are needed to confirm these results.

P2.03-26 A PROSPECTIVE COHORT STUDY OF TMB AND DETERMINANTS OF CTDNA DETECTION BY COMPREHENSIVE GENOMIC PROFILING IN STAGE I LUNG ADENOCARCINOMAS

K. Chen1, H. Zhao1, J. Bai2, F. Yang1, L. Chang2, Y. Guan2, X. Yi1, L. Feng3, S. Cheng1, J. Wang1
1Thoracic Surgery, Peking University People’s Hospital, Beijing/CN, 2Geneplus-Beijing Institute, Beijing/CN, 3National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Background: Plasma tumor mutational burden (TMB) is a predictor of immune checkpoint inhibitors treatment in advanced lung cancer patients. A preliminary study has shown the feasibility of PD-1 treatment in resectable lung cancer. However, few studies investigated TMB and plasma circulating tumor DNA detection in stage I lung adenocarcinomas.

Method: We prospectively enrolled 67 consecutive patients with pulmonary nodule who intended to undergo curative lung resection (NCT03320044). Comprehensive genomic profiling were used to identify somatic variants in both tissue and matched blood samples. Tissue clonal mutations were defined if mutations were in the cluster with the highest mean varied allele frequency with PyClone.

Result: Mean effective depth of coverage of 1045x and 27410x were obtained in tissue and plasma samples, respectively. Resected stage I lung adenocarcinoma patients were included (4 IA1, 20 IA2, 9 IA3, 12 IB)(Fig.1). An increasing tissue TMB was detected in Stage IA1, Stage IA2, Stage IA3 (1.5mut/Mb, 3mut/Mb, 4mut/Mb, p<0.05). Mixed invasive subtype appeared the highest TMB, followed by invasive adenocarcinoma and minimally invasive adenocarcinoma (4mut/Mb, 3mut/Mb, 1mut/Mb, p<0.05). A significant rise of TMB was identified in pure ground-glass nodule, subsolid nodule and solid nodule (1.5mut/Mb, 2 mut/Mb, 4 mut/Mb, p<0.05). 30.3 % (10/33) patients were demonstrated to be ctDNA-positive with a mean ctDNA abundance of 0.0415% (ranged from 0.012 to 0.119%). A series of factors such as gender, pleural invasion and solid tumor size affected ctDNA detection. 50% patients detected clonal alterations in plasma. Unlike tissue, blood TMB showed no relation with clinical-pathological characteristics.

Conclusion: Loss of expression rather than cytoplasmic mislocalization of RUNX3 predicted worse outcome in NSCLC, which was quite different from what it manifested in other cancer types.
**Conclusion:** We evaluated the feasibility of TMB and determinants of ctDNA detection in stage I lung adenocarcinomas. TMB was related to the invasiveness of tumor, while no such correlation were found in ctDNA. Improving the sensitivity of ctDNA detection, such as incorporated methylation detection or cancer-related antibodies detection, may be necessary in early stage patients.

**Background:** Cellular folate status influences the DNA stability and integrity, and many epidemiologic, animal and human studies suggest that folate status modulates carcinogenesis. This study was conducted to investigate the association between single nucleotide polymorphisms (SNPs) in genes involved in folate metabolism and survival outcomes of surgically resected non-small cell lung cancer (NSCLC).

**Method:** We genotyped 182 potentially functional SNPs in folate metabolism pathway in a discovery study involving 354 NSCLC patients who underwent curative surgery. A replication study was performed in an independent cohort of 428 patients. Result: In the discovery set, 38 SNPs were significantly associated with survival outcomes in multivariate analyses. Among these, two SNPs (ALPL rs2242421G>A, MTHFD1L rs9397033A>T) were replicated in the replication set. In combined analysis, ALPL rs2242421G>A was significantly associated with better overall survival under a codominant model (adjusted hazard ratio [aHR] = 0.72, 95% confidence interval [CI] = 0.59–0.88, P = 0.002). MTHFD1L rs9397033A>T was significantly associated with worse disease-free survival under a recessive model (aHR = 1.45, 95% CI = 1.13–1.87, P = 0.004). In a luciferase assay, the rs2242421A allele showed significantly higher luciferase activity than the rs2242421G allele (P = 0.02) in H1299 cell lines. Consistently, the level of ALPL mRNA expression in tumor tissues increased as the number of A allele increased (P trend = 0.05).

**Conclusion:** Our results suggest that the 2 SNPs, especially ALPL rs2242421G>A could be used as a biomarker for predicting the clinical outcomes of patients with early stage NSCLC.

**Keywords:** non-small cell lung cancer, polymorphisms, folate

Background: During their life, women treated for breast cancer (BC) are at risk to develop lung cancer (LC): this risk is increased in smokers and if adjuvant radiation (aRT) was administered for BC. The relative risk of LC after treated BC ranges from 1.38 to 5.05. We hypothesized that genetic variants might predispose patients (Pts) to develop LC after BC. Our aim was to perform whole exome sequencing (WES) to identify genes associated with such predisposition. Method: 28 women who developed LC after BC (Study Population, SP) and 32 women treated for BC and with no secondary cancer after a follow-up >10 years (control population; CP) were enrolled. DNA was extracted from tumors and normal tissue samples from both SP and CP. Libraries were prepared with Agilent SureSelect All Exon kit and sequenced on Illumina HiSeq2500. Variant calling was performed with FreeBayes software. Result: The median age of SP at BC diagnosis was 63.5 years (range: 47-76); the median interval between diagnosis of BC and occurrence of LC was 4.5 years (range: 0-11). 13 Pts (46%) were never-smokers and, among the 21 Pts who had received aRT, 13 (62%) developed ipsilateral LC. At somatic analysis, no common mutation among known driver genes was shared between each BC and LC pair. WES performed on BC and LC samples identified two mutational signatures (S1 and S2). S1 (C->T substitutions) was observed in all BC samples and 16/28 (57%) LC samples and was more frequent in never-smokers (11 vs. 5 Pts) and among Pts who developed ipsilateral LC after aRT (10 vs. 6 Pts). S2 (C->A transversions) was observed in 12/28 LC samples (43%) and was strongly associated with smoking habit (10 vs. 2 Pts). When compared to COSMIC libraries, S2 resulted similar to COSMIC 4, common in LC samples collected from smokers. Since S1 was largely shared between paired BC and LC samples, we explored the eventuality of a genetic predisposition to S1-related malignancies with a gene-based burden test over rare germline variants in normal tissue of the LC samples (n=12). The identification of potential candidates was performed with a burden test (BET) (FDR<0.05). Conclusion: Our data identify two mutational S underlying the LC development. Germline analysis suggests that genetic variants may contribute to increase the risk of LC after BC.

P2.03-30 PROTEINS INVOLVED IN NECROPTOSIS AND DNA DAMAGE RESPONSE AND SURVIVAL OF STAGE I NON-SMALL-CELL LUNG CANCER PATIENTS

J. Ryu1, M. Jo2, J. Nam2, J.H. Lim3, H. Nam3, H.J. Kim4
1Inha University Hospital, Incheon/KR, 2Inha University, Incheon/KR, 3Institute of Medicine, Inha University Hospital, Incheon/KR

Background: Survival of patients with stage I non-small-cell lung cancer (NSCLC) was indicative of significant variability with biological complexity. In addition to repairing DNA damage, understanding for necroptosis as new mechanism of cell death is rapidly growing as one of the hallmarks of cancer. Therefore, the development of a diagnostic biomarker focusing on necroptosis and DNA damage is an intriguing issue. Method: Expression of eight proteins (RIPK3, MLKL, PELI1, P53, ATM, gH2AX, Chk2, and BRCA1) was performed in squamous cell carcinoma patients (aHR, Cox P: 2.92, 0.008 for RIPK3; 2.007, 0.033 for PELI1; 0.391, 0.003 for P53; 2.088, 0.018 for BRCA1). When combined effect of RIPK3 or PELI1 with P53 or DNA damage repair proteins analyzed, the effect on survival was markedly strengthened in squamous cell carcinoma patients. However, these effects were not detected in adenocarcinoma patients. Conclusion: Expression or their combination of proteins involved in necroptosis and DNA damage repair exhibited differential expression between squamous cell carcinoma and other histology. Low expression of RIPK3 showed a trend for having worse survival in the entire cohort. Analysis performed based on histology revealed that expression of RIPK3, PELI1, P53, or BRCA1 was an independent prognostic factor in squamous cell carcinoma patients (aHR, Cox P: 2.92, 0.008 for RIPK3; 2.007, 0.033 for PELI1; 0.391, 0.003 for P53; 2.088, 0.018 for BRCA1).

Background: To analyze the co-expression network of long non-coding RNA (lncRNA-BMB-AS1 in lung adenocarcinoma (LUAD) and to investigate its impact on prognosis by mining the molecular mechanisms and prognostic signature in silicon. Method: We performed a co-expression analysis of RMB-AS1 by integrating sixty thousand public Affymetrix microarrays data to reveal its associated signal pathways. QPCR and Western blot were performed to validate the significant genes. Furthermore, survival analysis of data in the Cancer Genome Atlas (TCGA) was applied to seek the prognostic value of RMB-AS1 and its co-expressed genes. Result: The most enriched signal pathways of RMB-AS1 co-expressed genes there was a significant correlation between pFyn expression and gender, pathological stage, p53 mutation status, and poor OS. The propensity score adjusted analysis revealed that the prognosis of pFyn positive group was significantly worse compared to the pFyn negative group (p<0.046), which was observed only in the patients with mutant EGFR.

P2.03-29 PROGNOSTIC SIGNIFICANCE OF PHOSPHORYLATED FYN IN PATIENTS WITH LUNG ADENOCARCINOMA

Thoracic Surgery, Graduate School of Medicine, Kyoto University, Kyoto/JP

Background: Src family tyrosine kinases, including Fyn, are non-receptor tyrosine kinases and they are known to drive malignancy in various kinds of cancers. Some papers have reported that Fyn is an effector of EGFR signaling. Additionally, Fyn is recognized as an additional therapeutic target. However, little is known about the clinical importance of phosphorylated Fyn (pFyn) in lung adenocarcinoma. The purpose of the present study is to clarify the prognostic significance of pFyn in lung adenocarcinoma. Method: A total of 251 lung adenocarcinoma specimens were collected from patients who underwent surgery in our institute. Tissue microarrays (TMA) were assembled from paraaffin-embedded tumor blocks. We analyzed pFyn expression through immunostaining of TMA and classified them as 0, +1, +2, +3. The association between pFyn expression as well as the patients’ clinical information was statistically analyzed. Correlations were compared using Pearson’s chi-square test and overall survival (OS) were compared using the log-rank test after propensity score matching (age, gender, smoking history, pathological stage, EGFR mutation status, and p53 mutation status). The Institutional Review Board approved this study and informed consent for tumor tissue usage was obtained pre-operatively. Result: Unadjusted pathologic stage distributions by TNM classification (WHO, 7th edition) were as follows: Stage 1A: 128 patients, Stage 1B: 73, Stage 1C: 23, Stage 2A: 2, Stage 2B: 4, Stage 3A: 23, pFyn was positive in 118 cases (47.6%).
were pathogenic Escherichia coli infection, gap junction and ubiquitin mediated proteolysis. Among the 30 validated genes, we found that a sixteen microtube-associated genes signature is an independent prognostic marker of OS of LUAD patients and demonstrates good performance for predicting 5-year OS.

Conclusion: Our results suggest that RGMB-AS1 may serve as a novel prognosis indicator and therapeutic target for LUAD patients.

Keywords: lung adenocarcinoma, microtube, RGMB-AS1

Figure 1: Identification of lung cancer survival associated m6A-modified RNA binding proteins. (A) Heatmap shows the differentially expressed m6A-modified RNA binding proteins. (B) IGF2BP1 expression is associated with poor survival of lung adenocarcinoma (P = 0.00058). (C) IGF2BP3 expression is associated with poor survival of lung adenocarcinoma (P = 0.005171). Conclusion: In this analysis, we revealed that IGF2BP1 and IGF2BP3 are potential m6A targets which may affect lung adenocarcinoma survival. Further biomolecular experiments are warranted.

**P2.03-33 ANTI-AGING GENE, KLOTHO IS A PREDICTIVE FACTOR OF PEMETREXED FOR LUNG CANCER TREATMENT**
K. Takeghara, J. Usuda
Thoracic Surgery, Nippon Medical School Hospital, Bunkyo-Ku/JP

**Background:** Adjunctive chemotherapy of lung cancer including cisplatin in patients with non-small cell lung cancer of p-stage IB-IIIA, who were surgical resection completely. In order to improve the prognosis of the patients with lung cancers, we need to find a new predictive factor for anti-cancer agents and establish a new adjutant chemotherapy. We reported that anti-aging gene Klotho expression was a prognostic factor for small cell lung cancer and LCNEC so far. In this study, we evaluated that the expression of the Klotho was a prognostic factor and predictive factor for lung cancer treatment. **Method:** We established a cell line, A549/Klotho, which stably overexpress Klotho. Next, we checked whether there is a relationship between the mutation related proteins such as N-cadherin, E-cadherin, Snail, Vimentin, etc., by Western blot analysis. Finally, we examined the sensitivity test for various anticancer agents including pemetrexed, CDDP, paclitaxel, gefitinib, etc., using A549 cells and A549/Klotho cells. **Result:** In Western blot analysis, no expression of N-cadherin was observed. This result indicated that overexpressing Klotho inhibit the expression of N-cadherin, and suggest that Klotho can regulate the EMT. Secondly, we performed sensitivity test by MTT assay. A549/Klotho cells were more sensitive seven times against pemetrexed compared to A549 cells (IC50; 0.1 micro M). There is no difference of sensitivity between A549/Klotho cells and A549 cells against molecular target drugs such as gefitinib. **Conclusion:** From these results, we conclude that overexpression of Klotho may regulate the sensitivity against pemetrexed and the inhibition of the invasion of N-cadherin. In the future, we may establish a new strategy of adjutant chemotherapy for lung cancer based on the expression of anti-aging gene Klotho.

**P2.03-34 THE RELATIONSHIP BETWEEN TREATMENT RESPONSE AND SERUM EGFR LEVEL IN NONSML CELL LUNG CANCER**
I. Tek1, H. Akbulut2, G. Utkan3, A. Demirkazik2, F. Cay Senleri1, F. Icli1
1Medical Oncology, Medicana International Ankara Hastanesi, Ankara/TR, 2Medical Oncology, Ankara University, Ankara/TR

**Background:** Early diagnosis and the improvement in the treatment options in cancer patients can prolong the survival in the majority of malignancies, although they add no benefit to the survival of patients with non-small cell lung cancer (NSCLC). Some patients with NSCLC respond to the treatment well while others do not. Therefore, new prognostic factors and biomarkers other than the stage of disease should be explored in NSCLC. The management of NSCLC may be different according to those biomarkers. The new biomarkers may help to the clinicians to identify who patients have poor prognosis and respond to the specific treatment. **Method:** The aim of this study is to investigate whether there is a relationship between the response to treatment and serum level of active EGFR or not. Thirty-three patients with locally advanced, metastatic or recurrent non-small cell lung cancer were enrolled into this study. Cisplatin docetaxel treatment was planned for those patients. Baseline and at the end of second and forth cycle of the treatment, serum EGFR were measured. Patients were divided into 2 groups according to their response to the treatment. **Result:** Of 33 patients, 4 were female and 29 were male. The average of age of patients was 52.12 patients were stage III, 21 were relapsed or stage IV. Objective response rate and overall survival patients were 15.6%, 34.4% respectively. Progression occurred 34.4% among patients in the study. When serum EGFR level cut off is 0.080 femto/ml, while in patients who didn’t respond, the positivity of serum EGFR level was 55.6%, it was 80% in patients who responded. Baseline serum EGFR levels were higher in patients with stage III disease compared to those of patients with relapsed and stage IV disease. In patients who responded to the therapy, baseline serum EGFR levels were found higher than those of the patients who didn’t respond. Following two cycles of treatment, if serum EGFR level is found high, then the probability to respond to the treatment increases significantly. **Conclusion:** In conclusion, the serum level of EGFR seems to be a useful biomarker for predicting and monitoring the response to the treatment in patients with NSCLC.

**Keywords:** Serum EGFR level, non-small cell lung cancer, Prognosis

**P2.03-35 NON-SMALL-CELL LUNG CANCER WITH SMO GENE VARIANTS OF UNCERTAIN SIGNIFICANCE SHARE DISTINCT MOLECULAR FEATURES**
W. Wang1, C. Xui2, Q. Zhang1, W. Zhung3, Y. Zhu2, Y. Chen4, G. Chen5, M. Fang1, T. Lv6, Y. Song6
1Zhejiang Cancer Hospital, Hangzhou/CN, 2Fujian Cancer Hospital, Fuzhou/CN, 3Pathology, Fujian Cancer Hospital, Fuzhou/CN, 4Medical Oncology, Fujian Cancer Hospital, Fuzhou/CN, 5Zhongda Hospital, Soochow /CN, 6Pathology, Fujian Cancer Hospital, Fuzhou/CN, 7Jinling Hospital, Nanjing/CN

**Background:** Recently, alterations of the Smothened (SMO) gene (mutation, amplification, mRNA overexpression) were found in 12.2% of tumors of The Cancer Genome Atlas (TCGA) lung adenocarcinomas by whole-exome sequencing. While the genetic locus of SMO mutation NSCLC patients is unclear. The aim of this study is to investigate mutations and prognosis of NSCLC harboring SMO mutations. **Method:** A total of 423 patients with non-small-cell lung cancer were recruited between July 2012 and December 2015. The status of SMO mutation and other genes were detected by next generation sequencing. **Result:** S0%-30% of patients yield no mutations (11/423) in non-small cell lung cancer, including T179M (4 patients), S566R (1 patient), P694fs*2 (1 patient), S590T (1 patient), P60L (1 patient), E211D plus G212C (1 patient) and M230I plus A289T (1 patient), and median overall survival (OS) for these patients was 24.0 months. Among them, all patients were SMO gene with co-occurring mutation. Briefly, patients with (n=6) or without (n=5) co-occurring EGRF mutations had a median OS of 19.0 months and 25.0 months respectively (P=0.23); patients with (n=2) or without (n=9) co-occurring TP53 mutations had a median OS of 19.0 months and 25.0 months respectively (P=0.36); patients with (n=3) or without (n=8) co-occurring KRAS mutations had a median OS of 23.0 months and 24.0 months respectively (P=0.75); patients with (n=4) or without (n=7) co-occurring BRCA2 mutations had a median OS of 16.0 months and 24.0 months respectively (P=0.01). **Conclusion:** SMO mutations may be a potential novel mechanism of acquired resistance in EGRF-mutated NSCLC patients. EGRF, TP53 and KRAS gene accompanied may have less correlation with SMO mutation in NSCLC patients. BRCA2 accompanied mutations might play a worse prognosis in SMO gene non-SMCL NSCLC. Screening of SMO alteration by the role of the Hh pathway suggests new opportunities to design new treatment strategies in NSCLC.

**P2.03-36 DNA METHYLATION: A MORE SENSITIVE MARKER FOR TREATMENT MONITORING?**
S. Xia1, S. Chua1, Y. Chen1, L. Huang2, W. Deng3, H.H. Zhang4, Y. Zhang1, F. Xu1, X. Ren1, T. Chen1
1Department of Oncology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/CN, 2Turning Rock Biotech, Guangzhou/CN

**Background:** Detection of genomic aberrations in cell-free DNA (cfDNA), requiring ultra-deep sequencing due to the low allelic frequencies (AF) of mutation, has been utilized to monitor treatment response. However, 20%-30% of patients yield no mutations (11/423) in non-small cell lung cancer despite deep sequencing depth, thus necessitating alternative monitoring method. The role of aberrant DNA methylation in the process of tumorigenesis both at individual genes and a genome-wide scale has been well elucidated. We investigated the potential of DNA methylation as a biomarker for treatment monitoring. **Method:** We investigated the performance of mutation and DNA methylation as biomarkers to evaluate response to osimertinib using a DNA methylation panel consisting of 168 lung cancer related genes with an average sequencing depth of 1,000x and 10,000x, respectively. Longitudinal plasma samples from 6 patients undergoing osimertinib were collected prior to treatment and at regular interval until disease progression, ranged from 6 to 9 times. We calculated the sensitivity and specificity of the panel of significantly methylated blocks, which were significantly hypermethylated blocks comparing to healthy individuals. **Result:** All patients had EGRF sensitizing mutation and T790M at baseline. Four patients had additional concurrent mutations, including TP53, RB1, DAXE1 and BRCA2. At PD,
all patients had detectable mutations except for one and 3 developed EGFR C797S. Four patients had at least two times of no detectable mutation during the treatment. Among them, PSOS and PDQ had 5 and 6 times of no detectable mutation, respectively. In contrast, all patients had significantly methylated blocks detected at every point. In general, the trend of changes in mutation AF corresponds to the changes in the percentage of significantly methylated blocks in all patients except for one, who only had mutations detected at baseline and had consistently detectable DNA methylation at every point. Collectively, DNA methylation reached nadir at best response and gradually increased thereafter. An elevation in mutation AF or the emergence of new mutation(s) (molecular PD) was observed in 4 patients prior to PD assessed by imaging. In all patients, an elevation of DNA methylation was observed prior to PD assessed by imaging; among them, 3 had changes in DNA methylation prior to molecular PD, suggesting DNA methylation may be a more sensitive biomarker for progression. Collectively, our study demonstrates DNA methylation, continuously increasing from the nadir (best response), can be utilized as a biomarker for treatment monitoring.

**P2.03-37 THE EFFICIENCY OF OCTAMER-4 SPECIFIC CYTOTOXIC T CELLS INDUCED BY CD40-B CELLS IN KILLING LUNG CANCER STEM-LIKE CELLS**

Z. Xiang, J. Xu, F. Hu, H. Wang, X. Zheng, Y. Zhang, Y. Lou, B. Han

Department of Pulmonary, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai, China

**Background:** This study aimed to investigate the correlation of Octamer-4 (OCT4) expression with clinicopathological features and prognosis in lung adenocarcinoma patients, and to further explore the killing effect of OCT4 specific cytotoxic T cells (CTLs) on lung cancer stem cells (LCSCs).

**Method:** 257 lung adenocarcinoma patients underwent thoracic surgery were enrolled in this study and tissue samples were obtained during the operation. OCT4 expression was detected by immunofluorescence staining assay. CD154+ feeder cells were constructed to transfect CD40-B cells, and then mixed with OCT4 antigen peptides and specific cytotoxic T lymphocytes extracted from peripheral blood of lung adenocarcinoma patients, subsequently the OCT4 specific CTLs were co-cultured with PC9 LCSCs to detect the killing efficacy. OCT4+ phenotype was illuminated to be associated with poor differentiation, worse disease free survival (DFS) and overall survival (OS). And Cox's analysis revealed OCT4 was an independent predictive factor for shorter DFS and OS. **Result:** CD40-B cells with antigen presenting capacity was successfully constructed induced by elevated CD86, human leukocyte antigens (HLA)-A+ and CD80+ cells percentage, and OCT4 specific CTLs was successfully activated suggested by increased CD3+, CD4+ and CD8+ cells percentage as well as elevated interleukin (IL-2) and interferon (IFN)-γ expressions. OCT4 specific CTLs presented an elevated cytotoxic activity on LCSCs at percentage 75.5% ± 8.2% compared with CMV pp65 CTLs (25.6% ± 5.1%) and blank control CTLs (20% ± 4.7%). **Conclusion:** In conclusion, OCT4 expression could be served as a convincing risk biomarker for prognosis in lung adenocarcinoma patients and potential target of CTLs as immunotherapy in killing LCSCs.

**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.04-01 ASSOCIATIONS HISTOLOGICAL SUBTYPE OF LUNG ADENOCARCINOMA AND PROGRAMMED DEATH LIGAND 1 (PD-L1) EXPRESSION IN TUMOR CELLS**

G. Cruz-Ríos1, X. Popa Navarro1, A. Avilés-Salas1, K.Y. Flores-Vélez1, A. Cardona2, L. Ramírez-Tirado1, E. Vergara1, F. Barron1, L.A. Cabrera-Miranda1, O. Arrieta1

1Instituto Nacional de Cancerología, México/MX, 2Clinical and Translational Oncology Group, Foundation for Clinical and Applied Cancer Research - Ficmac, Bogotá/CO, 3National Cancer Institute, Mexico City/MX

**Background:** The analysis by immunohistochemistry (IHC) of the programmed cell death-ligand 1 (PD-L1) protein expression is the most extensively explored biomarker for response to immunotherapy in non-small cell lung cancer (NSCLC). However, there are differences concerning diverse IHC assays and cut-off criteria: Pembrolizumab with the 22C3 proliferation programmed cell death-ligand 1, Immunotherapy, NSCLC

1Lung Cancer Unit, Ospedale Policlinico San Martino, Genova/IT, 2Clinical Epidemiology Unit, Ospedale Policlinico San Martino, Genova/IT

**Background:** Immunotherapy represents a dramatic change in the treatment of non small cell lung cancer (NSCLC), but nowadays prognostic and predictive factors of response to immune checkpoint inhibitors (ICIs) are still under debate. It has been observed that circulating biomarkers might have a prognostic role in lung cancer. The aim of this study was to determine whether circulating tumor cells (CTCs) as well as circulating free DNA (cfdNA) might predict the outcome of patients with advanced NSCLC treated with Nivolumab. **Method:** From May 2015 to April 2017 89 NSCLC patients were treated with Nivolumab as a second or further line of therapy. All patients underwent blood sample collection before the start of treatment (baseline) and after 4 and 7 cycles of Nivolumab to evaluate both biomarkers. CTCs were isolated from 3ml of blood by the filtration-based device ScreenCell Cyto (ScreenCell) according to manufacturer’s protocol. cfdNA was extracted using the QIAamp DNA Blood Mini Kit (Qiagen) and quantified (ng/mL) by qPCR method, using hTERT single copy gene. The median baseline CTC number and cfdNA content were used as cut-off values to discriminate patients with different outcomes. An univariate analysis was done to evaluate the overall survival (OS) in the study population based on CTC and cfdNA using the Kaplan Meyer method. **Result:** The median CTC number and cfdNA at baseline were 2/3ml and 836.5 ng/ml, respectively. Median OS was 8.8 and 6.2 months for patients with baseline CTC ≤2 and >2, respectively (HR 1.53, 95% CI 0.96-2.42; p=0.072). Similarly, patients with high level of cfdNA >836.5 ng/ml showed a worse OS as compared with those having lower cfdNA: 5.1 vs 9.4 months (HR 1.63, 95% CI 1.02-2.59; p=0.040). **Conclusion:** A statistically significant advantage in terms of OS was observed in the group of patients with baseline cfdNA below the median value. Similarly, a longer survival, although of borderline significance, was observed in the group of patients with baseline CTC ≤2. Longitudinal change evaluations of both circulating biomarkers compared to radiological tumor size are currently ongoing.

CD154+ feeder cells were constructed to transfect CD40-B cells, and then mixed with OCT4 antigen peptides and specific cytotoxic T lymphocytes extracted from peripheral blood of lung adenocarcinoma patients, subsequently the OCT4 specific CTLs were co-cultured with PC9 LCSCs to detect the killing efficacy. OCT4+ phenotype was illuminated to be associated with poor differentiation, worse disease free survival (DFS) and overall survival (OS). And Cox's analysis revealed OCT4 was an independent predictive factor for shorter DFS and OS. **Result:** CD40-B cells with antigen presenting capacity was successfully constructed induced by elevated CD86, human leukocyte antigens (HLA)-A+ and CD80+ cells percentage, and OCT4 specific CTLs was successfully activated suggested by increased CD3+, CD4+ and CD8+ cells percentage as well as elevated interleukin (IL-2) and interferon (IFN)-γ expressions. OCT4 specific CTLs presented an elevated cytotoxic activity on LCSCs at percentage 75.5% ± 8.2% compared with CMV pp65 CTLs (25.6% ± 5.1%) and blank control CTLs (20% ± 4.7%). **Conclusion:** In conclusion, OCT4 expression could be served as a convincing risk biomarker for prognosis in lung adenocarcinoma patients and potential target of CTLs as immunotherapy in killing LCSCs.

**P2.04-03 NF-kB AND HIF-1α: PLAY IMPORTANT ROLES IN REGULATING PD-L1 EXPRESSION BY EGFR OR KRAS MUTANTS IN NON-SMALL CELL LUNG CANCER CELLS**  
R. Guo1, J. Wang1, Y. Li1, H. Bai1  
1Cancer Hospital Chinese Academy of Medical Sciences, Beijing/CN, 2Peking University School of Oncology, Beijing Cancer Hospital and Institute, Beijing/CN  
**Background:** Programmed death ligand 1 (PD-L1) is expressed in various human tumors and is of critical importance for the immune escape of tumor cells. Some driver gene mutations including EGFR and KRAS have been reported to be involved in PD-L1 expression regulation. However, the potential role and precise mechanism of EGFR and KRAS mutants in PD-L1 expression regulation in non-small cell lung cancer (NSCLC) remain obscure. **Method:** The expression levels of PD-L1 and key molecules of EGFR and KRAS signaling pathways were examined in 11 NSCLC cells with wild-type or mutant EGFR and KRAS genes. Additionally, ectopic expression or deletion of EGFR or KRAS mutants and pharmacological inhibitors of MEK/ERK, PI3K/AKT, β2, and HIF-1α were employed to elucidate the effects of activation or inhibition of EGFR or KRAS pathway on PD-L1 expression regulation in NSCLC cells. The effects of pathway inhibitors on tumorigenesis and PD-L1 expression of EGFR or KRAS-mutated NSCLC cells were also examined using xenograft mouse model. Furthermore, the correlations between EGFR status and protein levels of HIF-1α and PD-L1 were analyzed in 97 NSCLC tissues. **Result:** Examination of PD-L1 and HIF-1α expression in NSCLC samples revealed an apparent association of PD-L1 overexpression with activation of MEK/ERK and PI3K/AKT pathways, especially with increased protein levels of p-erbB2 and HIF-1α. Notably, ectopic expression or deletion of EGFR or KRAS mutants and administration of EGFR or KRAS pathway inhibitors showed important interplay and cooperation between NF-κB and HIF-1α in PD-L1 expression regulation in NSCLC cells. Furthermore, administration of EGFR or KRAS pathway inhibitors significantly inhibited xenograft tumor growth and PD-L1 expression of NSCLC cells in nude mice. Moreover, NSCLC tissues with positive HIF-1α staining presented significantly increased positive rate of PD-L1 expression compared with tissues scored HIF-1α negative (49.1% vs. 20.5%, P = 0.003). NSCLC tissues with EGFR or KRAS mutations showed obviously elevated expression levels of HIF-1α and PD-L1 compared with tissues carrying wild-type EGFR and KRAS genes (68.4% vs. 43.4%, P = 0.018 and 50.0% vs. 28.3%, P = 0.035, respectively). **Conclusion:** Taken together, both EGFR and KRAS mutants were identified to regulate PD-L1 expression via signaling effectors, NF-κB and HIF-1α, suggesting the interaction between driver gene mutations and tumor immune escape in NSCLC.  
**Keywords:** EGFR, KRAS, PD-L1, NF-κB, HIF-1α, NSCLC.

**P2.04-04 EXPRESSION OF INTRATUMORAL PROGRAMMED CELL DEATH-LIGAND 1 (PD-L1) AND INTRATUMORAL CD4+ T CELL, CD8+ T CELL AND FOXP3+ T CELL IN LUNG CANCER**  
Y. Jin1, H. Shimada1, S. Yamauchi1, N. Inase1, O. Matsubara2  
1Respiratory Medicine, Hirosaki Kyosai Hospital, Hirosaki, Kanagawa/JP, 2Pathology, Hirosaki Kyosai Hospital, Hirosaki, Kanagawa/JP

**Background:** Overexpression of PD-1 and PD-L1 induces immune evasion by cancer cells. Blockade of this immune checkpoint could reverse the tumor immune system and activate the anti-cancer response. Nivolumab and pembrolizumab, anti-PD-1 and anti-PD-L1 antibodies, were recently approved for the treatment of advanced NSCLC. A PD-L1 positive expression status by immunohistochemistry (IHC) has been associated with a favorable response. However, responses to these drugs are limited, with the objective response rate ranging between 20%-30%. These results suggest that individual tumor microenvironments vary according to the immune evasion process of each cancer tissue. Consequently, the introduction of biomarkers, which predict the responders to the immune checkpoint blockade therapies, is necessary. In this study, we analyzed the expression of PD-L1, CD8+ TILs, and FOXP3+ TILs in advanced lung cancer tissues. The objective response rate (ORR) of Anti-PD-1/PD-L1 therapy was 46.7%, and it was significantly correlated PD-L1 positivity with CD8+ TILs (p<0.0001). Eleven cases having driver gene mutations did not show a tendency towards favorable response. Cases with PD-L1 overexpression showed consistently dense CD8+ TILs, even in subgroup analyses according to histological subtype, stage, age and smoking status. In cancer-associated stroma, CD4+ cells and FOXP3+ cells were detected, and cases with PD-L1-, low CD8+, and FOXP3+ status were also detected. **Conclusion:** Overexpression of PD-L1 with CD8+ TILs was associated with a favorable response to treatment with nivolumab and pembrolizumab. In contrast, PD-L1- with low CD8+ TILs and FOXP3+ TILs was not associated with favorable response. Therefore, assessment of PD-L1, CD8+ TILs and FOXP3+ TILs by IHC may be valuable for predicting response to treatment with nivolumab and pembrolizumab. PD-L1+ and CD8+ TILs may be indicative of a combination with other therapeutic agents. Investigation of novel combinations of immunotherapy according to individual tumor microenvironments is warranted.  
**Keywords:** PD-L1, CD8+ T cell, FOXP3+ T cell.

**P2.04-05 CORRELATION BETWEEN PD-L1 GENE PROMOTER POLYMORPHISMS AND EXPRESSION OF PD-L1 MRNA AND PROTEIN IN NSCLC PATIENTS.**  
T. Kucharczyk1, A. Grenda1, P. Krawczyk1, M. Nicols2, B. Jarosz2, J. Szumilo1, K. Reszka1, T. Trojanowski2, J. Milanowski3

**Background:** Immunotherapy, the most novel approach to cancer treatment, gives a promising option for non-small cell lung cancer (NSCLC) patients. Most drugs targeting PD-1 or PD-L1 have been proven to be effective when cancer tissue expresses PD-1 or PD-L1 protein on its surface. The promoter region of PD-L1 gene is responsible for regulating the gene expression, thus in effect the expression of the protein. We decided to check whether single nucleotide polymorphisms (SNPs) in PD-L1 gene promoter region may affect this expression. **Method:** The study included 47 NSCLC patients (20 male, 27 female; median age 63±17.6). PD-L1 protein expression was analysed using two IHC assays with SP142 and 22C3 antibodies, on corresponding analysis platforms. mRNA was analysed using qRT-PCR method. PD-L1 gene promoter region polymorphisms (rs822335C/T and rs822335C/G) were analysed using real-time PCR method, on illumina Eco platform. The analysis was performed in histological (resected tissue) and cytological (cellblocks from bronchoscopy biopsies) material (FFPE blocks). **Result:** There were significant positive correlations between expression of mRNA of PD-L1 gene and the percentage of PD-L1 protein positive cells: tumor cells in the reaction with 22C3 antibody (R=0.39,p=0.025), tumor cells in the reaction with SP142 antibody (R=0.45, p=0.006) as well as infiltrating immune cells in the reaction with SP142 antibody (R=0.49, p=0.006). The studied group consisted of 21 CC homozygotes, 23 CT heterozygotes and 3 TT homozygotes in rs822335, and 12 CC homozygotes, 24 CG heterozygotes and 11 GG homozygotes in rs822336 polymorphic sites. Slightly higher (p=0.08) percentage of tumor cells with PD-L1 expression was observed in patients with CC genotype compared to patients with CT and TT genotypes in rs822335 polymorphism. We observed significantly higher expression of mRNA for PD-L1 gene in patients with GG genotype compared to patients with CG genotype (p=0.05) in rs822336 polymorphism. Additionally, odds ratio analysis showed that a higher chance of high mRNA expression of PD-L1 gene occurred in patients with GG genotype as compared to patients with CC genotype (OR=7.0, ch2=4.46, p=0.035). **Conclusion:** Analysis of PD-L1 expression on tumor cells presents numerous problems – availability of material, tumor heterogeneity, different methods of detection. We have presented that analysis of PD-L1 gene polymorphisms may be useful in determination of PD-L1 expression. It might be carried out in blood samples, when surgical material is not available. The usefulness of PD-L1 gene polymorphisms, as a predictor of immunotherapy, should be investigated in clinical trials.

P2.04-06 INCREASED PLASMA CELL % AND DECREASED B-CELLS IN TUMOR IMMUNE INFILTRATES ARE ASSOCIATED WITH WORSE PROGNOSIS IN LUNG ADENOCARCINOMAS
Division of Anatomic Pathology, Mayo Clinic, Rochester/MN/US

Background: Clinical significance of tumor-infiltrating plasma cells and B-cells in lung adenocarcinoma is not well known. Method: CD3, CD20 and MUM1 immunostains were performed on representative tumor blocks selected from 120 consecutive lung adenocarcinoma cases resected. CD3-positive T-cells, CD20-positive B-cells, and MUM1-positive plasma cells were separately enumerated in the intraepithelial (IE) compartment and the stroma (ST) by digital image analyses. Distribution of measured tumor-infiltrating cells was systematically evaluated and their associations with patient’s overall survival (OS) modeled using Cox proportional hazards analysis. Result: Median age of patients was 69 years (range, 46-91 years) and 52 patients were male. Eighty-two, 17, and 21 patients were tumor stage I, II, and III/IV, respectively. Ninety years (range, 46-91 years) and 52 patients were male. Eighty-two, 17, and 21 patients were tumor stage I, II, and III/IV, respectively. Ninety patients had surgery only; 30 had surgery with adjuvant chemotherapy and/or radiation therapy. Median numbers (interquartile range) of CD20-positive B-cells per 1mm² in the tumor area (IE plus ST) and in IE compartment were 590 (224-1276) and 101 (38-109), respectively; the corresponding numbers of MUM1-positive plasma cells were 298 (30-650), and 67 (22-145), respectively. The percent of MUM1-positive plasma cells among all tumor immune infiltrate (i.e. MUM1-positive cells / [CD3-positive cells + CD20-positive cells + MUM1-positive cells] x 100) ranged from 0 to 60% (median 10%) in the tumor area and showed a significant association with OS by univariate Cox analysis (continuous variable; positive correlation with hazard ratio [HR]=0.81 [95% CI, 0.68-0.96]. Both parameters remained significant by multivariate analysis. Cut-off points (low vs high) showing significant associations with patient’s OS were found by log-rank test (Table 1).

P2.04-07 EFFECTS OF NEOADJUVANT CHEMOTHERAPY ON THE EXPRESSION OF PROGRAMMED DEATH LIGAND-1 AND TUMOR INFILTRATING LYMPHOCYTES IN LUNG CANCER TISSUES
W. Sun, K. Ma, X. Wang
The First Hospital of Jinlin University, Changchun/CN

Background: Immune checkpoints programmed death 1(PD1) and its ligand PD-L1,PD-L2 pathways can mediate negative synergistic stimulation signals. Immunochemistry combined with chemotherapy can increase the objective response rate of cancer patients, but the mechanism of combination therapy is not clear. This study aims to analyze the changes of PD-L1,PD-L2 in lung cancer tissues and the changes of TILs (CD4+,CD8+,CD28+, and CD56+ lymphocytes ) surrounding the tumor before and after neoadjuvant chemotherapy(platinum-based), in order to provide a theoretical basis for relevant clinical studies. Method: Tumor samples were obtained from 26 patients who confirmed primary lung cancer before and after NAC from 2009 to 2016 in the First Hospital of Jinlin University. The expression of PD-L1, PD-L2 in lung cancer specimens were assessed by IHC. Of 16 patients (since the biopsy tissue specimens were limited, only 16 cases of biopsy and postoperative tissue specimens were collected), the expression of TILs around the tumor before and after NAC were assessed by IHC. We analyze the changes of PD-L1 and PD-L2 in lung cancer tissues before and after NAC, the correlation between the changes of PD-L1 in lung cancer tissues and tumor shrink rate, the interval from the end of NAC to operation, pathological type, gender and smoking status. Of 16 patients, the changes of TILs around the tumor before and after NAC were also evaluated. Conclusion: 1. There were no statistically significant. Result: 1. When using 5%, 10%, and 20% as expression threshold to define PD-L1 positive status, PD-L1 was up-regulated after NAC (P=0.008,P=0.016,P=0.016). However, there were no obviously statistical significance about the expression of PD-L1 when using 30%, 50% expression threshold. The expression of PD-L2 were not show any statistical difference before and after NAC. 2. Of 16 patients, the expression of PD-L1, PD-L2 were also evaluated. P<0.05 was considered statistically significant. Result: 1. When using 5%, 10%, and 20% as expression threshold to define PD-L1 positive status, PD-L1 was up-regulated after NAC (P=0.008,P=0.016,P=0.016). However, there were no obviously statistical significance about the expression of PD-L1 when using 30%, 50% expression threshold. The expression of PD-L2 were not show any statistical significance before and after NAC. 2. Of 16 patients, the changes of PD-L1 in lung cancer tissues and tumor shrink rate, the interval from the end of NAC to operation, pathological type, gender and smoking status. Of 16 patients, the changes of TILs around the tumor before and after NAC were also evaluated. P<0.05 was considered statistically significant. Result: 1. When using 5%, 10%, and 20% as expression threshold to define PD-L1 positive status, PD-L1 was up-regulated after NAC (P=0.008,P=0.016,P=0.016). However, there were no obviously statistical significance about the expression of PD-L1 when using 30%, 50% expression threshold. The expression of PD-L2 were not show any statistical difference before and after NAC. 2. Of 16 patients, the expression of PD-L1, PD-L2 were also evaluated. P<0.05 was considered statistically significant. Result: 1. When using 5%, 10%, and 20% as expression threshold to define PD-L1 positive status, PD-L1 was up-regulated after NAC (P=0.008,P=0.016,P=0.016). However, there were no obviously statistical significance about the expression of PD-L1 when using 30%, 50% expression threshold. The expression of PD-L2 were not show any statistical difference before and after NAC. 2. P2.04 IMMUNOONCOLOGY
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00
**Background:** While the predictive value of programmed cell death ligand-1 (PD-L1) protein expression for immune checkpoint inhibitor therapy of lung cancer has been extensively studied, the impact of standard platinum-based chemotherapy on PD-L1 or programmed cell death-1 (PD-1) expression is unknown. The aim of this study was to determine the changes in PD-L1 expression of tumor cells (TC) and immune cells (IC), in PD-1 expression of IC, and in the amount of stromal mononuclear cell infiltration after platinum-based chemotherapy in patients with lung cancer.

**Method:** We determined the amount of stromal mononuclear cells and PD-L1/PD-1 expression by immunohistochemistry in bronchoscopic biopsy samples including 20 adenocarcinomas (ADC), 15 squamous cell carcinomas (SCC), 2 other types of non-small cell lung cancer (NSCLC), and 4 small cell lung cancers (SCLC) together with their corresponding surgical resection tissues after platinum-based chemotherapy. **Result:** PD-L1 expression of TC decreased in 10 patients (24.4%) and increased in 3 patients (7.2%) after neoadjuvant chemotherapy (p=0.051). The decrease in PD-L1 expression, however, was significant only in patients who received cisplatin-gemcitabine combination (p=0.020), while in the carboplatin-paclitaxel group no similar tendency could be observed (p=0.432). There was no difference between ADC and SCC groups. Neither PD-1 expression nor the amount of stromal IC infiltration showed significant changes after chemotherapy. **Conclusion:** This is the first study, in which both PD-L1 and PD-1 expression were analyzed together with the amount of stromal IC infiltration in different histological subtypes of lung cancer before and after platinum-based chemotherapy. Our results confirm that chemotherapy decreases PD-L1 expression of TC in a subset of patients, therefore rebiopsy and re-evaluation of PD-L1 expression may be necessary for the indication of immune checkpoint inhibitor therapy.

**P2.04-10 EARLY MONITORING OF BLOOD BIOMARKERS TO PREDICT NIVOLUMAB EFFICACY IN NSCLC PATIENTS**

F. Passiglia¹, A. Galvano¹, H. Soto Parra², S. Rizzo², A. Listi³, S. Mazzariti³, A. Perez³, M. Castiglia³, V. Calò³, V. Bazzani³, A. Russo³

¹Surgical, Oncological and Oral Sciences, Section of Medical Oncology, University Hospital of Palermo, Palermo/IT, ²Medical Oncology, A.O. Polinicino Vittorio Emanuele, Catania/IT, ³1. Department of Surgical, Oncological and Stomatological Disciplines, Section of Medical Oncology, University of Palermo, Palermo/IT

**Background:** In the present study we investigated whether early dynamic changes of circulating free (cf) DNA levels as well as peripheral blood cell count could predict resistance to nivolumab in pre-treated patients with advanced non-small cell lung cancer (NSCLC). **Method:** From September 2015 to January 2018, 45 NSCLC patients receiving i.v nivolumab 3 mg/kg every two weeks were included within a translational study. All the patients underwent CT-scan every 6 cycles and responses were evaluated by Response Evaluation Criteria in Solid Tumors (RECIST). Peripheral blood samples were obtained from the patients at baseline and at fourth cycle of therapy. The quantification of cfDNA (ng/µl plasma) was performed by qubit dsDNA HS assay and confirmed by qPCR evaluating a 115 bp fragment of ALU repeat. The median cfDNA level as well as the median neutrophil to lymphocyte ratio (NLR) value were calculated at the first and the fourth infusion of nivolumab. Time to progression (TTP) and overall survival (OS) were determined. The analysis was performed using the R statistical software for Windows (R Development Core Team). **Result:** cfDNA level was associated with inferior OS (7.2 vs 13.5 months, p=0.04) while high pre-treatment NLR predicted inferior TTP (4.5 vs 9.7 months, p=0.006). Patients with increased median cfDNA level >20% at fourth cycle reported significantly worse OS and TTP (OS: 5.7 vs 14.2 months, p=0.001; TTP: 3.3 vs 10.2 months, p<0.001). Patients with increased median NLR >20% at fourth cycle of therapy showed significantly worse OS and TTP (OS: 8.7 vs 14.6 months, p=0.035; TTP: 5.2 vs 10.3 months, p=0.039). Patients with a simultaneous increase >20% of both cfDNA level and NLR value showed significant worse survival outcomes as compared to patients with only one increased parameter or not increase of both parameters (OS: 5.8 vs 11.1 vs 11.5 vs 15.4 months, p=0.012; TTP: 3.2 vs 6.5 vs 7.3 vs 11.9, p=0.028). **Conclusion:** Early increase of both cfDNA level and NLR value is a marker of resistance to nivolumab and predict worse survival outcomes in pre-treated patients with advanced NSCLC, suggesting a potential role in the real time monitoring of immunotherapy efficacy.

**Keywords:** NLR, cfDNA, Nivolumab

**P2.04-11 AN IL-8/IFN-GAMMA/NLR PLASMA SCORE TO PREDICT NIVOLUMAB EFFICACY IN PATIENTS WITH NSCLC**

F. Passiglia1, A. Russol2, S. Ferro3, L. Lalli3, A. Cova4, H. Soto Parra3, L. Rizoli5, V. Huber2

1Department of Surgical, Oncological and Stomatological Disciplines, Section of Medical Oncology, University of Palermo, Palermo/IT, 2Fondazione IRCCS Istituto Nazionale Dei Tumori, Milano/IT, 3Medical Oncology, A.O.U. Policlinico Vittorio Emanuele, Catania/IT

**Background:** In the present study we investigated whether baseline plasma cytokines as well as neutrophil to lymphocyte ratio (NLR) could predict resistance to Nivolumab in pre-treated patients with advanced non-small cell lung cancer (NSCLC).

**Method:** From September 2015 to January 2018, 42 NSCLC patients receiving i.v. nivolumab 3 mg/kg every two weeks were included within a translational study. All the patients underwent CT-scan every 6 cycles and responses were evaluated by Response Evaluation Criteria in Solid Tumors (RECIST). Peripheral blood samples were obtained from the patients at baseline. A panel of cytokines and chemokines (IL-6, IL-8, CXCL10, CX3CL1, CCL2, VEGF, and IFN-gamma) were quantified in plasma by Cytokine Bead Array and their association with OS and TTP was assessed by Adaptive Index Modeling multivariable analysis. NLR in blood cell counts was also assessed for potential association with clinical outcomes.

**Result:** An Index Score was identified clustering patients into 4 groups with progressively worsening TTP and OS. The score was composed by higher IL-8 and NLR (above the cut-offs of 10.76 pg/ml and 5, 4 respectively) and lower IFN-gamma level (below cut-off of 11 pg/ml). Patients with score 0-1 (i.e. with none or 1 altered parameter; n= 17) displayed a median TTP of 11 months (95% IC 5-18.5) and median OS of 19 months (95% IC 5-38.5); patients with score 2-3 (2 or 3 altered parameters; n= 13) showed a median TTP of 10 months (95% IC 3.2-15.8) and median OS of 16 months (95% IC 7.8-29.2); in contrast patients with score 2-3 (2 or 3 altered parameters; n= 23) showed a median TTP of 5 months (95% IC 2-5) and median OS of 5 months (95% IC 2-5). The divergences among both TTP and OS Kaplan-Meier curves were statistically significant (P=0.0002). NLR alone showed instead neither a borderline association with OS (p=0.048) and no ability to predict TTP (p=0.23).

**Conclusion:** Baseline plasma levels of IL-8 and IFN-gamma potentiate the ability of NLR to predict resistance to nivolumab in pre-treated patients with advanced NSCLC. These data suggest that the systemic balance between neutrophil-related inflammation and lymphocyte anti-tumor immunity may condition response to immunotherapy in lung cancer.

**Keywords:** Nivolumab, NLR, cytokines

**P2.04-12 A GENOMIC SIGNATURE [JAK2, JAK3, PIA54, PTTP2, STAT3, IFNAR2] PREDICTS BASALINE RESISTANCE TO NIVOLUMAB IN ADVANCED NSCLC.

1Medical Oncology, University of Verona, Azienda Ospedaliera Universitaria Integrata (Aou), Verona/IT, 2Regina Elena National Cancer Institute, Rome/IT, 3Department of Diagnostics and Public Health, Section of Anatomical Pathology, University and Hospital Trust of Verona, Verona/IT, 4University and Hospital Trust of Verona, Verona/IT

**Background:** With the exception of PD-L1 expression for pembrolizumab, no biomarkers allow to maximize the benefit of immunotherapy in advanced pretreated non-small cell lung cancer (AP-NSCLC). The genomic abnormalities of genes involved in immune-escape/editing are suggested as baseline mechanisms of resistance. **Method:** A retrospective series of AP-NSCLC patients (pts) undergone Nivolumab (NIVO) was collected. FFPE-tumor blocks were analyzed to identify genomic abnormalities of genes involved in immune-escape/editing. End-points were overall-, progression-free-survival (OS/PFS) and objective response rate (ORR).

**Result:** Data from 24 consecutive AP-NSCLC pts who received NIVO were gathered (median age 69.5 yrs, median number of previous lines 3 [2-5], 2nd line NIVO [70.8%], median follow-up 6.8 months [range 1-23], deaths 14 [58.3%], male/female 79.2/20.8%, squamous/non-squamous 41.7/58.3%, EFRG mutant 5 [20.8%], ORR (partial) was obtained in 4 pts (16.6%, 95% CI 1.7-31.6%), with stable- and progressive-disease in 5 (20.8%, 95% CI 4.5-37.1%) and 15 (62.5, 95% CI 43.1-81.8%) pts, respectively. JAK3/JAK2 (6/3 pts, 25/12.5% CNVs, and IFNAR2/STAT3 3 Ms (2 pts, 8.3%) were the most frequent (>1 pts) abnormalities. The 12 pts with JAK3, PIA54, PTTP2, STAT3, IFNAR2 and JAK2/3 SMs/CNVs had a significantly lower median OS (4 months, 95% CI 1.1-8) and PFS (3 months, 95% CI 2-3.5) than the other 12 pts wild-type/other alterations (median OS 13 months, n.e.; median PFS 6 months 95% CI 5-9) [p=0.046 for OS, p=0.002 for PFS]. No objective responses were observed in the pts’ subgroup harboring the gene signature (p=0.09). At multivariate analysis, the genomic signature was independently associated with shorter OS (HR 2.20 95% CI 1.21-4.06, p=0.01) and PFS (HR 6.195% CI 2-18.7, p=0.001). No significant correlation between EGFR mutations and outcome was found.

**Conclusion:** Despite the small sample size, NIVO in AP-NSCLC pts who receives have a lower benefit from NIVO, supporting intrinsic resistance. A larger prospective validation is planned.

**Keywords:** Genomic signature, advanced NSCLC, Immunotherapy resistance
Background: Immune checkpoint inhibitors (ICI) improve overall survival in non-small cell lung cancer (NSCLC) in the 2nd-line setting and lead to prolonged disease control in a subgroup of patients (pts). Robust predictive biomarkers for ICI are highly desired. In an exploratory analysis of the CheckMate 026 study, high tumor mutation burden (TMB) assessed by whole-exome sequencing was associated with improved outcome of pts treated with nivolumab.

Method: From our institutional database, 41 pts with metastatic NSCLC were included in this study and identified as either having clinical benefit (CB; defined as complete/partial response (CR/PR) or stable disease (SD)) or having no clinical benefit. TMB was assessed using a targeted NGS assay that simultaneously detects variants in all coding regions / sequences of 409 cancer-related genes (Oncomine Tumor Mutation Load Assay, Thermo Fisher Scientific, Waltham, MA, USA). TMB values were normalized to tumor cell content. The correlation between TMB and CB rate was assessed. Mann-Whitney test was used and differences were considered significant at a p-value <0.05. Result: Of 41 pts (mean age 63.7 years), 73% were male, 87.8% smokers and 71% had adenocarcinoma histology. Nivolumab was the most frequently used ICI (70.7%), and it was most commonly used in the 2nd-line setting (61.0%). PR was observed in 29.2% of patients, and SD in 14.6%. CB rate was 43.8%. The median number of genomic mutations per Megabase (Mb) was 8.81. In pts with CB, median TMB with 11.52 mutations per Mb was significantly higher than in pts without response to therapy (7.71 mutations per Mb; p=0.02). Conclusion: TMB as determined by a targeted NGS panel comprising the coding regions of 409 cancer-related genes can reliably predict clinical benefit from ICI. These results need further confirmation due to limited sample size of this study. We are currently analyzing a second independent cohort, and results will be presented during the meeting.

Keywords: Predictive biomarker, tumor mutational burden, immune checkpoint inhibitor

Figure 1. HVEM has a negative correlation with PD-L1 expression in NSCLC. Figure 1A, a significant negative correlation in 527 NSCLC patient cohort (r=-0.274, p<0.001). Figure 1B, HVEM has a negative correlation with PDL1 expression in NSCLC cell line (r=0.055, p=0.764). Figure 1C, Western blot with the HVEM and PDL1 antibody on 5 selected cell lines.

Conclusion: HVEM was found to be overexpressed in patients of NSCLC with advanced disease or lymph node metastasis and has a negative correlation with PD-L1 expression, while, it did not have a prognostic role in patients with NSCLC.

P2.04-15 HETEROGENEITY AND CORRELATION BETWEEN IMMUNE MARKERS IN LUNG CANCERS: ANALYSIS OF TREATMENT-NAÏVE LESIONS

K. Suda1, J. Kim2, I. Murakami3, L. Rozeboom2, C. Rivard2, T. Mitsudomi4, A. Tan4, F. Hirsch1
1Division of Medical Oncology, University of Colorado Anschutz Medical Campus, Aurora/CO/US, 2Medical Oncology, University of Colorado Anschutz Medical Campus, Aurora/CO/US, 3Department of Respiratory Medicine, Higashi-Hiroshima Medical Center, Higashi-Hiroshima/JP, 4Division of Thoracic Surgery, Department of Surgery, Kindai University Faculty of Medicine, Osaka-Sayama/JP

Background: Immunotheapies are becoming a new standard of care for patients with lung cancers. Although a few immune-checkpoints are currently used as therapeutic targets and/or as predictive biomarkers, the complex correlation between immune-checkpoints is not well understood. Expression level of immune-checkpoint molecules is affected by numerous factors including tumor cells themselves, patients’ immunological characteristics, tumor microenvironment (metastatic sites), and previous treatments. To effectively investigate correlations of immune-checkpoints across multiple lesions, we analyzed gene expression data obtained from treatment-naïve autopsied patients.

Method: Our cohort of 5 lung cancer patients included thirty specimens of both primary and metastatic lesions. RNA sequencing reads were mapped to the hg19 reference genome using the TopHat/Cufflinks workflow and transcripts were quantified using the FPKM method. Expression data for immune-checkpoints and total numbers of detected mutations were compared. Result: We observed substantial inter-tumor heterogeneity in immune-checkpoint expression between lesions obtained from each patient. No consistent correlation was found by comparison of primary vs. metastatic lesions or between primary vs. specific metastatic sites. Evaluation of immune-checkpoints expressed by tumor cells and/or antigen presenting cells revealed a positive correlation between GAL9 and PD-L2 (R = 0.79) and GAL9 and HVEM (R = 0.69; Figure 1A). We also observed a strong correlation between these markers when lesions obtained from each patient were correlated to each other (Figure 1B and C). Comparisons between immune-checkpoints expressed by immune cells identified a positive correlation between PD-1 and LAG3 (R = 0.77). No correlation was found between immune-checkpoint expression and mutation burden.

(See next page)
Conclusion: We observed substantial inter-tumor heterogeneity in immune-checkpoints expression in each patient. We also found several positive correlations between immune-checkpoints which were consistent within the small cohort of patients. Further functional evaluation is warranted.

P2.04-16 CORRELATION BETWEEN PROGRAMMED DEATH LIGAND 1 (PD-L1) EXPRESSION AND SOLID COMPONENT ON HRCT IN STAGE I LUNG CANCER PATIENTS
R. Tsugitomi1, N. Nishimura1, H. Kanemra1, R. Ima1, N. Yoshiyasu2, K. Okafuji3, A. Kitamura4, Y. Tomishima4, F. Kojima5, T. Jinta5, T. Suzuki6, T. Tamura1
1Division of Pulmonary Medicine, St. Luke’s International Hospital, Tokyo/JP, 2Thoracic Surgery, St. Luke’s International Hospital, Tokyo/JP, 3Division of Pathology, St. Luke’s International Hospital, Tokyo/JP

Background: Programmed death ligand 1 (PD-L1) expression on lung cancer cell is one of the predictors of treatment response to immune checkpoint inhibitors. However, little has been reported about PD-L1 expression in patients with early stage lung cancer because previous clinical trials were mostly focused on advanced stage, and little has been also reported about association PD-L1 expression with high-resolution computed tomography (HRCT) findings. The purposes of this study were to describe PD-L1 expression in early stage lung cancer and to evaluate correlation with solid component on HRCT. Method: We evaluated patients with non-small cell lung carcinoma (NSCLC) who had been performed surgical resection between March 2017 and 2018, and resulted in pathological stage were stage I. Adenocarcinoma in situ was excluded. PD-L1 expression was assessed by means of the PD-L1 immunohistochemistry (IHC) 22C3 pharmDx assay (Agilent). PD-L1 expression was classified into three categories, negative group (PD-L1 expression less than 1%), low expression group (over 1% and less than 50%) and high expression group (over 50%). We also described HRCT findings of the tumor by solid/ground glass nodule (GGN)-ratio, calculating by the ratio of the solid component and GGN component area. The ratio was defined 0% in pure GGN cases and 100% in solid nodule cases. Result: During study period, 60 patients were evaluated. The mean age (±SD) was 67 (±10) years old, 28 patients (46.7%) were female. 47 patients (78.3%) were adenocarcinoma and, of these, 10 patients were minimally invasive adenocarcinoma. In radiological classification, 8 patients (13.3%) were pure GGN, 24 (40.0%) were part solid nodules and 28 (46.7%) were solid nodules. In PD-L1 expression, 33 (55.0%) patients were negative group, 23 (38.3%) patients were low expression group and 4 (6.7%) were high expression group. The mean PD-L1 expression (±SD) was 7.82 (±18.6)% and the mean solid/GGN-ratio (±SD) was 58.8 (±40.9)%. A Spearman’s correlation test showed significant correlation between PD-L1 expression and solid/GGN-ratio. (rho=0.43, p<0.001) Conclusion: There was a positive correlation between PD-L1 expression and solid component on HRCT in stage I NSCLC patients.

P2.04-17 PRE- THERAPY RADIOMIC FEATURES CAN DISTINGUISH HYPERPROGRESSION FROM OTHER RESPONSE PATTERNS TO PD1/ PD-L1 INHIBITORS IN NSCLC
P. Patil1, K. Bera1, P. Vaidya2, M. Khorrami3, P. Jain4, A. Madabhushi2, V. Velcheti1
1Tausig Cancer Institute, Cleveland Clinic, Cleveland/ OH/US, 2Department of Biomedical Engineering, Case Western Reserve University, Cleveland/ OH/ US, 3Biomedical Engineering, Case Western Reserve University, Cleveland/US, 4Department of Internal Medicine, Cleveland Clinic Foundation, Cleveland/US

Background: Immune checkpoint inhibitors (ICIs) can lead to durable responses in a fraction of patients with advanced non-small cell lung cancer (NSCLC), however a majority of patients do not respond to these agents. Of the non-responders, a subset of patients who have a dramatic increase in their tumor growth rates after ICI therapy have been previously described in the literature. There are currently no clinically validated biomarkers to identify these hyperprogressors (HPs). We sought to evaluate whether radiomic features of the tumor on baseline CT scans from patients with advanced NSCLC treated with ICIs could distinguish hyperprogressors from non-responders (NRs) and responders (Rs). Method: We retrospectively reviewed the charts of 336 patients with advanced NSCLC who received monotherapy with a PD1/PD-L1 inhibitor. For patients who developed progressive disease within 3 cycles of ICI therapy, pre-baseline, baseline and post treatment radiomic features were analyzed using the radiomics software package RadiomicsP (RStudio). Features were extracted from 3D volumes of interest (VOIs) that contained tumor on each CT scan. A total of 1440 radiomics features were extracted from each VOI. We used machine learning techniques (optimal tree-based ensemble models) to predict hyperprogression from responder status. The performance of the models was evaluated using the receiver operator characteristic (ROC) curve and the area under the curve (AUC) was calculated. Results: The area under the curve (AUC) for the ensemble model was 0.77. Conclusion: Pre-therapy radiomic features can be used to distinguish hyperprogressors from other response patterns to PD1/PD-L1 inhibitors in NSCLC.

Keywords: biomarker, Immune checkpoint molecules, GAL9
evaluated the prognosis after radiotherapy. IDO is a potential molecular marker of NSCLC to with reduced IDO activity had better OS and PFS than those increased patients with reduced IDO activity after radiotherapy had better OS than activity after radiotherapy is associated with prognosis in NSCLC. The and PFS (HR=6.667, 95%CI: 1.515~29.411, P=0.012 and HR=5.348, 95%CI: not reached vs. 10.9 months, P=0.006, respectively). In subgroup of patients who reduced K: T after radiotherapy had better OS and PFS than who with increased K: T after radiotherapy had better OS and PFS than who with increased K: T (median OS: not reached vs. 20.2 months, P=0.008 and median PFS: not reached vs. 10.9 months, P=0.006, respectively). Multivariate analysis also showed that IDO activity was a factor for OS and and PFS (HR=6.667, 95%CI: 1.515~29.411 P=0.012 and HR=5.348, 95%CI: 1.427~20.000, P=0.013, respectively). Conclusion: The change of IDO activity after radiotherapy is associated with prognosis in NSCLC. The patients with reduced IDO activity after radiotherapy had better OS than those with increased. Especially for patients who received SBRT, patients with reduced IDO activity had better OS and PFS than those increased after radiotherapy. IDO is a potential molecular marker of NSCLC to evaluated the prognosis after radiotherapy.

P2.04-19 CORRELATION OF CLINICOPATHOLOGICAL CHARACTERISTICS WITH TUMOR MUTATION BURDEN IN CHINESE PATIENTS WITH NSCLC

S. Lu1, Y. Yu2, G. Wang2, J. Wei1, Q. Xu2
1Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, Shanghai/CN, 2Genomicare Biotechnology (Shanghai) Co., Ltd., Shanghai/CN

Background: Higher tumor mutation burden (TMB) has been associated with improved immune checkpoint inhibitor objective response, progression-free survival and overall survival in non-small cell lung cancer(NSCLC). But the correlation of clinicopathological characteristics with tumor mutation burden (TMB) in Chinese patients with NSCLC remains unknown. Method: 266 lung adenocarcinoma (LUAD) and 66 lung squamous cell carcinoma (LUSC) patients from 18 hospitals across 11 provinces in China were recruited and the clinical whole exome of paired tumor/normal samples of each patient were sequenced. Result: Among the 332 prospectively enrolled NSCLC patients, 81.3% patients were recommended at least one FDA approved targeted/immunotherapy drug and 88.5% were matched at least one ongoing clinical trials. The mean TMB of Chinese NSCLC patients was 5.62 mutations/Mb and upper tertile was 7.87 mutations/Mb. TMB in Chinese LUSC cohort was slightly higher than the TCGA cohort (median: 10.6 mutations/ Mb vs. 9.0 mutations/Mb).While TMB in Chinese LUAD patients was slightly lower than the Cancer Genome Atlas (median 1.14 mutations/Mb vs. 6.3 mutations/Mb).Chinese LUAD patients with EGFR-mutant status (122/266) had significantly lower TMB compared with patients with EGFR wild-type (median: 4.90 mutations/Mb vs. 5.53 mutations/Mb, P=0.0013). This may help to explain why in EGFR-mutant advanced NSCLC, immune checkpoint inhibitors do not improve OS over that with docetaxel in secondline setting. However LUAD patients with KRAS- mutant status (31/266) had significantly higher TMB compared with patients with KRAS wild-type (median: 9.94 mutations/Mb vs. 4.84 mutations/Mb, P=0.021). A small subset (8/266) of NSCLC patients with CDKN2A-mutant possessed high TMB, although it did not reach statistical significance (P=0.0588). Consistent with previous research, mutant POLE/POLD1 (LUAD: 15/266 and LUSC: 8/66) was significantly associated with increased TMB. For all NSCLC in our study, patients with mutant POLE/POLD1 had significantly higher TMB compared with patients with wild-type POLE/POLD1 (Median: 10.18 mutations/Mb vs. 5.59 mutations/Mb, P=5.16e-7).TP53 and PTEN mutations were not enriched in NSCLC patients with high TMB. One EGFR (p.L858R) mutant LUAD patient with CTNNB1 (s.33F) co-mutation developed to be innate PD-1 and EGFR-TKI resistance. Increased β-catenin signaling led to poor T cells infiltration into tumors and promoted epithelial-mesenchymal transition (EMT) as well. This can be presented as a novel genomic predictor of de-novo resistance to immune checkpoint blockade in EGFR-mutant LUAD. Conclusion: High TMB caused by DNA repair deficiency such as POLE/POLD1 mutation is common in Chinese NSCLC patient, and clinical evidence sugg thatTMB status and cancer driver mutations can help to establish clinically available tool to identify patients who are most likely to benefit from immunotherapies or targeted therapies.

P2.04-20 IMMUNOLOGIC CHARACTERIZATION OF FIBRINOUS PERICARDITIS AS AN IMMUNE CHECKPOINT BLOCKADE TOXICITY IN NSCLC

M. Miyoshi1, M. Toki1, D. Carvaljal-Hausdorf1, S. Gettinger1, R. Herbst1, D. Rimm1
1Thoracic/head and Neck Medical Oncology, MD Anderson Cancer Center, Houston/TX/US, 2Department of Pathology, Yale University School of Medicine, New Haven/CT/US, 3Anatomic Pathology, Clinica Alemana-Universidad Del Desarrollo, Santiago/CL, 4Yale Cancer Center, New Haven/CT/US, 5Medical Oncology, Yale Cancer Center – Smilow Cancer Hospital, New Haven/US

Background: Immune checkpoint inhibitors have revolutionized the treatment paradigm in number of cancers including Non-Small Cell Lung Cancer (NSCLC) but unrestrained modulation of the immune system remains a challenge. Here, we characterized the immune infiltration in the toxicity site and compared immune profile in primary tumor in three patients treated with PD-L1-PD-1 axis inhibitors and developed fibrous pericarditis (FP) Method: We used the AQUA method of quantitative immunofluorescence (QIF) to assess multiplexed panels identifying immune cell populations and their activation status in pre-treatment,
post-treatment primary tumor, post-treatment metastatic tumor and the toxicity sites (including pericardial tissue) from 3 NSCLC patients. We also compared the expression of 730 immune-related genes across the 3 patients with FP and 2 NSCLC patients with different toxicity sites after immunotherapy (hypophysitis and myocarditis) using Nanostring 

Sprint platform. Result: In immune infiltration assessment, TILs markers' expression (CD4, CD8 and CD20) did not differ between primary tumor and toxicity site. There was a trend towards higher CD3+ expression in the toxicity samples but T-cell activation markers expression, Granzyme B and Ki67, was significantly lower in the pericarditis samples. Interestingly, inhibitory receptor expression in CD3- cells and CD68+ cells were seen in the pericarditis samples. CD68+ expression, as well as PD-L1 expression in macrophages, was significantly higher (p<0.0001) in the pericarditis samples. mRNA analysis confirmed the QIF findings, with the chemokine profile indicating an M1 macrophage polarization. Additionally, there was a trend towards higher NCR1, perforin1 and Granzyme B gene expression in the toxicity samples, further supporting a possible role of Natural killer (NK) cells in the development of toxicity.

Conclusion: Our findings suggest that macrophos and possibly NK cells contribute to inflammatory tissue damage in immune related adverse events. Conversely, T-cells that were infiltrating the toxicity sites had low expression of activation markers, further indicating that toxicity may be mediated by other cellular pathways.

P2.04-21 REAL WORLD EXPERIENCE OF IMMUNE CHECKPOINT INHIBITORS (ICI) IN NSCLC: OUR FIRST 10 MONTHS EXPERIENCE AT LEEDS CANCER CENTRE, UK

K. Ellenger, M. Flatley, K. Spencer, K. Clarke, K. Franks, P. Jain
Clinical Oncology, St James’s University Hospital, Leeds/GB

Background: Pembrolizumab and Nivolumab are monoclonal antibodies to the PD-1 receptor and have shown significant overall survival (OS) and progression free survival (PFS) in the second line setting compared to chemotherapy in non-small cell lung cancer (NSCLC). Pembrolizumab has shown significant OS and PFS in the first line setting in high PD-1 expression (≥50%). In January 2017, immune checkpoint inhibitors became standard of care in the UK in the second line setting and subsequently first line later that year. Studies report fewer treatment-related adverse events in the checkpoint inhibitor arm vs chemotherapy (10-20% vs 54%). We report our first 10 months experience with routine use of checkpoint inhibitors in NSCLC at Leeds Cancer Centre (LCC), UK.

Method: All patients receiving pembrolizumab and nivolumab between 1/1/17 and 31/10/17 at LCC, UK were included. Retrospective review of medical notes was performed and outcomes recorded including: checkpoint inhibitor received; time to response; OS and treatment-related adverse events. Kaplan-Meier survival curves were used to assess survival outcomes. Result: Thirty-six patients received checkpoint inhibitors during this period. Median age was 68 years. Eleven patients received pembrolizumab first line, with a response rate of 90% (n=10). Twelve-five patients received second line therapy with a response rate of 32% (n=8). For the whole cohort, median time to response was 52 days. Median time to progression in responding patients was not reached. Median PFS was 152 days (95% CI 57-232). Median OS was 467 days (95% CI 134-not reached). Pseudoprogression occurred in one patient. Treatment-related adverse events occurred in 58% (n=21). Of these, 57% (n=12) were non-autoimmune and 43% (n=9) were autoimmune. Grade 3-5 toxicities occurred in 8% (n=3), all were autoimmune mediated on pembrolizumab. In all cases, treatment was stopped. Thirty-one percent (n=11) remain on check-point inhibitors. Conclusion: Overall response rate to immune checkpoint inhibitors in this small cohort was better than reported data in both the first and second line setting (90% Vs 45% and 32% Vs 19% respectively). Time to response was comparable to previous trials (1.7 months Vs 2.1 months). Median PFS and OS were in keeping with large randomised controlled trials (PFS - 5months Vs 2.3-10 months and OS - 15months Vs 12.2 months). Frequency of treatment-related adverse events and clinical effects were lower in this cohort at 58% (n=8) respectively, compared to 69-73.4% and 10-26.6% in trials. In conclusion, our initial results in this real world cohort show immune checkpoint inhibitors are a safe, effective treatment in this group of patients.

P2.04-22 DENDRITIC CELL BASED IMMUNOTHERAPY IN STAGE IIB-IIIA NSCLC PATIENTS: 10-YEARS EXPERIENCE

N. Khranovsky1, O. Skachkova1, O. Gorbach1, V. Sovenko2, A. Ganul2, M. Tomislova3, V. Orel3
1Research Laboratory of Experimental Oncology, National Cancer Institute of Ukraine, Kyiv/UA, 2Department of Thoracic Oncology, National Cancer Institute of Ukraine, Kyiv/UA, 3Research Laboratory of Medical Physics and Bioengineering, National Cancer Institute of Ukraine, Kyiv/UA

Background: Current immunotherapy options for non-small cell lung cancer (NSCLC) patients include tumor vaccines, cellular immunotherapies and immune checkpoint inhibition therapy, but which of them is most efficacious is unknown. Here, we represent a data of 10-years follow-up study of DC-vaccine immunotherapy effectiveness in stage IIB-IIIA NSCLC patients. Method: Two hundred fifty-three eligible patients with stage IIB-IIIA NSCLC were enrolled into the study. Patients were randomly allocated into two groups: 1st - patients received DC-based immunotherapy as adjuvant treatment option, 2nd - control group of patients who received surgery only. DC in amount 4.6±10,3×106 per injection were injected intravenously in 1-3 courses (6 months interval). One course consisted of 5 injections with one-month interval. Patients were monitored for immune function measures before and 1 month after each DC administration. Correlation between EGFR and KRAS mutation and clinical outcome was investigated. Result: Log-rank test showed that the DC-based immunotherapy contributes to significant increase in 5- and 10-years overall survival (OS) and event free survival (EFS) of NSCLC patients. Thus, the 5-years OS rate was 44.4% vs. 30.4% and the 10-years OS rate - 30.3% vs. 13.8% in DC- immunotherapy and control groups respectively (p=0.009); HR=0.60; 95: CI = 0.43-0.85. For patients in DC-immunotherapy group, the 5-years EFS rate was 42.8% in contrast to 23.5% in patients of control group (p=0.0085). At 10-years follow-up, we could observe that the differences in EFS rates between two groups decreases, but remains statistically significant: 22.6% vs 10.5% (p=0.0032); HR=0.58; 95: CI = 0.42-0.80. DCs based immunotherapy is effective modulator of the immune system of NSCLC patients. After the 3rd DC administration, changes in the balance between Th1- and Th2-type immune response have been occurred. Prognostic significance of immunological parameters - TGF-β mRNA expression level, the number of CD4+CD45RO+ cells in circulation, the ratio of CD3+IFN-γ+CD3+IL-4+ after incubation with autologous tumor cells lysate has been revealed. According to proportional hazard Cox regression, EGFR and KRAS mutations were not found to be associated with DC vaccine efficacy in NSCLC patients. Conclusion: DC-based cellular immunotherapy enhanced 10-years OS and EFS in stage IIB-IIIA NSCLC patients. EGFR and KRAS mutations positivity was not predictive of survival benefit from DC based immunotherapy.

P2.04-23 IMMUNE-RELATED ADVERSE EVENTS: THE GROWING PAINS OF IMMUNOONCOLOGY

M. Mooradian1, I. Dagogo-Jack1, J. Gainor2, K. Reynolds3
1Cancer Center, Massachusetts General Hospital, Boston/MA/US, 2Massachusetts General Hospital, Boston/MA/US, 3Massachusetts General Hospital, Boston/US

Background: Immune checkpoint inhibitors (ICI) are associated with a distinct spectrum of toxicities, generally characterized as immune-related adverse events (irAEs). Despite increased recognition and improved treatment of these irAEs, there is a recognized need to develop more effective modulators of the immune system of NSCLC patients. After the treatment of these irAEs, the Massachusetts General Hospital has created a novel inpatient oncology service, the severe ICI toxicity service (SIC), which aims to refine treatment of these irAEs. Method: We retrospectively identified pts with advanced thoracic malignancies who had received standard ICI (anti-PD1/anti-CTLA-4 inhibition) and had been hospitalized at a grade ≥3 irAE. Demographic and clinical data were extracted from the medical chart and a descriptive analysis was performed. Result: We identified 32 pts who required admission for toxicity mgmt. (Table 1). Average age on admission was 67yo (53-86) with an equal distribution between genders. Toxicity onset occurred at 101days (2-579) after the 1st ICI dose with 93.5% receiving anti-PD-(L)1 monotherapy. The most common irAEs were pneumonitis (35%), hepatitis (22%) and colitis (19%). 84% of pts received high dose corticosteroids (1mg/kg) with 15% requiring a 2nd immunosuppressant. In pts who completed a steroid taper, duration of use was 81d (42-192). The average length of stay was 8d (2-24) with 7pts requiring re-admission for toxicity flare. Eight pts (25%) experienced a
grade 5 event (6 pneumonitis, 1 myocarditis, 1 hepatitis). Median PFS and OS were 6.3 months and 8.2 months, respectively.

**Conclusion:** Severe irAEs requiring inpatient admission, though infrequent, result in considerable morbidity and mortality. Improved understanding of these toxicities and the mechanisms underlying their development is crucial. Novel academic efforts, such as the SIC service, are needed to fully characterize irAEs and ultimately develop novel therapeutic strategies to manage them.

**P2.04-25 RANDOMIZED CLINICAL TRIAL COMPARING IMMUNOTHERAPY PLUS SABR (I-SABR) VERSUS SABR ALONE FOR EARLY STAGE NSCLC**

J. Chang,1 L. Feng,2 S. H. Lin,1 J. W. Welsh,1 M. B. Antonoff,1 D. Gomez,2 J. Heymach2

1Radiation Oncology, MD Anderson Cancer Center, Houston/US, 2MD Anderson Cancer Center, Houston/US

**Background:** Section not applicable Stereotactic ablative radiotherapy (SABR), which delivers high biologically effective radiation doses, can kill cancer cells, release tumor-associated antigens, and activate tumor-specific T cells, thereby functioning as a cancer-specific vaccine in situ. The combination of the immune-igniting effects of ionizing radiation with immune checkpoint inhibitors may leverage the effects of radiotherapy, transforming what was once considered a local therapy to a novel systemic treatment. Further, the combined effects of local tumor control plus systemic control may improve cure rate in early stage NSCLC.

**Method:** Section not applicable This is a randomized phase II trial (NCT03110978) designed to study SABR (biological effective dose >100 Gy) with or without concurrent and adjuvant Nivolumab for total of 7 doses in early stage or isolated recurrent NSCLC. Inclusion criteria: stage I disease (tumor size ≤5 cm, N0M0). OR selected cases of stage IIa disease (tumor size >5 cm but ≤7 cm, N0M0), including multiple primary tumors, OR isolated lung-parenchymal recurrent or persistent NSCLC suitable for SABR. Tumor size/blood/stool samples will be collected before/after treatment and at the time of recurrence.

**Results:** Patient free survival (Fx), defined as local recurrence, regional recurrence, distant metastasis, secondary malignancy and death; secondary endpoints: overall survival; toxicity; exploratory analyses of potential predictive markers and immunologic mechanisms of action. Statistical design: It is considered significantly different with a decrease of the 4-year cumulative event rate from 46% to 23%. Assuming a one-sided type I error rate of 0.05, an actual rate of 3.5 patients per month, and an additional 20 months of follow-up, a study with 70 patients in each arm will have 85% power to detect an improvement of 23% in 4-year DFS rate. One interim analysis will be done to allow early termination of the trial should evidence at that time reveal that I-SABR is superior to SABR-only or that no difference is found between the two treatment arms.

**Conclusion:** Section not applicable The trial is ongoing and met with anticipated enrolment rate.

**Keywords:** Immunotherapy, Nivolumab, non small cell lung cancer

**P2.04-24 NIVOLUMAB IN THE “REAL WORLD”: ARE THE RESULTS OF CLINICAL TRIALS REPRODUCIBLE?**

I. Ramos García1, A. Sanchez Gastaldo1, I. Barneto1, P. Ayala1, M. Berclano1, R. Bernabé2, M. Robles1, R. Collado1, M. Alonso2, T. García1, M. Cobo Díos1, J. M. Trigo1

1Radiology Oncology, MD Anderson Cancer Center, Houston/US, 2MD Anderson Cancer Center, Houston/US

**Background:** It has passed more than two years since the approval of nivolumab in the second or third lines of treatment of non-small cell lung cancer (NSCLC) in advanced or recurrent stages, so that we know the results in patients in our area.

The main objective of this study is to analyze the results in a "real" population of different hospitals in Spain since we will be able to compare our results with the once published previously. **Method:** We have reviewed 129 patients with NSCLC, advanced or recurrent stages, treated with nivolumab either in second and subsequent lines of treatment, after progression to a platinum-based scheme from its expanded use until April 2018, in five hospitals in Spain. The information was collected retrospectively of clinical, analytical, pathological and treatment characteristics of the patients. Statistical analysis was performed using the SPSS software vs 21.0, considering the statistical significance if p < 0.05. **Result:** With a median follow-up of 6 months (0-31), the overall survival (OS) was 9 months (5.86-12.14). Patients with ECOG 0-1 presented a median OS of 11 months compared to 3 months of median OS in patients with ECOG 2 (p: 0.001). If the response to previous treatment was complete response, partial response or stabilization of the disease, they will have a median OS of 12 months compared to 6 months if the best response was progression (p: 0.002). There is also a statistically significant difference in terms of overall survival in relation to the existence of toxicity for immunotherapy or not (median of 13 versus 6 months p: 0.004). The overall survival of patients who had progressed beyond 6 months after the start of treatment with prior chemotherapy was significantly greater than patients who had progressed in the first 6 months after the start of chemotherapy (median of 4 months versus median of 13 months, p: 0.001). **Conclusion:** Immunotherapy has come to stay taking part of the usual clinical practice of patients with lung cancer. The results obtained in our population are comparable to those previously published, with an important group of patients that responded to immunotherapy or stabilized even for a long time. However, we highlight that also there is a percentage of patients, who progress early. We see fundamental to find or recognize, not just the ideal biomarker that helps to predict response, but those clinical characteristics that can make us presage a poor result.

**Keywords:** Immunotherapy, Nivolumab, non small cell lung cancer

**P2.04-26 INTERIM RESULTS FROM A PHASE I/II TRIAL OF NIVOLUMAB IN COMBINATION WITH CIMAVAX-EGF AS SECOND-LINE THERAPY IN ADVANCED NSCLC**

G. Dy1, A. Dozier1, M. Reid1, K. Lee1, A. Miller1, P. Wallace1, I. Puzanov1, M. Opyrchal1, M. Enstoft1, C. Johnson1, Z. Mazorra1, D. Saavedra1, K. Leon1, A. Lage1, T. Crombet1

1Roswell Park Comprehensive Cancer Center, Buffalo/US, 2Center of Molecular Immunology, Havana/CA

**Background:** CIMAvax-EGF (CE), a recombinant anti-human epidermal growth factor (EGF) vaccine, has demonstrated survival benefit as maintenance therapy in advanced NSCLC. We report the results from the dose-escalation phase I portion of the study investigating CE in combination with Nivolumab (N) in patients (pts) with advanced...
stage, previously treated immunotherapy-naïve NSCLC. Method: This is an open-label phase I dose-escalation study with a 3+3 design. Intramuscularly injected in two dose levels (1.2 and 2.4 mg, given q 2 weeks x 4 doses during the induction phase, then q monthly during the maintenance phase) in combination with 240 mg iv q 2 weeks. Pts remain on treatment until disease progression, serious toxicity or consent withdrawal. The primary objective is to determine the safety and recommended phase II dose (RP2D) of CE in combination with N. Secondary objectives include tumor response and correlative markers of immune response. Toxicities are graded according to CTCAE v4.03. No intra-patient dose escalation is allowed Result: 9 pts have completed DLT assessments (7 female: 2 male). Median age is 58 (range 46–69). All pts have EGFR, KRAS and ALK wildtype NSCLC. Adenocarcinoma is the predominant histologic subtype (7/9). One pt had Gr 3 myocardiitis (LVEF 25%–30%) attributed to N alone on Cycle 1 day 8 and taken off study. LVEF improved (60%–65%) but pt eventually had Gr 3 brain hemorrhage due to brain metastasis, unrelated to treatment, on Cycle 1 day 29. No other treatment-related CTC grade 3+ AE attributed to either N or CE. The RP2D dose was established at 2.4 mg CE for Q. Objective response rate of 44% was seen (4 PRs: 3 adenocarcinoma, 1 squamous; 3 PD-L1 ≤ 1%, 1 PD-L1 60%). There is a significant inverse correlation (p<0.001) between the temporal change in anti-EGF Ab titers and the change in serum EGF levels based upon a generalized linear model. 71% of pts (95% CI: 63%–92%) achieved an anti-EGF Ab titer of > 1:4000 after 3 vaccine doses by day 43. We will present additional information on safety, efficacy profile and correlative data in the meeting Conclusion: Combination of N+CE did not show unexpected toxicities. Preliminary efficacy and immunological data warrant further investigation.

Keywords: CIMAvax, Nivolumab, Vaccine

Background: Bemcentinib (BGB324) is a first-in-class, highly selective oral inhibitor of the AXL tyrosine kinase currently in phase II clinical development across several cancer types. AXL overexpression has been observed in pts failing anti-PTD-1 therapy in several cancers whereas AXL inhibition via bemcentinib has shown synergetic effect with checkpoint blockade in pre-clinical models of NSCLC. In pts with advanced, pre-treated NSCLC, bemcentinib monotherapy led to disease stabilisation in 2 out of 8 pts including evidence of tumour reduction. Combination therapy of bemcentinib with EGFR inhibition indicated the potential of AXL blockade in resistance to targeted therapy in advanced EGFR therapy resistant NSCLC. Evidence of immune activation following bemcentinib monotherapy was observed in AML patients. This open label, single-arm, two-stage Phase 2 study was designed to test whether AXL inhibition via pembrolizumab in combination with advanced, previously treated adenocarcinoma of the lung. Method: Patients with documented Stage IV adenocarcinoma of the lung who had progressed on previous platinum chemotherapy and – if applicable – at least one other line of licensed EGFR or ALK inhibitors were eventually measured using the Discovery Map v3.3 panel (Myriad RBM) in pts pre-dose and at C2D1. Result: As time of writing, the study had fully recruited its first stage. Of 24 patients enrolled, 14 were ongoing. 6 of 10 patients who had reached their first scan showed evidence of tumor shrinkage including 3 pts with partial responses in their target lesions. 2 patients had stable disease. There were no grade 4 treatment-related events. Dose reduction from 200 to 100 mg/d of bemcentinib as a consequence of adverse events was required in 12% of patients. Correlation of AXL and PD-L1 expression with response was evaluated. Soluble AXL plasma levels were increased following the first cycle of treatment (p<0.001). Conclusion: A preliminary analysis of response to combination treatment during the first stage of this study as well as biomarker correlation will be presented at the meeting. Clinical trial information: NCT03184571

Keywords: Axl, Pembrolizumab, combination

P2.04 IMMUNOONCOLOGY TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.04-28 USE OF IMMUNE CHECKPOINT INHIBITORS (ICIS) IN PATIENTS WITH REFRACTORY NON-SMALL CELL LUNG CANCER (NSCLC) AND POOR PERFORMANCE STATUS (PS) J. Thompson, C. Arce-Lara, S. Menon
Medicine, Medical College of Wisconsin, Milwaukee/WI, US

Background: Patients with poor PS generally do not tolerate chemotherapy well, and best supportive care is advocated for patients with Eastern Cooperative Oncology Group (ECOG) PS of 3 or greater. However, immune checkpoint inhibitors (ICIs) are generally better tolerated than conventional chemotherapy, making these drugs attractive options for poor PS patients. Scant literature exists on the safety and efficacy of ICIs in patients with poor PS. Method: We retrospectively identified patients who received single-agent programmed death-1 (PD-1) or programmed death-ligand 1 (PD-L1) inhibitors for refractory NSCLC between January 2015 and December 2017 at our institution. Descriptive statistics of patient-, disease-, and treatment-related variables were generated. Overall survival (OS) was stratified by performance status and compared utilizing the Kaplan-Meier method. Multivariable survival analysis was performed using a Cox regression model. Result: In total, 111 patients received PD-1/PD-L1 inhibitors for refractory NSCLC. PS 0-1 was 6/5 (5%) patients, 1 in 93 (48%) patients, 2 in 37 (33%) patients and 3 in 10 (9%) patients, and 5 patients did not have a recorded PS. Median OS was significantly longer in the PS 0-1 group than the PS 2-3 group (11.3 months vs 4.1 months, p<0.02). Poorer PS (ECOG 2-3) was significantly associated with increased risk for death when controlling for confounding variables (HR 2.1, p=0.004). Specifically, within the PS 3 group, 2 of 10 patients developed objective responses (1 partial response, 1 complete response). Two patients (20%) had progressive disease. Six patients were non-evaluable for response due to death. The median overall survival was 2.6 months, with the two responding patients both alive over 540 days from initial ICI dose. However, 5 of the 10 patients died within 50 days of initial ICI dose. One of the responding patients developed nivolumab-induced pancreatitis requiring hospitalization, and the other responding patient developed significant, permanent cognitive decline without clear etiology. Conclusion: This study confirms PS as a strong predictor of OS in refractory NSCLC patients receiving ICIs. Overall, ICIs are well tolerated with PS 3 sufficient poor outcomes with ICIs. However, 2 patients with PS 3 responded to ICI, and both were still alive over 1.5 years from the initial ICI dose. Still, ICI toxicity was common in this population. More experience with PS 2-3 patients should be reported to further evaluate the safety and efficacy of ICIs in this setting. Bioinformatic selection with high tumor PD-L1 or tumor mutation burden may help improve appropriate utilization of ICIs in this challenging population.

P2.04-29 PRELIMINARY RESULTS WITH TISLELIZUMAB IN CHINESE PATIENTS WITH NON-SMALL CELL LUNG CANCER (NSCLC) AND POOR PERFORMANCE STATUS (PS) Y. Wu1, J. Zhao2, Q. Zhang3, H. Pan4, J. Wang5, Y. Bai3, J. Li6, Z. Wang6, C. Wei6, X. Li6, Q. Zhou1
1Guangdong Lung Cancer Institute, Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou/CN; 2Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Thoracic Medical Oncology of Medical College of Peking University Cancer Hospital & Institute, Beijing/CN; 3Harbin Medical University Cancer Hospital, Harbin/CN; 41st Run Run Shaw Hospital, Zhejiang University, Hangzhou/CN; 5Cancer Institute and Hospital, Chinese Academy of Medical Sciences, Beijing/CN; 6Beigene (Beijing) Co., Ltd., Beijing/CN

Background: NSCLC accounts for 80–85% of all lung cancers and has a poor prognosis at later stages. Immune checkpoint inhibitors have shown efficacy in patients (pts) with advanced NSCLC. Tislelizumab is a humanized IgG4 monoclonal antibody with high affinity/specificity for PD-1. Tislelizumab was specifically engineered to minimize FcγR binding on macrophages that, based on preclinical evidence, is believed to

Keywords: Tislelizumab, Chinese patient, PD-1

P2.04 IMMUNOONCOLOGY TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00
minimize potentially negative interactions with other immune cells. In a phase 1 study, tislelizumab was generally well tolerated and showed antitumor activity in NSCLC pts: 200 mg IV Q3W was established as the recommended tislelizumab dose. Method: In the ongoing indication-expansion phase of this study, Chinese pts with histologically confirmed NSCLC were enrolled into PD-L1-high (PD-L1+ ≥ 10% tumor cells expressing PD-L1) and PD-L1low (PD-L1–) cohorts. Antitumor activity (RECIST v1.1) and safety/tolerability (NCI-CTCAE v4.03) were assessed. Result: As of 8 Dec 2017, 42 NSCLC pts (median age 54 yr [range 37–72]) were enrolled; 17 were PD-L1+ and 25 were PD-L1–. Most patients were male (60%), former/current smokers (57%), and had received prior therapy (95%). Adenocarcinoma was the most prevalent histology (57%). Median follow-up was 4.5 mo and 23 pts remain on treatment. Of the 39 response-evaluable pts, 4 (n=2/14, PD-L1–; n=2/25, PD-L1+) achieved confirmed PR and 20 (n=6/14, PD-L1–; n=14/25, PD-L1+) achieved SD, including 4 (n=2, PD-L1–; n=2, PD-L1+) with unconfirmed PR. Across the study population, ORR was 10% and DCR was 61.5%. ORRs by cohort were 14% (PD-L1+) and 8% (PD-L1–), respectively. Common treatment-related AEs were increased AST (24%), increased ALT (19%), hypothyroidism (12%), and rash (12%). Five grade 3 or greater treatment-related AEs occurred in 4 pts (increased AST [n=2], hyperglycemia, increased ALT, and increased GGT [n=1 each]). No treatment-related grade 5 events were reported. Conclusion: Tislelizumab was generally well tolerated and demonstrated antitumor activity in previously treated pts with advanced NSCLC. A global phase 3 study (NCT03358875) of tislelizumab vs docetaxel as potential second/third-line therapy in NSCLC pts who progressed after a platinum-based regimen is ongoing.

TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.04-30 PD-1/PD-L1 INHIBITION MIGHT BE AN OPTION FOR THE TREATMENT OF ADVANCED PRIMARY PULMONARY LYMPHOEPITHELIOMA-LIKE CARCINOMA

K. Yin1, Z. Xie1, X. Yang1, W. Guo1, Y. Chen1, W. Yan3, J. Yang2, Q. Zhou2, W. Zhong1, Y. Wu2, X. Zhang2
1The Second School of Clinical Medicine, The Second School of Clinical Medicine, southern Medical University, Guangzhou/CN; 2Guangdong General Hospital, Guangdong Lung Cancer Institute, guangdong General Hospital, Guangzhou/CN

Background: Primary pulmonary lymphoepithelioma-like carcinoma (LELC) is a rare subtype of non-small-cell lung cancer mostly reported in Asian countries, which is frequently associated with Epstein-Barr virus (EBV) infection. There is no consensus on the choice for the treatment of advanced primary pulmonary LELC. The utility of PD-1/PD-L1 inhibitor to this cancer type remains poorly understood. Method: From January 2008 to April 2017, a total of 53 patients receiving surgical removal and diagnosed as primary pulmonary LELC in Guangdong Lung Cancer Institute (GLCI) were enrolled in this study. Sections formalin-fixed and paraffin-embedded (FFPE) tumor samples were stained with PD-L1 antibody (clone E1L3N, Cell Signaling Technology) by immunohistochemistry (IHC). PD-L1 expression more than 1% in tumor cells was considered as PD-L1 positive. In addition, the medical records of 13 primary pulmonary LELC patients who received the treatment of PD-1/PD-L1 inhibitors in GLCI. Their clinicopathological characteristics and relevant prognostic data were analyzed. Result: Among the 53 patients with operable disease, the median age was 56 (36–78), there were 26 males and 27 females, 15 smokers and 38 non-smokers. Positive rates of PD-L1 in the early pulmonary LELC were 78.8% (41/52, one specimen can’t evaluate) and 73.1% (38/52) and 23.1% (12/52) respectively at the cutoff values of 1% and 5% and 50% positivity in tumor cells. ORR of PD-1/PD-L1 inhibition in the evaluable 12 patients with advanced LELC was 16.7% (2/12), and DCR was 73.0% (9/12). In the 6 patients with positive PD-L1 expression, ORR was 33.3% (2/6), DCR was 100.0% (6/6). The two responder patients got 55% and 64% shrinkage of the tumors respectively. All patients had no EGRF mutations. Conclusion: This preliminary study showed that pulmonary LELC has remarkably high incidence of PD-L1 expression. PD-1/PD-L1 inhibition may be an option for the treatment of advanced primary pulmonary LELC, which needs further investigation.

P2.06 MESOTHELIOMA

TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.06-01 SHORT-TERM OUTCOME OF ENTIRE PLEURAL INTENSITY-MODULATED RADIOTHERAPY IN A NEOADJUVANT SETTING FOR MALIGNANT MESOTHELIOMA

J. Hong1, Y. Kim1, S. Kim2, S. Hong2, K. Kim3, S. Moon3
1Department of Radiation Oncology, Seoul St. Mary’s Hospital, Seoul/KR; 2Department of Internal Medicine, Seoul St. Mary’s Hospital, Seoul/KR; 3Department of Thoracic & Cardiovascular Surgery, Seoul St. Mary’s Hospital, Seoul/KR

Background: The purpose of this study is to evaluate the safety and efficacy of the tri-modality treatment with neoadjuvant intensity-modulated radiotherapy (IMRT) for a resectable clinical T1-3N0-1M0 malignant pleural mesothelioma (MPM). Method: A total of ten malignant mesothelioma patients who received neoadjuvant radiotherapy between March 2016 and April 2018 were reviewed. Patients received 25 Gy in five fractions to entire ipsilateral hemithorax including clinically suspicious lymph nodes. All patients were treated with helical tomotherapy. Result: All of the patients were men with a median age of 60 years. Epithelial subtype was found in nine patients (90%) and type was unknown in one patient (10%). All patients received neoadjuvant chemotherapy with Almita-cisplatin(AP) regimen. Nine patients (90%) completed 25Gy/5fxs radiotherapy and one (10%) completed 20Gy/4fxs. IMRT was well tolerated with only one acute grade 3 radiation pneumonitis. Surgery was performed one week (1 - 15 days, median 7.5) after completing IMRT. Extrapleural pneumonectomy (EPP) was performed in three patients (30%), and pleurectomy and decortications (PD) in six (60%). There was no grade 3+ surgical complication except one patient died from septic shock after EPP in one-month. Based on operative findings and pathologic stagings, adjuvant chemotherapy was delivered in six patients (60%), and one (10%) was decided to start adjuvant radiotherapy. After a median follow-up of 10.6 months (range 1.7 - 24.2), there is no evidence of local recurrence or distant metastasis. Conclusion: Neoadjuvant intensity-modulated radiotherapy (IMRT) can be safely delivered with a favorable radiation complication. An optimal strategy has an option on the basis of resectability. Further studies need to look at long-term outcomes.

P2.06 MESOTHELIOMA

TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.06-02 FEASIBILITY OF INTENSITY MODULATED RADIOTHERAPY AFTER PLEU'RECTOMY/DECORTICATION FOR MALIGNANT PLEURAL MESOTHELIOMA PATIENTS

Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerologia, Mexico City/MX

Background: Treatment strategies for patients with malignant pleural mesothelioma (MPM) include pneumectomy followed by radiation with considerable efficacy, although post-surgical morbidity and mortality are frequent. Recently, more conservative surgical approaches have been implemented, including Pleurectomy/Decortication (P/D), which spares the lung tissue while removing the malignant pleura and visible tumor. Although this approach significantly reduces surgical morbidity, it poses a challenge for post-surgical radiotherapy, as the risk of developing radiation pneumonitis is high. In this feasibility study we evaluated the loco-regional control and toxicity profile in patients with MPM treated with induction chemotherapy followed by P/C and Intensity Modulated Radiotherapy (IMRT) to the entire thoracic cavity. Method: Patients with MPM treated from October 2011 to February 2014 were screened for inclusion. All patients underwent 4 cycles of induction chemotherapy with cisplatin/gemcitabine or cisplatin/pemetrexed without progression followed by P/D. Thereafter, patients received IMRT to the thoracic cavity (54 Gy in 28-30 fractions), treated with 9-11 non-coplanar fields. Result: A total of 20 patients were screened for inclusion, from which 13 patients were included in the final analysis. The median age was 61.3 ±10.3 years. 62.9% (9/13) were classified as low risk according to the European Organization for Research and Treatment of Cancer prognostic group. From the 13 patients, 12 (92.3%) had a histological diagnosis of epithelioid mesothelioma, while one patient (7.7%) presented with a sarcomatoid histology. Partial response to chemotherapy was observed in 61.5% (8/13) and stable disease in 38.5% (5/13). After P/D, only 23% (3/13) had residual macroscopic disease. The median follow-up was 23.6 months (7.5–44.7). Nine patients had recurrence or progression (6 distant [67%] and 3 loco-regional recurrences [33%]). 2-year Progression Free Survival was 31.3% (95%CI[8.72-57.51]). Only one patient died due to
Liver metastases. Any grade Pneumonitis was reported in 69.2% (9/13), however only 22.2% (n=2) of patients presented grade ≥3 pneumonitis. The VS of the contralateral lung was above 70% and the V20 of the total lung was 45% in these patients. No IMRT-related deaths were observed throughout the study. Conclusion: Results from this pilot study show that it is feasible to administer IMRT to patients who have undergone P/D while maintaining an adequate toxicity profile. In our study pulmonary toxicity was frequent; however there was only one event of grade 4 pneumonitis, meanwhile the loco-regional control using this treatment modality shows great promise. However, a larger study with a more robust sample size is required to draw strong conclusions.

P2.06 MESTOHELIOMA
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.06-03 CAN WE PREDICT PATHOLOGICAL NODAL POSITIVITY IN MALIGNANT PLEURAL MESOTHELIOMA FROM PREOPERATIVE CLINICAL VARIABLES?
S. Buder, J. Hargrave, M. Di Martino, K. Lau, D. Waller
Thoracic Surgery, St Bartholomew’s Hospital, London/GNB

Background: The associated morbidity from radical surgery implies that it should only be offered to those with the best prognosis. The prognosis following radical surgery for mesothelioma is significantly influenced by the presence of pathological nodal metastases. However, the prediction of nodal positivity is inaccurate and complicated. This can be attributed to the unique lymphatic drainage pattern in which many nodal groups (internal mammary, intercostal) cannot be biopsied preoperatively. Previous studies have correlated preclinical variables with poor prognosis (Pass, J Thorac Oncol. 2014;9:956–64). Method: We have correlated clinical variables known to be associated with overall prognosis in mesothelioma with the pathological findings of systematic nodal dissection at thoracotomy and pleurectomy/decortication. The variables analysed: patient demographics, Haemoglobin and CRP, T and N stage on preoperative CT scan, duration of symptoms of weight loss and chest pain and cell type on preoperative biopsy. Data were summarised as median (range), mean (SD) and subject to Chi-squared test for the categorical data and Mann–Whitney Test for the numeric data and to regression analysis. Result: 32 patients (25 males; 7 females) underwent extended pleurectomy decortication with intraoperative systematic nodal dissection. On pathologic diagnosis post-resection, 20 (62%) patients required to draw strong conclusions. Meanwhile the loco-regional control using this treatment modality shows mean: pulmonary toxicity was frequent; however there was only one event of grade 4 pneumonitis, meanwhile the loco-regional control using this treatment modality shows great promise. However, a larger study with a more robust sample size is required to draw strong conclusions.

P2.06 MESTOHELIOMA
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.06-04 THROUGHPUT OF A SPECIALIST MESOTHELIOMA MULTIDISCIPLINARY TEAM MEETING AT A RADICAL TREATMENT CENTRE IN THE UNITED KINGDOM
E. Caruana, A. Dawson, S. Rathinam, A. Nakas
Thoracic Surgery, Glenfield Hospital, Leiceste/GB

Background: Multidisciplinary team (MDT) meetings are of particular value in cases where decision making is complicated by clinical equipoise. Patients should be actively considered for all established treatment and clinical trial options for which they are suitable. Method: A specialist regional mesothelioma MDT – involving physicians, radiologists, oncologists, surgeons, and allied health professionals - was established in 2013. Patients were considered for the full range from palliative to radical surgical treatment options, all of which are offered locally at our institution. Electronic records of MDT activity were retrospectively analysed. Result: 543 patients - 82% were male, average age 71 years - were discussed in our specialist MDT, between July 2013 and March 2017, with referrals from 50 hospitals from around the United Kingdom. 61% of patients were from outside the direct specialist referral (regional) catchment area. Patients were recommended for radical surgery (44%), chemotherapy or radiotherapy (11%), chemotherapy and radiotherapy (11%), or palliative care (6%). Average survival post MDT discussion was 8±6 months. Conclusion: A specialist regional mesothelioma MDT is invaluable in the context of patient throughput; and is valuable in determining treatment strategies. Its impact on survival and quality of life outcomes is still to be determined.

P2.06-05 TTFIELDS APPLIED TO THE TORSO AND UPPER ABDOMEN: SAFETY META-ANALYSIS OF 176 PATIENTS FROM FOUR PHASE II-III TRIALS
G. Ceseroli1, M. Pless2, M. Benavides3, I. Vergote4
1Cliniche Humanitas Gavazzeni, Department of Oncology, Bergamo/IT, 2Chefarzt Medizinische Onkologie, Winterthur/CH, 3Hospital Universitario Regional Y Virgen de La Victoria, Malaga/ES, 4University Hospitals Leuven, Leuven/BE

Background: Tumor Treating Fields (TTFields), a non-invasive, antimitotic treatment delivered through transducer arrays, is approved for glioblastoma. The phase 3 trial in newly diagnosed glioblastoma showed no significant increase in systemic adverse events (AEs) except for localized dermatitis underneath the arrays. The safety of TTFields was investigated in four phase I-II non-brain malignancies: non-small-cell lung cancer (NSCLC), malignant pleural mesothelioma (MPM), pancreatic cancer and ovarian cancer. Method: The TTFields phase I-II studies analyzed were: EF-15 (n=41, advanced NSCLC with pemetrexed), PANOVA (n=40, advanced pancreatic adenocarcinoma with gemcitabine +/- nab-paclitaxel), STELLAR (n=64, MPM with platinum/pemetrexed) and INNOVATE (n=31, recurrent ovarian carcinoma with weekly paclitaxel). TTFields were applied for 12-18 hours at 150-200 kHz per tumor histology. Patients received standard-of-care systemic chemotherapy for their disease. Severity and frequency of AEs and association with TTFields were evaluated (CTCAE V 4.0). Result: Patient median age was 69 years (range 41-81), 73 (49-81), 68 (43-78) and 60 (45-77) for EF-15, PANOVA, STELLAR and INNOVATE, respectively. Patients were ECOG status 0-1, except for 7 patients in EF-15 with ECOG ≥2. Observed toxicities were mostly related to underlying disease or standard chemotherapy. Grade 1-2 gastrointestinal (GI) toxicities were: constipation (16%), diarrhea (14%), nausea (27%) and vomiting (13%). Grade 1-2 general disorders such as asthenia were common but less than 20%. Grade 3-4 dyspnea was observed in 6% of NSCLC patients. No clinically significant cardiac AEs were observed and mild arrhythmias were observed in less than 2% of patients. The common TTFields-related AE was dermatitis under the transducer arrays (50% Grade 1-2; 6% Grade 3 dermatitis and 7% Grades 1-2 pruritus). Dermatologic AEs managed using published guidelines were fully resolved. Conclusion: Treatment of solid tumors with TTFields (150-200 kHz) to the lungs, pleura, abdomen and upper pelvis did not result in treatment-related pulmonary, cardiac, hematological or gastrointestinal toxicity. Expected dermatological toxicity (50%) beneath the transducer arrays was easily managed.

Keywords: TTFields; torso arrays; Safety meta-analysis

CT correctly predicted positive node status in 30% of cases and negative node status in 80% of cases. Conclusion: Nodal positivity in patients suitable for EPD cannot be reliably predicted by CT but can be inferred from certain clinical variables. Future work in a larger population is required to identify a definitive pre-operative model. This will allow for better selection of patients for primary surgical intervention or alternatively for induction chemotherapy.

Keywords: Mesothelioma, Lymph nodes, Pleura
**P2.06-06 ROLE OF GITRL-GITR SYSTEM IN PROMOTING PROLIFERATION OF MALIGNANT MESOTHELIOMA**

M. Cha$^{1}$, L. Wu$^{1}$, Z. Yun$^{1}$, Y. Zhao$^{1}$, M. Kohno$^{1}$, M. De Perrot$^{4}$

$^{1}$Latner Thoracic Surgery Research Laboratories, Division of Thoracic Surgery, Princess Margaret Cancer Centre and Toronto General Hospital, University Health Network, Toronto/ON/CA, $^{2}$Latner Thoracic Surgery Research Laboratories, Division of Thoracic Surgery, Princess Margaret Cancer Centre and Toronto General Hospital, University Health Network, Toronto/ON/CA, $^{3}$Latner Thoracic Surgery Research Laboratories, Toronto General Research Institute, Toronto/ON/CA, $^{4}$Thoracic Surgery, University Health Network, Toronto/ON/CA

**Background:** Using microarray analysis to compare the gene expression profile of untreated murine mesothelioma cell line (RNS), RNS treated with cisplatin, RNS treated with radiation, and enriched mesothelioma stem cell (RNS-EDS-Puro2), we found 41 genes potentially linked to cell stemness. Among these 41 genes, Tnfsf18 (GITRL) was one of the cell surface markers which is likely related to tumor proliferation. We therefore decided to analyze the role of this ligand and its receptor (GITRL-GITR system) in proliferation of human mesothelioma cancer cells.

**Method:** Three human mesothelioma cell lines (CRL5820, CRL5915, CRL5946) were used in this study. They were treated with cisplatin and Cs-137 irradiator respectively. The rt-PCR and Western Blot were used to evaluate the GITRL and GITR expression level at different time points. To evaluate the effect of GITRL-GITR system in mesothelioma cell lines we design in vitro and in vivo model for it. A neutralizing monoclonal antibody (mAb) could be demonstrated in vitro decreased cell growth and survival rate in mesothelioma cell lines after chemotherapy or radiotherapy. In vivo model we injected the CRL5946 cells into the peritoneal cavity and implanted patient-derived xenograft subcutaneously of the NOD/SCID mice. We sacrificed mice 4 weeks later to evaluate tumour spheres formation number and tumour growing curve.

**Result:** All the three mesothelioma cell lines demonstrated increased expression of Tnfsf18 (GITRL) and Tnfsf18 (GITR) at an mRNA and protein levels after treatment with chemotherapy or radiotherapy. Breaking the GITRL-GITR system with neutralizing mAb decreased cell growth and survival rate in mesothelioma cell lines after chemotherapy or radiotherapy. In vitro cell viability test, the MTT test results showed in cisplatin-treated or radiation-treated cell lines with adding mAb to break GITRL-GITR system, the cell viability decreased. In vivo xenograft model of CRL5946 cell line which is treated in advance by chemotherapy or radiotherapy, the average tumor sphere number (>100um) also decreased after using mAb intraperitoneally. The inhibiting effect of GITRL neutralizing monoclonal antibody could be demonstrated in vitro and in our in vivo model. In patient-derived xenograft subcutaneous model, the mAb could also delay cell growth. **Conclusion:** The results of our study demonstrate that the GITRL-GITR system could play an important role in mesothelioma cells growth and survival especially after chemotherapy or radiotherapy.

**Keywords:** Mesothelioma, GITR-GITL system

**Background:** Malignant mesothelioma (MM) is an aggressive malignancy of the pleura with limited therapeutic options, and is associated with a poor prognosis. EGFR is known to be highly over-expressed in mesothelioma with reported EGFR overexpression between 44 to 97%. We have developed an anti-EGFR antibody (ABT-806), which is tumour specific and robustly inhibits EGFR-expressing tumours. We aimed to establish the validity and feasibility of targeting tumour expressed EGFR in MM using ABT-806 novel ADCs (ABT-414 and ABBV-221).

**Method:** We evaluated EGFR and mAb 806 immunohistochemistry in 4 MM cell lines (MSTO-211H, MSTO-211H, NCI-H2052, NCI-H2052). In vivo xenograft models of ABT-414, and ABBV-221 were used to evaluate the anti-tumour activity of ABT-806 and ADCs. Tumour in-vivo was also shown.

**Result:** ABT-806 ADCs show potent anti-tumour activity in MM model, and warrant further exploration as a potential therapy for MM.

**Keywords:** antibody drug conjugate, epidermal growth factor receptor (EGFR), Mesothelioma

**P2.06-09 MIST3: A PHASE II STUDY OF ORAL SELECTIVE AXL INHIBITOR BEMCENTINIB (BGB324) IN COMBINATION WITH PEMBROLIZUMAB IN PTS WITH MALIGNANT MESOTHELIOMA**

M. Krebs$^{1}$, L. Carter$^{2}$, S. Villa$^{3}$, A. King$^{1}$, C. Massey$^{4}$, J. Lorenz$^{5}$, E. Darlington$^{6}$, D. Fennell$^{7}$

$^{1}$Experimental Cancer Medicine Team, the Christie NHS Foundation Trust, the University of Manchester and the Christie NHS Foundation Trust, Manchester/ GB, $^{2}$Experimental Cancer Medicine Team, The Christie NHS Foundation Trust, Manchester/GB, $^{3}$Leicester Cancer Research Centre, University of Leicester & Leicester University Hospitals, Leicester/GB, $^{4}$Bergenbio, Bergen/NO

**Background:** Malignant mesothelioma is a cancer with significant unmet need, with only one line of therapy licenced in the UK. AXL is a member of the TAM (Tyro3, AXL, Mer) family of receptor tyrosine kinases that regulate multiple cellular processes including survival, proliferation and migration. AXL analysis of AXL expression in patients with mesothelioma reported an overexpression in 74% of the tumours examined. Several cell types associated with the suppressive tumour immune microenvironment express AXL, including natural killer cells and tumour-associated macrophages. AXL is an important regulator of tumour plasticity.
related to epithelial-to-mesenchymal transition, thereby contributing to evasion of antitumour immune response. Hence, AXL signalling contributes uniquely to tumour intrinsic and microenvironmental immune suppression. Bemcentinib (BGB8324), a potent, selective orally bioavailable small molecule inhibitor of AXL, has demonstrated effective inhibition in pre-clinical models and is currently being trialled in combination with pembrolizumab in patients with advanced non-small cell lung cancer, breast cancer and melanoma. Pembrolizumab has high affinity and potent receptor blocking activity for PD-1, therefore inhibiting the interaction with PD-L1. Recent data showed that the combination of bemcentinib with axillary anti-PD-1 blockade profoundly enhanced antitumour activity in the syngeneic Lewis Lung (LL/2) lung cancer model. Method: This is a single arm phase IIa clinical trial of bemcentinib and pembrolizumab in patients with relapsed mesothelioma. MIST3 is one arm of a broader umbrella study - a stratified multi-arm phase IIa clinical trial to enable accelerated evaluation of targeted therapies for relapsed malignant mesothelioma. 25 patients recruited to MIST3 will receive a loading dose of 400mg bemcentinib, followed by daily doses of 200mg, alongside IV infusions of 200mg pembrolizumab on day-one of every 21-day cycle. The primary objective is to establish 12 week disease control rate (DCR), secondary objectives include safety and tolerability, objective response rate and 24 week DCR, as assessed by modified RECIST. Patients will continue therapy until disease progression, unacceptable toxicity or a maximum 2-year duration. A pre-treatment biopsy and serial plasma samples will be mandatory for exploratory research. Exploratory objectives include: correlation of PD-L1 and AXL expression levels with response, tumour mutation burden to interrogate tumour tissue, correlation of a standard chemotherapy regulated gene signature in RNA extracted from tumour samples, to correlate the impact of tumour infiltrating lymphocytes with response, and correlations between gut microbiome composition and response to therapy will be sought using 16sRNA sequencing. First patient first visit is anticipated: Q3 2018. Result: Section not applicable Conclusion: Section not applicable Keywords: Mesothelioma, Immunotherapy, Axl inhibition

P2.06 MESOTHELIOMA
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.06-11A PHASE I/II STUDY OF INTRAPLEURAL AD-SDG-REIC ADMINISTRATION IN PATIENTS WITH REFRACTORY MALIGNANT PLEURAL MESOTHELIOMA
Y. Goto1, Y. Ohe1, K. Kiribayashii, T. Nakano1, M. Okada1, S. Toyooka1, H. Kumon1, Y. Nakaniishi1
1Thoracic Oncology, National Cancer Center Hospital, Tokyo/JP, 2Department of Respiratory Medicine, Hyogo College of Medicine, Hyogo/JP, 3Division of Respiratory Medicine, Department of Internal Medicine, Otemae Hospital, Osaka/JP, 4Department of Thoracic Surgery, Hiroshima University Hospital, Hiroshima/JP, 5Department of Thoracic Surgery and Breast and Endocrinological Surgery, Okayama University Graduate School of Medicine, Okayama/JP, 6Department of Urology, Okayama University Graduate School of Medicine, Okayama/JP, 7Research Institute for Diseases of the Chest, Kyushu University, Fukuoka/JP

Background: Reduced expression in immortalized cell (REIC)/Dickkopf-3 (Dkk-3) is a tumor-suppressor gene and REIC/Dkk-3 expression was markedly downregulated in various human cancer cells. REIC/Dkk-3 protein is also known as a key player, namely an antagonist of the Wnt signaling pathway. Ad-SDG-REIC is an adenosinarovector carrying REIC/Dkk-3 that mediates cancer cell death induction and anti-cancer immunity augmentation. Method: We conducted a phase I/II, 3+3 design, dose escalation study in malignant pleural mesothelioma (MPM) patients (pts) with measurable lesions. Pts with refractory to or unsuitable for standard chemotherapy received 2 intrapleural administrations of Ad-SDG-REIC on days 1 and 4. Three escalating doses of level (DL) 1: 3.0×1010, DL2: 1.0×1012 and DL3: 3.0×1012 viral particles were employed. This dosage and regimen were set by considering the reason of safety, efficacy and dose-limiting toxicities (DLTs) of Ad-SDG-REIC. Result: 11 of 13 pts have been treated at DL1 (n=4 included one fatal case within 32 days), DL2 (n=3) and DL3 (n=6). Male: 100%; median age 70; PS 0: 23%, 1: 69%, 2: 8%; epithelial/biphasic histology: 69%/15%; Stage III-IV: 77%; previous chemotherapy use with platinum-pemetrexed: 92%. Treatment-related AEs (TRAEs) were all Grade 1-2 and no DLTs occurred. The most frequent TRAEs were fever and CRP increase based on adenovirus infection. Tumor responses assessed by independent central review showed that there was no objective response and DCR was 62% (8/13 pts). Median PFS was 3.4 months at all groups and 5.7 months at DL3. A remarkable increase of REIC/Dkk-3 concentration in pleural fluid was determined (6/13 pts, prominently high in DL3). Conclusion: The intrapleural administration of Ad-SDG-REIC up to 2 cycles was safe and well tolerated in MPM pts and promising results of efficient REIC/Dkk-3 expression and durable disease control were obtained. We are planning phase II study using repeated intrapleural or intratumoral administration. Keywords: Wnt antagonist, gene therapy, Mesothelioma

P2.06 MESOTHELIOMA
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.06-10 COMBINATION CHEMOTHERAPY WITH CISPLATIN, PEMETREXED, AND NIVOLUMAB FOR MALIGNANT PLEURAL MESOTHELIOMA: A TRIAL IN PROGRESS
N. Fujimoto1, K. Aoe2, T. Kozuki3, I. Oze4, K. Kato5, T. Kishimoto1, K. Hotta6

Background: Combination chemotherapy with cisplatin and pemetrexed is the standard treatment regimen for malignant pleural mesothelioma (MPM); however, the median overall survival (OS) is just about 12 months. Additional treatment options are urgently needed. The aim of this study is to assess the efficacy and safety of combination chemotherapy with cisplatin, pemetrexed, and nivolumab for unresectable MPM. Method: This is a single-arm, prospective, non-randomized, non-comparative, open label, multicenter, phase II trial. This study will assess the efficacy and safety of the first-line combination therapy of cisplatin, pemetrexed, and nivolumab for advanced or metastatic MPM. Key inclusion criteria includes 1) age older than 20 years, 2) pathologically-confirmed MPM, 3) measurable lesion designated by modified RECIST criteria, 4) tumor sample available to test for Programmed death-Ligand 1 (PD-L1) expression, 5) Eastern Cooperative Oncology Group Performance Status 0 or 1, 6) combination chemotherapy with cisplatin (75 mg/m2), pemetrexed (500 mg/m2), and nivolumab (360 mg/body) is administered every 3 weeks. The primary endpoint is to evaluate the efficacy and safety of the combination treatment. Result: From 07/2015 to 09/2017, a total of 13 pts have been treated at DL1 (n=4 included one fatal case within 32 days), DL2 (n=3) and DL3 (n=6). Male: 100%; median age 70; PS 0: 23%, 1: 69%, 2: 8%; epithelial/biphasic histology: 69%/15%; Stage III-IV: 77%; previous chemotherapy use with platinum-pemetrexed: 92%. Treatment-related AEs (TRAEs) were all Grade 1-2 and no DLTs occurred. The most frequent TRAEs were fever and CRP increase based on adenovirus infection. Tumor responses assessed by independent central review showed that there was no objective response and DCR was 62% (8/13 pts). Median PFS was 3.4 months at all groups and 5.7 months at DL3. A remarkable increase of REIC/Dkk-3 concentration in pleural fluid was determined (6/13 pts, prominently high in DL3). Conclusion: The intrapleural administration of Ad-SDG-REIC up to 2 cycles was safe and well tolerated in MPM pts and promising results of efficient REIC/Dkk-3 expression and durable disease control were obtained. We are planning phase II study using repeated intrapleural or intratumoral administration. Keywords: Wnt antagonist, gene therapy, Mesothelioma
Conclusion: Pretreatment PNI is a novel prognostic factor in MPM patients intended to be treated within MMT concept. Low PNI was significantly associated with low completion rate of MMT.

Keywords: Mesothelioma, nutritional status, multimodal treatment

1 Proportion of patients where mesothelioma histological subtype is recorded
2 Proportion of patients receiving one of surgery, radiotherapy or chemotherapy
3 Proportion of patients with PS 0-1 who received chemotherapy as treatment of their mesothelioma
4 Proportion of patients undergoing radical surgery as treatment of their mesothelioma
5 Proportion of patients receiving radiotherapy as treatment of their mesothelioma
6 Proportion of patients with mesothelioma who survive at least 1 year following diagnosis

Conclusion: Despite a rise in the number of eligible patients receiving chemotherapy, there remains poor long-term survival for patients with mesothelioma. As well as introduction of novel therapies, improvements in care and outcome could be achieved by reducing variation.

Keywords: Pleural mesothelioma, variation, outcome

**P2.06 MESOTHELIOMA**

**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.06-13 POOR NUTRITIONAL STATUS IS A POOR PROGNOSTIC FACTOR IN MALIGNANT PLEURAL MESOTHELIOMA**

M. Hashimoto, M. Friess, O. Lauk, W. Weder, I. Opitz
Thoracic Surgery, University Hospital of Zurich, Zurich/CH

**Background:** To investigate the clinical meanings of nutritional status in malignant pleural mesothelioma (MPM). **Method:** We retrospectively reviewed 87 MPM patients intended to be treated within a multimodality treatment (MMT) concept between September 1999 and April 2017. We used the prognostic nutritional index (PNI) to evaluate the nutritional status; serum albumin (g/l) + 5 × lymphocyte (G/L) in peripheral blood. Primary endpoint of this study was to investigate the correlation between PNI and overall survival (OS), and secondary endpoint was to investigate the association between PNI and completion rate of MMT. **Result:** Of 87 enrolled patients, 61 (70.1%) patients were completed MMT. Median pretreatment PNI was 45.1 (range: 24.5–58.8). We divided this cohort into Low-PNI group (PNI < 45, n=42) and High PNI group (PNI >= 45, n=45). The completion rate of MMT was significantly higher in High PNI group than Low (82.2% vs 57.1%, p=0.018). On survival analyses, Low PNI group had significantly (p=0.004) shorter median OS than High PNI group (12.0 vs 21.3 months, p=0.004). In multivariate analysis using Cox regression model, which showed Low PNI had increased the risk of death compared with High-PNI (HR: 2.64; 95%CI, 1.32-5.28; p=0.006), as well as elevated C-reactive protein (HR: 20.8; 95%CI, 1.17-3.70; p=0.012).

**Conclusion:** Pretreatment PNI is a novel prognostic factor in MPM patients intended to be treated within MMT concept. Low PNI was significantly associated with low completion rate of MMT.

**Keywords:** Mesothelioma, nutritional status, multimodal treatment
**P2.06.14** DOES SIZE MATTER? A POPULATION-BASED ANALYSIS OF MALIGNANT PLEURAL MESOTHELIOMA

J. He1, J. Shen2, H. Pan3

1Thoracic Surgery, Guangzhou Medical University First Affiliated Hospital, Guangzhou/CN, 2Taizhou Hospital of Zhejiang Province, Taizhou/CN, 3Guangzhou Medical University 1st Affiliated Hospital, Guangzhou/CN

**Background:** The malignant pleural mesothelioma (MPM) is a rare and aggressive malignancies. A validated staging system is crucial for disease evaluation, treatment selection and follow-up strategy. The 8th edition staging system for MPM has been recently proposed. However, it has not been widely accepted due to the absence of validation of large cohort. Besides, the size of tumor is not taken into consideration. We intend to elucidate the prognostic value of the size of MPM and evaluate the current staging system via the data of SEER database.

**Method:** All cases of primary MPM were identified and extracted from the SEER database during the period of 1973-2013. Kaplan-Meier method was used to analyzed overall survival and cancer-specific survival. The prognostic factors were identified by Cox regression. LOWESS smoothing regression curve was also utilized. The cut-off points of size in different strata were identified based on the graphical characteristics. The tumor stage was established incorporating tumor extension and size. The adjusted clinical staging system was proposed and compared with the previous TNM staging system by likelihood ratio test. **Result:** A total of 2138 patients were included. The 1.3 and 5-year survival rates of MPM were 39.4%, 11.8% and 3.8%. Tumor extension, lymph node involvement and metastasis, tumor size, histology and differentiation grade were significant prognostic factors. Radical surgery and local destruction might have metastasis, tumor size, histology and differentiation grade were significant in young patients, (19.8 ± 8.4 years). Group (2) included 67 patients with mean age of 58.6 ± 8.5 years (46 to 87 years). 68% of group (1) came from endemic areas which is significantly higher than group (2): (35.8%), p = 0.02. History of asbestos exposure was highly significantly different between the 2 groups, 77.1% in group (1) versus 38.8% in group (2), p < 0.001. Other factors showed no significant differences between the two groups. Overall clinical response (CR+PR) was 20% in group (1) versus 17.9% in group (2). P=0.7. There was a trend towards longer median PFS in young patients, (19.8 ± 8.4 versus 9.5 ± 1.4 months), p = 0.09. The median OS of young patients is significantly longer (20.6 ± 6.3 months) than older patients (11.1 ± 3.6) p = 0.05. **Conclusion:** Mesothelioma in the young adult is more sensitive to asbestos exposure, has better OS and likely a different disease entity which needs further studies to understand its underlying biological features.

**Keywords:** stage, SEER, malignant pleural mesothelioma

---

**P2.06.15** MALIGNANT PLEURAL MESOTHELIOMA IN YOUNG ADULT PEOPLE IN UGANDA

N. Igulu Bandese

Clinical, Hospice Africa Uganda, Kampala/UG

**Background:** Malignant pleural mesothelioma (MPM) is an aggressive malignancy and current therapy is essentially palliative. Novel therapy targets are urgently needed. YB-1 is a multifunctional oncoprotein associated with poor patient outcome and is related to increased chemoresistance in tumours including NSCLC. It is widely accepted that YB-1 plays a role in the chemoresistance of many cancers, and we recently confirmed this in MPM cells. Here, we begin to evaluate YB-1 as a therapeutic target in this disease.

**Method:** YB-1 expression was determined by Western blot in MPM cell lines and their drug resistant sublines. Growth and colony formation assays were conducted after transfection with YB-1- or control-siRNA. These were also carried out in combination with cisplatin, gemcitabine or vinorelbine treatment. Apoptosis was assessed by PI and annexin V staining in YB1 knockdown MPM cells.

**Result:** Migration of MPM cells was assessed using videomicroscopy and manual cell tracking. Luciferase-expressing MPM cells transfected with YB-1- or control-siRNA were injected into female SCID mice (n=10, intra-peritoneal injection). Tumour growth was monitored via measuring bioluminescence on an In Vitro Imaging System (IVIS) once a week for 4 weeks. Tumour weight determined after humane euthanasia of animals at the termination of the experiment. **Conclusion:** YB-1-siRNA significantly inhibited the growth of MPM cell lines in vitro and was overexpressed in MPM cells compared to the immortalised mesothelial cell line Met-5A. Growth of Met-5A and primary mesothelial cell lines was not affected significantly by YB-1 knockdown. Mice injected with YB-1 knockdown cells displayed significantly lower tumour burden, evidenced by bioluminescence in live mice using IVIS and lower tumour weight after harvest. TALI assays showed an increase in apoptotic cells after YB-1 siRNA transfection in vitro, and cells transfected with siRNA showed sensitisation to cisplatin and vinorelbine. YB-1 was expressed at higher levels, and higher migratory capacity was observed in drug resistant MPM cell lines compared to parental cell lines.

**Conclusion:** These results highlight the importance of YB-1 in MPM biology both in vitro and in vivo.

**Keywords:** YB-1, malignant pleural mesothelioma

**Background:** Malignant pleural mesothelioma (MPM) is an aggressive malignancy and current therapy is essentially palliative. Novel therapy targets are urgently needed. YB-1 is a multifunctional oncoprotein associated with poor patient outcome and is related to increased chemoresistance in tumours including NSCLC. Here, we begin to evaluate YB-1 as a therapeutic target in this disease.

**Method:** YB-1 expression was determined by Western blot in MPM cell lines and their drug resistant sublines. Growth and colony formation assays were conducted after transfection with YB-1- or control-siRNA. These were also carried out in combination with cisplatin, gemcitabine or vinorelbine treatment. Apoptosis was assessed by PI and annexin V staining in YB1 knockdown MPM cells. Migration of MPM cells was assessed using videomicroscopy and manual cell tracking. Luciferase-expressing MPM cells transfected with YB-1- or control-siRNA were injected into female SCID mice (n=10, intra-peritoneal injection). Tumour growth was monitored via measuring bioluminescence on an In Vitro Imaging System (IVIS) once a week for 4 weeks. Tumour weight determined after humane euthanasia of animals at the termination of the experiment. **Result:** YB-1-siRNA significantly inhibited the growth of MPM cell lines in vitro and was overexpressed in MPM cells compared to the immortalised mesothelial cell line Met-5A. Growth of Met-5A and primary mesothelial cell lines was not affected significantly by YB-1 knockdown. Mice injected with YB-1 knockdown cells displayed significantly lower tumour burden, evidenced by bioluminescence in live mice using IVIS and lower tumour weight after harvest. TALI assays showed an increase in apoptotic cells after YB-1 siRNA transfection in vitro, and cells transfected with siRNA showed sensitisation to cisplatin and vinorelbine. YB-1 was expressed at higher levels, and higher migratory capacity was observed in drug resistant MPM cell lines compared to parental cell lines. **Conclusion:** These results highlight the importance of YB-1 in MPM biology both in vitro and in vivo.

**Keywords:** YB-1, malignant pleural mesothelioma

P2.06 MESTOHELIOMA TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

---

**P2.06-17 REAL-WORLD ACCURACY OF MALIGNANT PLEURAL MESOTHELIOMA (MPM) PREOPERATIVE MAGNETIC RESONANCE IMAGING (MRI) FOR STAGING THE DIAPHRAGM.**

S. Katz, S. Mcnulty, K. Cengel, E. Alley, S. Singhal
University of Pennsylvania Perelman School of Medicine, Philadelphia/US

**Background:** Magnetic resonance imaging (MRI) of the chest is commonly employed for preoperative staging of patients with malignant pleural mesothelioma. Here we evaluate the accuracy of preoperative MRI for detection of diaphragmatic invasion in patients undergoing pleurectomy in a real-world setting. **Method:** All adult patients who had a MRI of the chest performed as part of routine preoperative staging with subsequent pleurectomy for malignant pleural mesothelioma during a 20-month interval were identified. Patients without available MRI imaging records were excluded. MRI reports for each patient were reviewed by a thoracic radiologist for evidence of diaphragmatic invasion and correlated with intraoperative findings. The MRI images for those patients with discrepant readings between MRI exam and intraoperative findings of diaphragm invasion were directly reviewed by the radiologist to assess for technical aspects that may have contributed to limitations in imaging interpretation. **Result:** A total of 16 adult patients with MPM, 14 male and 2 female, had preoperative MRI examinations performed with reports that were available for review, noting that a subset of examinations were obtained at outside community imaging sites resulting in variability of the imaging techniques and scanner types. Five patients had suspected or definitive diaphragmatic invasion on MRI, all of which were confirmed at pleurectomy. However, 9 of the patients that were initially assessed by MRI as not having diaphragmatic invasion, were later found at surgery to have some degree of diaphragmatic invasion necessitating diaphragmatic repair or diaphragmatic graft placement. When MRI exams were analyzed from patients that had missed diaphragmatic invasion on MRI interpretation, technical parameters such as differences in study image acquisition and technical artifacts due to cardiac, aortic pulsation and respiration motion may have contributed to the lack of identification of diaphragmatic invasion. **Conclusion:** MRI for preoperative planning in patients with MPM may miss diaphragmatic invasion. Further study is needed to determine if technical factors may contribute to limitations in detection of diaphragmatic invasion in MPM with a goal to optimize and harmonize MRI imaging protocols for preoperative staging.

**P2.06-18 COMPARISON OF EXTUBATION TIME OF PLEULECTOMY/DECORTICATION WITH LOBECTOMY UNDER GENERAL ANESTHESIA USING DESFLURANE**

K. Kawata¹, N. Funatsu¹, H. Tao¹, K. Okabe¹
¹Department of Anesthesiology, National Hospital Organization Yamaguchi-Ube Medical Center, Ube/JP
²Department of Surgery, Division of Thoracic Surgery, National Hospital Organization Yamaguchi-Ube Medical Center, Ube/JP

**Background:** Pleurectomy/decortication (P/D) is an operation to dissect the entire visceral and parietal pleura. Chief complications are hemorrhage and prolonged air leak. To avoid mechanical ventilation postoperatively, good recovery of spontaneous respiration and emergence are important. We evaluated emergence status in patients who were underwent P/D with desflurane (DES) anesthesia in the clinical settings. **Method:** Records of consecutive patients at our hospital who were underwent P/D from May 2013 to January 2018 and lung lobectomy via thoracotomy from June 2016 to August 2017 were collected. Patients anesthetized with DES were investigated. Lobectomy with chest wall resection were excluded. P/D group (n=19) and control group (n=20) were analyzed. General anesthesia was maintained with DES (3-5%), remifentanil, and rocuronium combined with epidural anesthesia. Administration of DES was abruptly discontinued just after postoperative X-ray examination. A patient was extubated after sugammadex was injected. Extubation time (T1) was defined as duration from the end of operation to extubation. Continuous variables were expressed as median and interquartile range (IQR). Fisher’s exact test and Mann-Whitney U-tests were used for statistical analysis. **Result:** There were no significant difference in demographic data (age, gender, BMI, PaO2, PaCO2, pH, HCO3, PaCO2-PaO2 between the two groups, except for %VC and FEV1%). All patients were extubated after surgery. There was no significant difference in T1 between the two groups. Despite significantly larger amount of blood loss, longer operation and anesthesia time in the P/D group, time independent recovery of DES was achieved as same as the control group.

**P2.06-19 TARGETING POLYAMINES AS POTENTIAL ADJUVANT THERAPY IN MALIGNANT PLEURAL MESOTHELIOMA XENOGRAFT MODELS**

S. K. Lam, S. Yan, S. Xu, J. C. Ho
Department of Medicine, The University of Hong Kong, Hong Kong Sar/HK

**Background:** Inhaling asbestos fibers is one of the commonest of causes of malignant pleural mesothelioma (MPM). Although the import and use of asbestos have been restricted, the incidence of MPM is still rising due to a long lag time in malignant transformation. In 2004, the US Food and Drug Administration approved a combination of pemetrexed with cisplatin for treatment of unresectable MPM. At the same time, development of novel adjuvant therapeutic options for resected early-stage disease is also urgently needed. Ornithine decarboxylase (ODC) is highly expressed in 211H and H226 MPM xenografts and clinical tumor samples. Upregulation of ODC increases polyamine production and enhances tumor growth. a-difluoromethylornithine (DFMO) is a specific ODC inhibitor. Recent preclinical studies have demonstrated the adjuvant effect of DFMO in colon cancers using xenograft model. However, adjuvant effect of DFMO in MPM has not yet been studied. This study aims to disclose the adjuvant effect of DFMO in MPM xenograft models. The findings from this study will provide scientific foundation for future design of clinical trials of DFMO for adjuvant therapy in early disease for advanced MPM. **Method:** Nude mice were fed with DFMO in drinking water 7 days before subcutaneous inoculation of 200,000 tumor cells (211H (biphasic) or H226 (epithelioid)). Mice with tumor size >600mm³ were considered reaching humane endpoint. Spermidine levels, protein expression, cytokines concentrations, NFkB translocation and apoptosis were investigated by Dot blot, Western blot, ELISA, immunofluorescence staining and TUNEL assay respectively. **Result:** DFMO suppressed tumor growth in both xenografts. DFMO increased mean survival from 49.5 days in control arm to 65 days in treatment arm in mice with 211H xenografts (p = 0.08), while from 44 days to 120 days in those with H226 xenografts (p = 0.0002). In H226 xenograft model, 43% of treated mice have not yet reached humane endpoint, mimicking long-term survival. Upon DFMO treatment, decrease in spermideine level, increase in nitrotrosine content, nuclear translocation of NFkB, elevation of serum IL-6 and activation of apoptosis were observed in both xenografts. In addition, increase in nitrotycline level, decrease in serum keratinocyte chemoattractant (KC), increase in serum TNF alpha, elevation of DNA lesion and inhibition of Akt/mTOR pathway were induced by DFMO in H226 xenografts, which may explain higher potency of DFMO in this xenograft. **Conclusion:** DFMO may have a potential role as adjuvant therapy in MPM especially epithelioid mesothelioma. Acknowledgment: This research was supported by Hong Kong Pneumoconiosis Compensation Fund Board, HKSAR.

P2.06-20 BACTERIA AS NOVEL ANTI-MESOTHELIOMA AGENTS.

S. Lansley1, J. Varano Della Verrigiana1, J. Creaney2, Y. Lee1
1Medical Center for Respiratory Health, Perth/WA/AU, 2University of Western Australia, National Centre for Asbestos Related Diseases, Perth/WA/AU

Background: Malignant pleural mesothelioma (MPM) is a universally fatal malignancy with rising global incidence. Research to date has failed to make significant progress towards the control of mesothelioma, let alone its cure. An entirely different approach is needed. The anti-cancer properties of bacteria have been utilized as novel treatments for some cancers, including resistant bladder cancer in which Mycobacterium bovis BCG forms standard treatment. The use of bacteria presents an attractive approach in pleural mesothelioma, as there is strong evidence to suggest that an infection in the pleural space may increase survival in these patients. Our study aimed to capitalize on this phenomenon and determine whether bacteria or their products can be used as anti-mesothelioma agents. Method: We tested the efficacy of live (10^5-10^8 CFU/mL) and attenuated (heat-killed) Streplococcus pneumoniae (n=5) and Staphylococcus aureus (n=5) clinical bacterial isolates obtained from patients with invasive bacterial infection and common laboratory reference strains (n=4) against primary (n=3) and established (n=6) mesothelioma cell lines collected from patients with malignant pleural effusions. Benign mesothelial cells served as controls. Alternatively, conditioned medium (CM) (from S. aureus), or mutated bacteria (ΔPly or WCH43ΔGlpO) were added to mesothelioma cells. Cell viability was assessed using live/dead staining and analysed using flow cytometry. We also measured key cytokines involved in the pathobiology of mesothelioma and bacterial infection including: IL-1β, IL-6, VEGF and IL-8 using ELISA’s. Result: Two of the five live Staphylococcus aureus and Streplococcus pneumoniae isolates consistently killed all mesothelioma cell lines (median(IQR)%: 90.4(51.4-97.6)% and 99.6(99.4-99.8)% respectively). The same S. pneumoniae isolates also potently killed benign mesothelial cells (99.7(99.4-99.8)%). However, the two S. aureus isolates demonstrated significantly less efficacy against benign mesothelial cells (13.7(5.0-23.0)%), supporting the potential for targeted therapy. Attenuated clinical isolates and bacterial CM were not efficacious against mesothelioma cells. We observed increased cytokine levels in response to the most potent clinical isolates in all mesothelioma cell lines. In contrast, cytokine responses were greatly reduced in benign mesothelial cells. Pneumolysin and GlpO (α-glycerophosphate oxidase) did not mediate the cytotoxic effects of S. pneumoniae isolates on mesothelial cells as evidenced by comparison of mesothelioma cell killing to wild-type controls. Conclusion: We showed, for the first time, that clinical bacterial isolates can potently kill patient-derived mesothelioma cells with some specificity. Combined with our published data, which demonstrated the efficacy of a bacterial toxin against mesothelioma tumours in vivo, our data suggests that bacterial therapy is a promising novel approach for the treatment of mesothelioma and warrants further investigation. P2.06-22 PROPOSAL OF A NEW LOCAL RECURRENCE SCORE FOR PATIENTS WITH MALIGNANT PLEURAL MESOTHELIOMA.

O. Lauk, M. Hashimoto, M. Friess, W. Weder, I. Opitz
Thoracic Surgery, University Hospital of Zurich, Zurich/CH

Background: Malignant pleural mesothelioma (MPM) is associated with high rates of local recurrence (LR) up to 75%. Second line treatment should be applied tailored to relapse pattern. The aim of the present study was to establish a new score for LR pattern with prognostic and treatment impact. Method: From 2001 until 2017, 165 consecutive MPM patients with LR after macroscopic complete resection either by extrapleural pneumonectomy (EPP) or (extended) pleurectomy/ decortication (eP/D) were enrolled in this retrospective study. Due to missing data 37 patients were excluded from analysis. Further analysis was done with remaining 128 patients (EPP: n=61 and eP/D: n=67). We divided the thoracic cavity into the following sections: chest wall (CW), mediastinum (Med), diaphragm (Di), lung parenchyma (LP), neo-pleural thickening (N-PT) and lymph node (LN) (Figure 1A). We assessed the prognostic impact of local recurrence score (LRS=size (Measurement of perpendicular diameter)) of recurrence sites multiplied by the number of LR sites) using cox regression model. Result: The frequency of the location was as follows: CW 47.7%, Di 24.2%, Med 38.3%, N-PT 61.7%, LP 25.0% and LN 55.5% (Figure 1B). The median LRS was 4 (range: 1-12). Low LRS (<= 4) was significantly correlated with longer survival after LR (low score 16.4 vs high score 9.8 months, p=0.03). Of 6 locations, first recurrence at CW (negative 17.2 vs positive 9.2 months, p=0.015) had significant negative prognostic impact on OS. In subgroup analysis, LRS was significantly higher after eP/D compared to EPP (median LRS: 6 vs 4, p=0.001), but survival after LR was significantly longer after eP/D compared to EPP (14.6 vs 9.6 months, p=0.004).

P2.06-21 LOW INTRATUMORAL PLATINUM CONCENTRATION IS ASSOCIATED WITH UNFAVORABLE CLINICAL OUTCOME IN MALIGNANT PLEURAL MESOTHELIOMA.

V. Lazliol1, T. Klikovits1, A. Tisza1, M. Bogdán1, M. Hoda2, W. Berger3, M. Grußenmayer, W. Klepetko1, B. Hegedüs2, A. Limbeck1, B. Dome1

Background: Malignant pleural mesothelioma (MPM) is a rare but devastating malignancy characterized by poor prognosis. Systemic anti-MPM therapy is based on platinum compounds. Unfortunately, however, chemoresistance is a major obstacle in the treatment of MPM. Although inadequate intracellular drug uptake is one of the most frequent causes of drug resistance, the impact of the tumour microenvironment on chemotherapeutic drug distribution and the clinical outcome is still unclear. Method: Spatial distribution and average tumour concentration of platinum was assessed by laser ablation-inductively coupled plasma-mass spectrometry (LA-ICP-MS) in tumor samples of MPM patients (n=26) receiving platinum-based induction chemotherapy followed by surgical resection. Circulating platinum concentration was also analyzed by ICP-MS in serum samples (n=29) taken prior to surgery. Tumor and serum drug levels were correlated with various clinicopathological parameters. Result: Patients with low average tissue platinum concentrations had significantly shorter overall survival. Interestingly, the spatial distribution of platinum was very heterogeneous in the tissue samples. The drug accumulated in collagen-rich, post-necrotic scar tissue compartments while its level was relatively low in the viable tumor areas. Circulating cisplatin levels negatively correlated with the time between the last chemotherapy cycle and blood sampling. Conclusion: By using an innovative technique for lateral trace element distribution analysis, we demonstrate here for the first time that low tissue platinum uptake is associated with significantly worse clinical outcome in MPM and, furthermore, that relatively higher platinum levels are confined to areas of intratumoral scar tissue. Our results suggest that insufficient drug uptake might be an important factor of cisplatin resistance in the clinics. Further studies are needed to clarify the significance of heterogeneous intratumoral platinum distribution. Keywords: mesothelioma, intratumoral platinum distribution, resistance...
P2.06-23 ASSOCIATION OF TWO BRM PROMOTER POLYMORPHISMS AND TOBACCO EXPOSURE WITH MALIGNANT PLEURAL MESOTHELIOMA (MPM) RISK AND SURVIVAL

1University of Toronto Faculty of Medicine; Princess Margaret Cancer Centre, Toronto/ON/CA, 2Princess Margaret Cancer Centre, Toronto/ON/CA, 3Dept of Medical Oncology and Haematology, Princess Margaret Cancer Centre, Toronto/ON/CA, 4Thoracic Surgery, University Health Network, Toronto/ON/CA, 5Division of Hematology & Oncology, University of Florida, Gainesville/US

**Background:** Brahma (BRM) is a critical ATPase subunit of the SWI/SNF chromatin remodeling complex. Homozygous 6-7bp insertion variants at two polymorphic promoter sites (BRM-741/BRM-1321) cause epigenetic suppression of BRM expression and they have been reported as susceptibility and/or prognostic markers in many malignancies, including non-small cell lung cancer. As epigenetic silencing of BRM can be reversed pharmacologically, targeting BRM polymorphisms has significant therapeutic potential. We evaluated BRM-741/BRM-1321 polymorphisms' association with risk and prognosis of malignant pleural mesothelioma (MPM). While the effect of tobacco in MPM remains controversial, its interaction with genetic polymorphisms in MPM is largely unknown. We evaluated associations between BRM polymorphisms-tobacco exposure and MPM. **Method:** MPM and age-distribution matched asbestos-exposed controls were recruited as part of an asbestos-exposure surveillance program. Participants were genotyped for BRM polymorphisms. Multivariable logistic regression assessed risk of MPM in case-control associations. Association of BRM variants with overall survival (OS) was assessed by multivariable Cox regression. Secondary subset analyses were performed, stratified by smoking status. **Result:** Of 265 MPM cases, 146 (55%) were ever-smokers; 51 (19%) were female; median age was 66 (range:21-84) years. Median OS was 18 months; median follow-up time was 15 months. Compared to 795 controls, there were no significant associations of BRM with risk (P>0.10, all comparisons). In contrast, compared to the wild-type genotype, the homozygous variant of BRM-741 and BRM-1321 were associated with lower OS, with adjusted hazard ratio (aHR)=2.56 [95%CI:1.7-3.8] and 2.07 [95%CI:1.4-3.1], respectively. Compared to patients carrying the double wild-type, patients homozygous at both loci had lower OS (aHR=2.70 [95%CI:1.7-4.4]). There was a significant differential effect of BRM polymorphisms on risk of MPM, by smoking status (interaction P<0.001); among ever-smokers, BRM homozygous variants in BRM-741, BRM-1321, or both conferred lower risks (adjusted odds ratios, aORs were between 0.18-0.28; each P<0.001), while for never-smokers, there was significantly greater risk conferred by carrying the homozygous variants (aORs between 2.7-4.4). Likewise, a similar differential effect by smoking status was seen in prognosis (interaction P<0.001): there was no association between BRM polymorphisms and OS in ever smokers (P>0.1, all comparisons), but in never-smokers, the aHR of carrying homozygous variants of BRM-741, BRM-1321 or both were 7.7 [95%CI:3.8-16], 4.0 [95%CI:2.1-7.7], and 8.6 [95%CI:3.7-20], respectively. **Conclusion:** Never-smokers who develop malignant pleural mesothelioma have an increased chance of carrying BRM homozygous variants in their germline DNA, which results in substantially worse prognosis. In contrast, in smokers, there may be a protective effect, with no difference in overall survival.

P2.06-25 COMBINED IMMUNE CHECKPOINT BLOCKADE IN MALIGNANT PLEURAL MESOTHELIOMA: IN VIVO VALIDATION OF IN VITRO RESULTS

E. Marcq1, J. De Waele2, J. Van Audenaerde3, J. Jacobs4, J. Van Loenhout1, P. Smits5, J. Van Meersck6
1Center for Oncological Research (Core), University of Antwerp, Wilrijk/BE, 2Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Distrito Federal/MX, 3Department of Pathology, Antwerp University Hospital, Antwerp/BE, 4Department of Pulmonology, Antwerp University Hospital, Edegem/BE

Background: To date, human malignant pleural mesothelioma (MPM) remains an aggressive cancer with a poor prognosis due to the limited impact on overall survival of the current treatments. Treatment with immune checkpoint inhibitors (ICIs) has shown promising results with room for improvement. Here we evaluate the effect of combined treatments and compare them to stand-alone treatment to select the best therapeutic strategy for MPM.

Methods: Human cell lines representative for the epithelioid (NCI-H2818 and NCI-H2795) and sarcomatoid (NCI-H2731) subtypes of MPM were placed in allogeneic co-cultures with healthy donor peripheral blood mononuclear cells. The co-cultures were treated with the following immune checkpoint blocking antibodies: anti PD-1 (Nivolumab®), BMS) or anti PD-L1 (Durvalumab®), AstraZeneca in combination with anti TIM-3 or anti LAG-3. Supernatant was collected and enzyme-linked immunosorbent assays and multiplex electrochemiluminescence were used to look at the secretion of 7 cytokines, being IFNg, IL-2/5/6/10, IL-1b and TNF-a, as well as the enzyme granzyme B. Statistical analysis was done to investigate the differences between the treatment conditions.

Results: Treatment with immune checkpoint blockers as monotherapy or in combination resulted in a significant increase in the secretion of granzyme B and the cytokines IFNg, IL-2, IL-5 and IL-10. Although the increased secretion was not always statistically significant for all 3 MPM cell lines of the two subtypes, the same trends were observed among them. Interestingly, highest concentrations of granzyme B and these 4 cytokines were noticed for monotherapy treatment with anti PD-1, anti PD-L1 or either of these antibodies with anti TIM-3. In vivo investigation of PD-1 or PD-L1 blockade in combination with TIM-3 or anti LAG-3 blockade is currently ongoing to validate our in vitro results. Conclusion: Our data show that treatment with anti PD-1, anti PD-L1 or their respective combination with anti TIM-3 resulted in the highest secretion of cytokines and granzyme B, suggesting that these treatments stimulate the antitumor response the most. In vivo experiments are currently ongoing for validation.

Keywords: Mesothelioma, Immune checkpoints, combination therapy

P2.06-26 RIBONUCLEOTIDE REDUCTASE SUBUNIT M1 BUT NOT M2 IS ASSOCIATED TO BETTER PFS IN PATIENTS WITH ADVANCED STAGE MESOTHELIOMA

1Subaddress Basic Research, National Cancer Institute, Mexico, Distrito Federal/MX, 2Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerología, Mexico City/MX, 3Hospital Infantil de Mexico Federico Gomez, Mexico/MX, 4Unidad Funcional de Oncología Torácica y Laboratorio de Medicina Personalizada, National Cancer Institute, Mexico City/MX

Background: Ribonucleotide reductase M1 (RRM1) is the catalytic subunit of ribonucleotide reductase, the enzyme responsible for de novo synthesis of most of the deoxyribonucleotides. Low-level expression of RRM1 has been associated to better prognosis in patients with solid tumors. A previous study identified that RRM1 is a predictor for freedom from recurrence in patients with malignant pleural mesothelioma (MPM) undergoing induction chemotherapy following extrapleural pneumonectomy. Ribonucleotide reductase subunit M2 (RRM2) is associated with apoptosis, cell proliferation, invasion and migration. Some studies have suggested that expression of RRM2 could play a role in tumorigenesis of several cancers; however, its role in MPM is unknown. Method: The expression of RRM1 and RRM2 was assessed by immunohistochemistry using commercial antibodies. Quantitative analysis was performed using computerized image software, namely digital pathology. All of the samples were scanned and the median value of each marker was used as the cutoff value, >median value corresponds to high expression level and <median value to low expression level. The expression levels were determined in samples from 91 patients with advanced MPM, who had received gemcitabine-based chemotherapy. We correlated these data with clinical parameters and disease outcome (Progression Free Survival [PFS]). Result: Our study population presented a median age of 60 years (53 -71 yrs), most were male 64.8 %, with asbestos exposure in 57.2% of cases and epithelioid histology in 85.7%. Almost half of the patients received gemcitabine as first-line treatment (n=43; 47.3%). Overall PFS was 14.1 months (95% CI 9.8-18.4 months) while PFS in patients receiving gemcitabine treatment was 6.8 months (95% CI 4.8-8.2 months). Several factors were associated to an improved PFS, including female vs. male sex (7.2 vs 6.6 months, p = 0.062) and epitheliol vs. sarcomatoid histology (7.2 vs 3.8 months, p =0.035) after gemcitabine treatment in univariate analysis. In the multivariate analysis, sex (HR 3.06, p =0.085) and no wood-smoke exposure (HR 2.55, p =0.092) were independently associated to gemcitabine treatment. Patients with high expression levels of RRM1 showed better PFS compared to patients with low expression levels (7.6 vs 5.5 months, p=0.049) in univariate analysis; with a HR 2.04 (p =0.050 -0.831) p=0.026 in multivariate analysis. Conversely, the M2 subunit (RRM2) did not show any significant associations (7.6 vs 6.6 months, p =0.363). Conclusion: Our results suggest that high protein expression levels of RRM1 could potentially serve as a biomarker of response to gemcitabine treatment in patients with advanced stage MPM.

Keywords: RRM2, response biomarker, RRM1

P2.06-27 EXTRAPLEURAL PNEUMONECTOMY, RADIATION THERAPY, AND CHEMOTHERAPY FOR EPITHELIOID MALIGNANT PLEURAL MESOTHELIOMA

Thoracic Surgery, Yamaguchi Ube Medical Center, Ube/JP

Background: The treatment strategy for malignant pleural mesothelioma (MPM) has not been established yet. Our improving results of trimodality therapy with extrapleural pneumonectomy (EPP), radiation therapy, and chemotherapy for epithelioid MPM are reported. Method: Twenty four consecutive EPP for epithelioid MPM which were performed from February 2011 to August 2017 in our hospital were reviewed. We have instituted a trimodality therapy protocol consisting of EPP, adjuvant 45-50.4 Gy hemithoracic radiation therapy, and adjuvant CDDP plus gemcitabine chemotherapy. 20 patients have been treated with this protocol. However, 4 patients were given induction CDDP plus PEM chemotherapy, and referred to us. They were scheduled to undergo EPP and adjuvant hemithoracic radiation therapy. Overall survival was calculated from the start of treatment using Kaplan-Meier method. Result: Median age at EPP was 60 (39 - 69) years old. Female was 8, and male was 16. Right side was 14, and left side was 10. Median EPP time was 7 hours 3 minutes (5 h 52 m – 8 h 56 m). No blood transfusion during EPP was 10 cases (42%). 30 day mortality was zero. Atrial fibrillation was the most common morbidity, and developed in 12 patients (50%). IMIG pathological stage was stage IV in 2, stage III in 13, stage II in 5, and stage Iib in 4. Adjuvant 45-50.4 Gy radiation therapy was completed for 21 patients (88%). 4 patients (17%) could not undergo chemotherapy. 18 patients (75%) underwent trimodality therapy. Postoperative median follow-up period was 4 years. Five year survival, two year survival, and median survival were 41%, 66%, and 40 months. (See next page)
Conclusion: This trimodality treatment strategy with EPP, hemithoracic radiation, and chemotherapy for epithelioid MPM is feasible. Although many advanced cases were treated, the prognosis has been greatly improved.

**P2.06-28 ASSESSMENT OF CHEST WALL MOTION USING STRUCTURED LIGHT PLETHYSMOGRAPHY (SLP) IN MESOTHELIOMA AND BENIGN PLEURAL DISEASE**

N. Oswald1, A. Kerr2, R. Mehdi2, A. Turner1, B. Naidu1

1University of Birmingham, Birmingham/GB, 2Thoracic Surgery Research, Heartlands Hospital, Birmingham/GB

Background: Diagnosis of mesothelioma can be a prolonged and distressing process for patients. Non-invasive assessment of ribcage and abdominal movements is possible with structured light plethysmography (SLP) which is quick and easy to perform; we sought to assess whether changes in respiratory movements could be used to differentiate benign pleural disease from mesothelioma. Method: Patients attending the preoperative assessment clinic prior to diagnostic pleural biopsy were recruited prospectively. SLP was performed prior to surgery and the recordings processed by a blinded technician. Binary logistic regression was used performed based upon histology results and the model was assessed with area under the curve (AUC) analysis. Survival analysis (Kaplan Meier plot and Log Rank test) was performed to assess whether survival was different depending on SLP results. Result: Seventy-five patients were recruited, meeting the required sample size (40 benign, 35 malignant). Factors entered into the model were the contribution of the affected hemithorax to ribcage tidal volumes, synchrony between abdominal and ribcage movements and variability of inspiratory to expiratory flow. The model was not significant (X2 = 4.234, p = 0.237, Nagelkerke R² = 0.073) and correctly classified 57.3% of cases. AUC was 0.581 (p = 0.230, 95% confidence interval 0.450 to 0.712), this is not sufficient to be a clinically useful test. The contribution of the affected hemithorax to ribcage motion showed a trend for association with survival in patients who had biopsy proven mesothelioma (mean survival 334 days for <45% contribution, 95% confidence interval 218-450, vs 993 days for >45% contribution, 95% confidence interval 633-1353, p = 0.065). Conclusion: Performing SLP prior to biopsy does not aid in the differentiation of benign versus malignant pleural disease. Further research into the usefulness of assessing chest wall motion in prognostication and staging of mesothelioma is required.

**P2.06-29 EXPRESSION OF ESTROGEN RECEPTOR BETA (ERB) AND ITS PROGNOSTIC VALUE IN THE PLEURAL MESOTHELIOMA**

J. Rodriguez-Cid1, O. García Acevedo2, D. Bonilla-Molina1, J.A. Alatorre Alexander1, L. Martínez Barrera1, J. Benjamin Contreras2, E.S. Peña Mirabal3

1Oncology Center, Instituto Nacional de Enfermedades Respiratorias, Mexico City/MX, 2Oncology Center, Médica Sur, Mexico City/MX, 3Department of Pathology, Instituto Nacional de Enfermedades Respiratorias, Mexico City/MX

Background: Overexpression of estrogen receptors in malignant pleural mesothelioma has shown to be a good prognostic marker of survival and the use of selective estrogen receptor beta agonists (ERb) increases the susceptibility to antitumor treatment. Method: Longitudinal, retrospective and uncenteric study that analyzes the response of malignant pleural mesothelioma with an expression of ERb to chemotherapy in the first line. The study had 22 patients pathologically diagnosed with malignant pleural mesothelioma between April 2014 to September 2015 at the National Institute of Respiratory Diseases, who underwent immunohistochemistry for ERb (mouse monoclonal antibody PP65/10), used a qualitative system determined by direct observation of the pathologist with a scale 1+ for weak staining and 3+ for very intense staining, as well as the percentage of expression, was considered as high when it was increased to 50% of the cells. The primary endpoint was overall survival and ERb expression variable; secondary outcomes were progression-free survival and response rate to chemotherapy based on RECIST 1.1. Result: The sample is formed by 13 men (59.1%) and 9 women (40.9%), with a clinical stage of IV in 54.5%, III in 36.4%, I and IIA both with 4.5%. Were smokers 54.5% with an average of 5.9 packs/year. In 95.5% there was an epithelioid pattern and 3.5% was biphasic. The 77.2% of the patients expressed a high percentage ERb 22.8% a low or null percentage. The response to the treatment by RECIST 1.1 was 54.5% for partial response (12 patients), stable disease in 22.7% (5 patients) and progression 13.6% (3 patients), no patient had a complete response. Of the patients who had a partial response, 75% (9 patients) had a high percentage of ERb expression in the tumor cells and 25% had a low or null percentage. The progression-free survival of patients with high ERb expression had a median of 12.2 months compared to 9.3 months with low or null expression (p = 0.67, 95% CI 4.5 - 12-9), overall survival was 19.5 months in those with high expression of the receptor and 10.3 months for patients with low or null expression (this had a greater tendency to be higher in the ERb high expression for 9.2 months) (p = 0.054, 95% CI 9.79-10.01) Conclusion: ERb high expression in patients with an advanced clinical stage of malignant pleural mesothelioma was associated with a better response to chemotherapy treatment (without being statistically significant), with a better progression-free survival and possibly overall survival trend.

**P2.06-30 ASSOCIATION OF HISTOPATHOLOGICAL PATTERNS OF MESOTHELIOMA AND RESPONSE TO TREATMENT WITH CHEMOTHERAPY**

J. Rodriguez-Cid1, D. Bonilla-Molina1, E.S. Peña Mirabal2, J.A. Alatorre Alexander1, L. Martínez Barrera1, J.P. Díaz Rico1, P. Santillan Doherty2

1Oncology Center, Instituto Nacional de Enfermedades Respiratorias, Mexico City/MX, 2Department of Pathology, Instituto Nacional de Enfermedades Respiratorias, Mexico City/MX

Background: Mesothelioma is a neoplasm with a high mortality, there are different prognostic factors that influence survival, within these, the histological type has been associated directly. Method: Descriptive, observational and retrospective study, that analyzes the response of the different histopathological patterns of malignant pleural mesothelioma to chemotherapy. The study had 28 patients pathologically diagnosed with malignant pleural mesothelioma between April 2014 to August 2015 at the National Institute of Respiratory Diseases. The primary objectives were overall survival and mesothelioma histopathological patterns variable, and secondary objectives was progression free survival and response rate to chemotherapy based on RECIST 1.1. Result: The sample was formed by 13 men (46.4%) and 15 women (36%). 57% had asbestos exposure and 43% another exhibition (textile, fiber glass, cement, fertilizer, petroleum, solvents and coal). The 46% were smokers with an average of 6.6 packs/year. The method of biopsy as a diagnostic was thoracoscopy, which was used in 57% of the patients. The 94.4% had epithelioid pattern and 3.5% was biphasic; in the epithelioid pattern, the solid subtype was the most predominant with 51.8%, followed by tubulopapillary with 14.9%, acinar with 14.8%,
P0.06 MALIGNANT PLEURAL MESOTHELIOMA PRESENTING AT A QUATERINARY THORACIC ONCOLOGY CENTER IN QUEBEC

Background: Malignant pleural mesothelioma (MPM) is a rare disease for which diagnostic and therapeutic trajectories are ill-defined. We hypothesize that MPM patients experience delays during their diagnostic and therapeutic trajectory with significant heterogeneity in care pathways. Thus, we evaluated management practices at the MUHC over the past 10 years to address the need for a centralized program and dedicated care team.

Method: We conducted a retrospective chart review of MPM cases diagnosed at our center from 2006 to 2016. Clinical, pathologic, and treatment variables were collected. We assessed time from first abnormal imaging to definitive diagnosis, time from definitive diagnosis to first treatment and time from definitive diagnosis to palliative care consult. Overall survival was analyzed by Kaplan Meir method.

Result: We identified 145 patients over a 10-year period and report outcomes on 92 cases with complete data. Demographic data are presented in Table 1. Overall survival was 1.4% at 5-years for all patients, with a median survival of 1 year following a definitive diagnosis. Forty-five percent of patients underwent an investigational PET/CT scan, 89% of patients achieved M0 status prior to palliative care consult, and 71% of patients had thoracic metastases. Sixty-three percent of patients received some form of treatment. Eight treatment combinations were identified, irrespective of intent, lymph node involvement, and metastatic status. With regards

Keywords: Malignant pleural mesothelioma, MPM, thoracic metastases, survival, management, treatment, heterogeneity.
to delays in care pathway, median time from first abnormal imaging to definitive diagnosis was 34 days (IQR 20.5 to 55), definitive diagnosis to first therapeutic intervention was 65 days (IQR 35.8 to 163.8), and definitive diagnosis to palliative consult was 289 days (IQR 3 to 1651).

Conclusion: Overall outcomes for MPM patients presenting at our center are equivalent to historical controls. However, significant heterogeneity and delays exist during the patient trajectory. A centralized approach to diagnosis and treatment may lead to a more efficient and beneficial trajectory for these patients.

P2.06 MESOTHELIOMA
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.06-35 PLEURECTOMY DECORTICATION VERSUS EXTRAPLEURAL PNEUMONECTOMY IN MALIGNANT PLEURAL MESOTHELIOMA: SPARCS DATA

M. Van Gerwen1, R. Flores2, B. Liu3, A. Wolf3, J. Gomez4, E. Taioli2
1Department for Population Health Science and Policy and Institute for Translational Epidemiology, Icahn School of Medicine at Mount Sinai, New York City/US.
2Department of Thoracic Surgery, Mount Sinai Medical Center, New York/US.
3Department for Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York City/US.
4Department of Thoracic Surgery, Icahn School of Medicine at Mount Sinai, New York/US.

Background: Malignant pleural mesothelioma (MPM) is a rare but grave cancer with poor survival. To date, the debate on the surgery of choice in patients with operable MPM is still ongoing. We evaluated surgery-related mortality and post-operative complications among patients treated with Extrapleural Pneumonectomy (EPP) vs Pleurectomy Decortication (P/D) in the New York Statewide Planning and Research Cooperative System (SPARCS) database. Method: SPARCS is an all payer claim database for the State of New York. Data of inpatient stays (1995-2012) were used to extract 3826 unique patients with a diagnosis of MPM (ICD-9-CM: 163 identifying 233 patients treated with EPP (ICD-9-CM codes: 325, 3259) and 267 patients treated with P/D (ICD-9-CM codes: 345, 3451). We used propensity score methods using a logistic regression model matching patients on the following variables: age, race, the presence or absence of comorbidities, type of insurance and type of admission (using 1:1 matching with absolute difference in scores of 0.08).

Result: There was no difference in the proportion of males between EPP (76.2%) and P/D (80.9%). EPP patients were younger (mean age 60.8 vs 68.6 years), significantly more likely to be white (94.0% vs 85.2%), privately insured (56.6% vs 29.9%) and admitted for an elective procedure (97.9% vs 56.6%). There were not significantly different between EPP and P/D patients, the odds of having postoperative complications was 1.22 (95% CI: 0.68-2.20) when comparing EPP and P/D, the in-hospital mortality in the matched patients groups comparing EPP and P/D was higher but not significant (ORadj: 2.82 (95% CI: 0.70-11.38)). The odds of having postoperative complications was 1.22 (95% CI: 0.68-2.20) when comparing EPP and P/D. The in-hospital mortality in the matched patients groups comparing EPP and P/D was higher but not significant (ORadj: 2.73; 95% CI: 1.14-6.50).

Conclusion: The analysis showed a tendency towards higher odds of in-hospital mortality for EPP versus P/D however not statistically significant. While the odds of postoperative complications were not significantly different between EPP and P/D patients, the odds of supraventricular arrhythmia as postoperative complication were 2.7 times higher after EPP versus P/D. A less invasive surgical approach, may provide a better option when technically feasible for MPM patients.

P2.06-34 INHIBITION OF THE HGF/C-MET PATHWAY FORMALIGNANT MESOTHELIOMA WITH AN INTRA-THORACIC INJECTION OF THE NK4 EXPRESSING ADENOVIRAL VECTORS

Y. Tada1, T. Morinaga1, I. Sekine1, T. Suzuki1, I. Shimomura1, K. Tatsumi1, T. Takiguchi1, H. Shimada1, K. Hiroshima1, M. Tagawa2
1Chiba University, Chiba/JP.
2Chiba Cancer Center Research Institute, Chiba/JP.

Background: The HGF/c-Met pathway is up-regulated in human mesothelioma. In a preclinical study, the HGF/c-Met suppression with NK4 homologous to HGF, produced anti-tumor effects to mesothelioma cells. Mesothelioma grows in a thoracic cavity and the distant metastasis to extra-thoracic organs is infrequent which is suitable for local treatment including gene therapy. Method: We conducted a phase 1 clinical trial of gene therapy using the NK4 gene-expressing adenovirus vectors (Ad-NK4) to control the intra-thoracic local tumor growth. We injected Ad-NK4 into the intra-thoracic cavity once with a dose escalation manner from 1010 to 1012 virus particles per patient and to examine safety and efficacy for a month after the administration. Result: A total of 11 patients compatible with the inclusion criteria entered into the study (Low dose 3, Medium dose 3, High dose 5). Most frequent occurred adverse event was Grade 1 transient fever after injection. Severe adverse effects (Grade 3 or 4) or treatment-related death were not found, and 3 long survivor were currently followed up. Tumor shrinkage were not observed and response to therapy were SD at best. Antibody to adenovirus was observed in most cases that lasting longer than 30-days. An investigation on a gene transduction level is now on-going. Conclusion: Direct injection of Ad-NK4 vectors into the pleural cavity, up to the dose of 1012 v,p is safe. Combination ANK4 gene therapy with chemotherapy or immunotherapy may be feasible.

P2.06-36 EORTC 1205: RANDOMIZED PHASE II STUDY OF PLEURECTOMY/DECORTICATION PRECEDED OR FOLLOWED BY CHEMOTHERAPY IN EARLY STAGE MPM

J. Raski1, V. Surmont2, B. Hasan1, E. De Maio3, P. Van Schill4, J. Van Meerbeeck4
1Thoracic Oncology, University Hospital Antwerp, Edegem/BE, 2Uz Gent, Gent/BE, 3Eortc, Brussels/BE, 4Thoracic and Vascular Surgery, Antwerp University Hospital, Edegem (Antwerp)/BE

Background: Case series show a prolonged survival in resectable malignant pleural mesothelioma (MPM) with a combined modality approach of surgery and chemotherapy. Pleurectomy/decortication is the most commonly used surgical procedure in MPM, but is associated with a significant morbidity; the MARS trial (Treasure, Lancet Oncol 2011) suggests no outcome benefit and a possible harm to the patient. Retrospective studies suggest a better outcome with lung sparing resection (extended pleurectomy/decortication, e-P/d-P), but the procedure lacks uniformity and standardization. The optimal sequence of surgery and chemotherapy, the latter given either adjuvant or neo-adjuvant has not yet been determined. Method: EORTC 1205 is a phase II, randomized (1:1) multi-centre trial comparing both approaches. Primary end-point is the successful completion of the multimodality treatment within 20 weeks. Secondary end-points are DFS, OS, treatment-failure-free survival (TFFS), toxicity/safety, operative mortality/morbidity and surgical quality and uniformity indicators. Patients with pathologically proven malignant pleural mesothelioma of all histological subtypes, early stage (cT1-3 N0-2 M0 according to TNM 7), WHO-PS 0-1 and fit for chemotherapy and surgery are eligible. No previous treatment, including prophylactic thoracic radiation, is allowed, except for diagnostic thoracoscopy with talc pleurodesis, which must be performed before randomization. Patients are randomized between arm A - immediate surgery (extended pleurectomy/decortication), followed by 3 cycles of cisplatin 75 mg/m² plus pemetrexed 500 mg/m² on day 1 q3w, or arm B - deferred surgery, preceded by 3 cycles of chemotherapy. Result: Currently 4 of 6 planned sites have opened and 10 patients have been randomized in 2 centres.

P2.06-37 FOUR IMMUNOHISTOCHEMICAL ASSAYS TO MEASURE THE PD-L1 EXPRESSION IN MALIGNANT PLEURAL MESOTHELIOMA

Department of Oncology, Immunology and Surgery, Nagoya City University Graduate School of Medical Sciences, Nagoya/IP

Background: Malignant pleural mesothelioma (MPM) is a rare disease with no effective standardized systemic therapy. Immune checkpoint inhibitors (ICIs) targeting the programmed death 1 (PD-1)/programmed death ligand 1 (PD-L1) pathway are expected to be a novel therapy for MPM patients. However, the PD-L1 expression, which is a predictor of the response to ICIs, is unclear in MPM. Method: We studied the PD-L1 expression using four immunohistochemical, companion diagnostic assays (SP142, SP263, 28-8 and 22C3) in 32 MPM patients. The PD-L1 expression in tumor cells (TCs) and immune cells (ICs) was evaluated to clarify the rate of PD-L1 expression and the concordance among the four assays in MPM. The cut-off values were set at 1% TC for 28-8, and 1% IC for SP142, 25% TC for SP263, 1% TC for 28-8, and 1% IC for 22C. Result: The positivity rate of PD-L1 expression was 35.1% TC for SP142, 28.1% for SP263, 53.1% for 28-8, and 56.3% for 22C. Nine cases were positive and 10 were negative for all assays. Discordance among the four assays was found in 13 cases. The concordance rates between SP142 and 22C and between 28-8 and 22C were the highest (84.4%). The concordance rates between SP263 and the other three assays were low (71.9% to 75.0%).

Conclusion: The PD-L1 expression in MPM was almost equivalent for three of the assays. Given the cut-off values set in our study, these findings suggested that these assays, except for SP263, can be used for accurate PD-L1 immunostaining in MPM.

Background: Cancer cell repopulation during treatments of chemotherapy or radiotherapy is a major factor resulting in treatment failure. It has been indicated that cancer stem cells (CSC) may play critical roles during this process. The goal of our study is to characterise mesothelioma stem cells (MSC) and evaluate the prognostic values in those patients with malignant pleural mesothelioma (MPM). The eventual aim would be to design specific target therapy against MSC and develop novel approaches in clinical practice. Method: We have screened a group of genes that are most likely MSC-specific. Further characterization of the selected genes will be of critical importance in tumorigenesis, progression and prognosis. Murine mesothelioma AB12 and RNS5 cells treated with either chemotherapy or γ-ray irradiation in culture, were used to compare

**P2.06-36** MALIGNANT PLEURAL MESOTHELIOMA ABSTRACTS

**P2.06-37** FOUR IMMUNOHISTOCHEMICAL ASSAYS TO MEASURE THE PD-L1 EXPRESSION IN MALIGNANT PLEURAL MESOTHELIOMA

**P2.06-38** MESOTHELIOMA STEM CELLS MAY BE THE CRITICAL FACTOR OF TREATMENT FAILURE
Keywords: Provide predictive and prognostic implications for MM patients. It is a mutation, commonly identified in non-small-cell cancer (NSCLC) patients, PIK3CA, KRAS, BRAF, CDKN2A, ERBB3, MET inhibitors administration. Besides, patients with the active or inactive of-function mutations, which suggests the possible sensitivity of mTOR NF1, NF2 (2), followed by fluid sample. The most frequently mutated genes were samples included 8 tumor tissue samples, 17 blood samples and 1 ascetic values are 0.0013, 0.0017 and 0.0035, respectively, when γ especially after that chemoradiation resulted in MSC enrichment. Upregulation of genes proportion of MSC significantly increased after RN5 parental cells were precursors captured with magnetic nanoparticles conjugated to anti-Msln and trapped in the microfluidic device in the presence of a magnetic field showed an increase over time from 2-2.5 weeks. Image analysis of human section slides indicated that total positive area of CD271 staining was significantly lower in those who were treated with SMART protocol than those with pre-SMART protocol (p=0.0025). Similar results were obtained in the high, medium and low positive areas from the SMART group, and p values were 0.0013, 0.0017 and 0.0035, respectively, when compared with the pre-SMART group. Conclusion: MSC-specific genes like CD271 and Tnfsf18 might be used as potential prognostic indicators and therapeutic targets.

P2.06 MESOTHELIOMA TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.06-39 NEXT GENERATION SEQUENCING REVEALS GENETIC LANDSCAPE OF MALIGNANT MESOTHELIOMA J. Ren 1, M. Yuan 2, Y. Song 1, L. Zhou 1, J. Zhao 1, Y. Chen 1, L. Chen 1, W. Wang 1, C. Xu 1, R. Chen 1, X. Xia 1
1Beijing Shijitan Hospital, Beijing/CN, 2Genetplus-Beijing, Beijing/CN, 3Thoracic Oncology, Beijing Cancer Hospital, Beijing/CN, 4Fujian Cancer Hospital, Fuzhou/ CN, 5Department of Medical Oncology, Sun Yat-Sen University Cancer Center, Guangzhou/CN, 6Zhejiang Cancer Hospital, Hangzhou/CN.

Background: Malignant mesothelioma (MM) is a rare form of cancer affecting the mesothelium lining. The 5-year survival rate of advanced patients is less than 1% due to the lack of effective medical therapies. To investigate the possibility of targeted therapy for MM patients, a deeper understanding of the genetic basis is required. Method: We reviewed 26 samples taken from 22 MM patients who underwent genetic testing at our institute from 2016 to the present. Somatic mutation profiles were analyzed using hybridization capture based next-generation sequencing (NGS), which enables the simultaneous detection of single-nucleotide variants, insertions/deletions, rearrangements, and copy-number alterations of at least 59 genes (range 59 - 1021 genes). Result: The 26 samples included 8 tumor tissue samples, 17 blood samples and 1 ascitic fluid sample. The most frequently mutated genes were TP53 (11/21), followed by NF2 (6), RB1 (4), NFI (3), FLI1 (3), BAP1 (2), EGFR (2), FAT2 (2), FGFR4 (2), KIT (2), MAP3K1 (2), MLH1 (2), STK11 (2), APC, ATR, BRAF, BRCA2, CDKN2A, ERBB3, FBXW7, MET, KRAS, PIK3CA and so on. Among these mutations, 5 of NF2 mutations and 2 of NF1 mutations were loss-of-function mutations, which suggests the possible sensitivity of mTOR inhibitors and the association between these genes and the active or inactive mutations of KRAS, BRAF, CDKN2A, ERBB3, MET and PIK3CA might be sensitive to corresponding targeted drugs. MET exon 14 skipping mutation, commonly identified in non-small-cell cancer (NSCLC) patients, had never been reported in MM patients before. c-Met inhibitors such as crizotinib and cabozantinib may be of efficacy for this patient. Apart from predicting therapeutic effectiveness of MEK inhibitors, the detection of KRAS activating mutation may also provide prognostic information. Conclusion: NGS can identify genetic mutations comprehensively and provide predictive and prognostic implications for MM patients. A cost-effective tool to describe the genetic landscape of MM, which will facilitate the development of novel therapeutics for the treatment of MM patients.

Keywords: Genetic landscape, Mesothelioma, NGS

P2.06-40 VISTA IS HIGHLY EXPRESSED IN MALIGNANT PLEURAL MESOTHELIOMA (MPM) AND INDEPENDENT OF PD-L1 EXPRESSION M. Zauderer 1, S. Muller 1, W. Lai 1, A. Niz 1, A. Jungbluth 2, M. Ginsberg 1, R. Daly 1, M. Hellmann 1, M. Ladanyi 1, J. Sauter 2
1Medicine, Thoracic Oncology Service, Memorial Sloan Kettering Cancer Center, New York/US, 2Pathology, Memorial Sloan Kettering Cancer Center, New York/NY/US, 3Memorial Sloan Kettering Cancer Center, New York/NY/US, 4Pathology Department, Memorial Sloan-Kettering Cancer Center, New York/NY/US

Background: PD-L1 blockade is effective in only a minority of MPM patients and predictors of response in MPM are unclear. Recent TCGA analysis of MPM revealed VISTA (V-domain Ig-containing suppressor of T cell activation), another inhibitory T cell checkpoint protein, to be frequently expressed in MPMs. In search of other immunotherapeutic targets in MPM, we evaluated the expression of VISTA, its relationship with expression of PD-L1, and the association with response to PD-1 blockade in MPM. Method: We retrospectively investigated the MPM database at Memorial Sloan Kettering to identify patients who received immune checkpoint inhibitors (ICIs). Archival tissue, where available, was obtained and we performed immunohistochemistry (IHC) using antibodies to PD-L1 (clone E1L3N) and VISTA (clone D2L2G), both from Cell Signaling Technology. Imaging studies were reviewed with a thoracic radiologist according to the modified RECIST criteria. Result: 37 patients were identified as having received at least one dose of ICIs, of whom 26 patients had tissue for VISTA/PD-L1 testing. VISTA was positive (≥1%) in 25 (96%) and >50% in 22 (84%). PD-L1 was positive in 11 (42%) ≥50% in 2 (8%). No evident correlation between VISTA and PD-L1 expression was seen. Correlation with response will be reported. Conclusion: In contrast to PD-L1, VISTA is highly expressed in malignant pleural mesothelioma with MPM. Its expression appears independent of PD-L1 expression. Molecules targeting VISTA and its ligand should be prioritized for clinical development in MPM.

Background: Current immunohistochemistry (IHC) biomarkers, or so-called “mesothelial markers”, lack sensitivity and specificity in differentiating sarcomatoid mesothelioma from pleomorphic carcinoma of the lung, and poorly differentiated chest wall sarcoma. Hence it frequently poses a diagnostic challenge for pulmonary pathologists. In this pilot study we evaluated the diagnostic performance of two recently proposed IHC biomarkers, GATA-3 and MUC4, in conjunction with BAP1. Method: Sarcomatoid mesothelioma or sarcomatoid- predominant biphasic mesothelioma (10 cases), pleomorphic carcinosarcoma of the lung (10 cases) and poorly differentiated primary or metastatic chest wall or pleural sarcoma (10 cases) were retrieved from our diagnostic archive. Resections or large biopsies were selected over small biopsies whenever possible. All the cases were diagnosed between 2009 and 2017 by a specialist pulmonary pathologist and discussed at the local multi-disciplinary team meeting in relation to final diagnosis. Whole slide GATA-3 (LS5-823, pre-diluted), MUC4 (B7G, 1:50) and BAP1 (C-4, 1:50) immunohistochemistry were performed using Ventana Benchmark ULTRA system. Lymphocytes (GATA-3/BAP1) and bronchiolar epithelium (MUC4) were used as internal positive controls. Loss of GATA-3/BAP1 and MUC4 staining was defined as complete loss of nuclear or membrane & cytoplasmic signals, respectively. Any staining intensity above the external negative controls was accepted as positive. Extent of positive staining was grouped as <1%, 1-50% and >50%. Result: GATA-3 was positive in 8/10 sarcomatoid mesothelioma, 6/10 chest wall/pleural sarcoma and 2/10 pleomorphic carcinoma of the lung. MUC4 positivity was observed exclusively in pleomorphic carcinoma of the lung (6/10), but only focally. BAP1 loss was infrequently observed in all three types of tumours.

Keywords: GATA-3/MUC4/BAP1 IHC
Background: With the recent clinical success of immunotherapy in non-small cell lung carcinoma, the character of the inflammatory infiltrate associated with these tumors is now the subject of increasing interest. Molecular studies have suggested that tumors can be stratified by the character of their inflammatory infiltrate. We now describe the detailed histological appearances of a multi-institutional series of early stage squamous carcinomas and correlate them with mutation burden, PD-L1 expression patterns and clinical outcome. 

Method: Histologic sections of from 250 tumors were evaluated by two pathologists independently for squamous subtype (WHO classification), percentage and character of intratumoral inflammatory cells, percentage and character of para-tumoral infiltrate and presence or absence of scalloping at tumor cell/stromal interface by inflammatory cells along the edges of tumor cell nests. A feature possibly related to existing immune reaction. The ratios of infiltrating inflammatory cells to tumor cells were estimated in 10% increments by microscopic inspection. Quantity and character of infiltrates was assessed by Kaplan-Meir testing for effect on survival and by Pearson bivariate testing for relationships among variables.

Result: The character and extent of inflammatory infiltrates were highly heterogeneous. The infiltrates could be divided into intratumoral and paratumoral patterns according to their location in relation to microscopic tumor cell nests. Intratumoral infiltrates could be further subdivided into two patterns: one consisted exclusively lympocytes, usually few in number; a second polymorphous pattern contained many inflammatory cell types including polymorphonuclear leukocytes (PMNs). In paratumoral tissue, three patterns could be discerned: lymphocytic, plasmacytic and polymorphous. Inflammatory cell infiltrate quantity or character did not correlate with survival for either intratumoral or paratumoral infiltrates and there was no evident relationship to mutational burden or to PD-L1 expression by IHC. Scalloping at the tumor/stromal interface was also not prognostically significant.

Conclusion: The inflammatory infiltrates in early stage squamous lung carcinoma are highly heterogeneous and are not associated with outcome. However, the complexity of tumor infiltrating inflammatory cells is worthy of further evaluation in future immunotherapeutic trials.

Keywords: Tumor-associated immune cell, infiltration patterns, early stage squamous lung carcinoma
with a diagnosis of NSCLC was selected. Each patient had a surgical specimen with a corresponding cytology sample (cell block), including 22 specular effusions, and/or a biopsy, for a total of 182 specimens. IHC was performed using 28-B and SP263 PD-L1 kits. PD-L1 staining was measured as the percentage of tumor cells with membranous staining (tumor proportion score, TPS) as rated blindly by four evaluators. Sixty sites were then blindly reevaluated for documenting intraobserver agreement. PD-L1 TPS was grouped as <1%, 1-49% and >50%. Fleiss and Cohen’s kappas were used to evaluate TPS concordance between tissue and cytology specimens and to assess the inter and intraobserver agreement. Result: Respectively for 28-B and SP263 kits, 37.5 and 25.0% of the 32 patients with a cytology sample had a PD-L1 TPS of >50% with a good agreement between the kits (k=0.73, CI95% 0.50-0.97). The agreement between the cytology and surgical specimen was good (28-B: k=0.76, CI95% 0.46-1.0, SP263: k=0.75, CI95% 0.42-1.0) and was slightly better between the 21 patients with a biopsy and a cytology specimen (28-B: k=0.71, CI95% 0.31-1.0, SP263: k=0.67, CI95% 0.19-1.0). For the evaluation of PD-L1 TPS in cytology specimens, the interobserver agreement was good (28-B: k=0.71, CI95% 0.60-0.82, SP263: k=0.63, CI95% 0.52-0.74) and the intraobserver agreement was excellent (k=0.93, CI95% 0.85-1.0). Conclusion: We showed that PD-L1 TPS evaluated in cytology samples have a good concordance with biopsy and surgical specimens. We also demonstrated that the evaluation in cytology specimen is feasible as the inter and intraobserver agreement of PD-L1 expression was good to excellent. Overall, our results support the use of PD-L1 IHC on cytology specimens, however, this will need to be correlated with the clinical response to immunotherapy.

P2.09 PATHOLOGY, TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.09-03 RAPID-IMMUNOCYTOCHEMISTRY FOR EVALUATION OF SURGICAL MARGIN IN SUBLOBAR PULMONARY RESECTION
1Thoracic Surgery, Akita University Graduate School of Medicine, Akita/JP, 2Thoracic Surgery, Iwate Medical University, Morioka/JP, 3Division of Clinical Pathology, Akita University, Akita-City/JP, 4Division of Thoracic Surgery, Shizuoka Cancer Center, Suntou-Gun/JP

Background: Histological evaluation of surgical margin for pulmonary malignant tumor in sublobar resection is difficult in automatic suture instrument (stapler) used in thoracoscopic surgery. In order to solve this problem, we devised a novel surgical margin assessment method that combined with rapid-immunocytochemistry (R-IHC) analyses within 20 minutes. By applying this device to R-IHC, we can perform intraoperative R-IHC within 30 minutes. By using this method, it is a possibility that the surgical margin can be accurately evaluated more than papanicolaou staining alone.

Method: From September 2016 to December 2017, we examined 21 lesions of pulmonary malignant tumor in 21 patients who underwent sublobar resection at Akita University Hospital. There were 12 male and 9 female patients whose ages ranged from 45 to 83 years old. Six patients underwent segmentectomy and 15 of ones underwent wedge resection. Histological diagnosis of staple stump and cytological diagnosis of staple lavage fluid (papanicolaou staining) and R-IHC were performed. The cases underwent segmentectomy and 15 of ones underwent wedge resection. There were 12 male and 9 female patients whose ages ranged from 45 to 83 years old. Six patients underwent segmentectomy and 15 of ones underwent wedge resection. Histological diagnosis of staple stump and cytological diagnosis of staple lavage fluid (papanicolaou staining) and R-IHC were performed. The cases were classified by pathological results, and each cases were followed up.

We performed R-IHC using each antibodies against for cytokeratin (CK) 7-20, CD and Thyroid transcription factor-1 (TTF-1) in adenocarcina, p-40 in squamous cell carcinoma, respectively. Result: The histological diagnoses were 4 lung adenocarcinomas, 5 squamous cell carcinomas, 7 colorectal adenocarcinomas, 1 renal cell carcinoma, 1 hepatocellular carcinoma, 1 duodenal cancer, 1 endometrial cancer and 1 bile duct cancer. No histological diagnosis of staple stump was observed in malignant findings in all cases. On the other hand, in conventional cytological diagnoses there were 2 cases of class V, 1 case of class IV and 1 case of class III, R-IHC were positive in all 4 cases of class III or higher. Among 4 cases of class IV, we performed additional resection in 2 cases of class V but not in the other two cases because difficulty in further resection. In the case of class IV without additional resection, local recurrence was observed in 4 months after surgery. Conclusion: Among 21 cases, local recurrence was observed in one patient with positive cytological diagnosis and positive R-IHC diagnosis. There is a possibility that staple lavage fluid cytology can more accurately evaluate the stump than the tissue crushed by the staple. If there are very few cancer cells in the lavage fluid, R-IHC may be useful for cancer cell detection.

Keywords: surgical margin, sublobar pulmonary resection, rapid-immunocytochemistry

P2.09 PATHOLOGY, TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.09-04 PD-L1 EXPRESSION IN PRIMARY LUNG ADENOCARCINOMA AND ITS RELATION WITH EGFR / KRAS MUTATION AND CLINICOPATHOLOGICAL FEATURES
L. Li1, C. Guo1, L. Guo2, H. Dai3, J. Ying1, Y. Gao4
1Department of Pathology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN, 2State Key Laboratory of Molecular Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Background: Programmed cell death-1 (PD-1)/programmed cell death-ligand 1 (PD-L1) pathway-targeted immunotherapy is becoming standard primary malignant tumor in lung cancer. The expression of PD-L1 and PD-L2 in normal epithelial cells is a negative feedback mechanism to prevent excessive immune infiltrates into tumors. PD-L1 protein is expected to apply to evaluate therapeutic or to predict the response to PD-1-blocking antibodies. The immunohistochemistry(IHC) assay for PD-L1, 22C3 pharmDX, has revealed that about 30% of all non-small cell lung cancer (NSCLCs) express the PD-L1 with a high level. The association between PD-L1 positivity and the clinicopathological features in lung adenocarcinoma (ADC) remains unclear, however. Method: We retrospectively evaluated the PD-L1 expression in the surgically resected tumor tissues by IHC with the 22C3 assay, from 233 primary lung ADC patients. The PD-L1 tumor proportion score (TPS) was calculated as the percentage of at least 100 viable tumor cells with complete or partial membrane staining. TPS was reported in three categories (no expression, <1%, low expression, 1-49% and high expression, ≥50%). Result: Of the 233 cases analyzed, the median age was 60 (range, 34-84) years. 149 (63.9%) patients were female, 167 (71.7%) patients were never-smokers, and 55 (23.6%) patients had stage III (50) and IV (5) disease. Among them, 139 (59.7%) patients had activating EGFR mutations, and 133 (58.9%) patients were KRAS mutant. P<0.05, 233 patients with a corresponding cytology sample (cell block), including 22C3 AND SP-142 ANTIBODIES IN COHORT OF PATIENTS TREATED ON KEYNOTE-001
A. Lisberg1, S. Hu-Lieskovan1, T. Grogan1, J. Carroll1, P. Shintaku1, M. A. Albertson2, Y. Minamiya1
1Thoracic Surgery, Akita University Graduate School of Medicine, Akita/JP, 2Thoracic Surgery, Iwate Medical University, Morioka/JP, 3Division of Clinical Pathology, Akita University, Akita-City/JP

Background: We performed a retrospective analysis of 28 NSCLC patients treated on KEYNOTE-001. Method: We performed a retrospective analysis of 28 NSCLC patients treated on KEYNOTE-001. Result: This investigation shows that in primary lung adenocarcinoma the PD-L1 expression was significantly associated with younger age, male, smokers, high stage/disease, EGFR wild-type and KRAS mutant. Therefore, it is rational to choose a different checkpoint inhibitor according to the driver gene mutation status and to combine targeted therapies and anti-PD-L1 agents.

Keywords: PD-L1, Adenocarcinoma, lung
were grouped similarly (either <1%, 1-49%, or >50%) by both antibodies. Specifically, compared to 22C3 staining, SP-142 led to the same grouping for 63% (58/88) pts with >50% staining, 85% (11/13) pts with 1-49% staining, and 14% (1/7) pts w <1% staining. Evaluating the relationship between PD-L1 grouping and clinical outcomes via the SP-142 antibody revealed improved PFS and OS in pts with higher PD-L1 expression levels, while the 22C3 antibody predicted for improved PFS in these patients, but not improved OS [SP142 (PFS,OS): (p=0.0039, p=0.0425)][22C3 (PFS,OS): p=0.0121, p=0.1222]. The PD-L1 results from the SP-142 and 22C3 antibodies were strongly associated (r =0.58, p=0.001). Conclusion: The PD-L1–stained tumor cell levels in the majority of patients evaluated were similarly grouped into one of three categories (<1%, 1-49%, or >50%) by both 22C3 and SP142. This analysis is limited by small patient number, but suggests that the number of PD-L1–stained tumor cells identified by each antibody is similar and a higher PD-L1 level identified by either antibody predicts for improved clinical outcomes with pembrolizumab.

P2.09 PATHOLOGY
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.09-06 EXPRESSION OF PD-L1 ON ROUTINE NON-SMALL CELL LUNG CARCINOMA SECTIONS: COMPARATIVE ASSESSMENT OF SP263 (VENTANA) AND 22C3 (DAKO PHARMDX)

A.M. Quinn1, J. Gosney1, P. Bishop1, R. Bloom1, C. Harrel1, C. McNulty1, R. Bowden2, A. Moss5, S. Forrest2, A. Montero6, A. Chaturvedi6, L. Joseph1, A. Paiva-Correia1, H. Doran2, P. Taniere7, P. Crosbie2, F. Blackhall5, Y. Summers5

Background: The SP263 (Ventana Benchmark) antibody as a predictive immunohistochemical marker for pembrolizumab therapy provides an avenue for local testing. Pathologists without access to the Dako Autostainer Link 48 platform (certified for the Dako 22C3 antibody) have been restricted to referrals at external departments, resulting in an increased turnaround time. Here we report the results of our local verification of SP263. Method: Specimens previously assessed for 22C3 PD-L1 expression at either Royal Liverpool Hospital or Queen Elizabeth Hospital Birmingham were selected from the archives of Wythenshawe Hospital. Cases with less than 100 viable residual tumour cells were excluded. The same tumour block was selected for staining with the Roche SP263 clone and specimens were assessed for tumour proportion score (TPS), immune cell proportion and staining intensity. Assays were reported as disagreeing if a differing TPS changed the therapeutic cut-off ranges. Result: Expression levels of 22C3 and SP263 were compared across 100 cases (43 resections, 26 biopsies, 26 lymph node aspirates, 5 node excisions); 59 adenocarcinomas, 33 squamous carcinomas, 8 not otherwise specified (70 primary, 30 metastatic). The TPS ranges (<1%, 1 - 49%, > 50%) were in agreement for 78 samples. Of the 22 cases with differing ranges, 15 reflected a TPS of <10% and 7 had greater differences e.g. 10% versus 60%. Reasons for discrepancies included faint membranous staining on a few of the 22C3 sections (not apparent on SP263), scoring of carcinoma in situ, possible scoring of cells at a deeper block level, and variation in interpretation by the scoring pathologists. The overall Pearson correlation coefficient (r) was 0.9025, p < 0.00001.

**Conclusion:** Tumour expression profiles of PD-L1 are similar for the 22C3 and SP263 antibodies, with a rate of variation similar to previous reports. Cases that are discrepant may reflect differences in pathologist interpretation rather than the assay.

**Keywords:** PD-L1, SP263, 22C3

P2.09-07 DOES METASTATIC SITE MATTER FOR PD-L1 TESTING IN STAGE IV NSCLC?
H. Wang¹, J. Agulnik², G. Kasymanova², P. Fiset¹, S. Camilleri-Broët¹, M. Redpath¹, D. Small¹, V. Cohen³, A. Spatz¹
¹Department of Pathology, McGill University Health Center & McGill University, Montreal/QC/CA, ²Division of Pulmonary, Jewish General Hospital & McGill University, Montreal/QC/CA, ³Department of Oncology, Jewish General Hospital, Montreal/CA

Background: Stage IV non-small cell lung cancer (NSCLC) often presents with metastasis to multiple distant sites. Currently PD-L1 expression by immunohistochemistry (IHC) testing with Tumor Proportion Score (TPS) ≥50% and ≥1% is required for first- and second-line Pembrolizumab treatment respectively. However, it is not well known if PD-L1 expression differs in NSCLC specimens sampled from different distant metastatic sites. In this study, we evaluate PD-L1 expression in distant metastasic sites.

Method: A total of 400 NSCLC specimens from distant metastatic sites were included in this study. The metastatic sites include brain, bone, non-regional lymph nodes, serous membranes (pleura, pericardium and peritoneum) and organs outside the chest (liver, adrenal gland, skin, soft tissue). The samples are either cytology cell blocks, small biopsies or surgical resections. IHC was performed using Dako PD-L1 IHC 22C3 pharmDx. A total of 100 viable tumor cells is required for adequacy. TPS ≥50% and 1-49% are defined as high and low PD-L1 expression respectively. Result: Overall, the rate of TPS ≥50% ranges from 36-47% in different metastatic organ sites (Table 1). The prevalence of PD-L1 high and low expression is similar for all distant metastatic sites (P=0.91). Brain metastases have a slightly lower rate of high PD-L1 expression but the difference is not statistically significant.

P2.09-08 CLINICAL OUTCOMES OF HISTOLOGY VERSUS CYTOLOGY PD-L1 22C3 ANTIBODY TESTING IN ADVANCED NON- small CELL LUNG CANCER
Y. Wang¹, M. Butler², A. Naqvi³, J. Cutz², R. Juergens⁴
¹Medical Oncology, McMaster University, Juravinski Hospital and Cancer Centre, Hamilton/CA, ²Oncology, McMaster University, Escarpment Cancer Research Institute, Hamilton/CA, ³McMaster University, Pathology and Molecular Medicine, Hamilton/ON/CA, ⁴McMaster University, Escarpment Cancer Research Institute, Hamilton/CA

Background: Immune checkpoint inhibitors (CPIs) are now an accepted standard of care along the treatment algorithm for advanced non-small cell lung cancer (NSCLC). PD-L1 expression using 22C3 immunohistochemistry (IHC) help determine the line of therapy in which CPIs are used. Previous studies demonstrated that PD-L1 expression is comparable on cytology versus solid biopsy/histology specimens. We assess the clinical outcomes between patients with PD-L1 expression ≥50% (high positive) tested using cytology versus histology specimens.

Method: This retrospective cohort study includes specimens processed between January 2015 to June 2017 on samples dating back to March 2014. Patients were included in the study if they were seen by a medical oncologist for consideration of systemic treatment for advanced NSCLC. Clinical characteristics were extracted from electronic medical records. Overall survival (OS) was defined as time from diagnosis of advanced NSCLC to death and compared by method of PD-L1 analysis (cytology versus histology), adjusting for age, ECOG, weight loss, and receipt of palliative intent radiotherapy, targeted therapy, and CPI. Result: 148 (30.8%) of 481 samples tested ≥50% for PD-L1 expression. Amongst those, 32 and 37 patients fulfilled eligibility criteria with cytology and histology samples respectively. Baseline characteristics of the two groups are comparable in age, gender. ECOG, pathological subtype, and receipt of CPIs. The cytology group had a significantly higher number of patients with baseline pleural effusion (10 vs 4 patients, p=0.035) and receipt of any systemic therapy (28 vs 22 patients, p=0.009). The histology group received more palliative intent radiation (24 vs 13, p=0.044). There was no difference in OS between the cytology and histology groups. Median OS in the cytology group was 11.9 versus 8.0 months in the histology group; adjusted HR 0.98 (95% CI 0.43-2.66). Amongst patients who received systemic therapy, survival was longer if patients were exposed to CPI during their course of treatment regardless of cytology or histology groups; adjusted HR 0.45 (95% CI 0.22 – 0.90).

Conclusion: In advanced NSCLC, CPI treatment guided by specimens analyzed by cytology versus histology were equivalent in survival. Regardless of sample source, patients exposed to CPI in any line of therapy had significantly longer survival than patients without exposure to CPI amongst patients testing high positive for PD-L1. Ongoing analyses are comparing clinical outcomes in patients with other expressions of PD-L1.

P2.09-09 PRECISION AND REPEATABILITY OF VENTANA DLL3 (SP347) ASSAY IMMUNOHISTOCHEMISTRY ASSAY IN FINE NEEDLE ASPIRATIONS OF SMALL CELL LUNG CANCER
B. Admire¹, B. Holmes², E. Elgabry³, C. Powell², D. Tyree³, R. Marati³, A. Hanlon Newell², B. Damadadze³, D. Dalvi³, R. Huang²
¹Ventana Medical Systems, Inc, Tucson/AZ/US, ²Global Medical Affairs, Ventana Medical Systems, Tucson/US, ³Ventana Medical Systems, Tucson/US

Background: Fine needle aspirations (FNA) are a common type of sample that is obtained for diagnostic purposes in small cell lung cancer (SCLC) patients due to its relatively less invasive nature. Several delta-like protein 3 (DLL3) therapies that target DLL3 in SCLC are under development. We recently developed an immunohistochemistry assay utilizing a rabbit monoclonal antibody that can be used to identify patients that may potentially respond to DLL3 targeted therapies. Due to the high prevalence of FNA samples in SCLC, the robustness of the VENTANA DLL3 (SP347) Assay (DLL3 (SP347)) in FNAs is examined.

Method: Formalin-fixed, paraffin-embedded (FFPE) FNA samples of SCLC were used in a series of studies addressing precision of performance of DLL3 (SP347). FNA SCLC samples were stained with the VENTANA DLL3 (SP347) Assay and assessed by a pathologist for percent tumor cell staining (%TC), at any stain intensity at ≤4X magnification. The samples were placed into quartile bins (0-24, 25-49, 50-74 and 75-100 %TC) and evaluated for intra-day repeatability and inter-day precision. For each case, the modal staining result based on %TC bin was determined and the result from each test sample was compared to its respective case-level modal staining result and deemed concordant or discordant. Results were aggregated across cases and the overall percent agreement (OPA) was calculated for each study. Result: Both studies (Table 1) showed >90% OPA for DLL3 concordance to the %TC bins.

Table 1: Precision and Repeatability of FNA SCLC Samples

**P2.09-10 QT-R-PCR AS AN EFFICIENT AND RELIABLE DIAGNOSTIC SCREENING APPROACH FOR THE DETECTION OF EML4-ALK FUSION GENE IN NSCLC SAMPLES: A PILOT STUDY**
A. Choughule1, V. Noronha1, S. Banavali1, P. Bagayakara2, K. Prabhask2
1Tata Cancer Centre, Tata Memorial Centre, Mumbai/IN, 2Tata Memorial Centre, Mumbai/IN

**Background:** ALK gene rearrangement occurs in 3-5% of NSCLC patients and provides an oncogenic driver in these tumors and generally responds to Crizotinib therapy. Identification of this EML4-ALK fusion gene requires a very sensitive and specific method. Both FISH and IHC are widely used in clinical laboratories for the detection of ALK rearrangements in NSCLC tumor samples. RT-PCR-based assays have not yet been as widely used as FISH and IHC for the detection of ALK rearrangements in NSCLC. Our aim is to review performance of RT-PCR assay in comparison with FISH and IHC for the detection of EML4-ALK in NSCLC. **Method:** A total of 100 cases of EGFR wild type were selected and were performed by FISH, IHC and RT-PCR simultaneously. **Result:** Out of 105 tumor FFPE samples of NSCLC, 76% of tumor samples were biopsies and cytology and 24% were resections of archival lung and brain metastasis. The RT-PCR test (diagnostic cut-off a Ct of ≤ 8) was shown to be highly sensitive (100%) when compared to FISH and IHC. The overall specificity of the RT-PCR test for the detection of ALK in cases without full-length ALK expression was 94% in comparison to FISH. No significant association was observed between EML4-ALK fusion gene and clinical stage. **Conclusion:** In contrast to FISH (Vysis ALK Break Apart probe) testing, as per the WHO guidelines, today IHC (Ventana ALK (DSF3 FDA approved) method) is well accepted for the detection of EML4-ALK. However, in our study using FISH and IHC alone in comparison to RT-PCR have demonstrated that RT-PCR has a high sensitivity and specificity. This test has also shown the rapid TAT and has advantage of ease as compared to FISH and IHC and can be done on biopsy as well as on cytology samples with lower tumor content. Our result indicates that identification of the specific variant by RT-PCR based ALK assay can potentially be used as a reliable stand-alone diagnostic screening approach and cost effective test and, which may apparently become important in the future for predicting patient response to ALK inhibitors. NGS fusion panels as the sole platform for detecting ALK and other NSCLC biomarkers in a single test are attractive.

**Keywords:** FISH, IHC, qRT-PCR comparison

**Background:** It has been proposed that a combination of assays may refine the prediction of response to checkpoint inhibitors, with tumour mutation burden (TMB) being lately the strongest biomarker associated with efficacy. Although some targeted next generation sequencing (NGS) assays provide a good estimate of whole exome sequencing, TMB, they are only available throughout referral laboratories. We sought to investigate the possibility of profiling TMB in-house with a commercially available targeted NGS assay, and to correlate the results with survival, the status of TP53, PD-L1 overexpression and tumor infiltrating lymphocytes (TILs). **Method:** The study included samples from 40 patients diagnosed with early-stage lung squamous cell carcinoma. PD-L1 immunohistochemistry (IHC) was performed with two clones (SP263 and SP142, Ventana Medical Systems). CDB+ TILs were scored with a digital algorithm. The status of TP53 (exons 4-10) was investigated with direct sequencing. Ion Torrent™ Oncomine™ Tumor Mutation Load Assay (ThermoFisher Scientific), a targeted NGS assay which covers a 1.7M across 405 cancer driver genes, was used to assess TMB, NGS was performed on genomic DNA from FFPE tumor samples using the Ion S5™ system. The results were analyzed with the Ion Reporter™ software. According to the manufacturer’s instructions, TMB was calculated based on the number of non-synonymous somatic mutations, after removing polymorphisms and known or predicted driver mutations from all the variants. We investigated the correlation between TMB and clinicopathological characteristics or NSCC favor SqCC subtypes.

---

**P2.09-12 EGFR MUTATION STATUS IN SQUAMOUS CELL CARCINOMA OR NON-SMALL CELL CARCINOMA FAVOR SQUAMOUS CELL CARCINOMA DIAGNOSED FROM SMALL LUNG BIOSPICES**
H. Ho1, H. Kao1, T. Chou1
1Pathology and Laboratory Medicine, Taipei Veterans General Hospital, Molecular Pathology, Taipei/TW, 2Pathology and Laboratory Medicine, Molecular Pathology, Taipei/TW

**Background:** Epidermal growth factor receptor (EGFR) mutation testing is strongly recommended in non-small cell lung cancer (NSCLC) patients with adenocarcinoma subtypes, or patients with mixed-type tumors containing adenocarcinomatous components. However, in clinical practice, patients showing squamous cell carcinoma (SqCC) morphologies on small biopsies cannot be ruled out to have an adenocarcinomatous component elsewhere in the lesion due to sampling bias. Therefore, EGFR mutation testing may have been neglected in such circumstances, which would affect the clinical management of patients. In this study, we sought to examine the frequency of EGFR mutations in lung cancer patients with SqCC or Non-Small Cell Carcinoma (NSCC) favor SqCC diagnosed from small biopsies. **Method:** One hundred and forty-eight patients diagnosed as SqCC or NSCC favor SqCC from small lung biopsies were enrolled. All of these cases were histologically confirmed by evaluating cellular morphology using hematoxylin-eosin (HE) staining and TTF1, p40 or CK5/6 expression using immunohistochemistry. EGFR mutations were examined using real-time PCR based assay. **Result:** Among 148 small biopsy cases, 135 (91.2%) were diagnosed as SqCC while 13 (8.8%) were NSCC favor SqCC. Approximately 8% (13/148) of all cases were found to have EGFR mutations, including 7 (53.8%) L858R, 4 (30.8%) exon 19 deletion, and 2 (15.4%) cases with coexistent L858R and T790M mutations. EGFR mutation-positive cases accounted for 5.2% (7/135) in SqCC, 46.2% (6/13) in NSCC favor SqCC, and 83.3% (10/12) of all these cases were never smokers. The multivariate analysis showed that EGFR mutations were more prevalent in non-smokers than those in smokers (83.3% versus 16.7%, p = 0.03) and in patients diagnosed as NSCC favor SqCC than in those diagnosed as SqCC (46.2% versus 5.2%, p = 0.002). In addition, 4 out of 13 EGFR mutation-positive patients with SqCC or NSCC favor SqCC morphology were eventually diagnosed as adenocarcinoma after further undergoing surgical resection. **Conclusion:** To the best of our knowledge, this is the first study directly addressing the importance of EGFR mutation testing in lung cancer patients with SqCC or NSCC favor SqCC diagnosed from small biopsies. Our findings suggest that EGFR mutation testing should not be excluded in such populations, especially in never-smokers, or patients with NSCC favor SqCC subtypes.
P2.09-13 CORRELATION OF ROS1 (SP384) IMMUNOHISTOCHEMISTRY WITH ROS1 REARRANGEMENT DETERMINED BY FLUORESCENCE IN SITU HYBRIDIZATION

R. Huang, D. Smith, B. Richardson, C. Le, W. Liu, A. Hanlon Newell, G. Pate, I. Menzl
Ventana Medical Systems, Tucson/AZ/US

Background: With the approval of crizotinib as treatment for ROS1 positive patients, identification of ROS1 status has become standard of care for non-small cell lung cancer (NSCLC). Immunohistochemistry (IHC) can be used to detect aberrant ROS1 expression; however, current commercially available IHC assays do not have optimized recommended protocols, or data correlating ROS1 protein expression to fluorescence in situ hybridization (FISH). Hence, the ROS1 (SP384) Rabbit Monoclonal Primary Antibody (ROSI3SP384) was developed, and here we present correlation data to ROS1 FISH status across multiple scoring algorithms using our optimized IHC staining protocol. Method: 120 formalin-fixed, paraffin-embedded (FFPE) NSCLC cases with known FISH status were procured. 4μm sections were cut and stained with H&E, Rabbit Monoclonal Negative Control Ig, and ROS1 SP384. The slides were evaluated for percent positivity of tumor cells in each intensity level (evaluated separately for staining within the nuclear, cytoplasmic, and membranous compartments). The intensity level of staining was evaluated on an integer scale of 0-3: 0 = no, 1 = weak, 2 = moderate and 3 = strong staining intensity. The data was analyzed several scoring algorithms to assess its correlation with FISH status. Result: ROS1 SP384 showed high correlation with FISH status, with multiple scoring algorithms (Table 1) examined. Of note, a positive percent agreement of 97.8% and negative percent agreement of 89.2% was achieved when comparing ROS1 SP384 IHC staining ≥2+ at a cutoff of > 30% staining in the cytoplasm of tumor cells with FISH status. Table 1. VENTANA ROS1 (SP384) Rabbit Monoclonal Primary Antibody IHC vs FISH analytical comparison data

Conclusion: Herein, we present evidence that ROS1 (SP384) Rabbit Monoclonal Primary Antibody may provide an effective means of stratifying cases by aberrant ROS1 protein expression prior to confirmation with orthogonal methods.

Keywords: ros1, Immunohistochemistry, crizotinib

P2.09-14 THE DETECTION OF EGFR GENE MUTATION FROM WASHING SOLUTION OF DEVICES USED FOR THE BRONCHOSCOPIC EXAMINATION

R. Nakahara1, T. Kasai2, Y. Kamiyama2, Y. Nakamura2, T. Sugiyama2, I. Wakahatsu1, N. Hoshi1, K. Nakano1, H. Matsuguma1
1Division of Thoracic Surgery, Tochigi Cancer Center, Utsunomiya, Tochigi/JP, 2Department of Clinical Laboratory, Tochigi Cancer Center, Utsunomiya, Tochigi/JP

Background: The detection of epidermal growth factor receptor (EGFR) gene mutation is necessary for selection of lung cancer treatment. Recently, biopsy specimens are used in many genomic and immunohistochemical examination methods to select the treatment policy, so it is important not to waste valuable cancer cell samples. For detection of EGFR gene mutation we examine the washing solution of devices used for the bronchoscopic examination in order to solve the issue. In this report, we investigate the detection ratio of EGFR mutation from this cytological sample. Method: A total of 336 washing solution samples from lung cancer patients were examined for EGFR gene mutation testing in the period between November 2010 and October 2017. 328 cases of 336 excepting 8, which were carried out as re-biopsy, were surveyed in this examination. After the regular biopsy or scraping method, all devices were washed with 10ml saline liquid. Half volume of washing solution was used for regular cell examination to detect cancer cells. Only if a sufficient amount of non-small cancer cells were observed from it, the other volume was submitted for EGFR mutation examination. Final diagnosis was decided by histological specimen. Presence or absence of EGFR mutation and their types were observed from 328 samples retrospectively. Result: Histological diagnosis of all 328 biopsy specimens are as follows; 200 Adenocarcinoma (AD), 100 Squamous cell carcinoma (SQ), 13 non-small cell lung carcinoma(NSCLC), 3 adenosquamous cell carcinoma(ADSQ), 7 high grade neuroendocrine carcinoma (HGNEC), and 5 others. The detection number of EGFR mutation from AD, SQ, ADSQ and NSCLC are 65, 4, 2, and 3 respectively. There is no EGFR mutation from remaining histology cases. In all of 74 EGFR mutation positive cases, Exon 19 deletion was detected in 33 cases (45%) and 33 cases (45%) and Exon 21 L858R was detected in 33 cases (45%). Conclusion: The detection rate of EGFR gene mutation from washing solution of devices is 33% (65/200) in AD and 4% (4/100) in SQ. These results are approximate to previous reports. Consequently, it is acceptable to use this method to investigate EGFR gene mutation of non-small lung cancer patients. Furthermore, it is an advantage that we can carry out an EGFR mutation test using this method with a cytology sample earlier than a method with a histology sample.

Background: The detection of epidermal growth factor receptor (EGFR) gene mutation is necessary for selection of lung cancer treatment. Recently, biopsy specimens are used in many genomic and immunohistochemical examination methods to select the treatment policy, so it is important not to waste valuable cancer cell samples. For detection of EGFR gene mutation we examine the washing solution of devices used for the bronchoscopic examination in order to solve the issue. In this report, we investigate the detection ratio of EGFR mutation using this cytological sample. Method: A total of 336 washing solution samples from lung cancer patients were examined for EGFR gene mutation testing in the period between November 2010 and October 2017. 328 cases of 336 excepting 8, which were carried out as re-biopsy, were surveyed in this examination. After the regular biopsy or scraping method, all devices were washed with 10ml saline liquid. Half volume of washing solution was used for regular cell examination to detect cancer cells. Only if a sufficient amount of non-small cancer cells were observed from it, the other volume was submitted for EGFR mutation examination. Final diagnosis was decided by histological specimen. Presence or absence of EGFR mutation and their types were observed from 328 samples retrospectively. Result: Histological diagnosis of all 328 biopsy specimens are as follows; 200 Adenocarcinoma (AD), 100 Squamous cell carcinoma (SQ), 13 non-small cell lung carcinoma(NSCLC), 3 adenosquamous cell carcinoma(ADSQ), 7 high grade neuroendocrine carcinoma (HGNEC), and 5 others. The detection number of EGFR mutation from AD, SQ, ADSQ and NSCLC are 65, 4, 2, and 3 respectively. There is no EGFR mutation from remaining histology cases. In all of 74 EGFR mutation positive cases, Exon 19 deletion was detected in 33 cases (45%) and 33 cases (45%) and Exon 21 L858R was detected in 33 cases (45%). Conclusion: The detection rate of EGFR gene mutation from washing solution of devices is 33% (65/200) in AD and 4% (4/100) in SQ. These results are approximate to previous reports. Consequently, it is acceptable to use this method to investigate EGFR gene mutation of non-small lung cancer patients. Furthermore, it is an advantage that we can carry out an EGFR mutation test using this method with a cytology sample earlier than a method with a histology sample.

P2.09-13 CORRELATION OF ROS1 (SP384) IMMUNOHISTOCHEMISTRY WITH ROS1 REARRANGEMENT DETERMINED BY FLUORESCENCE IN SITU HYBRIDIZATION

R. Huang, D. Smith, B. Richardson, C. Le, W. Liu, A. Hanlon Newell, G. Pate, I. Menzl
Ventana Medical Systems, Tucson/AZ/US

Background: With the approval of crizotinib as treatment for ROS1 positive patients, identification of ROS1 status has become standard of care for non-small cell lung cancer (NSCLC). Immunohistochemistry (IHC) can be used to detect aberrant ROS1 expression; however, current commercially available IHC assays do not have optimized recommended protocols, or data correlating ROS1 protein expression to fluorescence in situ hybridization (FISH). Hence, the ROS1 (SP384) Rabbit Monoclonal Primary Antibody (ROSI3SP384) was developed, and here we present correlation data to ROS1 FISH status across multiple scoring algorithms using our optimized IHC staining protocol. Method: 120 formalin-fixed, paraffin-embedded (FFPE) NSCLC cases with known FISH status were procured. 4μm sections were cut and stained with H&E, Rabbit Monoclonal Negative Control Ig, and ROS1 SP384. The slides were evaluated for percent positivity of tumor cells in each intensity level (evaluated separately for staining within the nuclear, cytoplasmic, and membranous compartments). The intensity level of staining was evaluated on an integer scale of 0-3: 0 = no, 1 = weak, 2 = moderate and 3 = strong staining intensity. The data was analyzed several scoring algorithms to assess its correlation with FISH status. Result: ROS1 SP384 showed high correlation with FISH status, with multiple scoring algorithms (Table 1) examined. Of note, a positive percent agreement of 97.8% and negative percent agreement of 89.2% was achieved when comparing ROS1 SP384 IHC staining ≥2+ at a cutoff of > 30% staining in the cytoplasm of tumor cells with FISH status. Table 1. VENTANA ROS1 (SP384) Rabbit Monoclonal Primary Antibody IHC vs FISH analytical comparison data

Conclusion: Herein, we present evidence that ROS1 (SP384) Rabbit Monoclonal Primary Antibody may provide an effective means of stratifying cases by aberrant ROS1 protein expression prior to confirmation with orthogonal methods.

P2.09-15 A NEXT GENERATION SEQUENCING (NGS) RNA-SCAN MULTIPLEX PANEL (QIAseq) TO IDENTIFY GENE-REARRANGED NON-SMALL CELL LUNG CANCER

R. Tay1, S. Huang2, M. Carter2, A. Wallace2, F. Blackhall1
1Medical Oncology. The Christie NHS Foundation Trust, Manchester/GB, 2Manchester Centre for Genomic Medicine, Central Manchester University Hospitals NHS Foundation Trust, Manchester/GB

Background: Oncogenic fusion gene rearrangements are detected in up to 10% of advanced NSCLC with important therapeutic (e.g. ALK, ROS1) or translational impact (e.g. RET, NTRK1). The QIAseq® fusion panel is a 31-gene NGS multiplex assay that synchronously detects multiple oncogene fusion transcripts from formalin-fixed paraffin-embedded (FFPE) tissue derived RNA (Figure 1).

Method: QIAseq analysis was undertaken in 33 samples (31 NSCLC samples, 2 commercial controls). 12/31 NSCLC samples were positive controls with a known fusion genotype identified by Quantide X NGS or FISH +/- RT-PCR. The remaining 19/31 fusion negative NSCLC controls included 6 samples with EGFR/KRAS/NRAS mutations. Analysis required a minimum 2x SuM thick FFPE scrolls with >30% neoplastic cell content. Manual RNA extraction was undertaken in all samples except n=6 (ExScale automation extraction). NGS fusion breakpoints, crossing and spanning reads were calculated in QIAseq fusion-detected samples. An additional validation cohort of 40 NSCLC samples, including 20 with unknown fusion status will optimise QIAseq thresholds for fusion detection. Result: 48 QIAseq sequencing experiments was undertaken in 33 samples with ≥2 sequencing runs in 12 samples. QIAseq analysis detected a corresponding NGS fusion breakpoint in 14/14 (100%) positive controls including EML4-ALK (n=8), CLTC-ALK (n=1), CD74-ROS1 (n=3), CCDC6-RET (n=1) and 5-fusion control (n=1). QIAseq analysis was negative in 17/19 (89.4%) negative controls samples including all KRAS (n=4), NRAS (n=1) and EGFR (n=1) mutation samples. QIAseq detected novel fusion gene CD74 Exon 6-CAMK2A Exon 2 in n=1 sample subsequently confirmed on Sanger sequencing. Two separate runs detected TPM3 Exon 8-S100A7A Exon 2 fusion in n=1 sample not identified with Sanger sequencing. Both fusions have uncertain clinical significance. Validation cohort results will be presented. Conclusion: QIAseq detects NSCLC oncogenic fusions with high sensitivity and specificity. Future applications include optimising use of small biopsy specimens for synchronous gene rearrangement screening and identification of novel gene fusion targets.

P2.09-16 HETEROGENEITY ANALYSES OF MSLCS——ESPECIALLY IN THE EGFR MUTATION-POSITIVE ONES

Y. Xu, X. Wang, Y. Cai, Y. Guo, C. Sun, K. Ma
Cancer Center, The First Hospital of Jilin University, Changchun/CHN

Background: Multiple synchronous lung cancers (MSLCs) are diagnosed as multiple tumour nodules in the same or different lung lobes. MSLCs present a clinical dilemma whether they are primary tumors or metastases. Recent studies showed that MSLCs shared an identical germline genetic background and environmental exposure in the same individual patient, however, different tumor nodules showed highly different heterogeneity, even in all the EGFR mutation-positive focusses. Therefore, we performed this study to further analyze MSLCs as to estimate the pathology and molecule heterogeneity among these nodules. Method: Tumor samples were obtained from nine patients diagnosed with MSLCs. Immunohistochemistry were performed by professional pathologists. Whole-exome sequencing (WES) was conducted by illuminaNovaseq with sequencing depth of 200X. NeoTyping was used to describe the dispersion of sequencing data among MSLCs of the same patient. Result: We found different tumor nodules showed obviously pathological and molecular heterogeneities in the same individual (Figure 1). More different dispersion was observed among the nodules with more different pathologies in the same patient. The dispersion of 20%, 50% and 100% were observed in MSLCs with the same driver genes (such as EGFR exon21 L858R and L861Q) of lung adenocarcinoma, different evolutional stages (AAH, MIA and IA) and completely different pathologies (adenocarcinoma and squamous cancer), respectively. All the sequencing data showed MSLCs had different gene information, even in all the EGFR mutation-positive nodules, maybe similar, but not the same, which supported that each nodule in one patient was independent with others.

Conclusion: MSLCs could be independent with each other due to their pathological and molecular heterogeneities, even for EGFR mutation-positive nodules which hold the same driver gene, but different mutation site in just one patient. WES should be an effective way to recognize this heterogeneous characteristic, which would be helpful for the whole precise management of one MSLC patient.

P2.09-17 A CALL TO ACTION: RAPID COLLECTION OF POST-MORTEM LUNG CANCER TISSUE IN THE COMMUNITY TO ENABLE LUNG CANCER RESEARCH

1Department of Pathology, H. Lee Moffitt Cancer Center and Research Institute, Tampa/FL/US, 2Ob-Gyn, New York University School of Medicine, New York/US, 3Thoracic Oncology, H. Lee Moffitt Cancer Center and Research Institute, Tampa/FL/US, 4District 12 Medical Examiner’s Office, Sarasota/US

Background: Posthumous rapid tissue donation (RTD) provides an opportunity to understand treatment-resistant lung cancers with preservation of valuable tumor and non-tumor specimens from primary and metastatic sites. Method: Consent to participate in the lung RTD program was obtained during patient care. When death occurred, tumor and paired non-tumor, cytology, and blood specimens were preserved as formalin-fixed and frozen specimens. Tissue sections were evaluated with hematoxylin and eosin (H&E) staining and programmed death ligand-1 (PD-L1) immunohistochemistry. Massively parallel sequencing was performed on 11 specimens. Result: To date, 21 patients consented to participate in the RTD program. Post-mortem specimens (N=180) were preserved from 9 patients and the other patients remain alive. Evaluation of H&E slides confirmed well-preserved tissue. PD-L1 immunohistochemistry revealed heterogeneous expression between tumor sites. Next generation sequencing provided high quality data on all 11 tested samples. Conclusion: Rapid donation of post-mortem tissue from lung cancer patients is feasible and provides high quality specimens for research. Post-mortem tissue collection of primary and metastatic tumors facilitates studies of tumor mutation evolution, mechanisms of drug resistance, and biomarker expression.

**P2.09-18 A CLINICOPATHOLOGIC ANALYSIS OF PULMONARY SCLEROSING PNEUMOCYTOMA IN KOREA: A MUTICENTER STUDY**

**S.Y. Ha 1, M.H. Kang 1, M.S. Roh 2, K.S.O. The Cardiopulmonary Pathology Study Group 3, H.K. Kim 4**

1Pathology, Gachon University Gil Medical Center, Incheon/KR, 2Pathology, Dona-A University College of Medicine, Busan/KR, 3Pathology, Korean Society of Pathologists, Seoul/KR, 4Pathology, Korea University Guro Hospital, Incheon/KR

**Background:** Sclerosing pneumocytoma is a rare benign pulmonary neoplasm, which in Asia, most commonly occurs in middle-aged women. Because of the rarity of this disease, no data is available on its nationwide incidence or clinical characteristics. This nationwide survey was conducted by the Korean Cardiopulmonary Pathology Study Group to document the incidence and clinical characteristics of sclerosing pneumocytoma in a Korean population. Method: A total of 220 cases of sclerosing pneumocytoma diagnosed at 15 tertiary medical centers in Korea during the period 1994 to 2012 were collected and retrospectively studied. Clinical parameters evaluated were sex, age at diagnosis, tumor size, tumor location, surgical procedure type, status of lymph node metastasis, and distant metastasis. Result: The female to male ratio was 7:15:1, and the tumor occurrence rate in middle or lower lobes was significantly higher than that in upper lobes (P < 0.001). The peak incidence rate appeared to occur in the sixth decade of life. Tumor was located in right lung in 121 cases and in left lung in 96 cases (43.6%). The mean tumor size in female patients (2.63 cm) was significantly larger than in male patients (2.19 cm) (P = 0.037). In 2 cases (0.9%) metastatic tumors were found in regional lymph nodes, and one case (0.5%) showed metastatic lymph nodes and distant metastasis in a lumbar vertebra. Conclusion: Age distributions, mean tumor sizes, and tumor locations were similar to those previously reported for sclerosing pneumocytoma, and the female-to-male ratio in our Korean cohort was similar to those previously reported in Asia, but higher than those reported in the West.

**P2.09-19 UTILISING HETEROGENEITY: USING A DIGITAL DATABASE OF LUNG CANCERS AND IMMUNE PROFILE TO COMPLEMENT SUBJECTIVE ASSESSMENT**

**A. Haragan 1, J. Field 2, M. Davies 3, C. Escru 1, A. Gruner 1, J. Gosney 1**

1Royal Liverpool University Hospital, Pathology Department, Floor 6, Duncan Building, University of Liverpool, Liverpool/GB, 2Institute of Translational Medicine, University of Liverpool, Liverpool/GB, 3The Clatterbridge Cancer Centre, Clatterbridge/GB, 4Diagnostic and Experimental Pathology, Eli Lily and Company, Indianapolis/IN/US, 5Cellular Pathology, Royal Liverpool University Hospital, Liverpool/GB

**Background:** Traditional pathological assessment of tissue sections involves subjective analysis of complex and heterogeneous features, typified by the challenge of ‘measuring’ PD-L1 expression in non-small cell lung cancer (NSCLC) as a guide to its treatment with immune checkpoint inhibitors. Such heterogeneity is generally perceived as a problem but might, in fact, reflect not only biologically important epitope variation, but also important features of the tumour microenvironment and, by extension, be a tool for predicting behaviour. In-depth analysis of a single slide of a tumour by digital pathology, image analysis and machine learning makes more accurate and meaningful analysis a possibility. Method: Expression of PD-L1 was assessed by immunochemistry in 250 sections from 137 resected NSCLCs using the Ventana SP263 antibody and a validated protocol and its distribution compared with morphology as revealed by corresponding H&E-stained sections. Slides were scanned to create a digital image using Aperio Scanscope with division of images into 1mm² squares using QuPath opensource software, each of which was assigned x and y co-ordinates. Squares were assessed subjectively by two pathologists for morphological features and PD-L1 expression and also subject to automatic image analysis including cell counting and membrane detection. Co-ordinates and values were stored in Microsoft Excel and a digital database was generated for every slide. In-depth analysis of digital data points was achieved using “R” software custom algorithms that included simulating biopsy sampling and applying spatial analysis packages. Result: The resulting database, comprising approximately 30,000 data points from the 137 tumours, is being used to simulate needle-core biopsies, assess heterogeneity of PD-L1 expression and relate this to the tumour micro-environment including immune cell populations, immune signature and tumour mutational burden. Conclusion: The vast amount of information in every NSCLC cannot be extracted by conventional histopathological analysis. By utilising new technologies and considering alternative paradigms for data acquisition, powerful new approaches may be developed that give information pertaining to not just diagnostic and prognostic features of a tumour, but behavioural traits including likely responses and resistances to novel drugs such as immune checkpoint inhibitors. The methodology described here is an attempt to extract these data in a more objective way and complement the still crucial subjective analysis that is traditionally the prerogative of the histopathologist.

**Keywords:** Digital Pathology, PD-L1, image analysis

**P2.09-20 MINOR COMPONENTS OF SOLID PATTERN IS A SIGNIFICANT POOR PROGNOSTIC FACTOR IN PATHOLOGICAL STAGE I LUNG ADENOCARCINOMA**

**M. Huang, S. Li, Y. Yang**

Department of Thoracic Surgery II, Peking University Cancer Hospital & Institute, Beijing/EN

**Background:** Lung adenocarcinoma with solid pattern (SP) predominant subtype was reported to be associated with poor prognosis. However, whether minor components of SP predict poor prognosis remains unknown. The present study aimed to clarify the influence of different proportion of SP on the prognosis of pathological stage I lung adenocarcinoma. Method: Tumors of 341 patients who underwent radical resections were classified according to the IASLC/ATS/ERS classification. Patient contained less than 5% SP in the tumor was determined SP negative and SP positive patients were reclassified to SP minor (5-50%) and SP major (≥50%) groups. Survival analyses were used to determine the association between each group with patient survival. Result: 50 (15%) patients were SP positive and compared to SP negative group they showed a significantly lower five-year disease-free survival (DFS) rate (85.2 vs. 55.4%, p<0.001) and overall survival (OS) rate (97.3 vs. 66.7%, p<0.001). Multivariate analysis for DFS showed that SP positive, lepidic pattern negative, KRAS mutation and pathological stage IB were independent poor prognostic factors. In addition, higher proportions (<5%, 5–50% and ≥50%) of SP components were associated with a poorer prognosis (85.2, 76.6, and 40.0% of Sy-DFS, respectively, p<0.001).

Policlinico Vittorio Emanuele, Catania/IT, 11Department of Oncology, Mauriziano Umberto I Hospital, Torino/IT

Background: In women, lung cancer (LC) and ovarian cancer (OC) are, respectively, the second and eighth malignancies for incidence in developed Countries. Despite increasing incidence and mortality of LC, association with OC is rare and no literature data are available on this topic yet. Our aim was to describe a series of patients with synchronous or metachronous LC and OC and to identify common clinical and pathological patterns.

Method: We retrieved the medical charts of patients who referred to 30 European Oncological Institutes from 2008 to 2018. When patients with synchronous (up to 3 months of time interval in onset) or metachronous LC and OC were found, we collected detailed medical history, pathological features and clinical outcomes. Whenever available, formalin fixed paraffin embedded tumor tissue from both specimens was collected for centralized pathology revision with an immunohistochemical marker panel including TTF-1 and PAX-8. In ambiguous cases, a broader panel was performed (p40, CK-7, WT1, CA125, Calretinin, EMA, CEA, CgA, Vimentin, Napsin-A).

Result: As of April 2018, among 30 European Oncological Centers (Italy, France, Slovenia), 11 retrieved in their series patients with a history of LC and OC, for a total of 18 cases in the last 10 years. Paired histological specimens were available in 6 cases. One patient was excluded, since pathology revision revealed that lung lesions were metastases from serous OC. Thus, analyses were performed on 17 patients. In 10/17 cases (58.8%), LC and OC were metachronous and, in 6/10 cases, OC preceded LC diagnosis, with a median interval of 4.5 years. Median age at diagnosis of the first malignancy was 62 years, the majority of patients (64.7%) were never-smoker, 6 had cancer familial history. Interestingly, 4 patients (23.5%) reported also a third or fourth malignancy. After a median follow-up of 36.7 years, 5 patients are alive. Regarding histology, most of LC were adenocarcinoma (14/17, 82.3%). Molecular status was available in 9/14 cases: 4 had EGFR mutation, 1 B-RAF mutation and 2 ALK translocation. OC were mostly high-grade serous (83.3%), BRCA status was available in 6 patients: 2 mutated, 2 wild-type and 2 affected by variants of unknown significance (USV). Moreover, one synchronous case presented both BRCA-USV and B-RAF mutation. Conclusion: In our series, synchronous and metachronous LC and OC were often driven by genetic alterations. Further genetic analysis with next generation sequencing technology has already been planned.

P.09-22 RELEVANCE OF RESULTS OF INTRAOPERATIVE PLEURAL LAVAGE CYTOLOGY AND HISTOLOGICAL SUBTYPE IN LUNG ADENOCARCINOMA
Kitsato University School of Medicine, Sagamihara/JP

Background: Pleural lavage cytology (PLC) can be simply and easily performed on patients undergoing surgery for primary lung cancers. Although clinical factors related to tumor progression, such as lymph node metastasis and pleural invasion, are reportedly risk factors for positive PLC, the association between PLC and histological subtype remains unknown. The present study aimed to evaluate the impact of a micro papillary pattern (MPP) in lung adenocarcinomas on results of PLC and assess the complementary role of these two factors as prognostic predictors and their significance in a clinical setting.

Method: We retrospectively reviewed 600 consecutive patients with surgically resected pulmonary adenocarcinomas and investigated the relationship between PLC status and clinicopathological factors including a histologically identified MPP component. In cases of MPP observed ≥5% in a largest cut surface was defined as MPP-positive group. Positive PLC was significantly associated with MPP (p=0.0001), lymph node metastasis (p=0.01), and pleural invasion (p<0.0001) according to multivariate analysis. Patients with other established predictive factors for positive PLC, such as large tumor size, lymph node metastasis, pleural invasion, and lymphovascular invasion, have an increased risk of positive PLC when their tumor include histological MPP. With regard to lymph node metastasis, two factors, MPP and positive PLC, were associated with a higher N2 lymph node metastasis. Among 25 patients with positive PLC, 18 (72%) were upstaged in postoperative pathologic examination whereas 139 of 575 (24%) patients with negative PLC were upstaged postoperatively. The prognosis of adenocarcinomas with MPP or positive PLC was significantly worse than that of patients without these features. Moreover, the survival rate of MPP and positive PLC group (MPP+ PLC+) was significantly worse than that of MPP and negative PLC group (MPP+ PLC−: p=0.03). Postoperative recurrences were found in 52% (13/25) of patients with positive PLC and 18% (103/575) of patients with negative (p=0.001). Conclusion: The presence of MPP in lung adenocarcinoma can be an independent predictor of positive PLC. These two factors have complementary and synergistic roles as prognostic factors. Detailed pre- or intra-operative examination of histological subtype and intraoperative PLC findings may provide important information for prediction of tumor progression and decisions regarding surgical procedure.

P.09-23 A COMBINATION OF PODoplanIN AND E-CAdHERIN EXPRESSION IN Lung SqCC may be A Prognostic Indicator: A Propensity Score-Matched analysis.
Thoracic Surgery, Graduate School of Medicine, Kyoto University, Kyoto/JP

Background: The combination of clinicopathological prognostic factors for lung squamous cell carcinoma (SqCC) has not been still advocated. The aim of this study is to analyze the combination of prognostic markers of SqCC. Method: Retrospective chart review was performed to identify patients undergoing resection for SqCC between 2003 and 2015 (Ethical approval #: E2235). We examined the expressions of E-cadherin, vimentin, and podoplanin in cancer cells on tissue microarray to evaluate their prognostic value. Survival outcomes were analyzed with Kaplan-Meier method and log-rank test. To eliminate selection bias, propensity score-matched analysis on the basis of clinicopathological factors was performed. Result: Two hundred and two patients underwent complete resection with curative intent were identified (Median follow-up: 50.0 months, range: 0.67-150, 5y-OS: 67.5%, 5y-DFS: 53.4%). There was no significant difference in the prognosis of patients with low E-cadherin expression alone (OS: p=0.242 and DFS: p=0.401) and podoplanin-positive alone (OS: p=0.389 and DFS: p=0.874). However, OS and DFS in the combination of podoplanin-positive and low E-cadherin expression (OS: p=0.032 and DFS: p=0.01) were significantly worse than those in another group (OS: 75.0% vs 57.0%, respectively, p=0.034, DFS: 65.2% vs 44.2%, respectively, p=0.031). Conclusion: A combination of podoplanin-positive and low E-cadherin expression in lung SqCC may be a poor prognostic indicator.

P.09 PATHOLOGY
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00
XMT-1536 is a NaPi2b targeting ADC (Antibody Drug Conjugate) comprised of a humanized antibody (XMT-1535) conjugated with 10-15 auristatin F-HA (AF-HA) payload molecules via the Dolaflexin platform. AF-HA is capable of controlled bystander-effect killing, resulting in efficacy in models with heterogeneous antigen expression, and is metabolized intra-tumorally to an active non-permeable metabolite to enable greater systemic tolerability. Previously, we demonstrated pre-clinical activity of XMT-1536 in human primary xenograft models of non-small cell lung cancer (NSCLC). MERS67 is a human-rabbit chimeric antibody derived from XMT-1535. MERS67 has been formatted for use as an immunohistochemical reagent by multiple methods and expression has been shown to correlate with response in an unselected series of primary ovarian cancer xenografts. (AACR-EORTC, 2017) We evaluated MERS67 to see if it would preferentially stain lung adenocarcinoma (ACA), as has been demonstrated using other NaPi2b antibodies. Method: An immunohistochemical assay for MERS67 was established on a Leica BondRx Instrument. The assay was performed on tissue microarrays (TMA), including NSCLC and small cell lung cancer (SCLC) cell line arrays, and a NSCLC human tumor array. TMA arrays had previously been classified based on morphological features only. All arrays were scored based on the H-score method. To characterize the primary tumors further, the tumor TMA was stained with TTF-1 and p40, markers of ACA and squamous cell carcinoma (SqCC), respectively. Results of this staining were compared to MERS67 staining patterns. Result: H-Scores in the NSCLC cell line TMA ranged from 0-260, and from 0-100 in the SCLC TMA. Within the tissue microarray, 99 individual cases were evaluated. By morphologic classification 63 cases were SqCC, and 23 cases were ACA. Using an arbitrary cut of H>50, there was a statistically significant difference in the number of NaPi2b positive ACA cases (19/23) vs SqCC cases (3/63). Among 43 cases where p40 and TTF-1 were evaluable and were in agreement with morphologic diagnosis, 7/7 cases of ACA were positive for NaPi2b, while 0/36 SqCC were positive. Conclusion: MERS67 is an anti-NaPi2b antibody that frequently demonstrates immunoreactivity in lung ACA. MERS67 is a chimeric antibody related to XMT-1536, a proprietary anti-NaPi2b ADC. Target expression using MERS67 is being evaluated in an ongoing XMT-1536 Phase 1 clinical trial enrolling non-squamous NSCLC patients. Keywords: XMT-1536, NaPi2b, Adenocarcinoma

P2.09-25 ABUNDANT TUMOR PROMOTING STROMAL CELLS IN LUNG ADENOCARCINOMA WITH HYPOXIC REGIONS
H. Nakamura1, T. Ichikawa2, S. Nakasone3, K. Akoage1, M. Tsuboi1, K. Suzuki2, G. Ishii3
1General Thoracic Surgery, Juntendo University, Tokyo/JP, 2Division of Thoracic Surgery, Department of Thoracic Oncology, National Cancer Center Hospital East, Kawasaki/JP, 3Thoracic Oncology, National Cancer Center Hospital East, Kawasaki/JP

Background: Carbonic anhydrase IX (CAIX) is a marker of hypoxia and its expression by cancer associated fibroblasts (CAFs) was reportedly associated with the poor prognosis of lung adenocarcinoma. This study aimed to characterize the hypoxic microenvironment containing CAIX (+) CAFs. Method: First, we evaluated the clinicopathological significance of CAIX expression by CAFs in 3 cm and above lung adenocarcinoma (n = 188). We then compared the expressions of E-cadherin, ezrin, ADHLD1, CD44, EGFR, HSF 5-1, Glut-1, and PD-L1 in cancer cells, as well as those of CD204 and podoplanin in stromal cells between CAIX (+) CAFs and CAIX (-) CAFs cases (n = 25, each). Result: In total, 48 patients had CAIX (+) CAFs (26%). Multivariate analysis revealed that CAIX expression by CAFs could serve as an independent unfavorable prognostic factor for recurrence-free survival (RFS) and disease-specific survival (DSS). The staining score of hypoxia marker Glut-1 in cancer cells was significantly higher in cases with CAIX (+) CAFs than in those with CAIX (-) CAFs (median: 20 vs. 0, p < 0.01). In addition, the numbers of CD204 (+) tumor associated macrophages (TAMs) and podoplanin (+) CAFs were significantly higher in the CAIX (+) CAFs group than in the CAIX (-) CAFs group (TAMS: 31.5 vs. 17.0; p < 0.01, CD204: 20 vs. 0; p < 0.05). The staining score of the other markers did not differ between the groups. Conclusion: Our results indicate that the presence of abundant tumor promoting stromal cells, CD204 (+) TAMs, and podoplanin (+) CAFs is characteristic of the tumor microenvironment containing CAIX (+) CAFs, which contributes to an increase in aggressive behavior in lung adenocarcinoma with hypoxic regions. Keywords: tumor microenvironment, CAF, Hypoxia

P2.09-26 CLINICAL SIGNIFICANCE OF SUBCELLULAR LOCALIZATION OF MASPIN IN PATIENTS WITH PATHOLOGICAL STAGE IA LUNG ADENOCARCINOMA
T. Ohno1, Y. Nosa2, W. Fujiwara1, T. Miyamoto1, T. Kadonaga1, Y. Kidokoro1, M. Wakahara1, Y. Takagi1, Y. Tanaka1, T. Haruki1, K. Miwa1, Y. Suzuki1, Y. Taniguchi1, H. Nakamura1, Y. Umekita1
1Department of Surgery, Division of General Thoracic Surgery, Tottori University, Faculty of Medicine, Tottori/JP, 2Department of Pathology, Division of Organ Pathology, Tottori University, Faculty of Medicine, Tottori/JP

Background: There were a lot of tumor-associated proteins before. Maspin is a tumor-suppressor protein and its prognostic value in lung adenocarcinoma has been reported. However, little is known about the clinical impact of subcellular localization of maspin in early-stage lung adenocarcinoma. We aimed to evaluate the clinical significance of subcellular localization of maspin in patients with pathological stage (p-stage) IA lung adenocarcinoma patients categorized by the new eighth edition TNM classification. Method: We immunohistochemically analyzed 181 tissue samples from p-stage IA1 (n = 37), IA2 (n = 92) and IA3 (n = 52) lung adenocarcinomas using antibody for maspin. Result: The 181 cases fell into five predominant subtypes: lepidic (n = 32), acinar (n = 97), papillary (n = 30), solid (n = 20) and micropapillary (n = 2). The frequencies of maspin staining were: cytoplasmic-only in 24.9%, pancellular (nuclear and cytoplasmic) in 8.8%; nuclear-only in 0.6%; no staining in 65.7%. Cytoplasmic-only staining significantly correlated with high pathological T-classification (p = 0.039), lymphatic invasion (p = 0.002) and poorer tumor differentiation (p = 0.002). The patients were followed up for 12-151 months (median=74 months), and the cytoplasmic-only staining was significantly correlated with shorter disease-free survival (DFS) (p = 0.034) and disease-specific survival (DSS) (p = 0.036) by log-rank tests. In Cox’s multivariate analysis, lymphatic invasion had the most significant effect on shorter DFS and DSS. Conclusion: The expression of maspin in the cytoplasm alone could be useful for predicting unfavorable prognoses in patients with p-stage IA lung adenocarcinoma. Keywords: Adenocarcinoma, Immunohistochemistry, Maspin
Keywords: examination. could improve the detection of ITC compared with routine pathological enrichment by immunomagnetic bead, IF and iFISH techniques, which and pN0 disease were enriched by immunomagnetic beads, detected ITC by iFISH was 1 positive cell. The sensitivity and specificity were 60% ROC curve analysis. p53+/DAPI+/CD45- cells were detected in 90.9% nine patients with non-invasive adenocarcinoma were collected for nodes from ten patients with NSCLC and eighteen lymph nodes from Result: mutation. Pathologically negative lymph nodes were detected for ITC technology was employed to detect p53+/DAPI+/CD45- cells for TP53 from non-invasive adenocarcinoma as control, the best cut-off values of optimal cut-off value for the diagnosis of ITC by IF was 3 positive cells detected in 60% metastatic lymph nodes and 6.25% lymph nodes in the control group (P<0.001). The optimal cut-off value for the diagnosis of ITC by iFISH was 1 positive cell. The sensitivity and specificity were 60% and 93.75%, respectively. Combining the two detection techniques, the sensitivity and specificity increased to 90% and 93.75%, respectively. Sixty lymph node samples from thirty patients with invasive NSCLC and pN0 disease were enriched by immunomagnetic beads, detected for ITC by IF, and iFISH. ITC were detected in 18.3% (11/60) of the pN0 lymph node samples. The pNO status was reclassified as NO1 (mod+) in 33% (10/30) patients based on the recommendation of the American Joint Committee for Cancer. Conclusion: We established a new method to identify ITC in the regional lymph nodes by a combination of negative enrichment by immunomagnetic bead, IF and iFISH techniques, which could improve the detection of ITC compared with routine pathological examination. Keywords: lung cancer, TNM stage, natural language processing

P.02.09-28 DETECTION OF ISOLATED TUMOR CELLS IN REGIONAL LYMPH NODES FROM PN0 LUNG CANCER BY NEGATIVE SELECTION USING IMMUNOMAGNETIC BEADS

X. Sui1, G. Liu1, J. Wang1
1Department of Thoracic Surgery, Peking University People’s Hospital, Beijing/CN, 2Peking University People’s Hospital, Beijing/CN

Background: Isolated tumor cells (ITC) referred to single tumor cells or small clusters of cells detected by routine hematoxylin and eosin stains or immunohistochemistry. Early detection of ITC in regional lymph nodes could identify a subset of lung adenocarcinoma with potential risk of disease relapse. This study aimed to establish a new method to detect ITC based on a combination of immunomagnetic bead enrichment, immunofluorescence (IF) and immunofluorescence in situ hybridization (FISH). Method: Lymph nodes were obtained from lung cancer patients intraoperatively. After immunomagnetic negative enrichment, tumor cells were identified using IF and iFISH, respectively. P53+/DAPI+/CD45- cells were detected in 90.9% of non-invasive adenocarcinoma as control, the best cut-off values of the positive cells number was determined using the receiver operating characteristic (ROC) curve to predict ITC. Single cell sequencing technology was employed to detect p53+/DAPI+/CD45- cells for TP53 mutation. Pathologically negative lymph nodes were detected for ITC using this newly established method. Result: Eleven metastatic lymph nodes from ten patients with NSCLC and eighteen lymph nodes from nine patients with non-invasive adenocarcinoma were collected for ROC curve analysis. p53+/DAPI+/CD45- cells were detected in 90.9% metastatic lymph nodes and 44.4% in the control group (P<0.001). The optimal cut-off value for the diagnosis of ITC by IF was 3 positive cells according to ROC curve analysis. The sensitivity and specificity were 81.82% and 94.44%, respectively. Four p53+/DAPI+/CD45- cells were tested using single-cell sequencing technique. All these cells were present with TP53 gene mutations. CEPI+/DAPI+/CD45- cells were detected in 60% metastatic lymph nodes and 6.25% lymph nodes in the control group (P=0.002). The optimal cut-off value for the diagnosis of ITC by IFISH was 1 positive cell. The sensitivity and specificity were 60% and 93.75%, respectively. Combining the two detection techniques, the sensitivity and specificity increased to 90% and 93.75%, respectively. Sixty lymph node samples from thirty patients with invasive NSCLC and pN0 disease were enriched by immunomagnetic beads, detected for ITC by IF, and iFISH. ITC were detected in 18.3% (11/60) of the pN0 lymph node samples. The pNO status was reclassified as NO1 (mod+) in 33% (10/30) patients based on the recommendation of the American Joint Committee for Cancer. Conclusion: We established a new method to identify ITC in the regional lymph nodes by a combination of negative enrichment by immunomagnetic bead, IF and iFISH techniques, which could improve the detection of ITC compared with routine pathological examination. Keywords: lung cancer, Immunomagnetic bead negative method, Lymph node micrometastases

P.02.09-29 AUTOMATIC LUNG CANCER STAGING FROM MEDICAL REPORTS USING NATURAL LANGUAGE PROCESSING

X. Sui1, T. Liu1, Q. Huang1, Y. Hou1, Y. Wang1, G. Kang1, H. Guo1, N. Li2, Y. Li2, Z. Wang2, J. Wang1
1Department of Thoracic Surgery, Peking University People’s Hospital, Beijing/CN, 2Baidu Inc., Sunnyvale/CA/US

Background: Accurate TNM staging plays an important role in the diagnosis, treatment, and prognosis of lung cancer. In current clinical practice, the staging of lung cancer is usually decided by physicians. We aim to develop an automated lung cancer staging system using machine learning and verify the staging correctness. Method: In this work, we constructed a feature generalizing and automatically extracting model using NLP techniques. The parameters required for Tumor (T), Lymph nodes (N) and Metastases (M) categories of the eighth edition of the International Lung Cancer Research Association (IASLC) TNM staging system were automatically extracted from de-identified electronic medical records of pathology, operation note, CT scan, PET/CT scan, cranial MRI, bone scan, and ultrasound. A technical solution using Bayesian reasoning network was developed for automated staging. The stage was automatically predicted while the reasoning basis was given. All the reports were reviewed by thoracic surgeons to obtain the gold standard for evaluation.

P.02 PATHOLOGY TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P.02.09-30 CLINICOPATHOLOGICAL INVESTIGATION OF FOUR RESECTED CASES FOR PLEOMORPHIC CARCINOMA OF THE LUNG

K. Taguchi1, H. Inoue, O. Kawamata
Department of Surgery, Onomichi Municipal Hospital, Onomichi City, Hiroshima/JP

Background: Pleomorphic carcinoma (PC) of the lung has a poor prognosis and no established standard treatment. Particularly, cases of recurrence after surgery often result in death within one year of recurrence. At our hospital, we experienced four cases of PC, and all these patients remain alive, including those with recurrence. We report these cases of PC together with our histopathological findings. Method: We examined four patients with PC who underwent thorascopic lobectomy and mediastinal lymph node dissection between October 2014 and March 2017. The histopathological findings were expression of programmed death ligand 1 (PD-L1) and CD8-positive tumor-infiltrating lymphocytes (CD8-TILs), which were examined for their relationship with prognosis. The expression of CD8-TILs was evaluated using the ratio of CD8+/CD45- (leukocyte common antigen) TILs. Result: While all patients survived, two of four patients experienced recurrence. Case 1 experienced recurrence 5 months after surgery and remains currently alive 35 months after recurrence using radiation therapy alone. Case 2 developed pleural dissemination and recurrence 10 months after surgery and remains alive 29 months after recurrence with a good partial response to chemotherapy and immune checkpoint inhibitors (nivolumab). Case 3 and 4 are both alive without recurrence 28 months and 12 months after surgery, respectively. All cases have high PD-L1 expression (tumor
The expression of CD8+ TILs may be associated with prognosis of PC. We plan to continue investigating how PD-L1 expression and the CD8+ TILs ratio are related to recurrence and therapeutic response.

Keywords: Pleomorphic carcinoma, programmed death ligand 1, CD8-positive tumor-infiltrating lymphocytes

**P2.09 PATHOLOGY**

**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.09-31 CISPLATINUM SUPPRESSED METASTASIS OF NSCLC BY INHIBITING MACROPHAGE M2-LIKE POLARIZATION**

Y. Xu, Y. Fan
Chemotherapy, Zhejiang Cancer Hospital, Hangzhou/CN

**Background:** Although M2-like tumor-associated macrophages (TAMs) have been considered as a vital therapeutic target in cancer therapy due to their role in promoting tumor progression and metastasis by inducing expression of CCR2 and CX3CR1 through IL-10 secretion, few compounds have been identified to inhibit M2-like polarization of TAMs.

**Method:** In vitro analysis of cisplatinum in preventing macrophage M2-like polarization was conducted. Expression of cell surface marker CD206 and CDH1, CCR2, CCL2 and CX3CR1 genes were detected. The migration of non-small lung cancer cells promoted by the conditioned medium from M2-like macrophages was conducted by Transwell migration assay. The percentage of M2-like macrophages in tumor and normal lung tissues were analysed after the administration of cisplatinum for one week.

**Result:** We showed that cisplatinum significantly prevented macrophage M2-like polarization induced by IL-10 in vitro, as illustrated by reduced expression of cell surface marker CD206 and CDH1, CCR2, CCL2 and CX3CR1 genes. Furthermore, the migration of non-small lung cancer cells promoted by the conditioned medium from M2-like macrophages could be restrained by cisplatinum. Furthermore, cisplatinum reduced the number of metastasis of lung cancer without affecting tumor growth. Both in tumor and normal lung tissues, the percentage of M2-like macrophages decreased after the administration of cisplatinum for one week.

**Conclusion:** Taken together, data suggest that cisplatinum is able to inhibit macrophage M2-like polarization, which plays a vital role in cisplatinum suppressed metastasis of NSCLC.

**Keywords:** M2-like polarization, NSCLC, TAM

**P2.09 PATHOLOGY**

**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.09-32 DETACHED EPITHELIAL CELL CLUSTER SIZE IN LUNG ADENOCARCINOMA IS A MARKER OF POOR PROGNOSIS**

A. Yoshizawa1, K. Kondo2, N. Nakajima2, Y. Teramoto2, M. Rokutan-Kurata2, S. Sumiyoshi2

1Diagnostic Pathology, Kyoto University Hospital, Kyoto/JP, 2Department of Diagnostic Pathology, Kyoto University Hospital, Kyoto/JP

**Background:** Various types of detached epithelial cell clusters (DECs) are occasionally seen within lung adenocarcinoma (L-ADC): small clusters containing a small number of tumor cells (type 1); medium-sized clusters comprising 5-20 tumor cells (type 2); and large clusters comprising more than 20 tumor cells (type 3). In general, type 2 DEC is considered a micropapillary pattern (MP-p). Although MP-p is known to be a sign of worse prognosis than other growth patterns, the prognostic significance of type 1 and 3 DEC structures is not well known. This study aimed to analyze the prognostic significance of DEC by histologically reviewing 921 resected L-ADCs.

**Method:** We investigated the presence of DEC, the DEC pattern (type 1, 2, or 3), and their associations with clinicopathological parameters. Furthermore, we studied the prognostic significance of DEC in resected L-ADCs.

**Result:** Two hundred sixty-four tumors (28.6%) were DEC-positive. These DEC-positive tumors were significantly associated with higher levels of T factor (P < 0.001), node positivity (P < 0.001), higher tumor stage (P < 0.001), lymphovascular invasion (P < 0.001), and the presence of spread through air spaces (STAS) (P < 0.001). On the other hand, no association was observed between DEC positivity and EGFR, KRAS, or ALK gene alterations. Patients with DEC-positive tumors had significantly worse prognoses than those with DEC-negative tumors, as assessed by both overall survival and disease-free survival (P < 0.001 for both). Furthermore, patients with tumors showing type 2 DEC had the worst prognoses, followed by patients type 2 DEC. Patients with type 1 or no DEC had significantly better prognoses (P < 0.001).

P2.10-01 SUCCESS OF A PHARMACY-DRIVEN SMOKING CESSATION PROGRAM
C. Burdalski1, S. Dalpoas1, J. Feliciano2, M. Lang1, B. Ewachi1
1Department of Pharmacy, Johns Hopkins Bayview Medical Center, Baltimore/MD/US, 2Department of Oncology, Johns Hopkins Medicine, Baltimore/MD/US

Background: While national oncology organizations advocate smoking cessation integrated into cancer management, only 30–40% of oncologists provide assistance with quitting. Barriers to this service are well documented. Pharmacy learners are poised to provide this intervention with the incorporation of smoking cessation therapies in accredited PharmD curricula. Previous pharmacist-driven programs reported 30-day quit rates of 23%. A pharmacy-driven pilot was initiated in April 2017 in a Thoracic Oncology Center of Excellence. The purpose of this study was to establish a new standardized infrastructure for a cessation program, determine its feasibility, and determine 30-day smoking cessation success rates for patients in a thoracic multidisciplinary clinic (MDC). Method: Patients seen in the thoracic MDC between April 2017 and March 2018 were included. Primary endpoints included patient capture rate in clinic, acceptance rate of tobacco assessment and smoking cessation counseling, and 30-day cessation rates. Tobacco use assessments and smoking cessation counseling were performed and documented by a pharmacy learner (pharmacy resident or student), under the supervision of a licensed pharmacist, prior to the history and physical by a health care provider. All patients who were active smokers or former smokers who quit within the last three months were offered cessation counseling and follow up. Nicotine replacement therapy was immediately available and provided to eligible patients based on tobacco use. Participants were followed up in clinic or by phone every two weeks for the first three months, at six months, nine months, and one year of program enrollment. At least two follow up phone call attempts were made until determined not successfully reached. Result: One-hundred sixty-four of 189 patients seen in MDC were assessed by the pharmacy team. Forty-five (27%) of 164 assessed patients met eligibility criteria. Thirty-two (75%) of 43 eligible patients participated in same day counseling for smoking cessation and agreed to enroll in the follow up program. Quit rates at 30 days for enrolled patients were 44% (14/32). At one, three, and six months, 25%, 56%, and 81% of patients, respectively, were unavailable by phone. Conclusion: The majority of eligible patients enrolled in the smoking cessation program. More than 40% of enrolled patients were successful in smoking cessation at 30 days, which compares favorably to previous reports. Telephone follow up was challenging. Future efforts to expand smoking cessation in a comprehensive cancer center utilizing a pharmacy-driven intervention are warranted.

Keywords: tobacco, pharmacy, Smoking Cessation

P2.10-02 VARIATIONS IN SMOKING CESSATION ACTIVITIES AT ONTARIO’S REGIONAL CANCER CENTRES
N. Schwartz1, M. Haque1, E. Cameron1, S. Khan1, R. Truscott1, A. Peter1, W. Evans2
1Cancer Care Ontario, Toronto/ON/CA, 2Department of Oncology, McMaster University, Hamilton/ON/CA

Background: Tobacco use is the largest preventable cause of cancer and cancer mortality, with approximately 85% of lung cancers resulting from smoking. In 2012, Cancer Care Ontario (CCO) developed a smoking cessation (SC) initiative for cancer patients across the province’s 14 Regional Cancer Centres (RCCs). The purpose of this analysis was to examine variations in the rates of screening for tobacco use and SC referrals for lung and non-lung cancer patients in Ontario RCCs. Method: A descriptive analysis was conducted on data submitted to CCO from 14 RCCs on their SC activities among new ambulatory cancer patients in 2017. Data were aggregated and cleaned resulting in 64,635 patient records; two SC performance indicators (Tobacco Screening and Accepted a SC Referral) were calculated by RCC, for lung and non-lung cancer patients. Result: In 2017, 67.8% of all new cancer patients in Ontario were screened for tobacco use (70.2% of lung cancer and 67.5% of non-lung patients). Screening rates for all cancer patients ranged from 51% to 96% across RCCs, with similar ranges for lung and non-lung patients. Within the RCCs, the screening rate differed by up to 12% between lung and non-lung cancer patients. Among all new cancer patients (15% of non-lung patients), seen at RCCs, were identified as current or recent smokers (smoked within the past 6 months), but the proportion was higher among patients with lung cancer at 37%. Overall, 21.5% of all smokers accepted a SC referral (23.7% lung cancer vs 20.9% non-lung patients). Rates ranged from 9% to 43% for all cancer patients, with similar ranges observed across patient groups. Within the RCCs, differences of up to 17% were observed in SC referral acceptance rates between lung and non-lung cancer patients. For both the screening and accepted a referral metrics, the direction of the differences was inconsistent, with higher rates observed in lung cancer patients at some RCCs and lower rates at others. Conclusion: In Ontario, more than twice as many lung cancer patients were smokers compared to non-lung cancer patients. Although aggregate provincial Tobacco Screening and Accepted a SC Referral rates showed little difference between these patient groups, large variations in rates for both metrics were observed in RCCs between lung and non-lung patients. Further research is necessary to understand the underlying factors that might be contributing to these wide differences in screening and referral practice.

P2.10-03 FEASIBILITY AND ACCEPTABILITY OF E-CIGARETTES AS AN AID TO QUITTING SMOKING IN LUNG CANCER PATIENTS: A PILOT STUDY
S. Harrow1, L. Bauld2, J. Macphee1, A. Ford3, L. Sinclair2, J. Mickel1, A. Morrison3
1Clinical Oncology, Beatson West of Scotland Cancer Centre, Glasgow/GB, 2Institute for Social Marketing, University of Stirling, Stirling/GB, 3New Nicotine Alliance, Stirling/GB

Background: Many patients diagnosed with lung cancer continue to smoke even though this can make treatment less effective and increase side effects. E-cigarettes form part of the UK’s tobacco harm reduction policy landscape and are smokers’ most popular quit attempt method. This pilot study explores feasibility and acceptability of e-cigarettes as an aid to smoking cessation among lung cancer patients with advanced disease undergoing chemotherapy. Method: smokers with Stage IV lung cancer were recruited in NHS Greater Glasgow and Clyde and NHS Lanarkshire. Participants were provided with a 2nd generation e-cigarette device and a four week supply of e-liquid. Abaseline home visit was conducted by a researcher and an experienced e-cigarette user. Participants were followed-up over 16 weeks. We explored participants’ experiences of using e-cigarettes including CO validated smoking cessation at 4 and 16 weeks. Qualitative interviews were conducted with participants (n=13), their significant others (n=6) and health professionals (n=8) engaged with lung cancer patients to obtain their views on the study. Result: Twenty-nine patients were recruited and completed baseline data collection. Three patients died during the study. Of the 26 remaining, 35% (n=9) were CO validated as having stopped smoking at four weeks and 15% (n=4) at 16 weeks. Study procedures were viewed as feasible and acceptable. Patients’ experiences of using e-cigarettes were mixed. Some
felt unwell during treatment making stopping smoking more challenging. Those who managed to quit were very positive about e-cigarettes as were their partners. Healthcare professionals expressed concern about longer term e-cigarette safety but welcomed the study. **Conclusion:** Smoking cessation should be offered to patients who have incurable disease. It is feasible and acceptable to offer e-cigarettes for smoking cessation to the South East cancer patients during treatment. Outcomes were positive and comparable with local cessation services. Future research involving a pilot randomised controlled trial is warranted but should include patients with less advanced cancer and assessment of longer term outcomes.

**P2.10-04 PATTERN AND FACTORS ASSOCIATED WITH INTENTION TO QUIT TOBACCO USE IN A RURAL COMMUNITY OF ANAMBRA STATE OF NIGERIA**

U. Ofonakara1, M. Ilo2, A. Ejekoro3, C. Ikpe4
1Community Medicine, Federal Teaching Hospital, Abakaliki/NG, 2Pharmaceutical Sciences, Enugu University of Science and Technology, Agbani/NG, 3World Health Organization, Asaba/NG, 4Community Medicine, Lagos University Teaching Hospital, Lagos/NG

**Background:** Prevalence studies have consistently reported higher rates of tobacco use among adults of Ndua But little is known about the pattern and factors associated with the intention to quit tobacco use in these parts of the country. The aim of this study was to determine the pattern of tobacco use and intention to quit among residents of Ukpo community of Dunukofia LGA of Anambra State, South Eastern Nigeria.

**Method:** A cross-sectional descriptive study was carried out among 490 residents of Ukpo community selected using a two-stage sampling method. Data was collected using pre-tested interviewer administered questionnaires adapted from Global Adult Tobacco Survey. Odd ratios and 95\% confidence intervals were computed and P values of < 0.05 were considered statistically significant. **Result:** The results showed that respondents were mostly male 300(61.2\%) and aged between 20 and 70 years with a mean of 42.2 ± 15.4 years. Almost half, 210 (42.9\%) had ever used tobacco. For smoked tobacco, only 116(23.7\%) have ever used this form. Age (p < 0.0001), male gender (OR 12.78;CI 5.0-0.05 were considered statistically significant. **Conclusion:** We recommend programmes to help people who are willing to quit tobacco use and establishment of tobacco cessation clinics to help ensure successful tobacco control in Nigeria.

**Keywords:** Intention, quit, tobacco

**P2.10-05 PROVIDER MEDICAL SPECIALTY INFLUENCES SMOKING CESSATION COUNSELING AT AN ACADEMIC MEDICAL CENTER AND VETERANS AFFAIRS IN U.S. MID-SOUTH**

J. Lewis1, H. Chen2, K. Weaver3, L. Spalluto4, K. Sandler5, L. Horn6, R. Dittus7, P. Massion8, C. Roumie1, H. Tindle1
1Veteran’s Health Administration-Tennessee Valley Healthcare System Geriatric Research Education Clinical Center, Nashville/US, 2Vanderbilt University Medical Center, Nashville, TN/US, 3Social Sciences & Health Policy, Wake Forest, Winston-Salem/NC/US, 4Radiological and Radiological Sciences, Vanderbilt University Medical Center, Nashville/TN/US, 5Department of Medicine, Division of Hematology/ oncology, Vanderbilt University Medical Center, Nashville/US, 6Department of Medicine, Pulmonary and Critical Care Medicine, Veteran’s Health Administration, Nashville/TN/US, 7Department of Medicine, Division of General Internal Medicine and Public Health, Vanderbilt University Medical Center, Nashville/TN/US

**Background:** Tobacco accounts for 11.5\% of deaths worldwide and approximately 30\% of U.S. cancer deaths. Smoking cessation counseling using the 5 A’s (Ask, Advise, Assess, Assist, Arrange) is standard-of-care for all smokers. We tested the hypothesis that certain provider characteristics (general internal medicine [GIM]), those with lung cancer screening [LCS] knowledge, and those who perceive smoking cessation as very effective) would be associated with smoking cessation counseling. **Method:** We surveyed all GIM, pulmonology, hematology/oncology, and gynecology providers (physicians/advanced practice providers) at a large academic institution in the Mid-South and affiliated VA from February to May 2017. The primary predictor variables were provider characteristics including: specialty, LCS guideline knowledge (high knowledge=identified stage A, B, 30 pack-years, current & former smokers), and perceived effectiveness of smoking cessation, colonoscopy, and pap smear at reducing cancer mortality (very/moderately/minimally/not effective). The primary outcome was self-reported smoking cessation counseling using the 5 A’s within the past year. Data were summarized using counts, proportions, and medians. We used multivariable logistic regression adjusted for years in practice and healthcare system to evaluate the association of medical specialty with counseling. Logistic regressions of perceived effectiveness and LCS guideline knowledge as predictors of counseling were further adjusted for specialty. **Result:** Of 623 providers invited, 407 (65\%) responded, 378 (60.5\%) questionnaires were analyzed, of which 58\% were GIM, 19\% hematology/oncology, 13\% gynecology, 10\% pulmonology. There were 255 of 350 providers (73\%) who reported performing smoking cessation counseling within the past year (77\% GIM vs 77\% pulmonology vs 57\% hematology/oncology vs 72\% gynecology, χ2 p = 0.013). In adjusted multivariable logistic regression, GIM (aOR 2.52 95\% CI 1.40, 4.54; p=0.002) and pulmonology (aOR 2.52 95\% CI 1.00, 6.36;p=0.05) providers were more likely to perform smoking cessation counseling than hematology/oncology providers. 41\% vs 59\% of those who provided counseling had high LCS knowledge vs low LCS knowledge. Fewer providers (71\%) reported smoking cessation as very effective at reducing cancer-specific mortality compared to colonoscopy (77\%) and pap smear (74\%). Perceived effectiveness and high LCS guideline knowledge did not predict smoking cessation counseling (aOR 1.1 95\% CI 0.64,1.78;p=0.78; aOR 1.2 95\% CI 0.72, 2.0 p =0.47 respectively). **Conclusion:** Providers in general internal medicine and pulmonology were more likely than those in hematology/oncology to report performing smoking cessation counseling. Perceived effectiveness and LCS guideline knowledge did not predict smoking cessation counseling. Targeted interventions, especially in hematology/oncology, are needed to increase smoking cessation counseling using the 5 A’s. Future education should also address knowledge gaps in smoking cessation effectiveness and LCS guidelines.

**P2.10-06 THE RISK OF SMOKING AMONG WOMEN WHO START SMOKE AS TEENAGERS**

M. Tagbarha
Public Health, University of Abuya, Abuya/NG

**Background:** To examine the effect of smoking on lung cancer risk in a large population-based cohort of women, many of whom started smoking as teenagers. **Method:** We followed 102,098 women, ages 30 to 50 years, completing a mailed questionnaire at recruitment to the Nigerian-Ethiopia Cohort Study in 2016/2017, through December 2017. We used Cox proportional hazard regression models to estimate relative risk (RR) of lung cancer associated with different measures of smoking initiation, duration, and intensity adjusting for confounding variables. We conducted analyses on the entire study population, among women who had smoked for at least 20 years, among non drinkers, and separately for each country. **Result:** Altogether, 1,240 women were diagnosed with incident, invasive lung cancer. Compared with never smokers, women who smoked for at least 20 years and who smoked 10 cigarettes or more daily had a RR of 1.34 (95\% CI, 1.06-1.70). Likewise, those who initiated smoking during their first birth had a RR 1.27, 1.00-1.62, before menarche (1.39, 1.03-1.87), or before age 15 (1.48, 1.03-2.13) had an increased risk. In contrast, women who had smoked for at least 20 years, but started after their first birth, did not experience an increased lung cancer risk. The increased RR associated with smoking was observed among nondrinkers of alcohol, women with and without a family history of lung cancer, pre-menopausal and post-menopausal women, and in both countries. **Conclusion:** Our results support the notion that women who start smoking as teenagers and continue to smoke for at least 20 years may increase their lung cancer risk. **Keywords:** smoking, lung cancer risk, teenagers
Background: Tobacco consumption is the leading cause of preventable illness and death in the developing world. Health professionals (HPs) have a key role in Tobacco cessation counselling (TCC) and make tobacco users to quit. This study is to evaluate smoking prevalence, knowledge and attitude, and tobacco cessation training amongst HPs in city Bengaluru, India. Our study is conducted as a part of anti-tobacco program, in HPs towards Tobacco cessation (TC). Method: The cross sectional survey was conducted from Spandan oncology centre, Bengaluru, using a structured questionnaire consisting of 22 questions related to tobacco/smoking habits, cessation training and role of HPs in TC between February to April 2018. Result: A total of 552 HPs answered the questionnaire. 39.8% were medical, 28.9% were dental and 31.1% were non allopathic HPs. Male: female ratio was 1.84:1. The age of tobacco smoking initiation amongst HPs was 19 to 20 years, and the percentage of smokers was 24.8% of the sample. 75.2% of HPs were non-smokers. 35.14% of HPs were involved in smoking prevention, Tobacco Control, Education

P2.10-07 HEALTH PROFESSIONAL’S PERCEPTION TOWARDS SMOKING: A CROSS-SECTIONAL STUDY FROM BANGALORE, INDIA.

P2.10-08 SMOKING PREVENTION PROJECT IN SCHOOL POPULATION: MY HEALTH IS IN MY OWN HANDS
T. Kovačević1, D. Bokan2, B. Zaric3, V. Stojić1, T. Boskovic1, P. Simurdić1, A. Andjelkovic1, L. Ergelasev1, J. Stanić1
1Clinic for Thoracic Oncology, Institute for Pulmonary Diseases of Vojvodina, Faculty of Medicine, University of Novi Sad, Sremska Kamenica/RS, 2Clinical Trials Unit, Institute for Pulmonary Diseases of Vojvodina, Faculty of Medicine, University of Novi Sad, Sremska Kamenica/RS, 3Center for Thoracic Surgery, Institute for Pulmonary Diseases of Vojvodina, Faculty of Medicine, University of Novi Sad, Sremska Kamenica/RS

Background: According to the WHO report on the global tobacco epidemic 2017, estimated smoking prevalence in Serbia for people aged >15 for year 2015 was 39.4. Prevalence of smoking for use in 2017 was 40.2 in adults and 17.8 in youths (13-15 YO). Aims of this project were to educate and to raise awareness in young people in elementary and high schools about harm of tobacco, to prevent cigarette/tobacco smoking and to initiate conversation among students about the harmful influence of tobacco on their health. Method: This project was conducted in elementary schools for students aged between 12 and 13 and in high schools for students aged between 14 and 18. A team of young superbacians gave lectures about harm of smoking in biology classes in elementary schools. Workshops were conducted in high schools in cooperation with school psychologist. Adequate brochures and posters were made to initiate conversation among students about the harmful influence of tobacco on their health. Special accent was given to smoking as a main reason for lung cancer. A questionnaire was used for the evaluation of the usefulness of the project. Conclusion: Incidence and mortality of lung cancer in Serbia is among the highest in the world and young people are not well educated about the harmful influence of tobacco use. Accent of further lectures needs to be on physical appearance and lung cancer as possible cause of death in the future. There is a high need for more aggressive and continuous anti-tobacco campaigns in elementary and high schools starting early in population even younger than 14.

Keywords: smoking prevention, Tobacco Control, Education

P2.10-09 THE BELIEFS, ORIENTATION, KNOWLEDGE, UNDERSTANDING, ATTITUDES AND TREATMENT ACCESS TO LUNG CANCER AMONGST RURAL MEN IN NIGERIA
M. Tagbarha
Public Health, University of Abuja, Abuja/NG

Background: Evidences of lung cancer cases from scientific researches have being on the rise in the last few decades and tobacco which is a major risk factor causes about 80% of cancer diagnosed around the world. The need to reduce this scourge has become more important. Method: An interview guide was designed specifically for these studies in which 1505 rural men in Nigeria most of which were age 35 and over took part in it. It contained beliefs, orientation, knowledge, understanding and attitudes about Lung Cancer Diagnosis and incidences. In addition, questions assessing the variables of the Health Belief Model and health motivations also were included. The data were obtained during face-to-face interviews in the primary language of the participating people. The interviews were translated into English. Result: Out of the 1505 men who participated, only 10% of the participants knew about lung cancer, 5% had undergone at least one Lung Cancer Diagnosis during their lives, and 85% were not aware of the disease. There was little or no access to treatment even at early detection in these rural areas. The developing vulnerability to loss of life. Majority of these men (95%) said they knew little or nothing about lung cancer. While 10% of the men said detecting cancer early was important, only 5% reported that cancer could be cured. Age, education, or mother tongue showed no statistically significant relationship with the lung health practice scores. However, proficiency with the English language (p = 0.009) and number of years exposed to awareness and education (p = 0.009) had a significant relationship with the lung health practice scores. The significant explanatory factor for the variable lung health practices was a cue to action (p = 0.009). Conclusion: The level of awareness and treatment access to lung cancer amongst Nigeria’s rural men is extremely low thereby making them not to engage in screening and/or detection practices. This alarming situation calls for urgent intervention of medical/health organizations to provide immediate lung cancer awareness, diagnosis and care so as to reduce incidences or threat at early detection. Tobacco which is known as a major cause of cancer (90%) is widely used by these rural men thereby making them so vulnerable. Awareness is suggested while providing smoking cessation for smokers who intend to quit.

Keywords: smoking prevention, Tobacco Control, Education
Background: Lung cancer is currently the leading cause of cancer deaths in the United States. Past reports have shown an increased incidence of lung cancer in individuals at younger ages, especially under age 40. The purpose of this report is to examine the relationship between lung cancer survival and related factors among individuals <40 versus those over age 40. We examined demographic, clinical and socioeconomic factors, including insurance type. Method: Data for this project were derived from the Surveillance, Epidemiology and End Result (SEER) Program of the National Cancer Institute. SEER consists of 18 population-based, central cancer registries. All lung/bronchus cancer diagnoses from 2007–2014 were obtained using ICD10 codes 34.0–34.9. The following data were collected from the SEER database: year of diagnosis, age, sex, race, insurance, marital status, stage at diagnosis, histology and rural–urban residence. We focused on individuals under age 65 due to insurance and income changes commonly occurring around 65. Hazard ratios (HRs) from Cox proportional hazards' regression models were used to assess differences between those above and below age 40, adjusting for demographic, clinical and socioeconomic factors. Result: Out of 12,401, 407 individuals were identified for this analysis and 2,134 were <40 years and 110,283 were over age 40. Slightly more females than males were <40 (51% vs 49%) compared to those over 40 (53% males vs 47% females) and over 70% of both age groups were white, with a mean age of 33 years for those <40 and 57 years for those >40. Median survival time was shorter for those <40 (19 vs 12 months). Cox proportional hazards regression models revealed a significantly increased probability of dying for individuals under age 40 (HR=1.10, 95% CI=1.04, 1.18), adjusting for covariates. Those with adenocarcinoma and later stage diagnoses had a 4 and 13% increased probability of dying, respectively (p<0.001). Those with private versus no insurance had a 14% decreased probability of dying (HR=0.86, 95% CI=0.82, 0.90; P trend<0.0001). There were no significant differences in survival according to tumor size, extension and other non-insurance socioeconomic factors. Conclusion: This SEER analysis shows that individuals <40 have worse prognosis than individuals >40 (up to 65 years), and that those with private insurance fared better than the uninsured, even after adjustment for important demographic and clinical factors. Future epidemiologic studies of younger individuals under age 40 are needed and are currently being planned to further assess risk factors for younger individuals and the reasons for worse prognosis.

P2.10 PREVENTION AND TOBACCO CONTROL
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.10-10 LUNG CANCER SURVIVAL IN YOUNGER PATIENTS (<40 YEARS): ANALYSIS OF SURVEILLANCE, EPIDEMIOLOGY AND END RESULTS PROGRAM DATA
M. Bittoni, J. Fisher
Comprehensive Cancer Center. The Ohio State University, Columbus/US

Background: Tobacco use is a leading cause of lung cancer deaths and smoking cessation has been shown to improve survival. The purpose of this research is to examine the impact of smoking status on lung cancer survival in younger patients. Method: Data from the Surveillance, Epidemiology and End Results (SEER) program for the years 2000-2014 were used to study lung cancer patients aged <40 years. Survival curves were generated using the Kaplan-Meier method and log-rank tests were used to compare survival based on smoking status. Results: There were 2,174 lung cancer patients aged <40 years, 1,392 (64.2%) of whom were smokers and 782 (35.8%) were nonsmokers. The smoking group had a significantly shorter median survival of 16 months compared to the nonsmoking group of 48 months (p<0.001). In a Cox proportional hazards model with adjustment for tumor characteristics, smoking was associated with a 35% decreased risk of dying compared to nonsmokers (HR=0.65, 95% CI=0.54, 0.79). Conclusion: Smoking has a significant negative impact on lung cancer survival in younger patients and efforts to help patients quit smoking are needed to improve survival.

P2.10-11 IMPACT OF SMOKING ON MULTIPLE PRIMARY CANCERS SURVIVAL – A RETROSPECTIVE ANALYSIS
A. Rosaszkowski-Wojtowicz1, A. Bucinski2, A. Doboszyńska2
1Department of Pulmonary Medicine and Infectious Diseases, University of Warmia and Mazury, Olsztyn/PL, 2Department of Biopharmacy, Nicolaus Copernicus University, Collegium Medicum, Bydgoszcz/PL

Background: The incidence of multiple primary malignancies (MPCs) in the population of cancer patients amounts to 14.98%. However it is 6.84% in the total study population. Survival time and the interval between the first and new cancer development are longer for patients who never smoked or ceased smoking as compared to active smokers. Smoking cessation after the first cancer diagnosis prolongs the period of time before a new cancer is detected, as well as the total survival time for patients since the first cancer diagnosis.

Keywords: survival, tobacco smoking, multiple primary malignancies

P2.10 PREVENTION AND TOBACCO CONTROL
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.10-12 PREVALENCE, PATTERN AND FACTORS ASSOCIATED WITH DUAL TOBACCO USE IN A RURAL COMMUNITY IN SOUTH EASTERN NIGERIA
U. Onanakari1, M. Illo2, O. Odukoya2, C. Ikpe3
1Community Medicine, Federal Teaching Hospital, Abakaliki/NIG, 2Pharmaceutical Sciences, Enugu University of Science and Technology, Abagani/NIG, 3Community Medicine, Lagos University Teaching Hospital, Lagos/NIG

Background: Dual tobacco use is a greater health problem than mono use and needs to be researched. The aim of this study was to determine the pattern and predictors of dual tobacco use, and their health related knowledge and social attitudes towards its use among residents of a rural community in south Eastern Nigeria Method: A cross-sectional descriptive study was carried out among 490 residents of Ukpo community selected using a two-stage sampling method. Data was collected using a pre-tested interviewer administered questionnaires adapted from Global Adult Tobacco Survey. Odds ratios and 95% confidence intervals were computed and P values of < 0.05 were considered statistically significant. Result: The results showed that respondents were mostly male 300(61.2%) and aged between 20 and 70 years with a mean of 42.2 ± 15.4 years. Almost a quarter of the respondents, 101 (20.6%) were ever- dual tobacco users. Dry snuff (73.8%) and manufactured cigarettes 82.2% were the most common form of tobacco used. The primary reasons for tobacco use were: to relieve stress (61.2%), to increase levels of alertness (56.4%); for personal pleasure (55.9%) and social acceptance (52.1%). Age (p<0.0001), male gender (p<0.0001), Igbo tribe (p<0.0001) and lower educational attainment (p<0.0001) were associated with dual tobacco use. About half of the respondents (51%) were aware that dual tobacco is more dangerous to human health than mono use and only about (27.1%) were aware that tobacco use is associated with lung cancer. Many of the respondents agreed that tobacco is a way of promoting friendship (65%) and should be used within their community (73%). Conclusion: Efforts targeted at raising community awareness of the health effects of dual tobacco use are needed in rural communities where dual tobacco use is disproportionately high.

Keywords: Tobacco, Lung Cancer, Tobacco, Cancer, knowledge
Background: In 1798, Le Roux, fellow of Bichat, reported that primary lung cancer was nonexistent. Today it is the leading cause of cancer death worldwide with 1.7 million in 2015. The aim of this study was to estimate the primary lung cancer prevalence changes around the world from the end of the 18th century to 1950, when the first registries became available. Method: International autopsic studies results from 1760 to 1950 were collected. All major international electronic databases were queried and paper files were obtained when electronic data were not available. Result: In 22 countries across America, Europe, Asia, Africa, 1899 references representing 4067041 autopsies were found. We estimate that, in the first half of the 19th century, lung cancer crude prevalence ranged from 1.82*10^-5 in France (with a mean age at death of 62.3) to 5.4*10^-3 in Germany. This was followed by a period of stability in the second part of the 19th century with a prevalence ranging from 0 in Italy to 0.16 in UK. These figures increased dramatically from the beginning of the 20th century to reach a prevalence of 0.39 in 1947 in Germany. Conclusion: To our knowledge, it is the first study reporting historical lung cancer prevalence for this period: Lung cancer was rare 200 years ago but increased significantly from the beginning of the twentieth century onwards, reflecting probably the introduction of manufactured cigarettes.

P2.10-16 FINDING THE RELATIONS BETWEEN LUNG CANCER AND ASSOCIATED RISK FACTORS IN PAKISTANI POPULATION
A. Fatima1, S.S.A. Zaidi2
1Shaoukt Khanum Cancer Hospital and Research Centre, Lahore/PK, 2WeCare Medical Centre, Lahore/PK

Background: In Pakistan incidence and mortality rates due to lung cancer are rising with time. Lung cancer is affecting more people than it was before. One of the most common malignancies in world today is lung cancer. Determination of risk factors can help people in preventing this lethal disease. Unfortunately limited data is available on determinants of lung cancer in Pakistani population. Very few studies have been carried out till now. The relationship between various risk factors and lung cancer was evaluated in case control study. Method: Five hundred lung cancer patients cytological or pathologically diagnosed were enrolled. Enrollment was done from different hospitals all across Pakistan. By questionnaire socio-demographic, occupational, lifestyle variables were extracted. Result: Odds ratio (ORs) and 95% confidence intervals (95%CI) were calculated & dose response associations were also assessed for suitable factors. Smoking(ORs=8.3, 95%CI=6.9-12.8), second hand smoking(ORs=5.1, 95%CI=3.5-8.0), diesel exhaust(ORs=4.2, 95%CI=3.2-5.0), family history(ORs=2.9, 95%CI=1.3-6.2)previous lung disease(ORs=1.8, 95%CI=1.2-2.6). Strongest dose-response relationship was observed for smoking. Conclusion: The comparison between cases and controls showed that lung cancer determined from Pakistan cross-Canada radon survey, the Canadian population risk of radon-induced lung cancer was assessed. The theoretical estimates show that about 14 – 16% of lung cancer deaths among Canadians are attributable to indoor radon exposure. The results strongly suggest that it is important to test your homes for radon, and take actions as required to effectively prevent and reduce radon-induced lung cancer.

P2.10-17 ENVIRONMENTAL TOBACCO SMOKE EXPOSURE AND EGFR MUTATIONS IN NON-SMOKERS WITH LUNG CANCER: A DOSE-RESPONSE ANALYSIS OF PUBLISHED DATA
W. Liang1, H. Liang1, L. Zhao1, G. Qi1, Y. Wen2, J. He2
1The First Affiliated Hospital of Guangzhou Medical University, National Clinical Research Center for Respiratory Disease, China State Key Laboratory of Respiratory Disease, Guangzhou/CN, 2Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou Institute of Respiratory Disease & China State Key Laboratory of Respiratory Disease, Guangzhou/CN

Background: Tobacco smoke is a well-known strong mutagen, however, as EGFR mutations (EGFRmut) in lung cancer were predominantly enriched in never smokers, people used to consider tobacco smoke is that release small bursts of energy. This energy is absorbed by nearby lung tissue, damaging the lung cells. The World Health Organization has identified radon exposure being the second leading cause of lung cancer after tobacco smoking. Method: Recent epidemiological studies on indoor radon and lung cancer in Europe, North America and Asia provided strong evidence that radon causes a substantial number of lung cancers in the general population. Using the risk model developed by the US Environmental Protection Agency and with the radon distribution obtained from a recent cross-Canada radon survey in about 14,000 homes, the Canadian age-specific rates for overall and lung cancer mortality rates averaged over five years from 2008 to 2012 and the Canadian age specific smoking prevalence data in 2002, the Canadian population risk for radon induced lung cancer was assessed. Result: The population risk of radon-induced lung cancer is assessed by an attributable risk (AR). The ARs for Canadian males are 0.15 for ever-smokers and 0.29 for never-smokers. For Canadian females, the ARs are 0.14 for ever-smokers and 0.28 for never-smokers. The detailed breakdown of AR in different radon ranges showed that the risk increases with increased radon concentration. Conclusion: Based on the more accurate radon distribution characteristics obtained from the recent cross-Canada radon survey, the Canadian population risk of radon-induced lung cancer was assessed. The theoretical estimates show that about 14 – 16% of lung cancer deaths among Canadians are attributable to indoor radon exposure. The results strongly suggest that it is important to test your homes for radon, and take actions as required to effectively prevent and reduce radon-induced lung cancer.

Keywords: Radon, Non-smokers
mutually exclusive of EGFRmut. We believed that the reason for the relatively lower EGFRmut rates in smokers was the confounding effect from the greater population of known smoke-directing lung cancers. Therefore, it remained interesting to know whether environmental tobacco smoke (ETS) exposure will influence EGFRmut rate. Method: We searched relevant studies from electronic databases. Different ETS exposure groups of non-smokers and the corresponding EGFRmut rates were extracted from eligible studies. The ETS exposure was measured by the duration (pack-years). A weighted linear regression model was used to examine the correlation by adjusting the sample size of each group. Result: A total of 7 studies involving 1,447 patients were included. Although no difference was observed between patients with any level ETS exposure and those without any ETS exposure (OR=1.01, 0.94-1.08, P=0.787), we found a positive correlation between ETS exposure duration and occurrence of EGFRmut (R²=0.436, P<0.001; Figure 1).

Conclusion: The current results suggested that tobacco smoke exposure might also be an inducing factor for EGFR mutations. The true impact of tobacco on EGFR mutations should be calculated based on general population rather than lung cancer population to avoid enrichment bias in the future studies.

P2.11 SCREENING AND EARLY DETECTION
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.11-01 BLOOD TRANSCRIPTOMICS ENABLES DETECTION OF PRE-INVASIVE & MINIMALLY-INVASIVE LUNG ADENOCARCINOMA
B. Han1, F. Qian1, W. Yang1, X. Zuo1, J. Qian1, B. Zhang1, S. Wang1, L. Zhang2
1Shanghai Chest Hospital, Shanghai/CN, 2East China Sanatorium, Wuxi/CN

Background: Although the low-dose computed tomography scan has been proved a useful tool for lung cancer screening, its highly false positive rate that usually over 90% limits its effectiveness for early detection of lung cancer. There is an urgent need to develop a non-invasive and cost-effective method to detect lung cancer at early stage. Method: Peripheral blood samples were collected from patients pathologically diagnosed pre-invasive or minimally-invasive lung adenocarcinomas and healthy volunteers who reported with no any pulmonary disorders. Total mRNA from peripheral whole blood was processed according to PAxGene Blood RNA Kit protocol. In this study, we compared blood gene expression data from 95 samples using microarray analysis. Quantitative PCR was then used to validate biomarker candidates identified by differential expression analysis in microarray hybridization (N = 45). The gene panel finally selected was validated in an independent population (N = 54) using quantitative PCR. Logistic regression was performed on multiple combinations of common probe sets, and data were evaluated in terms of discrimination by computing the area under the receiving operator characteristic curve. Result: The lung cancer specific gene signatures were identified to construct predictive model based on 6-gene panel such as HSP90AA1, UQCRQ, NDUFB2, RPL24, CKLF and GLRX, which correctly classified 29 of 39 pre-invasive or minimally-invasive lung adenocarcinomas, 30 of 38 health controls with 76.6% accuracy in training set, and 7 of 8 lung cancer, 8 of 10 health controls with 83.3% accuracy in test set. Validation by quantitative PCR confirmed the Affymetrix microarray data, with 75.7% accuracy, 75.0% sensitivity, 76.6% specificity, 0.83 of area under curve (AUC) in training set, and 91.9% accuracy, 91.7% sensitivity, 92.3% specificity, 0.94 of AUC in test set. Independent validation testing confirmed these specific gene signatures did not derived from the result of random chance with 83.3% accuracy, 84.6% sensitivity and 79.3% specificity. Conclusion: Our results indicated the feasibility of blood-based genetic signatures to identify pre-invasive and minimally-invasive lung adenocarcinoma as screening for lung cancer at very early stage.

Keywords: Blood-based genetic signatures, lung cancer, early stage

P2.11-02 DIRECT COMPARISON OF NEW SOLID NODULES DETECTED IN WOMEN AND MEN DURING INCIDENCE SCREENING ROUNDS OF THE NELSON TRIAL
J. Walter1, M. Heuvelmans1, R. Vliegenthart2, P. Van Ooijen1, H. De Koning1, M. Oudkerk1
1Center for Medical Imaging North-East Netherlands, University of Groningen, University Medical Center Groningen, Groningen/NL, 2Center for Medical Imaging North-East Netherlands, Department of Radiology, University of Groningen, University Medical Center Groningen, Groningen/NL, 3Public Health, Erasmus University Medical Center, Rotterdam/NL

Background: Low-dose computed tomography (LDCT) lung cancer screening is recommended by US guidelines. Women are commonly underrepresented in lung cancer screening trials and evidence is derived from a predominantly male population. New solid nodules that develop after baseline screening have a high lung cancer probability. There is very limited evidence concerning the potential differences of new solid nodules detected in women and men. Method: In the randomized Dutch-Belgian Lung Cancer Screening (NELSON) Trial, 7,557 participants (16%) had undergone baseline screening. Three incidence rounds took place after intervals of 1year, 2years and 2.5years respectively. We included participants with solid non-calciﬁed nodules registered after baseline as new and not visible in retrospect on a previous screen. Continuous variables were compared using the Mann–Whitney U test or student’s t test and are presented as medians with interquartile range (IQR) or means with standard deviation (±) respectively. Nominal variables were compared using the chi-squared test. Result: In total, 699 participants (12%) with 1,130 new solid nodules (21% in women, 889 [79%] in men) were included. Eventually, 5.4% of women with a new solid nodule and 10.4% of men with a new solid nodule were diagnosed with lung cancer (P=0.083), corresponding to 3.3% of new solid nodules being malignant in women and 6.5% being malignant in men (P=0.060). The female participants were signiﬁcantly younger than the male participants (58±5 years vs. 60±5 years, P=0.008), while there was no signiﬁcant difference in smoking pack-years (39 years [IQR 30-49] vs. 39 years [IQR 30-52], P=0.696). Comparing new nodule size at initial detection in women and men, there was a signiﬁcant difference for benign new nodules (51mm3, IQR: 29-128mm3 vs. 66mm3, IQR: 35-177mm3, P=0.019), but not for lung cancers (449mm3, IQR: 52-1050mm3 vs. 447mm3, IQR: 196-1135mm3, P=0.553). The currently advocated cutoff of ≥30mm3 (about 3.9mm) reached >95% sensitivity in both genders. At ﬁrst follow-up after detection, new solid nodules in women had resolved signiﬁcantly more frequently than in men (69% vs. 58%, P=0.003). Adenocarcinomas were signiﬁcantly more common in women than in men (88% of lung cancers vs. 31% of lung cancers, P=0.002), whereas the stage I detection rate was comparable (67% of lung cancers vs. 63% of lung cancers, P=0.789). Conclusion: While there are signiﬁcant differences between new solid nodules detected after baseline in women and men, there is no indication for a sex speciﬁc nodule management approach in LDCT lung cancer screening.

P2.11 SCREENING AND EARLY DETECTION
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.11-03 CARDIOVASCULAR RISK PREDICTION IN A COMMUNITY-BASED LUNG CANCER SCREENING PROGRAMME
H. Balata, M. Evison, R. Booton, P. Crobbie
North West Lung Centre, Manchester University NHS Foundation Trust, Manchester/ GB

Background: Cardiovascular disease (CVD) is a major cause of morbidity and mortality in populations eligible for lung cancer screening. The aim of this study was to determine whether a brief CV risk assessment, delivered as part of a community-based lung screening programme, was effective in identifying individuals at high risk who might benefit from primary prevention. Method: The Manchester Lung Screening
Pilot consisted of annual low dose CT (LDCT) over 2 screening rounds, targeted at individuals in deprived areas at high risk of lung cancer (age 55-74 and 6-year risk ≥1.5%, using PLCO risk model). All participants of the second screening round were eligible to take part in the study. Ten-year CV risk was estimated using QRISK2 in participants without CVD and compared to age (±5 years) and sex matched Health Survey for England (HSE) controls; high risk was defined as QRISK2 score ≥10%. Coronary artery calcification (CAC) was assessed on LDCT scans and compared to QRISK2 score. Result: Seventy-seven percent (n=920/1,194) of screening attendees were included in the analysis; mean age 65.6 (4.4 and 50.4%) female. QRISK2 and lung cancer risk (PLCO2012) scores were correlated (r=0.26, p<0.001). Median QRISK2 score was 21.1% (IQR 14.9–29.6) in those without established CVD (77.6%, n=714/920), double that of HSE controls (10.3%, IQR 6.6–16.2; n=714) (p<0.001). QRISK2 score was significantly higher in those with CAC (p<0.001). Screening attendance was 10-fold more likely to be classified high risk (OR 10.2 [95% CI 7.3–14.0]). One third (33.7%, n=310/920) of all study participants were high risk but not receiving statin therapy for primary CVD prevention. Conclusion: Opportunistic CVD risk assessment within a lung cancer screening programme is feasible and is likely to identify a very large number of individuals suitable for primary prevention.

Keywords: Screening, Early Detection, Cardiovascular risk assessment

P2.11 SCREENING AND EARLY DETECTION TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.11-04 TREATMENT CAPACITY REQUIRED FOR IMPLEMENTING LUNG CANCER SCREENING IN THE UNITED STATES

E. Blom1, K. Ten Haaf2, D. Arenberg2, H. De Koning1

1Department of Public Health, Erasmus MC, Rotterdam/NL, 2Division of Pulmonary & Critical Care Medicine, University of Michigan, Ann Arbor/MI/US

Background: Implementing Low-Dose Computed Tomography screening for lung cancer will lead to an increased detection of early stages. The required resources to treat those cancers remains unknown. Method: We extended a well-established microsimulation model with data from the National Cancer Database to assess the number of lung cancer patients requiring surgery, radiotherapy, chemotherapy, and no therapy when implementing lung cancer screening in the United States in 2018. Screening policies were assessed: the United States Preventive Task Force (USPSTF) recommendations; the Centers for Medicare & Medicaid Services (CMS) recommendations; and the most cost-effective policy from a study for Cancer Care Ontario (annual screening, ages 55-75, at least 40-pack year smoking history, currently smoking or quit within last 10 years). Base-case screening adherence was 50%. Sensitivity analyses assessed 20%, 35%, 65% and 80% adherence. Result: Implementing the USPSTF recommendations with 50% screening adherence would require 35.3% more lung cancer surgeries in 2015–2040 compared to no screening. However, 2.1% less radiotherapy and 5.1% less chemotherapy treatments would be required. Furthermore, 6.2% fewer patients would receive no therapy. The required number of lung cancer surgeries would be 1.7, 3.79, 8.08, 15.15 in 2023, 53.69 in 2028, and 45.007 in 2040. Compared to no screening, this is an increase of 9.2% in 2017, 44.3% in 2023, 36.8% in 2028, and 23.0% in 2040. Screening adherence strongly influenced results. By 2040, the required number of surgeries ranged from 53,666 (with 20% adherence) to 96,953 (with 80% adherence). Results for the CMS and Ontario policies were similar to the USPSTF policy, although changes compared to no screening were smaller. Conclusion: Implementing lung cancer screening in the United States requires a major increase in surgical capacity. The current workforce of thoracic surgeons in the United States may not be able to cope with this increased demand.

P2.11 SCREENING AND EARLY DETECTION TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.11-05 RECRUITMENT STRATEGIES FOR THE LUNG CANCER SCREENING PILOT FOR PEOPLE AT HIGH RISK

G. Darling, N. Sandhu, T. Karapetyan, A. Banaszewska, M. Tammemagi

Cancer Care Ontario, Toronto/CA

Background: Cancer Care Ontario (CCO) launched the Lung Cancer Screening Pilot for People at High Risk on June 1, 2017, at three centres. Recruitment strategies were developed to recruit individuals through partner and community-led recruitment strategies and emphasized supporting equitable access to screening through targeted recruitment activities. A major aim of the pilot is recruiting highest risk individuals who are known to have the highest rates of cigarette smoking; lower socioeconomic status (SES) and First Nations, Inuit and Metis (FNIM). Methods: The CCO supported provider recruitment and implemented recruitment strategies built upon findings from an internal literature review. Strategies were used to recruit potentially eligible screening participants, especially those at higher risk. Recruitment strategies were implemented at all pilot sites and informed regional/local outreach activities. A report was developed to locate areas of predicted high risk populations as well as targeted segment populations using market research to recommend recruitment modalities for specific sub-groups such as lower SES, older, lower-income-suburban residents. To facilitate recruitment, an accredited Continuing Professional Development course about the lung cancer screening pilots was developed for primary care leads and collaborative educational sessions were held with primary care providers and FNIM provider groups. CCO collected recruitment related data from each pilot site quarterly, and collected patient-level data (e.g., provider-referred vs self-presenter, number of people found eligible for screening) monthly. Recruitment events were also tracked. Result: Based on early results, June to November 2017, 1038 eligible individuals were recruited across the three pilot sites. The leading methods of recruitment were physician referrals, newspaper advertisements, word of mouth and nurse practitioners. The majority of individuals, 60.4%, were referred by family doctors. 13.2% indicated newspaper advertisements as source of recruitment. 6.3% were recruited through word of mouth and 6.0% were recruited through nurse practitioners. Approximately 27% of eligible individuals were recruited from low income postal codes (average annual household income < $70,000 CAD). 6.3% of eligible individuals identified as FNIM. Updated data will be presented at the conference. Conclusion: Early results have shown that provider-led recruitment strategies have been an effective method in enlisting individuals and is the primary source of recruitment for the pilot. However, recruitment of higher risk individuals such as FNIM and those with a lower socioeconomic status remains low. CCO is working with pilot sites and organizational partners to better understand how to engage and recruit these higher risk individuals.

Keywords: Benign Biomarker Diagnosis

P2.11 SCREENING AND EARLY DETECTION TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.11-06 A NEW HISTOPLASMOSIS ANTIBODY ENZYME IMMUNOASSAY FOR THE DIAGNOSIS OF LUNG BENIGN NODULES

S. Deppen1, E. Grogan1, P. Massion2

1Thoracic Surgery, Vanderbilt University Medical Center, Nashville/TN/US, 2Division of Allergy, Pulmonary and Critical Care Medicine, Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center, Nashville/TN/US

Background: Granulomas caused by infectious lung diseases often present as indeterminate pulmonary nodules on radiography. Newly available antibody enzyme immunoassay (EIA) test for histoplasmosis has not been studied for the evaluation of lung nodules suspicious for cancer. This study investigates serum biomarkers for histoplasmosis measured by a new CLIA-certified test as a response to exposure when positive and as a predictor of benign disease in indeterminate pulmonary nodules from a highly endemic region. Method: 376 serum samples from our institution’s registry of patients presenting with pulmonary nodules ≤30mm in maximum diameter were analyzed for histoplasmosis by the IgG and IgM EIA. Manufacturer-suggested levels for histoplasmosis diagnosis was used to indicate a positive test for antibodies. Final diagnosis was determined pathologically or by radiographic follow-up. Diagnostic test characteristics with 95% confidence intervals (CI) for benign lung disease were estimated. Result: Cancer prevalence was 59% (n=223). Seventy-seven (20%) samples were positive for IgG anti-Histoplasma antibodies (Table 1). Twenty-one (5.6%) were IgM antibody positive and 84 (22%) were positive for either antibody. Positive diagnostic likelihood ratios (DLR) for benign disease were 3.22 (95% CI: 2.08; 4.98) for IgG antibodies, 6.19 (95% CI: 2.13; 18.1) for IgM antibodies each separately, and 2.92 (95% CI: 1.95; 4.37) if either IgG or IgM were positive when both IgG and IgM antibodies were present. Conclusion: Seventy-one (14%) nodules were cancerous. A positive EIA test offered clinically informative results. A positive EIA test for both IgG and IgM strongly suggests benign granuloma and ruled out malignancy for 9% of benign nodules arising from a highly endemic area of the country. The new EIA test may improve the diagnostic evaluation of indeterminate pulmonary nodules and avoid harmful invasive biopsies. Additional investigation in conjunction with other non-invasive cancer biomarker tests is warranted.

Keywords: Benign Biomarker Diagnosis
P2.11-07 LUNG CANCER IN A TERTIARY CARE SETTING: SO NEAR, YET SO FAR
K. Garg1, S. Binji2, V. Saini1, S. Jaswal3, U. Handa2, J. Kaur2
1Pulmonary Medicine, Government Medical College and Hospital, Chandigarh/IN, 2Biochemistry, Government Medical College and Hospital, Chandigarh/IN, 3Pathology, Government Medical College and Hospital, Chandigarh/IN

Background: Lung cancer patients usually present in advanced stage. Once diagnosed, these patients do not take treatment/tend to leave it in-between, because of various financial and psychosocial problems, and issues related to administration of chemotherapy and side effect profile. If diagnosed at an early stage, lung cancer has a high overall 5 year survival. In developing countries, with a high burden of lung cancer and its associated morbidity and mortality, there is a need to screen the ‘at risk’ population, thus facilitating early diagnosis. Lung cancer patients were hence studied at presentation and followed up to 10-12 weeks after diagnosis. The utility of a biomarker, Heat shock protein 90-beta (Hsp 90-beta) was assessed along with.

Method: 60 individuals were included: 20 histologically/cytologically proven patients of lung cancer before treatment initiation (Group A), 20 patients with benign lung diseases (Group B) and 20 apparently healthy individuals (Group C). After thorough investigations and staging (TNM classification), patients of Group A were administered chemotherapy (NCCN guidelines), and followed up to 10-12 weeks after diagnosis. Also, 5ml of venous blood was collected from all individuals for Hsp90-beta evaluation by ELISA.

Result: In Group A, 1/20 patient was diagnosed with stage 3, rest 19/20 patients were diagnosed with stage 4 lung cancer. Predominant histopathological type was squamous cell carcinoma (14/20 patients), followed by adenocarcinoma (4/20) and small cell carcinoma (2/20). At follow up, 35% (7/20) patients were dead/lost to follow up. 13 patients were given chemotherapy, 10/13 had partial response and 3/13 had progressive disease (RECIST Criteria). The 3 groups were age and gender matched. Mean serum Hsp90-beta levels were 242.850, 129.825 and 107.150ng/ml in group A, B and C respectively. Group A had significantly higher levels (p<0.0005, cut off value:146.5ng/ml). 95% sensitivity and specificity. The levels did not differ with histological type/stage of cancer. At follow up, in 13 patients of Group A, mean Hsp90-beta levels showed an increase.

Conclusion: Majority of the patients presented in stage 4 signifying the urgent need of a diagnostic/screening tool for detection in early stages. Also, various factors which could be responsible for a high attrition rate due to death/lost to follow up need to be studied, so that specific interventions can be planned. Serum Hsp90-beta could be a valuable biomarker in diagnosis/screening of lung cancer. However, its prognostic role needs elucidation. Detailed studies with larger sample size, different histologies and different stages are required to establish various strategies for early diagnosis and timely comprehensive management, so as to drive the final treatment outcomes in a positive direction.

Keywords: lung cancer, staging, diagnosis

P2.11-08 TUMOR AUTOANTIBODY PANEL CAN IMPROVE THE ACCURACY OF EARLY DIAGNOSIS IN LUNG CANCER PRESENTING WITH GGNS /SOLID NODULES
Y. He1, C. Zhou2, F. Hirsch3
1Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN, 2Medical Oncology, Shanghai Pulmonary Hospital, Tongji University, Shanghai/CN, 3Oncology Department, Aurora/CO/US

Background: Autoantibody is an attractive diagnostic approach for early detection of malignant tumors. We performed this study to validate the performance of an autoantibodies (TAAs) panel (p53, PGP9.5, SOX2, GAGE7, GBU4-5, MAGE A1, CAGE) to aid early diagnosis of lung cancer, ground-glass nodules (GGNs) and/or solid nodules.

Method: A prospective audit was conducted on 540 individuals known to have GGNs and/or lung nodules. These patients included 311 pulmonary malignant or borderline lung diseases, 229 lung benign GGNs and/or nodules. We detected TAAs quantitation by ELISA method.

Result: The sensitivity and specificity of autoantibody assay were 48.6% and 92.7% respectively. In lung invasive adenocarcinoma, the sensitivity of autoantibody assay was 51.9%. When autoantibody assay were 48.6% and 92.7% respectively. In lung invasive adenocarcinoma, the sensitivity of autoantibody assay was 51.9%. In lung adenocarcinoma, the sensitivity of autoantibody assay was 51.9%.

Conclusion: The greatest impact of using the new seven-autoantibody panel was the highly significant improvement in the sensitivity and specificity of the test in the clinical setting. Our study suggested that the seven-autoantibody panel can be combined with CT imaging to aid diagnosis of lung cancer with GGNs and/or solid nodules.

Keywords: early diagnosis, tumor autoantibody panel, lung cancer, ground-glass nodules (GGNs)
Background: Lung cancer is a type of cancer with a very high mortality rate, mostly caused by misdiagnosis of the cancer during early stage when most of the treatment are supposed to be adequate. A type of medical diagnosis known as molecular diagnosis has been developed to alleviate this problem. One example of this diagnosis method is targeted therapy based on specific DNA for biomarking. In Non-Small Cell Lung Cancer (NSCLC), mutation in EGFR gene will activate Tyrosine Kinase response and the decay of auto inhibitor system. The standard method to identify EGFR mutations is tissue biopsy that requires the sampling of tissue. A secondary method using molecular diagnosis has been developed to increase the success rate of the lung cancer diagnosis. Plasma circulating tumor DNA (ctDNA) is a DNA fragment which contains tumor-specific alteration, mostly found in body fluids such as blood, urine, saliva, sputum, and pleura. ctDNA fragments in urine can easily be sampled for biopsy, a type of molecular analysis on the urine to look for these altered DNAs can be used as another option for lung cancer detection as well.

Method: A total of 30 frozen urine sample were collected from NSCLC patients. The patients were diagnosed with positive EGFR mutation from the cell line. The exon 18 and 20 of EGFR were the target for molecular analysis, ctDNA from urine was amplified using polymerase with original primer for sequencing. Result: Among 30 samples, 6% was detected as G718X mutations, 50% detected as T790M mutations, 60% was detected as G777Q mutations. Urine samples was determined as viable testing methods like DNA direct sequencing from tissue. Conclusion: Lung cancer harboring exon 18 and exon 20 mutations can be detected using DNA direct sequencing method. The use of urine biopsy was proven to be viable as an alternative to tissue biopsy when tissue isn’t available for molecular testing.

Keywords: ctDNA, EGFR mutation, urine liquid biopsy

P2.11-10 POTENTIAL UTILITY OF A POSITIVE EARLCYT®-LUNG BLOOD BIOMARKER TEST IN IDENTIFY PULMONARY NODULES

J. Jett1, G. Healey2, A. Murray3, G. Hamilton-Fairley4, S. Fraser2, L. Peek2, P. Mazzone4, P. Massion7
1Oncimmune Llc, Napa/CA/US, 2Statistics, Oncimmune Llc, Nottingham/GB, 3Oncimmune Llc, Nottingham/GB, 4Oncimmune Llc, London/GB, 5Oncimmune Llc, Desoto/KS/US, 6Respiratory Institute, Cleveland Clinic, Cleveland/OH/US, 7Vanderbilt-Ingram Cancer Center, Nashville/TN/US

Background: EarlyCyt®-Lung is a blood-based biomarker of risk for lung cancer and is able to detect early stage disease. Indeterminate pulmonary nodules (IPN) of 8-20 mm are a common clinical problem. Approximately 20% of IPNs are malignant in many series, but determining which ones are malignant versus benign is a dilemma. The ACCP guidelines recommend surgical resection for IPN of high risk for malignancy (>65%). A moderate positive EarlyCyt-Lung (sensitivity 40%; specificity 93%) has been shown effective approach, 9 single nucleotide polymorphisms (SNPs) in 5 genes were assessed for disease control of lung cancer patients. Genotyping was performed with the TaqMan® allelic discrimination technology. The results were analysed using SPSS 24.0 software. Result: Among the 5 studied genes, we found a significant association for the IL17A (rs7747909) polymorphisms. IL-6 rs1800587, TNFA rs1800623 trend of association was observed without reaching the significance level. No significant association was observed for the remaining SNPs in the following genes: MIF(rs755622, IL-6(rs2282145, IL-6ST(rs2282044, TYK2(rs32034856, rs34536443, rs35018800), STAT3(rs2293152). Conclusion: The results found suggest the important role of genetically determined high inflammatory response in the pathogenesis of lung cancer in the Moroccan population.

Keywords: lung cancer risk, Inflammatory system, Moroccan population

P2.11-11 METABOLOMICS ANALYSIS IN LUNG CANCER FOR SCREENING AND EARLY DETECTION

Thoracic Surgery. Tokyo Medical University, Tokyo/JP

Background: Metabolomics, a simultaneous measurement technique for hundreds of low weight molecules, generally called metabolites, is an efficient technique to understand how metabolism is changed by various factors, including environment and diseases, particularly malignant diseases. Body fluids, such as urine or saliva, harvested non-invasively have been used in this analytical technology, which yielded a potential of practical early detection of carcinoma of various organs. The diagnosis of various carcinoma in advanced lung cancer has begun to be reported based on the pattern information of metabolites. It can be used for practical clinical early detection of carcinoma of various organs. However, practical metabolomic analysis regarding lung cancer has not been reported yet. We used surgically resected specimen of lung cancer to analyze and clarify metabolomic profiles as an aspect of lung cancer. Method: We obtained blood and saliva from 110 patients with lung cancer after obtaining informed consent for this study and compared the metabolomic profiles of both blood and saliva in 83 who had neither pulmonary disease nor past history of any cancer in terms of various clinical aspects. Metabolomic analysis was performed by capillary electrophoresis time-of-flight mass spectrometry (CE-TOFMS) of metabolites of the blood and saliva, then analysed ionized sample which contained the most metabolites in primary pathways. Result: Analysis of serum and metabolite organization by CE-TOFMS revealed that the intermediate metabolite levels of several pathways changed markedly in lung cancer blood and saliva. We identified characteristic metabolic patterns in advanced lung cancer with metabolomic clinical information by analysing the association with the overall metabolism profile. Conclusion: We identified metabolomic biomarkers which were characteristic of lung cancer using blood and saliva in this study. At present, we are analysing various body fluids for analysis of lung cancer cases including prognostic implications. Applications to non-invasive, simple, easy and low-cost cancer screening are expected in the future.

Keywords: metabolomics, lung cancer, Early Detection
P2.11-13 PRECISE EARLY DETECTION OF LUNG CANCER AND BLOOD CELL CIRCUIT

O. Kshivets
Surgery, Roshal Hospital, Roshal/RU

Background: Significance of blood cell circuit in terms of early detection of lung cancer (LC) was investigated. Method: In trial (1987-2018) consecutive cases after surgery, monitored 115 LC patients (LCP) (m=100, f=15) by using the pathological stage IA (tumor size=1.86±0.30 cm; squamous=51, adenosinocarcinoma=59, large cell=5; TNM0=115; G1=39, G2=42, G3=34, 5-year survival=100%) and 120 healthy donors (HD) (m=69, f=51) were reviewed. Variables selected for study were input levels of blood cell circuit, sex, age, TNM. Differences between groups were evaluated using discriminant analysis, clustering, nonlinear estimation, structural equation modeling, Monte Carlo, bootstrap simulation and neural networks computing.

Result: It was revealed that early detection of LC from HD (n=235) significantly depended on: leucocytes (abs, total), segmented neutrophils (%). abs, total), lymphocytes (%), monocytes (abs, total) (P<0.012-0.000). Neural networks computing, genetic algorithm selection and bootstrap simulation revealed relationships of early detection of LC and lymphocytes (rank=1), stick neutrophils (rank=2), monocytes (3), segmented neutrophils (4), leucocytes (5), eosinophils (6). Correct detection of early LC was 100% by neural networks computing (error=0.0000; area under ROC Curve=1.0). Conclusion: Early detection of LC from HD significantly depended on blood cell circuit.

P2.11 SCREENING AND EARLY DETECTION
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.11-14 MALIGNANCY ASSOCIATED CHANGE AND THE LuCED® TEST FOR DETECTION OF EARLY STAGE LUNG CANCER

M. Meyer, L. Kelbauskas, R. Kadare, C. Presley, C. Hamilton, D. Sussman, T. Bell, A. Nelson
Visiogenerate, Phoenix/AZ/US

Background: Early detection remains the most reliable and effective strategy for curing lung cancer. Many approaches, however, are limited by poor sensitivity or specificity that increase health care costs and potentially risk patient health through unneeded procedures. The association between cell morphology and cancer has been established in the pathology literature. However, through the so-called field effect, cancer can introduce subtle morphological changes into non-cancerous cells that are proximal to the tumor site. The Cell-CT® platform and LuCED® test represent a promising new method for detecting lung cancer with high (92.3%) sensitivity and (95.3%) specificity based on cytopathological abnormal cells. In this research we investigate use of the Cell-CT to detect malignancy associated changes in normal cells near the cancer with a view towards enhancing LuCED test performance. Method: We present a study of 3D morphological alterations in non-cancerous cells obtained from spum of healthy subjects and biopsy confirmed lung cancer patients. Three major cell types were analyzed from 235 patients: bronchial epithelial columnar, squamous intermedia, and mature macrophages. We used the Cell-CT® platform to measure over 700 different structural biomarkers for each cell. The measurements were used to define prominent clusters of cells through a hierarchical process that were then used under supervised learning, with case status as ground truth, to create classifiers that optimally separated cancer vs. normal cases. Results: The table gives classifier development and performance characteristics:

<table>
<thead>
<tr>
<th>Cell Type</th>
<th>Number of cells from cancer patients</th>
<th>Number of cells from normal patients</th>
<th>Cluster-based Supervised Learning – aROC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Squamous</td>
<td>2316</td>
<td>684</td>
<td>0.94</td>
</tr>
<tr>
<td>Intermediate</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Macrophages</td>
<td>4960</td>
<td>5040</td>
<td>0.99</td>
</tr>
<tr>
<td>Columnar cells</td>
<td>3227</td>
<td>3234</td>
<td>0.92</td>
</tr>
</tbody>
</table>

Conclusion: Our results indicate that the Cell-CT can discriminate cell features that are too subtle to distinguish by a human. The study suggests that detection of cells with Malignancy Associated Changes may be used to further enhance the LuCED test’s performance beyond published levels.

Keywords: Cell-CT, The LuCED test, Early Detection

P2.12-15 IDENTIFYING PATIENTS FOR WHOM LUNG CANCER SCREENING IS PREFERENCE-SENSITIVE: A MICROSIMULATION STUDY

T. Caverly1, P. Cao2, R. Hayward3, R. Meza4
1Center for Clinical Management Research, Veterans Administration, Ann Arbor/MI/US, 2Epidemiology, University of Michigan, Ann Arbor/MI/US, 3Institute for Health Policy Innovation, University of Michigan, Ann Arbor/MI/US

Background: Many health systems are still exploring how to implement an effective, patient-centered low-dose computed tomography (LDCT) screening program. Objective: Examine factors that influence when LDCT screening is preference-sensitive. Method: Design: State-transition microsimulation model Data Sources: Two large randomized trials, published decision analyses, and the Surveillance, Epidemiology and End-Results cancer registry Target Population: US-representative sample of simulated patients meeting current US Preventive Services Task Force screening eligibility criteria Time Horizon: Lifetime Perspective: Individual Intervention: LDCT screening annually for 3 years Outcomes Measures: Lifetime quality-adjusted life-years and reduction in lung cancer mortality. To examine the effect of preferences on net benefit, we varied dissimilarities (i.e., negative feelings) quantifying the burden of screening and follow-up across a likely range. We also examined the effect of varying the rate of false-negative scans and overdiagnosis associated with screening. Results of Base-Case Analysis: Moderate differences in preferences about the downsides of LDCT screening affected whether screening was appropriate for eligible persons with < 0.3% annual lung cancer risk or life-expectancy < 10.5 years. For higher-risk eligible persons with longer life-expectancy, roughly 50% of the study population, LDCT screening overcame even highly negative views about screening and its downsides. Results of Sensitivity Analysis: Rates of false-positive findings and overdiagnosed lung cancers were not highly influential. Limitation: The quantitative thresholds we identified may vary depending on the structure of the microsimulation model. Conclusion: Identifying circumstances under which LDCT screening is more vs. less preference-sensitive may help clinicians personalize their approach to discussing LDCT screening, tailoring to both preferences and clinical benefit. This article has been accepted for publication in the Annuals for Internal Medicine. Given its relevance, we would like the opportunity to present our findings at the WCLC.

Keywords: Preference sensitive, Risk-thresholds, CT screening

P2.11 SCREENING AND EARLY DETECTION
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.11-16 COMPARISON OF TWO LUNG CANCER SCREENING PROGRAMS IN ONE MEDICAL CENTER: DOES EXPERIENCE OF THE SCREENING TEAM AND INDICATIONS AFFECT THE RESULTS?

M. Ostrowski1, T. Marjanski1, R. Dzieczik1, M. Jablito-Gorska2, K. Dzialdowski3, W. Ryman1
1Department of Thoracic Surgery, Medical University of Gdańsk, Gdańsk/PL, 2Department of Radiology, Medical University of Gdańsk, Gdańsk/PL

Background: Onset of lung cancer (LC) screening programs in Europe is expected in near future in form of stepwise process. Yet, several issues need improvement. We compared two screening programs performed in Gdańsk, Poland by one multidisciplinary team in over 14,000 individuals – Pomeranian Pilot Lung Cancer Screening Program (PPP) and Moltest Bios (MB). We assessed how do the indications and learning curve affect results. Method: Between 2009-2011, 8,49 healthy volunteers (aged 50-75, >20 pack-years) were recruited to PPP. Between 2016-2017, 5,534 healthy volunteers (aged 50-79, <30 pack-years) entered MB. Early MB results are presented as it will be closed in May 2018. Positive computed tomography’s (LDCT) result in the first round led to secondary screening. Three rounds of LDCT screening in PPP and two rounds in MB were performed in suspected lung nodules. All positive results were assessed by this same multidisciplinary team. Result: Detection rates of lung nodules requiring follow-up were 34.7% of PPP and 17.6% of MB patients (p<0.0001). LC was diagnosed in 107 (1.24%) PPP and 105 (1.90%) MB participants (p=0.0016). Three hundred (3.5%) PPP and 199 (3.6%) MB patients were referred for further diagnostic work-up (p=0.6890). Yet, more MB patients were sent for diagnostic work-up after first screening round - 85.9% vs 75.7% in PPP (p=0.0050). Fine needle aspiration biopsy was more often positive among LC subjects in MB (84.7% vs 54.0% in PPP; p=0.0002). Surgical resection was performed in 125 (1.5%) PPP and 80 (1.5%) MB patients (p=0.0385), with 12.3% and 15.0% of futile interventions, respectively. Cobectomies or segmentectomies were performed in 84.0% and 90.0% of LC patients in PPP and MB, respectively (p=0.2160). MB patients more often...
underwent video-assisted thoracoscopic resections – 73.0% vs 24.0% in PPP (p=0.0001). Complication rates were comparable in both programs – 11.2% in PPP vs 17.1% in MB (p=0.0560). Majority of subjects with nonsmall cell lung cancer (NSCLC) had stage I or II – 86.4% in PPP and 83.4% in MB (p=0.442). Rate of stage I NSCLC within surgical group was higher in MB (86.0% vs 79.0% in PPP; p=0.001). Conclusion: Narrower inclusion criteria (≥30 pack-years) and increased upper age limit (79 years) led to higher detection rate and number of operated early stage NSCLC patients. Experience gained in PPP has resulted in reduction of number of nodules requiring follow-up but not reduction of “unnecessary” diagnostic work up and surgical treatment. Minimally invasive surgery was applied significantly more often with broader experience.

P2.11 SCREENING AND EARLY DETECTION
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.11-17 MICRORNAS IN EXHALED BREATH CONDENSATE AND BRONCHIAL BRUSHINGS AS BIOMARKERS FOR EARLY DIAGNOSIS OF LUNG CANCER

B. Pattnaik1, S. Chakraborty2, P. Bajpai2, A. Agrawal2, R. Guleria3, A. Mohan4
1Pulmonary Medicine & Sleep Disorders, All India Institute of Medical Sciences, New Delhi/IN, 2Molecular Immunogenetics Lab, CSIR-Institute of Genomics & Integrative Biology, New Delhi/IN

Background: Lung cancer is one of the primary causes of death worldwide. According to Global Burden of Disease (GBD), highest prevalence and mortality of NSCLC is found in men in India. These typically may present as nodules or masses in the lung. The circulating microRNAs delineate stable and reproducible markers for lung cancer and may play important role in non-invasive diagnostic marker. We have previously discovered miRNA signatures in the exhaled breath condensate (EBC) that are suitable for early diagnostics of various lung diseases. Since miRNAs have roles in the pathogenesis of lung diseases, they can be potentially useful in the early diagnosis of lung cancer and may as well complement the other conventional investigative methods such as low dose computerized tomography (LDCT) to avoid high false positive rates. Due to paucity of thoracic surgeons and interventional bronchoscopists in India, the inaccessibility of the suspected tumor tissue for pathological diagnosis is a big challenge. All India Institute of Medical Sciences, New Delhi is one of the pioneer institutions that provides medical care to patients coming from different ethnic and socioeconomic backgrounds in India. Based on our previous work and expertise in this area along with emerging consensus in the field, this work is expected to yield promising outcomes.

Method: Exhaled Breath Condensate Collection: Samples were collected from the suspected NSCLC patients during OPD by using RTube. miRNA isolation from c-DNA synthesis using Quantimir qPCR kit qPCR reaction setup for profiling Bronchoscopy procedure: Bronchial brushings were collected after obtaining written informed consent during routine diagnosis. miRNA isolation c-DNA synthesis by using Kit from Applied Biosystems qPCR reaction setup for profiling Bronchoscopy procedure: Bronchial brushings were collected after obtaining written informed consent during routine diagnosis. miRNA isolation c-DNA synthesis by using Kit from Applied Biosystems qPCR reaction setup by using Kapafast SybrGreen Result: In this study, we found the pro tumorigenic miRNAs like miR-19a, let7b, miR-132 and miR-181c found to be downregulated in the NSCLC patients. Surprisingly, exhaled breath of NSCLC patients. Further we validated these miRNAs in bronchial brushings samples taken from diagnosed NSCLC patients. The known pro tumorigenic miRNAs were found to be upregulated and anti tumorigenic miRNAs were downregulated. Hence, these biomarkers could either be used as a preliminary non-invasive screening method for the diagnosis of NSCLC. Apart from this, these miRNAs could be novel therapeutic targets for the treatment of NSCLC.

P2.11 SCREENING AND EARLY DETECTION
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.11-18 A COMPREHENSIVE LUNG CANCER SCREENING PROGRAM: 5 YEARS IN REVIEW

A. Plank1, M. Reiter1, L. Reagan2, B. Nemesure3
1Radiology, Stony Brook Medicine, Stony Brook/NY/US, 2Cancer Center, Stony Brook University Medical Center, Stony Brook/NY/US, 3Preventive Medicine, Stony Brook Medicine, Stony Brook/NY/US

Background: Lung cancer screening provides an opportunity for early detection, improved survival and tobacco cessation. The purpose of this report is to provide outcome measures and lessons learned during the first five years at Stony Brook’s Center for Lung Cancer Screening and Prevention. Method: The screening programs’ REDCap database was queried for the results. Demographic information, CAT scan data, lung cancer diagnoses, adherence rates, and tobacco cessation rates were computed. Result: TCLCSP has enrolled 825 patients. 26 patients (3.15%) were diagnosed with lung cancer.

P2.11-19 MICRORNAS AS LIQUID BIOPSY BIOMARKERS FOR EARLY DETECTION IN LUNG CANCER.

Keywords: plasma miRNAs as potential biomarkers for early disease detection in lung cancer.

Background: microRNAs (miRNAs) control the expression of key driver genes associated with tumorigenesis in several cancer types and can be detected as stable circulating molecules in body fluids. Deregulated miRNAs have been identified as potential biomarkers in plasma from cancer patients. In lung cancer, the most promising clinical application of circulating miRNAs is early disease detection, since late diagnosis is a major clinical problem associated with patient death.

Method: 38 plasma samples from patients with lung adenocarcinoma and squamous cell carcinoma and 21 healthy controls from a screening population were profiled for an 800 miRNA set using the Nanostring nCounter® platform. Validation was performed in an independent sample set of 40 patients and 40 controls, paired by age and sex, using TaqMan® quantitative real-time PCR. Statistical analyses were performed using the Mann Whitney test, and miRNA signatures identified by Elastic net, improved Maximizing R Square Analysis (MARSA) and C-Statistics. Bioinformatic approaches were applied for external data validation against other miRNA expression datasets.

Result: A subset of 149 miRNAs was significantly over-expressed in patient plasma compared to controls with fold change ≥2, p<0.01 and FDR<0.05. In addition, three distinct miRNA signatures with 12 unique miRNAs were identified in the discovery set (hsa-miR-16-5p, hsa-miR-92a, hsa-miR-106b-5p, hsa-miR-148b-3p, hsa-miR-155-5p, hsa-miR-217, hsa-miR-378e, hsa-miR-451, hsa-miR-484, hsa-miR-1285-3p, hsa-miR-1285-5p and hsa-miR-664a-3p). All signatures were validated in the independent sample set. Being able to distinguish patients from controls. Interestingly, miRNAs identified herein control the expression of tyrosine kinase, transcription factors and immune system related genes associated with lung tumorigenesis.

Conclusion: By using a highly specific and sensitive assay and stringent criteria on sample selection and data analyses, we were able to identify known and novel miRNAs that are significantly deregulated exclusively in plasma from patients with a diagnosis of lung adenocarcinoma or squamous cell carcinoma. Our results contribute to the identification of circulating plasma miRNAs as potential biomarkers for early disease detection in lung cancer.

**P2.11-21 FACTORS PREDICTING ATTRITION IN COMMUNITY-BASED HEALTHCARE NETWORK LUNG CANCER SCREENING PROGRAMS**

K. Spiegel1, J. Rayburn1, C. Wilshire1, E. Rauch1, J. Handy1, C. Gilbert1, R. Weerasinghe1, G. Grunkemeier1, S. Chang1, J. Gorden1

1Division of Thoracic Surgery and Interventional Pulmonology, Swedish Cancer Institute, Seattle/WA/US. 2Thoracic Surgery, Providence Health and Services, Portland/OR/US. 3Thoracic Surgery, Providence Cancer Center, Portland/OR/US. 4Medical Data Research Center Department of Biostatistics, Providence St. Joseph Health, Portland/OR/US

**Background:** Since publication of the National Lung Screening Trial, the national focus has been on implementation of Lung Cancer Screening Programs (LCSPs). However, lung cancer screening (LCS) is a continuum where the benefits are derived from long-term engagement and, to date, little is known about attrition in LCS. We aimed to identify the rate of attrition within two of our healthcare network, community-based LCSPs and identify the factors predictive of attrition. **Method:** We reviewed 2364 individuals who underwent LCS within two of our healthcare network, community-based LCSPs and identify the factors predictive of attrition. **Result:** We reviewed 2364 individuals who underwent LCS within two of our healthcare network LCSPs from 01/01/2012-03/31/2017. One LCSP is centralized (shared decision making/evaluation/management at a single site) and the other is decentralized (shared decision making/evaluation/management occur in geographically diverse community care settings with support from a central LCSP coordinator). Attraction was defined as declining further screening or lost to follow-up. Continuous data reported as median and 25%-75% interquartile range, and univariate/multivariable logistic regression analyses was performed to identify predictors of attrition. **Conclusion:** Overall attrition is low at 15%. Factors that correlated with failure to follow-up were young age, active smoking, being in a decentralized program, and lack of nodule on first scan. Ongoing efforts are necessary to ensure that screening is a continuum, particularly in populations of individuals at high-risk of attrition.

**P2.11 SCREENING AND EARLY DETECTION**

TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00
monitor key metrics for lung cancer screening and smoking cessation efforts. In this study, we evaluated compliance with USPTF lung cancer screening guidelines and the use of EMRs for the documentation of tobacco use. **Method:** We retrospectively reviewed data from consultations in a large urban, academic, outpatient clinic between January 2017 and June 2017. We evaluated documentation in the built-in functions in a well-established EMR system (Epic) and in medical visit notes for each pt. **Result:** A total of 1,124 pt charts were reviewed. 63% of pts were female and the median age was 61 years. 39% of pts were African American, 32% Hispanic, 5% Caucasian, 1% Asian, and 23% other. All charts had documentation of smoking status in the EMR social history flowsheet. 34% (379/1124) of pts had a history of tobacco use, out of which 39% (146/379) were current smokers. For current smokers, tobacco use disorder was documented as an active issue in the EMR medical problem flowsheet in only 37% (54/146) of cases. In 66% (96/146) of cases, smoking cessation addressed in the physician’s note and smoking cessation counseling or medications were offered during the consult. 18% of smokers (69/379) met USPTF criteria, of whom 44/69 (64%) were referred for LDCT. For pts who were not referred for LDCT, 92% (23/25) had a prior CT of the chest in the last year. 82% (36/44) of pts underwent the LDCT screening test and 100% had LDCT results documented in the EMR. 47% (17/36) of screened pts had pulmonary nodules and/or findings suspicious for lung malignancy. 76% (13/17) of pts had follow-up imaging studies and 12% (2/17) of pts subsequently underwent biopsy that yielded a diagnosis of lung cancer. **Conclusion:** Our data showed suboptimal compliance with the LDCT lung cancer screening guidelines in clinical practice. Current EMR-centered databases are being well implemented for the acquisition of critical information that is integrated with clinical decision-making. However, there are instances of poor documentation and underutilization of existing built-in flowcharts in EMR systems that could help identify active smokers, better address smoking cessation efforts, and more efficiently monitor high-risk pts in need of future screening.

**Background:** To make lung cancer screening feasible, populations with the highest risk of developing cancer need to be targeted. Furthermore, factors which motivate individuals to participate in lung cancer screening programs should be integrated into recruitment strategies. Among these motivators, an individual’s perception of their lung cancer risk is an important consideration. This paper analyzes factors associated with risk perception in subjects enrolled in the Pan-Canadian Early Detection of Lung Cancer Study (PanCan), and assesses the relationship between subjects’ risk perception and actual calculated risk. **Method:** The PanCan low-dose screening CT study recruited individuals from the general population who were current or former smokers age 50-75 having at least a 10% risk of lung cancer as calculated by the PanCan model. Risk perception was captured at baseline with a 5-point Likert scale question asking the subject to assess their personal chances of being diagnosed with lung cancer compared with other smokers of the same age. Multivariate linear regression analysis was used to assess the relationship between risk factors and risk perception. Baseline risk variables in the model include demographics, smoking history, symptoms, medications, occupation, previous chest imaging, history of COPD, medical comorbidities, and family history of cancer. **Result:** 2514 patients were included in the analysis. Median age was 62.3, 55.3% were female, median pack-year smoking history was 50 years (range 2.2-230), and median calculated lung cancer risk was 3.42% over 6 years (range 2-38.2). Calculated lung cancer risk increased by 0.08% (SE 0.02, p-value=0.001) for each increased in Likert risk perception category. On multivariate analysis, the following variables were associated with risk perception category: cigarettes smoked per day (+0.003 increase in category / cigarette, p=0.083), presence of dyspnea (+0.192), presence of wheeze (+0.272), known COPD (+0.110), no family history of lung cancer (-0.385) (all p<0.001). Increased perception of risk was associated with intent to quit smoking within 6 months (p=0.001). Conclusion: In this lung cancer screening study, risk perception was positively associated with calculated risk for lung cancer, despite a minimum 2% risk in the cohort. Individual factors and family history of cancer predicted risk perception. Risk perception was also associated with a willingness to quit smoking. Self-risk perception, and associated factors could be used to tailor recruitment strategies to screening programs. The link between risk perception and willingness to quit smoking could aid integrated tobacco cessation programs.

\(^1\)Center for Medical Imaging North-East Netherlands, University of Groningen, University Medical Center Groningen, Groningen/NL, \(^2\)Center for Medical Imaging North-East Netherlands, Department of Radiology, University of Groningen, University Medical Center Groningen, Groningen/NL, \(^3\)Public Health, Erasmus University Medical Center, Rotterdam/NL

**Background:** Low-dose computed tomography lung cancer screening is recommended by US guidelines. New solid nodules are regularly found in incidence screening rounds and have a higher lung cancer probability than baseline nodules. Contrary to baseline nodules, new nodules develop within a known screening interval (time between previous screen and new nodule detection). There is limited evidence concerning the impact of varying screening interval lengths on new solid nodules. **Method:** In the randomized Dutch-Belgian Lung Cancer Screening (NELSON) Trial, 7,557 participants underwent baseline screening. Three incidence rounds took place after intervals of 12 months, 24 months and 30 months respectively and follow-up intervals ranged from 2-12 months. We included solid non-calcified nodules registered after baseline as new and not visible in retrospect. Using logistic regression, screening interval length was assessed as predictor for lung cancer whilst adjusting for nodule size. The correlation of screening interval length and new nodule size was assessed with Spearman’s rank correlation. Discriminative performance for lung cancer was quantified as area under the receiver operating characteristics curve (AUC). **Result:** Overall, 1,130 new solid nodules were included with 6% being lung cancer. Of the nodules, 13% were detected after a screening interval of <10months, 28% after 10-14months, 4% after 15-21months, 37% after 22-26months, and 20% after >26months. While the proportion of new solid nodules that subsequently resolved until first follow-up decreased with longer screening interval (76%, 70%, 59%, 57%, 41% respectively, p<0.001), the lung cancer proportion after 10-14months vs. 0.84 at >26months). Comparing malignant nodules detected after 10-14months, 22-26months or >26months, the proportion of stage IA lung cancers decreased (73%, 63%, 39% respectively, p=0.139) and all IIIb/IV cancers were found after >22months. Comparing malignant nodules detected after 10-14months, 22-26months or >26months, the proportion of stage IA lung cancers decreased (73%, 63%, 39% respectively, p=0.139) and all IIIb/IV cancers were found after >22months. Conclusion: The longer the screening interval prior to new nodule detection, the lower the nodule’s probability to resolve and the higher the nodule’s lung cancer proportion. While a longer screening interval might facilitate the discrimination between benign and malignant new solid nodules, there was a trend for less favorable staging.

**Keywords:** incidence screening rounds, new nodules, screening interval length
P2.11 SCREENING AND EARLY DETECTION
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.11-15 LUNG CANCER SCREENING IMPLEMENTATION IN COMMUNITY PRACTICE: KAISER PERMANENTE WASHINGTON EXPERIENCE 2015-2018
K. Werndli1, H. Gao2, J. Leblanc1, J. Nazarko3, D. Buist1

Background: We describe the implementation of lung cancer screening program at Kaiser Permanente Washington (KPWA), an integrated medical insurer and healthcare provider in Washington state. Since the US Preventive Services Task Force recommendation to screen for lung cancer, data is scarce on the implementation of community experience with lung cancer screening, and whether community experience is like the experience in clinical trials. Method: We purposefully employed a soft-launch of our lung cancer screening program with low-dose CT (LDCT) so we could rapidly evaluate our experience through audit and feedback. The program began in January 2015 and included several key implementation components: 1) guideline review supporting lung cancer screening; 2) continuing medical education to physicians regarding implementation; 3) Epic-registry build to account for eligible members, orders for LDCT, completion of LDCT, and radiologic results; 4) Nurse care coordinator to follow-up with screen positive members to return for imaging; 5) Development of a shared decision making tool for patient and provider discussions. LDCT is read by radiologists using American College of Radiology Lung-RADSTM grading system. We describe the uptake of LDCT in an age- and smoking-eligible population and alignment of LDCT findings with expected population estimates over all annual exams conducted from 2015-2018. Negative screen is defined as Lung-RADSTM 1 or 2. Positive screen includes Lung-RADSTM 3 and 4. Result: With an estimated 15,000 adults eligible for lung cancer screening, about 1,800 annual visits have a documented shared decision-making. While the majority of patients (99%) opt-in to screening, about 26% of those patients cancel or do not show up for their LDCT exam. As of March 2018, KPWA completed 3,092 LDCT exams: 2,104 initial screens and 988 subsequent screens. Among all initial LDCT performed, 84.6% screened negative; the proportion increased slightly to 88.6% on subsequent LDCT exams. On initial LDCT, the proportion of positive exams were as follows: Lung-RADSTM 3 (7.8%); Lung-RADSTM 4A (3.3%), and Lung-RADSTM 4B, C, X (2.4%). On subsequent LDCT exam, these proportion decreased slightly to 5.2% and 2.2% for Lung-RADSTM 3 and 4A, respectively. Conclusion: Overall implementation of KPWA lung cancer screening suggests an ability to identify eligible patients, engage in shared decision-making, appropriate referral and uptake of LDCT, appropriate use of Lung-RADSTM assessment, and patients who return for follow-up and subsequent annual screening. Opportunities remain for improvement in acceptance of LDCT based on patient needs and further adoption within our system.

P2.11-27 A RAPID ACCESS LUNG CANCER CLINIC REDUCES VARIATION IN LUNG CANCER DIAGNOSTIC AND TREATMENT SERVICES.
1Clinical Governance, Western NSW Local Health District, Orange/NSW/AU, 2Respiratory Medicine, Dubbo Base Hospital, Dubbo/NSW/AU, 3Medical Oncology, Dubbo Base Hospital, Dubbo/NSW/AU, 4Radiation Oncology, Orange Health Services, Orange/NSW/AU, 5Cancer Services, Western NSW Local Health District, Orange/NSW/AU, 6Medical Oncology, Orange Health Services, Orange/NSW/AU

Background: The Western NSW Local Health District has one of the highest incidence and mortality rates of lung cancer in Australia. Previous research revealed that there was a significant variation in timely access to lung cancer diagnostic and treatment services. In 2015, the Respiratory Clinic at Dubbo Base Hospital introduced a lung cancer fast track clinic which aimed to review all patients referred by GPs for lung cancer assessment within 14 days of referral. Method: A retrospective medical records audit of all patients diagnosed with primary lung cancer from July 2016 to August 2017 was conducted. Interval times from Referral to Diagnosis, Diagnosis to First Treatment and Referral to First Treatment were recorded. Diagnostic and treatment referral time intervals were compared for patients residing within a 100km radius of the referral hospital (Local patients) and those whose place of residence was beyond the 100km radius (Remote patients). We also compared overall survival rates between Fast track and non-fast track pathway patients. Result: 55 patients were included in the study. 82%, 37% and 50% of patients met our District recommended time intervals of 21, 21 and 42 days for Referral to Diagnosis, Diagnosis to First Treatment and Referral to First Treatment, respectively. Time taken to access diagnostic and treatment services was not statistically different for remote versus local patients. Patients referred through a lung cancer fast track clinic had a higher probability of surviving for at least 12 months following a diagnosis (51% versus 28%; CI 0.002 - 4.37) than non- fast track pathway patients. Conclusion: The lung cancer fast track clinic has resulted in equitable access to diagnostic and referral services at Dubbo Base Hospital in the Western NSW local Health District of Australia. We have now introduced a lung cancer rapid access system in all our facilities within the district and are extending that to cover lung cancer treatment services. Future studies looking at larger populations are needed to evaluate the possible improvements in lung cancer survival rates.

P2.11-26 FIRST OF ITS KIND MULTI-PROMED TRAINING FOR PCPS IN AN EPICENTER OF LUNG CANCER – WHAT WAS ACHIEVED IN TWO YEARS?
C. Worth1, M. Jones1, R. Mattingly1, C. Sorell1, J. Studtz2
1Kentucky Cancer Program, University of Louisville, Louisville/KY/US, 2Department of Behavioral Science, University of Kentucky College of Medicine, Lexington/KY/US

Background: Kentucky’s lung cancer (LC) rates have been the highest in the U.S. and amongst the highest in the world. Primary care provider (PCP) understanding and adoption of the U.S. Preventive Services Task Force (USPSTF) recommendation for LCS with low-dose CT (LDCT) were very low over a year after its release. LDCT is the only recommended tool for early detection of LC; making PCP education crucial for impacting the leading cause of cancer death. Method: The Kentucky LEADS (Lung Cancer Education Awareness Detection and Survivorship) Collaborative was initiated to reduce the LC burden through novel interventions to provide provider education (PE), survivorship care, and prevention/early detection. The PE component sought to improve referral of high-risk patients to LCS incorporating quality shared decision-making and tobacco cessation counseling through multi-pronged continuing education (CE) programs for PCPs statewide. Four unique interventions were developed, implemented, and evaluated: an interactive online course, didactic presentations with audience response system, academic detailing with a LEADS Primary Care Toolkit, and a webinar. Result: Participation in these CE programs was unprecedented including 1,400+ PCPs (more than 20% of the state’s total) and 2,700+ health professionals total. Participation based on platform type, provider discipline, specialty, and years in practice will be shared, as well as self-reported changes in practice behaviors as a result of the training(s) and feedback on which elements were of most value. A remarkable increase in LDCT scans in accredited facilities statewide for eligible patients after the intervention period will be discussed, as well as potential for lower numbers needed to screen for the early detection of LC in higher risk geographic areas, as compared to those for the National Lung Screening Trial (NLST), upon which the USPSTF recommendation was based. Conclusion: Appropriate utilization of LCS must be an urgent and pervasive priority among referring providers. Limitations for screening such as LDCT availability, patient awareness and acceptance, and negative perceptions of treatment options are being diminished. However, PCP requirements for appropriate referral must be addressed as utilization of our screening tool. These include provider understanding of recommendations, eligibility, and screening risks, benefits, and limitations, as well as knowledge of available screening facilities, reimbursement for shared decision making, screening coverage, and available resources. Adoption of new screening modalities by providers and patients alike always takes time, but education for referring providers is the “next big thing” in improving LC outcomes. It is imperative that it be comprehensive, appealing, innovative, and evidence-based.

P2.11-28 A FOCUS GROUP AND INTERVIEW STUDY TO EXPLORE THE INFORMATION-NEEDS OF LUNG CANCER SCREENING PARTICIPANTS

M. Ruparel¹, S. Quaife², D. Baldwin³, S. Janes⁴, J. Waller⁵

¹Lungs for Living Research Centre, UCL Respiratory, University College London, Wce Jf/Gb, ²Health Behaviour Research Centre, University College London, London/Gb, ³Respiratory Medicine, Nottingham University Hospitals, Nottingham/Gb.

Background: Lung cancer screening (LCS) by low-dose CT has been shown to improve mortality, but individuals must consider the potential benefits and harms before making an informed decision about taking part. In the US a shared decision-making process is mandated to qualify for LCS reimbursement. However, screening eligible individuals’ (SEI) specific views of these harms, and their preferences for accessing this information, are not well described. Method: 16 semi-structured interviews were carried out with general practitioners, public health consultants, respiratory physicians and lung cancer nurse specialists. 35 SEI participated in seven focus groups, which were divided into current vs. former smokers and lower vs. higher educational backgrounds. Interviews and focus groups were audio-recorded and transcribed. Data were coded inductively and analysed using the framework method. Result: Lung cancer was generally perceived as an incurable condition, and smokers appeared to be particularly fatalistic. Despite this, a belief in screening emerged from the interviews and focus groups. Participants’ appetite for information varied; with many expressing a ‘right to be given all the information’, while others cautioned against too much information, and HCPs also acknowledged this dichotomy. Of the harms of screening, false positives and false negatives generated the most concern, though for most participants, even these were unlikely to deter them from screening. Participants were aware of harms of smoking though many current smokers perceived other factors as more detrimental to their health than smoking. Regarding smoking cessation advice at screening, most focus group and interview participants preferred an emphasis on the benefits of quitting, and for advice to be delivered in a positive and empowering manner. Conclusion: These findings can be used to directly inform the way in which information is presented to SEI in order to aid the shared decision-making process, motivate smoking cessation and minimise barriers to uptake of LCS.

P2.11 SCREENING AND EARLY DETECTION

TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.11-29 IMPACT OF AN INFORMATION-FILM TO PROMOTE INFORMED DECISION-MAKING IN INDIVIDUALS TAKING PART IN A LUNG CANCER SCREENING DEMONSTRATION PILOT

M. Ruparel¹, S. Quaife¹, B. Ghimire³, J. Dickson¹, C. Horst¹, S. Tisi¹, A. Bhowmik¹, N. Navaian¹, D. Baldwin¹, S. Dufty¹, J. Waller¹, S. Janes¹

¹Lungs for Living Research Centre, UCL Respiratory, University College London, London/Gb.

Background: Lung cancer screening by low-dose CT (LDCT) is underway in the United States, where a shared decision-making process is mandated for insurer funding. The potential harms of screening are complex and difficult to communicate. Participants do not always read written materials and audio-visual aids have been shown to improve informed decision-making in other areas of medicine. There are limited studies on the use of decision aids in lung cancer screening. Method: A five-minute information-film was made to explain the benefits and risks of lung cancer screening. Qualitative research informed the content and format to make it accessible for individuals of varying demographic and educational backgrounds. A sub-sample of participants (n=229) from a lung cancer screening pilot were randomised to watch the film and read a written booklet alone, without raising decisional conflict or reducing attendance for LDCT.

Conclusion: The information-film was well-accepted and increased knowledge scores more than a written booklet alone, without raising decisional conflict or reducing attendance for LDCT.

Background: Topotecan is recommended as second-line treatment for patients with progressive/recurrent extensive-stage small cell lung cancer (ES-SCLC) after platinum-based combination chemotherapy. Although some topotecan-treated patients may have at least an objective response (OR), response duration is often short. Belotecan, a camptothecin derivative topoisomerase i inhibitor, has shown promising antitumor activity and modest toxicities against advanced SCLC and ovarian cancers. We report efficacy data from a phase IIb randomized multicenter study of belotecan as second-line treatment for progressive/ recurrent limited-disease (LD)- or ES-SCLC.

Method: This study, conducted from March 2010 to March 2018, was designed to prove the non-inferiority of belotecan to topotecan in patients with progressive disease (PD) or stable disease (SD). The primary endpoint was objective response rate (ORR; complete response [CR] or partial response [PR]) based on RECIST criteria; secondary endpoints were progression-free survival (PFS), overall survival (OS). Result: Overall, 148 patients (belotecan, n=72; topotecan, n=76) were eligible in the full analysis set (FAS; patients who received at least one dose); 113 patients (belotecan, n=62; topotecan, n=51) were evaluable in the per-protocol set (PPS; patients who completed the study protocol). Clinical characteristics were well balanced between the two treatment arms. In the FAS, ORR was 33.3% (belotecan) and 21.0% (topotecan), respectively (95% CI: -0.0195 to 0.2651, p=0.0927). One belotecan recipient had a CR. Median OS was 396 days (belotecan) and 247 days (topotecan), respectively (p=0.0178); median PFS was 144 and 115 days, respectively (p=0.9608). Similar efficacy outcomes were observed in the PPS.

P2.12 SMALL CELL LUNG CANCER/NET
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.12-02 PHASE II STUDY OF COMBINATION OF NAB-PACLITAXEL AND GEMCITABINE FOR RELAPSED SMALL CELL LUNG CANCER (SCLC)
M. Furqan, J. Zhang, G. Clamon, T. Abu-Hejleh
Medicine, University of Iowa Hospitals and Clinics, Iowa City/US

Background: Almost all patients with extensive stage and two-thirds of limited stage small cell lung cancer develop disease recurrence or relapse after initial therapy. Most of these patients receive Topotecan as their subsequent therapy, which across multiple studies have shown response rates of approximately 15%. Though some of the newer agents have shown promising efficacy in biomarker selected patient-population, in non-selected patients with relapsed SCLC, however, response rates with Nivolumab, Nivolumab in combination with Iplimumab and Rovalpituzumab were only 10%, 23% and 18%, respectively. Among the conventional chemotherapies, both Gemcitabine and Paclitaxel have shown single agent activity in relapsed-refractory SCLC. Therefore, we hypothesized that combination of Gemcitabine and Nabo-Paclitaxel will have additive effect, which will lead to improvement in therapeutic response compared to current standard of care. Based on the toxicity profile of this regimen in patients with advanced pancreatic cancer, we believe it will be better tolerated than Topotecan.

Method: This is a single-arm phase II study. Primary end-point of the study is response rate as defined per RECIST 1.1 criteria. Eligible subjects will receive gemcitabine 1000 mg/m2 and nab-paclitaxel 100 mg/m2 on days 1 & 8 of every 21-day cycle. Response assessment will occur every 6 weeks. Target accrual is 32 with 28 evaluable subjects. This would account for 82% power to detect a difference of 20% to current standard of care therapy, using a one-sided binomial exact test for comparison of proportion.

Conclusion: Our data met the hypothesis that the antitumor efficacy of belotecan is non-inferior to that of topotecan as second-line treatment for patients with progressive/recurrent LD- or ES-SCLC. Belotecan was also associated with significantly longer OS. (ClinicalTrials.gov. ID: NCT01497873; https://clinicaltrials.gov/ct2/show/NCT01497873)

Keywords: Gemcitabine, nab-paclitaxel, small cell lung cancer

P2.12-03 PHASE II/I TRIAL OF 177Lu-DOTA-Tyr3-Octreotate (LUTATHERA) AND NIVOLUMAB FOR PATIENTS WITH EXTENSIVE-STAGE SMALL CELL LUNG CANCER (ES-SCLC)
C. Kim, D. Subramanian, S. Liu, G. Giaccone
Georgetown University, Washington/DC/US

Background: Despite initial sensitivity to chemotherapy, most patients with ES-SCLC relapse quickly. Studies have shown that somatostatin receptors are expressed in SCLC. Lutathera is a 177Lu-labeled somatostatin analog that targets somatostatin receptor positive cancer cells, which is approved for the treatment of somatostatin receptor-positive gastroenteropancreatic neuroendocrine tumors. Lutathera and nivolumab, an anti-PD-1 antibody, may have synergistic effects on the generation of antitumor immunity and this combination given as maintenance treatment may delay progression in patients with ES-SCLC. Moreover, this is a multicenter phase II/I trial of Lutathera and nivolumab in patients with ES-SCLC (NCT03325816). The phase I portion includes patients with either relapsed/refractory ES-SCLC or non-progressing ES-SCLC after first-line platinum-based chemotherapy, or advanced grade I-II pulmonary neuroendocrine tumors. The primary objective is to determine the recommended phase 2 dose (RP2D) of Lutathera when given with nivolumab. The phase I portion follows the standard 3+3 design, assessing two dose levels (dose level 1: Lutathera 3.7 GBq QBW for 4 doses with nivolumab 240 mg Q2W; dose level 2: Lutathera 7.4 GBq QBW for 4 doses with nivolumab 240 mg Q2W). In the phase II portion, patients with ES-SCLC not progressing after completion of first-line platinum-based chemotherapy are randomly assigned to either maintenance combination with Lutathera and nivolumab or observation. The primary endpoint for the phase II part is progression-free survival. Cross-over to the maintenance combination is allowed for those assigned to the observation group.

Result: Three patients were enrolled at dose level 1. All patients had ES-SCLC at study entry with 2 patients with progressive disease and 1 patient with stable disease after platinum-based chemotherapy. No dose-limiting toxicities (DLTs) were observed at dose level 1. Treatment-related adverse events include anemia (n=1), arthralgia (n=1), and non-cardiac chest pain (n=1), all of which were grade 1 events per CTCAE 4.03. At first tumor assessment performed 8 weeks after starting treatment, one patient achieved a partial response and two patients had progressive disease per RECIST. Assessment of dose level 2 is underway. Updated safety and efficacy results will be presented.

Conclusion: Early evidence from the phase I/I trial of Lutathera and nivolumab suggests that the combination is safe, well tolerated and showed initial signs of antitumor activity. The safety and efficacy of the combination will be further explored.

Keywords: Nivolumab, lutathera, small cell lung cancer

P2.12-04 LIPOSOMAL IRINOTECAN VS TOPOTECAN IN PATIENTS WITH SMALL CELL LUNG CANCER WHO HAVE PROGRESSED ON/ AFTER PLATINUM-BASED THERAPY
1Hospital Universitario 12 de Octubre, Madrid/ES, 2National Taiwan University Hospital, 3Cancer Center, Medical University Vienna, 4Oncology Department, Aou San Luigi, University of Turin, Turin/IT, 5Hospital de Clinicas de Porto Alegre, Porto Alegre/BR, 6Oncology, Sarah Cannon Research Institute, Nashville/TN/US, 7Lung Cancer Network Nowel; Pius Hospital, Medical Campus, Hospital Universitario 12 de Octubre, Madrid/ES, 9Royal Brompton, London/UK, 9Shire GmbH, Zug/CH, 11Cancer Center and Department of Medicine, University of Colorado Denver/CO/US

Background: Small Cell Lung Cancer (SCLC) accounts for ~15% of all lung cancers; it is an aggressive disease marked by rapid growth and early metastasis. Patients typically demonstrate initial sensitivity to chemotherapy and radiotherapy, followed by rapid relapse and development of drug resistance. Topotecan, a topoisomerase 1 (TOP1) inhibitor, is the only agent approved for second-line treatment in the United States and Europe. Liposomal irinotecan (nal-IRI) has demonstrated sustained TOP1 inhibition, with liposomal deposition in tumor tissue through leaky vasculature, followed by irinotecan release and subsequent conversion to the active metabolite SN-38. Pre-clinical data suggests that nal-IRI has improved anti-tumor activity compared to topotecan. The current trial (NCT03088813) is being undertaken to investigate the safety and efficacy of nal-IRI versus intravenous topotecan in patients with SCLC who have progressed on or after platinum-based first-line therapy. Method: There are two parts of this study, Phase I and Phase II. Phase I is an open-label, single-arm, safety run-in phase and Part 2 is a randomized, controlled, efficacy assessment phase. Key inclusion criteria include ECOG performance status of 0–1, adequate organ function, histopathologically/cytologically confirmed SCLC, evaluable disease (RECIST v1.1), and life expectancy ≥12 weeks. Primary exposure of immuno-oncology therapies is allowed. Key exclusion criteria include a diagnosis of large cell neuroendocrine lung carcinoma, prior treatment regimens with TOP1 inhibitors, and retreatment with the same platinum-based regimen after relapse of first-line platinum chemotherapy. In Part 1, patients will be treated with different doses of nal-IRI to identify a tolerable dose level; this dose level will be expanded to include a total of 24 patients. The primary endpoint is safety and tolerability, with secondary endpoints including overall response rate (ORR), progression-free survival (PFS) and overall survival (OS). In Part 2, ~450 patients will be randomized in a 1:1 ratio between nal-IRI and IV topotecan. The primary endpoint is OS, followed by PFS, ORR, patient-reported outcomes, and exploratory analyses.

TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

**P2.12-05 SUKSES (SMALL CELL LUNG CANCER UMBRELLA KOREA STUDIES): A PHASE II BIOMARKER-DRIVEN UMBRELLA STUDY IN RELAPSED OR REFRACTORY SCLC**
Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Seoul/KR

**Background:** Although initial platinum-based treatment demonstrated high response rate (RR) in extensive stage SCLC, limited options are available for subsequent systemic therapy. Recent studies with comprehensive genomic profiling identified cell cycle-related gene alteration, such as TP53 and RB1 inactivation, and RICTOR amp as a major characteristic of SCLC. Based on this observation, we designed umbrella clinical trial based on the hypothesis that controlling cell cycle checkpoint, DNA damage repair mechanism, and mTOR pathway with small molecules and monoclonal antibodies targeting these pathways might be an effective approach for the later line SCLC treatment.

**Method:** SUKSES trial (NCT02688894) is a phase 2 study with seven treatment arms. Four arms for the biomarker-positive population. Arm A (AKT1 mt); Arm B (BRCA1 or BRCA2 mt, ATM deficiency, MRE11A mt or other HR pathway gene mt); Arm C (MYC family protein amplification or CDKN2A mt either of which combined with TP53 mt); Arm D (RICTOR amp). Three arms for the biomarker-negative population. Arm-N1, N2, and N3. Pathologically confirmed SCLC patients are eligible for the molecular screening. For study participation, patients must have at least one measurable lesion after progression from first-line platinum-based therapy. Patients are enrolled in either second or third line based on their initial treatment response. Following treatment is applied after allocation: Arm-A (AZD5363); arm-C (AZD1775); arm-D (AZD2014); arm-N1 (AZD1775); arm-N2 (Olaparib and AZD6738); arm-N3 (AZD2811). Primary endpoint for this study is objective RR. Duration of treatment, disease control rate at eight weeks, progression-free survival, exploratory biomarker will be evaluated as secondary endpoint. As of May 2018, 157 patients have been screened for the molecular profiling. Arm A was closed due to low discovery rate of AKT1 mutation. Of the planned 28 patients for each biomarker positive arm, 9 for arm B, 7 for arm C and 4 for arm D have enrolled. For the negative-biomarker arms, 24 out of 45 patients are recruited for arm N1 and 9 patients for Arm N3. Arm N2 is under review by Institutional Review Board. **Result:** Section not applicable

**Conclusion:** Section not applicable

**P2.12-06 THE EFFICACY OF APATINIB PLUS TOPOTECAN AS LATERLINE THERAPY FOR ADVANCED SMALL CELL LUNG CANCER**
H. Qin, H. Gao
307 Hospital of PLA, Beijing/CN

**Background:** Small cell lung cancer (SCLC) is a malignant, aggressive and rapidly progressing cancer. There is no standard treatment strategy for patients with advanced SCLC who experienced progression with first line of chemotherapy. Apatinib, an oral tyrosine kinase inhibitor targeting vascular endothelial growth receptor 2 (VEGFR 2), has shown well anti-tumor activity and manageable toxicities in SCLC. Some previous cases showed that apatinib plus topotecan for laterline therapy for advanced SCLC patients is safe and effective, but there is no similar studies at home and abroad. Small cell lung cancer (SCLC) is a malignant, aggressive and rapidly progressing cancer. There is no standard treatment strategy for patients with advanced SCLC who experienced progression with first line of chemotherapy. Apatinib, an oral tyrosine kinase inhibitor targeting vascular endothelial growth receptor 2 (VEGFR 2), has shown well anti-tumor activity and manageable toxicities in SCLC. Some previous cases showed that apatinib plus topotecan for laterline therapy for advanced SCLC patients is safe and effective, but there is no similar studies at home and abroad. **Method:** Our study retrospectively assessed the efficacy and safety of apatinib plus topotecan in patients with advanced SCLC after the first line of chemotherapy. The primary endpoint was progression-free survival (PFS). The study was expected to enroll 25 patients who received apatinib (250mg QD) plus topotecan (2mg QD; day1-5, every four weeks). Treatment was continued until disease progression and the tumor response was determined according to the Response Evaluation Criteria in Solid Tumors (RECIST) Version 1.1. **Result:** The main results are showed as follows.

P2.12-07 UTILITY OF STEREOTACTIC BODY RADIOTHERAPY IN PULMONARY CARCINOID TUMORS

R. Ramirez1, B. Voros1, P. Page2, J.P. Boudreaux3, R. Thiggarajan3, E. Woltering3
1Neuroendocrine Tumor Program, Ochsner Medical Center - Kenner, Kenner/US, 2Thoracic Surgery, Nanfang Hospital, Guangzhou/CN, 3Oncology, Nanfang Hospital, Guangzhou/CN

Background: Pulmonary carcinoid (PC) tumors are rare malignant neoplasms, accounting for approximately 2% of all lung cancers. While most patients with PC undergo surgical resection, some patients either decline surgery or are not surgical candidates. Stereotactic body radiotherapy (SBRT) is primarily used in patients with early stage, inoperable non-small cell lung cancer or patients who refuse surgery. We sought to determine the role of SBRT in patients with PC.

Method: The records of all patients with PC seen at our clinic were retrospectively reviewed. Demographics, pathologic characteristics, and treatment data were collected. Only patients meeting the World Health Organization criteria for typical and atypical carcinoids were included. Radiographic evaluation of all patients was performed at 3-month intervals.

Result: Of the 251 patients with PC who were retrospectively reviewed, 3 patients were identified who underwent SBRT at our institution. All patients were female with a median age of 72 years. All patients received SBRT consisting of 50 Gy over 5 fractions. Median follow up time was 7 months. Median decrease in tumor size following SBRT was 29%. No adverse events from SBRT were reported.

Conclusion: Our study demonstrates that SBRT is safe and feasible in patients with PC tumors. SBRT may represent a treatment option in patients with PC who are deemed inoperable due to comorbid conditions or decline surgery. Larger studies are needed to further determine the role of SBRT in PC.

Keywords: Atypical carcinoid, pulmonary carcinoid, typical carcinoid

P2.12-08 NETWORK META-ANALYSIS OF ANGIOGENESIS INHIBITORS ON SURVIVAL OF PATIENTS WITH SMALL CELL LUNG CANCER

X. Shi1, X. Liu2, Y. Wang3, D. Lu1, X. Dong1, S. Feng1, K. Cai1
1Thoracic Surgery, Nanfang Hospital, Guangzhou/CN, 2Oncology, Nanfang Hospital, Guangzhou/CN

Background: This network meta-analysis aimed at providing a comprehensive evaluation of the effects of angiogenic inhibitors on small cell lung cancer by using network meta-analysis. Method: The relative efficacy of angiogenesis inhibitors vandetanib (Van), bevacizumab (Bev), Rh-endostatin (End), sunitinib (Sun) and thalidomide (Tha) was evaluated by conducting a network meta-analysis of progression-free survival and overall survival.

Result: Nine phase II-III RCTs involving 1599 participants that investigated angiogenesis inhibitors on the treatment of SCLC were included. Sun and Bev achieved better PFS than Tha (Bev VS. Tha, HR=0.88, 95%CI: 0.79-0.98, Sun VS. Tha, HR=0.80, 95%CI: 0.65-1.00). Moreover, Sun and Bev were superior to placebo in terms of PFS (Bev VS. Placebo, HR=0.89, 95%CI: 0.81-0.97, Sun VS. Placebo, HR=0.81, 95% CI: 0.66-1.00). No significant difference of OS was found.
Method: A total of 398 patients were eligible for analysis. Median follow-up was 8.2 years. The median age was 67 (range: 40-87). Overall, 94% of patients received chemotherapy, 82% received radiotherapy and 65% received both concurrently. Both hypofractionated (40 Gy in 15 fractions) and conventionally-fractionated (50-66 Gy in 25-33 fractions) radiotherapy were used. Prophylactic cranial irradiation was used in 45% of patients. The median OS for the entire cohort was 15.4 months, with a 5-year OS of 19.7%. Overall median PFS was 9.3 months, with a 5-year PFS of 14.1%. On multivariable Cox regression, age, Eastern Cooperative Oncology Group (ECOG) performance status, tumor location and baseline presence of any pleural effusion (non-malignant or unknown status) were prognostic of OS, while performance status and T-stage were prognostic of PFS. RPA model of OS divided patients into favorable (ECOG 0-2, no pleural effusion, middle/lower lobe location: 5-year OS 31%), intermediate (ECOG 0-2, no pleural effusion, non-middle/lower lobe location: 5-year OS 21%) and unfavorable (ECOG 3-4 or any pleural effusion: 5-year OS 5-8%) groups (log-rank p < 0.001). RPA for PFS divided patients into favorable (ECOG 0-2, <=T3: 5-year PFS 21%) and unfavorable (ECOG 3-4 or T4: 5-year PFS 5-9%) groups (log-rank p < 0.001). Conclusion: Novel prognostic factors for OS and PFS based on baseline patient characteristics were successfully identified for patients with limited-stage SCLC. RPA prognostic models were able to separate patients into distinct risk groups for OS and PFS. Our results will benefit from further external validation and can be useful in stratifying patients in future prospective studies.

Keywords: small cell lung cancer, Prognosis, recursive partitioning analysis.

P2.12-11 A PROGNOSTIC MODEL INTEGRATING IMMUNOHISTOCHEMISTRY MARKERS FOR EXTENSIVE-DISEASE SMALL-CELL LUNG CANCER

R. Fu1, C. Zhang2, J. Zhang3, J.-. Yang1, Q. Zhou4, X. Yang2, Y. Wu5, W. Zhong1, J. Huang1

1Guangdong Lung Cancer Institution, Guangzhou/CN, 2Thoracic Oncology, Guangdong Lung Cancer Institute, Guangzhou/CN, 3Guangdong Lung Cancer Institute, Guangzhou/CN, 4Division 3 of Pulmonary Oncology, Guangdong Lung Cancer Institute; Guangdong General Hospital(Ggh) & Guangdong Academy of Medical Sciences, Guangzhou/CN, 5Guangdong Lung Cancer Institute, Guangzhou General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/CN

Background: Extensive-disease small-cell lung cancer (ED-SCLC) is a subtype of high-grade neuroendocrine carcinoma (HGNEC) with poor prognosis. We tend to build a prognostic nomogram and illustrate the failure pattern of first line etoposide/irinotecan with paclitaxel (EP/IP) treatment. Method: 250 ED-SCLC patients received first line EP/IP treatment were enrolled. Cox regression analysis was used to identify the prognostic factors to establish nomogram. The predictive accuracy of nomogram was evaluated by concordance index (C-index). Further stratification based on k67 and brain metastasis was performed through X-tile plot and Kaplan Meier. Result: Cox regression analysis indicated brain metastasis as the prognostic factor and we further selected NSE, gender, TTF-1, Syn, tumor size and smoking status under clinical consideration for nomogram. C-index of nomogram suggested 0.65 with moderate predictive effect. Subgroup analysis showed patients with K67 lower than 85% had poorer prognosis than those over 90% (HR 0.59, 95%CI 0.39-0.92, p=0.02). Those without brain metastasis at baseline achieving partial response (PR)/complete response (CR) suggested no prognostic significance in brain progression compared to other progression group. (See next page)
Conclusion: Established nomogram could well predict prognosis in ED-SCLC. Ki67 might play a potential role in prognosis of SCLC. Application of preventive cranial irradiation might be challenged in ED-SCLC patients without brain metastasis.

### P2.12 SMALL CELL LUNG CANCER/NET

**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.12-12 PLASMA VITAMIN D LEVEL IS AN INDEPENDENT PROGNOSIS FACTOR IN SCLC PATIENTS TREATED WITH PLATINUM PLUS ETOPOSIDE AS FIRST-LINE CHEMOTHERAPY**

X. Wang, C. Zhang, K. Ma, W. Li
The First Hospital of Jinlin University, Changchun/CN

**Background:** Small cell lung cancer accounts for approximately 13.6% of all lung cancer cases, which is a very aggressive form of lung cancer and associated with a very poor prognosis. Investigations into the prognostic factors of SCLC may help in the development of new biotherapeutic regimens. VD deficiency has been well documented to be unfavorable for the prognosis of patients with several types of cancer. However, there is no study focus on the relationship between the plasma VD level and the prognosis of SCLC patients. The primary objective of this study was to examine the prognostic role of the plasma 25-hydroxyvitamin D (25(OH)D) level in SCLC patients treated with platinum plus etoposide as first-line chemotherapy.

**Method:** A total of 178 SCLC patients were consecutively and prospectively hospitalized to receive platinum plus etoposide as first-line chemotherapy. The baseline 25(OH)D level was measured at the time of diagnosis. Main outcome measures included overall survival (OS) and progression-free survival (PFS).

**Result:** The median OS values of patients with 25(OH)D < 10 ng/mL and ≥ 10 ng/mL were 12.5 months (95% confidence interval [CI], 9.4–18.0 months) and 21.3 months (95% CI, 12.8–29.1 months), respectively. Both univariate and multivariate analyses showed that having a plasma 25(OH)D level < 10 ng/mL was associated with a significantly shorter OS (P = 0.000), while the baseline plasma 25(OH)D level was not significantly associated with PFS.

**Conclusion:** Plasma vitamin D level is an independent prognosis factor in small cell lung cancer patients treated with platinum plus etoposide as first-line chemotherapy.

### P2.12-13 EFFECTIVENESS OF HYPOFRACTIONATED THORACIC RADIOTHERAPY IN LIMITED-STAGE SMALL-CELL LUNG CANCER: A PROPENSITY SCORE ANALYSIS

Radiation Oncology, London Health Sciences Centre, London/ON/CA

**Background:** Hypofractionated thoracic radiotherapy may be advantageous in limited-stage small-cell lung cancer (LS-SCLC) due to shorter overall treatment times, decreased resource utilization, and patient convenience. However, there are no randomized data comparing hypofractionated radiotherapy (HFRT; defined as 40–45 Gy in 15–20 fractions) and high dose conventionally-fractionated radiotherapy (CFRT; defined as ≥ 60 Gy in 2 Gy fractions) in LS-SCLC patients. The objective of this study was to compare the survival outcomes and toxicities of HFRT and CFRT using propensity score-matched retrospective data to simulate the setting of a clinical trial.

**Method:** This retrospective study examined institutional records of patients diagnosed with LS-SCLC between January 2000 and December 2013 who were treated with HFRT or CFRT. Propensity scores were estimated by logistic regression using age, performance status, concurrent chemoradiation usage, and prophylactic cranial irradiation (PCI) usage. Nearest neighbor-matching was performed on a 1:1 basis using a caliper distance of 0.1, without...
replacement. Overall survival (OS) and progression-free survival (PFS) endpoints were estimated by the Kaplan-Meier method and compared with log-rank tests. Cumulative incidences of normal tissue toxicity were compared with Fisher’s exact tests. A two-sided significance level of 0.05 was used. Result: Among 398 LS-SCLC patients reviewed, 57 patients treated with HFRT and 61 patients treated with CFRT were included in the unmatched analysis. Five-year OS was 26% for the HFRT cohort and 24% for the CFRT cohort (p = 0.82). Five-year PFS was 22% for both cohorts (p = 0.79). Significant differences in age, performance status, concurrent chemoradiation usage and PCI usage were noted in the unmatched cohorts. After propensity score-matching, the balanced cohorts each contained 37 patients. Five-year OS was 25% and 27% (p = 0.72) and 5-year PFS was 25% and 24% (p = 0.63), respectively, for the HFRT and CFRT cohorts. Incidence of any esophageal toxicity was not significantly different between the cohorts (92% HFRT vs. 84% CFRT, p = 0.60), though there was a trend towards a higher incidence of any pulmonary toxicity in the CFRT cohort (59% vs. 38%, p = 0.06). Skin toxicity was significantly higher for CFRT (39% vs. 14%, p = 0.01). Conclusion: OS and PFS were similar between HFRT and CFRT in balanced cohorts. HFRT was associated with a potentially reduced incidence of pulmonary and skin toxicity. As such, HFRT could result in an improved therapeutic ratio in patients with LS-SCLC. A randomized controlled trial would provide level 1 evidence in this comparison.

Conclusion: MRI surveillance combined with multiple rounds of SRS in case of limited BM development might provide reasonable alternative to PCI or therapeutic WBRT in SCLC. SRS in SCLC warrants prospective evaluation.

P2.12-14 STEREOTACTIC RADIOSURGERY FOR BRAIN METASTASES IN SMALL CELL LUNG CANCER.

E. Dudnik1, S. Yust-Katz2, N. Michaeli3, T. Shochat3, N. Peled3, A. Zer4, O. Rosner4, A. Anis1
1Thoracic Cancer Service, Davidoff Cancer Center, Rabin Medical Center, Petach Tiqwa/IL, 2Neuro-Oncology Unit, Davidoff Cancer Center, Rabin Medical Center, Beilinson Campus, Petah Tiqwa/IL, 3Department of Diagnostic Radiology, Rabin Medical Center, Beilinson Campus, Petah Tiqwa/IL, 4Statistical Consulting Unit, Rabin Medical Center, Affiliated To the Sackler Faculty of Medicine, Petah Tiqwa/IL, 5Soroka Medical Center, Ben-Gurion University. Beer Sheva, Israel, Beer Sheva/IL

Background: Prophylactic cranial irradiation (PCI) omission in favor of brain magnetic resonance imaging (MRI) staging and surveillance in the management of small cell lung cancer (SCLC) is controversial yet accepted by some centers policy. The latter strategy implies stereotactic radiosurgery (SRS) treatment (Tx) for limited brain metastases (BM). Data regarding SRS efficacy in this setting is limited. Method: Ten consecutive SCLC patients (pts) with BM treated with SRS at Davidoff Cancer center between Aug 2012 and July 2017 were identified through the institutional database; pts receiving PCI or whole brain radiotherapy (WBRT) as a replacement. Overall survival (OS) and progression-free survival (PFS) were reported after stereotactic radiosurgery (SRS) administration. Results of the multivariate regression analysis of overall survival (OS) and progression-free survival (PFS) were analyzed. Result: Baseline pt characteristics are presented in the Table. SRS dose ranged from 16 Gy to 22.5 Gy. IORR comprised 57% by RECIST 1.1 and 60% by mRECIST 1.1. Intracranial progression developed in 8 pts; median IFPS was 3.9 mo (95% CI, 1.7-7.2). In-site, off-site and combined pattern of intracranial failure was seen in 0, 6, and 2 pts, respectively; median number of new BM per disease course was 2 (range, 1-11). Nine additional rounds of SRS were delivered in 6 pts (median number of lesion irradiated per round-1, range-1-5). WBRT was ultimately administered in 3 pts; 4 pts died. Median TTWD comprised 23.2 mo (95% CI, 1.9-26.8). Median OS since SRS administration was 23.2 mo (95% CI, 4.2-26.8).

Keywords: small cell lung cancer, radiation therapy, Propensity score

P2.12 SMALL CELL LUNG CANCER/NET

Tuesday, September 25, 2018 - 09:45-18:00

P2.12-15 PROGNOSTIC AND PREDICTIVE COVARIATES IN LIMITED-STAGE SMALL-CELL LUNG CANCER: ANALYSIS OF THE PHASE 3 CONVERT TRIAL

A. Salemi1, H. Mistry1, S. Falk2, C. Faivre-Finn3
1Division of Cancer Sciences, University of Manchester, Manchester/GB, 2Radiotherapy Related Research, The Christie NHS Foundation Trust, Manchester/GB

Background: The majority of patients with limited-stage small cell lung cancer (LS-SCLC) progress after concurrent chemo-radiotherapy (cCRT). Data from the CONVERT trial was analysed to investigate prognostic and predictive covariates in LS-SCLC patients. Method: CONVERT is an international multi-centre phase III trial that randomly assigned fit patients to receive either twice-daily (45Gy in 30 fractions) or once-daily (66Gy in 33 fractions) radiotherapy starting on day 22 of chemotherapy cycle 1 (ClinicalTrials.gov NCT00433563). Chemotherapy consisted of 4 or 6 cycles (centres choice) of cisplatin and etoposide. Prophylactic cranial irradiation was offered, if indicated. The following covariates were investigated for prognostic and predictive significance (benefit from twice-daily radiotherapy and completion of cCRT): clinical (age, performance score, TNM staging, smoking status, weight loss >10% and lung function), laboratory (alkaline phosphatase, sodium and lactate dehydrogenase) and dosimetric (gross tumour volume (GTV), heart and lung dose). Completion of chemotherapy was defined as delivery of all planned cycles while completion of radiotherapy was defined as delivery of all fractions. Results of the multivariate regression analysis of overall survival (OS) and progression-free survival (PFS) were reported after correcting for multiple comparisons. Result: Of 547 patients recruited to CONVERT, 449 with complete covariate and outcome data were eligible for this analysis. GTV was the strongest prognostic covariate of OS (hazard ratio (HR) 1.37 (95% confidence interval (CI) 1.21-1.56); p<0.001). The addition of weight loss and performance score modestly improved the concordance probability (0.59 to 0.61) of this model. The HR for OS between high and low risk groups using this model was 2.72 (95% CI 1.94-3.81), median OS: 21 months (95% CI 19-26) vs 44 months (95% CI 36-not reached), respectively. For PFS, the HR between high and low risk groups was 2.55 (95% CI 1.86-3.5), median PFS: 13 months (95% CI 12-15) vs 26 months (95% CI 18-48), respectively. None of the tested covariates predicted patient benefit from twice-daily radiotherapy. Increase in patient age (continuous variable) predicted non-completion of planned chemotherapy (p<0.002). Due to the high completion of radiotherapy (86% in twice-daily and 80% in once-daily group), a multivariate analysis to predict radiotherapy completion was not performed. Conclusion: We report a clinical prognostic model in LS-SCLC, providing information that clinicians can relay to their patients to aid clinical decisions. The addition of biological covariates could help refine these prognostic models in the future.

Keywords: CONVERT, prognostic & predictive, SCLC
**Background:** Nirvolumab plus ipilimumab demonstrated an approximately 20 percent response rate in patients with Small Cell Lung Cancer (SCLC) who had received 1 or more previous regimens (Antonia et al., 2016). The study did not include data on the clinical response and toxicity in patients who had received previous radiotherapy. However, there is pre-clinical (Deng et al., 2015; Dovedi et al., 2017) and clinical evidence (Antonia et al., 2017) that radiation may potentiate effectiveness of anti-PD-1/PD-L1 immune checkpoint inhibitors. Tumor responses and toxicities in six patients with progressive SCLC treated with second line nirvolumab plus ipilimumab after chest radiotherapy and/or radiotherapy to a metastatic site are described. **Method:** This is a retrospective study of 6 patients who had received radiotherapy within 90 days to at least 1 site of gross disease. Response to immunotherapy was assessed by CT scans approximately 8 weeks after beginning treatment. RECIST criteria was utilized in determining responses. Patients were followed for at least 120 days after initiation of immunotherapy. **Result:** Three patients with extensive stage SCLC progressed after chemotherapy at 79, 98, and 125 days prior to starting immunotherapy. Three patients with limited stage SCLC had progression after chemoradiation at 23, 99, 304 days prior to starting immunotherapy. All six patients had grade 3 or 4 toxicities that required discontinuation or delay of immunotherapy. Toxicities included two patients with myasthenia gravis, two patients with grade 3 rashes, one patient with grade 3 fatigue, and one patient with grade 3 stomatitis. At time of initial re-assessment CT scan, four patients had partial response and two patients had stable disease. At 120 days, all six patients had tumor responses. Currently, four patients continue with durable responses. One patient has remained progression free at 182 days after receiving one dose of nirvolumab plus ipilimumab. One patient has remained progression free at 197 days after two doses of nirvolumab plus ipilimumab. Two patients have remained progression free at 183 and 209 days after two doses of nirvolumab plus ipilimumab followed by nivolumab maintenance. In two patients, progression occurred at 132 and 192 days after receiving two doses of nirvolumab plus ipilimumab without maintenance nirvolumab. **Conclusion:** These observations support that combined immune checkpoint inhibitors following radiation are associated with severe immune mediated toxicity in SCLC patients. The rapid tumor responses and relatively long disease control in these patients with aggressive disease suggest that modified versions of this treatment strategy should be considered. **Keywords:** small cell lung cancer, Immune Mediated Toxicity, Radiotherapy

---

**P2.12-18 INTERSTITIAL LUNG ABNORMALITIES ARE A RISK FACTOR FOR RADIATION PNEUMONITIS IN PATIENTS WITH LIMITED-STAGE SMALL-CELL LUNG CANCER**

F. Li, S. Liang, H. Wu, Y. Cai, Y. Xu, M. Chen

**Background:** Previous studies reported that patients with preexisting developing radiation pneumonitis (RP) after thoracic radiation therapy (TRT). The present study aimed to evaluate the incidence and predictors of RP after TRT in patients with limited-stage small-cell lung cancer (LS-SCLC) with or without preexisting radiological ILAs. **Method:** A total of 183 consecutive patients with LS-SCLC between January 2015 and December 2016, who were treated with thoracic intensity-modulated radiation therapy at our institution, were analyzed. The diagnosis of ILAs was reviewed by two experienced thoracic radiologists based on the pretreatment high-resolution computed tomography (CT) imaging, such as honeycomb, subpleural reticular opacities, ground-glass opacity, and traction bronchiectasis. Univariate and multivariate analyses were used to assess the correlation of clinical factors, preexisting radiological ILAs, and dose-volume histogram-based dosimetric parameters with RP. The correlation between the preexisting ILAs score on CT findings and the grade of RP was analyzed by Pearson Correlation. **Result:** Twenty (10.9%) patients had preexisting radiological ILAs. The median follow-up time was 10.9 months. RP was observed in 75 (41.0%), 35 (19.1%), 11 (6.0%), and 0 (0%) patients with grades 1, 2, 3, and ≥4 RP, respectively. The incidence of ≥2 grade and 3 RP at 1 year was 26.3% and 6.2% in the entire cohort, respectively. Preexisting radiological ILAs were associated with an increased risk of ≥2 grade 2 RP (84.1% in ILAs+ vs 18.7% in ILAs-, P < 0.001) and ≥3 grade 3 RP (27.7% in ILAs+ vs 3.8% in ILAs-, P < 0.001) at 1 year. Preexisting radiological ILAs was a significant predictors of ≥2 grade 2 RP and ≥3 grade 3 RP in multivariate analysis (P < 0.001, P = 0.004, respectively). Lower forced expiratory volume in 1 second was a significant predictor of ≥2 grade 2 RP in multivariate analysis (P = 0.043). The ratio of CD4 and CD8 cells has a tendency to predict ≥3 grade 3 RP in multivariate analysis (P = 0.053). There was a moderate correlation between the preexisting ILAs score on CT findings and the grade of RP (Pearson Correlation Coefficient = 0.364, P < 0.001). **Conclusion:** Preexisting radiological ILAs is associated with an increased risk of ≥2 grade 2 RP and ≥3 grade 3 RP after TRT in patients with LS-SCLC. **Keywords:** small-cell lung cancer, Interstitial lung abnormalities, Radiation pneumonitis
calculate brain metastases, survival rate, and adverse events. Summary results were pooled using the random-effect model. Result: Of 1,124 identified citations, we included 13 trials reporting on 1,286 patients with extensive SCLC. PCI did not associate with significantly improved OS (HR: 0.82; 95%CI: 0.60-1.11; P=0.192) or PFS (HR: 0.82; 95%CI: 0.68-1.00; P=0.052) compared with patients not receiving PCI, while PCI did associate with significantly decreased brain metastases (RR: 0.54; 95%CI: 0.41-0.72; P=0.001). We noted further that PCI significantly increased the 1-year survival rate (RR: 1.50; 95%CI: 1.05-2.14; P=0.027) while it had no significant effect on either the OS or PFS. Conclusion: Since metastatic disease is a common site of progression for patients receiving tyrosine kinase inhibitors (TKI), the management of brain metastases in this population remains a challenge since several methods of treatment are available. TKI-treatment, especially with second or third generation drugs can be effective but the role of radiation therapy, with either whole brain radiotherapy (WBRT) or stereotactic radiosurgery (SRS), has not been fully elucidated. A retrospective study was conducted at our Institution in order to evaluate the frequency of brain metastases in this subgroup of patients and in order to explore clinical features associated with survival.

P2.13 TARGETED THERAPY

1The Christie NHS Foundation Trust, Manchester/GB, 2The Ipswich Hospital NHS Trust, Ipswich/GB, 3Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne/GB, 4Guy’s and St Thomas’ NHS Foundation Trust, London/GB, 5Oncology, Chelsea & Westminster Hospital, London/GB, 6University Hospitals of Leicester, Leicester/GB, 7Dorset County Hospital NHS Foundation Trust, Dorset/GB

Background: ALK positive NSCLC is estimated to account for 1,600 cases per year in England. Brigatinib is a next generation ALK inhibitor with proven efficacy after crizotinib but its role in 1st line is still under investigation. If licensed in Europe it may further extend survival for this rare group of patients. Method: We conducted a multicentre retrospective study across hospitals from the National Health System (NHS) in England on ALK positive patients who were offered treatment with the newer generations of ALK inhibitors. For this analysis, patients who received treatment with brigatinib through Compassionate use program or clinical trials between 2012 and 2018 were selected. The results were pooled using the random-effect model. Results: A total of 30 patients with an ALK positive lung adenocarcinoma were included with their 1-year survival rate. However, PCI is associated with a significantly increased risk of adverse events.

Conclusion: The findings of this meta-analysis suggest that patients with extensive SCLC who receive PCI can reduce the risk of brain metastases and increase their 1-year survival rate. However, PCI is associated with a significantly increased risk of adverse events.

Keywords: ALK, brain metastases

P2.13 TARGETED THERAPY

P2.13-02 ALK-TRANSLOCATION AND BRAIN METASTASES: A RETROSPECTIVE STUDY. CORRELATION BETWEEN CLINICAL OUTCOME, DISEASE BURDEN AND MANAGEMENT. O. Grundberg1, S. Friedland1, S. Abdel-Halim1, S. Gigatek1, R. Karimi1, O. Ojdahl-Boden2, G. Tsakonas2, M. Bradic-Lindh2, K. Kolbeck2, G. Wagenius1, S. Ekman3, K. Lindberg4, L. De Petris
1Pulmonary Oncology, Karolinska University Hospital, Stockholm/SE

Background: Brain metastases from non-small cell lung cancer is often regarded as the ominous sign of disease progression. In the ALK-translocated population, brain metastases are seen in a higher incidence, either at diagnosis or as a common site of progression for patients responding to ALK tyrosine kinase inhibitors (ALK-TKI). The management of brain metastases in this population remains as such several methods of treatment are available. TKI-treatment, especially with second or third generation drugs can be effective but the role of radiation therapy, with either whole brain radiotherapy (WBRT) or stereotactic radiosurgery (SRS), has not been fully elucidated. A retrospective study was conducted at our Institution in order to evaluate the frequency of brain metastases in this subgroup of patients and in order to explore clinical features associated with survival.

Method: 88 consecutive patients with advanced ALK+ adenocarcinoma were treated at our institution, during the period 2011-2018. Data on CNS imaging modality, treatment strategy and outcome was collected by chart review. Result: CNS-imaging with either MRI or CT (in 38% and 62% of the cases respectively) was performed in 73 cases. 44 patients (61%) were found to have CNS metastases (Male/female ratio 48/52%; median age 60y). 23% were found at the time of primary cancer diagnosis, 38% on time of PD on chemotherapy, 34% on PD on crizotinib and 7% at PD on 2nd gen ALKInh . 27% of the patients had 1-3 metastases, 34% 4-10 met and 39 % >10. Pathological treatments in the group as a whole: chemotherapy (n=38); crizotinib (n=35); ceritinib (n=10); ceritinib (n=20); brigatinib (n=3), lorlatinib (n=1). Radiotherapy was administered in 57% as either SRS or WBRT (52/48%). Treatment strategies upon discovery of CNS-metastases: Radiotherapy solely 27%, combination of radiotherapy and pharmacological treatment in 25%, switch to crizotinib and 2nd gen ALKi in 18 and 13% respectively. Median OS from the diagnosis of CNS metastasis was 29months (95% CI 11-59). 1- and 2-year survival was 61% and 51%, respectively. Neither gender, age, timing for diagnosis of CNS metastases nor the use of radiotherapy influenced OS (Cox proportional hazard analysis). Use of 2nd gen ALKi as treatment strategy seemed to be superior to crizotinib and radiotherapy alone even if median OS not yet was reached. Conclusion: The high incidence of CNS metastases in this subpopulation of patients (Caucasian with advanced ALK+ NSCLC) was confirmed in this study. The wider implementation of 2nd generation ALKi in clinical practice will probably change the prognosis of these subjects.

Keywords: ALK, brain metastases

P2.13 TARGETED THERAPY

P2.13-03 REAL-LIFE EXPERIENCE WITH BRIGATINIB IN PRETREATED EML4-ALK TRANSLOCATED NSCLC PATIENTS M. Hochmaier1, J. Naber1, S. Schwab1, U. Setinek1, D. Krenbek1, M. Holzer1, H. Fabikan1, S. Watzka2, R. Koger1, A. Fazekas1, E. Bitterlich4, A. Valipour1, G. Burghuber1
1Department of Respiratory and Critical Care Medicine, and Ludwig Boltzmann Institute of Copd and Respiratory Epidemiology, Otto Wagner Hospital, Vienna/AT, 2Department of Thoracic Surgery, Otto Wagner Hospital, Vienna/AT, 3Institute of Pathology and Clinical Microbiology, Wilhelminenspital, Vienna/AT, 4Department of Pulmonology, Salzkammergut-Klinikum, St. Gilgen/AT

Background: Patients with lung cancer, who show EML4-ALK translocation are routinely treated with ALK inhibitors (ALKi) as Alectinib, Ceritinib or Crizotinib, but develop resistance over time in the majority of cases. Brigatinib, a new next-generation ALKi, is FDA approved in crizotinib-refractory ALK-positive NSCLC. The role of Brigatinib after Ceritinib or Alectinib failure is unknown in clinical practice. We report about our experience with Brigatinib in EML4-ALK translocated NSCLC patients, who became resistant to Alectinib, Ceritinib or Crizotinib.

Method: We treated 35 EML4-ALK translocated NSCLC patients with Brigatinib. Patient characteristics including sex, age, race, presence/absence of brain metastases and smoking history of ALK+ NSCLC patients were collected. All data were obtained from Otto-Wagner hospital from August 2015 until April 2018. Before receiving Brigatinib, the patients were either only treated with Crizotinib (n = 15), with Crizotinib and then...

P2.13-04 OUTCOMES OF ALK-POSITIVE NON-SMALL-CELL LUNG CANCER (NSCLC) PATIENTS TREATED WITH CRIZOTINIB: A MULTICENTER COHORT RETROSPECTIVE STUDY.

Xin 5, L. Liang 6, H. Liang 7, Y. Du 5, Z. Zhang 6, J. Li 1

Methods: We reviewed medical records of 484 unselected ALK-positive NSCLC patients treated with crizotinib at five cancer centers in China from January 2013 to November 2017. Clinical data were collected from crizotinib initiation to RECIST-defined progressive disease (PD) and post-PD systemic treatment outcomes were also analyzed. Result: A total of 428 eligible ALK-positive NSCLC patients were enrolled. Among them, 273 (63.8%) patients received crizotinib as first-line treatment. The median progression-free survival (PFS) of crizotinib was 7.5 months (range 1.2-11) and treatment of 21 patients is still ongoing. Of the 15 patients, who received only Crizotinib before Brigatinib, 2 patients were complete responders. 12 were partial responders and 1 had disease progression. Among the 72 patients who received Crizotinib followed by Brigatinib, 2 patients had complete response and 9 partial response. Post-PD systemic treatment was continued. All other patients demonstrated a partial response except two patients who had disease progression with Brigatinib following Crizotinib/Alectinib treatment. Brigatinib was well tolerated overall. Conclusion: Brigatinib was highly effective in these pretreated EML4-ALK translocated NSCLC patients in clinical practice.

Keywords: NSCLC, EML4-ALK, crizotinib.

P2.13-05 REAL-WORLD CLINICAL BENEFIT OF CONTINUING CRIZOTINIB BEYOND PROGRESSION DISEASE (CBPD) IN PATIENTS WITH ADVANCED ALK-POSITIVE NSCLC.

D. Ma 1, P. Xing 2, Q. Wang 2, D. Ma 1, X. Hao 1, M. Wang 2, Y. Wang 1, L. Shan 4, T. Min 3, L. Liang 4, H. Liang 4, Y. Du 5, Z. Zhang 6, J. Li 1

Background: Most ALK-positive NSCLC patients treated with crizotinib would ultimately develop progressive disease (PD), and continuing crizotinib beyond initial PD (CBPD) may be potentially beneficial. We aim to evaluate the survival outcomes of patients with crizotinib resistance in real-world setting and to explore the clinical efficacy of continuing CBPD treatment. Method: A total of 261 ALK-positive NSCLC patients treated with crizotinib experienced RECIST-defined PD and were included in this multi-center retrospective analysis. Clinical pathologic characteristics, progressive pattern, post-PD treatment and overall survival (OS) were compared between patients continuing CBPD and those not. Result: 140 patients who continued crizotinib after disease progression were allocated to CBPD group and others were non-CBPD group. Two-sided Chi-square test showed that patients who never smoked (P<0.001) and with EGFR 0-1P<0.001), isolated intracranial progression (P<0.001) and <median PFS of initial crizotinib (P=0.002) were more likely in the CBPD group. At the analysis, 84 patients had re-PD and the median duration of crizotinib treatment post-PD was 6.8 months (95% CI: 3.639-9.869). The median OS for the overall population from the time of PD (post-PD OS) was 15.3 months (95% CI: 11.376-19.181), and was significantly longer in CBPD patients than non-CBPDs (24.1 months vs. 8.5 months, 95% CI: 0.326-0.669, HR 0.467, P<0.001). Furthermore, next-generation ALK inhibitors (ALKis) following crizotinib failure was associated with improved post-PD OS (24.9 months vs. 10.7 months, 95% CI: 0.307-0.686, HR 0.459, P<0.001). Conclusion: Continuing CBPD treatment after crizotinib resistance favorably impact survival outcomes of advanced ALK-positive NSCLC patients in the real-world setting. Next-generation ALKis may provide survival improvement, but comparative studies between different subsequent treatment options after PD on crizotinib are still needed.

Keywords: crizotinib, Anaplastic lymphoma kinase, Treatment beyond disease progression.

P2.13-06 TP53 STATUS IN RELATION TO RESPONSE TO ANTI-ALK AGENTS IN PATIENTS WITH EML4-ALK-TRANSLOCATED NSCLC.

M. Canale 1, A. Delmonte 1, C. Dazziti 2, A. Gamboni 1, M. Puccetti 1, S. Bravaccini 1, C. Casano 2, M. Papi 2, M. Mariotti 1, N. De Luigi 1, G. Minuti 2, D. Callistrì 1, M. Bonafè 2, L. Cirino 1, P. Ulibi 1

Methods: EML4-ALK-translocated NSCLC patients with TP53 mutations were observed in 14 (23%) patients, 2 (40%) in exon 5, 1 (20%) in exon 6 (43%) showing a mutation in exon 5, 17% in exon 6, 3 (21%) in exon 7 and 4 (28%) in exon 8. We found one deletion (7%), one deletion (7%) and 12 point mutations (86%). Of the 28 patients treated with an anti-ALK agent, 5 (20%) showed TP53 mutations, 2 (40%) in exon 5, 1 (20%) in exon 6.

Background: Patients with non-small-cell lung cancer (NSCLC) carrying the EML4-ALK translocation are responsive to anti-ALK agents, such as crizotinib. However, about 40% of patients show primary resistance to crizotinib. We previously demonstrated that TP53 mutations are associated with poorer prognosis in EGFRR-mutated patients treated with tyrosine-kinase inhibitors. In the present study we analyzed the impact of TP53 mutations on response to anti-ALK treatment in EML4-ALK-translocated NSCLC Method: Eighty-three patients with EML4-ALK-translocated NSCLC identified in the wide Catchment Area of Romagna between 2012 and 2016 were considered. TP53 status was evaluated in 61 patients on the basis of DNA availability. Of these, 28 patients received an anti-ALK agent as second-or-more-line treatment and follow-up data were available. TP53 status was analyzed in relation to disease control rate (DCR): complete response (CR), partial response (PR) or stable disease (SD). Result: Overall, TP53 mutations were observed in 14 (23%) patients, 6 (43%) in exon 5, 1 (7%) in exon 6, 3 (21%) in exon 7 and 4 (28%) in exon 8. We found one deletion (7%), one deletion (7%) and 12 point mutations (86%). Of the 28 patients treated with an anti-ALK agent, 5 (20%) showed TP53 mutations, 2 (40%) in exon 5, 1 (20%) in exon 6.

P2.13 TARGETED THERAPY
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00
5 and 2 (40%) in exon 8. Clinical response was not evaluated in 3 patients due to rapid disease progression (2 had a stop mutation in exon 5 of TP53). DCR for the 2 patients was 60% and 100%. In conclusion, EML4-ALK rearrangements are present in 3% of NSCLC patients. In this series, EML4-ALK rearrangement were associated with higher EGFR mutation frequency (75%) compared to K-ras and rearrangements (55%). TP53 mutations were observed in the 2 patients with progression on erlotinib, and xenograft studies have supported the role of ALK downstream signaling pathways. Result: After detection of CUX1-ALK fusion gene, RNA-seq analysis of FFPE sections from the primary tumor specimen was applied to reveal a 57 nt fragment from CUX1 intron 8 inserted before the 53 nt position of ALK exon 20. Expression of the CUX1-ALK fusion protein in 293T cells confirmed the self-phosphorylation of the fusion protein and the activation of ALK downstream signalling pathways, including MAPK, JAK-STAT, and PI3K/AKT signaling pathways, which all could be inhibited by the addition of crizotinib. Furthermore, the patient showed a superior response to crizotinib with a progression-free survival of 20 months.

Conclusion: This study provides the novel finding of CUX1-ALK fusion gene from NSCLC patient which could provide personalized treatment solutions for the maximum benefit to NSCLC patients.

Keywords: next generation sequencing, crizotinib, CUX1-ALK fusion

P2.13-09 EFFICACY AND SAFETY OF OSIMERTINIB AFTER PRIOR EGFR TKI: ANALYSIS OF PATIENTS UNDERREPRESENTED IN RANDOMIZED CLINICAL TRIALS

C. Camargo Cancer Center, Sao Paulo/BR

Background: Osimertinib is a new standard of care in non-small cell lung cancer (NSCLC) after progression of an EGFR TKI in the presence of T790M mutation. Following results of the phase III study AURA 3, which led to the approval of osimertinib worldwide, we have conducted ASTRIS in Brazil. Method: This is a phase IV, international, multicentric, open trial, with the aim of confirming the efficacy and safety of osimertinib at a dose of 80 mg daily, orally. Eligible patients presented with diagnosis of T790M-positive NSCLC on progression after prior EGFR TKI. Herein, we present the Brazilian experience of ASTRIS, including subsets that were underrepresented in the phase III trial. Result: Eighty-eight patients were enrolled in Brazil between August 2015 and March 2017. The median age was 64 years (34-89), and most were females (66%). Fifty-four patients (61%) had received prior therapy with erlotinib, forty-two (48%) with gefitinib, and 3 (3%) with afatinib. Nineteen patients (22%) were exposed to a EGFR TKI more than 6 months before enrolment. Importantly, 11 patients (12.5%) presented with a PS of 2, 23 (26%) presented with brain metastases, and 3 with leptomeningeal disease. The response rate was 58.2% (95%CI 46.6-69.2), and median progression-free survival was 9.4 months (95%CI 8.2-not reached). Thirty patients (34%) presented an adverse event, 14 of which led to dose modification and 5 to treatment discontinuation. The most common adverse events were infection in 14 cases (15%), gastrointestinal and hematologic (4 cases each). Nineteen patients (22%) had a serious adverse event, mostly infections (14 cases). Conclusion: The profile of patients enrolled in Brazilian institutions highlights the presence of cases with poor PS, which was excluded in the AURA 3 trial. Despite these features, the efficacy and safety of osimertinib was confirmed, suggesting that results could be extrapolated to a broad range of subsets. This study also underscores the role of liquid biopsy in the detection of T790M, in detriment to tumor re-biopsy.

Keywords: osimertinib, T790M, NSCLC
P2.13-10 PH II/I STUDY OF ORAL SELECTIVE AXL INHIBITOR BEMCINETIN (B8G32A4) IN COMBINATION WITH ERLOTINIB IN PTS WITH EGFRM NSCLC

1Thoracic/Head & Neck Medical Oncology, UT MD Anderson Cancer Center, Houston/TX/US, 2Moore Cancer Center, UC San Diego Health, La Jolla/CA, 3Oncology Consultants, Houston/CA, 4Sarah Cannon Research Institute, Nashville/TN/US, 5Oncology, UCSF Comprehensive Cancer Center, Los Angeles/CA/US, 6Horizon Oncology Center, Lafayette/IN/US, 7Thoracic Oncology, H. Lee Moffitt Cancer Center and Research Institute, Inc. Tampa/FL/US, 8Mary Crowley Cancer Research Unit, Dallas/US, 9UT Southwestern, Dallas/TX/US

Background: Bemcetinib is a first-in-class, oral, selective AXL TKI which is being evaluated as a combination therapy across several phase II clinical trials. Increased AXL expression is associated with innate immune suppression and the appearance of resistance to targeted therapies in models of NSCLC and pt samples. AXL inhibition via bemcetinib prevents the appearance of such resistance in vivo and has shown immunomodulatory effect in AML patients.

Methods: This study was designed to confirm the safety and tolerability of bemcetinib as a monotherapy and when administered in combination with erlotinib (arm A). Pts with activating EGFR mutation driven NSCLC who had progressed on an approved EGFR inhibitor (arm B) or were receiving erlotinib in the first line setting (arm C) were treated with bemcetinib at 210 mg (Arm A), 320 mg (Arm B), and 320 mg at RP2D in combination with full dose erlotinib to evaluate the potential of bemcetinib to reverse or prevent resistance to EGFR targeted therapy, respectively. Plasma protein biomarker levels were measured using the DiscoveryMAP v3.3 panel (Myriad RBM) at C1D1 and C2D1. Result: 2 out of 8 pts (25%) with stage IV disease who received bemcetinib monotherapy achieved SD for close to 1 year including evidence of tumour shrinkage of 19% in 1 pt. 1 pt who had progressed on previous erlotinib monotherapy (12.5%) achieved a PR receiving bemcetinib in combination with erlotinib and remains on treatment well beyond 2 years later (arm A). A further 3 pts had SD at 6 wks. 11 patients (4 female, median age 58; 38-67) were enrolled in arm B and had received a median of 2 (1-4) previous lines of cytotoxic chemotherapy and a median of 2 previous EGFR-TKI treatments. 2 of these 11 pts (18%) including 1 pt who was refractory to erlotinib therapy at the onset of combination therapy remain on treatment more than 6 months into therapy at the time of writing with best responses of PR and SD, respectively. 1 further pt had SD at 6 weeks. The most common treatment-related AEs have been gastrointestinal and rash. There was no evidence of any impact of bemcetinib on erlotinib pharmacokinetics. Protein biomarkers predictive of pt benefit following bemcetinib treatment were identified. Conclusion: Bemcetinib can be safely administered in combination with erlotinib to pts with NSCLC and brings additional benefit in a population of patients who do not have T790M and have progressed on erlotinib inhibition or are maintained on erlotinib alone. Clinical trial information: NCT02424617.

P2.13-13-11 EGFR AMPLIFICATION AND SENSITIZING MUTATIONS CORRELATES WITH SURVIVAL FROM ERLOTINIB IN LUNG ADENOCARCINOMA PATIENTS (MTP-C LiC AMP4)

A. Cardona1, A. Ruiz-Patiño1, C. Castro1, L. Rojas2, O. Arrieta3, Z. Tatarian-Barrón1, H. Barranco4, C. Vargas5, J. Otero6, L. Corrales7, C. Martín7, R. Rosell7
1Clinical and Translational Oncology Group, Foundation for Clinical and Applied Cancer Research - Ficam, Bogotá/CO, 2Medical Oncology, Clinica Universitaria Colombia, Bogotá/CO, 3Unidad Funcional de Oncología Torácica y Laboratorio de Medicina Personalizada, Instituto Nacional de Cancerología, Mexico City/MX, 4Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerología, Mexico City/MX, 5Clinical Oncology, Hospital San José, San José/CR, 6Department of Clinical Oncology, Instituto Alexander Fleming, Buenos Aires/AR, 7Director, Cancer Biology & Precision Medicine Program, Catalán Institute of Oncology, Germans Trias i Pujol Health Sciences Institute and Hospital, Badalona, Barcelona/ES

Background: Tumor heterogeneity causes different EGFR mutation abundances, and is believed to be responsible for varied progression-free survival (PFS) in lung adenocarcinoma (ADC) patients receiving EGFR TKI treatment. EGFR amplification and its common presence in EGFR mutant allele might be determined by the EGFR copy number variation. Examination of EGFR amplification status in EGFR mutant patients could predict the efficacy of EGFR-TKI treatment Method: 72 lung ADC patients, who harbored EGFR activating mutations and received erlotinib as first line treatment, were examined for EGFR amplification by FISH. We analyzed the relationship between the EGFR mutational status and copy number profile with clinical outcomes including response rate, overall-survival (OS), and PFS. Result: Median age was 62 yr (20-87 yrs), 53 patients were females (73%), and 89% had common mutations. Twenty-two (30.6%) samples with EGFR activating mutations were identified as having EGFR amplification. EGFR amplification was more frequent in patients with exon 19 deletion (p=0.05) and in those with better performance status (p=0.01). Patients with EGFR gene amplification had significantly longer PFS (7.5 months vs 4.3 months, p=0.002) as well as better OS (EGFR amplified 37.8 months, 95%CI 30.9-44.7 vs. EGFR non-amplified 27.1 months, 95%CI 12.8-41.3; p=0.009). EGFR amplification significantly influenced the response to erlotinib (p=0.001). Conclusion: EGFR amplification occurs in one third of patients with lung ADC harboring EGFR activating mutations, and could serve as an indicator for better response and survival from EGFR-TKI treatment.

P2.13-12 THE DENOVO T790M MUTATION RECOVERED BY DDPCR IS ASSOCIATED WITH A POOR RESPONSE TO 1ST AND 2ND GENERATION EGFR-TKI IN LUNG ADENOCARCINOMA.

E. Y. Kim1, A. Kim2, Y. S. Chang2
1Division of Pulmonology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul/KR, 2Department of Internal Medicine, Yonsei University College of Medicine, Seoul/KR

Background: The discovery of the EGFR-tyrosine kinase inhibitor (TKI) sensitizing mutation and the customized application of the 1st generation EGFR-TKI dramatically improved the clinical outcome of patients with lung adenocarcinoma. However, EGFR-mutation positive lung adenocarcinoma has ultimately acquired drug resistance against EGFR-TKI, resulting in treatment failure. The EGFR T790M mutation is found in approximately 40 - 50% of patients with lung adenocarcinoma harboring EGFR activating mutations, and could serve as an indicator for the presence of T790M mutation in the treatment naive lung adenocarcinoma patients with clinical outcomes including response rate, overall-survival. *Depending on the results of additional experiments, the above information will be updated at the time of presentation. Conclusion: In treatment naive lung adenocarcinoma, the de novo T790M mutation is frequently observed and may related to the poor response to 1st and 2nd generation EGFR-TKI. The further studies on the applicability of EMSI to these subgroups and its clinical usefulness are required.

P2.13-14 THE CLINICAL USEFULNESS OF LIQUID BIOPSY FOR DETECTION AND DYNAMIC MONITORING OF EGFR T790M IN NSCLC PATIENTS ON EGFR-TKI THERAPY

A. Szpechcinski¹, K. Duk¹, M. Bryl², G. Cyzewicz², E. Wojda³, M. Florczuk¹, P. Siwiński⁴, A. Barinow-Wojewódzki⁵, J. Chorostowska-Wynimko¹

¹Division of Medical Oncology, Mount Sinai Hospital, Toronto/Toronto/ON/CA. ²Medical Oncology, Dept. of Thoracic Oncology, Centre Montfort/Montfort/ON/CA. ³Department of Medicine, Division of Medical Oncology, North York General Hospital, Toronto/ON/CA. ⁴Oncology, Tom Baker Cancer Centre, University of Calgary, Calgary/AB/CA. ⁵Oncology, R. S. McLaurin Durham Regional Cancer Center, Toronto/ON/CA.

Background: The genomic profiles of sixteen patients with advanced EGFR T790M-positive NSCLC, not amenable to curative surgery/radiotherapy, with confirmation of T790M and prior EGFR-TKI therapy were enrolled. Patients were included with World Health Organization performance status of 0 to 2, as well as those with asymptomatic stable central nervous system (CNS) metastases. Patients received osimertinib 80 mg once daily until loss of clinical benefit. The primary efficacy outcome was overall survival (OS), with secondary outcomes of investigator-assessed response rate (RR), progression-free survival (PFS), and time to treatment discontinuation (TTD). Result: From study start (14 January 2016) to DCO (20 October 2017), 99 patients were enrolled at 12 Canadian centres. Median age was 64 years (30-89 years). Patients were 68% female, 57% Asian, and had ECOG 0/1/2 of 22%/65%/13%. Twenty-five patients had CNS metastases at screening. Gefitinib was the most commonly used previous EGFR-TKI (gefitinib, erlotinib and afatinib were 80%, 14%, and 14%, respectively). Thirty-one percent had previous chemotherapy; 6% previous radiation therapy. All patients had T790M: 75% tissue, 7% blood and 18% cytology. Biomarker testing methods varied, with the majority (61%) identified by En trogen EGFR kit. At DCO, 45 patients had discontinued treatment, OS data were immature. Median PFS was 11.0 months (95% CI 8.9-13.3). Median TTD was 14.9 months (95% CI 11.2-22.0%). RR was 67.0% (95% CI 56.7-77.8%). Sub-analyses showed RR of 69.9% (58.0-80.1), 66.7% (22.3, 95.7) and 55.6% (30.8, 78.5) for patients with T790M by tissue, blood, and cytology, respectively. Serious adverse events (AES) were reported in 38% of patients, leading to dose modifications and discontinuations were reported for 12% and 5% of patients, respectively. Conclusion: The Canadian results from this real-world study of osimertinib in advanced/metastatic EGFR T790M-positive NSCLC, which includes heavily pretreated patients and various approaches to biomarker testing, were comparable to outcomes reported in the phase III study AURA3 (NCT02151981). These findings provide further support for osimertinib as standard of care for EGFR T790M-positive NSCLC.

Keywords: advanced NSCLC, EGFR mutated NSCLC, Osimertinib
survey. **Method:** The question ‘would you recommend EGFR-TKIs as adjuvant therapy in postoperative patients with EGFR mutation?’ - Yes; No was included on an online survey system. Interviewee personal information was also collected. Logistic regression model was conducted to explore factors associated with the choices. **Result:** We received 732 responses from lung cancer surgeons from 30 provinces of China, 618 (84.43%) doctors were from department of general thoracic surgery and 114 (15.57%) surgeons from department of thoracic oncology surgery. 660 (90.16%) were from tertiary hospitals and 65 (8.88%) from the secondary ones. The interviewees consisted of 93 (12.70%) master candidates, 15 (2.05%) doctoral candidates, 98 (13.39%) residents. 217 (29.64%) attending doctors, 174 (23.77%) associate chiefs of surgeon and 135 (18.44%) chiefs of surgeon. As a result, 572 (78.1%) surgeons selected “Yes”, 143 (19.5%) selected “No”, and the rest abstained. Logistic regression analysis revealed that the result was not influenced by different career duration, location, economic status of living, hospital grade, department type, etc. **Conclusion:** This national-wide large sample survey showed that recommending EGFR-TKIs as adjuvant therapy for postoperative EGFR-mutant NSCLC patients was widely supported by specialists in lung cancer in China.

**Keywords:** nationwide survey, adjuvant EGFR-TKIs, China

**P2.13-17 NON-SMALL LUNG CANCER IN THE VERY YOUNG: MORE EGFR/ALK MUTATION RATE THAN THE ELDER**

C. He, Y. Chen
Chest, Taipei Veterans General Hospital, Taipei/TW

**Background:** Lung cancer was the leading cause of cancer in worldwide1. Although it remains a disease of older patients, there is a subset of patients who are diagnosed at younger age, such as blow 40 year old. Several studies had shown that the younger group had more females, more non-smokers, more advanced stages of disease, and better survive rate. However, most of these studies didn’t include tumor EGFR/ALK mutation data, especially for the younger group. We retrospectively studied the clinical difference between the younger and the older in patients, including pathologic type, treatment characteristics, and EGFR/ALK mutation rate. **Method:** We retrospective reviewed data of NSCLC patients diagnosed during Jun. 2007 to Dec. 2014, and whose age was less than 90 year-old. at Taipei Veterans General Hospital(TPEVGH).

**Result:** There were 5,051 cases of NSCLC, including 168 patients who were <40 years old (younger group) and 4,883 patients aged 40 years or older (older group). It was found younger group had significantly higher EGFR mutation rate than older group (22.6% VS 16.2%, p=0.026), and ALK mutation (4.2% VS 0.5%, p<0.001). Although the younger group had more stage IV patients (60.1% VS 49.6%, p=0.002), they had better (one-year:73.7% VS 66.2%, five-year:44.4% VS 33.7%) overall survival rate(OS) (median survival time: 55 VS 26 months, p=0.002). Regarding histologic subtype, younger group had less squamous cell carcinoma (4.2% VS 16.1%, p=0.001), while adenocarcinoma subtype was similar between two groups (76.8% VS 76.5%, p=0.924).

**P2.13-18 A MULTICENTER PROSPECTIVE BIOMARKER STUDY TO EXPLORE MECHANISMS OF AFATINIB RESISTANCE BASED ON DIGITA PCR AND NEXT-GENERATION SEQUENCING**

1Department of Comprehensive Clinical Oncology Faculty of Medical Sciences, Kyushu University, Fukuoka/JP, 2Genome Biology, Kindai University, Osaka-Sayama/JP, 3Division of Respiriology, Neurology and Rheumatology, Department of Internal Medicine, Kurume University School of Medicine, Kurume/JP, 4Department of Thoracic Oncology and Medicine, NHO Shikoku Cancer Center, Matsuyama/JP, 5National Kyushu Cancer Center, Fukuoka/JP, 6Okayama University Hospital, Okayama/JP, 7The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo/JP, 8Kansai Medical University Hospital, Osaka/JP, 9Respiratory Medicine, Miyagi Cancer Center, Morioka/JP, 10Department of Internal Medicine, Wakayama Medical University, Wakayama/JP, 11Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa/JP, 12Clinical Research Support Center Kyushu, Fukuoka/JP, 13Department of Research and Development of Next Generation Medicine, Kyushu University Graduate School of Medical Sciences, Fukuoka/JP, 14Research Institute for Diseases of the Chest, Graduate School of Medical Sciences, Kyushu University, Fukuoka/JP, 15Department Genome Biology, Kinki University School of Medicine, Osaka-Sayama/JP

**Background:** Afatinib is an oral irreversible blocker of ErbB-family kinases and shows a pronounced anti-tumor efficacy for advanced non–small cell lung cancer (NSCLC) positive for activating mutations of EGFR. We applied digital polymerase chain reaction (dPCR) and next-generation sequencing (NGS) to explore mechanisms of afatinib resistance. **Method:** Eligible patients had advanced lung adenocarcinoma with EGFR activating mutations. Tumor and plasma samples were collected before afatinib treatment and after treatment failure with disease progression (systemic progressive disease, SPD). DNA from the samples was analyzed by dPCR and NGS.

**Result:** Thirty-five patients were enrolled, with a median follow-up time of 15.8 months. Among 25 patients with SPD, tumor, plasma, or both samples were available for 18, 23, and 16 individuals, respectively. dPCR and NGS detected EGFR T790M mutation in 13 (56.5%) and 11 (47.8%) of 23 plasma samples at SPD, with sensitivity and specificity compared with tumor samples being 83.3% and 70.0% (dPCR) and 50.0% and 70.0% (NGS), respectively. Applying the ratio of the number of T790M alleles to that of activating mutations (T/TA) for determination of the T790M positivity improved the sensitivity and specificity of plasma analysis compared with tumor analysis to 83.3% and 100% (dPCR) and 57.1% and 100% (NGS), respectively. Among 25 patients with SPD, the T790M mutation of EGFR alone (n = 11), copy number gain (CNG) of NRAS (n = 1), CNG of MET (n = 1), CNG of EGFR plus T790M (n = 1), and...
CNG and E545K of PIK3CA plus T790M of EGFR (n = 1) were identified by NGS as putative resistance mechanisms against afatinib. No tumor showed transformation to small cell carcinoma. Median progression-free survival was longer in patients with than in those without T790M at SPD (15.1 versus 10.9 months, P = 0.25). Median time to SPD was much longer in patients with than in those without T790M at SPD (17.9 versus 10.9 months, P = 0.18). Conclusion: Assessment of T/R ratio with dPCR or NGS improved specificity of plasma analysis for determination of T790M positivity compared with tumor analysis. dPCR and NGS analysis in tumor and plasma samples shed light on exploring mechanisms of afatinib resistance.

Keywords: afatinib, Resistance, liquid biopsy

P2.13 TARGETED THERAPY TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.13-19 PROGNOSTIC VALUE INFERRED FROM THE QUANTITATIVE MEASUREMENT OF EGFR MUTATION USING PNA-CLAMPING METHOD IN ADVANCED EGFR MUTANT NSCLC PATIENTS

M. Kim1, I. Kim2, J.S. Eom3, M.K. Lee2
1School of Medicine, Pusan National University, Busan/KR, 2Internal Medicine, Pusan National University Hospital, Busan/KR

Background: Lung cancer is the leading cause of cancer death worldwide, with non-small cell lung cancer (NSCLC) accounting for the majority of cases. Recent advances in the understanding of the biology of tumors and in highly sensitive detection technologies for molecular analysis offer targeted therapies, such as epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs). However, not all EGFR mutation positive NSCLC patients are equally responsive to EGFR-TKIs. Although many factors have been introduced to predict EGFR TKI response, there seems to be no factor that can clearly explain the mechanism. The aim of this study was to evaluate whether the quantification of EGFR mutation predicts clinical outcomes of EGFR-TKI therapy. Method: This study is retrospective analysis of prospectively collected data about all patients who underwent EGFR mutation test using peptide nucleic acid (PNA)-mediated clamping polymerase chain reaction (PCR) at the Pusan National University Hospital between October 2015 and December 2017. The efficiency of PCR clamping was determined by measuring the Ct value. The delta (Δ) Ct-1 value (standard Ct value minus sample Ct value) was calculated to measure the quantification of EGFR mutation. Result: Among the total 552 patients tested for EGFR mutations and 142 (25.7%) were positive for EGFR mutations. Seventy-one patients received EGFR-TKIs. The patient population was subdivided using a mean ΔCt-1 value of 5.28. There was no clinically significant difference between the two groups. Patients with high ΔCt-1 value had significantly longer median overall survival (OS) than did patients with low ΔCt-1 value (24.5 vs 16.7 months, p=0.022). Patients with common EGFR mutation (exon 19 deletion or L858R) and high ΔCt-1 value showed a significantly longer median OS than did patients with common mutation and low ΔCt-1 value (24.1 vs 18.0 months, p=0.014). Multivariate analysis revealed only high ΔCt-1 value was significant prognostic factor of survival in advanced advanced EGFR mutant NSCLC. Conclusion: The ΔCt-1 value, which refers to EGFR quantification by PNA-clamping method, is a significant good prognostic factor of survival to EGFR-TKI therapy. Keywords: PNA clamping method, EGFR mutation, Prognosis

P2.13 TARGETED THERAPY TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.13-20 THE COMPARATIVE EFFECTIVENESS OF GEFITINIB VERSUS ERLOTINIB ON THE INTRACRANIAL PROGRESSION-FREE SURVIVAL IN PATIENTS WITH BRAIN METASTASIS

Y. Kuo1, C. Lin2, C. Ho3
1National Taiwan University Hospital, Taipei/TW, 2Far Eastern Memorial Hospital, New Taipei City/TW

Background: The high peak plasma concentrations and better blood-brain barrier permeability of erlotinib compared with gefitinib was reported. However, there were few researches comparing their treatment effect for brain metastasis. This study aimed to investigate the comparative effectiveness of gefitinib versus erlotinib on the survival in patients with brain metastasis from lung adenocarcinoma. Method: Incident lung adenocarcinoma patients at National Taiwan University Hospital between Jan 2013 and May 2015 were reviewed and analyzed. The inclusion criteria were: (1) tumor harboring either EGFR exon 19 deletion or L858R mutation (2) patient taking gefitinib or erlotinib as their first-line treatment (3) patients with brain metastasis. Kaplan-Meier analyses with long-rank testing were used to estimate the intracranial progression-free survival (PFS) and overall survival between the gefitinib and erlotinib group. A Cox proportional hazard model was used to calculate the hazard ratio (HR) and 95% confidence intervals (CI) for age, gender, gefitinib vs. erlotinib, Eastern Cooperative Oncology Group performance status(ECOG), and pre-treatment for brain metastasis. Cumulative incidence of intracranial progression using competing risks regression model was also conducted. Result: A total of 84 patients were included: 61 patients were female. 37 patients harbored EGFR exon 19 deletion. 39 patients received erlotinib as their first-line treatment. 73 patients had Eastern Cooperative Oncology Group performance status scores of 0-1. 48 patients had multiple brain metastases (number >5) and 14 patients had brain metastasis ≥ 3 cm in size. 25 patients received whole brain radiation therapy and 7 patients received stereotactic radiosurgery before taking the tyrosine kinase inhibitors. The median overall survival for the gefitinib group and the erlotinib group was 874 vs. 750 days (p=0.86, Fig 1), and the median intracranial PFS 652 vs. 833 days (p=0.38, Fig 2). Multivariable analysis indicated that erlotinib was associated with a better intracranial PFS. (HR: 0.34, 95% CI: 0.12-0.97). The competing risks regression model showed erlotinib was associated with a trend toward lower probability of intracranial progression, with adjusted subdistribution hazard ratio of 0.40 (95% CI, 0.16-1.03; p=0.06, Fig 3).

Keywords: Tyrosine kinase inhibitors, Brain metastasis, intracranial progression-free survival

Conclusion: In patients with brain metastasis from lung adenocarcinoma, this study showed the beneficial effectiveness of erlotinib on the intracranial progression-free survival compared with gefitinib.
Background: Primary resistance to EGFR-TKI is observed in approximately 10% of patients with activating EGFR mutations. In a patient harboring L858R mutation and high cMET amplification (MET copy number 7.3, CEP7 ratio 3.4) who progressed after just 4 weeks of erlotinib (ERL), significant tumor regression was achieved with MET inhibition alone (Crizotinib, CRZ). We confirmed this phenotype in the corresponding patient-derived cell line model (A482) and identified EGFR-AXL interaction as a mechanism that can circumvent clonal cMET addiction. Method: We generated patient-derived cell lines from the patient’s baseline neck excision biopsy (A482) and evaluated the effect of mono and combination therapy (ERL, CRZ, ERL-CRZ) on A482, including viability (CellTiter-Glo Luminescent Assay, Promega), colony forming (Crystal Violet Assay), downstream signaling (Western blots) and adaptive pathways (Human Phospho-Receptor Tyrosine Kinase Array Kit, R&D systems). AXL was identified as a key mediator of resistance and subsequently subjected to further functional validation. Finally, we examined the prevalence of this clinical phenomenon in a retrospective series of MET amplified EGFR-mutant NSCLC. Result: Cell viability assays confirmed the patient-derived cell line to be more sensitive to MET inhibition as compared to ERL alone or with combination CRZ-ERL. Upregulation of AXL, RET and FGFR3 expression were identified as adaptive changes 24 hours upon ERL exposure. A targeted pharmacologic screen revealed A482 to be exquisitely sensitive to combination EGFR and AXL inhibition. Immunoprecipitation revealed a direct interaction between EGFR and AXL, which upon treatment with ERL resulted in attenuation of cMET addiction. Co-existing cMET amplification with demonstrated suboptimal response to ERL plus CRZ was found in 3% of MET amplified EGFR-mutant NSCLC in a retrospective series of patients. Conclusion: Targeting the EGFR-AXL axis through EGFR inhibition alone can lead to paradoxical MET pathway activation, while the combination of EGFR and AXL inhibition can circumvent downstream signaling in MET amplified EGFR-mutant NSCLC. AXL expression levels can potentially identify patients in whom combination or monotherapy with MET inhibitors may be most beneficial. Our data highlights the challenge in interpreting genomic alterations in NSCLC. AXL expression levels can potentially identify patients in whom combination or monotherapy with MET inhibitors may be most beneficial.

Keywords: TKI-resistance, cMET, Axl

P2.13-22 RESISTANT PATTERNS TO Osimertinib IN NON-SMALL CELL LUNG CANCER PATIENTS WITH BOTH T799OM AND SENSITIZING EGFR MUTATION

J.C. Lee1, S. Yang2, D.K. Oh3
1Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul/KR; 2Internal Medicine, Wonkwang University, Iksan/KR, 3Pulmonary and Critical Care Medicine, Asan Medical Center, Seoul/KR

Background: Osimertinib is a 3rd generation, EGFR-TKI which is active for both sensitizing mutations and T790M of EGFR. Although it has proven its efficacy, the acquired resistance eventually occurs requiring the investigation for resistant mechanisms to provide overcoming strategies. Method: We retrospectively reviewed the medical records of T790M+ lung cancer patients treated with osimertinib after acquiring resistance to 1st or 2nd generation EGFR-TKI between February 2016 and June 2017 to evaluate the efficacy and safety of the drug. In addition, the moleculo-pathologic data of re-biopsy samples after the development of resistance to osimertinib were analyzed. Result: In 23 patients included, the median age was 59.0 years and thirteen (56.5%) were female. The median duration of follow-up was 11.9 months. 17 patients achieved an objective response (73.9%) and the disease was controlled in 22 patients (95.7%). Median progression-free survival was 7.4 months (95% CI 3.6-13.0) and median overall survival was not reached. The adverse effects were minimal except one case of severe pneumonitis. Among 14 patients who finally experienced the disease progression during osimertinib, the re-biopsy was performed in 10 patients. T799OM disappeared in 7 patients (70%) and one of them showed the wild-type conversion. Transformation to small cell carcinoma was observed in 2 patients who responded well to chemotherapy with etoposide and cisplatin. A newly developed C797S mutation was detected in one patient. Interestingly, C797S disappeared after 6 cycles of pembrolizumab following osimertinib-resistance and the patient responded well to osimertinib again. Conclusion: Osimertinib showed the clinical activity and the favorable toxicity profile comparable to those of clinical trials in real world practice in Korea. The evaluation with repeated biopsy sample after osimertinib-resistance is needed to guide the following treatment strategy.

Keywords: T799OM, Resistance, Osimertinib

P2.13-23 Osimertinib Treatment Result of Plasma T799OM Positive/Indifferent Clinical Failure Modes After First-Line EGFR TKI ForeGMTruNT Mutant NSCLC

H. Li1, H. Yang1, K. Wang1, X. Wu2, F. Kong3, D. Lv4
1Pulmonary Medicine, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou Hospital, Taizhou/CN, 2Radiation Oncology, Laboratory of Cellular and Molecular Radiation Oncology, Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/CN, 3Pulmonary Medicine, The Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou/CN

Background: Acquired resistance is inevitable after epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) treatment in advanced NSCLC with EGFR mutation. Clinical modes of EGFR-TKI failure has been reported to be associated with the efficacy of subsequent treatment. More than 50% patients treated with first-line EGFR-TKI acquired resistance had a secondary EGFR Thr790Met (T790M) mutation. Osimertinib is a potent, Irreversible EGFR-TKI targeting EGFR T790M mutation. This study aimed to investigate the difference of disease control rate (DCR) and progression free survival (PFS) after Osimertinib treatment and examine their association with clinical failure modes after first line EGFR-TKI. Method: This is a secondary analysis of a prospective randomized study from two clinical centers. The eligibility criteria of the trial included: NSCLC Stage IIIB/IV; EGFR mutation positive; Failed after first-line EGFR-TKI treatment; Plasma T790M Positive; Second-line Osimertinib. According to Yang et al 2013, the clinical modes of EGFR-TKI failure were classified to dramatic progression, gradual progression, local progression. The primary endpoints were DCR and PFS. Result: From December 2016 to April 2017, a total of 48 patients enrolled: 11 patients dramatic progression,16 gradual progression, and 21 local progression. After a median follow-up of 12.6 (range 1.3-16.5) months, the DCR rate was 10 of 11(90.9%), 15 of 16 (93.8%), and 21 of 21 (100%). The dramatic progression, gradual progression, and local progression groups, respectively. The mean PFS for the dramatic progression, gradual progression, local progression groups were 5.7, 13.0, 15.1 months, respectively. The median PFS for the gradual progression and local progression groups have not reached. The median PFS for the dramatic progression was 4.5 months. There was a significant difference in PFS between the three groups (p<0.0001). (Figure 1)

Conclusion: Osimertinib has a significant better PFS in gradual progression and local progression groups than dramatic progression group with plasma EGFR T799OM mutations acquired resistance in NSCLC.

Keywords: osimertinib, Clinical failure modes, plasma T799OM
**P2.13-24 PROSPECTIVE EFFICACY OF OSIMERTINIB IN CIRCULATING TUMOUR DNA (ctDNA) T790M-NEGATIVE NSCLC PATIENTS**

J. Remon1, J. Thibaud2, C. Jovelet1, L. Lacroix1, D. Blanchard1, L. Mezquita2, K. Howarth1, E. Green1, V. Plagnol1, C. Morris1, N. Rosenfeld1, C. Caramella1, C. Lepechoux2, F. Aboubaker Nana3, A. Botticella1, J. Adam1, R. Ferrara1, A. Gazzah1, M. Ngocamus11, J. Soria1, B. Besse1

**Background:** Liquid biopsy circulating tumor DNA (ctDNA) analysis in advanced EGFR-mutant NSCLC patients is an approved tool for molecular profiling and disease surveillance when tissue is not available. Long-term efficacy of osimertinib in patients with the T790M resistance mutation positive detected only by ctDNA (without tissue information) has not been fully validated. **Method:** In a prospective study, EGFR-mutant advanced NSCLC patients with acquired resistance to EGFR TKI, in whom a repeat tissue biopsy was not feasible, were assessed for cDNA T790M mutation status using InVisionSeq™. T790M-positive NSCLC patients received osimertinib (80 mg daily; extended access program or approval) according to RECIST progression. The objectives were to assess: proportion of patients with acquired cDNA-T790M positive; overall survival (OS) of the overall EGFR-mutant population as well as OS comparison for T790M +vel-ve. Also, for those T790M-negative NSCLC patients who received osimertinib in a real world data we assessed: response rate (RR) according to RECIST 1.1 by investigator and progression free survival (PFS), calculated from the date of osimertinib initiation until the date of progression or death (whichever came first), or the date of last follow-up are also reported. **Result:** We recruited 82 patients (71% female, median age 64 years, 72% Del19 EGFR mutation, 71% never-smokers). The cDNA T790M mutation was detected in 55% (N=45) of NSCLC patients. Median OS of EGFR-mutant population was 38.2 months (mo.). According to T790M status, median OS was 41.2 months and 30.4 mo. for T790M-positive and T790M-negative NSCLC patients, respectively. Both cohorts had already received a median of 3 previous treatment lines. In 40 T790M-positive NSCLC patients who received osimertinib, RR was 55% (PR: 55%, SD 27.5% and PD: 12.5%) and median PFS of 8.5 mo. Median OS on osimertinib among 10 patients with brain and/or leptomeningeal metastases at baseline was of 13.4 months. **Conclusion:** In patients with acquired resistance to first- or second-generation EGFR TKIs, cDNA T790M detection by InVisionSeq™ is equivalent to what has been reported according to RECIST 1.1 by investigator and progression free survival (PFS). Long-term efficacy of osimertinib in patients with the T790M resistance mutation positive detected only by ctDNA (without tissue information) has not been fully validated.

**Keywords:** lung cancer, ctDNA, T790M

**P2.13-26 IMPACT OF CONCURRENT TUMOR SUPPRESSOR GENE MUTATION ON CLINICAL OUTCOMES IN EGFR MUTATED NSCLC TREATED WITH FIRST-LINE TKI**

S. Sharma1, C. Lee2, E. Miao2, N. Seetharamu1

1Hematology/medical Oncology, Monter Cancer Center, Northwell Health, New Hyde Park/NY/US, 2Department of Clinical Health Professions, St. John’s University, Queens/NY/US

**Background:** Epidermal growth factor receptor (EGFR) mutations confer good prognosis in non-small cell lung cancer (NSCLC) and a multitude of tyrosine kinase inhibitors (TKI) are currently available for treatment of these tumors. However, development of resistance to these drugs is imminent and remains a challenging clinical conundrum. Few studies have demonstrated the presence of concurrent tumor protein 53 (TP53) mutation to result in earlier resistance to TKI. We conducted a retrospective study to determine whether or not TP53 or other tumor suppressive gene mutations impacted clinical outcomes in EGFR mutated NSCLC. Progression free survival (PFS) and disease control rate (DCR) as defined by complete response (CR), partial response (PR) or stable disease (SD) were assessed. **Method:** Patients with EGFR mutated NSCLC treated with first-line TKI at our institution from January 2014 to June 2017 were included. Patients were dichotomized based on presence or absence of TP53 mutation. Comparisons were also made between patients with and without any tumor suppressor gene mutations. Descriptive statistics was used to summarize the data. Two sample t-test assuming unequal variance was used to compare mean PFS between groups and chi-square test to compare proportions. **Result:** Of 44 patients, 72.7% had exon 19 deletions and 27.3% had exon 21 L858R point mutation. 54.5% patients had a concomitant tumor suppressor gene mutation with TP53 being the most common gene mutated (47.7%). 45.4% patients had no concurrent mutations. Comparative results is shown in Table 1

**Keywords:** lung cancer, EGFR mutation analysis, cDNA, TP53
time-dependent AUC at 6, 12 and 18 months were 62.8%, 65.5%, and 67.4% respectively and the Harrell’s C and Somers’ D concordances were 0.6342 and 0.2684 respectively. The 12-month observed vs predicted overall survival (OS) probabilities were 0.56 vs 0.61, 0.64 vs 0.66, 0.55 vs 0.69, 0.77 vs 0.71, and 0.87 vs 0.73 respectively for each of the five risk groups described earlier, suggesting good calibration. Survival curves for the five risk groups also segregated well on visual inspection, and was corroborated by log-rank P < 0.001. Conclusion: We herein report a novel nomogram-based risk scoring system that incorporates biochemical, immune and clinical variables to provide fairly robust OS estimation in EGFR mutation-positive, advanced NSCLC patients treated with first-line EGFR TKIs.

**Keywords:** Risk prediction, EGFR, Nomogram

## P2.13-27 DEVELOPMENT, INTERNAL VALIDATION, AND CALIBRATION OF A RISK SCORE TO PREDICT SURVIVAL IN PATIENTS WITH EGFR MUTANT NSCLC

I. Ng, N. Kumarakulasinge, N. Syn, R. Soo
Department of Haematology-Oncology, National University Cancer Institute, Singapore, Singapore/SG

**Background:** The emergence of molecularly targeted therapy has transformed the clinical landscape of metastatic non-small cell lung cancer (NSCLC). We profiled a local cohort of EGFR mutation-positive, advanced NSCLC patients who were treated with first-line EGFR tyrosine kinase inhibitors (TKIs) and sought to develop a nomogram-based prognostic model for predicting clinical outcomes in this patient subgroup. **Method:** A cohort of 199 EGFR mutation-positive, advanced NSCLC patients was retrospectively analyzed, with the inclusion criteria as follows: at least one sensitizing EGFR mutation, diagnosed with metastatic disease at diagnosis or incurable disease recurrence, and subsequently treated with first-line EGFR TKI for at least one-month duration. The Mnet machine learning algorithm was used to select variables for inclusion into the Cox model, with an alpha of 0.06 and gamma of 3. Internal validation was performed by plotting the bootstrapped (n = 200 bootstrap samples) time-dependent AUC according to the method described in Uno et al. (2007), and the predictive power of the model was assessed by computing Harrell’s C and Somers’ D concordance statistics. Internal validation was calibrated using a plotted graph of observed vs predicted mortality risks of five risk groups (‘low risk’, ‘medium-low risk’, ‘medium risk’, ‘medium-high risk’, and ‘high risk’ quintiles), as well as the Kaplan-Meier survival estimates for each quintile. **Result:** The resultant prognostic nomogram included the following variables - total white blood cell (WBC) count, hemoglobin levels, serum LDH levels, Neutrophil/Lymphocyte Ratio (NLR), ethnicity (Chinese vs non-Chinese), Karnofsky-Performance Status (score of ‘90-100’ or ‘70-80’ vs ‘0-60’), Charlson Comorbidity Index (≥ 3, 2, or 1 vs 0), neurological symptoms, brain, lung/pleural and adrenal metastases. The time-dependent AUC at 6, 12 and 18 months were 62.8%, 65.5%, and 67.4% respectively and the Harrell’s C and Somers’ D concordances were 0.6342 and 0.2684 respectively. The 12-month observed vs predicted overall survival (OS) probabilities were 0.56 vs 0.61, 0.64 vs 0.66, 0.55 vs 0.69, 0.77 vs 0.71, and 0.87 vs 0.73 respectively for each of the five risk groups described earlier, suggesting good calibration. Survival curves for the five risk groups also segregated well on visual inspection, and was corroborated by log-rank P < 0.001. Conclusion: We herein report a novel nomogram-based risk scoring system that incorporates biochemical, immune and clinical variables to provide fairly robust OS estimation in EGFR mutation-positive, advanced NSCLC patients treated with first-line EGFR TKIs.

**Keywords:** EGFR, TKI, tumor suppressor gene mutation

## P2.13-28 COMPARISON OF DDPCR AND NGS IN LIQUID BIOPSY TO PATHOLOGY RESULTS IN EGFR-MUTATED NSCLC

C. Steendam1, R. Van Schaik2, E. Oomen - De Hoop3, P. Atmodimedjo4, E. De Jonge5, J. Von Der Thüsen6, W. Djinens5, E. J. Dubinkink5, J. Aerts1
1Pulmonology, Erasmus MC, Rotterdam/ NL; 2Clinical Chemistry, Erasmus MC, Rotterdam/NL; 3Medical Oncology, Erasmus MC, Rotterdam/NL; 4Pathology, Molecular Diagnostics, Erasmus MC, Rotterdam/NL; 5Pathology, Molecular Diagnostics, Molecular Diagnostics, Erasmus MC, Rotterdam/NL

**Background:** In the blood of EGFR-mutated NSCLC patients, primary activating mutations as well as the resistance mutation T790M can be detected in cfDNA (liquid biopsy). Several methods have been developed for this purpose but techniques are still evolving. We compared two techniques (BioRad digital droplet PCR (ddPCR) and IonTorrent/Oncomine next generation sequencing (NGS)) for ctDNA primary activating EGFR mutations and T790M to results of pathological investigation of a tissue biopsies or pleural fluid. **Method:** We collected the data on liquid biopsy performed on EGFR-mutated NSCLC patients from November 2016 until February 2018 at the Erasmus MC. In this study we analyzed all liquid biopsy results from patients with EGFR mutations at baseline or after progression from whom also pathology results in the same time frame of treatment were available. Liquid biopsy results obtained from the two methods were compared to each other as well as to the pathology results. Cohen’s kappa was calculated as measure of agreement. **Result:** In total, 29 out of 123 patients (24%) did meet the criteria and were included in our study. Concordance for the detection of the primary activating mutation between pathology results and blood was 66% for the BioRad ddPCR and 83% for the IonTorrent/Oncomine NGS (n=29). Concordance for the detection of the p.T790M between pathology results and blood was 76% for both ddPCR and NGS (κ=0.51, n=29). In 5 patients (17%), p.T790M was detected by pathology results but not in cfDNA. In 2 patients (7%), p.T790M was detected in blood but not in the pathology specimen. Concordance between ddPCR and NGS on blood for the primary activating EGFR mutation was 83% (κ=0.57, n=29) and for p.T790M detection 93% (κ=0.86, n=29). **Conclusion:** Detection of mutations in plasma show reasonable to high concordance with tissue biopsy. The method of testing defines the extent of the number of tested mutations and therefore the height of concordance. NGS seems to upscale the concordance of detection of the primary mutation due to examination of a broader panel of available mutations (in ddPCR only exon 19 deletions and exon 21 p.L858R are tested), but is comparable to ddPCR on the level of a specific mutation in the panel (p.T790M). Discrepant results between pathology specimens and liquid biopsy remain a difficult issue for clinical practice.

**Keywords:** EGFR, liquid biopsy, NSCLC

## P2.13-29 IL-22 CONFRAMES RESISTANCE TO EGFR-TKIS IN NON- Small cell lung cancer bearing egfr gene mutation and amplification

X. Wang, J. Yao, S. Jin, R. Guo, X. Lu
Department of Oncology, First Affiliated Hospital of Nanjing Medical University, Nanjing/CN

**Background:** The effect of epidermal growth factor receptor (EGFR)-targeted strategy is hindered by drug resistance. IL-22 can promote tumor growth and induce resistance to chemotherapy in human lung cancer cells. The aim of our study was to investigate the mechanism of IL-22-induced resistance to EGFR-Tyr kinase inhibitors(EGFR-TKIs) in the NSCLC. **Method:** The tissues and plasma of patients taking EGFR-TKIs
Conclusion: These results suggest that IL-22 contributes to tumor progression and EGFR-TKIs resistance in NSCLC. Therefore, IL-22 is a potential therapeutic target for EGFR-TKIs resistance.

Keywords: IL-22, EGFR, Resistance

Background: NSCLC patients with 21 L858R mutation are less responsive to EGFR TKI treatment. This study aims to determine if high-dose icotinib can improve tumor response and progression-free survival (PFS) in this patient population. Method: In this randomized, open-label, multicenter phase II trial (INCREASE), patients with treatment-naive, EGFR-mutant (19 deletion or 21 L858R at 1:2 ratio) lung adenocarcinoma were enrolled. Patients with 21 L858R were randomized to receive either routine-dose (125mg tid, 21 L858R-RD) or high-dose icotinib (250mg tid, 21 L858R-HD), whereas patients with 19 del receive icotinib 125mg tid until progression. The primary endpoint is PFS. Result: Between May 22, 2015 and November 15, 2017, 253 patients were enrolled (21 L858R-RD group, n=86; 21 L858R-HD group, n=90; 19 del group, n=77). Baseline characteristics were similar among groups with the exception of age. The median PFS (by IRC) were 9.20 months (95%CI 8.31, 10.74), 12.85 (10.09, 15.84), and 12.48 (9.23, 13.93) for 21 L858R-RD, 21 L858R-HD, and 19 del group, respectively, for modified intent-to-treat population (p=0.0848); and 8.84 months (8.21, 10.55), 12.62 (9.59, 14.26), and 12.22 (9.17, 13.60) for per-protocol set (p=0.0445). The ORR were 47.7%, 73.3%, and 75.3% for 21 L858R-RD, 21 L858R-HD, and 19 del group, respectively (p=0.0007). Patients in high-dose group experienced significantly higher incidence of AEs than routine-dose groups (21 L858R-RD vs 21 L858R-HD vs 19 del: 54.7% vs 81.1% vs 66.2%, p=0.0445), but the incidences of grade 3/4 AE were similar among the groups (4.7% vs 5.6% vs 5.2%, p=0.9632). (See next page)
primer pairs and oligonucleotide probes. The frequency of EGFR gene mutations was 8.4% (n=155), including deletions in exon 19 (n=84), p.Leu858Arg (n=56), insertions in exon 20 (n=9), p.Glu719X (n=1), p.Glu719X and p.Ser768Ile (n=5). All samples with a deletion in exon 19 were reanalyzed by PNA-LNA PCR clamp to confirm the test result. In case of a discrepancy between the outcomes, direct Sanger sequencing was performed.

Result: Upon reanalysis, 4 (4.8%) lung adenocarcinoma patients (3 female, 1 male) with initially identified deletion in exon 19 proved to be misdiagnosed. Instead, in all p.(Leu747Pro) substitution was decisively confirmed with direct sequencing. One patient with p.(Leu747Pro) mutation in EGFR gene gained clinical benefit from EGFR-TKI therapy. She achieved partial response according to RECIST while treated with erlotinib for 7 months.

Conclusion: Diagnostic laboratories as well as clinicians should be aware of the commercial real-time PCR based test limitations, despite their IVD certification. New methods such as next generation sequencing may solve misdiagnosis problem with the exon 19 deletion of EGFR gene. Data concerning rare variants in EGFR gene are limited and results are varied, the mechanism of the p.(Leu747Pro) variant response to EGFR-TKIs needs further investigation.

Keywords: EGFR mutation assessment, NSCLC, misdiagnosis

Conclusion: A prolonged PFS and improved ORR were observed in patients treated with high-dose icotinib in NSCLC patients harboring 21 L858R mutation with tolerable toxicity.

Keywords: EGFR 21 L858R mutation, non-small-cell lung cancer (NSCLC), icotinib

P2.13 TARGETED THERAPY
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.13-31 P.(LEU747PRO) MUTATION LEADS TO MISDIAGNOSIS IN EGFR MUTATION ASSESSMENT – ANALYSIS IN A COHORT OF 1841 POLISH NSCLC PATIENTS
K. Duk1, P. Skroński1, M. Skroński1, A. Zdrały1, D. Kowsalski1, P. Rudzinski3, R. Langfort4, T. Orlowski1, J. Chorostowska-Wynimko1

Background: Epidermal growth factor receptor (EGFR) mutation assessment is essential for targeted therapy of non-small cell lung cancer (NSCLC) as predictive biomarker of the response to EGFR tyrosine kinase inhibitors (EGFR-TKI). There is a number of well-known actionable mutations in EGFR gene such as deletions in exon 19 or p.Leu858Arg, still some others, infrequent or complex are also observed. Missense substitution p.(Leu747Pro) (c.2239_2240TT>CC) is one of the rare mutations that might be misdiagnosed if EGFR mutation analysis is performed with commercial real-time PCR based kits. The eventual clinical consequences are considerable. While p.(Leu747Pro) substitution is reported as a most likely inhibiting mutation, it might be confused with an activating deletion in exon 19 of EGFR gene. Up to date, majority of published reports providing data on p.(Leu747Pro) role in resistance towards EGFR-TKI came from Asia. The frequency of p.(Leu747Pro) in the European population has not been evaluated yet. It was detected accidentally in large NSCLC patients cohorts using varied molecular methods. The aim of the study was to assess the frequency of p.(Leu747Pro) in a group of 1841 NSCLC patients referred for EGFR mutation analysis between 2015 and 2017 to the National Institute of Tuberculosis and Lung Diseases. Method: EGFR mutation analysis was performed with CE-IVD real-time PCR kit using complementary primer pairs and oligonucleotide probes. The frequency of EGFR gene mutations was 8.4% (n=155), including deletions in exon 19 (n=84), p.Leu858Arg (n=56), insertions in exon 20 (n=9), p.Glu719X (n=1), p.Glu719X and p.Ser768Ile (n=5). All samples with a deletion in exon 19 were reanalyzed by PNA-LNA PCR clamp to confirm the test result. In case of a discrepancy between the outcomes, direct Sanger sequencing was performed. Result: Upon reanalysis, 4 (4.8%) lung adenocarcinoma patients (3 female, 1 male) with initially identified deletion in exon 19 proved to be misdiagnosed. Instead, in all p.(Leu747Pro) substitution was decisively confirmed with direct sequencing. One patient with p.(Leu747Pro) mutation in EGFR gene gained clinical benefit from EGFR-TKI therapy. She achieved partial response according to RECIST while treated with erlotinib for 7 months. Conclusion: Diagnostic laboratories as well as clinicians should be aware of the commercial real-time PCR based test limitations, despite their IVD certification. New methods such as next generation sequencing may solve misdiagnosis problem with the exon 19 deletion of EGFR gene. Data concerning rare variants in EGFR gene are limited and results are varied, the mechanism of the p.(Leu747Pro) variant response to EGFR-TKIs needs further investigation.

P2.13-32 TAK-788 IS A NOVEL AND POTENT TYROSINE KINASE INHIBITOR WITH SELECTIVE ACTIVITY AGAINST EGFR/HER2

J. Choutar, S. Vincent, R. Brake, S. Li

Background: Dysregulation of the EGFR family member HER2 (human epidermal growth factor receptor 2) plays an important role in many cancers. HER2 exon 20 in-frame insertion mutations occur in 2–4% of non-small cell lung carcinomas (NSCLC). Despite current HER2-directed treatments, no approved therapies exist for patients with cancers harboring HER2 mutations. Unlike other activating mutations, exon 20 insertions induce a conformational change leading to significant homology to the ATP-binding pocket of WT proteins. As such, clinical development of tyrosine kinase inhibitors (TKIs) against these insertions has been challenging, as inhibition of WT-EGFR is associated with clinical dose-limiting toxicities, such as diarrhea and skin rash. TAK-788 was designed to potently inhibit oncogenic variants with desirable selectivity over WT-EGFR. TAK-788 inhibits mutant EGFR and HER2 via covalent modification of EGFR-Cys797 and HER2-Cys805. Here, we characterized the non-clinical activity of TAK-788 in HER2 exon 20 insertion and substitution mutants and contrasted it with other TKIs. Method: In vitro activity was assessed by measuring viability in engineered Ba/F3 lines expressing different HER2 mutation variants (substitutions and insertions). Inhibition of WT-EGFR was assessed by measuring EGFR phosphorylation in A431 cells that overexpress WT-EGFR. In vivo activity was assessed by monitoring tumor volume. Result: TAK-788 inhibited all HER2 mutations tested, including exon 20 insertions and exon 20 mutations, more potently than it inhibits WT-EGFR (Figure), suggesting an acceptable therapeutic window compared with other TKIs. TAK-788 in vitro potency in these mutations has also been confirmed in vivo with tumor xenograft models and in a phase 1 clinical trial.

Conclusion: The favorable selectivity and potency observed in these in vitro experiments for HER2 exon 20 insertions/point mutations supports the ongoing exploration of TAK-788 in NSCLC patients with HER2 mutations (NCT02716116) as well as in other HER2 mutant–driven cancer patients.

Keywords: tyrosine kinase inhibitor, HER2, exon 20

Background: NRAS mutation occurs in <1% patients with non-small cell lung cancer (NSCLC). Pre-clinical lung cancer models with NRAS mutation have demonstrated response to single agent MEK inhibition with activation of the PI3K-AKT-mTOR pathway as a putative resistance mechanism. There are a paucity of data for MEK inhibition in the clinical setting for NRAS positive disease. To our knowledge, this is the first report of an NRAS positive NSCLC patient to be treated with a MEK inhibitor. Method: A 51 year old female with advanced NSCLC was identified to have an NRAS Q61K mutation in both archival tumour and circulating tumour DNA (ctDNA) within the TARGET study. Tumour was analysed for a panel of 24 genes using an amplicon based NGS assay and circulating tumour DNA using a hybridisation capture technique of 650 genes. The patient was allocated in the Molecular Tumour Board to participate in the Phase I study of LNP3794, a first-in-human dose escalation study of a MEK inhibitor with primary endpoint of safety and tolerability. Serial plasma samples were acquired since disease progression for cDNA analysis and fresh tissue was acquired pre-treatment and on disease progression. A PDX model was implanted from the disease progression sample to explore functional mechanisms of resistance Result: The patient was commenced on LNP3794 in Jun 2015 having previously progressed on first line chemotherapy with extensive lung metastases. Initially she exhibited G3 toxicity with LNP3794, managed by dose reduction and subsequently was well tolerated. Within 6 weeks the patient demonstrated an exceptional response with 44% reduction in tumour by RECIST 1.1, resolution of a number of lesions and with clear symptomatic benefit. She remained on study for 12 months with maintained PR. The NRAS mutant allele fraction in blood fell from 20% to undetectable within 6 months and subsequently started to rise 3 months prior to radiological progression. A PIK3CA Q546K mutation was identified by Foundation Medicine at progression. The PDX is currently growing at a slow rate and the hypothesis of re-sensitisation with a combination of an mTOR inhibitor with MEK inhibition will be explored. Conclusion: These data support the clinical activity and further evaluation of MEK inhibitors in patients with NRAS positive NSCLC. As a rare population a multi-site study would be required. Combination with inhibitors of the PI3K-AKT-mTOR pathway, if tolerated, may further prolong response and clinical benefit and should also be explored.

P2.13-34 LONG INTERGENIC NON-CODING RNA 00665 INDUCES ACQUIRED RESISTANCE TO GEFTINIB IN NON-SMALL-CELL LUNG CANCER

X. Liu1, X. Lu1, R. Guo2
1Department of Oncology, First Affiliated Hospital of Nanjing Medical University, Nanjing/CN, 2Department of Oncology, First Affiliated Hospital of Nanjing Medical University, Nanjing/CN

Background: Geftinib, a tyrosine kinase inhibitor of epidermal growth factor receptor (EGFR-TKI), has been used as the first choice of treatment for advanced non-small cell lung cancer (NSCLC). However, during the course of treatment cancer cells often develop resistance to gefitinib without fully understood mechanisms. In recent years, numerous studies have shown that long non-coding RNAs (lncRNAs) play vital roles in modifying various biological processes, such as cell apoptosis, proliferation, migration, and invasion. Nevertheless cancer drug resistance mechanisms related to lncRNAs and their important roles in cancer development are still poorly understood. In this study, we aimed to elucidate an important role of long intergenic non-coding RNA 00665 (LINC00665) in developing resistance to gefitinib. Methods: Quantitative reverse transcription PCR (RT-PCR) was performed to examine the expression levels of LINC00665 in 10 pairs of LUAD tissues from patients who had never been treated with gefitinib (NG) and those who were treated with gefitinib but developed resistance (GR). The effect of LINC00665 on proliferation and apoptosis in gefitinib-resistant cells was evaluated by CCK8, colony formation, flow-cytometric analysis and in vivo tumor formation assays. Western-blot and immunohistochemistry were used to evaluate the expression of EGFR and its downstream event Akt and ERK1/2. Result: LINC00665 expression levels were significantly increased in NSCLC patients who developed acquired resistance to gefitinib compared to the NG group. Furthermore, LINC00665 inhibition reversed gefitinib sensitivity both in vitro and in vivo by suppressing cell growth and inducing cell apoptosis. Importantly, knockdown of LINC00665 marked decreased activation of EGFR and its downstream event Akt and ERK1/2. Conclusion: Taken together, our study demonstrates that LINC00665 may be a potential biomarker of response to gefitinib as well as a novel therapeutic target for future treatment of NSCLC.

P2.13 TARGETED THERAPY
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.13-117 IMPACT OF TYROSINE KINASE INHIBITOR (TKI) DOSE ON OUTCOMES OF PATIENTS WITH LUNG CANCER
E. Miao1, S. Eng2, C. Lee3, N. Seetharamu3, K. Sullivan3

1College of Pharmacy and Health Sciences, St. John’s University, Queens/US.
2College of Pharmacy and Health Sciences, St. John’s University, Queens/NYUS.
3Monter Cancer Center of Northwell Health, New Hyde Park/US

Background: FDA approved starting doses of TKIs are based on maximum tolerated dose (MTD) in clinical trials. In practice however, patients are started on lower doses due to tolerability concerns or dose-reduced subsequently for toxicity. Very few studies have addressed the impact of dose on clinical outcomes. Most as well in a chart review of lung cancer patients receiving oral TKI therapy between 1/2014 and 6/2017 at our institution was conducted. Patients who were started on TKIs at the FDA dose (Group A) dose were compared to those started on a lower dose (Group B) for progression free survival (PFS), overall survival (OS), and time-to-discontinuation. Fisher’s exact test was used to compare groups on categorical variables and the Mann-Whitney test was used for continuous variables. The Kaplan-Meier method was used to estimate time-to-event stratified by group, and Cox regression models were used to adjust for potential confounders. Result: Seventy-nine patients were treated with an EGFR inhibitor and 11 patients were treated an ALK inhibitor. The Kaplan-Meier estimates of the median time-to-progression for Group A (n = 67) and Group B (n = 23) were 13.4 months (95% CI: 8.8, 15.5) and 15.1 months (95% CI: 5.6, 21.5), respectively; and for time-to-discontinuation, the estimates were 13.5 months (95% CI: 11,

Keywords: tyrosine kinase inhibitor, oral TKI therapy.
determined to be 55 mg/m² per week. DHFR expression was seen only in NSCLC, the MTD of AUY922 in combination with pemetrexed was achieved at 55 mg/m².

**Conclusion:**

AUY922 demonstrates preclinical activity in non-small cell lung cancer (NSCLC) cell lines by potently inhibiting HSP90. As a single-agent, AUY922 showed clinical activity for NSCLC patients in a phase II trial, particularly in those with driver mutations in epidermal growth factor receptor (EGFR) and anaplastic lymphoma kinase (ALK), client proteins of HSP90. We previously demonstrated that AUY922 reliably decreases dihydrofolate reductase (DHFR) mRNA expression. Therefore, we conducted a phase Ib trial of the combination of AUY922 with pemetrexed, an antifolate inhibitor of DHFR. **Method:** In the dose-escalation portion, 9 patients with previously-treated metastatic non-squamous NSCLC were treated using a standard 3 + 3 design with pemetrexed at the standard dose of 500 mg/m² plus: AUY922 40 mg/m², 55 mg/m², or 70 mg/m² per week, respectively. After the maximum tolerated dose (MTD) was determined, an additional 4 patients were treated at the MTD. The primary endpoint was safety and tolerability. **Result:** Of 13 total patients, 9 (70%) harbored an EGFR mutation. Two grade 3 dose-limiting toxicities were observed in the 70 mg/m² cohort (thrombocytopenia and supraventricular tachycardia). Therefore, the MTD was determined to be 55 mg/m² with pemetrexed. At the MTD, 71% (n=5) required a dose reduction, with a median relative dose intensity (RDI) of 88%. Common drug-related adverse events (DRAEs) included ocular toxicity or visual disturbances (n=9, 70%), fatigue (n=6, 46%), diarrhea (n=5, 38%), anemia (n=5, 38%), anorexia (n=4, 31%), and nausea (n=3, 23%). There were no grade 4-5 events. Maximum serum concentration (Cmax) of AUY922 was associated with increased grade 2 DRAEs (r = 0.74, p < 0.01). The volume of distribution (V2) was inversely associated with number of DRAEs (r = -0.81, p = 0.004) and number of ophthalmologic related DRAEs (r = -0.65, p = 0.04). The best response was partial response in one patient for 20 months, prior to expiration of all AUY922. Immunohistochemistry of available pre-treatment tumor tissue (n = 10) revealed that this responder was also the only patient with tumor HSP27 cytoplasmic and membranous pattern staining (2 to 3+ intensity). **Conclusion:** In patients with previously treated metastatic non-squamous NSCLC, the MTD of AUY922 in combination with pemetrexed was determined to be 55 mg/m² per week. DHFR expression was seen only in NSCLC, the MTD of AUY922 in combination with pemetrexed was achieved at 55 mg/m².

**Conclusion:** The analyses of the time to response and the magnitude of reduction of target lesions in the phase 3 comparative trial provide further support for clinical similarity of ABP 215 and bevacizumab.

**Keywords:** Biosimilar, ABP 215, bevacizumab
Patients were still on osimertinib treatment at the cut-off date. Median osimertinib, we observed 1 partial response, 13 patients with stable disease for 11 months, 2 patients afatinib, one patient experienced stable disease for 11 months, and the median number of prior systemic treatments was 1 (range 0 – 3). The mechanisms of DZ-SIM restore therapeutic response in cisplatin- and gefitinib-resistant human lung cancer cells was that it co-localizes with mitochondrial and lysosomal subcellular organelles. Conclusion: (1) D2-SIM, but not SIM, kills lung cancer cells in vitro and vivo inhibits lung tumors in vivo by inducing programmed cell death. DZ-SIM also sensitizes anti-tumor responses in CIS- and GF-resistant lung cancer cells in culture and tumors in mice. (2) D2-SIM accumulates in mitochondrial and lysosomal organelles and interrupts mitochondrial membrane potential, activates caspases, and DNA fragmentation in lung cancer cells. (3) D2-SIM can be employed as a promising targeting agent for killing and sensitizing therapeutically-resistant lung tumors to therapy in patients in the future.

P2.13 TARGETED THERAPY
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.13-42 OSIMERTINIB TREATMENT FOR PATIENTS WITH EGFR EXON 20 INSERTION POSITIVE NON-CELL LUNG CANCER

Background: Epidermal growth factor receptor (EGFR) exon 20 insertions are identified in 4-10% of all EGFR mutations in non-small cell lung cancer (NSCLC) and are generally associated with primary resistance to first and second generation EGFR tyrosine kinase inhibitors (TKIs). In vitro and preclinical animal studies have shown that osimertinib exerts antitumor activity in EGFR exon 20 insertion negative NSCLC cell lines. We report on a cohort of advanced stage NSCLC patients, harboring an EGFR exon 20 insertion, that was treated with osimertinib. Method: 17 patients with advanced NSCLC harboring an EGFR exon 20 insertion were treated with osimertinib 80 mg once daily, in four institutions in the Netherlands. Data were obtained retrospectively. EGFR mutation status was assessed by next-generation sequencing. Progression free survival (PFS) and disease control rate (DCR) and objective response rate (ORR) were assessed using RECIST v1.1. Result: Median age was 63 years (range 35 – 81), 71% was female and median number of prior systemic treatments was 1 (range 0 – 3). Ten patients (59%) received prior platinum-based chemotherapy, and 2 patients afatinib, one patient experienced stable disease for 11 months, the other patient showed progression. Among all patients treated with osimertinib, we observed 1 partial response, 13 patients with stable disease and 3 with progressive disease as best response (ORR 6%). Two patients were still on osimertinib treatment at the cut-off date. Median PFS was 3.7 months (95% CI: 2.3 – 5.4 months). Six of seventeen patients (35%) achieved DCR at five months.

Conclusion: Osimertinib has limited antitumor activity in patients with EGFR exon 20 mutated NSCLC, with an ORR of 6%. A subset of patients (35%) seems to derive benefit from osimertinib treatment with durable disease control for more than five months.

Keywords: EGFR Exon 20 Insertion, Osimertinib

P2.13-43 PHASE 1 STUDY OF THE ANTI-HER3 ANTIBODY DRUG CONJUGATE U3-1402 IN METASTATIC OR UNRESECTABLE EGFR-MUTANT NSCLC

Background: While outcomes for patients with EGFR-mutant NSCLC have significantly improved with the use of EGFR tyrosine kinase inhibitors, there remain limited treatment options for many patients once they develop resistance to these agents. The HER3/ERBB3 oncogene is overexpressed in many cancers, including NSCLC, and higher expression is correlated with poor outcomes. U3-1402 is a novel HER3-targeting antibody-drug conjugate (ADC) comprised of a recombinant fully human anti-HER3 antibody (patritumab) covalently conjugated via a cleavable peptide linker to a derivative of the topoisomerase I inhibitor exatecan. After U3-1402 binds to HER3 on the tumor cell surface, it is internalized and leads to apoptosis via inhibition of topoisomerase 1. This ADC achieves a high drug-to-antibody ratio (DAR) of ~8:1. In vivo xenograft mouse model studies with human tumor cell lines indicate that U3-1402 exhibits HER3 expression-dependent tumor growth inhibition activity. Method: This is a multicenter Phase 1, Dose Escalation and Dose Expansion study of U3-1402 in metastatic or unresectable adenocarcinoma NSCLC subjects harboring EGFR-activating mutations who (a) are T790M mutation-negative after disease progression during treatment with erlotinib, gefitinib, or afatinib or (b) develop disease progression while on osimertinib. Eligible subjects are at least 18 years of age, have ECOG PS 0 or 1, have radiological documentation of disease progression while receiving continuous treatment with an EGFR TKI, have at least one measurable lesion per RECIST v1.1, have adequate bone marrow and organ function, do not have LVEF < 45%, do not have QTc prolongation, and do not have spinal cord compression or clinically active brain metastases. In Dose Escalation, subjects receive U3-1402 via intravenous infusion in 21-day cycles. In Dose Escalation, escalation of U3-1402 dosing is based on dose-limiting toxicity data in subjects, guided by the modified Continuous Reassessment Method (mCRM) using a Bayesian logistic regression model (BLRM) following the escalation with overdose control (EWOC) principle. Additionally, intra-subject dose escalation may be considered in subjects who have completed at least 4 cycles of treatment without ≥ Grade 2 treatment-emergent adverse events. In Dose Expansion, subjects receive U3-1402 at the recommended dose for expansion (RDE) determined in Dose Escalation. Primary objectives are to determine the safety, tolerability, and RDE of U3-1402. Secondary objectives are to assess the pharmacokinetic parameters of U3-1402 and its components, and to assess antitumor activity.
activity of U3-1402 (RECISt v1.1). Enrollment to Dose Escalation cohort 1 was completed in April 2018. Clinicaltrials.gov identifier: NCT032650491

P2.13 TARGETED THERAPY - TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

**P2.13-44 TARGETING NFE2L2 MUTATIONS IN ADVANCED SQAMOUS CELL LUNG CANCERS WITH TORC1/2 INHIBITOR TAK-228**

P. Paik1, L. Ahn1, M. Ginsberg2, D. McFarland3, L. Doyle4, C. Rudin5
1Memorial Sloan Kettering Cancer Center, New York/NI/US, 2National Cancer Institute, MD/NI/US, 3Thoracic Oncology, Memorial Sloan Kettering Cancer Center, New York/NI/US

**Background:** Despite research efforts over the past decade, no targeted therapy options exist for patients with SQCLC. Analyses by TCGA and others (Paik Cancer Disc 2015) have identified a heretofore untargeted, frequently mutated oncogene (NFE2L2)/tumor suppressor (KEAP1) pair, each mutated in ~20% of patients with SQCLC. NFE2L2 encodes Nrf2, a transcription factor involved in the oxidative stress response which is targeted for degradation by KEAP1. NFE2L2 mutations occur exclusively in an exon 2 hotspot that encodes the Nhe2 domain (~aa-1-86), which is the binding site for Keap1. Mutations in this region disrupt Keap1 binding, leading to Nrf2 nuclear translocation and increased mTOR signaling through regulation of Ragb (Shibata Cancer Res 2010). We now report translational studies and preliminary results from a phase 2 trial of the oral TORC1/2 inhibitor TAK-228 in SQCLC patients with these mutations.

**Method:** Cytotoxicity, signaling, and xenograft experiments were performed using LK-2 SQCLC cells harboring an NFE2L2 E79K mutation treated with TAK-228, everolimus, rapamycin, or deforolimus with requisite vehicle controls. Patients with stage IV SQCLC harboring NFE2L2 mutations were treated on an NCI CTEP single-institution phase 2 study of TAK-228 3mg po qd (continuous, 28 day cycles; NCT02177013). Secondary endpoint: ORR, PFS/OS. The study utilizes a Simon 2-stage design with H0=5% (N=2/10 responses), HA=40% (N=2/10 responses). Result: TAK-228 exhibited significantly increased anti-tumor activity over TORC1/2 rapalogues in LK-2 cells. TAK-228 alone was cytotoxic at sub-[μM] (IC50 68nM); all other rapalogues exhibited increased anti-tumor activity over TORC1 rapalogues in LK-2 cells. TAK-228 demonstrated antiproliferative activity in vitro and anti-tumor activity in vivo.

**Conclusion:** Clinical trial information: NCT02387216

P2.13 TARGETED THERAPY - TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

**P2.13-46 COMPREHENSIVE INVESTIGATION OF ERBB2 TRANSMEMBRANE DOMAIN MUTATIONS (V659/660) IN 12,833 CHINESE LUNG CANCER PATIENTS**

R. Yu1, S. W. Yang2, H. Bačo3, S. Ou3, X. Wu4
2Geneseeq Technology Inc., Toronto/ON/CA, 3Nanjing Medical University, Nanjing/ CN, 4Medical Department, Nanjing Geneseex Technology Inc., Nanjing/CN, 5University of California at Irvine, Orange/CA/US

**Background:** The ERBB2/HER2 receptor tyrosine kinase belongs to the human EGFR family and is a known oncogenic driver in many cancers including lung cancer. Majority of ERBB2 mutations are within its N-terminal domain in non-small cell lung cancer (NSCLC). Rare transmembrane domain (TMD) mutations of ERBB2 have also been identified at V659/660 residues, which potentially stabilize ERBB2 heterodimerization with EGFR, favor a kinase activating conformation, and have shown to respond to afatinib (Ou et al, JTO 2017). **Method:** We interrogated next-generation sequencing data from 19,800 Chinese cancer patients, including 12,833 lung cancers between 2014 and 2017. Sample types include formalin-fixed paraffin-embedded (FFPE) or fresh tumor samples, and/or circulating tumor DNA (ctDNA) from pleural effusion or plasma. Patients' demographic and clinical data were further analyzed. **Result:** ERBB2 TMD mutations at V659/660 were identified in two adenocarcinomas patients (five with V659D and seven with V659E), accounting for 0.14% of lung adenocarcinomas and 0.09% of all lung cancers. However, no 660 mutations were observed in this patient cohort. There is no gender preference for patients carrying such mutations (50%/50%). The median age of these patients is 56 with a trend to be younger in female patients. Two cases also carry other known driver alterations, EGFR L858R mutation and PIK3CA amplification, respectively. One case has two tumor tissue samples from the right upper and lower lobe of the lung, respectively. One lobe harbors EGFR exon19del mutation and EGFR amplification, whereas the other lobe carries ERBB2 V585D and EGFR G719A mutation. No other driver mutations were identified in the remaining cases. Interestingly, a novel TMD mutation I649R on ERBB2 was found in two patients together with ERBB2 V659D mutation, which may involve in the regulation of heterodimerization between ERBB2 and ERBB3. All these ERBB2 TMD mutations present at a relatively high mutant allele frequency (MAF) in tumor tissues, ranging from 15% to 71%, as well as liquid biopsy samples up to 47.5% of MAF, indicating a high tumor burden in these patients and potential ERBB2 amplification. Three patients received afatinib treatment with progression disease for various potential reasons, and the details of their treatment course will be presented.

**Conclusion:** Among Chinese patients, ERBB2 TMD mutation V659/660 is rare and unique to lung adenocarcinomas (0.14%). The efficacy of ERBB2–specific targeted treatment in these patients especially ERBB2 antibody and/or TKI need to be further investigated.

**Keywords:** ERBB2, lung adenocarcinomas, transmembrane domain mutation

P2.13-45 SHERLOC: A PHASE 2 STUDY OF SERIBANTUMAB IN COMBINATION WITH DOCETAXEL IN PATIENTS WITH HEREGERIN POSITIVE, ADVANCED NSCLC

1Massachusetts General Hospital, Boston/MA/US, 2Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston/MA/US, 3Princess Margaret Cancer Centre, Toronto/CA, 4University of Munich, Thoracic Oncology Centre Munich, Munich/DE, 5Thoracic Oncology, Moffitt Cancer Center, Tampa/FL/US, 6Oncology, Hospital Universitario Vall D’Hebron, Barcelona/ES, 7Medical Oncology, Centre Leon Berard, Lyon/FR, 8Other: University of Colorado Cancer Center, Aurora/CO/US, 9Medical Oncology, National Cancer Centre Singapore, Singapore/SG, 10Merrimack Pharmaceuticals, Cambridge/MA/US

**Background:** HER3 and its ligand, heregulin (HRG), have been identified as a critical activator of PI3K and Akt signaling and a key pro-survival pathway in cancer cells. Seribantumab (MM-121) is a fully human, monoclonal IgG2 antibody that binds to the HRG domain of HER3, blocking HER3 activity. Preclinical data suggest that seribantumab reverses HRG-mediated drug resistance across many cancer models. In retrospective analyses of prior seribantumab Phase 2 studies, high levels of HRG mRNA appeared to predict poor outcome to standard of care (SOC) treatment. Addition of seribantumab to SOC appeared to improve progression-free survival (PFS) in patients with HRG positive (HRG+) tumors, consistent with the hypothesis that the blockade of HRG-induced HER3 signaling by seribantumab can restore drug sensitivity. **Method:** In the current randomized, open-label, international, Phase 2 study, patients with locally advanced or metastatic NSCLC historically classified as adenocarcinoma are screened for HRG using an RNA in situ hybridization assay on a recent biopsy tissue sample. The study uses 100 HRG+ patients will be enrolled and randomized in a 2:1 ratio to receive seribantumab plus docetaxel (experimental treatment Arm), or docetaxel alone (control Arm). Eligible patients must have no EGFR and ALK mutations and have progressed following one to two SOC for locally advanced and/or metastatic disease, including platinum-based therapy and anti-PI3K/PI-1/L1 therapy where available and clinically indicated. Primary trial endpoint is PFS. Secondary endpoints include overall survival, objective response rate, time to progression, and pharmacokinetic profile. The study has ≥ 80% power to detect a 3-month improvement in median PFS over 3 months (hazard ratio < 0.50), using a one-sided, stratified log-rank test at a significance level of 0.025. Study is ongoing and enrolling patients in seventy nine sites worldwide.

**Clinical trial information:** NCT02387216

**Result:** Section not applicable

**Conclusion:** Section not applicable

**Keywords:** Heregulin, Antibody, biomarker

P2.15 TREATMENT IN THE REAL WORLD - SUPPORT, SURVIVORSHIP, SYSTEMS RESEARCH
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.15-01 CANSCRIPT™ AS A PATIENT-DERIVED PREDICTIVE PLATFORM FOR INDIVIDUALIZING TREATMENT IN LUNG CANCER
1Medical Oncology, Kidwai Memorial Institute of Oncology, Bangalore/IN, 2Kidwai Memorial Institute of Oncology, Bangalore/IN, 3Cancer Biology, Mitra Biotech, Bangalore/IN, 4Molecular Pathology, Mitra Biotech, Bangalore/IN, 5Cancer Biology, Mitra Biotech, Woburn/US

Background: Lung cancer causes nearly 1.69 million deaths globally and 5-year survival rate is less than 20%. Several predictive and prognostic biomarkers have been identified, such as mutations in EGFR and KRAS, -rearrangement of ALK and ROS1, and PD-L1 expression seen amongst others, which have improved treatment selection and overall prognosis in lung cancer to some extent. However, clinical relevance of these biomarkers is limited to only a small percentage of patients who potentially benefit from these signatures. Hence, there is a need for a personalized tool that can accurately predict an individual’s response to a therapy, especially in scenarios where there is a choice of equivalent treatment regimens. References: http://www.who.int/en/news-room/fact-sheets/detail/cancer

Result: In the current study, 21 lung cancer patient tumors were evaluated using the CANscript™, were treated with one or more FDA approved regimens including targeted therapy and chemotherapy. We did not observe any advantage of targeted therapy (erlotinib and gefitinib) over chemotherapy agents used. Six tumors, which were non-responder to gefitinib, were predicted responders to chemotherapy (carboplatin/temozolomide or carboplatin/docetaxel). Further, out of 4 gefitinib responders, 3 were predicted to respond to chemotherapy (carboplatin/temozolomide or carboplatin/docetaxel). Higuest efficacy was observed in carboplatin/temozolomide and carboplatin/docetaxel arms (47% and 46% respectively). One out of 4 tumors treated with anti-PD1 responded to the therapy showing a response rate of 25%, matching the reported clinical response rate of anti-PD-1 therapy. Conclusion: CANscript™ is used as an ex-vivo, personalized platform that can predict an individual’s response to various classes of anticancer drugs. The platform has been validated over a large number of clinical samples and the current study indicates that CANscript is a preferred platform for selecting individualized drug responses for treatment of lung cancer.

P2.15-02 GENDER-ASSOCIATED DIFFERENCES IN PATIENTS WITH LUNG CANCER TREATED AT AN ARGENTINEAN UNIVERSITY HOSPITAL IN THE LAST 10 YEARS
C. Gabay, M. Tournour, M. Bonet, A. Giorlando, I. Boyeras, L. Thompson, M. Castro
Thoracic Oncology and Translational Research Unit, Instituto de Oncologia Angel H. Roffo, University of Buenos Aires, Buenos Aires/AR

Background: In the last 20 years, lung cancer became in the first cause of death worldwide among women and is responsible for 20,000 deaths yearly in Argentinean women. Retrospective data suggest differences in incidence and outcome according to gender. We report the clinicopathologic profile and outcome of lung cancer patients assisted in our institution in the last decade according to gender. Method: We retrospectively, relieved the female population with lung cancer with available data treated at Institute of oncology Angel H. Roffo in the last 10 years, and compare their clinical, pathological and epidemiologic variables such as: age, gender, histology, molecular testing (EGFR mutations, ALK rearrangement), PET-TC at diagnosis, stage, ECOG, PS and weight loss, with a cohort of male patients in the same period of time and their clinical data (OS). Result: From a total of 395 charts reviewed, 180 (45.6%) women and 215 (54.4%) men shared no differences in the median age of lung cancer diagnosis; 62 (30-92) and 63 (28-84) year, respectively (p=0.16). Differing from men, more women come from Buenos Aires urban and suburban areas (89 vs 79%)(p=0.003). Compared to men, women had a lower incidence of: SCC (squamous cell carcinoma) (24/180, 13% vs 38/215, 18%)(p=0.020), advanced disease (stage III-IV) (136/180, 75% vs 190/215 88%)(p=0.016), smoking history (126/180, 70% vs 203/215, 94%)(p=0.000), consumption of tobacco (Mean 24 pack/ year 130±4123) (p=0.000) and presence of symptoms at diagnosis (141/180, 78% vs 193/215, 90%)(p=0.006). At the molecular level, women had more positive cases (28, 15% vs 63%, 13%)(p=0.008) than men. Overall, median survival was superior for women (24 months; IC95%, 20-28 vs 20 months; IC95% 15-24) (p=0.15), especially in stage IV disease, but it was not statistically significant. Conclusion: Our data confirms gender-associated differences in the clinical and pathologic profile of lung cancer in an Argentinean cohort of patients. Although not statistically significant, women also had a better outcome than men. This analysis represents the first step of a prospective project to determine the clinic, epidemiological and molecular characteristics related to gender in lung cancer in our population

P2.15-03 AVAILABILITY AND REIMBURSEMENT OF DIAGNOSTIC TESTING AND NOVEL ANTI-CANCER DRUGS FOR NSCLC IN CEE: RESULTS OF A CEAGO SURVEY
L. Berc1, T. Cufner1, A. Ryska1, T. Cileuceta1, C. Zielinski2
1Institute of Pathology, Medical University of Graz, Graz/AIT, 2University Clinic of Pulmonary and Allergic Diseases Gornik, Golnik/SI, 3The Egerland Department of Pathology, Charles University Medical Faculty and University Hospital, Hradec Kralove/CZ, 4Prof. Dr. Ion Chiricuta” Institute of Oncology, Cluj-Napoca/RO, 5 Comprehensive Cancer Centre, Medical University Vienna, Vienna/AIT

Background: Current guidelines recommend routine molecular testing for EGFR, ALK, ROS1 and BRAF alterations in patients with advanced non-squamous non-small cell lung cancer (NSCLC) and in squamous NSCLC presenting specific clinical features. Precision medicine reflects the selection of appropriate targeted therapies (TTs) and immune-oncology (IO) treatment based on molecular testing. Method: To provide an overview of current situation, the Central European Cooperative Oncology Group (CECOG) has developed a survey with participation of national experts in the field of molecular pathology and oncology from 10 countries: Austria, Bulgaria, Croatia, Czech Republic, Hungary, Poland, Romania, Serbia, Slovakia, and Slovenia. First part of the survey referred to availability and reimbursement of molecular diagnosis in NSCLC, including testing policy ("reflex" vs on demand, parallel vs subsequent) and turnaround times. The second part evaluated the access and reimbursement of targeted and IO therapies. Result: There is large variability regarding molecular testing for NSCLC patients in CEE countries, both from access and reimbursement, and from the pattern of recommendation by oncologists. EGFR testing is reflex in Austria, Slovenia, Croatia, Czech Republic, and Slovakia and on demand in Bulgaria, Hungary, Poland, Romania, and Serbia, being fully covered by the public health system only in Austria and Slovenia. Similar situation is reported for ALK testing. ROS1, BRAF and PD-L1 are mainly tested on demand, once testing results for EGFR and ALK are found negative. Turnaround time ranges between 5 and 10 days for reflex testing influenced by technology, with delays for on demand testing. In the first line, EGFR TKIs are available and reimbursed, while IO is reimbursed only in 5 out of 10 countries. The majority of second line TTs and IOs are registered, but not yet reimbursed in many CEE markets, despite the unmet medical need. Austria can be a model in CEE, having rapid access and implementation of the new standards in testing and treatment (all second line TTs and IO available). Slovenia and Hungary follow with 7 out of 10 second line available novel treatments. Time from registration to reimbursement of a targeted treatment is usually long, lasting 1 year or more. Conclusion: This survey provides updated overview on availability and reimbursement of molecular diagnostic and precision medicines in CEE countries, for NSCLC patients. There is a strong need to standardize management guidelines and to facilitate access to novel therapies in routine clinical practice for better patient outcomes. Experts network, like CEACOG, can facilitate regional dialogue.

P2.15 TREATMENT IN THE REAL WORLD - SUPPORT, SURVIVORSHIP, SYSTEMS RESEARCH

TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

**P2.15-04 COSTS OF CARES ON THE MONTH BEFORE DEATH OF PATIENTS WITH LUNG CANCER: A FRENCH NATIONAL DATABASE SURVEY**

O. Bylicki1, C. Tournier2, F. Canoui-Poitrine3, C. Blein2, C. Chouaid4

1Pneumology, Hia Percy, Clamart/FR, 2Heva, Lyon/FR, 3Department of Public Health and Clinical Research Unit, Creteil/FR, 4Chî of Creteil, Creteil/FR

**Background:** There is a few data’s on the burden of the last month of life of patient with lung cancer and on impact of end of life (EOL) aggressiveness of cares. The aim of this study was to assess the costs of the month before death in patients with lung cancer and the impact of aggressiveness of cares during this period.

**Method:** Using a French hospital discharge database (PMSI, Programme de Médicalisation des Systèmes d’Information), all patients with lung cancer who death between January 1, 2015 and December 31, 2016 (cohort 2) were identified through the International Classification of Diseases 10th version (ICD-10).

**Result:** Patient, disease, and treatment related factors were recorded. Patient deceased between July 2016 and June 2017 who received lung cancer therapies were included in this analysis. The primary objective was to estimate the costs of the last month of life in two large academic institutions. **Conclusion:** Costs were expressed in 2017 Euros.

**Keywords:** financial toxicity, oral therapy, end of life

**P2.15-05 PRESCRIBING PATTERNS OF PHYSICIANS AND FINANCIAL IMPLICATIONS FOR LUNG CANCER TREATMENT AT THE END OF LIFE**

T. Chan1, B. EWachiw2, P. Huang3, L. Frändskä, J. Waldofgel4, C. Burdal5, P. Feliciano6

1Pharmacy, Johns Hopkins Bayview Medical Center, Baltimore/MD/US, 2Department of Pharmacy, Johns Hopkins Bayview Medical Center, Baltimore/MD/US, 3Oncology - Biostatistics and Bioinformatics, The Johns Hopkins Hospital, Baltimore/MD/US, 4Pharmacy, The Johns Hopkins Hospital, Baltimore/MD/US, 5Department of Pharmacy, Johns Hopkins Bayview Medical Center, Baltimore/MD/US, 6Department of Oncology, Johns Hopkins Medicine, Baltimore/MD/US

**Background:** Rates of systemic chemotherapy use at the end of life are estimated to be above 44%. Limited information exists on prescribing patterns of intravenous and oral treatments (immunotherapy, chemotherapy, and tyrosine kinase inhibitors) at the end of life. Use of systemic therapy in the last month of life may have a significant clinical and financial impact. This study aimed to evaluate prescribing patterns and costs associated with lung cancer treatments in the last month of life in two large academic institutions. **Method:** Patients (n=184) deceased between July 2016 and June 2017 who received lung cancer treatment were included in this analysis. The primary objective was to characterize prescribing patterns associated with end of life care. Patient, disease, and treatment related factors were recorded. Patient characteristics were compared between those who did and did not receive treatment in the last month of life using Wilcoxon and chi-square tests, respectively. **Result:** Forty-three (23%) patients received treatment in the last 28 days of life. Patient-related factors were similar between patients who did and did not receive therapy at the end of life. Patients who did not receive therapy at the end of life were more likely to be enrolled in hospice (72% vs 40%; p = 0.0035, chi-square test). Of therapies given within the last month of life, 47% were oral therapies, 31% were intravenous chemotherapy, and 16% were immunotherapy (p = <0.0001, chi-square test). Using average wholesale price, overall drug costs given in the last month of life were €422,454, of which oral agents accounted for €326,400. There were no statistical differences in patient factors, including age, creatinine, albumin, hemoglobin, Charison Index, and ECOG performance status between patients who received therapy at the end of life and those that did not (all p-values >0.05).

**Conclusion:** Oral therapies are the most commonly prescribed modality of treatment at the end of life compared to intravenous chemotherapy or intravenous immunotherapy. Oral therapies pose a significant financial burden to patients at the end of life. Using patient factors to determine candidates for therapy at the end of life continues to be an area of exploration. Further studies are warranted to identify when therapies should be discontinued or to identify patients who may not benefit from systemic therapy.

**Keywords:** financial toxicity, oral therapy, end of life

**P2.15-06 EXAMINATION OF OPTIMAL TIMING OF POST-SURGICAL SURVEILLANCE FOR EARLY STAGE LUNG CANCER PATIENTS AND ASSOCIATION WITH OUTCOMES**

E. Colwell1, P. Bhandari2, J. Benson2, H. He1, N. Lui1, M. Berry1, J. Shrager1, L. Backhus1

1Cardiothoracic Surgery, Stanford University, Stanford/CA/US, 2Stanford University, Stanford/US, 3Cardiothoracic Surgery, Stanford University, Stanford/US

**Background:** Guidelines for post-operative surveillance for NSCLC are variable. Historically, surgeons have used a one-size fits all approach, such that surveillance guidelines incorporate few important prognostic indicators for recurrence and survival. Recent NCCN guidelines recommend surveillance CT every 6 months for both stage I and II patients. This is in contrast to the recent IFCT-0302 Trial suggesting that CT scans every 6 months are not useful within the first 2 years following surgery. The goal of this study was to determine optimal timing for detection of recurrence by CT scan and the association between surveillance CT and overall survival. **Method:** This was a retrospective, single institution series of patients undergoing surgical resection (2008-2012) with stage I or II disease (AJCC 7th edition) with at least 6 months of follow-up. Guideline adherence was defined as receipt of CT every 6 months for the first two years and annually thereafter. **Result:** The cohort consisted of 162 patients (80% stage I 20% stage II) with median follow-up 57 months. Recurrence occurred in 27.5% of patients at a median of 29.5 months following surgery. The rate of adherence to guideline recommended surveillance ranged 61%-76.3% with the majority of all CT scans done for surveillance purposes (87%-98%). The percentage of CT scans with suspicious findings was relatively stable over time (30-35%), however, the rate of CT scans with recurrence was variable, peaking at 3-5 years following surgery. For those detected on CT scan, stage I recurrences peaked at 25-36 months whereas stage II peaked at 19-24 months. Timing of recurrences differed significantly on stage with 81% of recurrences occurring > 24 months following surgery for stage I patients compared to 41% of a Stage II patients. (p<0.01) Overall, higher rates of surveillance CT were associated with a reduced risk of death (HR 0.14 [95% CI 0.06-0.36] p<0.01). **Conclusion:** The majority of CT imaging performed within 5 years following surgery was done for surveillance purposes rather than symptoms. The timing of recurrence differs significantly based on stage such that few stage I patients have recurrences within 2 years following surgical resection. Additionally, rates of recurrence detected by surveillance CT scans performed less than 24 months following surgery is lower for stage I patients. These results should be examined within a larger cohort with longer longitudinal follow-up as timing of CT surveillance based on peak recurrence rates has the potential to eliminate unnecessary testing and expense for healthcare systems.

**Keywords:** early stage NSCLC, Surveillance

**P2.15-07 IMPLICATIONS FOR LUNG CANCER TREATMENT AT THE END OF LIFE AND REDUCTION OF THE FINANCIAL COSTS ASSOCIATED WITH LUNG CANCER TREATMENTS IN THE LAST MONTH OF LIFE**

O. Bylicki1, C. Tournier2, F. Canoui-Poitrine3, C. Blein2, C. Chouaid4

1Pneumology, Hia Percy, Clamart/FR, 2Heva, Lyon/FR, 3Department of Public Health and Clinical Research Unit, Creteil/FR, 4Chî of Creteil, Creteil/FR

**Background:** Using a French lung cancer patients’ database (PMSI, Programme de Médicalisation des Systèmes d’Information), we assessed the costs of the last month of life associated with lung cancer treatments in the last month of life. Association between patient factors and costs was analyzed using t-test and chi-square tests, respectively.

**Result:** Patient, disease, and treatment related factors were recorded. Patient deceased between January 1, 2015 and December 31, 2016 (cohort 2) were identified through the International Classification of Diseases 10th version (ICD-10). Aggressiveness of EOL cares was assessed by the following criteria’s: 1) chemotherapy administrated within last 14 days of life (DOL); 2) > 1 hospitalizations within 30 DOL; 3) ICU admission within 30 DOL; and 4) palliative care < 3 days before death. Direct hospital costs were assessed from the French public health insurer perspective based on DRG tariffs. Costs were expressed in 2017 Euros. **Conclusion:** Rates of systemic chemotherapy use at the end of life were more likely to be used in patients with lung cancer and the impact of aggressiveness of cares during this period. Using average wholesale price, overall drug costs given in the last month of life were €422,454, of which oral agents accounted for €326,400. There were no statistical differences in patient factors, including age, creatinine, albumin, hemoglobin, Charison Index, and ECOG performance status between patients who received therapy at the end of life and those that did not (all p-values >0.05).

**Conclusion:** Oral therapies are the most commonly prescribed modality of treatment at the end of life compared to intravenous chemotherapy or intravenous immunotherapy. Oral therapies pose a significant financial burden to patients at the end of life. Using patient factors to determine candidates for therapy at the end of life continues to be an area of exploration. Further studies are warranted to identify when therapies should be discontinued or to identify patients who may not benefit from systemic therapy.

P2.15 TREATMENT IN THE REAL WORLD - SUPPORT, SURVIVORSHIP, SYSTEMS RESEARCH
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.15-07 LUNG CANCER IN THE YOUNG
M. Galvez Nino1, R. Ruiz1, J. Pinto1, L. Raez1, L.A. Mas Lopez1
1Medical Oncology, Instituto Nacional de Enfermedades Neoplasicas, Lima/PE, 2Instituto Nacional de Enfermedades Neoplasicas, Lima/PE, 3Unidad de Investigacion Basica Y Translacional, Oncosalud-Auna, Lima/PE, 4Memorial Cancer Institute, Miami/FL/US, 5Medicn Oncology, Instituto Nacional de Enfermedades Neoplasicas, Lima/PE

Background: Lung cancer is the leading cause of cancer related death worldwide. Median age at diagnosis is 70 years. Its presentation in patients 40 or younger is uncommon and it has been proposed that maybe is a different disease due to its clinical characteristics and genetic makeup. There are a limited number of studies in this population and they report different survival and pathologic characteristics in comparison with older patients. Method: This is a retrospective analysis of patients 40 years or younger diagnosed with lung cancer between 2009 and 2015 at Instituto Nacional de Enfermedades Neoplasicas (INEN) in Lima, Peru. Patiency characteristics such as age, sex, smoking history, family history, symptoms, histological type, stage at diagnosis, and overall survival were collected from clinical files. Result: During the study period, we identified 2946 patients with lung cancer. Among these, 107 (3.63%) patients were 40 years or younger. Median age at diagnosis was 36 years and 58% of patients were female. Most patients (77.5%) lacked family history of cancer. A smoking history was present in 13.3% of patients and exposition to biomass fumes from inhouse cooking was reported in 19.5%. Mean time from onset of symptoms to diagnosis was 2 months. Frequent symptoms at diagnosis were cough (59.2%), weight loss (56.1%), chest pain (50%), dyspnea (44.2%), hemoptysis (18.4%) and fever (9.6%). Most patients (59.8%) had performance status (PS) of 1. Adenocarcinoma was the most histological type (64.5%), followed by not otherwise specified (NOS) lung cancer (15.1%), squamous carcinoma (10.3%) and neuroendocrine carcinoma (5.6%). Almost all patients (96.9%) had unresectable disease at diagnosis (7.3%, stage III; 89.6% stage IV). The median overall survival was 7 months (range 4.4 - 9.5). Conclusion: The proportion of young patients with lung cancer in our population is higher than that reported in the literature. Lung cancer in the young is mostly sporadic, more frequent in women and usually of adenocarcinoma type. Young patients tend to present with advanced disease at diagnosis, resulting in a very poor survival. The molecular characterization of this cohort of patients is ongoing.

Keywords: lung cancer, incidence, young

P2.15-08 IMPACT AND FEASIBILITY OF A SUPPORT GROUP FOR WOMEN WITH LUNG CANCER
J. Gottfried1, N. Dauboul1, J. Shin1, T. Zhang1, D. Manil1, C. Sitt1, P. Wheatley-Price1
1Department of Medicine, University of Ottawa, Ottawa/ON/CA, 2Department of Medicine, Hôpital Charles Lemoyne - Université de Sherbrooke, Greenfield Park/QC/CA, 3University of Ottawa, Ottawa/ON/CA, 4Ottawa Hospital Research Institute, Ottawa/ON/CA, 5Lung Cancer Canada, Toronto/ON/CA, 6Department of Medicine, University of Ottawa/the Ottawa Hospital Research Institute/lung Cancer Canada, Ottawa/CA

Background: Patients with lung cancer have limited psychosocial supports in the community. Participation in support groups provides emotional, social and educational support and may be beneficial for cancer patients. In our city there are no support groups for patients with lung cancer. We assessed the impact and feasibility of a lung cancer support group for women. Method: We conducted a weekly, 1.5-hour psycho-education support group for 6 sessions in 2017. Sessions were facilitated by a trained social worker with long experience in psychosocial oncology. Pre- and post-intervention quality of life tools were administered: the Canadian Lung Cancer Quality of Life (FACT-L), Impact of Events Scale (IES), and the Hospital Anxiety and Depression Scale (HADS). Median changes in scores were calculated. A negative (-) change represents improvement in the domain. Result: 10 women were enrolled. 60% completed the program. Demographics were available for 8 participants: median age 68 (range 26-80); median diagnosis year 2016 (range 2000-2017); 3 vs 5 women were ECOG PS 0 vs 1; 1 current smoker, 2 past smokers; 5 with metastatic disease; 5 undergoing palliative systemic therapy, 3 undergoing curative therapy. 1 had completed curative therapy, 1 receiving best supportive care. Both pre- and post-intervention tools were completed by 60% of participants. The CPC showed that 67% had reduced/stable problems after the intervention. The FACT-L, IES and HADS tools and their sub-scales generally showed a favourable change after the intervention. See Table 1 for the median pre- and post-intervention scores and median change in scores. 100% of participants agreed or strongly agreed that the group helped them cope with lung cancer.

P2.15-09 THE IMPACT OF TREATMENT EVOLUTION IN NSCLC (ITEN) MODEL: SURVIVAL AND COST OF TREATING PATIENTS WITH ADVANCED NSCLC IN 2017
D. Moldaver1, M. Hurry1, D. Tran1, W. Evans1, P. Cheema4, R. Sangha5, R. Burkes3, B. Melosky1, E. Orava1, D. Grima1
1Cornerstone Research Group, Burlington/CA, 2Astrazeneca Canada, Toronto/CA, 3Department of Oncology, McMaster University, Hamilton/ON/CA, 4William Osler Health System, University of Toronto, Toronto/CA, 5Cross Cancer Institute, Edmonton/AB/CA, 6Department of Medicine, Division of Medical Oncology, Mount Sinai Hospital, University of Toronto, Toronto/ON/CA, 7British Columbia Cancer Agency, Vancouver/BC/CA

Background: The life expectancy and healthcare costs of treating advanced NSCLC (aNSCLC) patients are expected to rise as new targeted and immuno-oncology (IO) therapies are approved for clinical practice. Here, we have used the ITEN model to estimate the cost of managing aNSCLC patients in Canada in 2017. Method: The ITEN model development and validation were presented in an accompanying abstract ("The ITEN model: Development and Validation"). A treatment algorithm for EGFRm, T790m, ALK re-arrangement and PD-L1+ aNSCLC patients in 2017 was generated through a modified Delphi process based on anonymous responses from Canadian clinical experts. The generated treatment algorithm was used to estimate the survival and life-time costs of managing patients. Health resource use and cost estimates included drug acquisition and administration, adverse events, laboratory and radiologic monitoring, physician visits and end of life costs (2018 costs). Cost estimates were based on published literature, Ontario formulary listings, Cancer Care Ontario recommendations and the Ontario Case Costing Initiative. The estimation of survival is described in the companion abstract. Result: Survey responses indicated that first-line...
therapy is consistent with current guideline recommended practice, but that care beyond the second-line is variable, particularly with respect to IO usage. Modelled life expectancy varied based on the molecular subtype of aNSCLC. Costs over the span of an average aNSCLC patient’s life-time were estimated to be $89,899 (range: $61,134-$194,158). In comparison, the life-time cost of treating a Canadian lung cancer patient in 2007 (ie, prior to the introduction of IOs and ALK TKIs), inflated to 2018 dollars, was an estimated $60,678 (de Oliveira et al., 2016).

P2.15-12 EXPAVEL VS. BUPIVACAINE FOR POSTOPERATIVE ANALGESIA AFTER VATS LUNG RESECTION: RESULTS OF A RANDOMIZED CONTROL TRIAL

S. Khandhar1, D. Collins1, C. Schatz1, C. Liu2, J. Chandy2
1Department of Surgery, Inova Fairfax Hospital, Falls Church/US, 2Fairfax Anesthesiology Associates, Falls Church/US

Background: Postoperative pain control practices are highly variable and opioid use is of considerable interest to clinicians and patients. This thoracic surgery program focuses on minimally invasive interventions and sought an optimal pain control regimen. Previously, tunneled pleural catheters with a continuous Bupivicaine infusion for 7 days were used. The shortened length of stay (LOS) and excellent patient satisfaction observed were attributed to this technique, however a prior randomized controlled trial (RCT) at this institution showed no differences in opioid use between catheters or singular injections of Bupivicaine. Exparaile (Liposomal Bupivicaine formulation) reports local anesthesia up to 72 hours. Exparaile’s emergence removed the catheter burden and compares local infiltration of Exparaile with standard 0.25% Bupivicaine injections into the subcutaneous space. Method: This RCT compares both injections’ analgesic effects on opioid use. Adult VATS lung resection patients from 2015-2017 were eligible. Patients with: chronic opioid use, pain medication allergies, liver or renal dysfunction, severe COPD, peptic ulcerative disease, or pregnancy were excluded. The primary endpoint measured differences in opioid utilization in postoperative days (POD) 0-7, via chart review and self-reported pain medication use post-discharge. Hydromorphone equivalents were utilized for opioid conversions. Wilcoxon rank-sum and Fisher’s exact tests compared all appropriate endpoints. Result: Sample sizes, opioid utilization, and pain scores are demonstrated in Table 1. No differences were observed for opioid utilization between groups for all PODs. No differences in pain scores (except for POD4), 30-day patient satisfaction (98% vs. 90% very satisfied), or LOS (0 [0-1] vs. 0 [0-1]) were observed.

Table 1: Comparisons of opioid utilization and self-reported pain scores between Exparaile and 0.25% Bupivicaine groups, stratified by postoperative day.

Table 1: Comparisons of opioid utilization and self-reported pain scores between Exparaile and 0.25% Bupivicaine groups, stratified by postoperative day.

**Conclusion:** These results suggest clinical equipoise between Exparaile and Bupivicaine and practitioners cannot justify routine use of Exparaile in this patient population for improved postoperative pain control. Appropriate preoperative preparation and attention to proven evidence-based metrics designed to decrease morbidity, such as ambulation, should take precedence over a focus on pain management.

**Keywords:** Exparaile (Liposomal Bupivicaine), Pain Management, VATS Lung Resections

P2.15-13 IMPLEMENTATION OF A DEMOCRATIZED APPROACH TO MULTI-OMIC MOLECULAR PROFILING VIA THE LUNGMATCH PROGRAM

J. Kingi1, R.J. Bender2, A. Clupek1, A. Jaitly1, T. Perloff1, K. Mason2, S. Madhavan1, E. Petricoin2

Background: For metastatic non-small cell lung cancer (NSCLC) guidelines include molecular testing for actionable biomarkers and recommend broad profile testing. Previous studies indicate that many patients with NSCLC are not receiving testing, even for actionable changes in EGFR, ALK, and ROS, BRAF, and PD-L1. There are widespread gaps in the community setting and Lung Cancer Alliance data shows that less than 50% of callers to the patient HelpLine have had molecular testing on their lung cancer. Method: The LungMATCH molecular testing program is operationalized via a turn-key precision medicine (PM) operation system. This approach provides a standardized workflow from tissue acquisition through multi-omic molecular profiling, treatment history integration, and AI-based computational analysis to produce a treatment decision support tool of therapeutic options matched to the patient. Longitudinal outcome is collected on every patient along with treatment decisions and patient experience. Result: The majority of the patient referrals (72%) came from non-academic centers across a wide geographic region that covered nearly 75% of the United States (36/50 states). Barriers to signing informed consent and completing biopsy have been identified including: patients in poor health, cost concerns, unsupportive physicians, and patient loyalty to the physician (discomfort with advocating for testing). For patients who have received reports, 72% (12/17) had actionable genomic alterations that indicated either a standard of care agent or a clinical trial. An additional 82% (9/11) had actionable proteomic findings and 31% (5/16) had high tumor mutational burden. Conclusion: There is broad patient interest in accessing PM information but still many barriers to widespread adoption. The LungMATCH program provides a turn-key solution to help provide a facile means to “democratize” access to PM information unbound by geography or community/academic setting. Importantly, the majority of patients who received a completed profiling report had actionable molecular alterations, which underscores the potential impact of testing. Treatment decisions and patient outcomes continue to be followed.

**Keywords:** molecular testing, biomarker, decision support

Conclusion: These results suggest clinical equipoise between Exparaile and Bupivicaine and practitioners cannot justify routine use of Exparaile in this patient population for improved postoperative pain control. Appropriate preoperative preparation and attention to proven evidence-based metrics designed to decrease morbidity, such as ambulation, should take precedence over a focus on pain management.

P2.15-14 SURVIVORSHIP OF ADVANCED LUNG CANCER PATIENTS WITH PSYCHIATRIC DISORDERS AND MALNUTRITION RISK
T. Kovacevic1, B. Zaric1, D. Bokan2

1Clinic for Thoracic Oncology, Institute for Pulmonary Diseases of Vojvodina, Faculty of Medicine, University of Novi Sad, Sremska Kamenica/RS. 2Clinical Trials Unit, Institute for Pulmonary Diseases of Vojvodina, Faculty of Medicine, University of Novi Sad, Sremska Kamenica/RS

Background: Advanced lung cancer (aLC) is often accompanied by anxiety and/or depression and malnutrition risk. The above stated burdens have a huge influence on patients' lives during the disease trajectory. Aim of this study was to assess the influence of depression and/or anxiety and malnutrition risk on overall survival (OS) in advanced lung cancer patients. Method: This prospective trial was conducted at the Institute for Pulmonary Diseases of Vojvodina, Serbia. Patients with advanced lung cancer were included in this study regardless of lung cancer type and therapy regimen. Patients rated themselves on the Hospital Anxiety and Depression Scale (HADS). Malnutrition universal screening tool (MUST) was used for assessment of malnutrition risk. Univariate and multivariate analysis was performed in order to correlate the data. Result: Out of total 134 patients, 76.9% were male and 23.1% female. Majority of patients were current smokers (58.2%), average age 61, with ECOG performance status 1 (79.9%) and diagnosed lung adenocarcinoma (48.5%). A psychiatric disorder was confirmed in 41.8% of patients (anxiety in 3.0%, depression in 19.4%, combined disorder in 19.4%). Malnutrition risk was observed in 35.0% of patients (low risk in 3.4%, medium risk in 21.6%, high risk 12.3 and for high risk 13.2 months). Median OS of patients with any psychiatric disorder accompanied by increased malnutrition risk was significantly lower than of patients without psychiatric disorder and nutrition risk (p<0.010). Analyses then examined second-opinion seekers versus non-second-opinion seekers separately to look for distinct patterns among aLC patients. Among NSCLC patients surveyed, 29% (N=158) indicated that they sought a second opinion when initially diagnosed. (See next page)

P2.15-15 DIFFERENTIATING CHARACTERISTICS OF PATIENTS SEEKING A SECOND OPINION: A SURVEY ON NON-SMALL CELL LUNG CANCER PATIENTS
K. Leonard, C. Robertson, S. Hayes, K. McNamara
Health Union Llc, Philadelphia/US

Background: Data on second-opinion seeking characteristics and behaviors is limited, especially for non-small cell lung cancer (NSCLC) patients. Seeking a second opinion could influence future treatment decisions, treatment satisfaction, and the patient-provider relationship. As patients are more involved in the decision-making process and care is more personalized than ever before, it is important to understand factors associated with seeking a second opinion. This research aimed to determine and describe differentiating characteristics of NSCLC second-opinion seekers. Method: An online survey was conducted with NSCLC patients (N=542) to gain insights on second opinion seeking characteristics. Measures included single-answer and multiple-answer multiple-choice questions, including self-reported risk factors. Responses were evaluated using descriptive statistics and comparisons using a Chi-square test. Result: Among NSCLC patients surveyed, 29% (N=158) indicated that they sought a second opinion when initially diagnosed. Second-opinion seekers were less likely to identify smoking as a personal risk factor than non-second-opinion seekers, (66% vs. 78%, X^2=7.68, p<.02). Analyses then examined second-opinion seekers versus non-second-opinion seekers separately to look for distinct patterns among ever-smokers and never-smokers. Among never-smokers, those who sought a second opinion were more likely to have been diagnosed with Stage IV NSCLC compared to those who did not seek a second opinion (56% vs. 29%, X^2=11.66, p=.001) and clinical trials (33%, X^2=7.74, p<.01). Conclusion: Late stage never-smokers are more likely to seek a second opinion, and they are more interested in information about treatment options and clinical trials. Stigma among ever-smokers may be preventing them from seeking a second opinion. Understanding these characteristics and potential bias or stigma related to smoking may help to tailor the conversation between patient and provider to ensure patient needs are met at initial diagnosis.

P2.15-16 CLINICAL ECONOMIC IMPACT OF IMPROVED GENOTYPING IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG ADENOCARCINOMA (NSCLC)
G. Lopes1, V. Raymond2, J. Scott3, C. Matthews4, S. Doshi4, E. Wang4, S. Skrzypczak5, R. Lannman5, D. Gandara6

1Hematology and Oncology, University of Miami, Sylvester Comprehensive Cancer Center. Miami/US. 2Guardant Health, Redwood City/US. 3Integraconnect, West Palm Beach/US. 4Boston Healthcare, Boston/US. 5Guardant Health, Redwood City/CA/US. 6Division of Hem-Oncology, UC Davis Comprehensive Cancer Center, Sacramento/CA/US

Background: Comprehensive genomic profiling (CGP) at diagnosis and progression identifies NSCLC patients who may benefit from targeted therapies and are unlikely to respond to immunotherapy, however many patients are incompletely or undergenotyped. We developed a cost benefit model to evaluate the clinical and economic impact of using plasma-based cfDNA CGP to guide treatment decisions in first- and second-line advanced NSCLC. Method: The model compares the clinical and economic impact of an NCCN guideline driven care paradigm, utilizing Guardant360® (G360), a CLIA certified, CAP accredited, NYSDOH approved cfDNA CGP test, for stage IIIb/IV NSCLC patients versus the current care paradigm and assesses the impact of additional genomic information to aid in therapy selection and subsequent effects on biopsy rates, drug costs, and clinical outcomes (RR, PFS, and median OS). The model targeted patients with NSCLC receiving first or second line treatment enrolled in a U.S. Commercial Health Plan with 10 million lives. Frequency of NCCN genomic targets in first-line patients was per The Cancer Genome Atlas with second-line frequencies modified to reflect the first-line testing, genotyping QNS, biopsy, and undergenotyping rates. Therapy current care distributions were derived from 2017 Integra Connect’s proprietary database. Result: Under the guideline directed care, immunotherapy and chemotherapy use decreased as patients are re-assigned to targeted therapy in both first line QNS and second line progression settings, resulting in improved clinical outcomes, including a second line repeat tissue biopsy rate reduction. Individual and overall cost savings were observed in both settings

(See next page)
and psychological support, physical activities, and complementary and alternative medicines. Items were rated on a 0 – 10 scale. Questionnaires were collected between September 2016 and October 2017.

Result:
After exclusion of non-valid patient questionnaires, 134 were analyzed. The mean age of these patients was 64.3 years (SD:8.5). There were 62% men and 37% women. Patients perceived the management of pain, AE and fatigue as the three most important items (7.5, 7.2, 6.0) while counselling with regards to employment (1.7), spiritual support (2.6), art therapy (2.6), and support groups for patients’ children (2.6) were the least important. Although most of the facilities were available at the point of care, complementary medicines, art therapy, and professional counselling were accessible for 29%, 33%, and 21%, respectively. Physicians frequently suggested pain and AE management (78%, and 75%, respectively), and diet counselling (51%). In contrast, fatigue management, sleep disorders, and sexual issues were less frequently addressed (35%, 44%, and 6%, respectively). Paradoxically, the four main unmet needs were management of fatigue, complementary medicines, psychological support for the patient’s family and friends and relaxation techniques (32%, 25%, 20%, and 20%, respectively).

Conclusion:
These key findings highlight the fact that support for pain and for the AE of cancer treatment are available, suggested and used. In contrast, unmet needs expressed by the patients were either available but not used and psychological support, physical activities, and complementary and alternative medicines. Items were rated on a 0 – 10 scale. Questionnaires were collected between September 2016 and October 2017. Result: After exclusion of non-valid patient questionnaires, 134 were analyzed. Background: Immune checkpoint inhibitors improve outcomes compared with chemotherapy in lung cancer. Tumor PD-L1 receptor expression is being studied as a predictive biomarker. The greatest challenge in oncology today is how to reconcile improvements in the management of cancer with the exponentially increasing costs of new treatment and this is a very important barrier in low and middle income countries. The objective of this study was to assess the cost-effectiveness and economic impact of second-line treatment with nivolumab and pembrolizumab with and without PD-L1 testing for patient selection in Colombia. Method: We designed a decision-analytic model to evaluate the cost-effectiveness of second-line immunotherapy versus docetaxel for advanced NSCLC. We considered the outcomes from randomized clinical trials (RCT). Direct and indirect costs were retrieved from local health care providers and published literature. ICER was calculated for each scenario with and without PD-L1 testing. Result: Nivolumab improved quality-adjusted life-years (QALY) by 0.417 among squamous tumors and 0.287 among nonsquamous tumors. The ICER was $135,093 COP and $179,391 COP, respectively. Pembrolizumab achieved a QALY gain of 0.346 and the ICER was $146,022 COP. The use of PD-L1 expression as a biomarker for nivolumab among non-squamous tumors improved incremental QALY by up to 157% and decreased the ICER by up to 61% compared with treating all patients. Considering a willingness to pay threshold of three times the Colombian Gross Domestic Product per capita, second-line immunotherapy was not cost-effective with or without patient selection by PD-L1 expression. Conclusion: Patient selection by PD-L1 expression increased cost-effectiveness of immunotherapy. Second-line immunotherapy was not cost-effective in Colombia due to its high cost. Taking into account the disparities in access to cancer innovative therapies, there is a need to promote strategies to reduce drug acquisition costs, such as price discrimination and the use of biosimilars or generics.

P2.15-19 INEQUALITY OF ACCESS TO NOVEL LUNG CANCER THERAPIES IN EUROPE

H. O’ Sullivan, L. Coate
University Hospital Limerick, Limerick City/IE

Background: With an estimated incidence of over 449,000 cases per year, lung cancer is one of the most common malignancies in Europe. Over the last decade the landscape of lung cancer treatment has evolved. We have entered a new era of lung cancer treatment and high costs has led to disparities in lung cancer care among different European countries. There is evidence of discrepancy in access to cancer therapies in Europe however access to contemporary targeted agents and immunotherapy for lung cancer hasn’t been studied. We analysed the reimbursement dates of novel lung cancer therapies in Europe. Method: The lung cancer therapies investigated include the tyrosine kinase inhibitors (TKI) alectinib, ceritinib, and crizotinib. Immunotherapy agents nivolumab, pembrolizumab and atezolizumab were also researched. National reimbursement dates of these drugs of these drugs in 29 European countries were obtained from national resources and from the pharmaceutical companies’ affiliates. Result: As of February 2018, Crizotinib was reimbursed in 24/29 (83%) of countries. Ceritinib was reimbursed in 21/29 (72%) of countries while Alectinib was reimbursed in 12/29 (41%) countries. Pembrolizumab and Nivolumab were reimbursed for previously treated NSCLC in 23/29 (72%) and 18/29 (62%) countries respectively. Atezolizumab was reimbursed in 7/29 (24%) countries for previously treated NSCLC patients. Pembrolizumab for first line treatment of NSCLC was reimbursed in 20/29 (69%) countries, while in 9/29 (31%) (all Eastern European Countries) not reimbursed. Eastern European countries reimbursed these drugs later than Western European countries.

Conclusion: The time from European Medicines Agency approval to reimbursement of these novel lung cancer treatments differs throughout Europe. Eastern European countries were less likely to have novel lung cancer therapies reimbursed. This research shows access to novel lung cancer therapeutics is unbalanced in Europe.

P2.15-25 ARE THERE ETHNIC DISPARITIES IN THE CLINICAL OUTCOMES OF NON-SMALL CELL LUNG CANCER HISPANIC PATIENTS TREATED WITH IMMUNOTHERAPY?

L. Raez, C. Meyer, C. González, L. Espinosa, E. Gómez, J. Velazco, I. Morales, E. Perdomo
Mayo Clinic Jacksonville, Jacksonville, FL, 2VA Medical Center, Houston, TX, 3Tampa General Hospital, Tampa, FL, 4Tampa VA Healthcare System, St Petersburg, FL

Keywords: Lung cancer, Hispanic, Immunotherapy

Background: The Hispanic population in the United States is constantly increasing and constitutes a significant portion of the lung cancer (LC) patient population. However, there is limited data regarding the outcomes of Hispanic NSCLC patients treated with immunotherapy. 

Methods: We performed a retrospective review of our institutional database of patients with NSCLC treated with immunotherapy at Mayo Clinic Jacksonville, St. Petersburg VA Health Care System, and Tampa General Hospital. The primary endpoints of the study were overall survival (OS) and progression-free survival (PFS) at 6 months. Secondary endpoints included objective response rate (ORR), disease control rate (DCR), and duration of response (DoR). The study population was classified into Hispanic (H), Non-Hispanic White (NHW), and Non-Hispanic Black (NHB) patients. The OS and PFS were calculated from the date of immunotherapy treatment initiation to the date of last follow-up or death. The chi-square test was used to compare categorical variables between the Hispanic and non-Hispanic groups. A Kaplan-Meier survival analysis was used to evaluate OS and PFS. The log-rank test was used to compare survival distributions between the Hispanic and non-Hispanic groups. The Cox proportional hazards regression analysis was used to evaluate the impact of various factors on OS in the Hispanic subgroup. 

Results: A total of 116 Hispanic patients (H), 827 NHW (N), and 65 NHB patients were included in the study. The median age of the study population was 66 years (range, 26–83). The median follow-up of the entire cohort was 35.8 months.

The OS at 6 months was 39.9% for Hispanic patients, 64.3% for NHW patients, and 54.8% for NHB patients (p < 0.01). The median PFS was 6.6 months for Hispanic patients, 12.7 months for NHW patients, and 7.3 months for NHB patients (p < 0.01). The ORR was 14.9% for Hispanic patients, 34.0% for NHW patients, and 21.5% for NHB patients (p < 0.01). The DCR was 85.2% for Hispanic patients, 94.4% for NHW patients, and 83.8% for NHB patients (p < 0.01). The median DoR was 7.2 months for Hispanic patients, 18.5 months for NHW patients, and 12.7 months for NHB patients (p < 0.01).

The univariate analysis showed that age, sex, histology, smoking status, and treatment line were significantly associated with OS in the Hispanic subgroup. The multivariate analysis showed that older age, male sex, and squamous histology were significantly associated with worse OS in the Hispanic subgroup. The median OS of Hispanic patients was 24.5 months, 31.5 months, and 24.6 months for patients ≥65 years, <65 years, and unknown age, respectively (p = 0.01). The median OS of Hispanic men was 24.3 months, 24.7 months, and 25.4 months for patients with squamous histology, adenocarcinoma, and unknown histology, respectively (p = 0.02).

Conclusion: Hispanic patients with NSCLC treated with immunotherapy had worse clinical outcomes compared to NHW patients. Older age, male sex, and squamous histology were significantly associated with worse OS in the Hispanic subgroup. These findings highlight the importance of developing more targeted immunotherapeutic strategies for Hispanic NSCLC patients.

P2.15-24 COMPARISON OF Pemetrexed ADMINISTERED Q 3 WEEKS VS Q 4 WEEKS AS MAINTENANCE THERAPY IN NSCLC: ANALYSIS OF REAL WORLD DATA FROM A SINGLE INSTITUTION
G. Dy, S. Reddy, K. Wang, M. Faber, A. Meagher, H. Chen, G. Dy
Roswell Park Comprehensive Cancer Center, Buffalo/US

Background: Pemetrexed maintenance 3 weeks has shown survival benefit in patients with advanced stage nonsquamous NSCLC. We sought to compare treatment outcomes in patients receiving alternate maintenance schedule (q 4 weeks) in real-world practice. Method: This is a single-center, IRB-approved retrospective study of over 500 advanced stage (IIIb&IV) nonsquamous NSCLC patients receiving pemetrexed between May 1, 2011 to June 30, 2016 as standard of care. Patients who received at least two doses of maintenance pemetrexed were included in the analysis. The end point was assessed with CT scan imaging every 6-9 weeks. Hematologic indices, hepatic, renal function, performance status, dose changes, subsequent dose or schedule changes, duration on therapy (discontinuation due to toxicity, switch in therapy or death) and overall survival data were obtained. Summary statistical analyses are provided for the demographic features of the patients included in this study in both. The difference between the two groups are evaluated using Fisher’s Test / Chi-Square Test / Logistic regression analyses for categorical variable, and T-Test / Generalized Linear regression analyses for continuous variables. Generalized Linear regression model are applied to compare outcomes between outcomes ASAS version 9.4 (SAS Institute, Cary, NC) will be used for statistical analyses. All tests were two-sided and performed at a nominal significance level of 0.05. Result: 136 patients were eligible to be included in the analysis. There were 90 and 48 patients who received pemetrexed q 3 weeks (group A) and q 4 weeks (group B), respectively. There were no differences in gender or EOCG performance status (PS) at baseline between the groups. Most common reasons documented for q 4 week schedule were patient preference or cumulative toxicities (lab abnormalities, poor tolerance or fatigue after induction treatment). Duration on therapy was longer in group B than in group A (262 days vs 156 days, p < 0.001). There were no differences in pre-and post treatment changes in hemoglobin, ANC, creatinine clearance, ALT or AST levels between the two groups. There was also no difference in the change in PS between groups. Platelet count was higher at the end of therapy in group A compared to group B (p<0.01). Survival outcomes and molecular profiling data will be presented in the meeting. Conclusion: Alternate q 4 week dosing schedule of pemetrexed is feasible and associated with longer time on treatment. There appears to be no difference in toxicities experienced between the two treatment schedules in this cohort.

Keywords: maintenance pemetrexed, alternate schedule. Real world data

P2.15-25 NIVELIX TRIAL (GECP 1605): NIVOLUMAB IN THE REAL WORLD: SPANISH EXPANDED ACCESS PROGRAM EXPERIENCE IN PRETREATED ADVANCED NSCLC PATIENTS
D. Rodríguez-Abreu1, J. Campillo2, F. Grau3, E. Carcereny4, R. Bernabé5, Y. García6, A. Artal Cortés7, M. González Caño8, O. Juan9, F. Garicano10, I. Gil-Bazo11, R. Blanco12, M. Guillot13, M. Provencio14, M. Majem15
1Univeristat Autònoma de Barcelona, Esplugues de Llobreda/ES, 2Hospital Universitari Vall d’Hebron, Barcelona/ES, 3Medical Oncology, Instituto de Investigación Sanitaria La Fe, Valencia/ES, 4Hospital Universitario de la Princesa, Madrid/ES, 5Hospital Universitario 12 de Octubre, Madrid/ES, 6Hospital Universitario de Salamanca, Salamanca/ES, 7Hospital Universitario de Salamanca, Salamanca/ES, 8Hospital Universitario de Navarra, Pamplona/ES, 9Hospital Universitario de Navarra, Pamplona/ES, 10Hospital Universitario de Navarra, Pamplona/ES, 11Hospital Universitario de Navarra, Pamplona/ES, 12Hospital Universitario de Navarra, Pamplona/ES, 13Hospital Universitario de Navarra, Pamplona/ES, 14Hospital Universitario de Navarra, Pamplona/ES, 15Hospital Universitario de Navarra, Pamplona/ES

Background: Nivolumab is a standard treatment for pretreated patients with advanced non-small cell lung cancer (NSCLC). Real world data about toxicity and efficacy of nivolumab is needed. Method: We have analyzed patients from the Expanded Access Program in Spain that included patients with advanced pretreated NSCLC. We have retrospectively analyzed 665 patients that had received nivolumab within 3mg/kg q2w from 01/2015 for squamous (Sq) and 06/2015 for non-Sq NSCLC. To 11/2017. Result: Median age was 61 (32-85) years. 73% were men, 85% had EG0 C-1, 88% were current or former smokers and 15% presented brain metastases. 128 (19,2%) patients presented Sq NSCLC and 537 (80,8%) patients Non-Sq NSCLC. 7% of patients presented EGFR mutation. PD-L1 was > 1% in 32,9% of analyzed patients. Best response was complete response 1,7%, partial response 22,4%, stable disease 24,1%, and progressive disease 37,1%, and was not assessed in 14,7% of patients. No differences in response rate were observed according to histology. After a median follow-up of 8,2 months, the median OS was 8,97 (95%CI 7,69-10,24) months, and the median PFS was 3,23 (95%CI 2,77-3,70) months. Estimated 1-year OS was 42,4% (95%CI 38,5-42,8%) and estimated 1-year PFS was 22,2% (95%CI 19,1-25,3). No differences in OS or PFS according to histologies were observed. 296 (44,5%) patients presented toxicity related to Nivolumab, that was grade ≥3 in 69 (10,4%) patients. Grade ≥3 diarrhea was reported in 1,2% of patients and pneumonitis occurred in 1,2% of patients (1 patient presented a grade 5 pneumonitis). According to the presence of grade ≥3 toxicity, the median OS was 14,57 (#C95% 8,45-20,68) months for patients with grade ≥3 toxicity and 8,73 (#C95% 7,50-9,96) months for patients without grade ≥3 toxicity (p= 0,074). Additional efficacy data including treatment lines, presence of immune-related adverse events, PS2, brain metastasis, response to first line, or post-nivolumab treatment will be presented.

Conclusion: Efficacy and safety of nivolumab was in line with previously shown data. There was a trend to a better OS for those patients experiencing grade ≥3 toxicity.

Keywords: real world, nivolumab, NSCLC

P2.15-26 RATES AND ECONOMIC BURDEN OF ADVERSE EVENTS IN PATIENTS WITH METASTATIC NSCLC TREATED WITH EGFR-TKIS
J. Subramanian1, F. Laliberté2, A. Fernandes3, M. Pavilack3, P. Jacques2, M. S. Duh3

Background: Trials of first- and second-generation epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitors (TKIs) have reported severe adverse events (SAEs) in 6%–49% of patients with EGFR-mutant (EGFRm) metastatic non-small-cell lung cancer (mNSCLC). This study describes the real-world rates and incremental cost of AEs in this population. Method: Adults with mNSCLC treated with EGFR-TKIs as first-line therapy (first dispensed defined as the index date) with ≥1 lung cancer diagnosis code, no claim for a lung surgery, and no administration of other NSCLC therapies during 3 months pre-index date were identified from the IQVIA™ Real-World Data Adjudicated Claims – US database (Q2/2012–Q1/2017). The select AEs identified from prescribing information of EGFR-TKIs were skin and ocular disorders, interstitial lung disease (ILD), diarrhea, microangiopathic hemolytic anemia, gastrointestinal perforation, cardiac and cerebrovascular events, renal failure, and hematotoxicity. AE rates per 1,000 patient-years and healthcare cost per-patient-per-month (PPPM) were calculated during first-line therapy. Multivariate linear regression was used to assess cost differences (CD) for patients with and without AEs, adjusting for baseline characteristics. All AEs (outpatient and hospitalization claims) and a subgroup of SAEs (hospitalization claims) were analyzed. Result: Among 1,646 patients, 86.1% were treated with erlotinib, 12.1% with afatinib, and 1.0% with gefitinib. During first-line therapy, 549 patients had ≥1 acute AE (33.4%, 870.9 per 1,000 patient-years) and 200 patients had ≥1 acute SAE (12.2%, 220.1 per 1,000 patient-years). Skin and ocular disorders (17.6%, 482.9 per 1,000 patient-years) and ILD (4.5%, 139.6 per 1,000 patient-years) had the highest rate among all AEs and SAEs, respectively (Figure). Patients with AEs had higher PPPM healthcare costs than patients without AEs (all AEs: CD=$1,079, p<0.001; SAEs: CD=$5,700, p<0.001).

LUNG VOLUME CHANGE AFTER LOBECTOMY ESTIMATED BY THREE-DIMENSIONAL IMAGE ANALYSIS SYSTEM

H. Suzuki1, H. Tsunezuka2, M. Inoue2

1Division of Thoracic Surgery, Osaka General Hospital of West Japan Railway Company, Osaka/JP, 2Division of Thoracic Surgery, Kyoto Prefectural University of Medicine, Kyoto/JP

Background: High-precision three-dimensional (3D) image analysis system has been used for preoperative planning in various fields including thoracic surgery. Such software has made us quite easy to measure lung volume. Change of pulmonary function after surgery has been surveyed in some reports, but there are few reports about lung volume change after surgery.

Method: We conducted a retrospective review of 49 patients who underwent lobectomy between January 2014 and June 2016 at General Hospital of Japan Railway Company. We used 3D image analysis system (SYNAPSE VINCENT, Fujifilm Corp, Tokyo, Japan) to calculate lung volume of each patient from computed tomography (CT) images which were taken twice, before surgery and 6 months after surgery. We estimated lung volume change from the difference between those two values.

Result: There were 19 right upper lobectomies (RUL), 7 right middle lobectomies (RML), 8 right lower lobectomies (RLL), 5 left upper lobectomies (LUL), and 10 left lower lobectomies (LLL). We performed lobectomies in three different surgical approaches; Thoracotomy (n=5), Hybrid Video-assisted thoracic surgery (VATS) (n=24), Complete VATS (n=20). 7 patients needed pleurodesis after surgery to treat air leakage. The average of total lung volume change was -10.4%. Right lobectomies showed 11.45% decrease of lung volume in average, while left lobectomies showed 5.34% decrease (p=0.18). Decrease ratio seemed to depend on the way of approaches; Thoracotomy was -19.98% and VATS (hybrid and complete) was -8.58% (p=0.12). Volume change of patients who underwent pleurodesis after surgery was -20.37%, while the ratio of the others was -7.84% (p=0.03).

Conclusion: Over one-tenth of patients suffered from SAEs, resulting in a sizeable economic burden. EGFR-TKIs with more favorable safety profiles may reduce substantial healthcare costs in this patient population.

Keywords: NSCLC, adverse events

Conclusion: VATS seemed to be better in the point of lung volume after lobectomy than thoracotomy. Pleurodesis turned out to reduce lung volume significantly. For further study, we will compare lung volume with pulmonary function on a larger amount of data.

Keywords: lung volume, lobectomy, 3D image analysis
Conclusion: Thai NSCLC patients with NHSI coverage were more likely to experience shorter overall survival than those with GEI. The difference in medical coverage in each type of insurance was especially in terms of coverage, treatment outcome, and immunotherapy may be associated with overall survival of patients. The Thai government should take into account this difference.

Keywords: Coverage, treatment outcome, Thai insurance
Conclusion: In a non-selected advanced SQ-NSCLC population, only half of these patients are ineligible to a second line anti-angiogenic treatments with a wide majority of tumoral blood vessel extensions and cavitations.

In collaboration with the GFPC* team and supported by an academic grant from Lilly pharmaceuticals. *GFPC: French Lung Cancer Group

**P2.15-30 MARITAL STATUS AND SURVIVAL IN PATIENTS WITH LUNG CANCER**

B. Wang, X. Wang

Northern Jiangsu People’S Hospital, Yangzhou/CN

**Background:** Multiple studies have shown that marital status is associated with the survival of various types of cancer patients. Majority of the findings support high survival rate for married patients is closely related to well social support and family care. However, another conclusion that there is no correlation between marital status and the length of cancer survival makes it controversial when talking about the survival benefit of cancer patients. To better explain the issue, here we did further investigation to study the effect of marital status on survival of lung cancer patients.

**Method:** In this study, we retrospectively extracted 136535 eligible lung cancer patients from the Surveillance, Epidemiology, and End Results (SEER) database in the period from 2010 to 2014. Marital status was categorized as married, divorced/separated, widowed, and Single/Partner. The latter three are classified as unmarried. Meanwhile, 1:1 propensity scores for marital status, which were calculated for each patient using a multivariable logistic regression model, were used to match 64749 unmarried patients with 71786 married patients. With accurate matching, the fault tolerance rate is set to 0. Chi-square tests were used to investigate the association between marital status and other variables. The Kaplan-Meier test was adopted to compare survival curves of different groups. Multivariate Cox regression analyses were conducted to estimate the effect of marital status on OS and CSS.

**Result:** We exactly matched 37105 unmarried patients with 37105 married patients. Married patients had higher OS than unmarried patients before matching (OS; HR: 0.903(0.891-0.916), P<0.001; CSS; HR: 0.917(0.904-0.931), P<0.001). But after matching, the OS is undifferentiated between married patients and unmarried patients (OS: HR: 0.985(0.967-1.003), P=0.1; CSS: HR: 1.004(0.985-1.024), P =0.695). Then we carried out subgroup COX analyses stratified by AJCC stage for OS and CSS. Result hints that the prognosis of married patients is better than that of unmarried patients in Stage I and II patients in lung cancer.

**Conclusion:** Marital status affects the prognosis of patients with advanced lung cancer. the prognosis of married patients is better than that of unmarried patients.

**Keywords:** lung cancer, SEER database, Marital status

**P2.15-31 THE EVOLUTION OF COSTS IN THE TREATMENT OF ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC) IN ONTARIO, CANADA BETWEEN 1999 TO 2014**

Y. Wang1, G. Pond2, A. Gafni3, H. Seow4, P. Ellis1

1Medical Oncology, McMaster University, Juravinski Hospital and Cancer Centre, Hamilton/CA, 2Department of Oncology, Ontario Clinical Oncology Group (Ocog), McMaster University, Hamilton/ON/CA, 3Department of Health Research Methods, Evidence, and Impact (Hei), McMaster University, Hamilton/ON/CA

**Background:** Treatment options for patients with advanced non-small cell lung cancer (NSCLC) have evolved substantially since the 1990s. Newer agents are more expensive to acquire and administer and the perception is the cost of lung cancer care has increased considerably in the last two decades. We conducted a cost analysis study to evaluate changes in the total cost of NSCLC care over time.

**Method:** We conducted a retrospective cohort study of all NSCLC patients diagnosed in Ontario from Apr 1, 1999 to Mar 30, 2014, who received palliative chemotherapy for advanced disease. Variables of interest were extracted from provincial registry data electronically linked by the Institute for Clinical Evaluative Sciences (ICES). The use of oral systemic therapy is not universally captured in these databases. The mean total cost of care including, systemic therapy, and supportive care (hospitalizations, physician billings, lab tests, out-patient visits, emergency visits, home care, and most prescription medications), was calculated in 2015 CAD dollars by fiscal year of diagnosis. Regression analysis was used to project costs in years with missing supportive care costs.

**Result:** Of all NSCLC cases diagnosed in Ontario (n=89,936), 21.6% (n=19,447) received any chemotherapy. We conducted a cost analysis study to evaluate changes in the total cost of NSCLC care over time.

**Conclusion:** The cost of systemic therapy for lung cancer patients is rising disproportionately to that of supportive care. Ongoing analyses are assessing the main drivers of cost of care and model the impact of oral targeted therapies and immunotherapies on the cost of lung cancer care.

**Keywords:** registry data, Cost analysis, advanced NSCLC
P2.15-32 NOVICE TRAINING: THE TIME COURSE FOR DEVELOPING COMPETENCE IN SINGLE PORT VIDEO-ASSISTED THORACOSCOPIC LOBECTOMY
C.F. Wu, M. Paradela, C.Y. Wu, D. Gonzalez-Rivas, Y. Chao
1Division of Thoracic and Cardiovascular Surgery, Department of Surgery, Chang Gung Memorial Hospital, Taoyuan County/TW, 2Coruna University Hospital, La Coruna/ES

Background: The competency in video-assisted thoracoscopic (VATS) lobectomy is expected to be achieved after surgeons practiced 30 to 50 cases according to previous reports. Does single port video-assisted thoracoscopic (SPVATS) lobectomy have a steeper learning curve and being harder to perform correctly, leading to long development times and high defect rates? Method: From January,2014 to February,2017, 8 individual surgeons (3 were novices, 5 were pioneers in SPVATS surgery) submitted their cases chronologically to evaluate the learning curve of SPVATS lobectomy. Propensity score match between two groups and cumulative sum(CUSUM) method were used to explore evolution of learning curve Result: Before propensity-score matching, a total of 356 cases were included (93 in junior consultant group (group A), 263 in senior consultant group (group B). There were no differences between the groups in operative time, conversion rate, postoperative complication rate, 30 and 90 day mortality rate. After propensity-score matching, operative time was longer in group A (214.33±62.18 v.s 183.62±61.25 mins, p=0.001). 2-year overall survival rate was similar among two groups (p=0.409). Competency was reached after junior surgeon completed 30th case if SPVATS lobectomy.

Conclusion: SPVATS lobectomy is safe for the novice surgeon who wants to adopt this new surgical approach under well-developed training program. The learning curves for competence in SPVATS lobectomy is similar to VATS lobectomy in our series.

Keywords: Single port VATS, learning curve, novice

P2.15 TREATMENT IN THE REAL WORLD - SUPPORT, SURVIVORSHIP, SYSTEMS RESEARCH
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.15-33 EVALUATION OF LIQUID BIOPSIES FOR MOLECULAR PROFILING IN PATIENTS (PTS) WITH ADVANCED NSCLC: WHAT HAPPENS AFTER PANEL TESTING BY NGS?
J. Zhao, S. Jiqiao, X. Li, C. Su, C. Zhou
Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN

Background: Molecular profiling is limited by tumor heterogeneity and access to sufficient tissue for comprehensive analysis. Circulating tumor DNA (ctDNA) is promising as a minimally-invasive liquid biopsy for testing gene alterations and monitoring personalised treatment strategies. Because of its high expense, translation of the sensitive and accurate next generation sequencing (NGS) into routine cancer care has been slow. Method: We retrospectively reviewed 60 advanced NSCLC pts who were performed gene test prior to treatment using tissue by ARMS. Blood collections (10ml K2-EDTA) were performed after disease progression and analysed by NGS using a 30-gene panel (EGFR, KRAS, BRAF, HER2, PIK3CA, ALK, ROS1, RET, MET and TP53). We evaluated the significance of the outcome of panel testing by NGS in guiding the subsequent treatment in clinical practice. Result: Among 60 NSCLC pts, 39 were male, 28 were never-smokers, and 56 were adenocarcinoma. ctDNA profiling detected alterations in 50 pts (83%). TP53 (53%), EGFR (48%) and KRAS (15%) were the most commonly detected. 25 pts (41%) received tyrosine kinase inhibitor (TKI) as first-line therapy. Among 20 EGFR mutant pts, T790M mutation was detected in 9 pts (45%), KRAS mutation was detected in 4 pts (20%), and TP53 mutation was detected in 13 pts (60%). While MET amplification was found in 1 pt (5%), 1 KRAS mutation and 1 TP53 mutation were detected in 2 ALK –TKI resistant pts, respectively. 28 pts (47%) reported as tissue negative had a positive liquid biopsy, including 4 MET 14 exon skipping mutations, 2 EGFR 19 DEL, 4 EGFR L858R and 1 EGFR L861Q, and 2 EGFR T790M mutations. The mutation abundance is all below 1%, except 2 EGFR DEL and 4 L858R. Ten pts received TKIs; 2 got partial responses, 5 stable diseases and 3 progressive disease. Conclusion: ctDNA can be used as a ‘liquid biopsy’ for molecular profiling of NSCLC pts, and NGS, as a highly sensitive method to detect mutations with low mutation abundance, can provide more chances to pts to receive precise treatment.

Keywords: next generation sequencing, non-small cell lung cancer, liquid biopsy

P2.16-01 PROGNOSTIC SIGNIFICANCE OF PREOPERATIVE CONSOLIDATION TO MAXIMUM TUMOR DIAMETER RATIO AND SUV-MAX IN PATHOLOGICAL STAGE I LUNG ADENOCARCINOMA

Background: Findings on computed tomography like tumor size, amount of consolidation and ground glass opacity, size of the solid component, maximum standardized uptake value by 18F-fluorodeoxyglucose positron emission tomography/CT and the ratio of the size of solid attenuation to the maximum tumor dimension (consolidation/tumor [C/T] ratio) are predictive for pathologic subtypes and prognosis after resection. There are many number of study about clinical early stage lung cancer in terms of C/T ratio. We aimed to investigate prognostic value of C/T ratio and SUV-max among patients with pathological stage I lung adenocarcinoma. Method: 258 patients were reviewed by using institution’s records who had undergone surgery for early stage lung adenocarcinoma. Only patients with pathological stage I (T1a, T1b and T2a without lymph node metastasis) were included. Synchronous tumor, oligometastatic disease and history of other organ malignancy was exclusion criteria. 14th TNM edition was used. Totally 168 patients’ demographic data, surgery types, clinical and pathological stage, pre-operative SUVmax and C/T ratio was recorded. Differences between patients with recurrence after surgery and without recurrence was demonstrated. Survival rates were analysed by divided into 3 groups according to C/T ratio (0.25-0.5, 0.5-0.75, 0.75-1.0) and cut-off value 50% of C/T ratio. Result: Two groups (C/T<0.5 and C/T=0.5-1) did not differ according to comparable factors like visceral pleural invasion, subtype of adenocarcinoma, median SUVmax. Median follow up time was 35 months. 54 patients were died of whom 8 (68%) patients were in C/T ratio<0.5 and 46 patients (67.8%) were in C/T=0.5-1 group. OS was 44.9±5.07 and PFS was 50.8±5.42 in CT<0.5 and C/T=0.5-1 group. OS was 69.7±3.34 and PFS was 77.2±3.12 in C/T=0.5-1 group (p=0.05). Three-year survival rate was 50% for C/T<0.5 and 72% for C/T=0.5-1 group (p=0.05). Mean SUVmax is 8.05±6.04 for C/T<0.5 and 10.07±6.85 for C/T<0.5% (p=0.43). Existence of visceral pleural invasion was higher in patients with C/T<0.5 (69 patients vs 6 patients, p=0.05). In univariate analyses age, gender and SUVmax value and in multivariate analyses only surgery type and SUV max value were predictors for OS (Surgery type: HR:1.33 (1.04-1.70), p=0.02 and SUVmax: HR:1.04 (1.00-1.08), p=0.04). For PFS, only surgery type had significant difference both univariate and multivariate analyses (Univariate: HR: 1.47 (1.15-1.89), p=0.002 and multivariate: HR: 1.67 (1.25-2.23), p<0.001). Conclusion: In pathological stage 1 lung adenocarcinomas, SUVmax and surgery type are important predictors for OS. For PFS only surgery type has significance. Even visceral pleural invasion rates are higher in C/T<0.5 group. SUVmax is superior to the C/T ratio for predicting prognosis particularly for solid type lung cancer.

Keywords: Consolidation/tumor ratio, SUVmax, Prognosis
P2.16-02 PREDICTING PATHOLOGICAL NONINVASIVENESS IN T1 NON-SMALL CELL LUNG CANCER ON CHEST CT SCAN USING DEEP LEARNING ALGORITHM
K. Beck1, S. Park1, J.H. Hong1, S.J. Na1, Y.H. Ko1
1Radiology, Seoul St. Mary's Hospital, College of Medicine, the Catholic University of Korea, Seoul/KR; 2Deagene Inc. Kast, Daegu/KR; 3Division of Oncology, Department of Internal Medicine, College of Medicine, the Catholic University of Korea, Seoul, Republic of Korea; 4Nucler Medicine, College of Medicine, the Catholic University of Korea, Seoul/KR; 5Division of Oncology, Department of Internal Medicine, College of Medicine, the Catholic University of Korea, Seoul/KR

Background: Because of the risk of recurrence, lobectomy is indicated even for small lung cancers. If we could accurately predict and classify noninvasive small lung cancers on CT images using deep learning algorithm prior to surgery, a more refined selection of candidates who would benefit from limited resection without increasing the risk of recurrence would be possible. The purpose of this study was to evaluate the ability of an artificial intelligence (deep learning algorithm) to predict pathological noninvasiveness of T1 non-small cell lung cancer (NSCLC) using computed tomography (CT) images. Method: 468 preoperative CT images of NSCLC smaller than 3 cm, resected from our institution from 2008 to 2015 were used to train and validate the deep learning algorithm. Noninvasiveness was defined as the absence of nodal involvement, vascular or lymphatic invasion, and malignant invasion. End points were classified as either noninvasive or invasive according to the pathological reports. A deep 3D convolutional neural network (CNN) was trained using 5-fold cross-validation method. To normalize input data, we rescaled CT image to let the voxel size be represented as (1mm,1mm,1mm). Input image size was (32mm, 32mm, 32mm). Horizontal flip and vertical flip augmentation were applied, and max-pooling and dropout layer were used to avoid overfitting. Receiver operating characteristic (ROC) curves and areas under the curve (AUCs), accuracy, and sensitivity/specificity were used to assess the performance of 3D CNN. We also added tumor size as an external feature to the 3D CNN model and evaluated the performance of the combined model using Kxgboss classifier. Result: 157 out of 486 samples (33.5%) were invasive. A subsample group composed of 10% of the data (32 noninvasive and 16 invasive samples) was retained for the validation set. The 3D CNN showed an AUC of 0.826. 77.08% accuracy, 68.7% sensitivity, and 81.2% specificity. Adding tumor size to the 3D CNN model showed an AUC of 0.855, 81.2% accuracy, 87.5% sensitivity, and 78.1% specificity. Conclusion: Artificial intelligence can accurately predict pathological noninvasiveness in T1 size NSCLC on CT images.

P2.16-03 CHECKMATE 816: A PHASE 3 TRIAL OF NEOADJUVANT NIVOLUMAB PLUS IPILIMUMAB OR CHEMOTHERAPY VS CHEMOTHERAPY IN EARLY-STAGE NSCLC
1Vall d'Hebron Institute of Oncology, Barcelona/ES; 2Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore/MA/US; 3Dana-Farber Cancer Institute, Boston/MA/US; 4Thoracic Surgery, Kindai University Faculty of Medicine, Higashiosaka City, Osaka/JP; 5Institut Curie, Paris/FR; 6Pathology, Aberdeen Royal Infirmary, Aberdeen/GB; 7Division of Thoracic Surgery, McGill University Health Centre, Montreal/QC/CA; 8Bristol-Myers Squibb, Princeton/NJ/US

Background: Approximately 20–25% of patients with NSCLC are diagnosed with early or localized disease, which has a relapse rate of 36%–60% with surgery. Although neoadjuvant chemotherapy can reduce the risk of relapse, it only provides a pathological complete response (pCR; no viable tumor cells) rate of 4%. The neoadjuvant setting presents abundant tumor-associated neoantigens derived from the primary tumor that may allow immunotherapy to prime a long-lasting immune response. Clinical trial results support the use of immuno-oncology agents as neoadjuvant treatment for early-stage NSCLC. In a pilot study in patients with untreated, surgically resectable early-stage (stage I–IIIA) NSCLC, nivolumab (a fully human PD-1 immune checkpoint inhibitor antibody) and nivolumab plus ipilimumab (a CTLA-4 immune checkpoint inhibitor antibody) were administered as neoadjuvant treatment (3 mg/kg for 2 cycles during the 4 weeks prior to surgery) induced a pCR in 10% of patients and a major pathological response (MPR; ≤10% residual viable tumor cells in resected primary tumor) in 45% of patients. nivolumab and nivolumab plus platinum-doublet chemotherapy, and platinum-doublet chemotherapy as neoadjuvant treatment for early-stage NSCLC. Method: A total of 642 patients aged ≥18 years with early-stage (stages IB–IIIA) resectable NSCLC, ECOG performance status 0–1, pulmonary function capable of tolerating lung resection, and available lung tissue will be enrolled in North America, South America, Europe, Asia, and Africa. Patients are ineligible if they have active autoimmune disease or had received prior treatment with immune checkpoint inhibitors. Patients will be randomized (1:1:1) to receive neoadjuvant nivolumab plus ipilimumab, nivolumab plus platinum-doublet chemotherapy, or platinum-doublet chemotherapy. Primary endpoints are event-free survival and pCR. Key secondary endpoints are overall survival and MPR (≤10% residual tumor in lung and lymph nodes). The start date was January 2017. The estimated primary completion date is May 2023. Result: Section not applicable. Conclusion: Section not applicable

Keywords: neoadjuvant, Nivolumab, NSCLC

P2.16-04 PROGNOSTIC VALUE OF LYMPHOVASCULAR INVASION AND EFFECT ON PATTERNS OF RECURRANCE IN T1-3N0 NON-SMALL CELL LUNG CANCER
Y.S. Kim1, J.H. Hong1, S.Y. Sung2, Y. Kwak2, S. Lee1, J.K. Park1, K.S. Kim2, K.Y. Lee1
1Department of Radiation Oncology, Seoul St. Mary's Hospital, Seoul/KR; 2Department of Thoracic & Cardiovascular Surgery, Seoul St. Mary's Hospital, Seoul/KR; 3Department of Pathology, Seoul St. Mary's Hospital, Seoul/KR

Background: The purpose of this study is to clarify the prognostic value of lymphovascular invasion (LVI) in patients with surgically resected T1-3N0 non-small cell lung cancer (NSCLC) according to the eighth edition of the TNM Classification of the AJCC. Methods: A total of 442 NSCLC patients who received curative surgery and were confirmed with pathologic T1-3N0 between March 2000 and August 2015 were reviewed. The pathological stages were re-evaluated according to the eighth edition of the TNM Classification of the AJCC. Result: The 5-year recurrence-free survival (RFS) rate for total cohort was 69.7%, and the 5-year overall survival (OS) rate was 78.0%. LVI was present in 89 patients (19.9%). The presence of LVI decreased the 5-year RFS rate significantly (47.5% vs. 72.3% in patients without LVI, p < 0.001) and the 5-year OS rate (62.5% vs. 81.1%, p < 0.001). The differences between LVI group and non-LVI group were more remarkable in T2a-bN0 staged patients compared with T1a-c staged patients (T1a-c patients: 63.6% vs. 46.2%, p = 0.029; T2a-b patients: 74.4% vs. 52.2%, p = 0.029; T2a-bN0 patients: 71.1% vs. 41.5%, p = 0.026). Survival analysis revealed that the presence of LVI was a significant predictor for RFS (p < 0.001) but an insignificant factor for OS. In T2a-bN0 staged patients, the 5-year OS rate was significantly lower in patients with LVI than in patients without LVI (50.0% vs. 74.4%, p = 0.045), whereas T1a-c staged patients did not show a significant difference in 5-year OS according to the presence of LVI (p = 0.196). Conclusion: LVI is a significant associated factor for RFS in patients with stage 1-3N0 NSCLC. Prognostic impact of LVI is more remarkable in patients with more than T2N0 stage compared to patients with the T1N0 disease.

Keywords: non small cell lung cancer, lymphovascular invasion, patterns of recurrence

P2.16-05 HYPERMETHYLATION OF SOX1, RASSF1A, HOXA9, CDH13 AND DAPK GENES PLAYS A ROLE IN NSCLC PATHOGENESIS
M. Kontic1, D. Jovanovic1, S. Oganjnovic2
1Oncology, Clinic for Pulmonology, Clinical Centre of Serbia, Belgrade/RS; 2Mayo Graduate School, Mayo Clinic, Rochester/MI/US

Background: A number of genes have been reported as aberrantly methylated in lung tumors. Here, we investigate the relationship between gene methylation in lung tumors relative to matching normal lung tissue.
and whether DNA methylation changes can be detected in paired blood samples. **Method:** Primary tumor samples (n=65), corresponding nonmalignant lung tissues (n=65) and matching blood samples (n=51) were obtained from NSCLC patients undergoing curative resectional surgery. Using bisulfite pyrosequencing, CpG methylation was quantified at seven genes (RASSF1A, CDH13, MGMT, ESRI, HOXA9, SOX1 and DAPK) in lung tumor, matching pathologically normal lung tissue, and circulating blood samples. We wanted to determine whether these methylation changes are specific to lung tumors, and test whether these changes are detectable in patients’ blood samples. We also analyzed possible associations between DNA methylation and clinicopathologic features. **Result:** We observed that genes SOX1, RASSF1A, HOXA9, CDH13 and DAPK were significantly hypermethylated in lung tumors compared to match normal tissue. However, these changes could not be detected in patients’ blood samples, indicating a low feasibility of detecting lung cancer by analyzing these genes in a blood-based test. We confirmed that hypermethylation of SOX1, RASSF1A, HOXA9, CDH13 and DAPK play a role in NSCLC pathogenesis, but also showed that these genes are not suitable markers for early detection of NSCLC. Lastly, we confirmed that hypermethylation of SOX1, RASSF1A, HOXA9, CDH13 and DAPK were associated with methylation at the CDH13 gene, while stage was associated with methylation at MGMT.

**Conclusion:** Our results show higher methylation of SOX1, RASSF1A, HOXA9, CDH13 and DAPK genes in lung tumors compared to matching normal lung tissue. The lack of reflection of these methylation changes in blood samples from patients with NSCLC indicates their poor suitability for a screening test.

**P2.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.16-06 DEVELOPMENT AND VALIDATION OF A GENE EXPRESSION-BASED NOMOGRAM TO PREDICT RELAPSE IN STAGE I NSCLC: A RETROSPECTIVE, MULTI-COHORT STUDY**

Q. Mao, L. Xu

Thoracic Surgery, Jiangsu Cancer Hospital, Nanjing/CN

**Background:** Increasing patients were diagnosed with stage I non-small cell lung cancer (NSCLC), and in 30% of diagnosed patients, recurrence will develop within 5 years. Optimal postoperative adjuvant therapy is still ambiguous for stage I NSCLC. Here, we aimed to develop and validate a feasible tool for recurrent risk assessment of stage I NSCLC. **Method:** This retrospective study incorporated the gene expression profiles from 14 public NSCLC cohorts, including 13 microarray data sets and 1 RNA-Seq data set for The Cancer Genome Atlas (TCGA) lung adenocarcinoma cohort. In discovery phase, multiple eligible microarray data sets were used to select statistically significant genes thought to be predictive by two algorithms, Least Absolute Shrinkage and Selector Operation and Support Vector Machine-Recursive Feature Elimination. In the training phase, candidate genes were used to generate a recurrence related signature in TCGA cohort by penalized Cox regression. Recurrence related signature and other clinical variables were included in the discovery phase. 42 significant genes were used as candidate predictors by two algorithms. A 13-gene based signature related to recurrence were generated by penalized cox regression and categorized training cohort into high-risk and low risk subgroups with significantly different recurrence free survival (HR = 8.873, 95% CI: 4.228-18.480, P<0.001). The performance of signature was tested in two external cohorts: HR=3.256, 95%CI: 1.226-8.286, P=0.001; HR=2.586, 95%CI: 1.226-5.286, P=0.007). Furthermore, a nomogram integrating recurrence related signature, age, and histology was developed to predict the recurrence-free survival in the training cohort, and it performed well in the two external validation cohorts. Concordance index: 0.737, 95%CI:0.732-0.742, P<0.001; 0.666, 95%CI: 0.650-0.682, P<0.001; 0.651, 95%CI: 0.637-0.665, P<0.001 respectively. **Conclusion:** The proposed nomogram is a promising tool for estimating recurrence free survival in stage I NSCLC, which might have tremendous value in guiding adjuvant therapy. Prospective studies are needed to test the clinical utility of the nomogram in individualized management of stage I NSCLC.

P2.16 INFLUENCE OF TUMOUR LOCATION AND HISTOLOGICAL SUB-TYPE OF NON-SMALL CELL LUNG CANCER ON PATIENT SURVIVAL

A. McWilliam, A. Davey, E. Vasquez Osorio, M. Aznar, C. Faivre-Finn, M. Van Herk
Division of Cancer Sciences, University of Manchester, Manchester/GB

**Background:** In non-small cell lung cancer (NSCLC), adenocarcinomas tend to arise peripherally and squamous cell carcinomas (SCC) centrally. Tumour location is known to impact patient survival: in previous work, we showed that right-sided tumours show worse survival, n=1101; HR=1.25, p<0.01. In this study we extended the laterality analysis by including histological sub-type and explore its correlation with overall survival.

**Method:** 529 unselected NSCLC patients (treated with 55Gy/20fr), with confirmed adenocarcinoma or SCC, were included. All patients were spatially normalised using non-rigid registration to a reference anatomy, allowing tumour probability maps to be created from the outlined tumours. A Kolmogorov-Smirnov test assessed differences in distributions. Kaplan-Meier curves, grouped by histological sub-type, were plotted. Tumour volumes were extracted for all patients and included in a multi-variate analysis including N-stage, performance status, gender and median dose to left and right lungs, encoding laterality. Result: 326 adenocarcinomas and 203 SCC were found. Tumour probability maps show a clear separation in tumour locations between the sub-types (Fig.1a, p<0.001) and a general location of SCC tumours along the major airways. Tumour volumes were significantly different (SCC larger, median 56cm³ versus 14cm³, p<0.001, Fig.1b). Histology also influences nodal involvement, 20% adenocarcinomas versus 80% SCC are N+. Location and volume impacts on normal tissue doses, mean lung and heart doses: 8.8Gy and 4.9Gy for adenocarcinomas, 15.6Gy and 18.8Gy for SCC. SCC patients showed worse survival (median 12 versus 21 months, Fig.1c). Multivariate analysis shows right lung mean doses significantly correlate with survival for adenocarcinomas, p=0.04, but not for SCC, p=0.2, indicating the spatial location of the tumour may have an interaction with our previously described laterality effect.

**Conclusion:** Differences in the spatial locations and volumes of histological sub-types influence normal tissue doses including the effect of tumour laterality on survival. Further work will explore possible mechanisms, including ventilation/perfusion variation in the lungs.

**Keywords:** Radiotherapy, histology, normal tissue dose
The Kaplan-Meier method, and the estimates were compared with the analysis for OS and recurrence-free survival (RFS) was conducted with the peak level of postoperative CRP could serve as a prognostic marker with cancer progression; however, the prognostic impact of elevated CRP was not understood. The purpose of this study is to evaluate the prognostic role of combined pulmonary fibrosis and emphysema (CPFE) in patients with clinical stage I primary lung cancer with interstitial pneumonia (IP). Method: We defined as the presence of both emphysema and IP on high-resolution computed tomography (HRCT). Of 836 consecutive patients with clinical stage I primary lung cancer who underwent complete resection between April 2007 and March 2016, 65 patients with CPFE were identified. The log-rank tests and Cox proportional hazard models were used to test for survival differences. Result: There was a significant difference in overall survival (OS) between patients with CPFE (n = 65: 5 y-OS rates, 62.6%) and those without CPFE (n = 771: 5 y-OS rates, 66.3%, P < 0.001). However, in patients with interstitial pneumonia, multivariable backward stepwise Cox analysis revealed that histology, NSCLC, radiologic il-5 pattern, and surgical procedure were independent prognostic factors for OS, but the presence of CPFE was not. Conclusion: CPFE was not an independent prognostic factor for OS in patients with clinical stage I lung cancer with IP. The presence of interstitial pneumonia pattern may explain poor survival in patients with CPFE.

Keywords: Combined pulmonary fibrosis and emphysema, lung cancer, Interstitial pneumonia.

P2.16-12 EXPANDED DATA CONFIRM MOLECULAR TESTING IDENTIFIES LUNG ADENOCARCINOMA PATIENTS, INCLUDING STAGE IA, WHO BENEFIT FROM ADJUVANT CHEMOTHERAPY

Surgery, University of California, San Francisco, San Francisco/CA/US

Background: A clinically certified, 14-gene quantitative PCR expression assay has been validated to assess mortality risk in early-stage lung adenocarcinoma. Molecular stratification may identify those stage I-II A patients who are in most need of potentially life-saving intervention after resection, including stage IA patients for whom chemotherapy is never recommended. Method: Prospective molecular risk-stratification by the 14-gene assay was performed on 200 consecutive patients with stage I-II A lung adenocarcinoma after complete surgical resection at a single institution. Adjuvant chemotherapy was recommended for molecular high-risk patients. Kaplan-Meier analysis and log-rank tests were used to evaluate differences in disease free survival. Result: Average age of 34.4 years. Proportion of stage I patients was 62%. 50% of patients had stage I IA disease. Inclusion criteria were: no evidence of extracapsular or intrapulmonary lymph node involvement, no residual tumor at surgical margin, no vascular invasion, and no other metastatic disease. The median follow-up was 2 years. Results: The study population included 198 patients. 14-gene expression levels were measured on formalin-fixed paraffin-embedded tissue from resected specimens by quantitative real-time PCR. The 14-gene expression was categorized into high and low risk groups using a previously validated threshold. Result: In this study, 148 patients (74.7%) were alive and 50 had deceased (25.3%). The median length of follow-up for all cases was 61.3 months (2.3 years) (IQR = 85.8). Pathological staging was significantly lower in the high CRP group than the low CRP group, (75.3% vs. 85.6%; P = 0.016). This was also seen for the pathological stage II and III patients (61.2% [95% CI=38.8–77.5] vs. 81.0% [95% CI=63.9–90.6]; P = 0.045). A Cox hazard proportional model for OS adjusted for age, sex, smoking history, pathological staging, and Glasgow prognostic score revealed that high CRP was associated with a favorable prognosis (hazard ratio, 0.36; 95%CI=0.20–0.65; p = 0.045). Conclusion: Our findings indicate that high CRP may be a favorable prognostic predictor in patients with non-small cell lung cancer following lobectomy. Evaluating the change in postoperative CRP levels should be considered as a prognostic marker of OS.

Keywords: Prognosis, non-small cell lung cancer, C-reactive protein.
patients was 68 +/- 10 years, 62% were female and mean follow up was 24 months. The recurrence rate among all patients was 9%. However, 87 patients (44%) were found to be molecular high-risk and had a recurrence rate of 17%, whereas the 113 patients (56%) who were molecular low-risk had a recurrence rate of only 3% (p<0.0001). Even among the stage IA patients, 41 (33%) were found to be molecular high-risk. The recurrence rate in molecular low-risk stage IA patients was only 1%, compared to 15% in stage IA patients who were identified as molecular high-risk (log-rank p=0.003). Of the 41 stage IA patients found to be molecular high-risk, 24% agreed to undergo adjuvant chemotherapy; there have been no recurrences among these treated high-risk patients. In contrast, the KM estimate of 5-year disease free survival among stage IA high-risk patients who did not receive adjuvant chemotherapy was 51% (log-rank p=0.005).

Conclusion: This prospective, single-institution study further demonstrates the clinical utility of the 14-gene molecular prognostic assay in the management of early stage lung adenocarcinoma. Adjuvant chemotherapy guided by molecular prognosis in the earliest stages of disease, including stage IA, may prevent a significant number of recurrences and deaths.

Keywords: molecular testing, Early Stage Lung Adenocarcinoma, adjuvant chemotherapy

Conclusion: We suggest using T descriptor only for clinical high-risk subsolid nodule. Prognosis of low-risk nodules is excellent, no clear relationship with tumor size or CTR.

Keywords: ground-glass opacity, Tumor size, Prognosis

Background: To determine factors affecting treatment outcomes for SABR in inoperable early stage lung cancer (ESLC) patients treated by TROG member centers. Method: A total of 386 ESLC patients treated with SABR between 2009-2017 were retrospectively analyzed. Factors related to disease, treatment and patients' characteristics were recorded. Primary endpoints were overall survival (OS), progression free survival (PFS), local control (LC), regional control (RC) and radiation-related toxicities. Results: Median follow-up was 21 months. Median SABR dose was 54 Gy (30-70 Gy), corresponding to a biological equivalent dose (BED) of 112 Gy (48-180 Gy) administered in median 5 fractions. Patient and treatment characteristics are in Table 1. Response evaluation was made in median 3 months after SABR and complete response: partial response, stable disease and progression rates were 48%, 36%, 5.7% and 0.5%, respectively. One and 3 years LC and RC rates were 97%, 91% and 93%, 86%, respectively. On multivariate analyzes BED10<90 Gy (HR 3.6; 1.3-9.9), SCC histology (HR 2.2; 1.2-4) and less than complete response were significant predictors of lower LC. One and 3 years PFS and OS rates were 86%, 84/70% and 52/28%, respectively. In univariate analysis, 2-year LC was lower for lesions with no CR and for colorectal cancer lesions. Only "no CR" was significant (100 vs. 51%; HR=18.2, CI 2.3-146, P=0.006) in final multivariate analyzes. Median OS was significantly lower in patients with grade 3+ toxicity (5 months after grade 3+ toxicity, vs. 39 months in others [HR 4.7, CI 2.1-11.2, P=0.0001]). OS was marginally lower in patients with primary lung cancer compared to patients with OM tumors (19 vs. 49 months, HR 2.3, CI 1.5-6.6, P=0.06). Among 17 toxicities, 5 reached grade 5. For patients with grade 3+ toxicities, TFS was lower after Re-RT (2-year TFS 63% vs. 96%, HR 5.1, CI 1.3-20.3, P=0.022) but did not differ significantly for lesions abutting TBT (2-year TFS 69% vs. 93.4%, HR 0.35, CI 0.9-13.9, P=0.08). Conclusion: SABR is an effective treatment modality in centrally located lung tumors. SABR to re-irradiated lesions and possibly lesions abutting TBT have the higher risks for serious toxicities. Further studies are indicated.

Background: To evaluate factors associated with local control (LC), overall survival (OS) and toxicities after SABR to centrally located primary non-small cell lung (PL) and oligometastatic (OM) tumors. Method: Seventy centrally located tumors abutting tracheobronchial tree [TBT], <2cm from TBT, or intersecting mediastinum) in 65 patients treated with linear accelerator-based SABR between 2009 and 2016 were retrospectively studied. Impact of patient, tumor, and treatment parameters on LC, OS and toxicity-free survival (TFS) were evaluated by multivariate analyzes. Results: Forty-eight PL and 22 OM lesions were analyzed, including 20 (28%) re-irradiation (Re-RT) cases. Median total, fractionated, and biological equivalent doses in BED10 and BED3 were 55 (30-60), 9.75 (4-18), 110 (41-151), and 228 (90-378) Gy, respectively. Doses given as Re-RT were lower (median Re-RT BED10 dose 94 vs. 110 Gy, P=0.009). Complete response (CR) was obtained in 43 (61%) lesions. None of the analyzed factors correlated to CR. After a median follow-up of 57 (48-65, 95CI) months, 10 (14%) lesions had relapsed and 37 (57%) patients had died (2 and 5-year LC and OS rates were 84/70% and 52/28%, respectively). In univariate analysis, 2-year LC was lower for lesions with no CR and for colorectal cancer lesions. Only "no CR" was significant (100 vs. 51%; HR=18.2, CI 2.3-146, P=0.006) in final multivariate analyzes. Median OS was significantly lower in patients with grade 3+ toxicity (5 months after grade 3+ toxicity, vs. 39 months in others [HR 4.7, CI 2.1-11.2, P=0.0001]). OS was marginally lower in patients with primary lung cancer compared to patients with OM tumors (19 vs. 49 months, HR 2.3, CI 1.5-6.6, P=0.06). Among 17 toxicities, 5 reached grade 5. For patients with grade 3+ toxicities, TFS was lower after Re-RT (2-year TFS 63% vs. 96%, HR 5.1, CI 1.3-20.3, P=0.022) but did not differ significantly for lesions abutting TBT (2-year TFS 69% vs. 93.4%, HR 0.35, CI 0.9-13.9, P=0.08). Conclusion: SABR is an effective treatment modality in centrally located lung tumors. SABR to re-irradiated lesions and possibly lesions abutting TBT may have the higher risks for serious toxicities. P2.16-16 SABRTOOTH: A FEASIBILITY STUDY OF SABRVERSUS SURGERY IN PATIENTS WITH PERIPHERAL I NSCLC CONSIDERED TO BE AT HIGHER RISK FOR SURGERY.

1Clinical Oncology, Leeds Cancer Centre. 2Department of Thoracic Oncology, University of Leeds, Leeds/GB. 3Respiratory Medicine, Leeds Teaching Hospitals, Leeds/GB. 4Department of Respiratory Medicine, Leeds Teaching Hospitals Trust, Leeds/GB. 5University of Leeds, Leeds/GB. 6Manchester University Hospitals NHS Foundation Trust, Manchester/GB. 7Manchester Thoracic Oncology Centre, Manchester University NHS Foundation Trust, Li/GB. 8Department of Clinical Oncology, University of Manchester and the Christie NHS Foundation Trust, Manchester/GB.

Keywords: alternative study designs are being developed to provide an answer for not to be feasible. However, establishing which patients should have underwent SABR. Therefore, conducting a large RCT in the UK was shown to SABR, 1 received radical radiotherapy, 1 was lost to follow-up. 6 received SABR, 1 radical radiotherapy and of 2 patients randomised with 29% preferring surgery and 42% SABR. Overall 9/24 (38%) did not 54-88). The main reason for declining the study was patient preference was embedded into the study with interviews for patients who was permitted. SABR was delivered as per the UK SABR (1:1) before consulting a surgeon or oncologist. Surgery was preferably multidisciplinary team consensus. Eligible patients were approached by a respiratory physician and research nurse, consented and randomised (1:1) before consulting a surgeon or oncologist. Surgery was preferably by lobectomy with lymph node sampling/resection although sub-lobar resection was permitted. SABR was delivered as per the UK SABR guidelines. An average recruitment rate of 3 patients/month from the 5 centres over a formal monitoring period was set to prove feasibility of a larger RCT. Meetings with the trial sites and patient representatives were held through-out to improve recruitment. Qualitative research was embedded into the study to inform recruitment of patients who declined participation or randomised treatment. Result: Between July 2015-January 2017 318 patients were assessed for eligibility of which 106 were initially considered eligible. 84 patients were approached and 74 (88%) were randomized (1:1). Despite recruiting at higher rate/centre than previous SABR studies were included.

(1) Questionnaires were returned by 47 (47%) patients centres. The ratio of patients with ILD who have received RT for exacerbation (AE). The indication for RT in such patients is determined for radiation therapy (RT) for lung cancer in patients who have interstitial lung disease (ILD) is considered to be a risk for acute exacerbation (AE). The indication for RT in such patients is determined in each facility. The ratio of patients with ILD who have received RT for lung cancer, the incidence of AE, and the indications for RT for AE are unclear. To clarify these, a nationwide survey was carried out by the Lung and Mediastinal Tumor Committee of the Japan Radiation Oncology Study Group (JROSG). Method: (1) Questionnaire survey on the diagnosis of ILD, determination of the indication for RT, and implementation. (2) Multi-institutional retrospective cohort study in fiscal year 2014. Statistical analysis of risk factors for AE. ILD confirmation using CT images by two central radiation diagnosticians. These two studies were included. Result: (1) Questionnaires were returned by 47 institutes. RT was not an option even for patients with ILD depending on conditions of the case in 39 of the institutes. In 37 of the institutes, 3.7% of lung cancer patients (78/2128 patients) in fiscal year 2014 had ILD. (2) Sixty-seven patients were enrolled. AE occurred in 5 cases including 4 photon RT cases. AE occurred in 4 (7.7%) of 52 cases in which photon RT was performed, and there was one RT-induced AE-related death (25.0%). Regarding risk factors for AE, in the t-test, grade

Background: Stage I NSCLC is curable by surgery and Stereotactic Ablative Radiotherapy (SABR). Many patients have co-morbidities that place them at higher risk of surgical complications. For such patients it is unknown whether the potential benefits of surgery are outweighed by the risks since published randomised trials comparing surgery with SABR have been underpowered. The SABRtooth study was designed to determine the feasibility of randomising patients between the two treatments and thus performing a larger RCT. Method: Four thoracic oncology centres and a referral site participated with patients with peripheral tumours (from the main airways) stage T1-T2N0M0 NSCLC were considered for study entry. Patients at higher risk were identified using several criteria including Thoracoscore and the Nottingham Risk Score and confirmed by multidisciplinary team consensus. Eligible patients were approached by a respiratory physician and research nurse, consented and randomised (1:1) before consulting a surgeon or oncologist. Surgery was preferably by lobectomy with lymph node sampling/resection although sub-lobar resection was permitted. SABR was delivered as per the UK SABR guidelines. An average recruitment rate of 3 patients/month from the 5 centres over a formal monitoring period was set to prove feasibility of a larger RCT. Meetings with the trial sites and patient representatives were held through-out to improve recruitment. Qualitative research was embedded into the study to inform recruitment of patients who declined participation or randomised treatment. Result: Between July 2015-January 2017 318 patients were assessed for eligibility of which 106 were initially considered eligible. 84 patients were approached and 74 (88%) were randomized (1:1). Despite recruiting at higher rate/centre than previous SABR studies were included.

(1) Questionnaires were returned by 47 (47%) patients centres. The ratio of patients with ILD who have received RT for exacerbation (AE). The indication for RT in such patients is determined in each facility. The ratio of patients with ILD who have received RT for lung cancer, the incidence of AE, and the indications for RT for AE are unclear. To clarify these, a nationwide survey was carried out by the Lung and Mediastinal Tumor Committee of the Japan Radiation Oncology Study Group (JROSG). Method: (1) Questionnaire survey on the diagnosis of ILD, determination of the indication for RT, and implementation. (2) Multi-institutional retrospective cohort study in fiscal year 2014. Statistical analysis of risk factors for AE. ILD confirmation using CT images by two central radiation diagnosticians. These two studies were included. Result: (1) Questionnaires were returned by 47 institutes. RT was not an option even for patients with ILD depending on conditions of the case in 39 of the institutes. In 37 of the institutes, 3.7% of lung cancer patients (78/2128 patients) in fiscal year 2014 had ILD. (2) Sixty-seven patients were enrolled. AE occurred in 5 cases including 4 photon RT cases. AE occurred in 4 (7.7%) of 52 cases in which photon RT was performed, and there was one RT-induced AE-related death (25.0%). Regarding risk factors for AE, in the t-test, grade

Background: Stage I NSCLC is curable by surgery and Stereotactic Ablative Radiotherapy (SABR). Many patients have co-morbidities that place them at higher risk of surgical complications. For such patients it is unknown whether the potential benefits of surgery are outweighed by the risks since published randomised trials comparing surgery with SABR have been underpowered. The SABRtooth study was designed to determine the feasibility of randomising patients between the two treatments and thus performing a larger RCT. Method: Four thoracic oncology centres and a referral site participated with patients with peripheral tumours (from the main airways) stage T1-T2N0M0 NSCLC were considered for study entry. Patients at higher risk were identified using several criteria including Thoracoscore and the Nottingham Risk Score and confirmed by multidisciplinary team consensus. Eligible patients were approached by a respiratory physician and research nurse, consented and randomised (1:1) before consulting a surgeon or oncologist. Surgery was preferably by lobectomy with lymph node sampling/resection although sub-lobar resection was permitted. SABR was delivered as per the UK SABR guidelines. An average recruitment rate of 3 patients/month from the 5 centres over a formal monitoring period was set to prove feasibility of a larger RCT. Meetings with the trial sites and patient representatives were held through-out to improve recruitment. Qualitative research was embedded into the study to inform recruitment of patients who declined participation or randomised treatment. Result: Between July 2015-January 2017 318 patients were assessed for eligibility of which 106 were initially considered eligible. 84 patients were approached and 74 (88%) were randomized (1:1). Despite recruiting at higher rate/centre than previous SABR studies were included.

(1) Questionnaires were returned by 47 (47%) patients centres. The ratio of patients with ILD who have received RT for exacerbation (AE). The indication for RT in such patients is determined in each facility. The ratio of patients with ILD who have received RT for lung cancer, the incidence of AE, and the indications for RT for AE are unclear. To clarify these, a nationwide survey was carried out by the Lung and Mediastinal Tumor Committee of the Japan Radiation Oncology Study Group (JROSG). Method: (1) Questionnaire survey on the diagnosis of ILD, determination of the indication for RT, and implementation. (2) Multi-institutional retrospective cohort study in fiscal year 2014. Statistical analysis of risk factors for AE. ILD confirmation using CT images by two central radiation diagnosticians. These two studies were included. Result: (1) Questionnaires were returned by 47 institutes. RT was not an option even for patients with ILD depending on conditions of the case in 39 of the institutes. In 37 of the institutes, 3.7% of lung cancer patients (78/2128 patients) in fiscal year 2014 had ILD. (2) Sixty-seven patients were enrolled. AE occurred in 5 cases including 4 photon RT cases. AE occurred in 4 (7.7%) of 52 cases in which photon RT was performed, and there was one RT-induced AE-related death (25.0%). Regarding risk factors for AE, in the t-test, grade
of radiation pneumonitis, FEV1, and lung V30 were significant. Age, lung mean dose, lung V20, and D2cc were marginally significant. However, they were not significant in multivariate analysis. AE occurred in 1 of 15 cases in which particle RT was performed. In a review of CT images, 59 cases were analyzable. ILD was confirmed in 58 cases (98.3%). Diagnosis of ILD by each institute was almost the same as that in the review by central radiation diagnosticians. Post-irradiation exacerbation of ILD (PIL-ILD) on CT was revealed in 23 (43.4%) of 53 cases. We considered that PIL-ILD does not necessarily progress to AE. Conclusion: We surveyed actual conditions of RT for patients with ILD in Japan. RT was an option even for patients with ILD in many institutes, though cases in which it was actually implemented were limited.

P2.16-19 FEASIBILITY AND OUTCOMES OF RADIOFREQUENCY ABLATION AS SALVAGE MODALITY AFTER HYPOFRACTIONATED RADIATION/SBRT FOR EARLY NSCLC

R. Harjani Hinduja, J. Seeley, A. Gupta, V. Naik, G. Cook, R. Macrae
1Radiation Oncology, The Ottawa Hospital- Cancer Centre, Ottawa/CA, 2Radiology, The Ottawa Hospital Cancer Centre, Ottawa/CA

Background: Local recurrences after radiotherapy (RT) for early non-small cell lung cancers (NSCLC) may be amenable to curative treatments. One such modality is Radio Frequency Ablation (RFA). There is paucity of data about outcomes after RFA salvage. We aim to evaluate the feasibility and outcomes of RFA when used as salvage therapy after hypo-fractionated radiation for early NSCLC. Method: We retrospectively reviewed consecutive early NSCLC patients treated with SBRT or hypo-fractionated radiation followed by RFA salvage in an ethics board approved study. RFAs were performed using CT guidance and under general anesthesia using LeVeenTM needle. Its immediate and follow up complications were assessed. The end points of interest were local recurrence free survival (LRFS), distant relapse free survival (DRFS) and overall survival (OS). The end points were compared by the tumour size and Positron Emission Tomography (PET) maximum Standardized Uptake Value (SUVMax) Result: 20 individuals with 21 tumours were treated with salvage RFA after RT for early tumours between 2005 and 2017. The median age was 76 years (52-94). Initial treatment was SBRT in 55% (11/20) tumours, 55% (11) tumours were adenocarcinomas, 25% (5) were squamous and 20% (4) were NSCLC- not otherwise specified. The median tumour size (long axis diameter) was 31.5mm. PET was available for 16 tumours and the median SUVmax was 6.15. The median interval since prior radiation was 24 months (8-56). The procedure was well tolerated. One individual developed pneumotheorax requiring pigtail catheter drainage. The median hospitalization period was 1 day. One procedure was performed midway due to leukopenia and platelets, and a median dysphonia. The median EFRS was 31.8 months. When stratified by ≤ or >30 mm, there was no statistically significant difference in mean EFRS, but a trend was noted. The overall metastases was slightly earlier in larger tumours but not statistically significant. The median overall survival for tumours ≤ or >30 mm was 42.8 months and 17.4 months respectively (p=0.015). The LRFS was 27.7 and 60.45 months (p<0.29). DMFS was 27.8 an 54.7 months (p=0.11) for patients with PET SUV >5 and ≤5 respectively. Conclusion: RFA is an effective and feasible salvage modality in early NSCLC after radiation. This study is limited by its retrospective nature and limited numbers. A larger prospective analysis will help ascertain its role.

P2.16-20 PROGNOSTIC UTILITY OF PET IN NON-SMALL CELL LUNG CANCER AFTER EMPIRIC STEREOTACTIC BODY RADIOTHERAPY (SBRT)

S. Hasan, R. Petek, D. Petrov, A. Colonias, T. Mickus, M. Van Deussen, R. Wendling
1Radiation Oncology, Allegheny Health Network Cancer Institute, Pittsburgh/PA/US, 2Radiology, Allegheny Health Network Cancer Institute, Pittsburgh/PA/US, 3Thoracic Surgery, Allegheny Health Network Cancer Institute, Pittsburgh/PA/US, 4Radiation Oncology, Allegheny Health Network Cancer Institute, Pittsburgh/US

Background: Positron emission tomography (PET-CT) is valuable for diagnosing early stage non-small cell lung cancer (NSCLC) in the absence of biopsy. Here we investigate the diagnostic, prognostic, and treatment response of PET-CT in NSCLC treated with empiric stereotactic body radiotherapy (SBRT). Method: We retrospectively reviewed 78 empiric lung SBRT cases with pre-treatment PET scans treated to biologic equivalent dose-100 Gy. We correlated pre and post-treatment standard uptake values (SUV) with local, regional, and distant control. Statistical analysis was conducted via SPSS v20. Result: A total of 44 males and 34 females median age 77 were treated to 48 Gy in 4 fractions (n=47) or 50 Gy in 5 fractions (n=31). Lung nodules were 1.6 cm (0.6-4.5 cm) with a median planning target volume of 19.1 cc (3.7-97.4 cc). Median pre-treatment SUV=4.1 (0-20). Of the 43 patients with post-treatment PETs, median SUV = 2.7(0-7.2) or 53%(0-302%) of the pretreatment SUV. The median follow-up was 18 months with a 3-year survival of 50% for all patients. Local, regional, and distant control rates at 3 years were 91%, 81%, and 78%, respectively. Relative sisease control for pre-treatment SUV<4.0 compared to >4.0 is shown in Table 1:

<table>
<thead>
<tr>
<th>Pre-treatment SUV</th>
<th>Hazard Ratio (95% CI)</th>
<th>P value</th>
</tr>
</thead>
<tbody>
<tr>
<td>≤4 vs &gt;4</td>
<td>2.26 (1.14 – 4.48)</td>
<td>0.02</td>
</tr>
</tbody>
</table>

Overall Progression:

- Local Failure: 3.62 (1.43 – 9.12) <0.01
- Regional Failure: 6.67 (1.86 – 23.98) <0.01
- Distant Failure: 3.28 (1.10 – 10.55) 0.04
- Overall Progression: 3.62 (1.43 – 9.12) <0.01

There was no difference in tumor size, location, nodule morphology, or prior cancer/smoking history between patients with pre-treatment SUV <4 and >4 (n=38). Receiver operating characteristic curve analysis identified optimal SUV cutoff values of 6.0, 3.5, and 4.0 to predict local, regional, and distant failure, respectively. Post-SBRT PET scans with SUV reduction>50% demonstrated a 2-year freedom from progression of 89% compared to 57% with SUV reduction<50% (p=0.08). Conclusion: Our study demonstrates a strong correlation between initial PET avidity and regional/distant recurrence, and a trend with local recurrence. Perhaps patients with pretreatment SUV>4 warrant a mediastinal evaluation or closer vigilance in follow-up, though this warrants prospective investigation.

P2.16-21 POST-TREATMENT SURVIVAL DIFFERENCE BETWEEN LOBECTOMY AND STEREOTACTIC ABLATIVE RADIOTHERAPY IN STAGE 1 NON-SMALL CELL LUNG CANCER IN ENGLAND

2Department of Epidemiology and Public Health, University of Nottingham, Ng Pb/GB, 2Addenbrookes Hospital, Cambridge/GB, 2Lungs for Living Research Centre, UCL Respiratory, University College London, Wc 2GB, 2Division of Respiratory Medicine, Derby Teaching Hospital NHS Foundation, Derby/GB, 2Department of Epidemiology and Public Health, University of Nottingham, Nottingham/GB

Background: Non-small cell lung cancer (NSCLC) accounts for almost 85% of all lung cancer cases diagnosed in England. Stage 1 lung cancer represents around 15-20% of all NSCLC cases, and while surgical resection (the current standard of care) offers the best chance to improve survival and is the standard of care in early lung cancer, not all patients undergo surgical treatment due to their advanced age and/or multiple comorbidities, while others may refuse surgery. Stereotactic ablative radiotherapy (SABR), a non-invasive external beam radiotherapy, has become an established treatment option for such patients. The aim was to compare survival at 90 days, 6 months, one year and overall for patients who received either lobectomy or SABR for NSCLC stage IA and IB. Method: We used data from the 2015 National Lung Cancer Audit (NLCA) database that was collected by Public Health England (PHE) and linked with Hospital Episode Statistics (HES) and the Radiotherapy Dataset (RTDS) to identify patients with NSCLC stage IA-IB and performance status 0-2 who underwent surgery or SABR treatment. We looked at survival risk difference at 90 days, 6 months, 1 year and 3 years between the two patient groups using propensity score derived statistical analysis. Result: We identified 2373 patients in our cohort, 476 of whom had SABR. The median difference between date of diagnosis and date of treatment for surgery patients was 17 days while for SABR patients it was 73 days.

The median difference between date of diagnosis and date of treatment for surgery patients was 17 days while for SABR patients it was 73 days. Increasing age and worsening performance status were associated with having SABR rather than surgery. Patients who had SABR had 1.4% better survival at 90 days; however, this survival benefit dropped at 6 months.
after treatment started and patients who had surgery had 14% better overall survival. Conclusion: Our analysis suggests that, while patients who underwent SABR have better short-term survival, patients who have surgery have better overall survival. However, the time to the start of treatment with SABR was 8 weeks longer than for surgery. Thus early survival may be underestimated for SABR although other (conflicting) factors may be at play including stage-shift (more in SABR group) and length time (potentially more indolent tumours in the SABR group).

P2.16-22 COMPARING TWO COMMON RADIOTHERAPY REGIMENS IN NON-SMALL CELL LUNG CANCER - A RETROSPECTIVE STUDY

W. Poon, P. Mcloone, Y. Flanagan, S. Currie, D. Keiller, S. Harrow
Clinical Oncology, Beatson West of Scotland Cancer Centre, Glasgow/GB

Background: In patients with inoperable non-small cell lung cancer (NSCLC), a variety of radiotherapy regimens are used as potentially curative treatments. At the Beatson West of Scotland Cancer Centre (BWoSCC), continuous hyperfractionated accelerated radiotherapy (CHART; 54 Gy in 36 fractions over 12 days) and hypofractionated radiotherapy (55 Gy in 20 fractions over 4 weeks) are the standard fractionations. The aim of this study was to review the clinical outcomes.

Method: A retrospective study was performed assessing clinical and dosimetric records of all radically treated NSCLC patients at the BWoSCC in 2010 and 2015. We excluded all patients who had received chemotherapy sequentially or concurrently. Patient demographics, tumour characteristics, radiotherapy and survival data were collected and analysed. Result: A total of 254 patients received radical radiotherapy. 113 were treated in 2010 (52 CHART and 61 with 55/20); 141 were treated in 2015 (43 CHART and 98 with 55/20). Median age for CHART patients was 76 (IQR (70-81)), and for 55/20 patients 74 (68-79). Overall, CHART patients had poorer performance status (PS). 32% of CHART patients had a PS 2/3 compared to 19.5% of 55/20 patients (p<0.01). In 2010, 68% of CHART patients were PS 0/1 and 32% were PS 2/3. In 2015, 53% were PS 0/1 and 47% were PS 2 (p<0.01). In 2010, more CHART patients had unknown staging compared with the 55/20 patients (28% versus 14%). By 2015, there was no statistically significant difference. The max planning target volumes (PTV) were on average larger in 2015 than 2010. The PTV of CHART patients increased by 19.8%. The PTV of the 55/20 patients increased by 3.4%. Median progression free survival (progression or death) was 14.3 months 95%CI (11.0 to 18.0) for 55/20 patients and 14.6 months 95%CI (11.0 to 18.7) for CHART patients. Median overall survival was 23.2 months 95%CI (16.2 to 30.2) for 55/20 patients and 22.2 months 95%CI (14.5 to 29.2) for CHART patients.

Conclusion: In this single centre study, we present a series of patients treated with 2 different radical radiotherapy regimens. Despite PTV volumes on average increasing from 2010 to 2015, the median survival has decreased for CHART. In our centre we introduced Stereotactic ablative radiotherapy as a new option for patients with stage I and II disease. Many patients who previously received CHART or 55/20 will now be eligible for SABR. It may be that this has changed selection criteria, with more advanced patients being put forward for CHART.

P2.16-23 FOCAL THERAPY FOR SMALL LUNG CANCER WITH ETHANOL RELEASE HEAT-GENERATING POLYMER

J. Shimada1, M. Shimagaki2, T. Taniguchi1
1Division of Thoracic Surgery, Department of Surgery, Kyoto Prefectural University of Medicine, Kyoto/JP; 2Toray Medical, Urayasu/JP; 3Toa Chemical, Osaka/JP

Background: As opportunities to take high resolution CT images of lungs by lung cancer screening increase, the lung cancer lesions of small GGO lesions are increasingly found. As such an elderly person who found a small lesion reveals low durability for surgery and sometimes has many medical complications around chronic diseases. In this study, we have synthesized “Ethanol Release Heat-Generating Polymer”, for focal therapy of micro lung cancer. Method: We have synthesized low viscosity silicon material which absorb a trace amount of water, generates heat and indurate in a few minutes under industry-academia collaboration. We have adjusted the concentration of titanium catalyzer, and a fine image obtained. We performed CT imaging experiment. We perfumed rat experiments that 0.03 mL of injected viscous liquid resin was injected into rat lungs under micro surgery. Histological images of alveolar epithelial cells inside and around the resin injection area were examined by HE staining. Also, in order to analyze three-dimensionally whether the target site is surrounded without cracks, we used the micro CT apparatus of Shimadzu Corporation. Rat lungs are divided in 1 micron unit CT imaging, the indurated conditions of thermosetting resin in the lungs was analyzed as 3D DICOM image data. Result: Alveolar cells close to the resin were denatured. According to the 3D micro CT views of the indurated resin in the rat lung (Fig), it was was hardened three-dimensionally without cracks, the surrounding cells were damaged. The CT value of the resin itself was high, and it was distinguished as white induration from the cell components of the lung.

Conclusion: We have succeeded in synthesizing “Ethanol Release Heat-Generating Polymer” for focal therapy of micro lung cancers. This work was PCT patent pending JP2017/025044 and supported by JSPS KAKENHI Grant Number JP15K15517.

P2.16-24 RACIAL DIFFERENCES IN TREATMENT AND SURVIVAL OF STAGE I NSCLC: A COMPARISON OF VETERANS AFFAIRS (VA) AND SEER-MEDICARE POPULATIONS

C. Williams1, N. Alpert2, A.J. Bullard3, T. Redding1, E. Taioli1
1Durham Va Health Care System, Durham/NC/US; 2Department of Population Health Science and Policy, Institute for Translational Epidemiology, Icahn School of Medicine at Mount Sinai, New York/US

Background: Disparities in treatment and survival continue to persist in early-stage non-small cell lung cancer (NSCLC), yet they vary among different patient populations. The objective of this study is to compare racial differences in demographic, clinical, treatment and survival characteristics among veteran and non-veteran patients with stage I NSCLC. Method: Patients with stage I NSCLC diagnosed 2001-2009 were identified in the Surveillance, Epidemiology, and End Results (SEER) Medicare database and Veterans Affairs (VA) cancer registry. In both cohorts, analyses were restricted to Black and White males aged ≥ 65 years. Descriptive statistics were used to compare racial differences in demographic and clinical factors. Multivariate logistic regression models estimated odds ratios (OR) and 95% confidence intervals (95% CI) for the association between race and receipt of treatment. Cox proportional hazards models were used to assess 5-year survival. Result: Among patients in VA (N=7895) and SEER (N=8744), the proportion of Black patients was 13% and 7%, respectively. In VA, 50% of both Black and White patients were diagnosed at ages 65-74 years (p=0.60); in SEER, Black patients were younger than Whites (60% vs 50%; p<0.0001). The predominant histology was squamous cell in Blacks (47%) and adenocarcinoma in Whites (42%) in SEER; 40% of both Blacks and Whites in VA had squamous cell histology. In SEER, 11% of Whites and 14% of Blacks had a comorbidity score ≥ 3 (p=0.003); corresponding proportions in VA were 29% and 28% (p=0.10). While 84% of SEER patients and 77% of VA patients received treatment, after adjusting for covariates, Blacks were less likely than Whites to get any treatment (ORadj: 0.66, 95% CI 0.57-0.77 in VA; ORadj: 0.56, 95% CI 0.47-0.68 in SEER), and to receive surgery alone when treated (ORadj: 0.73, 95% CI 0.62-0.86 in VA; ORadj: 0.57, 95% CI 0.47-0.70 in SEER). Among treated patients, there was no significant difference in overall survival for Blacks and Whites, after adjusting for type of treatment (HRadj: 0.99, 95% CI 0.91-1.09 in VA; HRadj: 1.00 95% CI 0.89-1.13 in SEER). Conclusion: Among older stage I NSCLC patients, the proportion of Blacks in VA was nearly twice that in SEER, and Blacks and Whites were more similar in VA than in SEER. Despite population differences, similar racial differences in receipt of treatment

P2.16-25 LOWER HILAR LYMPH NODE UPSTAGING IN EARLY NSCLC VATS SURGERY IS RELATED TO TUMOR LOCATION AND DOES NOT AFFECT SURVIVAL

M. Boada1, R. Guzman1, M. Montesinos1, A. Libreros1, A. Guirao2, D. Sánchez2, J.M. Gimferrer1, L. Molins2
1General Thoracic Surgery, Hospital Clinic de Barcelona, Barcelona/ES, 2General Thoracic Surgery, Hospital Clinic Barcelona, Barcelona/ES

Background: Nodal upstaging after early stage lung cancer surgery is not only inevitable, but it is also considered a quality marker for surgical lymphadenectomy. Underdiagnosis of pN1 has important significance and leads to undertreatment. Lymphadenectomy has been questioned in video thoracoscopic surgery (VATS) since its description. Recently some authors published lower pN1 upstaging incidence after VATS resection compared to open thoracotomy. We want to evaluate the rate of upstaging in our centre after starting a VATS program. Method: All patient who required an anatomical resection for non-small cell lung cancer (NSCLC) in our department have been retrospectively reviewed. Patients were divided in two groups in relation of the performed surgical approach, thoracotomy (THO) and VATS. Both groups were compared in terms of gender, age, smoking history, comorbidities, lung function, histology, clinical stage and tumour location. Rate of hilar lymph node upstaging (pN1) and mediastinal lymph node upstaging (pN2) were compared between both groups. Univariate and multivariate analysis was performed to identify independent risk factors for pN1 upstaging. Overall survival was compared between both techniques in pN0 patients. Result: Between January 2011 and October 2017, 1,081 lung resections were carried out in our centre. 323 of those were anatomical resections for early stage (≤ IIIB) non-small cell lung cancer (NSCLC). There were no differences among groups except for FEV1, previous history of Diabetes Mellitus, tumour size and location (p<0.05). pN1 ratio was 20.5% in THO vs. 8.6% in VATS (p < 0.05) when performed accesses was compared. No differences were observed regarding pN2 upstaging (6% in THO and 6.5% in VATS, p=0.05). Only gender and centrality were identified as independent risk factors for hilar lymph node upstaging in a multivariate analysis. For those patient with no upstaging (pN0) there were no survival differences comparing open and VATS approaches. Conclusion: In our series pN1 upstaging is less frequent in VATS than in open surgery. When analysed, tumour centrality has shown to be an independent risk factor for hilar lymph node upstaging in a multivariate analysis. For those patient with no upstaging (pN0) there were no survival differences comparing open and VATS approaches. In conclusion, lower incidence of unnoticed pN1 in VATS surgery could be related to a selection bias, because thoracotomy was preferred when tumour considered central. Furthermore, the fact that no differences on survival in pN0 patients were detected suggests that no patients have been underdiagnosed and in consequence undertreated.

Keywords: early stage NSCLC, upstaging, VATS

P2.16-26 LUNG CANCER RESSECTION IN PATIENTS WITH CRITERIA FOR LUNG CANCER SCREENING PROVIDES SATISFACTORY SHORT TERM RESULTS

D. Boulate, S. Guiraud, A. Bouvier, S. Musso, D. Mitilian, D. Fabre, O. Mercier, E. Fadel
Thoracic and Vascular Surgery, Hopital Marie Lanelongue, Le Plessis-Robinson/FR

Background: Criteria for lung cancer screening (LCS) include age 55-74 years old, a smoking history ≥ 30 pack-years with < 15 years smoking cessation. The lack of data regarding the operative risk for lung cancer resection (LCR) in patients with LCS criteria is a limit for national reimbursement of LCS in France. We aimed to determine whether the operative risk for LCR is increased in patients with LCS criteria. Method: We performed a retrospective analysis of consecutive LCR operated between October 2015 and October 2016 in a high volume tertiary center with routine minimally invasive thoracic surgery (videothoracoscopy). Among 241 patients who underwent a LCR, the study population were the 169 patients aged 55-74 years old. We compared the perioperative characteristics of patients with and without LCS criteria.

Result: LCS criteria were present in 92 patients out of 169. Preoperative and operative/postoperative data were reported in Tables 1 and 2, respectively. Despite an increased preoperative cardiovascular risk and a poorer respiratory function, patients with LCS criteria presented a similar postoperative morbidity, mortality and hospital readmission compared with patients without LCS criteria.

Table 1: preoperative characteristics of patient aged 55-74 years old undergoing lung cancer resection. Comparison between patients with and without lung cancer screening (LCS) criteria. M: male; F: female; BMI: body mass index; CV: cardiovascular; EA: endarterectomy; ENT: ear nose and throat; NLR: neutrophil to lymphocyte ratio; CRP: C-reactive protein; FEV1: forced expiratory volume in 1 second. Quantitative data are expressed as mean ± standard deviation; qualitative data are expressed as n and %.

P2.16-28 COMPARISON OF OUTCOMES OF VATS SEGMENTECTOMY VERSUS LOBECTOMY FOR NON-SMALL CELL LUNG CANCER USING A PROPENSITY SCORE MATCHING ANALYSIS
1Smg-Snu Boramae Medical Center, Seoul/KR, 2Seoul National University Hospital, Seoul/KR, 3Department of Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul/KR, 4Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul/KR
Background: The aim of this study was to compare surgical and oncologic outcomes between thoracoscopic segmentectomy and lobectomy for the patients with non-small cell lung cancer (NSCLC). Method: Between 2009 and 2016, 250 thoracoscopic segmentectomies (Group S) and 1,550 thoracoscopic lobectomies (Group L) were performed in patients with NSCLC in our institute. Indications for segmentectomy were peripherally located tumor with smaller than 2 cm size, or the patients with limited pulmonary reserve and multiple comorbidities. Propensity score matching was conducted using preoperative clinical parameters and 240 patients in each Group S and L were included in the study. Result: Most commonly performed segmentectomies were left upper lobar upper division segmentectomy (26.7%) and right lower lobar superior segmentectomy (17.1%). Operation time and length of hospital stay were comparable between the groups (162.9 ± 52.8 min and 5.7 days in group S vs. 163.2 ±
40.1 min and 8.7 days in group L; P=0.97 and P=0.13, respectively). Although postoperative mortality rates were not different between the two groups (0.8% vs. 0.8%, P=1.0), post-operative complication rate was significantly lower in the group S (11.2% vs. 19.2%, P=0.02). Especially, pulmonary complication rate including pneumonia, ARDS, and prolonged air leakage was significantly lower in the group S (2.5% vs. 8.3%, P=0.01). Postoperative decrease of diffusion capacity (DLco) was significantly lower in the group S (13.1% ± 16.4 vs. 18.2% ± 19.7, P=0.02), Recurrence-
free survival (RFS) and overall survival (OS) were not significantly different between patients who underwent lobectomy (5-year RFS, 84.0%; 5-year OS, 90.2%) and segmentectomy (5-year RFS, 89.0%; 5-year OS 88.4%). (Figure 1)
Conclusion: LCS program would allow us to achieve similar operative outcomes than patients without LCS criteria despite poorer respiratory function and increased cardiovascular risk.
Keywords: lung cancer, Screening, Surgery.
Conclusion: Thoracoscopic segmentectomy could achieve excellent early surgical outcomes with lower complication rates and preserved pulmonary function compared to lobectomy without jeopardizing long-term oncologic outcomes.

Keywords: lung cancer, segmentectomy, lobectomy

P2.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.16-29 CLINICAL OUTCOMES OF SURGICALLY RESECTED EXTRAABDOMINAL CHEST WALL DESMOID TUMORS
S. Kim, S. Song, J.S. Yun, K.J. Na
Department of Thoracic and Cardiovascular Surgery, Chonnam National University Hwasun Hospital, Jeonnam/KR

Background: Extraabdominal chest wall desmoid tumors are uncommon soft tissue tumors. This study was performed to examine the outcomes of patients with extraabdominal chest wall desmoid tumors and adjacent structures treated with surgery. Method: A detailed retrospective clinicopathological study was performed in 17 patients (8 men and 9 women) treated in our institution for extraabdominal desmoid tumors of the chest wall between March 2001 and June 2017. The patients had a median age of 44 years (range, 17-62 years), and the mean pathological diameter of the resected tumors was 92.1 mm. Result: Complete resection was performed in 13 of the 17 patients (76.5%). One patient had positive microscopic margin and three had gross residual disease. Chest wall reconstruction surgery was necessary in five patients (29%), synthetic patches were used in two patients, muscle flaps in two patients, and a metal plate in one patient. Complications were found in one patient, and there were no cases of operative mortality. Five patients (29%) received postoperative adjuvant therapy (only radiotherapy in three, radiotherapy and chemotherapy in two). Follow-up was complete in all patients who underwent limited resection (n = 52) and lobectomy (n = 76), respectively (p = 0.0963), whereas in 104 patients with ≤ 1.7 cm of solid component size and CTR, and 47 of the 97 patients (48%) with > 1.7 cm of solid component size and > 86% of CTR developed the pathological metastasis and/or involvement. In 104 patients with > 1.7 cm of solid component size and < 86% of CTR, the 3-year locoregional recurrence-free probabilities were 70% versus 84% in patients who underwent limited resection (n = 21) and lobectomy (n = 76), respectively (p = 0.0963), whereas in 104 patients with ≤ 1.7 cm of solid component size and ≥ 86% of CTR, the 3-year locoregional recurrence-free probabilities were 95% versus 97% in patients who underwent limited resection (n = 52) and lobectomy (n = 52), respectively (p = 0.8622). Conclusion: An indication for limited resection may be decided with caution in clinical stage IA patients with the predictors of the pathological metastasis and/or involvement because of relatively higher incidence of postoperative locoregional recurrence after limited resection when compared with lobectomy.

Keywords: non-small cell lung cancer, limited resection, sublobar resection

P2.16-30 SURGICAL STRATEGY FOR CLINICAL STAGE IA NON-SMALL CELL LUNG CANCER PATIENTS WITH RISK FACTORS OF PATHOLOGICAL INVASION AND/OR METASTASIS
T. Koike1, M. Nakamura1, Y. Shimizu1, T. Goto1, S. Sato1, S. Toyabe1, M. Tsuchida1
1Thoracic and Cardiovascular Surgery, Niigata University Graduate School of Medical and Dental Sciences, Niigata/IJP 2Niigata University Crisis Management Office, Niigata University, Niigata/IJP

Background: Because pathological metastasis and involvement are thought to be associated with postoperative recurrence and poor outcomes in non-small cell lung cancer (NSCLC) patients, limited resection for high risk patients of pathological metastasis and involvement is controversial. The aim of this study was to examine a postoperative locoregional control in these patients. Method: We retrospectively reviewed completely resected clinical stage IA NSCLC patients on the 8th edition of the TNM classification (solid tumor component size of ≤ 3 cm on computed tomography; CT). The pathological metastasis and/or involvement was defined that pleural involvement, pulmonary metastasis, lymph node metastasis, and/or lymphovascular involvement were identified on pathological examination. To identify predictors for the pathological metastasis and/or involvement, demographic and clinical factors were analyzed by an univariate analysis and multivariate logistic regression analysis. For the significant factors, optimal cutoff points were determined with a receiver operating characteristic analysis. Locoregional recurrence-free probabilities were calculated using the Kaplan-Meier method in patients with/without the identified predictors, and were compared between patients who underwent limited resection and lobectomy by the log-rank test. Result: Of the 286 eligible patients, pleural involvement, pulmonary metastasis, lymph node metastasis, lymphatic permeation, and vascular invasion were identified in 43 (15%), 5 (2%), 11 (4%), 15 (5%), and 32 patients (11%), respectively, and in total, 73 patients (26%) developed the pathological metastasis and/or involvement. Univariate and multivariate logistic regression analysis revealed solid tumor component size on CT (OR: 1.090) and consolidation/tumor ratio on CT (CTR; OR: 1.043) as significant predictors. The optimal cutoff points were determined as ≤ 1.7 cm and 86% for solid component size and CTR, respectively, and of the 97 patients (48%) with > 1.7 cm of solid component size and > 86% of CTR developed the pathological metastasis and/or involvement. In 104 patients with ≤ 1.7 cm of solid component size and < 86% of CTR, the 3-year locoregional recurrence-free probabilities were 70% versus 84% in patients who underwent limited resection (n = 52) and lobectomy (n = 52), respectively (p = 0.0963), whereas in 104 patients with ≤ 1.7 cm of solid component size and ≥ 86% of CTR, the 3-year locoregional recurrence-free probabilities were 95% versus 97% in patients who underwent limited resection (n = 52) and lobectomy (n = 52), respectively (p = 0.8622). Conclusion: An indication for limited resection may be decided with caution in clinical stage IA patients with the predictors of the pathological metastasis and/or involvement because of relatively higher incidence of postoperative locoregional recurrence after limited resection when compared with lobectomy.

P2.16-31 EXAMINATION OF THE INTERSEGMENTAL ISOLATION METHOD IN THE SEGMENTAL RESECTION CONSIDERING RESPIRATORY FUNCTION PRESERVATION
K. Kojima1, M. Yano2, K. Okubo3
1Thoracic Surgery, Karatsu Red-Cross Hospital, Karatsu-Shi, Saga/IJP 2Thoracic Surgery, Musashino Red-Cross Hospital, Musashino-Shi, Tokyo/IJP 3Thoracic Surgery, Tokyo Medical and Dental University, Bunkyo-Ku, Tokyo/IJP

Background: Segmental resection is often performed as limited operation for early lung cancer because it is usually considered the procedure to preserve respiratory function. There are two methods to isolate the intersegmental line. One is the method to isolate along intersegmental plane exactly (=ISPG) and the other is to cut with automatic suture instruments (=ASCG). Result: Of the 286 eligible patients, pleural involvement, pulmonary metastasis, lymph node metastasis, lymphatic permeation, and vascular invasion were identified in 43 (15%), 5 (2%), 11 (4%), 15 (5%), and 32 patients (11%), respectively, and in total, 73 patients (26%) developed the pathological metastasis and/or involvement. Univariate and multivariate logistic regression analysis revealed solid tumor component size on CT (OR: 1.090) and consolidation/tumor ratio on CT (CTR; OR: 1.043) as significant predictors. The optimal cutoff points were determined as ≤ 1.7 cm and 86% for solid component size and CTR, respectively, and of the 97 patients (48%) with > 1.7 cm of solid component size and > 86% of CTR developed the pathological metastasis and/or involvement. In 104 patients with ≤ 1.7 cm of solid component size and < 86% of CTR, the 3-year locoregional recurrence-free probabilities were 70% versus 84% in patients who underwent limited resection (n = 52) and lobectomy (n = 52), respectively (p = 0.0963), whereas in 104 patients with ≤ 1.7 cm of solid component size and ≥ 86% of CTR, the 3-year locoregional recurrence-free probabilities were 95% versus 97% in patients who underwent limited resection (n = 52) and lobectomy (n = 52), respectively (p = 0.8622). Conclusion: An indication for limited resection may be decided with caution in clinical stage IA patients with the predictors of the pathological metastasis and/or involvement because of relatively higher incidence of postoperative locoregional recurrence after limited resection when compared with lobectomy.

P2.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.16-31 EXAMINATION OF THE INTERSEGMENTAL ISOLATION METHOD IN THE SEGMENTAL RESECTION CONSIDERING RESPIRATORY FUNCTION PRESERVATION
K. Kojima1, M. Yano2, K. Okubo3
1Thoracic Surgery, Karatsu Red-Cross Hospital, Karatsu-Shi, Saga/IJP 2Thoracic Surgery, Musashino Red-Cross Hospital, Musashino-Shi, Tokyo/IJP 3Thoracic Surgery, Tokyo Medical and Dental University, Bunkyo-Ku, Tokyo/IJP

Background: Segmental resection is often performed as limited operation for early lung cancer because it is usually considered the procedure to preserve respiratory function. There are two methods to isolate the intersegmental line. One is the method to isolate along intersegmental plane exactly with electric knife or ultrasonic scalpel and another is to cut with automatic suture instruments with automatic suture instruments. The superiority of the respiratory function preservation effect among two is not known. So we examined which is better method in the respiratory function preservation. Method: We targeted the cases respiratory function test were performed one year after operation among all patients which we underwent segmental resection for primary lung cancer between November in 2000 and March in 2017. We compared the recovery rate of postoperative vital capacity for preoperative vital capacity (=RRVC) and the one of postoperative forced expiratory volume in one second for preoperative forced expiratory volume in one second (=RFRFEV1) between the group with the method to cut with automatic suture instruments (=ASCG) and the group with the method to cut with automatic suture instruments (=ISPG). Result: 176 cases satisfied above detail. There were 119 cases in ISPG and 56 cases in ASCG. RRVC was 94% in ISPG and 88% in ASCG. RRVC was 94% in ISPG and 90% in ASCG. The significant difference was shown in both RRVC (p = 0.005) and RFRFEV1 (p = 0.03). The procedure which has the better recovery rate was the segmental resection of right S2 and either S6. Almost all other simple and complicated segmental resections were in ISPG. RFRFEV1 in the segmental resection of right S2 was 100% in ISPG and 85% in ASCG. RFRFEV1 in the segmental resection of right
S2 was 98% in ISPG and 84% in ASCG. RR_{cv} in the segmental resection of right or left S6 was 88% in ISPG and 88% in ASCG. RR_{cv} in the segmental resection of S6 was 93% in ISPG and 91% in ASCG. The significant difference was shown in RR_{cv} of the segmental resection of right S2 (p = 0.04). Conclusion: We consider the isolation along intersegmental plane exactly is superior to the method with automatic suture instruments from the viewpoint of respiratory function preservation while the difference may depend on the resected segment. We guess it is expected that the difference of the respiratory function preservation effect between the two groups grows as much as the intersegmental plane is large.

Keywords: respiratory function preservation, segmental resection, isolation of the intersegmental plane

TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.16-32 SURVIVAL IMPLICATIONS AND FACTORS ASSOCIATED WITH THE ANATOMIC LEVEL OF INCOMPLETE NON-SMALL-CELL LUNG CANCER (NSCLC) RESECTION
Y. Leel1, M. Smeltzer2, M. Ray3, N. Faris4, C. Fehnel5, C. Houston-Harris6, O. Akınbokula4, P. Ojeabulu4, E. Owen5, R. Eubanks6, H. Dox6, D. Talton6, H. Wiggins6, B. Wolff6, P. Levy1, E. Robbins1, R. Osarogiagbon7,8,9
1Epidemiology and Biostatistics, University of Memphis School of Public Health, Memphis/TN/US, 2Epidemiology and Biostatistics, University of Memphis School of Public Health, Memphis/TN/US, 3Baptist Cancer Center, Baptist Memorial Healthcare, Memphis/TN/US, 4Thoracic Oncology Research Group, Baptist Cancer Center, Memphis/TN/US, 5Thoracic Surgery, Methodist North Hospital, Memphis/TN/US, 6Thoracic Surgery, Baptist Memorial Hospital - Golden Triangle, Columbus/MS/US, 7Thoracic Surgery, Baptist Memorial Hospital - North Mississippi, Oxford/MS/US, 8Thoracic Surgery, North Mississippi Medical Center, Tupelo/MS/US, 9Thoracic Surgery, St. Bernard’s Medical Center, Jonesboro/AR/US

Background: Incomplete resection impairs NSCLC survival, but the relative significance of specific anatomic levels of margin involvement is uncertain. We examined the survival implications of the anatomic level of margin positivity. Method: We analyzed curative-intent primary NSCLC resections from 11 hospitals in 4 contiguous Dartmouth Hospital Referral Regions in West Tennessee, East Arkansas, and North Mississippi from 2009-2018. Overall survival (OS) was evaluated with Kaplan-Meier estimates and hazard ratios (HR) from Cox models. Result: Of 3097 resections, 137 (4.4%) had positive margins. The anatomic sites of margin positivity were: mainstem bronchus 28%; peribronchial margin 24%; chest wall margin 21%; lung tissue margin 12%; great vessels 1%; mediastinum 2%; bronchial carcinoma in-situ 1%; not reported 11%. Compared to patients with negative margins, positive margins were more likely in patients who were male (66% v 51%, p = 0.0003), had poorly/undifferentiated tumor grade (45% v 34%, p = 0.0143), squamous NSCLC (45% v 34%, p = 0.0143), had poorly differentiating squamous lung cancer (37% v 25%, p = 0.039), and had higher pT (p < 0.0001) and pN (p < 0.0001), or lung tissue (HR = 2.92, p = 0.0007) had a negative prognostic impact. Positive margins at chest wall (HR = 1.66, 0.3310) and lung tissue margins (HR = 2.24, p = 0.0137) had the most significant prognostic impact after controlling for age, sex, race, histology, primary site, tumor grade, ct, ct, and adjuvant chemo/radiation (Table).

Conclusion: Incomplete NSCLC resection at the chest wall or the lung tissue margins cannotes worse survival than other anatomic sites of margin involvement.

P2.16-33 ADENOSQUAMOUS CARCINOMA OF THE LUNG: COMPARISON OF SURGICAL OUTCOMES WITH SQUAMOUS CELL AND ADENOCARCINOMA
H. Maleki1, G. Getinkaya2, A.S. Bayram3, E.U. Akyildiz3, E. Yenturk1, E. Özer1, T. Sevinc1, C. Gebitekin1
1Thoracic Surgery, Uludag University, Bursa/TR, 2Pathologist, Uludag University, Bursa/TR

Background: Lung adenosquamous carcinoma (ASC) is a rare subtype of lung cancer that contains squamous cell carcinoma (SCC) and adenocarcinoma (AC) components. Clinical and prognostic features have not been fully established. The aim of the study is to compare the clinical characteristics and survival outcomes of ASC, AC and SCC. Method: In our clinic, the data of 1076 patients who underwent segmentectomy, lobectomy, or pneumonectomy due to non-small cell lung cancer between 1996-2016 was reviewed retrospectively. Patients with histologically proven tumor cell type ASC (n = 25, 2.32%), AC (n = 350, 32.52%) and SCC (n = 740, 50.18%) were included in the study. Univariate and multivariate analysis were performed to determine prognostic factors. The Kaplan-Meier method was used for survival analysis. Result: Our study group consisted of 915 patients (834 (91.15%) male, mean age 60.87 ± 9.02 (30-87) years). 65 (7.1%) patient underwent segmentectomy, 711 (77.7%) lobectomy and 139 (15.2%) pneumonectomies were performed as lung resections. Morbidity was seen in 326 patients (35.6%). Postoperative 90-day mortality rate was 2.95% (n = 27). When the demographic data was analyzed between the three groups, female gender was 18% in AC and 4% in ASC and SCC, respectively (p <0.001). In the preoperative positron emission tomography, the maximum standard uptake median value was 13.47 in SCC and 11.73 and 9.40 in ASC and AC, respectively (p <0.001). Pneumonectomy rate was 20.74% in SCC and 16% and 6.57% in ASC and...

P2.16-34 VISCERAL PLEURAL INVASION IS CLOSELY ASSOCIATED WITH NODAL SPREAD IN CSTAGE I A LUNG ADENOCARCINOMA
T. Mizuno1, T. Arimura1, H. Kuroda1, N. Sakakura1, Y. Yatabe1, Y. Sako2

1Division of Thoracic Surgery, Aichi Cancer Center Hospital, Nagoya/JP
2Department of Pathology and Molecular Diagnostics, Aichi Cancer Center Hospital, Nagoya/JP

Background: Survival outcomes of patients with clinical Stage IA (cIA) lung adenocarcinoma (LAD) are favorable after resections. In this decade, limited resection without lymphnodes dissections have been indicated for selected cases based on the radiological findings and intraoperative hilar explorations, while we sometimes experience occult lymphnodes metastases among them. These facts refer that limited resections could potentially induce underestimation of the disease, local failure and worse patients' prognoses. In the present study, we retrospectively investigate the clinicopathological and oncogenic factors in association with the occult nodal spread and skip metastases, and aim to identify population for standard resection in cIA LAD.

Method: We retrospectively investigated 287 patients with cIA LAD who underwent standard pulmonary resections with mediastinal dissections from January 2013 through December 2017. Clinicopathological factors including location of the tumor, radiological pleural invasion and oncogenic status (EGFR/KRAS/ALK/Triple Negative) were reviewed for outcomes of occult nodal spread and skip metastasis. According to the ROC curves analyses, cutoff values of total diameter (TD), solid diameter (SD), mediastinal window diameter (MD) in CT image and pathological invasive size (IS) were settled to diagnose nodal metastases and skip pN2, respectively.

Result: Among 287 patients with cIA LAD, 34 (11.8%) with lymph node metastases and 8 (2.8%) with pN2 without hilar metastases (skip pN2) were identified. Univariate analyses revealed that high serum CEA level, TD, MD, SUVmax, IS and pathological pleural invasion (pl) were predictive for nodal metastases and 8 (2.8%) with pN2 without hilar metastases (skip pN2) were identified. Furthermore, multivariate analysis showed that pl was closely associated with nodal metastases (Odds Ratio: 3.3, p=0.007). Furthermore, multivariate analysis following the univariate analyses also showed that presence of pl was the factor closely associated with skip N2 metastases (Odds Ratio: 5.7, p=0.029), whereas radiological findings nor oncogenic status were not. In the clinical valuables, serum CEA level, SD, MD, SUVmax were significantly associated with pl.

Conclusion: In resected cIA LAD, pathological pleural invasion was closely associated with both occult nodal spread and skip pN2, while other preoperative factors and oncogenic status were not. New diagnostic modalities for pl may provide the candidates for standard resections in cIA LAD.

P2.16-35 ANALYSIS OF PRE AND INTRA OPERATIVE FACTORS RELATED TO THE OPERATION TIME OF LOBECTOMY IN VATS: IS THE SHAPE OF THORACIC CAVITY A PREDICTIVE FACTOR?
T. Nagashima1, H. Ito1, H. Yamasaki2, K. Inafuku3, J. Osawa3, J. Samejima4, T. Harashimo1

1Department of Thoracic Surgery, Kanagawa Cancer Center, Yokohama/JP
2Department of Thoracic Oncology, Kanagawa Cancer Center, Yokohama/JP
3Thoracic Surgery, Kanagawa Cancer Center, Yokohama/JP

Background: Video-assisted thoracoscopic surgery (VATS) to treat lung cancer is less invasive than thoracotomy. However, prolongation of the operation time can make VATS more invasive. An understanding of the preoperative factors of patients scheduled to undergo VATS may help us decide the operative approach and select patients for training young surgeons. We investigated preoperative and intraoperative factors related to prolongation of the operation time required to thoracoscopically perform lobectomy with mediastinal lymph node dissection for lung cancer.

Method: We reviewed all 166 patients who had undergone VATS lobectomy with mediastinal lymph node dissection for lung cancer between April 2013 and September 2016 in our hospital. The depth and width of the thoracic cavity was measured on preoperative computed tomographic scans. Preoperative and intraoperative factors were entered in multiple regression analysis to identify independent predictors of a prolonged operation time. We analyzed the relation between the numbers of factors related to a prolonged operation time and the operation time by one-way ANOVA.

Result: The average operation time was 175 minutes. On univariate analysis, the shape of the thoracic cavity was not associated with operation time. On multivariate analysis, smoking index (>600), location of the resected lobe (right middle and left upper lobes), clinical lymph-node metastasis, massive adhesion in thoracic cavity, and the number of autotomies for lobe division (3 or more) were independent factors related to a prolonged operation time. The presence of more factors was related to a longer operation time (p<0.001; no factor: 153 min, one factor: 163 min, two factors: 194 min, three factors: 219 min, and four factors: 222 min).

Conclusion: The shape of the thoracic cavity was not associated with operation time. We identified 5 predictors of a prolonged operation time. Our findings may be useful for deciding the operative approach and selecting patients suitable for training of surgeons.

P2.16-36 ADJUVANT CHEMOTHERAPY IS EFFECTIVE FOR COMPLETELY RESECTED STAGE IB NON-SMALL CELL LUNG CANCER
M. Nakata, Y. Nojima, K. Nanba, S. Saihso, K. Shimizu
General Thoracic Surgery, Kawasaki Medical School, Kurashiki/JP

Background: The efficacy of adjuvant chemotherapy for completely resected stage IB non-small cell lung cancer (NSCLC) still remains controversial. The Cancer and Leukemia Group B (CALGB) 9633 trial reported that the adjuvant chemotherapy with paclitaxel and carboplatin showed a significant survival advantage in a subset of patients with tumors larger than 4cm in diameter. In Japan, uracil-tegafu (UFT) has been recommended for stage IB NSCLC. The purpose of this study is to compare the efficacy of platinum-based regimens with UFT as the adjuvant chemotherapy for stage IB NSCLC.

Method: Patients who underwent complete resection with systemic nodal dissection for stage IB NSCLC between January 2008 and December 2017 in our hospital were retrospectively studied. Disease stage was defined according to the 6th edition of UICC TNM classification. Patients who underwent sublobar resection or any induction therapy prior to surgery were excluded from this study. This study was conducted with the approval of the Ethics Committee of Kawasaki Medical School.

Result: There were 135 eligible patients consisting of 91 male and 44 female, with mean age of 72.1 years (range, 43-87 years). Of 135 patients, 59 patients (43.7%) underwent adjuvant chemotherapy (platinum-based 15, UFT 44). Median follow-up period was 37.9 months (range 1.1-107.3 months). Overall survival of patients undergoing adjuvant chemotherapy was significantly better compared with that of patients with surgery alone (p=0.032). There were no differences in recurrence-free survival between the two groups (p=0.470). Patients who underwent adjuvant chemotherapy with platinum-based regimens survived significantly longer than patients who underwent surgery alone (p=0.029). Overall survival of patients with platinum-based regimens tended to be better than that of patients with UFT. In a multivariate analysis including sex, age, histologic type, and tumor size, adjuvant chemotherapy was an independent prognostic factor for overall survival (p=0.037).

Conclusion: Adjuvant chemotherapy especially with platinum-based regimen, provided a significant survival advantage for completely resected stage IB NSCLC.

P2.16-27 THE INTRODUCTION OF ROBOTIC LOBECTOMY FOR NON-SMALL CELL LUNG CANCER IN SOUTH EAST ASIA: A 5-YEAR SINGLE CENTRE STUDY
K. Ong, A.A. Fazuludeen, D. Aneeza
Division of Thoracic Surgery, Department of General Surgery, Tan Tock Seng Hospital, Singapore/SG

Background: Over the past decade, minimally invasive robotic-assisted thoracic surgery has gradually evolved into the preferred platform for oncological thoracic resection, demonstrating respectable perioperative and long-term outcomes. The aim of this study is to evaluate the feasibility of completely portal robotic lobectomy (CPR4) for non-small cell lung cancer (NSCLC) at a geographical region that has yet to assimilate this relatively new platform. Method: This is a 5-year retrospective review of consecutive patients with NSCLC who underwent CPR4 by a single surgeon at our institution from January 2013 – October 2017. Result: A total of 80 patients (female 55%, median age 67 years) underwent elective completely portal robotic lobectomy CPR4 for NSCLC. 67.5% were non-smokers. The top 3 co-morbidities were hypertension (60%), hyperlipidaemia (55%) and diabetes (21.3%). 17.5% had previous non-lung related malignancies. Median operative time was 202 mins (range 80 – 335 mins). Conversion rate was 12.5%, the vast majority were due to non-progression of the case. Median ICU/HNU stay, chest tube duration and length of hospital stay were 1 day (range 1 – 4 days), 3 days (range 1 – 34 days) and 4 days (range 2 – 30 days) respectively. There was no perioperative (30-day) mortality in this study. The two commonest complications were prolonged chest tube duration (11.3%) and atrial fibrillation (3.75%). Median tumour size on histology was 2.3cm (range 0.9 – 7cm). Most were adenocarcinomas (85%), followed by squamous cell carcinoma (7.5%), adeno-squamous cell carcinomas (2.5%) and other rare tumours. Final pathological staging distribution was 68.8% stage 1, 15.8% stage 2, 9.2% stage 3A and 5.3% stage 4. 25% were upstaged after pathological staging. Median follow up was 2 years (range 0.2-5.33 years). All lung cancer related mortality occurred within 2 years after surgery. Stations 4 (70.3%), 7 (73.6%), and 10 (33.8) were most frequently sampled preoperatively, 4, 7 and 9 intraoperatively (Table 2). Except for station 7, there was little overlap in anatomic station examination between invasive clinical and pathologic nodal staging.

P2.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.16-38 CHARACTERISTICS OF PREOPERATIVE NSTAGING IN PATIENTS WITH OPTIMAL PATHOLOGIC NSTAGING OF NON SMALL CELL LUNG CANCER(NSCLC)
M. Ray1, M. Smeltzer1, N. Faris2, Y. Lee3, C. Fehnel1, C. Houston-Harris1, O. Akinbobola1, P. Ojeabulu1, E. Owen4, R. Eubanks5, H. Dox6, P. Talton7, G. Valaulikar8, H. Wiggins9, B. Wolf10, P. Levy11, E. Robbins12, R. Oroszi13

Background: Despite its prognostic value, the thoroughness of clinical and pathologic nodal staging varies significantly. We compared anatomic preoperative nodal sampling details to anatomic surgical lymphadenectomy details in resections meeting National Comprehensive Cancer Network (NCCN) quality criteria. Method: Patients had curative-intent NSCLC resections between 2009-2018 in 12 hospitals in 4 contiguous Dartmouth Hospital Referral Regions in the mid-Southern USA. Univariate statistics were calculated to summarize characteristics. Result: 1,346 of 3,297 resections (40.8%) met all 4 NCCN criteria (anatomic resection, negative margins, examination of >0 N1 nodes and ≥3 mediastinal stations). Of these 1,346, 1,114 (83%) received PET/CT scans and 148 (11%) received invasive nodal staging (all had EBUS/EUS/TBNA); 10 (1%) also had mediastinoscopy. Among 148 invasively staged patients, 72% were histologically node-negative, 19% were node-positive: 34 (23%) were down-staged and 20 (13.5%) were up-staged after surgery. Stations 4 (70.3%), 7 (73.6%), and 10 (33.8) were most frequently sampled preoperatively, 4, 7 and 9 intraop (Table 2). Keywords: Completely portal robotic lobectomy, non-small cell lung cancer, Surgery

**P2.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE**

**Tuesday, September 25, 2018 - 09:45-18:00**

**P2.16-39 THE APPLICATION OF 3D MEDICAL IMAGE ANALYZER AND A FLUORESCENCE GUIDED SURGERY FOR PULMONARY SUBLOBAR RESECTION**

Y. Sekine1, T. Itoh2, T. Toyoda3, D. Kaiho1, H. Hoshino1, H. Oheda1, E. Koh1

1Department of Thoracic Surgery, Tokyo Women’s Medical University Yachiyo Medical Center, Yachiyo/JP, 2Kimitsu Central Hospital, Kimitsu/JP

**Background:** The confirmation of an appropriate resection margin from the tumor is crucial for reducing the risk of local recurrence after sublobar resection for lung cancer. Furthermore, the precise anatomical sublobar resection is also important for preserving pulmonary function. We developed the novel operation method for pulmonary sublobar resection.

**Method:** From Aug. 2014 to Apr. 2018, 43 primary lung cancers were enrolled. Active limited resection was done in 29 and passive limited resection was done in 14. Preoperatively, each patient underwent computed tomography for creating several virtual sublobar resections by using Volume Analyzer Synapse VINCENT (Fujifilm, Tokyo, Japan). We measured the shortest distance from the tumor to the resection margin in each simulated resection and selected the most appropriate area of sublobar resection based on the adequate resection margin of approximately 2 cm from the tumor. After the simulation, we performed sublobar resection by using an infrared thoracoscopy with transbronchial ICG instillation. Before operation, 10ml of 10-fold diluted ICG with autologous blood and 400ml of air were instilled into each associated subsegmental bronchus. sublobar resection was performed under ICG visualization.

**Result:** The types of sublobar resection were subsegmental resection in 3, simple segmentectomy which was defined a simple plane cut surface of pulmonary division in 13, complex segmentectomy which was defined multiple plane cut surfaces of pulmonary division in 10 and extended segmentectomy which was defined segmentectomy with adjacent subsegmental resection in 14 and super deep extended wedge resection in 3. Average number of simulation was 4.3+/−1.5. The shortest distances from the tumor to the resection margin by simulation and an actual measurement were 23.6+/−11.6 mm and 24.6+/−8.6 mm, respectively (p=0.647). Postoperative recurrence was found in 5 cases (distant in 3 and mediastinal or supra-clavicular lymph node in 2) who all underwent passive limited resection. No ipsilateral lung recurrence was found.

**Conclusion:** The advantages of this method are applicable to any type of sublobar resection, initial determination of resection area at operation, possible super deep wedge resection without broncho-vascular transaction with enough margin, long identification of fluorescence, and indication in case of COPD, IP, reoperation and adhesion. On the other hand, the drawbacks are the necessity of a near infrared thoracoscopy and 3D medical image analyzer, knowledge of precise bronchial anatomy and advanced manipulation skills of bronchoscopy, uniformity of ICG distribution and distribution of ICG into the adjacent area with the passage of time.

**Keywords:** fluorescence imaging, three dimension image analysis, sublobar resection

**P2.16-40 IMPACT OF PREOPERATIVE PECTORALIS MUSCLE QUANTITY AND DENSITY ON OUTCOME AFTER COMPLETE RESECTION OF NON-SMALL CELL LUNG CANCER**

Department of Thoracic Surgery, The University of Tokyo Hospital, Tokyo/JP

**Background:** Body composition measures may predict outcomes of cancer surgery. In this study we evaluated the prognostic significance of pectoralis muscle quantity and density in patients with surgical non-small cell lung cancer.

**Method:** Preoperative pectoralis muscle quantity and density were retrospectively assessed in 181 patients undergoing lobectomy and lymph node dissection for non-small cell lung cancer from 2009 to 2013. The pectoralis muscle index (cross-sectional area/height2) and density (average Hounsfield unit, HU) at the fourth thoracic vertebra level were measured and calculated on preoperative plain computed tomography. Overall survival was analyzed between the lowest gender-specific quartile of the pectoralis muscle index and density and the other quartiles.

**Result:** Positive correlations between pectoralis muscle index and density and body mass index (BMI) were identified in the cohort (Pearson’s r=0.349, p<0.001; r=0.206, p=0.005, respectively). The gender-specific lowest quartile cut-off values of the pectoralis muscle index and density was 10.14cm2/m2 and 28.97HU for males, 7.86cm2/m2 and 21.23HU for females, respectively. The cumulative five-year overall survival rates were significantly shorter in patients with low pectoralis muscle index (51.7% vs. 76.0%, p=0.009), while for low pectoralis density (66.0% vs. 70.7%, p=0.391). The multivariate analysis including age, smoke index, BMI, c-reactive protein, carcinoembryonic antigen and pathologic stage revealed that the pectoralis muscle index, not the pectoralis density or BMI, was an adverse independent risk factor for overall survival (p=0.002, hazard ratio: 2.815; 95% confidence interval: 1.473–5.377).

**Conclusion:** A low preoperative pectoralis muscle index was associated with a poor postoperative outcome in surgical patients with non-small cell lung cancer. Pectoralis muscle quantity which is more predictive than density and BMI as a convenient measure, may be included in the preoperative assessment when surgical intervention is considered for non-small cell lung cancer.

**Keywords:** pectoralis muscle, non-small cell lung cancer, prognostic factor
Keywords: VATS can accurately locate non-palpable small sized lung tumors.
intraoperatively by using IO-CT scans. All tumors were completely identified.
the pleura was 7.2 mm. All tumors were identified pathologically, 10 were primary lung cancers, 7 were metastatic lung nodules (GGN) type, 2 were part-solid type, and 11 were pure solid type; tumors sensitivities and accuracies to detect N2 by two methods.
the pathological findings. Primary aim was to compare the sensitivities and accuracies to detect N2 by two methods. Result: Out of 85 patients with cN1 on PET-CT, a mediastinal metastasis was disclosed in 29 patients (34.1%). Of 56 patients who underwent VAMLA 24 (42.9%) were found to have N2/N3 disease, whereas standard mediastinoscopy revealed N2/N3 disease in 7 patients(24.1%) (p = 0.029) VAMLA and standard mediastinoscopy had both sensitivities of 85.7% to detect N2 disease(p = 1). The NPVs were 87.5% and 85.7% by VAMLA and standard mediastinoscopy respectively(p = 0.821).
Conclusion: VATS is more accurate to detect mediastinal nodal disease in operable cN1 lung cancer, and could be used in patients with cN1 NSCLC patients since it discloses N2 disease in a important fraction of patients.

P2.16-44 LONG-TERM OUTCOME OF PULMONARY SEGMENTECTOMY FOR C-IA NON-SMALL CELL LUNG CANCER
Department of General Thoracic Surgery, Chiba University Graduate School of Medicine, Inohana, Chuo-Ku Chiba-Shi, Chiba/JP
Background: Pulmonary segmentectomy is being accepted as a favorable treatment option for small peripheral non-small cell lung cancer (NSCLC) although lobectomy is the standard surgical procedure. The long-term outcome and related issues of postoperative recurrence after pulmonary segmentectomy needs to be investigated. Method: We retrospectively reviewed 306 and 313 patients with clinical (c-) stage IA NSCLC who underwent segmentectomy (S) or lobectomy (L) from January 2008 to December 2015. Patient demographics, prognostic, recurrence sites, and occurrence of second primary lung cancer were reviewed and compared between the 2 groups. Segmentectomy was intentionally selected when a target tumor was less than 3cm in diameter and ground-glass predominant. Solid part predominant tumors were also eligible for segmentectomy if its diameter was 2cm or less. Segmentectomy was reluctantly selected instead of lobectomy if patients presented insufficient vital organ function or have other pulmonary lesions which needed to be removed. Result: In segmentectomy group, the average age was 68.1± 9.1 and 74 males were included. The solid tumor diameter and consolidation-tumor ratio in the S group were statistically smaller than those in the L group. There were no statistical differences in 5-year overall survival (S: 92.0% vs L: 91.5%) and relapse-free survival (Sy-RFS) (S: 82.8% vs L: 84.4%) between the 2 groups. The 5-year RFS stratified by clinical T factors in 8 th edition showed no statistical differences between the 2 groups. Tumor recurrence occurred in 14 patients (10.4%), including loco-regional in 11 (8.1%) and distant metastasis in 3 (2.2%) patients. Recurrence on the intersegmental plane was developed in 2 patients. Loco-regional recurrence rates were similar in the 2 groups; however, loco-regional recurrence after segmentectomy tended to arise later than
those after lobectomy (median of loco-regional recurrence free survival: 1094 and 512 days). Multi-variate analysis showed that a risk factor for loco-regional recurrence was solid tumor diameter, not segmentectomy. Second primary lung cancer occurred in 7 and 12 patients after segmentectomy and lobectomy, respectively. Additional lung resection including completion lobectomy was applied and showed better outcome than non-surgical treatment. Conclusion: The long-term outcome of segmentectomy for selected patients is equivalent to those of lobectomy. However, careful follow-up is mandatory as recurrence and second primary lung cancer can occur in the same lobe after segmentectomy which is avoidable by lobectomy.

Keywords: segmentectomy, lung cancer

P2.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.16-45 SHOULD PATIENTS WITH STAGE IB NON-SMALL CELL LUNG CANCER RECEIVE ADJUVANT CHEMOTHERAPY?
J. Wang, W. Nan, C. Lv, S. Yan, Y. Yang
Department of Thoracic Surgery I, Peking University Cancer Hospital & Institute, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing/CN

Background: There’s much controversy over the necessity of adjuvant chemotherapy to stage IB non-small cell lung cancer (NSCLC). The aim of this study is to compare the efficacy of platinum-based adjuvant chemotherapy for patients with stage IB NSCLC according to the 8th and 7th editions of the TNM staging system who underwent complete surgical resection and systemic mediastinal lymph node dissection. Method: Subjects were 569 patients who underwent pulmonary resection for primary NSCLC. Survival characteristics were compared using the 8th and 7th editions of the TNM classification. Result: For patients in the observation and adjuvant groups, 5-year overall survival was 76.9% and 83.5%, respectively (p=0.044). In univariate analysis, lymphovascular invasion, TNM stage and performance status (PS) were risk factors for overall survival. In multivariate analysis, TNM stage (hazard ratio = 5.808, 95% confidence interval 3.980-8.475, p<0.001), PS (hazard ratio = 4.804, 95% confidence interval 3.133-7.413, p<0.001) and adjuvant chemotherapy (hazard ratio = 1.565, 95% confidence interval 1.069-2.291, p=0.021) were risk factors for overall survival. Subset analysis showed that for patients with stage IB NSCLC, 5-year overall survival was 87.6% in the observation group (n=265) and 82.4% in the adjuvant group (p=0.021). For patients with stage IIA NSCLC, 5-year overall survival was 79.3% in the observation group and 91.6% in the adjuvant group (p=0.001). For patients with ECOG 1, 5-year overall survival was 58.6% in the observation group and 17.2% in the adjuvant group (p=0.021). Conclusion: For NSCLC patients with surgically treated, platinum-based adjuvant chemotherapy might result in worse survival than observation alone to stage IB but improve survival to stage IIA. Moreover, patients with good PS (ECOG 0) benefit from adjuvant chemotherapy.

Keywords: NSCLC, adjuvant chemotherapy, the 8th TNM classification

P2.16-46 CLINICAL OUTCOMES AND TREATMENT STRATEGIES OF SARCOMATOID CARCINOMA OF THE LUNG
Y. Wang
Thoracic Surgery, The 4th Hospital of Hebei Medical University, Shi Jiazhuang/CN

Background: Sarcomatoid carcinoma of the lung is characterized by worse prognosis, and generally felt to be chemo-refractory compared with other non-small cell lung cancer. We conduct this retrospective study to investigate the clinical characteristics of patients with sarcomatoid carcinoma of the lung and determine the optimal treatment strategies. Method: We reviewed the medical records of 8176 patients with resected lung cancer in a single high-volume institution between 2008 and 2015. All patients with pathologically diagnosed sarcomatoid carcinoma were evaluated. Clinicopathologic data were analyzed using Kaplan-Meier analysis and Cox regression analysis. Subgroups stratified by pathological stage were analyzed to determine the optimal treatment modality. We also conducted subgroup analysis of overall survival among pulmonary sarcomatoid carcinoma and other NSCLC patients. Result: Kaplan-Meier and Cox regression analyses showed pathological stage (8th edition) is the independent prognostic factor (p=0.001, HR=2.601, 95%CI(1.447-4.675)) for pulmonary sarcomatoid carcinoma. Overall survival favored other NSCLC over PSC across subgroups.
Conclusion: Pathological stage (8th edition) is independent prognostic factor for sarcomatoid carcinoma of the lung. Surgery followed by adjuvant chemotherapy should be considered for stage I pulmonary sarcomatoid carcinoma. Further prospective studies are needed to confirm these results.

Keywords: Sarcomatoid Carcinoma of the lung, treatment, Prognosis
P2.16 OUTCOMES OF STAGE I LUNG CANCER PATIENTS TREATED WITH SEGMENTECTOMY VIA THREE-DIMENSIONAL UNIPORTAL VATS VERSUS TWO-DIMENSIONAL APPROACH

C. Yang, Y. Liu, W. Sun, Z. Li, S. Zhang
Department of Thoracic Surgery, Shenyang Chest Hospital, Shenyang/CN

Background: Three-dimensional uniporal Video-assisted Thoracic Surgery (3D-VATS) segmentectomy is an emerging technique for the surgical resection of early stage lung cancer. There were few reports on its benefits over two dimensional uniporal Video-assisted Thoracic Surgery (2D-VATS) procedure. This study aimed to compare the operative and perioperative data between 2D and 3D VATS anatomic segmentectomy and to identify the actual role of 3D-VATS in thoracic surgery.

Method: Between August 2016 and March 2018, a total of 125 consecutive stage I Non-small cell lung cancer (NSCLC) patients who underwent uniporal VATS anatomic segmentectomy in the Department of Thoracic Surgery, Shenyang Chest Hospital, were retrospectively reviewed. Incorporating preoperative clinical features were used to compare the perioperative outcomes and analyze the safety and efficacy of 3D-VATS and 2D-VATS anatomic segmentectomies for stage I NSCLCs.

Result: There were 64 patients in the 3D-VATS group and 61 patients in the 2D-VATS group from August 2016 and March 2018. During the operation, the anatomic segmentectomy took less time in the 3D-VATS than in the 2D-VATS (81.5±36.7 min vs 105.7±39.4 min, P < 0.05) group. The total operation duration, the volume of estimated blood loss (36.5±12.5 ml vs 41.5±18.4 ml, P = 0.24), and the length of postoperative hospital stay (4.5±1.6 days vs 5.1±1.9 days, P = 0.07) were similar between the two groups. Postoperatively, 3D-VATS and 2D-VATS groups showed similar results in terms of morbidity and mortality.

Conclusion: In the surgical resection of early-stage non-small cell lung cancer, 3D uniporal VATS anatomic segmentectomy is a safe and effective alternative to the 2D-VATS procedure. Nevertheless, further studies are necessary to better comprehend the role of 3D-VATS in modern thoracic surgery.

P2.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.16-48 WHICH NOMOGRAM IS MORE RELIABLE TO PREDICT RECURRENT OF PATHOLOGICAL STAGE IA LUNG ADENOCARCINOMA TREATED BY SURGERY?

L. Yang1, J. Zhao2, J. Zhang3, F. Xu1, H. Xu1, G. Yang1, J. Ying2, Y. Wang2
1Medical Oncology Department, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN; 2Surgical Oncology Department, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN; 3Department of Pathology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Background: Previous recurrence risk models offered individualized prediction using a more diverse set of factors than traditional staging measures American Joint Committee on Cancer Tumor Node Metastasis (AJCC TNM) Staging System. Several studies have demonstrated gene mutation as a new prognostic factor, such as EGFR, KRAS and so on. This study aimed to analyze a comprehensive and reliable Nomogram prognostic model to predict recurrence in stage IA lung adenocarcinoma (ADC) with radical resection. Method: This was a retrospective, single-center and case-control study. Clinicopathologic, genetic, therapeutic features and survival status were collected. Univariate and multivariate Cox proportional risk model was conducted. The nomogram for recurrence prediction was developed using Cox proportional hazards regression. Three nomograms were established based on a) AJCC 8th TNM Staging, b) multivariate analysis results and c) risk factors recorded in published references. The higher concordance index (C-index) of model identified better performance of nomogram. Result: 1499 patients with pathologic stage IA ADC from Cancer Hospital, Chinese Academy of Medical Sciences from October 2012 to December 2015 were enrolled in this study. The proportion of patients was 5% (53/180) patients randomly selected and analyzed in this study. Median DFS was not reached. The C-index of AJCC 8th TNM staging and the nomogram based on multivariate analysis was 0.598 (95% CI 0.538-0.659) and 0.696 (95% CI 0.629-0.764), respectively. The nomogram established on prognostic factors in previous studies, which included gene mutation such as EGFR, KRAS and ALK, showed higher discrimination with C-index 0.833 (95% CI 0.786-0.880).

Conclusion: This was the first individualized nomogram combining clinicopathologic features with genetic information to predict recurrence in ADC. The nomogram added with gene mutation status demonstrated superior predictive capability compared to other nomograms based on traditional AJCC T staging and multivariate analysis. Our nomogram was more reliable to guide prognostic factors and recurrence rate in stage IA ADC patients.

P2.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.16-50 DO PATIENTS HAVE PRECONCEIVED IDEAS ON VARIOUS SURGICAL APPROACHES? PATIENT PERSPECTIVE: OPEN VS. MINIMALLY INVASIVE SURGERY (PROMIS) SURVEY.

C. Yeung1, A. Martel1, M. Hanna2, A. Moledina2, A. Seeley3, D. Mazlai3, F. Shamji3, S. Sundaresan2, P. Villeneuve2, S. Gilbert3
1Thoracic Surgery, The Ottawa Hospital, Ottawa/ON/CA; 2Division of Thoracic Surgery, The Ottawa Hospital, Ottawa/ON/CA; 3Ottawa Hospital Research Institute, The Ottawa Hospital, Ottawa/ON/CA

Background: Patient perspectives on minimally invasive (MIS) versus open surgical approaches have not been well studied. Healthcare workers often presume that patients prefer MIS. The aim of this study was to objectively document patient viewpoint on pain, complication risks, cosmesis, travel burden, and functional outcomes throughout the course of treatment.

Method: From 2012-2017, of the 206 consented patients, 184 lung and esophageal surgical patients were prospectively enrolled in this observational cohort study. Participants were asked to complete PROMIS6 short form health survey (SF-36), which measures functional outcomes. They also completed the PROMIS questionnaire, which measures expectations regarding travel burden, pain, complications, and cosmesis on a continuous visual analog scale (VAS). The PROMIS questionnaires were also classified into three anatomic regions (neck, chest, and abdomen). Patients were surveyed pre-operatively, at 1 month and at 6 months. McNemar’s test, and paired and independent t-test were used as appropriate. Result: Of 206 patients, 184 (89%) completed the survey at least once. SF-36 showed physical functioning, role limitations due to physical health, energy level, pain, and social functioning worsened significantly at 1 month. All indices recovered to baseline at 6 months. Recovery of indices was similar in both MIS and open surgery patients. Patients indicated that pain after surgery (mean VAS = 7.3; 95% CI 7.0-7.6) was more important than size of incision (mean VAS = 4.5; 95% CI 3.9-5.1, p < 0.001) and travel burden (mean VAS = 4.0; 95% CI 3.4-4.5, p < 0.001). The risk of complications (mean VAS = 7.5; 95% CI 7.2-7.9) was more important than size of incision (mean VAS = 4.5; 95% CI 3.9-5.1, p < 0.001) and travel burden (mean VAS = 4.0; 95% CI 3.4-4.5, p < 0.001). These findings were similar at each time point and across each body regions. The MIS group perceived pain following surgery (mean VAS = 7.12; 95% CI 6.35-7.89) was more important than the open group though it was not statistically different (mean VAS = 6.02; 95% CI 5.25-6.79, p = 0.07). Conclusion: Early postoperative deterioration followed by 6-month recovery in functional outcomes was reported by all patients regardless of surgical approach (MIS vs. open). Complication risk and pain after surgery were perceived as more important than size of incisions and distance traveled for treatment. Patients maybe more open-minded to participation in trials comparing MIS to open surgery than expected.

P2.16-51 NATIONWIDE TRENDS IN SURGICAL TREATMENT OF LUNG CANCER IN ESTONIA, 2000-2015

T. Laisaar1, L. Lelebinna3, B. Sarana1, I. Benno1, P. Kiburi1, T. Vanakase1, I. Almre1, K. Laisaar2
1Thoracic Surgery Department, Tartu University, Tartu/EE; 2Institute of Family Medicine and Public Health, Tartu University, Tartu/EE; 3Thoracic Surgery, North-Estonian Regional Hospital, Tallinn/EE

Background: In last decades several changes have been observed in lung cancer incidence, morphology, diagnostic and treatment options. However, only a few studies have focused on these changes among surgically treated patients. The aim of the current study is to analyse changes in lung cancer surgical treatment, comparing surgically treated patients with all lung cancer patients. Method: Data on all surgically treated lung cancer patients in Estonia from January 2000 to December 2015 were obtained from hospitals’ medical records. Data on all patients diagnosed with lung cancer in the same period were obtained from the

P2.17-02 CARDIOPULMONARY EXERCISE TESTS IN LUNG CANCER PATIENTS TREATED RADICAL RADIOThERAPY AND CHEMOTHERAPY - FEASIBILITY STUDY

N. Mohammed\(^1\), R. Jones\(^1\), R. Carter\(^2\), G. McVay\(^3\), S. Thomson\(^4\), M. Glegg\(^4\), C. Lawless\(^5\), J. Paul\(^2\), R. Milroy\(^2\)

\(^1\)Radiation Oncology, Beatson West of Scotland Cancer Centre, Glasgow/GB, \(^2\)Respiratory Medicine, Glasgow Royal Infirmary, Glasgow/GB, \(^3\)Respiratory Medicine, Queen Elizabeth University Hospital, Glasgow/GB, \(^4\)Radiation Physics, Beatson West of Scotland Cancer Centre, Glasgow/GB, \(^5\)CRUK Clinical Trials Unit, Glasgow/GB, \(^6\)College of Medical, Veterinary & Life Sciences, CRUK Clinical Trials Unit, Glasgow/GB

Background: Cardiopulmonary exercise testing (CPET) is based on the principle that system failure can be detected when the system is under stress. CPET allows measurement of peak oxygen consumption (peak VO\(_2\)), the gold standard measure of exercise performance, and can identify the causes of exercise limitation. Variables measured at CPET can predict mortality in various disease states and is used to assess fitness for surgery. Lung cancer patients often have pre-existing cardiopulmonary disease, however there is limited data on the role of CPET in patients treated with radical radiotherapy (RRT). Recent RTOG 0617 study reported worse survival with RRT dose escalation, which was attributed to cardiopulmonary toxicity. This study aimed to investigate the feasibility of using CPET to study the effects of RRT on exercise capacity and to assess its cardiac and pulmonary components.

Methods: During the period 2003 – 2009, NSCLC patients undergoing RRT consented to participate in this prospective study. Alongside standard incremental CPETs, patients were assessed with pulmonary function tests and standardized measure of activity of daily living, the London Chest Activity of Daily Living scale (LCADL) at four different time points: pre-RRT and at 6 weeks, 6 months and 12 months post RRT. Result: Thirty-eight patients participated. Median age was 66 years, and Karnofsky Performance Status >70. Using TNM 5th Edition, staging was T1-2/T3-4 = 50%/50%, N0-X/N1-2 = 50%/50% and M0/1 = 92%/8%. Planned RRT was completed by 34 pts. Over the 12 months the peak VO\(_2\) (l/min) decreased (\(p_{\text{overall}} = 0.009\)) from a median 0.83 by a maximum of 0.12 at 6 m, thus demonstrating a decline in exercise performance. The \(V_c/VO_{2\text{max}}\) increased (\(p_{\text{overall}} = 0.005\)) post RT from a median 40, most clearly at 3 months (9, \(p = 0.028\)). Furthermore peak alveolar-arterial (A-a) gradient increased (\(p_{\text{overall}} = 0.001\)) from a baseline median value of 38.5 at 6w (3.15, \(p = 0.046\)) and 3m (5.75, \(p = 0.013\)) respectively. These results indicate a decline in ventilatory efficiency following RRT. No significant changes were seen in oxygen pulse, a surrogate measure of cardiac function. LCADL completion reduced after 6w. The median baseline score was 22 and a statistically significant difference could not be detected over time (\(p_{\text{overall}} = 0.502\)).

Conclusion: The results indicate that CPET is able to detect a decline in exercise performance after RRT and that in this study the decline appears to be driven by a reduction in respiratory function. These results require confirmation in a larger study.

P2.17-03 A PROPENSITY-MATCHED ANALYSIS OF NEOADJUVANT CHEMORADIOThERAPY AND ADJUVANT CHEMORadioTherAPY FOR IIIA(N2) NON-SMALL CELL LUNG CANCER

Y. Zhu\(^1\), C. Jiang\(^1\), Y. Chen\(^1\), J. Liu\(^1\), Y. Xu\(^1\), Q. Chen\(^1\), W. Mao\(^1\)

\(^1\)Shanghai Pulmonary Hospital, Shanghai/CHN, \(^2\)Zhejiang Cancer Hospital, Hangzhou/CHN, \(^3\)Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CHN, \(^4\)Department of Thoracic Surgery, Zhejiang Cancer Hospital, Hangzhou/CHN

Background: Multidisciplinary treatment is the preferred treatment for patients with IIIA(N2) non-small cell lung cancer (NSCLC). A subset of patients with potentially resectable disease is managed with trimodality therapy (surgery combined with chemoradiotherapy). However, little data exist to guide which one is better between neoadjuvant chemoradiation followed by surgery and surgery followed by adjuvant chemoradiotherapy. Given that prospective comparative data on these two management are limited, we compared the two treatments with a propensity-matched analysis.

Method: All patients undergoing treatment with trimodality therapy for clinical IIIA(N2) NSCLC between January 2012 and December 2016 were reviewed. Patients received individual chemotherapy regimens depending on the different pathological types: squamous cell carcinoma: Docetaxel 30mg/m\(^2\) d1,d8, Cisplatin 25mg/m\(^2\) d1-3, repeated every 3 weeks for 2 cycles; non-squamous cell carcinoma: Pemetrexed 500mg/m\(^2\) d1, Cisplatin 25mg/
m² d1-3, repeated every 3 weeks for 2 cycles) plus radiotherapy (46-50 Gy/23-25 fractions) at preoperatively to postoperative. Age, gender, tumor characteristics, histological types, pulmonary function, disease-free survival (DFS), overall survival (OS) data were collected. A propensity-matched analysis was performed. Result: A total of 31 patients underwent neoadjuvant chemoradiation followed by surgery, and 82 received surgery followed by adjuvant chemoradiotherapy. Median follow-up was 27 months. For the entire cohort, the median OS and DFS in neoadjuvant chemoradiation followed by surgery group were 24.0 months (95%CI: 17.1-29.2) and 16.6 months (95%CI: 10.9-21.5), which is shorter than 30.6 months (95%CI: 20.9-39.5) and 19.3 months (95%CI: 11.4-25.7) in surgery followed by adjuvant chemoradiation group (P=0.048 and P=0.037). A propensity matched comparison in a blinded manner (1:1 ratio, caliper distance=0.005) based on age, gender, WHO performance status, pulmonary function (forced expiratory volume in 1 second (FEV1) % and FEV1), pathological types, number of mediastinal lymph nodes and T stage resulted in 22 matched pairs. There were no significant differences between neoadjuvant chemoradiation followed by surgery and surgery followed by adjuvant chemoradiotherapy group (P>0.05). In the clinical trials is essential to define the indications and efficacy in a selected population.

P2.17 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.17-04 IMIQUIMOD ATTENUATES RADIATION-INDUCED PULMONARY FIBROSIS

M. Calik1, G. Yavas2, E. Celik3, C. Yavas4, G. Calik4, M. Sargon5, Y. Sanli6, M. Esme1, O. Ate1
1Department of Thoracic Surgery, Konya Training and Research Hospital, Konya/TR, 2Radiation Oncology, Selcuk University, Konya/TR, 3Pathology, Selcuk University, Konya/TR, 4Emergency Medicine, Necmettin Erbakan University, Meram Faculty of Medicine, Konya/TR, 5Anatomy, Hacettepe University, Ankara/TR, 6Radiation Oncology, Mersin Onco, Mersin/TR, 1Medical Oncology, Selcuk University, Konya/TR

Background: Radiation-induced lung injury (RILI) is a major dose limiting factor during thoracic irradiation. Imiquimod (I) stimulates the innate and adaptive immune pathways and induces cytokine production. We aimed to evaluate the impact of I on RILI. Method: Sixty rats were divided into 6 groups: Group (G) 1 control, G2 radiotherapy (RT) only, G3 and G4 5 and 10 mg/kg I; G5 and G6 RT plus 5 and 10 mg/kg I respectively. A single dose of 15 Gy RT was given to lungs. I was applied intraperitoneally with daily doses, until animals were sacrificed 6 and 16 weeks after RT. Conclusion: This propensity-matched analysis found multidisciplinary treatment remains a suitable option for a subset of patients with IIIA(N2) disease. Upfront surgery without invasive staging, followed by adjuvant chemoradiotherapy, appears reasonable in resectable N2 disease, simplifying patient care and reducing cost. Participation in clinical trials is essential to define the indications and efficacy in a selected population.

Keywords: IIIA(N2) non-small cell lung cancer, adjuvant chemoradiotherapy, neoadjuvant chemoradiotherapy

P2.17-06 FUNCTIONAL LUNG IMAGING IN RADIOTHERAPY FOR LUNG CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

N. Bucknell1, N. Hardcastle2, M. Bressell3, M. Hofman4, T. Kron1, S. Siva5
1Radiation Oncology, Peter MacCallum Cancer Center, Melbourne/AU, 2Physical Sciences, Peter MacCallum Cancer Center, Melbourne/AU, 3Biostatistics and Clinical Trials Unit, Peter MacCallum Cancer Center, Melbourne/AU, 4Cancer Imaging, Peter MacCallum Cancer Center, Melbourne/AU

Background: Advanced imaging techniques allow functional lung information to be derived and integrated into treatment planning. A prospectively registered systematic review was conducted to: i) assess pre-treatment functional dose metrics as predictors of radiation pneumonitis, ii) evaluate dose response relationships, iii) assess potential utility in radiotherapy treatment planning. Method: A structured search was performed for publications including key words for functional imaging, lung cancer and radiotherapy following PRISMA guidelines. Publications were required to have majority of the patients with lung cancer, age over 18, published in a peer reviewed journal and describe a radiotherapy application. Review articles and technical descriptions of functional imaging techniques were excluded. Studies with less than 10 patients were excluded from the meta-analysis. Literature searches were conducted in October 2017 in 3 electronic databases: Ovid Medline, Ovid EMBASE and Cochrane CENTRAL via the Wiley platform. The date of inclusion was restricted to 30 years onwards and searches were limited to articles in English only. Result: 814 articles were screened against the review criteria: 158 publications were selected for full text review, of these 114 met criteria. The most commonly used investigations were SPECT (64 publications), CT (44), MRI (12) and PET (5). Ten publications evaluated pre-treatment functional lung dose-metrics as predictors of radiation pneumonitis, 7 of these found that functional V20 and/or functional MLD correlate with the risk of clinically significant radiation pneumonitis. 6 studies comparing differences between functional and
anatomical dose metrics at predicting radiation pneumonitis found higher predictive values using functional dose metrics. Twenty one studies described a dose-response relationship on post-treatment functional lung imaging. Dose-response curves were provided in 5 papers with a majority of these curves exhibiting a sigmoid shape and two curves showing a threshold dose between of 4G-50Gy. 9 studies described the phenomenon of reperfusion post radiotherapy. Nineteen planning studies demonstrated the ability of functional lung optimized planning techniques to spare regions of functional lung. Meta-analysis of these studies found that mean (95% CI) functional volume receiving 20Gy was reduced by 4.1% [2.34; 6.04] and mean lung dose by 2.18Gy [1.09; 3.26] when plans were optimized to spare functional lung. Conclusion: There is significant heterogeneity identified in imaging techniques, definitions of functional lung and in the reporting of available studies. Whilst the current literature suggests possible correlations with dose to functional lung and clinical toxicity and the utility of functionally adapted radiotherapy delivery, there is a need for prospective interventional trials with clinical endpoints as outcome measures.

Keywords: functional imaging, Systematic review, Radiotherapy

P2.17 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC
TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00

P2.17-07 CONCURRENT CHEMORADIOThERAPY (CONCRT) USING CISPLATIN-VINORELBINE IN LocALLY ADVANCED (LA) NON-SMALL CELL LUNG CANCER (NSCLC)
H. Charalambous1, I. Constantinou1, D. Vorvassou2, N. Katodritis3, G. Papadopoulos4, F. Kypridinis5, I. Porfiriadis1, M. Decatis1
1Medical Oncology, Bank of Cyprus Oncology Centre, Nicosia/CY, 2Boc Oncology Centre, Nicosia/CY, 3Nicosia General Hospital, Nicosia/CY, 4Medical Oncology, Cheltenham General Hospital, Gloucester/GB

Background: We adopted ConCRT with cisplatin and vinorelbine as our standard of care for patients with LA NSCLC since 2005. This is an analysis of a register of all patients consecutively assigned ConCRT since 2005 in an intent to treat analysis. Method: From Feb 2005 to Dec 2015 we assigned ConCRT for 77 consecutive patients with LA NSCLC, who were deemed unresectable: this included T4/N3/“bulky” N2 disease or locally recurrent disease after initial surgery. Patients had ECOG performance status 0-2 and were treated with Cisplatin 75mg/m2 d1 and Vinorelbine 30mg/m2 d1-8. 3-weekly during the induction chemotherapy phase (i.e. full doses for the first 1-2 cycles) whilst with the addition of radical RT, Vinorelbine was reduced to 12.5mg/m2 d1 and Vinorelbine 30mg/m2 d1-8, 3-weekly during the induction chemotherapy phase. Results: 77 patients: 69 men and 8 women. Median age was 63 (43-81); PS 0-1 n=69, PS 2 n=8. Radiological stage IIIB n=40 (52%), IIIA n=30 (39%), IIIB n=7 (9%). Histology, squamous n=42, adenocarcinoma n=21, other NSCLC n=14. Treatment delivered: median 4 cycles (range 1-6). 71 patients (92%) completed ConCRT. Overall response rate 70% (49 partial and 5 complete responses), stable disease n=7, progressive disease n=8; of the remaining 8 non-evaluative patients, 6 patients did not complete ConCRT, either due to toxicity/death or disease progression. 11 patients who received ConCRT underwent surgery (5 lobectomies, 5 pneumonectomies). 6 of these 11 patients had a complete pathologic response (pCR). Median progression-free survival (PFS) 14.4 months (C.I. 9.0-19.8) and median overall survival (OS) 23.8 months (C.I. 17.2-30.4). Five year OS rate was 28.2%. There were 2 toxic deaths from neutropaenic sepsis during concurrent CRT and 1 after surgery. The incidence of grade 3-4 oesophagitis or pneumonitis was < 10% and manageable. Conclusion: This regimen has produced encouraging results with a 23.8 month median OS in a patient cohort with predominantly IIIB disease and with a significant minority of poor PS=2 patients, with 92% being able to complete the treatment. Finally 8% of patients had pathological pCR, with 28% of patients treated achieving long-term survival.

Keywords: chemoradiation, vinorelbine, Cisplatin

P2.17-08 HEART MOTION IN LUNG RADIOThERAPY: HOW REPRESENTATIVE ARE DENEliATIONS BASED ON 3DCT, AVERAGE AND MAXIMUM PROJECTION SCANS?
E. Vasquez Osorio1, H. Mccallum2, S. Iqbal3, A. Bedair4, A. McWilliam1, G. Price1, J. Byrne1, D. Cobben1
1Division of Cancer Sciences, University of Manchester, Manchester/GB, 2The Newcastle-Upon-Tyne NHS Foundation Trust, Newcastle-Upon-Tyne/GB, 3Western Health and Social Care Trust, Londonderry/GB, 4The Christie NHS Foundation Trust, Manchester Cancer Research Centre, Manchester/GB

Background: Evidence is emerging that the heart is more radiosensitive than previously assumed [1-2]. However, only delineations on the average projection or 3D CT scans are used for treatment planning. Therefore the motion of this organ due to respiration and contraction is not accounted for. In this pilot study, we assessed how representative the delineations based on the 3D CT scan, average (AVG) and maximum intensity projections (MIP) are. Method: Both 3D and 4D CT scans for 7 lung cancer patients treated by SABR were used in this study. Median delineations, derived from 3 independent observers following a previously agreed protocol, were calculated on the 3D CT, AVG and MIP and 25% exhale scans. Delineations on each 4D phase scan (n=8) were created by propagating the median 25% exhale contours using RayStation v5.99. The volume representing the maximum extent of motion was estimated as the union of all 4D phase delineations (U4D). Surface distances from the U4D to 3D, AVG, MIP volumes were calculated. Distances in the most extreme surface points (1cm most superior/inferior, 10% most right/left/anterior/posterior) are reported. Result: Figure 1 shows the distances for the most extreme surface points, for all patients and for each delineation. Patterns vary widely among patients. From the three delineations, MIP is the ‘closest’ to the maximum extent of motion, followed by AVG and 3D.

Conclusion: None of the delineations represented the heart’s maximum extent of motion for all patients, the MIP being the ‘most representative’ volume. All delineations would require an expansion to include all motion. Research including dosimetry measurements and inter-observer variability is required to determine the relevance of expanding the original delineations, and the corresponding margin magnitudes. [1] Johnson et al. Radiotherapy & Oncology. 2018. Volume 127:S170-1

Keywords: Delineation, Radiotherapy, Heart motion
**P2.17-09 EXPLORING THE IMPACT OF AGE ON THE EFFICACY OF ADJUVANT CHEMOTHERAPY AFTER RADICAL RESECTION IN NON-SMALL CELL LUNG CANCER**

C. Davidson1, K. Taylor2, P. Scullin2, L. Campbell2

1Northern Ireland Cancer Centre, Belfast/GB, 2Medical Oncology, Northern Ireland Cancer Centre, Belfast/GB

**Background:** Most adults diagnosed with Non Small Cell Lung Cancer (NSCLC) are over 65 years old. For those with resectable disease postoperative cisplatin-based chemotherapy (PC) has been shown to offer a significant survival advantage. However elderly patients are poorly represented in clinical trial cohorts, here we shall explore our regional experience of treating these patients. **Method:** Patients receiving PC with Vinorelbine 25mg/m², D1 & 8/ Cisplatin 75mg/m² (VC) following surgery for NSCLC between January 2004 and April 2017 were identified from the electronic computer database. Patients with synchronous tumours or metastatic disease were excluded. **Result:** 165 patients were identified, 63 (38%) >65yrs (range 65-77yrs). All were ECOG PS 0-1. 12 patients had Stage IIB disease (7 >65yrs), 63 Stage II A (20 >65yrs), 40 Stage III B (21 >65yrs) and 50 Stage III/A/B disease (17 >65yrs). 53.9% of patients > 65yrs compared to 81% patients < 65yrs completed 4 cycles of PC. 19.1% of patients required dose reductions due to toxicity, 12 were over 65yrs. Grade 3/4 neutropenia occurred in 21.2% of patients (18>65yrs vs. 17 >65 yrs) and febrile neutropenia in 9 patients > 65yrs vs. 11<65yrs. No toxicity deaths were recorded. Overall 85 (51.5%) patients, 26 > 65yrs had radiological evidence of disease recurrence. The median time to recurrence was 26.19 months, no significant difference was found in time to relapse based on age (p=0.21). Kaplan-Meier analysis revealed no significant difference in overall survival based on age (p=0.77). HR 1.069 (95%CI 0.68-1.67). Mortality 6 months post chemotherapy in patients > 65yrs was 1.58% vs. 2.94% in patients <65yrs.

**Conclusion:** This illustrates in routine practice, PC using VC is deliverable in older patients of good PS with resected NSCLC. Though they may experience more toxicity from PC the benefits in terms of disease recurrence and overall survival were equivalent to patients <65yrs.

**Keywords:** NSCLC, age, adjuvant chemotherapy

**P2.17-10 DAILY LOW-DOSE CISPLATIN AND HIGH DOSE RADIOTHERAPY FOR PATIENTS WITH STAGE III NSCLC IS WELL TOLERATED.**

E.M.T. Dielemans1, R. Van Os1, W. Kolf1, C.C.E. Koning1, J.T. Annema2, C.R.N. Rasch2

1Radiation Oncology, Amc, Amsterdam/NL, 2Pulmonology, Amc, Amsterdam/NL

**Background:** To assess how daily low-dose cisplatin (6mg/m²) combined with 66 Gy/24 fractions is tolerated by the elderly patient with stage III NSCLC. **Method:** All patients with stage III NSCLC were selected (2005-2015). The Cox regression model was used to investigate the difference between the younger and elderly patient group concerning toxicity and survival. The Kaplan-Meier method was used to show the difference between the dichotomized age factor. **Result:** The crude incidence of severe toxicity (STI) (grade 3–5) was 15% in patients ≤ 65 years (n=73) and 16% in patients >65 years (n=81)(Fig1). The median time to appearance of STI after treatment was 4 months. Age was a continuous variable in the Cox regression model. The p-value of age was 0.9 (HR=1.002,95%CI:0.968 –1.038) in univariate analysis and 0.4 (HR=1.02,95%CI:0.976-1.063) in multivariate analysis. The univariate analysis with factor age on overall survival showed a p-value of 0.2 (HR=1.01,95%CI:0.99-1.034) and in multivariate analysis a p-value of 0.06 (HR=1.02,95%CI:1.0-1.048) among other prognostic factors. Median follow-up was 31 months for patients ≤65 years and 16 months for patients >65 years(Fig2).

**Conclusion:** Daily low-dose cisplatin and high dose radiotherapy in stage III NSCLC is as tolerable for both young and older patients resulting in similar toxicity and overall survival.

**Keywords:** CCRT, NSCLC, elderly

P2.17-12 ELIMINATING RADIATION RESISTANCE OF NON-CELL LUNG CANCER BY DHA TROUGHBROABUGATING IMMUNITY ESCAPING VIA INHIBITING PD-L1 EXPRESSION

X. Gong 1, X. Li 1, Y. Xu 1, C. Zhou 1
1Radiation Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN, 2Tongji University Cancer Institute, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN, 3Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN

Background: Lung cancer is a highly immune-suppressing malignancy with numerous methods to evade antitumor immune responses, including deficiencies in antigen processing and presentation, release of immunomodulatory cytokines, and inhibition of T cell activation. Our previous research also demonstrate that radiation can induce a local inflammatory response and simultaneously induce programmed death ligand 1 (PD-L1) expression that attenuate the sensitivity of radiation response in NSCLC. Current data have implicated that the molecular mechanisms by which DHA functions as radiosensitizer are varied, such as inducing apoptosis, extracellular signal-regulated protein kinases 1/2 (Erk1/2) activity, nuclear factor-kappa-B (NF-κB), and so on. However, there is no research about the immunity system alterations after the treatment of DHA plus radiation. In the present study, we demonstrate that combined DHA and radiotherapy synergistically enhances the anti-tumor effect by inhibiting the expression of PD-L1, eradicating the local accumulation of tumor-infilrating regulatory T cells (Tregs) and myeloid-derived suppressor cells (MDSCs) and stimulating CD8+ T cell infiltration in the tumor microenvironment. Furthermore, DHA may also through inhibiting TGF-β, p-AKT and p-STAT3 pathways, epithelial-mesenchymal transition (EMT) process, facilitating apoptosis, and regulating TRIM21 to induce the synergistic anti-tumor effect. Method: Radiation resistance cell lines (A549/X) was induced from A549 by conventionally fractionated radiation. The relationship between PD-L1 expression and the radiation resistance and the immune cell was investigated by immunohistochemistry (IHC) and western blot in vitro and vivo. Apoptosis was evaluated by flow cytometry. The signaling pathway proteins, epithelial-mesenchymal transition (EMT)-related protein were analyzed by western blot. Result: PD-L1 was up-regulated after radiation in vivo and vitro. Concomitant with radiation-mediated tumor regression, combined DHA and radiotherapy synergistically enhances the anti-tumor effect by inhibiting the expression of PD-L1. DHA plus radiotherapy also reduced the local accumulation of tumor-infilrating regulatory T cells (Tregs) and myeloid-derived suppressor cells (MDSCs) and stimulate CD8+ T cell infiltration in the tumor microenvironment. Furthermore, DHA may also through inhibiting TGF-β, p-AKT and p-STAT3 pathways, epithelial-mesenchymal transition (EMT) process, facilitating apoptosis, and regulating TRIM21 to induce the synergistic anti-tumor effect. Conclusion: Our study demonstrated a synergistic anti-tumor effect of DHA in combination with radiation trough abrogating immunity escaping via inhibiting PD-L1 expression, which establish a basis for the rational design of combination therapy of DHA plus radiotherapy in NSCLC.

P2.17-13 GENOME-WIDECOPY NUMBER ALTERATIONS PROFILING PREDICT EFFICACY OF RESECTED STAGE-II-IIIA LUNG ADENOCARCINOMA

X. Han 1, Q. Tan 1, T. Xiong 2, S. Yang 1, W. Dai 1, D. Lin 3, Y. Zhou 2, H. Lin 4, T. Shi 1
1Department of Medical Oncology, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, National Cancer Center/Cancer Hospital,Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/CN, 2Ibi Genomics, Bgi-Shenzhen, Shenzhen/CN, 3Department of Pathology, National Cancer Center/Cancer Hospital,Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/CN, 4Department of Medical Record, National Cancer Center/Cancer Hospital,Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/CN

Background: The efficacy of platinum-based adjuvant chemotherapy(PBAC) varies for stage II-IIIA resected lung adenocarcinoma(RLUAD) patients, which necessitates the discovery of new potentially prognostic biomarkers. As a major source of genomic variations driving tumor evolution, somatic copy number alterations(CNAs) screening may identify predictive biomarkers. Method: The patterns of CNAs were analyzed by Oncoscan MIP array on formalin fixed paraffin embedded(FFPE) tumor specimens collected from 163 consecutive stage II-IIIA RLUAD patients, 145 out of which received PBAC. Result: Among the 163 patients, 91(55.8%) relapsed within three years after surgery. The most frequent aberrations identified were 1q, 5p, 5q, 7p, 7q, 8q, 14p, 16p, 17q, 20q for copy number gains and 8p, 9p, 13q, 16q , 18q for losses. GISTIC2 analysis generated 45 amplification peaks and 41 deletion peaks, including some significantly mutated genes TERT, EGF, MYC, CCND1, CDK4, MDM2, ERBB2, NFKB1, IAPP, PYROXD1, KRAS and KDM5A were associated with worse prognosis in our cohort(table), and validated in 506 LUADs from TCGA. 163 patients could be well classified into 4 groups with significantly different clinical outcomes based on thresholded copy number at reoccurring alteration and we suggest that a combination of amplification and deletion of 4q34.3 might be prognostic biomarkers for RLUAD. This result was validated in an independent 183 cases cohort in Imelimieli et al, indicating these two CNAs may contribute to RLUAD recurrence.

</table>

Conclusion: This study suggests that CNAs may be a potential prognostic classifier in RLUAD patients, amplifications of 12p12.1 and KDM5A might be prognostic biomarkers for RLUAD , and amplification of ERBB2 and deletion of 4q3.43 predicted early relapse after PBAC. These novel findings may provide implication for better clinical decision making.

OPTIMISATION OF SURGICAL TREATMENT OF N2 DISEASE IN NSCLC

Background:Bronchoplasty for lung cancer is a surgical procedure aimed at respiratory function preservation and curability. And it may be performed for tumors exposed in the respiratory tract or tumors with lymph node extranodal invasion. "Surgical margin positive for bronchial stump" in bronchoplasty surgery has both histologic and carcinogenic significance (CIS), but the difference is not detailed. In this study, we clarify how to evaluate bronchial stump in bronchoplasty. Method: Of 2221 patients with resected lung cancer performed in our hospital from January 2002 to December 2015, 130 patients underwent bronchoplasty with bronchoplasty. The patient's background and its prognostic factors were examined by using Kaplan-Meyer method. In addition, we examined details of microscopic residual disease (R1) of bronchial stump. Result: There were 101 males and the median age of patients was 67 years old. 19 cases performed sleeve pneumonecmy and 18 cases performed extended sleeve lobectomy. There were 34 cases of pN0, 49 cases of N1 and 49 cases of N2. 30-day mortality was 2.3% (3cases) and 14 cases were R1 resection. 11 of which were positive for bronchial stump. pN2 and incomplete resection cases were significantly poor prognosis (p=0.009). 5 of the 11 microscopic bronchial stump positive cases were due to CIS and 6 were due to out-of-wall positives. However, among these 11 cases, there was only one case of anastomotic recurrence. And there was no statistical differences, but CIS was often found in long-term surviving cases.Conclusion: In cases of pulmonary resection with bronchoplasty, pN2 and incomplete resection are poor prognostic factors. Even in bronchial stump positive cases of incomplete resection, there was only one case of local recurrence. And long-term surviving cases were observed. There are some CISs for long-term survival, but there is no statistical difference because of small cases. Further examination is required.

P2.17-16 RADICAL EN BLOC RESECTION FOR LUNG CANCER INVADING THE SPINE

M. Kato, S. Kenji, M. Murakami, H. Hiramatsu
Surgery, Hiramatsu Hospital, Ogi City/JP

Background: About 30% of patients with non-small cell lung cancer(NSCLC) have locally advanced cancer at the time of presentation. The local control for resectable tumors is obviously achieved by surgical intervention, provided the resection is complete and respectfull of oncologic principles. However,locally advanced NSCLC with vertebral invasion have been considered a contraindication to surgical resection for a long time and thus associated with a poor prognosis. In the present study, we review 11 cases in our 16-year experience with en bloc partial and hemi vertebrectomy for lung cancer invading the spine and report outcome and survival. Method: Eleven patients with lung cancer involving the spine who underwent en bloc resection. Ten patients underwent radiation therapy(40Gy, in daily fractions of 1.8 Gy, 5 times per week). Preoperative chemotherapy regimens were as follows. Four patients received 2 cycles of cisplatin(80mg/m2 on day1) plus UFT(400-600mg/m2 daily for 14 days), three patients received 2 cycles of cisplatin(80mg/m2 on day1) plus S-1(60-120mg/m2 daily for 14 days), three patients received 2 cycles of carboplatin(AUC5-6) plus paclitaxel(200mg/m2 on day1), one patient with interstitial pneumonitis received no preoperative chemoradiotherapy. The criteria for resection were(1) a histologic diagnosis of NSCLC; (2) a tumor fixed to the vertebral column;(3) absence of mediastinal nodal involvement; and (4) no distant metastasis. Lobectomy was performed in 11 patients. Hemivertebrectomy was performed in 5 patients, and partial vertebrectomy was performed in 6 patients. The number of resected vertebral bodies was 2 or 3 (2,n=4; 3,n=7). Combined resection of the spine and descending aorta was performed in two patients. Result: There was no immediate postoperative mortality. Morbidity was observed in 3 patients, including 1 (27%) complications related to the spinal surgery. The median hospital stay was 30 days. Five patients were alive after a mean follow-up of 112 months (range, 89-132 months). The 1- and 5-year survivals are 64% and 45%, respectively. Two local recurrences were observed. Tumor stage was IIB in 1 patient, IIIA in 10 patients. Surgical nodal status was N0 in 10 patients, N2 in 1 patient. Complete macroscopic and microscopic resection was achieved in 9 (82%) patients.

Conclusion: Our results suggest that en bloc vertebrectomy for non-small cell lung cancers attached to the spine may be performed with low morbidity, and long-term disease-free survival can be achieved even in patients with T4 invasion of the vertebral body. En bloc vertebrectomy resection with preoperative chemoradiotherapy is a treatment option for highly selected patients with NSCLC invading the spine.

P2.17-17 MULTIMODAL TREATMENT IN PATHOLOGICALLY CONFIRMED SINGLE-STATION RESECTABLE IIIA-N2 NON-SMALL CELL LUNG CANCER: A SINGLE CENTER EXPERIENCE

1Radiation Oncology, Hospital de La Santa Creu i Sant Pau, Barcelona/ES, 2Medical Oncology, Hospital de La Santa Creu i Sant Pau, Barcelona/ES, 3Thoracic Surgery, Hospital de La Santa Creu i Sant Pau, Barcelona/ES, 4Radiology, Hospital de La Santa Creu i Sant Pau, Barcelona/ES, 5Nuclear Medicine, Hospital de La Santa Creu i Sant Pau, Barcelona/ES, 6Pathology, Hospital de La Santa Creu i Sant Pau, Barcelona/ES

Background: Lung cancer has become increasingly resistant to chemotherapy, surgery, and radiation therapy. In our hospital, we treat 1,000 new patients with lung cancer per year, and about 10% of patients have pathologically confirmed single-station resectable N2 disease. In this study, we describe the results of multimodal treatment in patients with pathologically confirmed single-station resectable IIIA-N2 non-small cell lung cancer (NSCLC) at a single center. Method:From January 2004 to December 2015, 130 patients (5.8%) underwent pulmonary resection plus postoperative adjuvant chemotherapy. Of those, 110 patients were treated with multimodal therapy. Twenty-five of those patients were evaluated in this study. The median age was 56 years (SD - 11.1) and the male/female ratio was 35/14. Adjuvant therapy was performed for tumors exposed in the respiratory tract or tumors with lymph node extranodal invasion. "Surgical margin positive for bronchial stump" in bronchoplasty surgery has both histologic and carcinogenic significance (CIS), but the difference is not detailed. In this study, we clarify how to evaluate bronchial stump in bronchoplasty.

P2.17 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC

TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00
Background: The management of patients with resectable stage IIIA-N2 (7th Edition) non-small cell lung cancer (NSCLC) is controversial. Multimodal treatment with neoadjuvant chemotherapy (CT) and radiotherapy (RT) followed by surgery may be recommended for a selected group of patients. Method: We have retrospectively analyzed 21 patients with single-station resectable stage IIIA-N2 NSCLC treated in our center from April 2011 to June 2017. N2 was confirmed by EBUS or mediastinoscopy. Patients received CT with cisplatin (70 mg/m2)/ carboplatin (SAUC) + vinorelbine (25 mg/m2 C1, 15 mg/m2 C2-3) concurrent RT with the 2nd cycle of CT with a total dose of 60Gy. PET-CT and mediastinoscopy was performed after induction treatment, and only those patients with mediastinal downsizing disease were proposed for surgery (lobectomy + systematic lymph node dissection). Kaplan-meier analysis was used to evaluate local control (LC), Overall survival (OS), Cause-specific-survival (CSS) and Disease-free-survival (DFS). Result: 13 patients were males (62%) and 8 females (38%), median age was 63 (52-75). Histology was: 10(48%) adenocarcinoma, 6(28%) squamous and 5 (24%) NOS NSCLC. Surgery was not performed in 5 patients (24%): 1 presented progressive disease, 2 had persistent mediastinum disease and 2 were excluded due to comorbidities. No severe postoperative complications were observed in patients who underwent surgery. Table 1 shows the results. With a median follow up of 49 (10-84) months, significant differences in terms of OS (p=0.002) and in CSS (p=0.006) were observed between patients with/without surgery, with no difference in LC and DFS. In patients who underwent surgery, there was a trend to a better LC, OS, CSS, DFS when complete pathological response was achieved.

P2.17-18 A PROGNOSTIC SCORE FOR PATIENTS RECEIVING MULTIMODAL TREATMENT FOR LOCALLY-ADVANCED NON-SMALL CELL LUNG CANCER
Department of Radiation Oncology, University Hospital, LMU Munich, Munich/DE

Background: Locally-advanced non-small cell lung cancer (LA-NSCLC) represents a heterogeneous entity, distinct regarding patient- and primary tumor features. Introduction of a simple prognostic score can lead to personalized decision-making in clinical routine. The present study aimed to create a prognostic score for LA-NSCLC patients treated with multimodality therapy. Patients and methods: Data were collated on a total of 100 patients treated with curative-intent multimodal therapy for LA-NSCLC (UICC stage III). Several prognostic factors including gender, age, ECOG performance status, comorbidity, tobacco consumption, atelectasis before irradiation, COPD, emphysema and histology were analyzed for impact on overall survival (OS). Factors showing a significant negative association with OS on univariate analysis were included and scored with one point. A prognostic score was defined by the following 4 subgroups: low risk (0-1 points), medium risk (2 points), high risk (3 points) and very high risk (4-5 points). Result: Chemoradiotherapy (CRT) was completed by 96 (96%) patients with a total dose range of 50-70Gy. The absolute majority (81%) was treated with a total dose ≥ 60Gy. Intensity-modulated radiotherapy (IMRT) was delivered in 40 (40%) cases. 10 (10%) patients were treated with radiotherapy alone, 11 (11%) with sequential and 79 (79%) patients with concurrent CRT. 13 (13%) patients underwent surgery after completion of radiotherapy. Median OS for the entire cohort was 20.8 months (95% CI: 16.229–25.371). Impact on overall survival was found for age (negative in >60 vs. ≤60 years, p = 0.038), gender (negative in male vs. female, p = 0.016), pack years (PY) (negative in >21 PY vs. ≤20 PY, p = 0.017), presence of atelectasis before irradiation (negative in yes vs. no, p = 0.019) and tumor histology (negative in squamous cell carcinoma and NOS vs. adenocarcinoma, p = 0.027). Per definition, 11 (11%), 26 (26%), 37 (37%) and 26 (26%) patients were in the low, medium, high and very high risk subgroups, respectively. Median OS was not reached for those with low risk, was 26.4 for medium, 22.0 for high and 13.7 months for patients with very high risk, respectively (p<0.001). Conclusion: The simple prognostic score we developed for patients receiving multimodality treatment for stage III NSCLC may aid physicians in making individual therapeutic decisions and personalizing treatment by defining patients with compromised survival outcomes.

Keywords: prognostic score, LA-NSCLC, Chemoradiotherapy (CRT)
P2.17-21 EFFICACY OF CONCURRENT CARBOPLATIN-PACLITAXEL CHEMORADIOThERAPY WITH 66 GY FOR ELDERLY PATIENTS WITH STAGE III NON-SMALL CELL LUNG CANCER

S. Miura1, K. Inoue1, S. Hontsu2, H. Tanaka3, M. Miyauchi1, I. Asakawa1, T. Tamamoto1, M. Hasegawa1
1Radiation Oncology, Nara Medical University, Kashihara/JP, 2The Second Internal Medicine, Nara Medical University, Kashihara/JP

Background: The common radiation dose for concurrent chemoradiation for patients with stage III non-small cell lung cancer (NSCLC) is 60 Gy, however, we performed carboplatin-paclitaxel chemoradiotherapy with 66 Gy for elderly patients and examined whether that is feasible and effective. Method: One hundred forty-four lung cancer patients underwent radiotherapy in our hospital between 2012 and 2013. In the present study, we analyzed thirty-eight patients with stage III NSCLC out of 144, excluding patients treated with palliative intent in the present study. They were divided into three treatment groups according to age, ECOG performance status (PS) and complications of each patient. Group A patients, who were younger than 70 years old, PS 0 or 1, and without any complications, received the concurrent cisplatin-docetaxel chemoradiotherapy with 60 Gy / 30 fractions. Group B, aged 70 years or older, PS 0 or 1, and without any complications, or younger than 70 and PS 2 or with complications, received the concurrent carboplatin-paclitaxel chemoradiotherapy with 66 Gy / 33 fractions. Group C, aged 70 years or older and PS 2 or over, and with complications, received radiotherapy alone with 70 Gy / 35 fractions. Three-dimensional conformal radiation treatment planning including elective mediastinal nodal irradiation was performed. To evaluate treatment outcomes among the three groups, we estimated overall survival (OS), progression-free survival (PFS) and local progression-free survival (LPFS), and analyzed the differences in these indices statistically by means of EZR (ver1.32). We also evaluated the toxicity among these three groups with NCI-CTCAE ver.4.0. Result: The median of OS in Group A, B and C was 37.3 M, 40.4 M and 20.9 M, and that of PFS was 9.1 M, 17.9 M and 8.9 M, and that of LPFS was 25.9 M, 4.4 M and 22.8 M respectively. OS and LPFS were longer in Group A and B than C, and PFS was longer in B than C significantly (p<0.05). There were no significant differences between Group A and B in any indices. In Group A, Radiation pneumonitis and esophagitis were significantly less than Group B or C but blood toxicity was more (p<0.05). Conclusion: For elderly patients with stage III NSCLC, the concurrent carboplatin-paclitaxel chemoradiotherapy with 66 Gy is suggested to be feasible and effective.

Keywords: carboplatin-paclitaxel, 66Gy, non-small cell lung cancer

P2.17-22 CARDIAC BIOMARKERS IN CART STUDY (CARDIAC TOXICITY IN LUNG CANCER PATIENTS AFTER CHEMORADIOThERAPY).

N. Mohammed1, P. Welsh1, J. Stobo1, S. Nowicki1, K. Mangion1, M. Sankaratalingam1, N. O’Rourke1, M. Glegg1, J. Foster1, R. Woodward1, J. Paul1, C. Lawless1, C. Berry1, N. Sattar2
1Radiation Oncology, Beatson West of Scotland Cancer Centre, Glasgow/GB, 2British Heart Foundation Cardiovascular Research Centre, Glasgow/GB

Background: Lung cancer has the highest incidence and mortality. Chemo-radiation (CRT) can achieve curative outcomes, but there is limited knowledge of the associated toxicity. The results of the RTOG 0617 study highlighted the impact of cardiac toxicity. Further investigation of cardiopulmonary toxicity is required. Method: This is a single centre, prospective observational study in which NSCLC patients undergoing RRT with or without chemotherapy were invited to participate. Evaluations include clinical assessment, cardiac MRI and ECG. Biomarker results are available for lattermost patients. Evaluations performed at baseline, during treatment, 6 weeks and 6 months after treatment. Result: 11 patients underwent translational blood sampling. Key details are given in table 1. Change in biomarker results is shown in figure 1. In this limited sample the change did not reach statistical significance. This study showed that 3/11 patients achieved hsTnT > 14 (suggestive of myocardial damage) during study period. 8/11 patients had NTproBNP > 125 (suggestive of increased heart failure risk) at some point on study. 3/11 demonstrated an NTproBNP levels > 400, a recognised cut off warranting cardiac echo.

P2.17-23 OPTIMAL THERAPY OF STAGE III NSCLC: THE ROLE OF SURGERY IN THE ERA OF IMMUNOTHERAPY

S. Moore, C. Ho, B. Leung, J. Wu
Medical Oncology, BC Cancer, Vancouver/BC/CA

Background: Curative intent treatment of stage III NSCLC may include surgery, radiotherapy, chemoradiotherapy, or combination therapy. Management is influenced by both patient and disease characteristics. N2 disease is optimally treated with concurrent chemoradiotherapy (CRT) and the role of surgery after CRT remains a subject of debate. The recent PACIFIC study of adjuvant durvalumab after CRT in stage III showed unprecedented improvements in relapse free survival, which further calls into question the role of surgery. We sought to perform a real-world analysis of curative therapies in stage III NSCLC, and explore the impact of known prognostic factors on outcome. Method: A retrospective review was completed of all patients referred to BC Cancer from 2005-2012 with stage III NSCLC treated with curative intent including surgery, radiotherapy, chemoradiotherapy, and combined surgery and radiation +/- chemotherapy (S+RT+/-C). Information was collected on known prognostic factors. The primary outcome measure was overall survival.

Result: 688 patients were included in the study. Baseline characteristics: female 47%, median age 65, ECOG 0-1 65%, weight loss <5% 74%, stage IIIA/IIIB 73%/27%. Treatment: 82 (12%) surgery, 127 (18%) radiotherapy, 423 (62%) chemoradiotherapy, and 56 (8%) combined S+RT+/-C. Median overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m. In a multivariate model incorporating overall survival: surgery 28.6m, chemoradiotherapy 27.6m, radiotherapy alone 18.0m, and S+RT+/-C 55.9m.

Conclusion: In stage III NSCLC, the performance of surgery, chemoradiotherapy and radiotherapy alone are comparable after controlling for known prognostic factors. Combined S+RT+/-C appears to provide a significant benefit above other modalities in highly selected patients. The role of surgery post-CRT remains controversial, as immunotherapy demonstrates greater promise for improving outcomes for the diverse group of stage III NSCLC.

P2.17-24 DOES THE CHANGE IN BODY MASS INDEX DURING INDUCTION CHEMO/CHEMORADIOThERAPY AFFECT THE OUTCOME OF SURGERY IN LOCALLy ADVANCED NSCLC?

1Thoracic Surgery, Uludag University, Bursa/TR; 2Medical Oncology, Uludag University, Bursa/TR

Background: In the literature, the affect on prognosis due to changes in Body Mass Index (BMI) for patients diagnosed with cancer have been extensively analyzed. However, there are no studies investigating changes in BMI during induction therapy and its affect on postoperative outcomes. In this study, we aimed to identify how changes in BMI during induction therapy affected morbidity, mortality and long-term survival rates in patients undergoing surgery for locally advanced NSCLC.

Method: One hundred and seventy one patients with locally advanced NSCLC and undergoing lung resection after induction therapy between 2011 and 2016 were prospectively recorded into the database and retrospectively evaluated. Induction treatment consisted of chemotherapy in 131 (76.6%) and chemoradiation in 40 (23.4%) patients. Body mass index was calculated at the initiation of induction therapy and before surgery. Pathological complete response to induction treatment, morbidity, 90-days mortality, long-term survival and prognostic factors were compared in the light of BMI.

Result: All but 15 patients were male with a mean age of 59.4 (range 26-76y) years. The median BMI before induction treatment was 25.1 (16-39) and 25.2 (17-38) before surgery. The BMI decreased in 26.3% and remained steady/or increased in 73.7% of the patients during induction treatment. The complete response rate was 27(15.8%) patients [4 (11.8%) in the decreased BMI group and 23 (16.8%) in the BMI steady/increased group, p=0.47]. Morbidity rate was 42.6% (43.8% in decreased BMI and 38% in BMI steady/increased group, p=0.5). Mortality rate was 4% (5.8% in decreased BMI and 3.6% in BMI steady/increased group, p=0.7). Three years survival rate was 71% (55.6% in the decreased BMI group and 76% in BMI steady/increased group, p=0.029)

Conclusion: In this study we observed that nutritional status of the patients undergoing induction therapy and surgery needs clear attention because morbidity, mortality and long term survival rates were negatively impacted in patients with a decline in their BMI during induction treatment.

P2.17-25 POST-TREATMENT NEUTROPHIL TO LYMPHOCYTE RATIO IN LOCALLY ADVANCED NSCLC PATIENTS TREATED WITH CONCURRENT CHEMORADIOTherapy

E.-Y. Park¹, Y.S. Kim¹, Y. Kwak², S. Lee³, S. Hong⁴, J. Kang⁴, S.J. Kim³
¹Radiation Oncology, Department of Radiation Oncology, Seoul St. Mary's Hospital, College of Medicine, the Catholic University of Korea, Seoul/KR, ²Medical Oncology, Department of Medical Oncology, Seoul St. Mary's Hospital, College of Medicine, the Catholic University of Korea, Seoul/KR, ³Pulmonary Medicine, Seoul St. Mary's Hospital, College of Medicine, the Catholic University of Korea, Seoul/KR

Background: We aimed to investigate the relationship between NLR and prognosis in patients with locally advanced NSCLC who received concurrent chemoradiotherapy as the first line treatment. Method: We retrospectively analyzed 62 patients with locally advanced NSCLC treated with definitive CCRT between 2008 and 2016 at Seoul St. Mary's Hospital. We excluded patients who received induction chemotherapy to eliminate their influence on NLR. CCRT consisted of weekly chemotherapy using paclitaxel/carboplatin, docetaxel/cisplatin, docetaxel/carboplatin, and etoposide/cisplatin. Radiotherapy was performed with intensity-modulated radiotherapy (IMRT) or three-dimensional conformal RT (3D-CRT). The median radiation dose was 66 Gy in 33 fractions (range, 52 – 70 Gy). The pre-CCRT NLR was calculated from the nearest CBC within 1 week before CCRT and post-CCRT NLR was calculated using CBC 4 weeks after CCRT. Change of NLR before/after CCRT was also analyzed. The maximally selected log rank test was used to acquire the most significant NLR level related with overall survival (OS). Result: The NLR, post-CCRT NLR, and NLR change (post-CCRT NLR/pre-CCRT NLR) cut-off levels were 1.9, 3.15, and 1.6, respectively. The median follow up duration was 11 months (range, 2–71 months). The 3-year OS, loco-regional progression free survival (LRPFS), and distant metastasis free survival (DMFS) were 45.4%, 9.3%, and 6.2%, respectively. The post-CCRT NLR and NLR change were significantly associated with OS and LRPFS. The high post-CCRT NLR group (> 3.15) showed significantly worse OS and LRPFs compared to the low post-CCRT NLR group (≤ 3.15) (3-year OS: 21.2% vs. 46.9%, p=0.005; median LRPFs 7.7 months vs. 11.3 months, p=0.04). The high NLR change group (> 1.6) had significantly worse OS and LRPFs than the low NLR change group (≤ 1.6) (3-year OS: 32.7% vs. 36.9%, p=0.026; median LRPFs 7.7 months vs. 10.4 months, p=0.025). The pre-CCRT NLR showed a marginally significant difference in OS (3-year OS 29.1% vs. 56.9%, p=0.062). There was no correlation between NLR and DMFS. Conclusion: The pre- vs. post-CCRT high NLR and increased NLR after CCRT are associated with poor prognosis of survival in patients for locally advanced NSCLC. An elevated NLR after CCRT might be an indicator of an increased risk of loco-regional failure. Further studies are needed to confirm the predictive value of NLR and the treatment strategies using NLR.

P2.17-26 QUANTIFYING THE INTERFRACtIONAL MOTION OF THE ESOPHAGUS DURING RADIATION THERAPY FOR LOCALLY ADVANCED NON SMALL CELL LUNG CANCER

B. Qiu¹, B. Wang¹, H. Liu¹, Q. Li²
¹Radiation Oncology, Sun Yat-Sen University Cancer Center, Guangzhou/CN, ²Sun Yat-Sen University Cancer Center, Guangzhou/CN

Background: To quantify the interfractioinal motion of the esophagus during radiation therapy for locally advanced non small cell lung cancer using daily cone beam CT. Method: The analysis of interfractioinal esophagus motion was performed on treatment planning 4DCT scans and daily CBCT acquired from 35 patients with stage IIIA/B NSCLC. The simulation CT and CBCT were fused using bone registries and adjusted to the carina. Interfractioinal motion of the esophagus in the right-left (RL) and anterior-posterior (AP) directions at levels of sternal notch (A), carina (B), 2.5 cm below the carina (C), and the left lower pulmonary vein (D) was recorded and analyzed respectively. Result: A total of 612 CBCT image sets were obtained. The mean interfractioinal RL motion at level A, B, C and D was 0.5±2.9mm, -0.2±3.7mm, -0.5±3.9mm and -1.3±4.8mm, with the mean absolute value of 2.1±2.0mm, 2.7±2.6mm, 2.9±2.6mm and 3.4±3.6mm, respectively. The mean AP motion at level A, B, C and D was -0.3±2.0mm, 1.0±2.0mm, 1.3±2.2mm and 2.2±2.4mm, with the mean absolute value of 1.6±1.3mm, 1.7±1.6mm, 2.6±1.9mm and 3.4±3.6mm, respectively. Coverage of 95% of esophageal mobility requires 4.9 mm left, 4.4mm right, 3.1mm posterior and 3.7mm anterior margins at level A; 5.3 mm left, 6.5mm right, 4.5mm posterior and 1.9mm anterior margins at level B; 5.5 mm left, 7.2mm right, 4.8mm posterior, and 2.0mm anterior margins at level C; and 4.9 mm left, 7.9mm right, 6.3mm posterior, and 1.6mm anterior margins at level D.

Conclusion: In RL and AP directions, the average of the absolute interfractioinal motion of the esophagus was 3.4mm or less at all the four levels. The interfractioinal motion was the greatest at the level of left lower pulmonary vein. The absolute RL motion was greater than AP motion. These data helps to set margin for ITV for future IMRT trials to account for esophageal motion.

P2.17-28 REAL-WORLD DATA: SURVIVAL OUTCOMES OF CHEMOTHERAPY REGIMENS GIVEN CONCURRENTLY WITH RADIOTHERAPY FOR LOCALLOCALLY ADVANCED NSCLC

D.C.C. Tsui1, C. Butts2, S. Ghosh3, R. Sangha3
1University of Alberta, Edmonton/CA, 2Medical Oncology, Cross Cancer Institute, Edmonton/CA, 3Cross Cancer Institute, Edmonton/CA

Background: Initial management for inoperable Stage III non-small cell lung cancer (NSCLC) treated for curative intent is platinum-based chemotherapy concurrent thoracic radiotherapy (TRT). However, a lack of consensus on the optimal chemotherapy regimen administered with TRT remains. In Alberta, Canada, cisplatin/etoposide (EP), given Days 1-5 + 8 of a 28-day cycle, and cisplatin/vinorelbine (VP), given Days 1 + 8 of a 21-day cycle, have been the two regimens used preferentially. Weekly carboplatin/paclitaxel (CP) has historically been used as an alternative in patients with borderline performance status or contraindication to cisplatin. Here, we retrospectively compare survival outcomes of these chemotherapy regimens. Method: The Alberta Cancer Registry identified pts diagnosed with locally advanced NSCLC between 2010 and 2015 and treated with EP, VP or CP chemotherapy with concurrent TRT. Patient and tumour characteristics were collected along with treatment parameters. Progression-free survival (PFS) and overall survival (OS) were determined for each chemotherapy regimen. Survival outcomes were compared using Kaplan-Meier analysis and Cox proportional hazard regression models adjusting for age, gender, tumour histological subtype (squamous vs. non-squamous NSCLC) and 7th edition TNM (Stage IIIA vs. IIIB). Results: 148 pts reviewed, 44, 79, and 25 pts were treated with EP, VP, and CP, respectively, with median ages of 63, 62, and 68 years. Gender, tumour histological subtype, distribution of Stage IIIA vs. IIIB, and use of PET imaging for staging were balanced between regimens. Median PFS (EP 9.5 mo; VP 12.9 mo; CP 4.6 mo) and OS (EP 17.8 mo; VP 22.3 mo; CP 10.3 mo) were significantly different. Conclusion: This retrospective analysis of real-world data from 2010 to 2015, in the absence of consolidation durvalumab, shows that PFS and OS of NSCLC pts treated with concurrent chemoradiotherapy are similar for the EP, VP or CP regimens. Dose scheduling and respective toxicities will likely determine choice of chemotherapy regimen given with TRT. Further review of the CP regimen, given the small sample size in this study, and the use of next generation chemotherapy regimens such as platinum/pemetrexed for non-squamous NSCLC is warranted.

Keywords: Collagen Vascular Disease, interstitial lung disease, lung cancer

P2.17-29 IS COLLAGEN VASCULAR DISEASE-ASSOCIATED INTERSTITIAL LUNG DISEASE A HIGH RISK FOR LUNG CANCER SURGERY?

Y. Watanabe1, M. Fukui2, T. Matsunaga1, K. Takamochi2, S. Oh1, K. Suzuki1
1General Thoracic Surgery, Juntendo University School of Medicine, Tokyo/JP, 2Department of General Thoracic Surgery, Juntendo University School of Medicine, Tokyo/JP, 3Juntendo University School of Medicine, Tokyo/JP, 4General Thoracic Surgery, Juntendo University Hospital, Tokyo/JP

Background: Interstitial lung disease (ILD) frequently coexists with collagen vascular disease (CVD), and most of such patients are treated with immunosuppressive agents. Although the prognosis of CVD-ILD is better than that of idiopathic interstitial pneumonias (IIPs), the effect of CVD on the outcome and postoperative complications remains unclear. Here, we retrospectively compared the characteristics, postoperative complication and mortality of pts with ILDs due to CVD-ILD or IIPs. Method: The subjects of this retrospective study were 2272 patients who underwent surgical resection of lung cancer at our institute between 2009 and 2016. We compared the characteristics, postoperative complication, and outcome of 18 patients with CVD-ILD with those of 201 patients with IIPs. The pattern of ILD was based on chest computed tomography and classified into usual interstitial pneumonia (UIP) and the others. Results: The numbers of UIP patterns were 7 (39%) in CVD-ILD and 77 (38%) in IIPs. Thirteen patients (72%) were taking corticosteroids and 6 patients (33%) were taking immunosuppressive agents in CVD-ILD. Although postoperative AE occurred in 6 (3%) in IIPs, there were no AE in CVD-ILD. Female (P = 0.01), lower pack-year smoke (P = 0.04), never smoker (P = 0.04), high value of DLH (P < 0.01), and medication of corticosteroids or immunosuppressive agents (P < 0.01) were significantly more common in CVD-ILD. Although the number of significant differences on the incidents of postoperative complications and mortalities, the relation to postoperative oncologic event remains unclear. The longer-term follow-up is necessary. Conclusion: There were no significant differences on the cause of death between the 2 groups. There were no significant differences on the outcome and the incidence of postoperative complication, including AE.

P2.17-30 SERUM LIPOPROTEIN(A) CORRELATES WITH THE EFFECT OF ENDOSTAR COMBINED WITH CONCURRENT CHEMORADIOThERAPY IN PATIENTS WITH LOCALLOCALLY ADVANCED LSCC

H. Yang1, M. Wang1, B. Wang1, X. Wu2, W. Wang1, C. Zhou1, D. Lv1, F. Kong1
1Radiation Oncology, Laboratory of Cellular and Molecular Radiation Oncology, Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou Hospital, Taizhou/CHN, 2Pulmonary Medicine, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou Hospital, Taizhou/CHN

Background: The role of vascular targeting combined with concurrent chemoradiotherapy has produced many inconsistent results in locally advanced non-small cell lung cancer, especially in Lung squamous cell carcinoma [LSCC]. Lipoprotein(a) [Lp(a)] may be critical in development of tumor angiogenesis and its levels are individualized and determined genetically. The study aimed to determine whether Lp(a) is correlated with therapeutic effects of recombinant human endostatin [Endostar] combined with concurrent chemoradiotherapy for locally advanced LSCC. Method: Patients with locally advanced LSCC concurrent chemoradiotherapy in our hospital from December 2007 to December 2017 were retrospectively analyzed. Patients were divided into two groups: 1) Chemoradiotherapy group (CR group) which received weekly vinorelbine (12.5mg/m2) / carboplatin (AUC=2) concurrently with radiotherapy 60 Gy in 30 daily treatments, and 2) Endostar combination with chemoradiotherapy group (ECRT group) which received Endostar intravenous drip 1-14 days (every three weeks) concurrently with CRT.
Fasting venous blood samples were collected before the treatment for The measurement of serum Lp(a) level in all patients, the effect of Endostar was assessed by stratified analysis. **Result:** 94 patients were recruited in this study. There were 59 cases in CRT group and 35 cases in ECRT group. Overall, the median progression-free survival was 9.6 vs. 14.2 months (P=0.067) with overall survival 15.0 vs 20.6 months (P=0.114), in CRT and ECRT groups respectively. The median of Lp(a) was 218mg/l. In patients with serum Lp(a) less than 218mg/l, the median PFS was 10.0 vs. 9.4 months (P=0.406) and OS was 15.4 vs. 16.3 months (P=0.058), in CRT and ECRT groups, respectively. However, in patients with serum Lp(a) higher than 218ng/ml, the median PFS was 9.0 vs. 15.2 months (P=0.011) and OS was 14.0 vs. 21.1 months (P=0.055), in CRT and ECRT groups, respectively. Patients with Grade 3 and above AE were observed in 32.2% vs. 34.3% (P=0.658) in CRT vs. ECRT groups respectively.

**Conclusion:** The serum concentration of Lp(a) may serve as a biomarker to identify the patients who would benefit from Endostar treatment with concurrent chemoradiotherapy in stage III LSCC. Perspective study is needed to validate this finding.

**P2.17 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC**

**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.17-31 THE EFFECT OF THE EXTENDED BILATERAL MEDIASTINAL LYMPH NODE DISSECTION THROUGH A MEDIAN STERNOTOMY FOR NON-SMALL-CELL CARCINOMA OF THE LEFT LUNG.**

**T. Yokota** ¹, S. Ikeda²

¹Thoracic Surgery, Misui Memorial Hospital, Tokyo/JP; ²Thoracic Surgery, Mitsui Memorial Hospital, Tokyo/JP

**Background:** Whether mediastinal lymph node dissection (MLND) improves survival is controversial. But, lymph node dissection plays important role in oncologic surgery. The removal of the whole regional lymphatic system together with primary tumor is one of the fundamental rules in oncological surgery. For left-side tumors, upper zone lymph nodes are considered inaccessible. Due to anatomical limitations imposed by arch of aorta, it is difficult to perform complete dissection upper zone mediastinal lymph nodes through the left thoracotomy. According to the study of regional lymphatic drainage, we considered systematic extended bilateral mediastinal dissection and lung resection through a median sternotomy (ND3 operation) for patient with NSCLC of the left lung. This study aimed to investigate the prognostic impact of Extended bilateral mediastinal lymph node dissection for left NSCLC.

**Method:** We retrospectively studied 314 patients [220 male and 94 female, mean ages 61.2 years (range, 37-75)], underwent ND3 operation due to NSCLC, from January 1990 till December 2017. The patients with NSCLC who are estimated to be able to conventional radical operation and aged 75 year-old or less becomes the adaptation of ND3 operation.

**Result:** Postoperative survival rates calculated with Kaplan-Meier method. Clinical pathological data were compared according to the p stage. Overall 5-year survival rate in the 314 patients of left lung primary was 65.5%. Operative mortality in 314 patients was 2.8%. Lymph node metastasis to the mediastinum was confirmed in 95 (30.1%) patients (pN2 was 53 patients, pN3α was 23 patients, pN3β was 2 patients, pN3γ was 16 patients). According to pathological stages, five-year survival rate was 90.5% in stage IА, 75.8% in stage IВ, 58.7% in stage IIА, 68.2% in stagelIB, 51.2% in stagelIIA, 38.9% in stageIIIB. And it was 51.5% in pN2 cases, and 53.6% in pN3α cases. Five-year disease free survival rate was 84.3% in stage IА, 70.3% in stage IВ, 53.6% in stage IIА, 52.2% in stagelIB, 33.8% in stagelIIA, 15.6% in stagelIIIB, 34.0% in pN2 cases, and

---

**POSTER SESSION 2**

**TUESDAY, SEPTEMBER 25, 2018**

**WWW.IASLC.ORG**

**ABSTRACTS**
20.6% in pN3α cases. **Conclusion:** In this nonrandomized study, the postoperative survival of left side NSCLC patients with mediastinal lymph node metastasis would be remarkably improved. And better local tumor control by ND3 operation does not increase mortality. When faced with a patient with resectable mediastinal lymph node metastasis, we should consider Extended bilateral mediastinal lymph node dissection through a median sternotomy.

**P2.17 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC**
**TUESDAY, SEPTEMBER 25, 2018 - 09:45-18:00**

**P2.17-32 DYNAMIC MONITORING BEFORE AND AFTER NEO-ADJUVANT CRIZOTINIB IN NON-SMALL CELL LUNG CANCER: A BRIEF REPORT**
C. Zhang1, Y. Chen2, S. Dong1, Q. Nie1, J.-. Yang1, X. Yang1, X. Zhang4, Y. Wu4, W. Zhong3
1Thoracic Oncology, Guangdong Lung Cancer Institute, Guang Zhou/CN, 2Guangdong Lung Cancer Institute. Guangzhou/CN, 3Guangdong Lung Cancer Institute. Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou/CN, 4Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/CN

**Background:** Neo-adjuvant therapy has been considered as an optional approach for locally advanced non-small-cell lung cancer (NSCLC) patients. While targeted therapy has been widely applied in advanced NSCLC, neo-adjuvant targeted therapy remains poorly explored. **Method:** We describe four ALK-positive patients with pathological confirmed locally advanced NSCLC receiving neo-adjuvant Crizotinib. All patients received Crizotinib at a starting dose of 250mg twice daily for 1-3 months before surgical resection. One patients provided dynamic monitoring before and after neo-adjuvant therapy through next generation sequencing of plasma and tissue. **Result:** Three patients were partial response without apparent adverse event before surgery while one received pathological complete response to neo-adjuvant Crizotinib but suffering from grade 4 hepatic damage. One of them had disease recurrence but achieved long duration of response (PFS=15m) through first-line Crizotinib. Dynamic monitoring with both plasma and tissue indicated simultaneously decrease of sensitive ALK-signaling in a patient with partial response (-51%) and no ALK-dependent resistant variants were captured.

**Conclusion:** Neo-adjuvant Crizotinib may be feasible and well-tolerated in locally advanced disease for complete resection. Crizotinib prior to surgery may provide thorough elimination of circulating molecular residual disease and it did not influence the response of reusing Crizotinib in first-line setting.

**Keywords:** crizotinib, locally advanced non-small-cell lung cancer, neo-adjuvant therapy
P2.17 ROLE OF ADJUVANT THERAPY IN PULMONARY ADENOSQUAMOUS CARCINOMA
J. He, H. Pan
Thoracic Surgery, Guangzhou Medical University First Affiliated Hospital, Guangzhou/CN

Background: Lacking of the data on the pulmonary adenosquamous carcinoma causes difficulty in choosing therapies. No study reported the role of adjuvant therapy in stage I of this type. This study was performed to elucidate the necessity and effect of adjuvant therapy in patients who received complete resection for Stage I adenosquamous lung cancer.

Method: Patients with T1-2N0M0 adenosquamous lung cancer who underwent complete resection in the SEER database from 2004 to 2014 were identified. The overall survival were evaluated using Kaplan-Meier and Cox regression. Patients with pre-operative treatments were excluded.

Result: A total of 1152 patients with T1-2N0M0 adenosquamous lung cancer were included. Among them, 607 and 545 patients were diagnosed as IA/IB. 929 patients received surgeries alone whose 1, 5, 10-year survival rate were 92.4%, 73% and 56.8%, while 223 patients received adjuvant chemotherapy whose survival rate were 82.1%, 49.6% and 41.3%, respectively. Patients in IA without adjuvant therapy had better outcomes. No survival benefit was observed in IB. Tumor size, age, sex and grade were significant prognostic factors.

Conclusion: Adjuvant therapy may not be recommended to the patients with pulmonary adenosquamous carcinoma in stage IA-IB. More cases and clinical data are warranted to verify such findings and elucidate the roles of adjuvant therapy.

**Background:** T790M testing provides guidance for treatment decisions in NSCLC patients with acquired resistance to EGFR tyrosine kinase inhibitors (TKIs). However, tissue biopsy remains challenging while various detection methods using circulating tumor DNA (ctDNA) lack prospective clinical trial evidence to demonstrate their clinical utility as a stand-alone diagnostics test. This study aims to prospectively evaluate four T790M plasma detection platforms and clinical outcomes with osimertinib. **Method:** In this open-label, multicenter, single-arm study (ADELOS; NCT02997501), Chinese advanced NSCLC patients progressed on previous TKI therapy were evaluated by four platforms, including cobas real-time polymerase chain reaction (PCR), super amplification refractory mutation system (Super-ARMS) PCR, capture-based next-generation sequencing (NGS), and QuantStudio3d digital PCR (3D dPCR). Patients genotyped as plasma T790M+ and met treatment eligibility received osimertinib 80 mg/day until disease progression. The primary objectives were to evaluate concordance in plasma T790M genotyping between platforms (reported in 2017 WCLC), and PFS (using investigator assessments, per RECIST v1.1) in plasma T790M+ patients. **Results:** Of 256 NSCLC patients enrolled, 181 were plasma T790M+ and 167 received osimertinib. The number of events (progression or death) at data cut-off (April 24th, 2018) for primary PFS analysis was 100/167 (60% maturity). ORR and median PFS for plasma T790M+ patients were 56.9% and 9.7 months, and was consistent between platforms (Table 1, ORR: 61.8%, 63.4%, 54.7%, 62.8%; median PFS: 10.5, 10.9, 11.7, 11.0 months for cobas, Super-ARMS, 3D dPCR, NGS, respectively). OS maturity was not reached yet (27.5% events observed), number of death events was summarized in Table1. **Conclusion:** In this prospective study, the clinical outcomes of osimertinib in plasma T790M+ patients are equivalent to other studies with tissue T790M+ and the alternative choice to provide guidance for second-line treatment decisions.

**Keywords:** T790M detection, NSCLC

**P3.01-02 PATIENTS WITH A SMALLER PRIMARY TUMOR AND FEWER METASTASES COULD BE CURED EVEN IN ADVANCED NON-SMALL CELL LUNG CANCER**

1Respiratory Division, Internal Medicine, Tokai University School of Medicine, Isehara/JP, 2Department of Medical Education, Tokai University School of Medicine, Isehara/JP

**Background:** Various types of immunotherapies have been extensively developed in advanced non-small cell lung cancer (NSCLC). Although median survival times have been getting very long in a certain population, complete remission (CR) is still uncommon. This study aimed to elucidate features of CR cases with advanced NSCLC. **Method:** From our hospital database, 1,699 patients, registered as having lung cancer between August 2004 and April 2011, were examined. Those with stage III or IV histologically or cytologically confirmed NSCLC, whose treatment included chemotherapy, were retrospectively evaluated on Feb 13, 2017. **Results:** CR, for the purposes of this study, was defined as a sustained CR at the five-year follow-up without treatment for one year, and features of CR patients were compared with those of long-surviving patients whose overall survival time (OS) exceeded 3 years. **Conclusion:** There were 279 stage IV and 164 stage III patients. OS of 51 (18.3%) and 37 (22.6%) patients with stage IV and III were over 3 years, respectively. Five and 12 patients with stage IV and III, respectively, showed CR. The tate effects were observed in Stage III and IV advanced NSCLC mainly by chemotherapies without immunocheckpoint inhibitors. In stage IV, primary tumor diameters in the CR patients were shorter than those in the 3 ≤ OS < 5 patients, and metastatic numbers in the CR patients were fewer than those in the 3 ≤ OS < 5 patients. In stage III, there were no differences in primary tumor diameters and metastatic numbers among the 3 ≤ OS < 5, the 3 ≤ OS with existence of tumor, and the CR (3 ≤ OS without tumor) groups. **Conclusion:** This study demonstrated that CR might be possible in certain patients with small primary tumors and fewer metastases even in advanced NSCLC by employing combinations of various treatment modalities.

**Keywords:** advanced NSCLC, Complete remission

**P3.01-03 THE COST BENEFIT FROM SECOND LINE IMMUNOTHERAPY IN METASTATIC NSCLC: ASCO VALUE FRAMEWORK PROSPECTIVE**

A. Badawy, G. Khedr, W. Arafat

Clinical Oncology, Alexandria University, Alexandria/EG

**Background:** In recent years there has been a major paradigm shift in the management of advanced stage NSCLC with uses of novel immunotherapy. Three immune check point inhibitors were approved as second line in advanced stage NSCLC namely nivolumab, pembrolizumab and atezolizumab. The high cost of these drug making decision for both physicians and patients challenging. ASCO developed a tool for help in decision making based on data obtained from clinical trial **Method:** In this study we used ASCO Value Framework to compare the net health benefit (NHB) of second line immune check point inhibitors approved in metastatic NSCLC **Result:** Nivolumab was approved based on Checkmate 17 and check mate OS75 which compare nivolumab vs docetaxel in both squamous cell carcinoma and non-squamous NSCLC respectively with statistically significant improvement in overall survival with hazard ratio (0.59; 95% CI 0.44 to 0.79; P=0.00) and (0.73; 95% CI, 0.59 to 0.90; P = 0.002) for both squamous cell carcinoma and non-squamous respectively. The calculated NHB for nivolumab vs docetaxel were 62.8 and 49.8 in both squamous cell carcinoma and non-squamous NSCLC respectively. Pembrolizumab was approved based on Keynote 010 which compare pembrolizumab vs docetaxel in metastatic NSCLC with statistically significant improvement in overall survival with hazard ratio 0.71, 95% CI 0.58 – 0.88; p=0.0008. The calculated NHB for pembrolizumab vs docetaxel was 46.1. Atezolizumab was approved based on Keynote 016 which compare atezolizumab vs docetaxel for metastatic NSCLC with statistically significant improvement in overall survival with hazard ratio 0.73, 95% CI 0.62 – 0.87, p=0.0003. The calculated NHB for atezolizumab vs docetaxel was 49.8.

(See next page)
Six patients had chemotherapy plus ICI. 26 pts (55.3%) were female; median age was 65 years (range 50-90), 15 (31%) had squamous NSCLC. Median months of these, 13/16 (81%) had ≥ 2 irAEs or irAEs ≥ 3. Median overall survival (OS) for all patients was 9m (6.3-11.7). Landmark analysis at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 months: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 months: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks: RR = 38%, DCR = 53% and 6 of these (46%) were alive at 6 weeks.
has received four cycles of platin based chemotherapy and is doing well.

**Result:** “Section not applicable”

**Conclusion:** This case report shows the possible underlying relationship between SCLC transformation and the T790M mutation, and that liquid biopsy approach may help overcome the problem of heterogeneity in acquired resistance to EGFR-tyrosine kinase inhibitors. In advanced NSCLC with EGFR-mutation, delayed onset of TKI-resistance can occur. Re-biopsies have increased the chance of detecting a T790M mutation and transformation. “Liquid biopsies” may potentially help identify heterogeneous genetic resistance-mechanisms; however, assessment of mechanisms such as SCLC-transformation needs tissue biopsies.

**P3.01-07 OUTCOME AND PROGNOSTIC FACTORS IN ALK+VE METASTATIC ADENOCARCINOMA OF LUNG: SINGLE CENTER EXPERIENCE FROM EASTERN INDIA**

Tata Medical Center, Kolkata/IN

**Background:** Anaplastic lymphoma kinase (ALK) positive metastatic adenocarcinoma of lung constitutes 3-5% of all lung cancers. Outcome of this small sub-group improved substantially over last few years with discovery of many ALK-inhibitors. Indian patients scarcely represented in the registration trials of ALK-inhibitors. Here, we report our experience of clinic-pathological characteristics, treatment outcome & prognostic factors in ALK-positive metastatic adenocarcinoma of lung

**Method:** This is a single institutional review of patients treated between Oct’13 and Feb’18. ALK was assessed by Ventana immunohistochemistry and/or fluorescent-in-situ hybridization analysis. Response assessment was done by RECIST v1.1. Patient who received at least one cycle of chemotherapy or one month of ALK-inhibitor was assessed for survival analysis in a modified intent-to-treat analysis. **Result:** Seventy-eight patients were registered with median age of 53 years (range: 24–82). Baseline features and treatment details are mentioned in Table 1. After median follow-up of 15 months (range: 1–53), median overall survival (OS) was 52.2 months (95 CI: 37.2 – not reached) and median progression-free survival (PFS) was 17.8 months (95 CI: 13.1-24.2). Median OS was 37.2 months & not reached whereas median PFS was 14.2 months & 22 months in patients treated with upfront chemotherapy (n=24) and with upfront ALK-inhibitor (n=32), respectively. 2ndline PFS was 22.6 months among patients (n=13) treated with 2nd line treatment. On multivariate analysis, gender (p=0.007) and upfront treatment regimen (p=0.001) emerged as independent prognostic factors for PFS whereas performance status (p=0.02) and upfront treatment regimen (p=0.01) showed significance for OS. **Table 1:** Baseline characteristics & treatment details (n=78)

**P3.01-08 GENDER DIFFERENCES IN LUNG CANCER SURVIVAL**

L. Bitar, F. Seiverth, D. Srdić, A. Bačelić-Gabelica, S. Pleština, M. Samaržija, M. Jakopovic

Department for Respiratory Diseases Jordanovac, University Hospital Center Zagreb, Zagreb/HR

**Background:** Lung cancer death rate in women rose in the past years surpassing breast cancer as the main cause of cancer mortality. The rise in lung cancer mortality in women appears to correlate with the increased prevalence of smoking. Adenocarcinoma has become the most frequent histologic subtype in both genders, and women present with adenocarcinoma in a higher proportion than men do. **Method:** Medical records of the patients diagnosed with lung cancer in Clinical hospital center Zagreb, Department for respiratory diseases Jordanovac during the year 2012 were retrospectively collected and reviewed. Baseline data were reported using descriptive statistics. Survival analysis was measured and analyzed using the Kaplan-Meier and log-rank test. **Result:** During the year 2012 there were 661 patients diagnosed with lung cancer in our Department. 482 (73%) were men and 179 (27%) were women. Median age at diagnosis was 64 (37-90). Total lifetime amount smoked varied from 2 to 200 pack/years in the smokers, with median 41 pack/years. The most predominant histological type was adenocarcinoma (287 patients, 43%), followed by squamous cell carcinoma (185; 28%) and microcellular carcinoma (79; 12%). Women had proportionally more adenocarcinoma and less squamous cell carcinoma than men. Cumulative exposure of smoking (as measured by pack-years of cigarettes) is significantly different with 33.6% of men smoking more than 50 pack years compared to 11.7% of women (p < 0.01). No significant difference in stage was observed across genders (p = 0.40). There were no significant differences in treatment between genders. Median overall survival (mOS) for all diagnosed lung cancer patients was 9 months. 1-year survival for all lung cancer patients is 39%, and 5-year survival is 8.1%. Female patients had significantly better survival rates. 1-year survival for female patients is 46% versus male patients 37%, 5-year survival rate for female patients is 11% versus male patients 7%. **Conclusion:** Male gender has been reported as a significant independent negative prognostic factor for patients with lung cancer in previous studies. Our results are similar to these findings. Over the last 20 years there were changes in the epidemiology of lung cancer between men and women. Characteristics of our patient population reflect the current trends of lung cancer epidemiology. Female patients smoke less but seem more susceptible to develop lung cancer. Although adenocarcinoma is the most common subtype in both genders, women have proportionally more adenocarcinomas than men do. Women have better survival than men.

**Keywords:** gender, survival, lung cancer
**Background:** Although data suggests that disparities in ethnicity impact survival outcomes in lung cancer, little is known about whether disparities according to primary residence (rural vs urban) impact survival outcomes in metastatic non-squamous, non-small cell lung cancer (ns-NSCLC). The socioeconomic determinants of poorer outcomes in rural areas are not fully understood, and could support the formation of programs aimed at improving the socioeconomic determinants of lung cancer survival in our area. Further efforts to characterize lung cancer survival outcomes in rural patients with metastatic NSCLC, even in the presence of socioeconomic factors, are needed and could support the formation of programs aimed at improving the socioeconomic determinants of poorer outcomes in rural areas.

**Method:** This is a retrospective study of 176 patients with stage IV ns-NSCLC treated at our institution from 2014–2016. Patients were classified as urban or rural residents based on zip codes using the RUCA and SAS zip code databases. Socioeconomic factors were derived from the AHRQ database. Risk of death and overall survival (OS) were calculated using Cox proportional hazard regression. 

**Result:** Baseline characteristics are in Table 1. Patients from rural zip codes had worse median OS (12.2 mo; 95% CI 5.1–16.0) compared to patients from urban zip codes (15.7 mo; 95% CI 9.6–27.9), with a hazard ratio (HR) of 1.589 (95% CI 1.052–2.401, p = 0.0278). When adjusted for age, gender, smoking status, median income, percent in poverty per county, and EGFR mutational status, these results remained significant (HR 1.670, 95% CI 1.016–2.743, p = 0.0376). A secondary analysis based on median household income (MHI) showed that those from regions with MHI less than the median of the cohort were 1.931 times more likely to die than those from regions with greater MHI (95% CI 1.038–3.595, p = 0.0378).

**Conclusion:** Overall survival for rural patients with metastatic NSCLC was inferior to those living in urban areas. This risk was more pronounced after adjusting for potential confounders. Those from regions with MHI below the median also had increased risk of death compared to those from areas above the median, suggesting that rural financial toxicity may influence lung cancer survival in our area. Further efforts to characterize the socioeconomic determinants of poorer outcomes in rural areas are needed and could support the formation of programs aimed at improving access to care.

Further efforts to characterize the socioeconomic determinants of poorer outcomes in rural areas are needed and could support the formation of programs aimed at improving access to care.

**Keywords:** NSCLC, rural, health disparities
Non-small cell lung cancer (NSCLC) is the most prevalent lung cancer subtype, commonly presenting as advanced disease at diagnosis. Epidermal growth factor mutation (EGFRm) occurs in 10-15% of Western population with advanced NSCLC and its management includes the use of mutation-driver EGFR tyrosine kinase inhibitors (EGFR-TKIs). In Brazil, patients with EGFRm NSCLC may face barriers to access EGFR test and directed-therapy; otherwise, there is a lack of national clinical guidelines addressing this issue. This study intended to evaluate the access to molecular EGFR testing, initial treatment, and outcomes in patients setting in public and private institutions in Brazil.

Method: In this retrospective cohort, patients with newly diagnosed advanced NSCLC between January and December 2014 were consecutively included. Data were collected from medical records of 10 Brazilian cancer institutions, and recorded in an electronic clinical report form. Demographic data, medical history, tumor staging, pathological characteristics, treatments and outcomes were collected and analyzed. For each patient, maximum follow-up was 36 months. Result: 402 patients from 8 different Brazilian states were enrolled, and 391 were included in the analysis, being 236 men (60.4%). Median age was 64 years, 80% have been treated in the public and 20% in private health system; 74.9% (n = 293) were former or current smokers. The most frequent histological subtypes of NSCLC were adenocarcinoma (ADC) with 267 cases (68.3%) and squamous cell carcinoma (SqCC) with 87 cases (22.3%). Among smokers, 66.6% were diagnosed with ADC and 24.6% with SqCC; among never smokers (n = 63), 84.1% had ADC and 9.5% SqCC. Clinical staging (CS) at diagnosis was IV in 251 cases (81.6%) and locally advanced (stage IIIB) in 62 cases (18.4%). From patients diagnosed with ADC, only 52.1% (n = 139) have been tested for EGFR mutation and, of these, 21.6% (n = 30) had an EGFR activating mutation. Only 43.3% (n = 13) of those with EGFRm (n=30) received an EGFR-TKI as initial therapy, while the remaining were treated with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 mutated EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% with cytotoxic chemotherapy. Based on the number of patients with EGFRm, the rate of access of EGFR-TKIs in first-line treatment was 75% in private care, compared to 31.8% in public care. Only 8 of 13 muted patients (61.5%) treated with EGFR-TKI were evaluable for response, and the disease control rate was 62.5%. Conclusion: The frequency of EGFRm in locally advanced or metastatic ADC in Brazil was comparable to previous studies. Access to EGFR test and EGFR-targeted therapies are restricted specially in public health system. In Brazil, public policies to assure a broader access to these technologies must be implemented.

Keywords: advanced NSCLC, Targeted therapy, Health system

Survival times for NS WT are significantly greater than S WT NSCLC and behave more like EGFR/ALK. Clinical history may be more important than molecular biomarkers, but further study is needed.

Keywords: NSCLC, Prognosis, non-smoker
Background: EGFR TKIs have been approved as the first-line therapy for treating advanced non-small-cell lung cancer (NSCLC). However, treatment failures frequently occurred in NSCLC patients with EGFR-sensitizing mutations. Apatinib, a novel small molecule TKI targeted VEGFR2, recommended as third-line treatment for metastatic gastric cancer patients. This retrospective study tried to investigate the efficacy and safety of low dose Apatinib combined with original targeted drugs in treating advanced NSCLC after first-generation EGFR-TKIs treatment failure and trying to explore the underlying mechanisms. Method: From March 2016 to November 2016, 11 patients of advanced NSCLC acquired resistance for Erlotinib, gefitinib and Icotinib treated with original targeted drugs plus Apatinib(250 mg, once daily), and CT scan every 4 weeks. Meanwhile observe drug-related adverse events. Result: In 11 patients, there were 10 patients available for efficacy and safety evaluation. 2 of 10 patients were progress disease in 12 weeks. The disease control rate (DCR) was 80%. The rate of PFS at 12 weeks was 72.73%. The most frequent treatment-related adverse events were fatigue (20%, 2/10), rash (20%, 2/10), poor appetite (20%, 2/10), respectively. Severe AEs included grade 3 proteinuria (10%, 1/10). Conclusion: Low dose Apatinib combined with original targeted drugs is efficacious in treating patients with advanced NSCLC who failed to first-generation EGFR-TKIs treatment, with acceptable toxic effects. The mechanism may be related to Apatinib regulate tumor microenvironment and reverses multidrug resistance.

Keywords: low dose Apatinib; Advanced NSCLC; first generation EGFR-TKIs; tumor microenvironment

**Result:** Table nr 2 presents the efficacy and tolerability of Nivolumab. The patients obtained 190 injections of drug and only one patient requires 2.5 months break because of typical AE-tyreoiditis G3. Other short breaks were dependent on personal requests, not from AE. Treatment time is 12-17 months and is planning to continue. No progression has been noticed. Follow-up is planned.

**Conclusion:** Long surviving patients with significant interval between chemotherapy lines show excellent tolerability and good efficacy of Nivolumab regardless of the type of previous chemotherapy. Efficacy and tolerance of these patients are comparable to described group with better prognosis from trials Checkmate 003 and 153.

**Keywords:** Nivolumab, long survivors, NSCLC
P3.01-18 COMPARISON OF PD-L1 IMMUNOHISTOCHEMICAL ASSAYS AND CLINICAL RESPONSE TO ANTI-PD-1 CHECKPOINT INHIBITORS IN PATIENTS WITH LUNG CANCER

J.H. Cho1, J. Hyeon2, Y. Choi2, J. Sun3, S. Lee4, J.S. Ahn1, K. Park1, M. Ahn5

1Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Seoul/KR, 2Department of Pathology and Translational Genomics, Samsung Medical Center, Seoul/KR, 3Samsung Medical Center, Seoul/KR, 4Department of Medicine, Samsung Medical Center, Seoul/KR, 5Division of Hematology-Oncology, Department of Oncology, Sungkyunkwan University School of Medicine, Seoul/KR

Background: The anti-programmed cell death 1 (PD-1) immune checkpoint inhibitors, nivolumab and pembrolizumab, are currently approved for the treatment of patients with NSCLC. The PD-L1 expression represents the most validated predictive marker of response to PD-1 inhibitors. However, there are several different immunohistochemical assays to assess the PD-L1 expression using different antibodies, platforms, and cutoff values. We compared the PD-L1 expression evaluated by IHC 22C3 PharmDx with that observed by Ventana SP263 and analyzed correlation with response to anti PD-1 inhibitors. Method: We retrospectively analyzed 109 patients with lung cancer to be treated with anti-PD-1 inhibitors who have PD-L1 expression levels obtained with both the 22C3 and SP263 assays. We reviewed medical records to obtain information about the patient’s clinical characteristics, response evaluation and survival data. The relationship between PD-L1 expression levels evaluated by the 22C3 and SP263 assays was calculated using the concordance correlation coefficient, Pearson’s precision analysis. Result: Most patients were male (70%), smoker (65%), ECOG PS 1 (73%), and histologically adenocarcinoma (55%) or squamous cell carcinoma (29%). 30% of patients had EGFR mutations. Patients were treated with pembrolizumab (n=41, 38%), or nivolumab (n=67, 61%). The median cycle of anti PD-1 checkpoint inhibitor was three (range, 1-25). There was moderate analytical correlation between 22C3 and SP263 PD-L1 levels. At the clinically relevant cutoffs (< 1% vs. ≥ 1%; and < 1% vs. 1-49% vs. ≥ 50%), the concordance correlation coefficient between 22C3 and SP263 were 0.68 (95%CI: 0.59-0.77) and 0.66 (95%CI: 0.51-0.81), respectively. The overall response rate (ORR) was 25.0% for all patients. The ORR was comparable regardless of the cutoff levels of PD-L1 expression by SP263 assays (ORR 39.6%, 41.7%, and 47.4% respectively for PD-L1 expression by 1%, 10%, 50% cutoff levels). But, the correlation between ORR and PD-L1 expression by 22C3 assays was not statistically significant. At 1% cutoff value, progression free survival was longer in patients with high vs. low tumor PD-L1 expression (2.8 months vs. 1.2 months, HR 0.63, 95%CI: 0.41-0.97, p=0.03) by the 22C3 and (3.1 months vs. 1.3 months, HR 0.61, 95% CI:0.40-0.93, p=0.02) by the SP263, respectively. Conclusion: We showed a moderate correlation between PD-L1 expression data obtained with the 22C3 and SP263 assays. These two assays could be used interchangeably and might be helpful for decision with anti PD-1 checkpoint inhibitors. Further analysis will be updated.

P3.01-19 SEQUENCING OF RAMUCIRUMAB+DOCETAXEL POST-IMMUNE CHECKPOINT INHIBITORS IN ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS

J. Clarke1, V. Stefanaki2, M. Batus3, K. Winfree4, C. Molfie5, Z. Cuil6, Y. Han7, M. Tawney7, P. Bonomi7

1Duke Cancer Center, Durham/NC/US, 2Eli Lilly and Company, Indianapolis/IN/US, 3Hematology/oncology, Rush University Medical Center, Chicago/IL/US

Background: The Phase III REVEL study demonstrated the efficacy and safety of ramucirumab+docetaxel (ram+doc) in advanced non-small cell lung cancer (NSCLC) patients who had disease progression on prior platinum-based chemotherapy (chemo). Given recent positive data disclosures supporting the use of chemo+immune checkpoint inhibitor (ICI) combinations in frontline, there is a need for additional data on the sequencing of ramucirumab+docetaxel post-ICIs. Method: Baseline characteristics and outcomes were assessed for aNSCLC patients identified in the Flatiron Health EHR-derived database, who received ram+doc as 3rd line therapy (3L) between March 2015 - May 2017 in the United States after 1st or 2nd line platinum-based chemotherapy, with ≥ 3 months of potential follow-up. Analyses were conducted for the overall cohort and among the subset of patients who received 3L ram+doc post-ICI. Overall survival (OS) was calculated from start of 1st line therapy. Real-world progression-free survival (rwPFS) and time-to-progression (rwTTP) were measured from start of 3L ram+doc. OS, rwPFS, and rwTTP were estimated using Kaplan-Meier method. Result: Among platinum-treated patients who subsequently received ram+doc in 3L overall (N=98), of whom the majority (n=65, 66.3%) received ram+doc post-ICI, the median age was 66 years and the majority were male (54.1%), Caucasian (67.4%), and had nonsquamous histology (81.6%). Of the 61 (62.2%) with available ECOG performance status (PS) data, 72.1% had ECOG PS of 0 or 1. Baseline characteristics were similar between the overall cohort and ram+doc post-ICI patients, as were clinical outcomes between the two groups (Table 1).

Table 1. Clinical Outcomes for 3L Ram+Doc Treated Patients

</tbody>
</table>

Conclusion: In this real-world platinum-treated cohort, most 3L ram+doc usage was post-ICI. Clinical outcomes for ram+doc post-ICI patients were consistent with those for the overall 3L ram+doc cohort. These data may support the use of ram+doc post-ICI among platinum-treated patients with aNSCLC. Further research is needed to evaluate the efficacy and safety of ram+doc following chemo+ICI combinations.

P3.01-20 ADVANCED NSCLC TREATMENT AND OUTCOMES AFTER NIVOLUMAB

E. Connolly, I. Nordman, G. Mallesara

Dept. of Medical Oncology, Calvary Mater Newcastle, Newcastle/NSW/AU

Background: Nivolumab is now often used in the second line in non-small cell lung cancer (NSCLC). Fitness for further treatment and outcomes in clinical practice, after discontinuation of nivolumab, are not well documented. Method: A single centre retrospective analysis was conducted on all patients who had received and ceased nivolumab between July 2015 and February 2018. 61 patients were identified. Management after nivolumab and survival outcomes were reviewed. Result: The median age of patients was 66 years (range 28-82). 31 patients were male (51%). 71% had adenocarcinoma (n=43), 21% had squamous carcinoma (n=13), and 8% other NSCLC (n=5). 33 received nivolumab as second line therapy, 18 as third line, 9 as fourth line, and 1 as fifth line. 79% of patients ceased nivolumab due to progressive disease (n=48) and 16% due to toxicity (n=10). 3 patients discontinued treatment after developing unrelated medical issues. 36% of patients (n=22) underwent further treatment. Next line treatments included pemetrexed (n=10), platinum doublet rechallenge (n=4), docetaxel (n=4), vinorelbine (n=2), weekly gemcitabine (n=1), and crizotinib (n=1). Of those who received further treatment, 9 were alive at censoring and 13 were deceased. In Australia, carboplatin/gemcitabine is more likely to be used in first line treatment of metastatic adenocarcinomas because of Medicare restriction on reimbursement. Nivolumab and pemetrexed are used subsequently after progression. The efficacy of pemetrexed when used after nivolumab is not well documented. In our cohort, 10 patients received pemetrexed after nivolumab, and showed a median survival of 10.6 months after discontinuation of nivolumab. The median duration of pemetrexed therapy was 5.4 months. Median overall survival, from last nivolumab dose, of all patients was 4.4 months (n=61). The median survival, from start of 3L ram+doc. In patients who received any treatment after nivolumab was 10.5 months. Pemetrexed has efficacy in the 3rd line setting after platinum doublet therapy and this population had an increased median survival of 10.5 months. Pemetrexed has efficacy in the 3rd line setting after platinum doublet and nivolumab therapy.

Keywords: Advanced NSCLC treatment, Treatment after nivolumab, Survival after Nivolumab
P3.01-21 METASTATIC LUNG CARCINOMA — AN INSTITUTIONAL EXPERIENCE FROM EASTERN INDIA

Background: Carcinoma lung carries poor prognosis and is the leading cause of death among all malignancies. In developing countries like India, two-thirds of patients present with advanced stage of disease where survival is dismal. Hence a retrospective study was planned to be conducted to observe the clinicopathological profile of patients presenting with metastatic lung carcinoma and to analyse the treatment response and survival in these cases. Method: A retrospective analysis was done from hospital files of patients with metastatic carcinoma lung presenting to our hospital from January 2015 to April 2018. Result: Out of 55 patients of metastatic lung carcinoma, 36 (65%) were male and 19 (35%) were female. Majority of the patients were of elderly age group >60 yrs i.e 47% (36 patients), followed by 40–60 yrs age group i.e 31% (17 patients). Considering laterality of primary malignancy, right lung was more commonly affected than left lung (60% vs 40%). Histopathologically adenocarcinoma was the most common variety encountered (85.45%, 47 patients) followed by squamous cell variety (0.9%, 5 patients). Among 47 patients of adenocarcinoma variety, 20 patients (42.5%) have EGFR mutation, whereas 27 patients (57.5%) were EGFR nonmutated. The pattern of metastases shows single organ metastasis in 19 patients (34.5%) and multiple organ metastases in 36 patients (65.5%). Overall bone was the most common site (25 patients) of metastases whereas brain was the most common single organ metastasis site.

The follow-up period ranged from 2 months to 40 months (median follow-up period 7–9 months). One year and two year overall survival was 30% and 10.9% respectively. Subgroup analysis between patients who have received Tyrosine Kinase Inhibitors (TKI): chemotherapy group and those who have received chemotherapy only group showed median overall survival of 19 months vs 8 months respectively. Conclusion: Inspite of increased awareness, incidence of metastatic lung carcinoma is still high. Adenocarcinoma is the most common histopathological variety. Bone, contralateral lung and brain were the common organs involved by metastases. EGFR mutation status should be assessed in all cases of adenocarcinoma lung. Adding TKI in EGFR mutated cases has shown increased survival in our study. Larger sample size and longer follow-up period can further validate the results.

P3.01-22 AN EXPLORATORY ANALYSIS OF PD-L1 EXPRESSION AND SMOKING HISTORY IN A COHORT OF ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS
M. Davis1, R. Taniere2, M. Hayes3, J. Thomas3, K. Gaikwad3, M. Kalkat4, L. Campbell1, A. El Helali1, L. Feeney2, C. Davidson1, K. Taylor1, M.J. Devlin1, P. Scullin1, L. Moynihan2, C. Tee2, C. Davidson1, K. Taylor1, M.J. Devlin1, P. Scullin1, L. Moynihan2

1Radiotherapy, All India Institute of Medical Sciences, Bhubaneswar/IN, 2Pathology, All India Institute of Medical Sciences, Bhubaneswar/IN, 3Radiodiagnosis, All India Institute of Medical Sciences, Bhubaneswar/IN, 4Pulmonary Medicine, All India Institute of Medical Sciences, Bhubaneswar/IN

Background: Response to PD-1 checkpoint inhibitors in NSCLC is associated with high PD-L1 expression. One hypothesis is that PD-L1 expression may correlate with tumour mutational load, the latter reflecting past tobacco exposure. Method: We examined PD-L1 expression by tumour proportion score (TPS) in patients with advanced NSCLC and correlated this with the subjects’ smoking history. Number of pack-years was estimated by the same individual during the initial consultation. Demographic characteristics, performance status (PS), stage, histology were obtained from the electronic patient record. PD-L1 testing was performed using the Dako PD-L1 IHC 22C3 pharmDx test in all but 3 cases where the SP263 Roche antibody was used. We compared pack-years and smoking status of subjects with PD-L1 negative (TPS≤1%), weakly-positive (TPS1–49%) and strongly positive (TPS≥50%) NSCLC. Result: Between 12/2016–3/2018, 54 biopsy specimens from 52 patients with advanced NSCLC were tested for PD-L1 expression at UHB. In 5 specimens, material was not tested, as unsuitable in 4 (<100 tumour cells present) and testing was cancelled in 1 patient who declined treatment. For the remaining 47 biopsies patient characteristics were: Median age 70 (43–82), male/female 26/21, PS 0/1/2/3–4 was 10/26/8/3, stage I/II/III/IV 3/16/26, histology adenocarcinoma/squamous/mixed 33/11/3. Median pack-years in PD-L1 negative 30 (0–80), PD-L1 weakly positive 35 (0–80), PD-L1 strongly positive 33 (0–100); current+former smoker/never smoker numbers: PD-L1 negative 14/3 (82.4%/17.6%), PD-L1 weakly positive 11/1 (91.7%/8.3%), PD-L1 strongly positive 15/3 (83.3%/16.7%). Strong/weak PD-L1 expression was seen in 3/1 never smokers; of these 2 had EGFR mutation. Weak expression was also seen in 1 ALK-positive NSCLC patient, former light smoker (5 pack-years).

Conclusion: In this small retrospective cohort there were no differences in median pack-years of smoking or proportions of current+former smokers between PD-L1 negative and positive tumours. Smoking history alone may not be the only factor influencing PD-L1 expression. Non-smoking status and EGFR-mutated/ALK-positive NSCLC should not be excluded from PD-L1 testing.

Keywords: PD-L1, smoking, pack-years
performed at designated time intervals. However, 27 patients (43.5%) that underwent surveillance with CXR had confirmed intra thoracic chest CT imaging. Median OS for CTR detected recurrence was 27.5 months (range 6.5 – 99.1 months) and 27.45 months (range 5.9 to 104.2 months) for chest CT detected recurrence (p-value 0.46). **Conclusion:** There is a paucity evidence specifically around the follow-up and surveillance modalities aimed at detecting relapse to improve survival after curative intent therapy in NSCLC. Our data demonstrate that 3 monthly CXR is an appropriate surveillance modality for initial detection of intra-thoracic disease recurrence.

**P3.01-24 THE IMPORTANCE TO SWITCH FROM EGFR-TKI TO CYTOTOXIC CHEMOTHERAPY FOR EGFR MUTATION-POSITIVE ADENOCARCINOMA**

D. Endo1, T. Okano, Y. Kawaguchi, J. Maeda, M. Hagiwara, M. Kakkhana, N. Kajiwara, T. Ohira, N. Ikeda

*Surgery, Tokyo Medical University, Tokyo, JP*

**Background:** Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) have become the first-line treatment for EGFR-positive non-small cell lung cancer (NSCLC) patients all over the world. Furthermore, EGFR-positive patients who received not only EGFR-TKI but also chemotherapy have good prognosis. However, transition rate from first-line EGFR-TKI to chemotherapy is low.**Method:** A total of 229 consecutive patients with adenocarcinoma were treated with EGFR-TKI from January 2010 to December 2016 at Tokyo Medical University Hospital. Among these, 159 patients were analyzed in the present study. After excluding 70 patients (45 patients underwent first-line treatment, 7 received chemoradiotherapy, and 18 received osimertinib). The prognosis according to treatment sequence and the reasons patients could not switch from first-line EGFR-TKIs to chemotherapy were analyzed.**Result:** The median follow-up period was 22.5 months. Of the total 159 patients, 113 (71%) were female, 114 (72%) were <75 years old, and 86 (54%) showed postoperative recurrence. The most frequent subtypes of EGFR were exon 19 deletion in 84 patients (53%) followed by exon 21 L858R in 54 patients (34%). EGFR-TKIs were administered as a first-line therapy in 93 (58%) patients, and chemotherapy was administered in 66 (42%) patients. The most common first administered EGFR-TKI as a first-line therapy was gefitinib in 133 (84%) of 159 patients. Among the 93 patients who were administered EGFR-TKIs as a first-line treatment, 32 (34%) patients transitioned to chemotherapy. The median survival times (MST) of patients who received EGFR-TKI as a first-line therapy, 1.69L/64.8% predicted (range: 1.36-2.66/33-80%), 1L/39.4% predicted (range:0.78-1.26/28-60%) and 33.3% (range: 13.3-54), respectively.**Conclusion:** There is a paucity evidence specifically around the follow-up and surveillance modalities aimed at detecting relapse to improve survival after curative intent therapy in NSCLC.

**P3.01-25 FEASIBILITY OF MODERATE HYPOFRACTIONATED THORACIC IRRADIATION FOR NON-SMALL CELL LUNG CANCER PATIENTS WITH VERY LIMITED LUNG FUNCTION**

F. Manapov1, O. Roengvongaphol1, J. Taugner1, M. Dantes1, L. Käsmann2, C. Wijaya1, N. Schmidt-Hegemann1, C. Belka1, C. Eze2

1*Department of Radiation Oncology, University Hospital, Lmu Munich, Munich/DE,*
2*Department of Pulmonology, Asklepios Fachkliniken München-Gauting, Munich/DE,*
3*Department of Radiation Oncology, University Hospital, Lmu Munich, Munich/DE*

**Background:** To determine the feasibility of moderate hypofractionated image-guided thoracic irradiation (modHypo-IGRT) in locally advanced node-positive non-small cell lung cancer patients with very limited pulmonary function.**Method:** Eight selected patients with highly diminished pulmonary function (FEV1 ≤ 1.0L and/or DLCO ≤ 40% and/or long-term oxygen therapy) were treated with modHypo-IGRT. Planning was based on 18F-FDG-PET/CT and 4D-CT. Gross tumour volume (GTV) included primary tumor and involved lymph nodes. Internal target volume (ITV) was defined through the overlap of GTVs on 10 phases of 4D-CT. An isotropic margin of 5 mm was added to ITV to generate the planning target volume (PTV). modHypo-IGRT was delivered to a total dose of 45 Gy (ICRU) in 15 daily fractions under strict image-guidance. Vital capacity (VC), forced expiratory volume in 1s (FEV1), and single-breath diffusing capacity of the lung for CO (DLCO-SB) were analyzed prior to, and 3 and 6 months after modHypo-IGRT.**Result:** Eight patients completed modHypo-IGRT. The median follow-up was 20 months. The median age was 64 years. Two, 4 and 2 patients presented with stage IIIA, IIIB, and IIEC. Seven patients were with performance status ECOG 2 and 1 with ECOG 3. Five patients (63%) were on long-term oxygen. Three patients received chemotherapy prior to modHypo-IGRT. The median PTV was 226.9 cm3 (range: 100.17 – 379.80). The median overall (OS) and progression-free survival (PFS) for the entire cohort were not reached. The 1- and 2-year OS rates were 100% and 87.5%. The 6- and 12-months PFS rates were 100% and 63%. Three patients developed local failure. Median mean lung dose was 9.4 Gy (range: 5.3-11.8). V15 and V20 for both lungs were 22% (range: 10-25) and 15% (range: 6-19). Median mean esophageal dose was 12.76 Gy (range: 2.1-26.7). There was no case of radiation pneumonitis. Four patients developed grade 2 radiation esophagitis. Median initial VC, FEV1 and DLCO-SB was 1.68L/64.8% predicted (range: 1.36-2.66/33-80%), 1L/39.4% predicted (range:0.78-1.26/28-60%) and 33.3% (range: 13.3-54), respectively. Median value for VC, FEV1 and DLCO-SB 3 months after modHypo-IGRT was 2.05L/56.35% predicted (range: 1.34-2.33/47-81.5), 1.08L/47.5% predicted (range: 0.74-1.60/50.8-59.59%) and 38.55% (range:2e88). At 6 months post-treatment, the median value for VC, FEV1 and DLCO-SB was 1.64L/66% predicted (range: 1.41-2.79/35.5-5.75%), 1.0L/47% predicted (range: 0.65-1.28/24.5-5.14%), and 31% (range: 27-43%).**Conclusion:** modHypo-IGRT can be considered for individual patients with locally advanced node-positive NSCLC patients with very limited pulmonary function hence inadequate for conventional treatment. This protocol is being assessed in an ongoing single-center prospective study.

**Keywords:** Radiotherapy, survival, NSCLC
drug-medium, clonal cell lines were selected from H1650 cultured in the presence of 25 or 50 μM osimertinib plus 10 μM verapamil, and selected from H1975 cultured in 6 or 10 μM osimertinib alone or 5 μM osimertinib plus 10 μM verapamil.

Result: The H1650 osimertinib-resistant cell lines (H1650/osi-25a/VPL and H1650/osi-50a/VPL) are 1.6- to 1.8-fold resistant to osimertinib. The H1975 osimertinib-resistant cell lines (H1975/osi-6b, osi-10c, and osi-5b/VPL) were, respectively, 90-, 95-, and 38-fold resistant to osimertinib. None of the cell lines was cross-resistant to imatinib. The compound 2-(benzylsulfonyl)-1-(1H-indol-3-yl)-1,2-dihydroisoquinoline (IBR2) is an inhibitor of the DNA repair protein RAD51 and enhances cytotoxicity of EGFR inhibitors against numerous cell lines (Ferguson et al., JPET 2018, doi.org/10.1124/jpet.117.241661). IBR2 decreased osimertinib-resistance by up to 80% in the H1650- and H1975-derived osimertinib-resistant cell lines. Further analyses of the resistant cell lines are being undertaken.

Conclusion: The H1650 and H1975 osimertinib-resistant cell lines are a valuable resource in which to test methods to circumvent resistance to third generation EGFR TKIs.

Keywords: Resistance, EGFR-TKI, osimertinib

Progress to date:

Stage 0: We defined in 80 patients the optimal MRI sequences suitable for GTV and organ at risk (OAR) contouring: T2 Turbo Spin Echo (TSE), T2 TSE with fat sat, T1 radial gradient echo, and DIXON TSE. Two radiology-led workshops were organized and inter-observer agreement was assessed for OARs. These led to a consensus-based OAR atlas. A study is being prepared to compare the image quality of the current standard CBCT and MR images at baseline and mid-treatment for treatment verification and set-up correction.

Stage 1: we will investigate the clinical feasibility of the MRL for standard of care radiotherapy and the scope for adaptive radiotherapy (margin reductions) and detecting changes in oxygenation during treatment on the MRL in patients with locally advanced (LA) NSCLC.

Stage 2a/b: Based on the results from stage 1 we will design a study aiming to reduce margins around the tumour and dose escalate in patients with LA NSCLC.

Conclusion: The aim of this programme of work is to generate robust evidence to support the introduction of the MRL and to improve outcomes of patients with LA NSCLC.

P.01-28 THE CLINICAL IMPACT OF COMPREHENSIVE CFDNA GENOMIC TESTING IN LUNG CANCER
S. Geva1, A. Bellilowski Rozenblum1, T. Twito2, R. Grininberg1, A. Dvir1, L. Soussan Gutman1, R. Roisman3, M. Ilouze1, E. Dudnik1, A. Zer2, O. Rotem1, R. Lanman1, N. Peled3
1Thoracic Cancer Service, Davidoff Cancer Center, Rabin Medical Center, Petach Tikva/IL, 2Oncostat Teva Pharmaceutical Ltd, Petah Tikva/IL, 3Soroka Medical Center, Ben-Gurion University, Beer Sheva, Israel, Beer-Sheva/IL, 4Cancer Institute, Soroka Medical Center, Beer-Sheva/IL, 5Guardant Health, Redwood City/CA/US, 6Soroka Medical Center, Ben-Gurion University, Beer Sheva, Israel, Beer-Sheva/IL

Background: Next-generation sequencing (NGS) of cell-free circulating tumor DNA (cfDNA) enables a non-invasive option for comprehensive genomic analysis of non-small cell lung cancer (NSCLC) patients. Although plasma-detected genomic alterations have been shown to predict targeted therapy response, evidence of durability of response is lacking or limited to small cohorts as is the impact of cfDNA NGS results on clinical decision making. Method: In this retrospective study, data was collected on stage IIIB/IV NSCLC patients between the years 2014-2017 in Israel. We utilized cfDNA NGS (Guardant360) which covers the seven genes targetable with FDA-approved therapies in NSCLC. Result: 116 consecutively NSCLC patients were tested, 41.4% (48/116) before 1st line therapy (Group A), 34.5% (40/116) upon progression on chemotherapy or immunotherapy (Group B1) and 24.1% (28/116) upon progression on EGFR TKIs (Group B2). Targetable genomic alterations were found in 65% of group A (15/24), 53% in group B1 (21/40) and 71% in group B2 (20/28). Treatment decision was changed to targeted therapy based on cfDNA NGS analysis in 23% (11/48), 25% (10/40) and 32% (9/28), respectively (total cohort 26%, 30.14% Response assessment (RECIST) showed complete response in 4% (1/28), partial response in 39% (11/28) and progressive disease in 25% (7/28). Total objective response rate (ORR) was 43% and disease control rate was 75% for 5 months treatment duration. Conclusion: Comprehensive cfDNA testing impacted clinical decisions in 23% of naïve patients, 25% in patients who progressed on chemotherapy and 32% in EGFR TKI progressed. Median treatment duration was 5 months. This retrospective study extends previous reports by showing that responses based on cfDNA are durable and change treatment decisions at initial presentation and at progression.

P.01-29 ST.JV LUNG ADENOCARCINOMA TREATED BY FIRST-LINE EGFR-TYROSINE KINASE INHIBITORS-SURVIVAL, EGFR MUTATION, HISTOLOGIC SUBTYPE
T. Gil1, G. Cyżywicz2, M. Skoczek1, P. Wojcik1, P. Hajder1, B. Kołodziejezyk1, W. Ciesiak1, J. Kudzda1
1Department of Thoracic Surgery, Jagiellonian University, John Paul II Hospital, Krakow/PL, 2Jagiellonian University, John Paul II Hospital, Krakow/PL, 3Agh Ust, Department of Applied Computer Science and Modelling, Krakow/PL

Background: The aim of the study is to evaluate the correlation of survival, EGFR mutation and histologic subtype of stage IV lung sensitive mutant adenocarcinoma treated with first-line EGFR-tyrosine kinase inhibitors (EGFR-TKI). o:p> Method: We retrospectively analyzed the clinical outcomes of 60 consecutive patients with EGFR-TKI sensitive mutations (exon 19 deletion or exon 21 L858R ) who received first-line erlotinib, gefitinib or afatinib therapy between October 2011 and September 2017. Histologic subtype was classified according to the IASLC/ATS/ERS classification. Result: There were 60 patient enrolled, including 26 men, mean age 68.88 years (range: 44-82) and 34 women, mean age 65.68 years (range: 44–82). The average survival in women was 14.1 months and in men it was 13.3 months. Average survival in 28 patients were treated with Erlotinib was 14.51 months, in 18 patients treated with Gefitinib it was 12.79 months and in 14 patients treated with Aftatinib it was 13.55 months. In 30 patients with the mutations (exon 19 deletion), the mean survival was 14.56 months. In the group of 26 patients with mutations (exon 21 L858R ), the mean survival was 13.65 months. The mean survival in the group of patients with acinar adenocarcinoma was 15.49 months, and in solid adenocarcinoma - 4.8 months. Currently, 21 patients are alive and remain in observation, 12 of them are treated and 39 patients died. In the multidimensional linear regression analysis, smoking was a factor decreasing the survival at p = 0.12, male gender decreased the survival rate p = 0.04, and the type of cancer subtype increased the survival rate p = 0.04. Erlotinib influenced the increase in survival at p = 0.15 Conclusion: Mutation in (exon 19 deletion), histological subtype of tumor and Erlotinib treatment are factors significantly affecting the survival of patients with stage IV adenocarcinoma of the lung. EGFR mutation frequency is higher in the acinar subtype than in other subtypes.

P.01-30 TREATMENT SEQUENCING IN PATIENTS WITH ANAPLASTIC LYMPHOMA KINASE (ALK)-POSITIVE NON-SMALL CELL LUNG CANCER (NSCLC) IN JAPAN
Y. Goto1, N. Yamamoto2, E. Masters3, H. Kikikawa1, J. Mardekian1, R. Willsshire1, K. Togo4, H. Ma5, Y. Ohe1

New York/NY/US, 4Pfizer Japan Inc. Tokyo/JP, 5Pfizer Inc. Tadworth/GB, 6University of Michigan School of Public Health, Ann Arbor/MI/US

Background: Limited data are available on real-world treatment patterns and outcomes of ALK inhibitors used sequentially. Access to a large medical records database and availability of multiple ALK inhibitors in Japan, the first country to approve alectinib in 2014, presents a unique opportunity to evaluate real-world treatment sequencing and outcomes in ALK-positive NSCLC patients. Method: This descriptive, retrospective observational study used inpatient/outpatient medical and prescription records, claims and diagnoses from the Japan Medical Data Vision (MDV) Database. Included patients had confirmed diagnosis of lung cancer, an ALK test and first prescription order for an ALK inhibitor (prescription date = index date) on or before March 31, 2017. Descriptive analyses included demographics, baseline characteristics, treatment patterns including ALK inhibitor sequences, non-ALK inhibitor treatments received, and treatment duration. Result: Overall, 378 patients (mean age 61 years; 53% female; 48% no history of smoking) met inclusion criteria. Baseline characteristics were similar among mutually exclusive groups of patients receiving 1, 2, or 3 ALK inhibitors. Similar proportions of patients received crizotinib (52%) and alectinib (48%) as index ALK inhibitor. Prior to the index date, 40% of patients received chemotherapy. ALK inhibitor sequences are shown (Table). In patients who had discontinued all ALK inhibitors, the next treatments were chemotherapy (46%) and immunotherapy (6%). The most common sequence was a crizotinib-led sequence of 2 ALK inhibitors; median duration of treatment was 53 months. Changes in treatment patterns over time and further duration of treatment data will be presented.

Conclusion: Treatment patterns in ALK-positive NSCLC patients have evolved over time. The most common sequence for patients receiving > 1 ALK inhibitor was crizotinib-led. Median duration of treatment with crizotinib-led sequences is consistent with what has been reported previously. Additional research is warranted to evaluate non-crizotinib-led sequences as data mature.

Keywords: ALK-positive NSCLC, treatment sequencing, tyrosine kinase inhibitor
Background: Postoperative outcome for non-small cell lung cancer (NSCLC) patients with mediastinal lymph node metastasis who undergo complete resection with systematic nodal dissection is unfavorable even after complete resection. To identify the subgroup of NSCLC patients who are candidates for adjuvant chemotherapy, we sought to investigate prognostic factors in these patients.

Method: We retrospectively reviewed NSCLC patients who underwent complete resection with systematic nodal dissection from 2000 and 2016. Demographic, clinical, and pathological factors were analyzed. We performed univariate analyses and a Cox proportional hazards regression model for multivariate analysis. The prognostic factors were the following: sex, age, smoking status, clinicopathological stage, number of positive mediastinal lymph nodes (1-2 vs 3 or more), number of positive mediastinal nodal stations [single station vs multiple stations], number of positive mediastinal lymph nodes 1-2 vs 3 or more, epidermal growth factor receptor (EGFR) mutation status, and adjuvant chemotherapy. Adequate chemotherapy was performed in 26 patients. The details of adjuvant chemotherapy were cisplatin-based combination chemotherapy in 18 patients, and carboplatin-based combination chemotherapy in 8. The 3-year and 5-year OS in patients with EGFR-negative cases (p=0.001). The 3-year and 5-year OS in patients who underwent adjuvant chemotherapy or none were 75.3/70.3% vs 55.3/32.3%, respectively (p < 0.001). Conclusion: Even if NSCLC patients have mediastinal lymph node metastasis, favorable postoperative prognosis may be expected in patients with low preoperative serum CEA. Adjuvant chemotherapy should be considered in patients with mediastinal lymph node metastasis on pathological examination.

1UC Davis Comprehensive Cancer Center, Sacramento/CA/US, 2University of Washington, Seattle/WA/US, 3Florida Hospital Cancer Institute, Orlando/FL/US, 4University of California, Los Angeles/CA/US, 5UT Southwestern Medical Center, Dallas/TX/US, 6Ucsf Moores Cancer Center, Los Angeles/CA/US, 7Baylor College of Medicine, Houston/TX/US, 8Astrazeneca, Gaithersburg/MD/US, 9Astrazeneca, Cambridge/GB, 10Astrazeneca, Istanbul/TR

Background: Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) are recommended first-line treatment for patients with advanced NSCLC and EGFR-TKI sensitizing mutations (EGFRm). However, most patients develop resistance to first- and second-generation EGFR-TKIs, with approximately 50% of the patients acquiring a secondary EGFR T790M mutation. Osimertinib is a third-generation, irreversible, CNS-active oral EGFR-TKI that potently and selectively inhibits both EGFRm and T790M resistance mutations, and is approved for treating patients with T790M-positive advanced NSCLC who have progressed on first- or second-generation EGFR-TKIs. Tumor tissue is the preferred sample for T790M testing at progression; however, a tumor biopsy may not be feasible because of tumor inaccessibility, inadequate tissue, and/or safety considerations. Non-invasive options to detect T790M include circulating tumor DNA analyses from plasma or urine. The RADIANCE study is designed to determine if plasma and urine tests combined can deliver a T790M detection rate similar to biopsy testing. Method: RADIANCE (NCT03317264) is an open-label, prospective biomarker study planned to be conducted at approximately 50 sites in the US and Canada. The primary objective is to assess the analytic concordance between non-invasive testing (Guardant360®, plasma; Trovera®, urine) and tissue testing (cobas® EGFR Mutation Test v2) for T790M detection in patients with advanced NSCLC. Patients with EGFRm NSCLC (N=470) with evidence of disease progression during or after first- or second-generation EGFR-TKI therapy will be eligible for enrollment in the study. Patients who received prior treatment with osimertinib or another T790M-directed therapy will be excluded. In this two-part study, Part 1 (diagnostic analytic validity) will include testing all enrolled patients for T790M using plasma (cobas/Guardant360), urine (Trovera), and tumor biopsy (cobas) tests. Patients with T790M-positive NSCLC detected by the cobas tissue and/or cobas plasma test may choose to receive osimertinib (daily or QD) and continue to Part 2, while patients with T790M-negative NSCLC will be ineligible to continue in the study. In Part 2 (clinical outcomes), patients with T790M-positive NSCLC receiving osimertinib will be followed for 18 months or until disease progression or death and evaluated for tumor response rate, duration of response, and progression-free survival (investigator-assessed RECIST v1.1), as well as safety. The study is currently enrolling patients. Result: Section not applicable Conclusion: Section not applicable

Background: There has been important developments in NSCLC since the understanding of molecular pathways. The aim of the study is to find the EGFR mutation frequency and its correlation to survival and clinicopathological features. We reported our data in this subject three years ago. We aim to resubmit our updated data. Method: In this multicenter study, 1352 NSCLC (adenocarcinoma) patients were included retrospectively to find out the EGFR mutation status with age, sex, performance status, histopathological diagnosis, smoking history, stage, and grade. Survival correlations were determined. The aim of the study was to find out the EGFR mutation status with all of the features in the database. Result: The median age was 59 (24-87) years. Median follow-up time was 14 (2-17) months. 26.2% were female. 85.2% were stage IIB-IV and 86% was adenocarcinoma. EGFR mutation frequency was 22.3 % including exon 19 (63.0%). There was no correlation between mutational status and age, performance status, and stage at diagnosis (p>0.05). However, there was a correlation between gender and smoking. (p= 0.000 and 0.001 respectively). The frequency of mutation was more pronounced in non-smokers/ex-smokers. In the group that can perform survival analysis (827 pts), median progression-free survival was 9 months and overall survival was 20 months. The overall survival (OS) (SE:1; 95% CI 16-21) months in EGFR negative cases (p=0,008). The 3-year and 5-year OS were 88.3/70.8% vs 41.0/17.9%, respectively (p<0.001). The 3-year and 5-year OS in patients who underwent adjuvant chemotherapy or none were 75.3/70.3% vs 55.3/32.3%, respectively (p = 0.009). Conclusion: Even if NSCLC patients have mediastinal lymph node metastasis, favorable postoperative prognosis may be expected in patients with low preoperative serum CEA. Adjuvant chemotherapy should be considered in patients with mediastinal lymph node metastasis on pathological examination.
