Background: Intravenous administration of magnesium is recommended for patients receiving high-dose cisplatin with a short hydration regimen in terms of protection against cisplatin-induced nephrotoxicity. However, the optimal dose of the magnesium supplementation has not been clarified. The aim of this trial was to investigate the safety and efficacy of short hydration regimen with 20mEq of magnesium supplementation for lung cancer patients receiving cisplatin-based chemotherapy. Method: The key eligibility criteria included cytologically or histologically proven lung cancer, candidates for cisplatin (≥60 mg/m²) based chemotherapy or chemoradiotherapy, no prior chemotherapy, age ranged 20 and 75 years old and adequate renal function. Cisplatin was administered with pre-hydration containing 20 mEq of magnesium sulfate. Mannitol was administered just before the cisplatin infusion as an enforced diuresis. The primary endpoint was the proportion of patients without a Grade 2 or higher elevation in creatinine. The study was registered at UMIN-CTR as UMIN000011687. Result: Forty patients with a median age of 66 years (range, 35-74) were enrolled in the study. Of these, 16 had adenocarcinoma, 12 had squamous cell carcinoma, 5 had small cell carcinoma, 2 had large cell carcinoma and 5 had other histology. The median baseline creatinine value was 0.71 mg/dl. The median dose of cisplatin at the first cycle was 80 mg/m². Twenty-nine patients received cisplatin and vinorelbine as their most frequent regimen and 24 patients received 4 cycles of chemotherapy. In the first cycle, no patients developed Grade 2 creatinine toxicity. During the whole treatment period, one patient developed Grade 2 creatinine elevation, and thus, the proportion of patients without a Grade 2 or higher elevation in creatinine was 97.5% (95%CI 86.8-99.9). Grade 1 hypermagnesemia was observed in 8 patients. Conclusion: This study indicates short hydration regimen with 20mEq of magnesium supplementation was safe and feasible for lung cancer patients receiving cisplatin-based chemotherapy without risk of severe nephrotoxicity. Keywords: lung cancer, cisplatin, hydration

P3.01-35 OUTCOMES IN ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS RECEIVING DISCONTINUATION OF PD-1 CHECKPOINT INHIBITOR DUE TO TOXICITY: A RETROSPECTIVE STUDY
J. Hill, A. Nagrial, R. Hu
Clinical Trials Unit, Crown Princess Mary Cancer Centre, Westmead/AU

Background: Programmed cell death ligand (PD-1) checkpoint inhibitors have been shown to improve survival in advanced non-smart cell lung cancer. Although immune-related adverse events from single agent anti PD-1 or PD-L1 are manageable, severe toxicities require treatment discontinuation. There are limited data on patient outcomes after treatment discontinuation and the necessary cessation of treatment can cause concern of disease control for the patient and clinician. This retrospective study examined disease outcomes in patients after discontinuation of PD-1 checkpoint inhibitor due to toxicity. Method: Patients treated with pembrolizumab or nivolumab monotherapy for advanced non-small-cell lung cancer at our cancer centre were identified. A retrospective review of electronic and paper records was performed. Information including patient baseline characteristics, progression-free survival, overall survival, toxicity leading to treatment discontinuation and time to progression after treatment cessation were obtained. Imaging was reviewed to confirm events of disease progression. Result: 54 advanced non-small cell lung cancer patients treated between 2012 and 2017 with single agent pembrolizumab or nivolumab were included in the analysis. 8 (14.8%) patients experienced toxicity necessitating treatment discontinuation. Baseline characteristics including age, ECOG performance status, prior lines of therapy and smoking status were similar in patients with or without severe immune-related toxicities. Pneumonitis was the most common toxicity requiring treatment cessation (n=4). Other toxicities included colitis (n=1), vasculitis (n=1), myositis (n=1) and bullous pemphigoid (n=1). The overall survival at 1 year was 42.6% for all patients versus 75% for patients with toxicities requiring treatment cessation. 2 of the patients with pneumonitis died as a result of this toxicity prior to achieving disease control. The patient with bullous pemphigoid and those survived pneumonitis had not experienced disease progression at time of analysis (all censored, and progression free for minimum of 6 months after treatment discontinuation). Time to progression in the patients with colitis, myositis and vasculitis. Conclusion: With the limitations of this small study at a single site, patients requiring treatment cessation from toxicity had comparable progression-free and overall survival to those without severe toxicities. The risk of Grade 5 immune-related pneumonitis might have contributed to the numerically lower survival rates in the group that experienced toxicity. Prolonged disease control was observed in patients who survived pneumonitis despite treatment discontinuation. Keywords: non-small cell lung cancer, Immunotherapy, toxicity

P3.01-36 PROGNOSTIC FACTORS IN ELDERLY PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER
M. Honorio1, N. Guerra Pereira2, A. Tereso1, M.A. Almeida1
1Hospital Prof. Fernando Fonseca, Amadora/PT, 2Hospital Nosso Senhora Do Rosario, Barreiro/PT

Background: There is no consensus method for identifying frail older patients. A number of clinical screening tests are now available but the prediction of outcome of treatment is difficult. Sarcopenia, as simply defined by a baselineComputed Tomography (CT) image, has been shown to be predictive of outcome in Lung Cancer (LC). The purpose of this analysis was to determine the prognostic significance of CT determined sarcopenia, and other clinical parameters, on overall survival (OS) among elderly patients with advanced-stage Non-Small Cell Lung Cancer (NSCLC) and on active treatment. We also sought to determine the OS of this population, according to the different clinical parameters evaluated. Method: A retrospective analysis of 77 patients older than 65 years old with advanced NSCLC and ECOG PS 0-2 treated between 2014 and 2017 was performed. The variables tested were age, gender, ECOG PS, polypharmacy (the use of 5 or more medications), The Charlson Comorbidity Index (CCI), Body Mass Index (BMI), Lactate dehydrogenase value and sarcopenia. For the quantification of Sarcopenia two methods were used: Total Psoas Index (TPI) and the Hounsfield Unit Calculation (HUC). Both obtained from a single axial Computed Tomography (CT) image at L3 level. Median OS was assessed by Kaplan-Meier method. Cox survival analysis was performed for a 95% CI for the hazard ratios, considering a p value of 0.05 as an indicator of statistical significance. Analyses were performed with use of SPSS v.18 software. Result: On our population we found sex, CCI and polypharmacy as independent risk factors associated with mortality. Median OS of the population was 14 months. Men and patients who presented with ECOG PS 2, BMI below 22 Kg/m2 and sarcopenia had worse outcome, but without statistical significance. Conclusion: Clinical variables may help to discuss prognosis with elderly LC patients. The identification of these factors can be used to improve patient selection for the different treatment options. Keywords: lung cancer, Elderly patients, prognostic factors

P3.01-37 PHASE II STUDY OF AMRUBICIN PLUS ERLOTINIB IN PREVIOUSLY TREATED, ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS WITH WILD-TYPE EGFR T790M
S. Hosokawa1, T. Otani1, J. Sasaki1, T. Fukui1, Y. Nakahara2, A. Besho1, N. Fukamatsu1, Y. Nakamura1, T. Kajii1, T. Sugiyama1, T. Tokibori1, N. Seki1, A. Hamada1, N. Masuda1, H. Okamoto2

Background: To date, EGF receptor mutations in NSCLC are considered one of the best targets to improve survival. However, the EGFR T790M is one of the most common EGFR resistant mutations (60%). This study indicates the survival benefit of AMRUBICIN plus ERLOTINIB in EGFR T790M-negative, previously treated, advanced NSCLC patients. Method: A total of 20 patients were enrolled. The median age of the patients was 65 years old with advanced NSCLC and ECOG PS 0-2 treated between 2016 and 2017. First-line chemotherapy was platinum-based chemotherapy in all cases. The primary endpoint was overall survival with a best cut-off of OS 12 months. Result: The median OS was 23 months. Men and patients who presented with ECOG PS 2, BMI below 22 Kg/m2 and sarcopenia had worse outcome, but without statistical significance. Conclusion: Clinical variables may help to discuss prognosis with elderly LC patients. The identification of these factors can be used to improve patient selection for the different treatment options. Keywords: lung cancer, Elderly patients, prognostic factors
**Background:** The combination of amrubincin (AMR) and erlotinib (ERL) was reported to have synergistic effect on non-small cell lung cancer (NSCLC) cell line with wild-type EGFR in vitro. We accomplished a phase I study of AMR plus ERL in previously treated advanced NSCLC patients, and determined the maximum tolerated dose (MTD). Furthermore, we observed a high response rate of 33% (Am J Clin Oncol 2015). **Method:** We conducted a multi-center, single-arm phase II trial to evaluate the efficacy of AMR and ERL combination therapy in patients with previously treated, advanced NSCLC with wild-type EGFR. **Result:** There were 123 cases accompanied 19del and 86 cases had no 19del. Among 209 cases, 190 were candidates for target genotyping. We observed a high response rate of 33% (Am J Clin Oncol 2015). **Conclusion:** The combination of AMR and ERL in induction and maintenance phase showed promising antitumor activity in vitro and vivo. The phase III clinical study (ICOGEN) showed that icotinib has a good efficacy and tolerability in Chinese patients with advanced non-small cell lung cancer (NSCLC) compared with gefitinib.

**Keywords:** NSCLC, Amrubincin, Erlotinib

**P3.01 ADVANCED NSCLC**

**Title:** TREATMENT OF SUPER ELDERLY PATIENTS FOR NON-SMALL CELL LUNG CANCER IN JAPAN

**Authors:** T. Ibe, H. Kodama, Y. Hamamoto

**Background:** Japan is one of the country with the longest life expectancy in the world; many elderly Japanese are treated for lung cancer. The number of people dying from lung cancer is consistently increasing, and nearly half of lung cancer patients are older than 75 years of age. It is said that 60% patients of the elderly patients are over 75 years. Approximately 60% of non-small lung cancer patients are 60-79 years old who were diagnosed with advanced non small cell lung cancer. We conducted a retrospective analysis of patients over 80 years old who were diagnosed with advanced non small cell lung cancer.

**Method:** We retrospectively reviewed the outcome of patients over 80 years old who were diagnosed with advanced non small cell lung cancer between 2012 to 2016. Result: 48 patients were incorporated in the study; 26 were treated by chemotherapy (Median age 84 years (80-89), 16 males), 22 were in BSC (Median age 84 years (80-96years), 13 males). 69% (18/26) of the treatment group were in Performance Status 0-1, compared to 18% (4/22) in the BSC group. The phase III clinical study (ICOGEN) showed that icotinib has a high response rate of 33%.

### P3.01-41 ANATOMICAL AND CLINICAL BASIS OF #11 LN BY SYSTEMATIC BILATERAL MEDIASTINAL NODAL DISSECTION FOR LEFT LUNG CANCER THROUGH MEDIAN STERNOTOMY

**S. Ikeda, T. Yokota, K. Fukui, T. Hoshino**

Surgical Department of Respiratory Center, Mitsui Memorial Hospital, Tokyo/JP

**Background:** Patients with mediastinal lymph node metastasis have a poor prognosis, and lung operation is not typically indicated. We performed bilateral mediastinal lymph node dissection by median sternotomy to resect lung cancer and dissect the bilateral mediastinal lymph nodes. Although some studies have examined the communications between the left and right lymphatic pathways in lung cancer cases, we anatomically analyzed this technique of bilateral lymph node dissection, and confirmed its usefulness. There are some reports on 11LN positive cases and other lymph nodes metastasis cases. We investigated metastatic status between 11LN lymph node positive cases and other lymph nodes by systematic bilateral mediastinal nodal dissection for left lung cancer through median sternotomy.

**Method:** We performed this operation in 314 patients with primary left lung cancer excluding small cell carcinoma and stage IV since 1987. From among the 314 patients, 25 had in p-N1, 50 in p-N2, 24 in p-N3 lymph node metastases. Based on macroscopic dissection procedures, dissection of the lymphatics from the lungs to the supraclavicular lymph nodes was performed by sequential removal of the related organs. In particular we examined the metastatic status and clinical significance of #11 lymph node in 114 cases. We systematically compared and analyzed the route of lymphatic communications to the contralateral side with emphasis on the anatomical significance of the left-to-right lymphatic communications of the bilateral mediastinal lymph nodes.

**Result:** The overall 5-year survival rate (Kaplan-Meier method), including operative deaths and deaths due to unrelated diseases, was 65.5% (MST 11.3 years) in the patients with left lung cancer. With respect to the p-N factor, the 5-year survival rate were 40% in p-N1, 48.7% in p-N2, 53.6% in p-N3, 38.3% in #11LN positive in left lung cancer patients. We will report the investigation of the prognosis of left non small cell lung cancer patients who underwent initially our extended bilateral mediastinal dissection, focused on the patients with #11LN positive cases.

**Conclusion:** We identified the route of lymphatic communications to the contralateral side, and systematically analyzed the anatomical significance of the left-to-right lymphatic communications in 11LN positive cases. The overall 5-year survival rate (Kaplan-Meier method), including operative deaths and deaths due to unrelated diseases, was 65.5% (MST 11.3 years) in the patients with left lung cancer.

### P3.01-42 PHASE II TRIAL ALLOWED SURGERY AFTER INDUCTION CHEMOTHERAPY OF CBDCa+PTX, BEVACIZUMAB IN PATIENTS WITH STAGES IIIA-IV NONSQUAMOUS NSCLC

1Thoracic Surgery, Akita University Graduate School of Medicine, Akita/JP,
2Cardiovascular/respiratory Medicine, Akita University Graduate School of Medicine, Akita/JP,
3Clinical Oncology, Akita University Graduate School of Medicine, Akita/JP

**Background:** Surgery remains the best therapy for cure in non-small cell lung cancer (NSCLC). However, the treatment strategy for advanced NSCLC patient including Stage III with N2 remains controversial. Bevacizumab (Bv), a humanized monoclonal antibody targeting VEGF, combined with the standard platinum doublet-based chemotherapy is approved for the first-line treatment of NSCLC. This study aimed to determine whether the treatment allowed surgery after induction chemotherapy of carboplatin (CBDCa) and paclitaxel (PTX) with Bv provides a reduction in the risk of progression in patients with stages IIIA to IV nonsquamous NSCLC. **Method:** This clinical trial was an open-label, multicenter, single-arm study involving 10 institutions in Akita, Japan (UMIN000007916). Chemotherapy/radiation-naïve patients > 20 years of age, ECOG performance status of 0 to 1, and adequate hematologic, hepatic, and renal function with cytologically or histologically confirmed stages IIIA to IV nonsquamous NSCLC not amenable to surgical resection or radiation with curative intent, were eligible. Treatment plan is showed in Figure 1.

**Result:** Between April 2012 and October 2017, a total 29 patients were enrolled. The overall response rate was 72.4%, 10 of 29 patients underwent radical surgery included lymph node dissection 2a-2 basically after the chemotherapy. Complete resection was achieved in 7 patients of them (70%) in the induction chemotherapy group. Bronchial stump and anastomoses were buttressed with a pericardial flap or intercostal muscle flap in some cases. The 30-day hospital mortality was 0% in all patients. Grade 3 or 4 adverse events occurred in 72.4% such as neutropenia, just one case has pulmonary hemorrhage and GI bleeding. **Conclusion:** These results suggest that CBDCa+PTX, Bv which has higher response rate will introduce the better potential to reduce tumor size, increase operability, and eradicate micro-metastases. However, a survival benefit might be limited even though surgery was added after induction chemotherapy.

### P3.01-43 PREDICTIVE VALUE OF COMPUTED TOMOGRAPHY MORPHOLOGIC CHARACTERISTICS FOR NIVOLUMAB RESPONSE IN PRETREATED NON-SMALL CELL LUNG CANCER

1Division of Respiratory Medicine, Gunma Prefectural Cancer Center, Gunma/JP,
2Department of Pulmonary Medicine, Fukushima Medical University, Fukushima/JP,
3Thoracic Oncology, Ohara General Hospital, Fukushima/JP,
4Division of Thoracic Oncology, Tochigi Cancer Center, Toshigi/JP,
5Respiratory Medicine, Ibaraki Prefectural Central Hospital & Cancer Center, Ibaraki/JP,
6Department of Surgery, Fukushima Medical University, Aizu Medical Center, Fukushima/JP,
7Department of Respiratory Medicine, Saitama Medical University, International Medical Center, Saitama/JP,
8Department of Chest Surgery, Fukushima Medical University School of Medicine, Fukushima/JP,
9Department of Respiratory Medicine, National Hospital Organization Hokkaido Cancer Center, Hokkaido/JP

**Background:** The efficacy and safety of nivolumab for the treatment of pretreated non-small cell lung cancer (NSCLC) have been established. We conducted a retrospective multicenter trial to determine the significance of computed tomography (CT) morphologic characteristics as a predictor of nivolumab efficacy for advanced NSCLC patients. **Method:** From April 2013 to March 2017, 78 pretreated NSCLC patients were enrolled. Our radiologist assessed the following tumor characteristics on CT before nivolumab treatment: interstitial septal thickening, peritumoral ground-glass opacity, spiculated margin, air bronchogram, cavity or necrosis, adjacent organ invasion, bulky lymph node (≥ 2.5 cm), and accumulation of small lymph nodes. After nivolumab treatment, objective response rate (ORR), disease control rate (DCR) and progression free survival (PFS) were analyzed with logistic regression and Cox proportional hazards regression models. Patient and CT morphologic characteristics were retrospectively analyzed. Significant parameters identified by univariate analysis were included in a multiple analysis. **Result:** Of the 78 patients, 60 (77%) were male and 72 (92%) patients were of performance status 0 to 1. Heavy smoking was related to higher ORR than light or never smoking (28% vs 0%, p<0.01). No morphologic characteristics were related to ORR or DCR. Interstitial septal thickening was significantly associated with shorter PFS (p=0.015, 77 vs 126 days). Adjacent organ invasion was also significantly associated with shorter PFS (p=0.047, 72 vs 118 days). However, they were not found to be significant on multivariate analysis. **Conclusion:**
Interstitial septal thickening and adjacent organ invasion may be negative prognostic factors of nivolumab treatment for NSCLC.

**P3.01-44 CYFRA 21-1 AS A PREDICTOR TO RESPONSE TO CHEMOTHERAPY AND OVERALL SURVIVAL IN PATIENTS WITH ADVANCED NSCLC**

K. Iqbal

**Hospital, Kurume/JP**

**EGFR mutation have been reported, the effect and resistant mechanisms to of acquired resistance to 3rd generation EGFR-TKI such as EGFR C**

**resistant to 1st or 2nd generation EGFR-TKIs. Although some mechanisms (EGFR) tyrosine kinase inhibitor (TKI) was developed to target the**

**Background:** Within ever evolving, promising new therapies for advanced NSCLC, early predictors of response are needed. We evaluated early variations in serum CYFRA 21-1 of patients with advanced NSCLC receiving first line chemotherapy and correlated the results with objective tumor response and overall survival.

**Method:** 29 consecutive untreated patients of advanced NSCLC with measurable disease on CT scans were evaluated. All patients were treated with conventional systemic chemotherapy. Serum samples were obtained before start of 1st and 2nd cycles. CYFRA 21-1 was measured with an electrochemiluminescence immunoassay. All patients were followed for a period of five years.

**Response was evaluated using RECIST. Result:** 10 patients had partial response, 9 had stable disease and 9 had progression. None had complete response. 21/29 patients had elevated baseline value of CYFRA. 18/29 patients had decrease in CYFRA 21-1 after 1 cycle of chemotherapy. The average reduction in 2nd reading was irrespective of baseline value being normal or not. The average reduction was statistically significant (P = 0.002). 8/10 patients with partial response had reduction in their 2nd reading which was significant. We observed that 6/10 patients whose disease remained stable had a decrease in their subsequent reading (P = 0.0106), though was not significant statistically. 5/9 patients who had an increase in their 2nd reading had progression, it was not statistically significant (P = 0.537). 14/19 who had partial response or stable disease, had a reduction in their 2nd value of CYFRA 21-1 and was significant statistically (P = 0.004). We observed that except for 1, all patients who had decrease of 42% or more were responders (P = 0.001), which was statistically significant. We followed all patients for five years. None was alive at 5 years. 10 patients were alive at 3 years and 6 were alive at 4 years. All patients who progressed after chemotherapy died within 1 year. 7/10 and 4/6 patients had reduction in their CYFRA 21-1 but was not statistically significant (P = 0.24 95%CI: 0.6-1.47-15.7). We observed that 3/4 patients who were alive at 4 years had a decrease of 30% or more in their subsequent CYFRA 21-1 level. **Conclusion:** We conclude that monitoring CYFRA 21-1 early during first-line chemotherapy may be useful prognostic tool for evaluation of early tumor response in patients with advanced NSCLC. Although decrease in CYFRA 21-1 was not statistically significant for monitoring overall survival, it can be used as surrogate marker in identifying patients for aggressive treatment but it needs validation by large RCT.

**P3.01-45 MULTIFACTORIAL GENE ALTERATIONS IN EGFR BYPASS PATHWAY ARE INDUCED BY AFATINIB IN T790M-MUTANT NSCLC**

**1Division of Respiratory, Department of Internal Medicine, Kurume University School of Medicine, Kurume/JP, 2Department of Genome Biology, Kindai University Faculty of Medicine, Osaka-Sayama/JP, 3Department of Respiratory Medicine, Shin Koga Hospital, Kurume/JP**

**Background:** The 3rd generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) was developed to target the EGFR T790M resistance mutation in non-small cell lung cancer patients resistant to 1st or 2nd generation EGFR-TKIs. Although some mechanisms of acquired resistance to 3rd generation EGFR-TKI such as EGFR C797S mutation have been reported, the effect and resistant mechanisms to afatinib following C797S is still well-known. **Method:** Nine patients with EGFR T790M-mutant NSCLC resistance to 3rd generation EGFR-TKI were enrolled in this study and treated with afatinib. Plasma samples were collected before treatment, 4 weeks after treatment, and at disease progression. Mutation profile and tumor mutation burden (TMB) were evaluated. All patients were treated with conventional systemic chemotherapy and correlated the results with objective tumor response and overall survival. **Result:** The objective response rate and median progression-free survival of afatinib were 0% and 2.0 months, respectively. At the time of 4 weeks after treatment, four patients developed disease progression and five patients showed stable disease. A total of 36 somatic mutations or amplification were detected in plasma cfDNA before afatinib treatment; EGFR activating mutations in 8 patients, T790M mutation in 4, TPS3 mutations in 6, PIK3CA mutations in 3, BRAF mutations in 3, MET amplification in 3, CTNNB1 mutations in 2, ERBB2 mutations in 2, C797S mutation in 1, SMAD4 mutation in 1, EGFR minor mutation in 1, KRAS mutation in 1, and ALK mutation in one patient. EGFR C797S mutation in cfDNA was detected during afatinib treatment in two cases. In the patients having stable disease at 4 weeks after treatment, mutant allele frequency and TMB tended to decline once, and then increased in association with disease progression. **Conclusion:** Detection of mutant allele frequency and TMB of cfDNA by CAPP-seq could monitor the effectiveness and resistance to afatinib. Resistant mechanisms to afatinib might be characterized by multifactorial bypass pathway activation.

**P3.01-46 PROGNOSTIC UTILITY OF ADVANCED LUNG CANCER INFLAMMATION INDEX (ALI) IN THORACIC MALIGNANCIES: A META-ANALYSIS**

H. Elosta, S. Jafri

**Medical Oncology, UT Health McGovern School of Medicine, Houston/TX/US**

**Background:** We developed ALI as a prognostic marker in metastatic non-small cell lung cancer. ALI has now been validated in a variety of cancers. Here we report a meta-analysis of ALI as a prognostic marker in thoracic malignancies **Method:** ALI is calculated as follows: ALI= BMI x ALB/NLR, where BMI= body mass index, ALB= serum albumin, NLR= Neutrophil/lymphocyte ratio. ALI <18 is a marker of shorter progression free and overall survival. We searched database in PubMed up until January 31, 2018. We selected all the studies that compared the survival of patients with thoracic malignancies according to their ALI. We used the random effect model to calculate the pooled hazard ratio of overall survival. Meta-regression analyses, heterogeneity of data and publication bias were also appreciated. **Result:** A total of 6 studies, all retrospective in design, were included in the meta-analysis. Among these, 3 evaluated the prognostic value of ALI score in non-small-cell lung cancer, 2 in small cell lung cancer and 1 in esophageal cancer. By random effect model, we detected a statistically significant higher overall survival for patients with high ALI score (ALI≥18). This corresponded to a pooled hazard ratio of death of 0.619 (95% confidence interval: 0.531-0.721, p-value <0.001), with the subgroups of patients with low ALI score used as reference. Interestingly, no heterogeneity of data was found (Q-value=1.398, I-square = 0.009, p-value=0.609). By meta-regression analysis, the covariate “type of tumor” (non-small cell lung cancer vs. others) did not influence the predictive value of ALI score (test of model Q-value=0.34, p-value=0.55). No publication bias was detected by Egger test (p-value=0.24).

P3.01-47 CLINICAL CHARACTERISTICS AND OUTCOME FOR PATIENTS WITH ADVANCED LUNG ADENOCARCINOMA TREATED WITH FIRST-LINE PEMETREXED PLUS PLATINUM

X. Ji, X. Hu, Y. Zhu, Y. Liu, L. Lin, P. Xing, X. Hao, Y. Wang, J. Li
Department of Medical Oncology, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Background: To evaluate the efficacy and safety of pemetrexed combined with platinum first-line therapy for advanced lung adenocarcinoma, as well as the clinical factors influencing outcomes. Method: We retrospectively evaluated the data from 450 pemetrexed-treated patients with stage IIIB/IV lung adenocarcinoma that confirmed by cytology or histology from February 2011 to August 2017. Patients were divided into 2 groups according to the presence of maintenance therapy (yes or no) after the first-line chemotherapy. The primary endpoint was progression-free survival (PFS), secondary endpoints included objective response rate (ORR), disease control rates (DCR), and safety. Result: A total of 292 received only first-line pemetrexed-based therapy, while 158 patients received maintenance pemetrexed after induction. The overall median PFS was 5.83 months (95% CI was 0.33 to 55.72 months). The maintenance treatment group had longer PFS (9.92 months, 95%CI: 3.98 to 5.21 months) than (P < 0.001) the non-maintenance treatment group (4.60 months, 95%CI: 8.70 to 11.14 months) after the first line chemotherapy (P < 0.001). The ORR and DCR of 450 patients with lung adenocarcinoma was 33.6% and 87.6%, respectively. Single-factor and multiple-factor analysis showed that positive prognostic factors for survival. The main adverse reactions of the patients were hematological toxicity, gastrointestinal reaction, abnormal liver function. However, low incidence of grade 3 or higher toxicity was seen in this study. Conclusion: First-line therapy with pemetrexed combined with platinum is safe and effective for advanced lung adenocarcinoma, and pemetrexed maintenance therapy has a better survival benefit. Keywords: advanced lung adenocarcinoma, first-line and maintenance therapy, pemetrexed

P3.01-48 THE EFFICIENCY OF LOW-DOSE APATINIB TREATMENT OF ADVANCED LUNG SQUAMOUS CELL CARCINOMA

1The Second People’s Hospital of Yibin, Yibin/CN, 2North Sichuan Medical College, Nanchong/CN

Background: Chemotherapy is the main treatment for advanced lung squamous cell carcinoma (LSCC) patients due to lack of effective targeted agents. Previous studies proved that apatinib, which is an antiangiogenic and small-molecule targeted drug, showed clinical benefit in patients with advanced non-squamous non-small cell lung cancer. In this study, we assessed the efficacy and safety of low-dose (125mg or 250mg, QD, oral) apatinib in the treatment of advanced LSCC. Method: A total of 8 advanced LSCC patients clinical data were reviewed retrospectively including 1 patient treated only by apatinib and 7 patients combined with other anti-tumor therapies (i.e., bronchial artery embolization (BAE), chemotherapy, radiotherapy or surgery) between May 2016 to July 2017. Efficacy was evaluated with the RECIST version 1.1 and adverse effects (AEs) were graded using the NCI CTC version 4.0. Result: One SD and 7 PR were confirmed, resulting in an objective response rate of 87.5% (7/8) and a disease control rate of 100% (8/8), respectively. The median progression-free survival (PFS) was 197 days (95% CI, 122-272 days), and the median overall survival (OS) was 252 days (95% CI,161-342 days). Both PFS and OS were 93 days for the patient with monotherapy, while the median PFS and median OS were 212 days (95% CI, 132-292 days) and 274 days (95% CI,182-366 days), respectively for the 7 patients with combined treatment. Patients with grade 3 or 4 AEs included 2 hemoptysis, 1 leukopenia and 1 fatigue. Patients characteristics are shown in the table below. Conclusion: Low-dose apatinib combined with BAE, chemotherapy, radiotherapy or surgery is effective and well tolerated in advanced LSCC patients. Risk of massive hemoptysis should be considered in LSCC patients treated with apatinib alone. BAE or radiotherapy may play a role in the prevention and treatment of severe hemoptysis associated with apatinib. Further prospective studies with larger numbers of patients are required. Keywords: Apatinib, antiangiogenesis, Lung Squamous cell carcinoma

P3.01 ADVANCED NSCLC
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.01-49 EFFICIENCY OF LOW-DOSAGE APATINIB MONOTHERAPY IN TREATMENT OF ADVANCED LUNG SQAMOUS CELL CARCINOMA
The Affiliated Changzhou No 2 People’s Hospital of Nanjing Medical University, Changzhou/CHN

Background: Lung squamous cell carcinoma (SqCC) is the second most common histology in non-small-cell lung cancers (NSCLCs). Chemotherapy of two drugs based on platinum is the standard treatment of advanced lung SqCC. However, few drugs could be selected when the disease progressed after second-line treatment. Apatinib, a small molecule inhibitor of vascular endothelial growth factor receptor-2 (VEGFR-2), have shown benefit in advanced NSCLC patients. This study aimed to preliminarily assess the efficacy and safety of apatinib at a lower dosage (125–500mg/d) in patients with advanced lung squamous cell carcinoma. Method: Eligible patients should be definitive diagnosed SqCC, who refused chemotherapy or failed first line, second line or even later lines of chemotherapy. Key exclusion criteria included major blood vessel involvement and massive haemoptysis with the amount more than 20ml. Apatinib was given every day, and treatment was continued until disease progression or unacceptable toxic effects. Progression free survival (PFS) was assessed by Kaplan–Meier test. Tumor responses were assessed according to the Response Evaluation Criteria in Solid Tumors (RECIST 1.1). Results: Total 19 patients were enrolled from July to August 2017. Among them, 12 patients suffered from distant metastases before apatinib administration; 11 patients were with ECOG 2-3. Ten patients (52.6%) received 250mg daily of apatinib, 4 received 125mg, 1 received 375mg and 2 received 425mg and 500mg daily. Two patients failed to evaluate efficacy for personal reason so that 17 patients were eligible for tumor response to apatinib evaluation. Followed up to April 2018, 14 of 19 patients were dead, and 1 year survival rate was 21.1% (4/19). The median PFS was 5.3 months (95% CI: 2.7–7.9 months). Three patients achieved partial response (PR) and the objective response rate (ORR) was 17.6% (3/17) and the total disease control rate (DCR) was 76.5% (13/17). There was no significant associations between the dose of apatinib and efficacy (p=0.648). The main adverse events were fatigue (47.4%), hypertension (36.8%), hemoptysis (26.3%), loss of appetite (21.1%) and hand-foot reaction (15.8%). No grade 4 adverse event was reported. All the dead events were not drug-related by physician’s judgment. Conclusion: Apatinib monotherapy at a lower dosage might be an optimal choice for patients with advanced lung squamous cell carcinoma. Perspective clinical studies with large sample size are needed to validate our results.

P3.01 ADVANCED NSCLC
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.01-50 IDENTIFICATION OF EGFR MUTATIONAL PROFILE IN LUNG CANCER MOROCCAN COHORT
H. Kaanane1, H. El Atar2, L. Badre2, A. Louahabi1, H. Berradi1, M. Khayathi1, S. Nadifi1
1Laboratory of Genetics and Molecular Pathology, Faculty of Medicine and Pharmacy of Casablanca, Casablanca/MA, 2Laboratory of Anatomot-Pathology Moulay Idriss 1Er. Casablanca/MA, 3Laboratory of Biology Sebta, Casablanca/MA, 4Laboratory of Oncovirology, Institut Pasteur Casablanca, Casablanca/MA

Background: Despite recent progress in diagnostic and oncology therapy, lung cancer constitutes the leading cause of cancer-associated mortality worldwide, with approximately 85% of lung cancer cases being non-small cell lung cancer (NSCLC). The study of epidermal growth factor receptor (EGFR) gene mutational profile in non-small cell lung cancer patients has a special clinical significance in the selection of tyrosine-kinase inhibitors. The aim of this study was to identify the frequency and spectrum of EGFR mutations in a cohort of Moroccan patients with lung cancer using the ADx-ARMS technology. Method: We performed a retrospective study by processing 125 cases of NSCLC patients recruited between March 2015 and December 2017. Using the DNA extracted from the FFPE tissue, we attempted to identify somatic mutations in exons 18 to 21 of the tyrosine-kinase “TK” domain of EGFR gene. We evaluated EGFR mutations using HRM polymerase chain reaction (PCR) and real time PCR “ADx-ARMS technology” for results confirmation. Result: Most of our patients were males (69.6%) in the age range of 32–82 years old, with an average age of 61.5 ± 8.62. The most represented histological type in the studied sample was adenocarcinoma (ADK: 88%) and only 12% of squamous cell carcinoma (SCC) subtype. In regards to the smoking status 57.6% of the analyzed patients were smokers and 42.4% were nonsmokers. Six different point mutations were detected in 25 patients, representing 20% of our study population. Among the mutant positive cases, the resulting mutations were as follows: 60% of patients have a deletion in exon 19 (12% T790M and 4% S768L), 12% in exon 18 (G719/A/C) and 12% in exon 21(L858R). The EGFR mutations were more frequent among males compared to females (64.0% and 36.0% respectively), all of the positive patients with EGFR mutations were ADK and 40.0% of them were smokers. Conclusion: The presented method can be implemented at the laboratories to identify the most frequent EGFR mutations that are important for targeted therapy of advanced lung cancer patients.

P3.01-51 OUTCOMES WITH SYSTEMIC CHEMOTHERAPY IN ADVANCED NSCLC PATIENTS WITH PERFORMANCE STATUS 2 AND ABOVE AND WITHOUT DRIVER MUTATION
H. Kancharla1, P.S. Malik1, S. Khurana2, N. Gundu3, A. Yadav1, D. Jain1, S. Pathy1, S. Kumar1
1Medical Oncology, All India Institute of Medical Sciences, Delhi/IN, 2Medical Oncology, All India Institute of Medical Sciences, New Delhi/IN, 3Medical Oncology, All India Institute of Medical Science, Delhi/IN, 4Pathology, All India Institute of Medical Science, Delhi/IN, 5Radiation Oncology, All India Institute of Medical Science, Delhi/IN, 6Surgical Oncology, All India Institute of Medical Science, Delhi/IN

Background: Platinum-based combination chemotherapy is recommended as the standard treatment for patients with advanced NSCLC, but its benefit is limited to patients with performance status (PS) 0 or 1. However, it is not clear whether these benefits apply to patients with poor performance status (PS 2 and above). These patients have inferior outcomes and have been excluded from clinical trials. This population accounts for a significant portion (up to 30%) of patients of our practice and some of them have been treated with systemic chemotherapy based on clinician’s discretion. We have analyzed the outcome of these patients who have been treated with chemotherapy despite poor performance status. Method: We performed a retrospective analysis of patients of advanced NSCLC with poor PS (ECOG PS 2 or more) registered at our lung cancer clinic between January 2016 and September 2017 and treated with systemic chemotherapy. Patients with driver mutations who were treated with first line TKIs were excluded. Hospital case records were reviewed for baseline characteristics, treatment details and outcome data. Result: A total of 78 patients were found to be eligible for this analysis. Median age was 60 years (33-77 years) including 15% patients 70 years or above. At presentation out of these 78 patients, 48 (62.5%) were smokers, 24 patients (30%) had pleural effusion and 8 patients (10%) had brain metastasis. Majority patients had ECOG PS 2 but 35 % had PS 3 or 4 also and 38(48 %) had one or more associated comorbidities. The most common chemotherapy regimen used was platinum-based combination chemotherapy, 23 % of patients had 4 cycles of chemotherapy. Objective response rates were 16% (3/19) and improvement in survival. Further studies addressing this neglected subgroup are indicated.

P3.01 ADVANCED NSCLC
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.01-52 OUTCOMES OF ADEQUATE CHEMOTHERAPY IN ADVANCED NSCLC PATIENTS WITH PERFORMANCE STATUS 2 AND ABOVE WITH BRAF V600E MUTATION
M. Kumar1, C. Goel1, R. Rana1, L. Tiwari1, S. Singh1, A. Pan2, S. Jha1
1Department of Medical Oncology, AIIMS, New Delhi/IN, 2Department of Pathology, AIIMS, New Delhi/IN

Background: Brahmal (BRAF) and RAS mutations account for a significant portion (up to 30%) of patients of our practice even though these mutations are not included in the list of “driver” mutations. These patients have inferior outcomes and may be associated with better symptom palliation with clinical benefit but their outcomes and have been excluded from clinical trials. This population accounts for a significant portion (up to 30%) of patients of our practice and some of them have been treated with systemic chemotherapy based on clinician’s discretion. We have analyzed the outcome of these patients who have been treated with chemotherapy despite poor performance status. Method: We performed a retrospective analysis of patients of advanced NSCLC with poor PS (ECOG PS 2 or more) registered at our lung cancer clinic between January 2016 and September 2017 and treated with systemic chemotherapy. Patients with driver mutations who were treated with first line TKIs were excluded. Hospital case records were reviewed for baseline characteristics, treatment details and outcome data. Result: A total of 78 patients were found to be eligible for this analysis. Median age was 60 years (33-77 years) including 15% patients 70 years or above. At presentation out of these 78 patients, 48 (62.5%) were smokers, 24 patients (30%) had pleural effusion and 8 patients (10%) had brain metastasis. Majority patients had ECOG PS 2 but 35 % had PS 3 or 4 also and 38(48 %) had one or more associated comorbidities. The most common chemotherapy regimen used was weekly paclitaxel and carboplatin (50 %) followed by pemetrexed and carboplatin (23 %). Majority (61.5 %) patients could complete 4 or more cycles of chemotherapy however 10 patients (13%) could receive only one cycle and 21 (27%) patients even received maintenance chemotherapy. Chemotherapy was interrupted or stopped due to toxicity in 33% patients. At least one point improvement in ECOG PS from baseline was observed in 44 patients (56%) after 2 cycles of chemotherapy. Objective response and disease control rates were 21 % and 48.6 % respectively. After a median follow up of 8.6 months, median progression free survival was 5.8 months. Conclusion: Systemic chemotherapy in modified doses and schedules in advanced NSCLC patients with PS 2 and above is feasible and may be associated with better symptom palliation with clinical benefit and improvement in survival. Further studies addressing this neglected subgroup are indicated.

P3.01-52 THE ROLE OF SERUM CARCINOEMBRYONIC ANTIGEN TO PREDICT THE RESPONSE OF TREATMENT IN NONSMALL CELL LUNG CANCER PATIENTS

N. Akdeniz1, M.A. Kaplan1, M. Kucukoner1, Z. Urakci1, O. Karhan1, A. Isikdogan2
1Dicle University Diyarbakır, Turkey/TR, 2Dicle University Diyarbakır, Turkey/TR

Background: Imaging techniques are routinely used in non-small cell lung cancer (NSCLC) to monitor response to chemotherapy. Biomarkers have been investigated in NSCLC for monitoring treatment response. We have measured tumor marker levels at the time of diagnosis and response assessment. In this study, the change in serum carcinoembryonic antigen (CEA) levels and the association with treatment response was evaluated.

Method: We retrospectively evaluated patients with NSCLC diagnosed in our institution between 2013-2017 and patients who had received investigational EGFR-TKIs were excluded. One hundred and thirty-five treatment responses were evaluated from 100 patients. Age, sex, stage, histologic subtype, tumor marker levels in the diagnosis, the change in serum CEA levels and the association with treatment response were analyzed. The treatment responses of the patients were evaluated as those with clinical response (stable disease (SD) + complete response (CR) + partial response (PR)) versus progression disease (PD) and with CEA level were assessed.

Result: Seventy-four (74%) patients were male, and the median age was 69 years (range: 41 to 82); 39% male; 26% performance status (PS) 0, 69% current or former smokers. With regard to EGFR mutation type, 30% had exon 19 deletions, 13% had exon 21 L858R, 1% had exon 18 G719X, L861Q, and/or S768I mutations.

Conclusion: Before (Group A) and after (Group B) the approval of afatinib in Japan. Overall survival (OS) was measured from the first day of first-line systemic therapy until death or the final day of the follow-up period. A total of 23 patients (11 in Group A, and 12 in Group B) were included in this study. The characteristics of the 23 patients were: median age 69 years (range: 41 to 82); 39% male; 26% performance status (PS) 0, 43% PS 1, 13% PS 2 and 4% PS3; 48% with brain metastasis; and 57% current or former smokers. With regard to EGFR mutation type, 30% had G719X, 30% had L861Q, 5% had S768I, 22% had complex of uncommon mutations, and 13% had both uncommon and common mutations.

Keywords: non-small cell lung cancer, EGFR-TKI, uncommon EGFR mutations

P3.01-54 A HISTORICAL COMPARISON OF PATIENTS WITH ADVANCED NSCLC HARBORING UNCOMMON EGFR MUTATIONS BEFORE AND AFTER THE APPROVAL OF AFATINIB IN JAPAN

T. Kawamura1, H. Murakami1, H. Kobayashi1, K. Nakashima1, S. Omori1, K. Wakuda1, A. Ono1, H. Kenmotsu1, T. Naito1, M. Endo1, T. Takahashi1
1Division of Thoracic Oncology, Shizuoka Cancer Center, Shizuoka/JP, 2Division of Diagnostic Radiology, Shizuoka Cancer Center, Shizuoka/JP

Background: Afatinib demonstrated durable responses in patients with metastatic non-small cell lung cancer (NSCLC) harboring uncommon non-resistant epidermal growth factor receptor (EGFR) mutations (G719X, L861Q, and/or S768I) in a pooled analysis of three clinical trials. However, the clinical impact of afatinib therapy in patients with these uncommon EGFR mutations remains unclear.

Method: We retrospectively evaluated patients with advanced NSCLC whose tumors have uncommon EGFR mutations, and who had received first-line systemic therapy at the Shizuoka Cancer Center between January 2010 and December 2017. Patients with resistant EGFR mutations (T790M, exon 20 insertions) and patients who had received investigational EGFR-TKIs were excluded from this study. Characteristics, therapy regimens and survival outcomes were compared between patients who had received a systemic therapy before (Group A) and after (Group B) the approval of afatinib in Japan. Overall survival (OS) was measured from the first day of first-line systemic therapy until death or the final day of the follow-up period. A total of 23 patients (11 in Group A, and 12 in Group B) were included in this study. The characteristics of the 23 patients were: median age 69 years (range: 41 to 82); 39% male; 26% performance status (PS) 0, 43% PS 1, 13% PS 2 and 4% PS3; 48% with brain metastasis; and 57% current or former smokers. With regard to EGFR mutation type, 30% had G719X, 30% had L861Q, 5% had S768I, 22% had complex of uncommon mutations, and 13% had both uncommon and common mutations.

Patient characteristics were similar in the two groups except for PS. First-line systemic therapy regimens were: gefitinib 73%, erlotinib 8% and platinum-doublet chemotherapy 18% in Group A; gefitinib 8%, erlotinib 25% and afatinib 67% in Group B. Median OS was 10 months for Group A and 25 months for Group B. A significant difference in OS was observed between the two groups (P = 0.018). In a subgroup analysis of patients with PS 0 or 1, there was also a significant difference in OS between the two groups (median, 10 months for Group A vs. 25 months for Group B; P = 0.033).

Conclusion: After the approval of afatinib in Japan, a majority of patients with advanced NSCLC harboring uncommon EGFR mutations received afatinib therapy as first-line systemic therapy, and it may be related to OS improvement.

Keywords: non-small cell lung cancer, EGFR-TKI, uncommon EGFR mutation

P3.01-53 COMPARISON OF THE TREATMENT EFFICACY OF OSIMERTINIB IN YOUNG AND ELDERLY PATIENTS WITH T790M-POSITIVE NSCLC

Y. Kato1, Y. Hosomi2
1Department of Thoracic Oncology and Respiratory Medicine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo/JP, 2Department of Thoracic Oncology and Respiratory Medicine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo/JP

Background: Osimertinib is a third generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI). The AURA3 trial showed that osimertinib is superior to platinum doublet chemotherapy in T790M-positive non-small cell lung cancer (NSCLC) with acquired resistance to first or second generation EGFR-TKIs in patients, irrespective of age. In contrast, another study showed that first or second generation EGFR-TKIs may have poorer efficacy and prognosis in young subjects than in elderly patients with EGFR mutation-positive NSCLC. Thus, we aimed to determine whether osimertinib exerted similar effects on young and old patients with T790M-positive NSCLC.

Method: We retrospectively investigated T790M-positive NSCLC patients with acquired resistance to first or second generation EGFR-TKIs who were administered osimertinib therapy from May 2015 to January 2018 by referring to their charts in the Tokyo Metropolitan Cancer and Infectious Disease Center, Komagome Hospital, Japan. We defined patients < 65 years old as elderly and those ≥ 65 years old as young. We compared the clinical characteristics, overall response rate (ORR), progression-free survival (PFS), and overall survival (OS) of the two age groups. Result: Total 31 patients with acquired resistance to first or second generation EGFR-TKIs were administered osimertinib. Twenty-three subjects belonged to the older age group, while 8 belonged to the younger age group. The median ages of the elderly and young patients were 75 years (range: 65–88 years) and 54 years (34–64 years), respectively. There were no significant differences in their clinical characteristics (sex, Eastern Cooperative Oncology Group Performance Status, smoking history, histology, type of de novo EGFR mutation, initial EGFR-TKI therapy, re-biopsy sample, central nervous system metastasis, and osimertinib line). The median PFS duration after initial EGFR-TKI treatment was greater in the elderly patients (17.2 vs. 10.5 months; hazard ratio; 2.86; 95% confidence interval [CI]; 1.03–7.97; P = 0.022); the ORR of osimertinib in the elderly and young patients was 53.3% and 37.5%, respectively. The median follow up interval after osimertinib initiation was 10.1 months. The total median PFS duration was 5.6 months. The median PFS duration tended to be greater in elderly patients (3.5 vs. 9.1 months; hazard ratio; 1.90; 95% CI, 0.75–4.78; P = 0.17). The median OS duration after osimertinib initiation was significantly greater in elderly patients (5.3 months vs. NA; hazard ratio; 3.36; 95% CI, 1.11–10.1; P = 0.027).

Conclusion: Osimertinib showed poorer efficacy in younger patients than in elderly patients with T790M positive NSCLC.

Keywords: NSCLC, EGFR-TKI, osimertinib
Background: Lung cancer is one of the most common malignant tumors in the world, and the incidence has been increasing in women, which has an unfavorable prognosis. Due to the relative failure of current therapeutic protocols, there is an urgent need for the development of new treatments. Then, new classes of drugs may be considered. The development of new drugs could benefit a large portion of the population affected by lung cancer. The enzyme CTP: phosphoethanolamine cytidyltransferase (Pcyt-2), which has phosphoethanolamine as the substrate, is a key regulator in eukaryotic cells and, therefore, the reduction of its production could directly affect cell division and apoptosis. Method: In the present study it was evaluated the cytotoxic effects of a new prototype, named as SF2, in NSCLC. In order to evaluate the effect of SF2 on Pcyt-2, the radiolabeling assay and the colorimetric assay of the Kennedy pathway was performed. The cytotoxic activity was investigated in A549 and NCi-H460 cell lines by the MTT colorimetric assay. Mitochondrial membrane depolarization and apoptosis analysis were performed by High Content Screening (HCS) using TMRE probe and double annexin V / PI labeling, respectively.

Conclusion: SF2 was able to reduce the activity of Pcyt-2 enzyme (65% related to control group, p<0.01). This reduction also lead to the decrease of the CDP-ethanolamine (CDP-Etn) production (29%, p<0.001) and the transport of ethanolamine (Etn) (69% related to control, p<0.001). SF2 presented IC50 values of 40 and 90 μM for A549 and NCi-H460 cell lines, respectively.

Keywords: Phosphatidylethanolamine, NSCLC, CTP: phosphoethanolamine-cytidyl-transferase

---

Background: Immune checkpoint inhibitors in metastatic non-small cell lung cancer (NSCLC) can result in improved quality of life and survival when compared with cytotoxic chemotherapy. While immune checkpoint inhibitors are disrupting the management of patients with cancer, some patients experienced progressive disease. On the other hand, there is another special response pattern of rapid progressions, (i.e., hyperproliferative disease or HPD), suggesting potentially effects of therapy. Therefore, SF2 is a potential candidate of antitumor drug by the inhibition of Pcyt-2 enzyme in NSCLC models.

Keywords: immune checkpoint inhibitor, EGFR, hyperproliferation

---

Background: For patients with aNSCLC without known mutations, demographic and clinical characteristics may impact second-line (2L) treatment decisions. Describing predictors of 2L drug utilization may help optimize outcomes of patients with aNSCLC who eventually progress. This study evaluated predictors for 2L IO vs. C use in patients with aNSCLC treated with 1L C (proxy for patients without treatment-altering mutations). Method: A retrospective cohort of continuously enrolled adult patients with lung cancer initiating 1L C <6 months before diagnosis was identified from Inovalon's MORE® Registry® claims post IO approval in lung cancer (Mar 2015 - Dec 2016). Patients receiving 2L systemic therapy following 1L C were selected, excluding patients with SCLC, treated for secondary malignancies, with <1 month follow-up, or on clinical trials. The influence of baseline characteristics on choice of 2L IO vs C was evaluated using binary logistic regression (LR), excluding targeted therapy (TT) due to small sample. Odds ratio (OR) >1 indicated greater chance of IO use. P-value <0.05 was considered significant. Result: Of 2,700 patients initiating 1L C, 829 (31%) received 2L: 539 (65%) received C, 262 (32%) IO, 26 (3%) TT. By subgroup (C, IO, TT), 46%, 54%, 57% (p<0.05) were females; mean age at 2L start was 65.3, 66.0, 61.0 years (p=0.045); Charlson comorbidity index: 2.8, 2.0, 1.5 (p=0.001); lines of therapy per patient: 2.4, 2.3, 2.5 (p=0.012); comorbidity count: 1.5, 1.1, 0.7 (p<0.001); follow-up from 1L start: 11.3, 10.9, 11.6 months (p=0.499); 18%, 21% (p=0.028) commercially insured; 70%, 68%, 39% (p=0.003) had evidence of smoking cessation/ counseling; 30%, 30%, 11% (p=0.001) had evidence of another malignancy at diagnosis; 7% 3%, 0% (p=0.032) had evidence of diabetes with chronic complications at diagnosis. LR model showed factors increasing likelihood of 2L IO use included evidence of chronic obstructive pulmonary disease (COPD) at diagnosis (OR=1.5, 95% CI=1.2, 1.9, p=0.025), longer time to 1L discontinuation (1.27, p=0.001), and commercial insurance (2.29, p=0.001). Factors negatively impacting IO choice were: 1L combination therapy use (0.48, p<0.001), evidence of secondary malignancy at diagnosis (0.21, p<0.001), and evidence of diabetes with chronic complications at diagnosis (0.33, p=0.031).

Conclusion: This retrospective RW study showed that aNSCLC patients with COPD, longer 1L treatment, on 1L monotherapy, and private insurance are more likely to receive 2L IO vs C. As such, early consideration needs to be given in order to monitor these patients more closely.
patients with advanced lung adenocarcinoma in the first affiliated hospital of Wenzhou Medical University from 1 April 2016 to 1 January 2017. EGFR mutation detection in tumor tissue and plasma cfDNA by Adx-ARMS and Adx-SuperARMS were all tested. We enrolled patients with EGFR-mutant in tumor tissue and receiving EGFR-TKIs. Mutation-positive plasma by both methods carried high abundance of EGFR mutations. Plasma that was mutation-positive by Adx-ARMS but the result by Adx-ARMS was negative harbored medium abundance. Mutation-negative plasma by both methods was recognized as low abundance group. The correlation between EGFR mutation abundance and clinical benefit from EGFR-TKIs treatment was analyzed using Kaplan–Meier curve. Chi-square test and Cox proportional hazards model. The study protocol was approved by the Institutional Review Board of the first affiliated hospital of Wenzhou Medical University (2016-017).

**Result:** 71 patients were enrolled, 42 harbored EGFR mutations in plasma detected by Adx-ARMS, while 53 were found positive result in plasma by Adx-SuperARMS. Median PFS was 10.0m and ORR was 64.8% in the patients with EGFR-mutant in tumor tissue. According to the results of the plasma detected by Adx-ARMS and Adx-SuperARMS, 42 were found high abundance of EGFR mutations, 11 were recognized to be medium abundances group while the other 18 as low abundances. The ORRs were 69.0%, 63.6% and 55.6% for patients with high, medium and low abundance of EGFR mutations, respectively. Pwt high abundances of EGFR mutations were seemed to acquire high ORRs, the difference was significant between high and low abundances group (P=0.006) but the differences were not significant when compared high abundances group with medium abundances group (P=0.732) and medium abundances group with low abundances group (P=0.114). Medium PFS for high, medium and low abundances groups were 11.0m, 8.5m and 9.0m, respectively (P=0.001). For the patients with 19–Del in tumor tissues, the ORRs were 70.4%, 57.1% and 54.5% in high, medium and low abundance of EGFR mutations groups, respectively. Medium PFS of high abundance group was longer than medium and low abundance groups (12.0m vs 9.0m vs 9.0m). As for L858R, the ORRs were 66.7%, 50.0% and 50.0%, respectively. Medium PFS were 9.6m, 5.5m and 9.5m. **Conclusion:** The relative EGFR mutation abundance in plasma could predict tumor response to EGFR-TKI treatment for advanced adenocarcinoma. The higher the EGFR mutation abundance is, the better efficacy of EGFR-TKI is.

**Keywords:** Abundance, EGFR, lung adenocarcinoma

**P3.01 ADVANCED NSCLC**

**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.01-59 COMPARISON OF LOBECTOMY, SEGMENTECTOMY AND WEDGE RESECTION FOR EARLY STAGE NSCLC: A DIRECT AND NETWORK META-ANALYSIS**

W. Liang

Thoracic, Peking University Cancer Hospital and Institute, Beijing/CN

**Background:** Aim: The purpose of this study was to compare the effect of lobectomy, segmentectomy and wedge resection for early stage non-small cell lung cancer (NSCLC) treatment. Surgical section is a first choice of lobectomy, segmentectomy and wedge resection for early stage non-small cell lung cancer (NSCLC); their prognostic role in advanced NSCLC is undetermined. The major target of the study was to determine whether the surgical section differences in patients undergoing sublobar resection. It is gradually considered that pneumonectomy is unnecessary. However, sublobar resection for NSCLC treatment remains controversial due to an increased risk in local recurrence and poorer long-term survival compared to lobectomy, thus additional local therapy is recommended to patients undergoing sublobar resection. **Method:** Eligible studies were retrieved from PubMed, Embase, and Cochrane Library. The 1, 2 or 5-year overall survival (OS) and disease-free survival (DFS), and complications rate were used as outcomes indicators. The pooled results for comparison indicators were measured by odds ratios (ORs) with 95% confidence interval (CI) as dichotomous variables. The random effects model was used for all test models in the present study. The consistency assessment in this network meta-analysis was conducted by Node-splitting analysis. Results: A total of 85 studies encompassing 13,406 early stage NSCLC patients were included into this network meta-analysis. The results revealed that although 1, 2 and 5-year OS and DFS of lobectomy was superior to segmentectomy and wedge resection, and segmentectomy was better than wedge resection, except for 2-year OS, only result of 5-years OS between groups (wedge resection vs. segmentectomy, OR= 0.56, 95%CI: 0.36-0.87; wedge resection vs. lobectomy, OR= 0.51, 95%CI: 0.33-0.79) were significant difference. On the contrary, the complications rate in wedge resection was significant lower than that of lobectomy (lobectomy vs. wedge resection, OR= 1.73, 95%CI: 1.05-2.72) and segmentectomy (segmentectomy vs. wedge resection, OR= 1.06, 95%CI: 1.02-2.74), and it was highest in lobectomy. **Conclusion:** Segmentectomy might be recommended as a reasonable alternative to lobectomy with lower complications rate for early stage NSCLC treatment.

**P3.01-60 A NOVEL MET D1246H MUTATION AFTER PROGRESSION OF EGFR-TKI/MET INHIBITOR COMBINED THERAPY IN A NSCLC PATIENT WITHACQUIRED MET AMPLIFICATION**

Y. Liang1, Q. Chen1, Y. Lin1, H. Liu2, B. Qiu2

1Medical Oncology, Sun Yat-Sen University Cancer Center, Guangzhou/CN, 2Sun Yat-Sen University School of Medicine, Guangzhou/CN

**Background:** MET amplification was the second common acquired resistance mechanism to epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) in patients with advanced non-small cell lung cancer (NSCLC). It may be benefited by combinations of EGFR TKIs and the MET inhibitor. However, the acquired resistance mechanism to the combination therapy in tumor tissue is undetermined. The next generation sequencing (NGS) based circulating tumor DNA (ctDNA) assay was performed. Results were applied to discover a novel mutation after resistance to target therapy. **Result:** A 52-year-old Chinese never-smoking woman with EGFR L858R mutant adenocarcinoma had systemic progression after gefitinib and pembrolizumab. NGS-based ctDNA assay was performed again and it showed that L858R mutation (MAF 11.4%) and MET amplification (LR 4.9) presented. The patient started treatment with crizotinib (250mg Bid) and gefitinib (250mg/d). The NGS was performed after progression of this combination therapy. It revealed two novel mutations of MET D1246H (MAF 0.9%) and EGFR T790M mutation (MAF 0.2%), in addition to the initial presence of EGFR L858R mutation (MAF 9.8%) and MET amplification (LR 6.7). The patient started to receive osimertinib (80mg/d) and cabozantinib (240mg/d and later increased to 40mg/d). The patient tolerated this combination well while the symptoms did not relief. After 8 weeks, the re-scan CT showed pulmonary lesions progressed. The NGS-based ctDNA assay performed again and it showed that L858R mutation (MAF 11.4%) and MET amplification (LR 4.9) presented while the EGFR T790M mutation and MET D1246H disappeared. Then the patient received osimertinib (80mg/d) and crizotinib (250mg Bid). The patient felt symptoms improved greatly after 1 week’s administration and CT scan after 2 months showed good response. However, one month later, the patient felt deteriorative symptoms of dyspnea and chest X-ray showed increasing pleural effusion, progressing pulmonary lesions. The NGS-based ctDNA assay at that time revealed that MET D1246H (MAF 14.4%) appeared again, in addition to the initial presence of EGFR L858R mutation (MAF 22.4%) and MET amplification (LR 8.2) while the EGFR T790M mutation was not existed. However, the patient died because of respiratory failure. **Conclusion:** MET mutations might be a potential acquired resistance mechanism after progression during EGFR-TKI/MET inhibitor combined therapy in advanced NSCLC patient with primary EGFR mutation and secondary acquired MET amplification.

**Keywords:** non-small cell lung cancer, Met mutation, acquired resistance mechanism

**P3.01-61 EGFR AND KRAS MUTATIONAL STATUS AND SIGNIFICANCE IN GREEK PATIENTS WITH ADVANCED NON SMALL CELL LUNG CANCER**

H. Linardou, V. Koutoula, G. Kouvatseas, V. Karavasilis, G. Mountzios, E. Samantas, A. Kalogera-Fountzila, D. Televantou, K. Papadopoulou, X. Yat-Sen University School of Medicine, Guangzhou/CN, 3Thoracic Surgery, Sun Yat-Sen University Cancer Center, Guangzhou/CN

**Background:** KRAS mutations are reported in 20-25% of non-small cell lung cancer (NSCLC); their prognostic role in advanced NSCLC is still under dispute. Given that ethnicity may play a role on mutual...
profiles of NSCLC, we report here on KRAS mutations in Greek NSCLC patients. **Method:** KRAS and EGFR genotypes were evaluated in 424 NSCLC patients, from March 2000 to December 2012 and associated with clinicopathological parameters. Outcome comparisons were performed in 234 metastatic patients with available treatment data, following 1st line chemotherapy without tyrosine kinase inhibitors. **Result:** KRAS mutations were found in 71 tumors of all histologies (22.2% in adenocarcinomas); most common types were p.G12C (39.5%), p.G12D (32%) and p.G12V (14%). EGFR mutations were found in 45 tumors (14.8% in adenocarcinomas; 72.6% of the classical type) and were mutually exclusive with KRAS mutations except for one case. At a median 3-year follow-up for all patients, KRAS status was a strong negative prognostic factor for overall survival (OS, p=0.0213) but not for progression-free survival (PFS), irrespective of mutation type. KRAS mutations conferred 64% increased risk of death in all 1st line treated patients and the worst OS compared to EGFR and any wild-type status in 1st line platinum-treated patients (p=0.0547). Rare EGFR mutations conferred significantly better outcome to platinum-treated patients (OS, p=0.0074; PFS, p=0.0338).

**Conclusion:** The presence of KRAS mutations seemed of adverse prognostic significance for survival, also in the presence of platinum-based 1st line treatment, while no prognostic differences were seen among different types of mutations.

**Keywords:** KRAS, EGFR, NSCLC

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

**P3.01-62 A NEW METHOD FOR NON-INVASIVE PREDICTION OF RADIOTHERAPY: SDHS DEPLETION ENHANCES RADIOSensitivity BY REGULATING P53**

J. Liu, Y. Zong, G. Wu
Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/CN

**Background:** Radiotherapy is an important and effective treatment for lung cancer. Some molecules can predict the effect of radiotherapy, but it is an invasive test that will cause trauma to patient. So the development of reliable non-invasive methods for predication of radiotherapy has become essential to guide therapy. **Method:** We initiated an analytical, observational, open, and retrospective study (ChiCTR1800014878) of 53 patients with stage III lung adenocarcinoma who were ready for radiotherapy. The performance status (PS) scores of the patients are all over 2. Blood and tumor tissue before treatment were collected to detect SDHS concentration. We then evaluated the prognostic role of SDHS expression in these patients. To further verify the effect of SDHS on radiosensitivity, two mice models (orthotopic mice bearing lung cancer and SDHS gene knock-out mice) were established and the internal mechanism between SDHS and radiotherapy was explored. **Result:** The patient whose tumor volume shrink significantly one month after radiotherapy had lower expression of SDHS in tumor, and loss of SDHS expression correlated with down regulation of DNA-PKcs and ku86. More importantly, SDHS can be directly detected in blood by qRT-PCR, and the result is consistent with that in tissue. And more exciting, patients with the deficiency of SDHS had longer PFS and OS after radiotherapy, and the results in blood and in tumor are consistent. To further verify the effect of SDHS on radiosensitivity, in vivo experiments were carried out. In the orthotopic model, SDHS knock down tumors showed higher radiosensitivity with smaller volume. In SDHS knock-out mice, lung epithelial cells exhibited elevated DNA damage after radiation. Moreover, our data indicated that SDHS depletion causes P53 translocated from cytoplasm to nucleus, which enhances radiosensitivity of non-small cell lung cancer. Furthermore, consistent with in vivo data, the tumor growth was partially reversed when p53 was co-depleted with SDHS. **Conclusion:** In this experiment we found that SDHS regulated radiosensitivity by P53 and it can be detected in tumor tissue. It is a suitable marker for predicting radiosensitivity. More than this, the expression of SDHS can be directly measured by qRT-PCR in the blood, and it is consistent with that in the tumor tissue. This provides a novel non-invasive method for predicting the radiosensitivity of the patients unable to tolerant the biopsy.

---

**Background:** Immune checkpoint inhibitor therapy has shown optimal efficacy in advanced non-small-cell lung cancer (NSCLC). However, the biomarkers of immunotherapy response are not well established. In the present study, we aimed to determine baseline prognostic factors associated with progression-free survival (PFS) in anti-PD1/PD-L1 treatment and to identify a predictive biomarker for immunotherapy response. **Method:** Data of 54 advanced NSCLC patients receiving anti-PD1/PD-L1 treatment were prospectively collected in Shanghai Chest Hospital from Dec. 2015 to May 2017. Clinical data included baseline routine blood examination and demographic characteristics of patients prior to immunotherapy. Systemic inflammatory biomarkers were obtained from routine blood tests to calculate leukocyte-to-lymphocyte ratio (LLR), neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), lymphocyte to monocyte ratio (LMR) and systemic immune-inflammation index (SII, neutrophil × platelet/lymphocyte). Receiver operating characteristic (ROC) and area under the curve (AUC) were used to identify the optimal cut-off value of LLR, NLR, PLR, LMR and SII for survival analysis. Endpoints were PFS and objective response rate (ORR) following anti-PD1/PD-L1 treatment. Univariate and multivariate analyses for PFS was used by Kaplan-Meier method and statistical differences were determined by Log rank test. The Cox proportional hazards model was used for multivariable analysis. **Result:** A total of 54 cases were analyzed, with 38 treated with Atezolizumab and 16 treated with Nivolumab. Median PFS was 2.81±0.18 and 1.81±1.2 months, respectively (P = 0.988). 44 patients received second-line anti-PD1/PD-L1 treatment and 10 patients underwent three-line or above. The median PFS of the two groups were 2.81±0.88 and 2.8±0.23 months, respectively, (P=0.851). ROC and AUC identified LLR=6.3, NLR=4.5, PLR=124.45, LMR=3.4 and SII=1066 as the best cut-off values. Univariate survival analysis showed that LLR, age, pathological type, neutrophil percentage, hemoglobin, platelet count, albumin, serum lactate dehydrogenase (LDH), NLR and SII were associated with PFS (P<0.05). Cox multivariate analysis showed that LLR (P=0.003;HR 2.99;95%CI: 1.45-6.17), albumin (P=0.000;HR 8.11;95%CI: 2.63-25.06) and LDH (P=0.000;HR 4.55;95%CI: 2.13-9.73) were independent prognostic factors for PFS. For patients with favorable (1 IN 3 factors), (2 IN 3 factors) and (3 IN 3 factors) biomarker profile median PFS were 0.94, 1.63 and 8.17 months, respectively (P=0.000). **Conclusion:** Blood markers predict survival in advanced NSCLC treated with immune checkpoint blockade. Our findings show that baseline LLR, NLR, SII, normal serum levels of albumin and LDH were independently and advantageously associated with the PFS of patients receiving anti-PD1/PD-L1 treatment, and they may help identify patients with benefit from immune therapy.

**P3.01-64 PRELIMINARY DATA OF DIVERSE THERAPIES IN PATIENTS WITH ADVANCED NON-SMALL-CELL LUNG CANCER HARBOURING RET-REARRANGEMENT**

C. Lu1, H. Tu1, H. Yan1, X. Zhang1, B. Wang1, Z. Wang1, A. Li2, J. Lin1, Y. Li1, E. Ke1, J. Song1, S. Chen1, Y. Wang1, Y. Guan1, X. Xian1, X. Yi1, Y. Wu1, J.-., Yang1
1Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/CN, 2Division 1 tumor center, Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/CN

**Background:** Activating RET-rearrangement has been discovered to play a crucial role in NSCLC tumorigenesis. However, the lack of specificity narrowed efficacy of multi-kinase inhibitors (MKIs) and the optimal treatment remains unknown. In this study, we compared chemotherapy, immunotherapy and MKIs in this group of patients. **Method:** We retrospectively evaluated the efficacy of these three treatments in advanced, RET-rearranged NSCLC patients between January 2013 and April 2018 at our institution. RET-rearrangements were assessed by Next-generation sequencing (NGS) or any of FISH, IHC, RT-PCR. Treatment data were collected after the patients had been diagnosed with RET-rearranged advanced NSCLC. Progression-free survival (PFS) was measured from treatment start to disease progression, all-cause
mortality or last follow up. Median follow-up time was 5.1 months. NGS was performed to assess somatic mutation of available samples. **Result:** A total of 30 patients with RET-rearrangement were investigated in this study. After the diagnosis, 15 patients, genetic profiles confirmed by NGS, received chemotherapy (n=10), checkpoint-inhibitors (n=7) and RET targeted MKI (n=6) with evaluable response. Several patients take any two of these three treatments as different line therapies. The disease control rate of chemotherapy, immunotherapy, MKI group was 70.0%, 71.43% and 50%, respectively. While the median PFS of three groups was 2.50 months, 2.70 months, 0.30 months, respectively, which of no significance. The NGS data of 10 patients showed that RET-rearrangement co-occurred with several other genes, including TP53, NTRK, CDK4, ERBB4. A low mutation burden (mean 4.5 mutations) was observed (Figure 1).

**Conclusion:** We confirmed relatively low PFS in advanced RET-rearranged NSCLC with MKIs reported in previous studies. But further investigation is warranted. Treatment with checkpoint-inhibitors seemed to encouragingly prolong PFS but a larger group of patients is needed to draw a definite conclusion.

**Keywords:** Immunotherapy, RET rearrangement, advanced NSCLC

**P3.01 ADVANCED NSCLC**

**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.01-65 FIRST-LINE RADICAL LOCAL THERAPY MAY PROVIDE ADDITIONAL SURVIVAL GAIN FOR PATIENTS WITH EGFR-MUTANT METASTATIC NSCLC RECEIVING TKIS**

X. Lu, J. Wang, C. Wang, N. Bi, Z. Zhou, Y. Wang, L. Wang
National Cancer Center/Cancer Hospital Chinese Academy of Medical Sciences, Peking Union Medical College, Beijing/CN

**Background:** Tyrosine kinase inhibitors (TKIs) have been widely accepted as first-line therapy for patients with EGFR-mutant metastatic non-small cell lung cancer (NSCLC), achieving a median progression free survival (PFS) and overall survival (OS) of 8.0 to 13.1 months and 19.3 to 30.9 months respectively. Patterns-of-failure studies suggest that the first progression after first-line TKIs occurs most often at sites of disease known to exist at the baseline. In this retrospective study, we aimed to investigate whether the radical local therapy could offer survival benefit in addition to first-line therapy for patients with activating EGFR mutations and treated with TKIs as first-line management after the diagnosis of stage IV disease (either synchronous or metachronous) between 2010 and 2017 at our institution were reviewed. All enrolled patients should receive radical local therapy (either surgery or radiotherapy with curative intent) at least to the main site of disease. We defined the main site as the primary site for synchronous IV-stage patients and at least 1 progression site for metachronous IV-stage patients. OS and PFS were calculated from the first day of IV-stage treatment. Kaplan-Meier method was used for survival estimation and Log-rank test was rendered for survival comparison between groups. **Result:** A total of 45 patients entered into the final analysis, including 18 with synchronous stage IV diseases and 27 patients with metachronous diseases. A total of 208 gross tumor sites were identified and 130 of them received local treatment, including 90 sites treated with radical approaches and another 30 sites with palliative therapy. At a median follow-up period of 37.8 months, the median OS was 51.4 months, with 1-, 3- and 5-year rate of 97.7%, 58.7% and 25.2%, respectively. The median PFS was 16.4 months, with 1-, 2- and 3-year rate of 64.7%, 29.1% and 6.8%, respectively. There was no difference between synchronous and metachronous groups. In 38 patients who progressed, 19 (42.2%) involved new metastatic sites only, 12 (26.6%) involved initial sites only, and 3 (6.7%) involved both.

**Conclusion:** Metastatic EGFR-mutant NSCLC patients who received TKIs and radical local therapy in our study obviously provided longer OS and PFS compared with historical results using TKIs alone. Prospective randomized evidences are warranted to clarify the clinical efficacy of additional local therapy to first-line TKIs for this highly selective subgroup of patients.

ADENOCARCINOMA MUTATION STATUS OF PULMONARY INVASIVE MUCINOUS ADENOCARCINOMA

F. Lu
Thoracic Surgery II, Peking University Cancer Hospital, Beijing/CN

Background: In the 2015 classification, invasive mucinous adenocarcinoma (IMA) is categorized as one but an uncommon subtype of lung adenocarcinoma. This study attempted to clarify the clinicopathological characteristics and mutation status of IMA.

Method: A total of 37 patients with IMA from among 1376 surgically resected patients with lung adenocarcinoma were enrolled. We analyzed them from the standpoints of clinicopathological characteristics, mutation status and the prognosis.

Result: KRAS mutations were observed in 9 patients and all of them were Codon 12 mutations. A total of 10 cases exhibited EGFR mutations. ALK rearrangement was detected in only 1 case. The DFS at 5 years were 68.0%. On univariate analysis for DFS, high CEA level (p = 0.024), lymphatic permeation and vascular invasion (p = 0.015), pleural invasion (p = 0.031), tumor size (p = 0.023) and N staging (p = 0.027) were poor prognostic predictors for DFS.

Conclusion: The results revealed that different mutation statuses were observed in IMA. So, we believe that IMA would be subclassified into distinct subtypes with mutation status. And CEA level, lymphatic permeation and vascular invasion, pleural invasion, tumor size and N staging may be the factors related to mitigating DFS in IMA.

Keywords: mutations, Prognosis, Mucinous Adenocarcinoma
free survival (PFS). The adverse events (AEs) were assessed. **Result:** A total of 20 patients were enrolled between September 2016 and March 2018. Median age was 69 years (range 62-80). There were 9 males and 11 females. A baseline KPS was scored above 70 in 18 patients, 60 in 2 patients. Sixteen patients had stage IV disease and 4 had IIb. There were 11 patients with 190d and 9 patients with L858R mutations. After a median follow-up time of 10.4 months (range 3-19.3), only one patient had disease progression around the treated primary tumor. Nine patients had disease progression distantly outside of radiated region. Median PFS was 15.2 (95% CI 8.5-21.9) months for the whole cohort. At 10 months of follow-up, the rates of OS, PFS, local and distant PFS were 100%, 67.2%, 100% and 67.2% respectively. There were no acute or late grade 3+ treatment related toxicities. **Conclusion:** Early primary tumor SBR improved primary tumor control without causing serious side effects. SBR may delay the development of icotinib resistance in patients with advanced NSCLC harboring EGFR mutations. Randomized study is needed to determine whether early SBR can improve PFS and overall survival.

**P.3.01-69 STEREOTACTIC ABLATIVE RADIOTHERAPY IMPROVES PROGRESSION-FREE SURVIVAL & LOCAL CONTROL IN OLIGOMETASTATIC LUNG CANCER PATIENTS**

F. Maldonado
Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerología, Mexico City/MX

**Background:** Non-small cell lung cancer (NSCLC) represents approximately 75% of the histological types of lung cancer. In patients with oligometastatic NSCLC, definitive treatment to primary tumor and low thoracic tumor burden are associated with better outcomes. The use of stereotactic ablative radiotherapy (SABR) has demonstrated high rates of local control for lung metastases and long-term survival improvement. The aim of this study is to evaluate Local Control (LC), Progression Free Survival (PFS) and toxicity of patients with oligometastatic NSCLC treated with SABR. **Method:** A prospective study was conducted with oligometastatic NSCLC patients. From July 2016 to December 2017, with a median follow up of 21.7 months, eighteen patients were enrolled. All patients received systemic therapy, those with partial response (PR), assessed by PET CT, were referred for SABR treatment (45-60 Gy in 3-7 fractions) to the thoracic lesion (primary or metastatic) depending on location, size and number of lesions, always keeping BED (Biologically Effective Dose) >100 Gy for tumor. **Result:** Eighteen patients were treated with SABR, response to treatment was as follows: global response was 95%, partial response 2% and complete response 72.2%. Mean time to progression after SABR treatment was 7.04 months (CI 95% 0.27-17.84 months). Progression free survival since beginning of any treatment was 20.14 months (CI 95% 12.92 - 27.35 months). The pattern of recurrence/ progression was as follows: local (in field) 1/18, regional (mediastinal lymph node) 1/18 and systemic 4/18 (1/18 for lymph node and 3/18 for distant). Sixteen patients developed grade 1 pneumonitis; one patient developed grade 2 pneumonitis and grade 3 pneumonitis was reported in one patient. Only three patients required treatment with steroids (16.7%). **Conclusion:** SABR is a suitable and well-tolerated therapeutic option for patients with oligometastatic NSCLC. SABR have shown to improve local control and increase progression-free survival. Future clinical trials are required to fully evaluate the effects of this treatment.

**Keywords:** NSCLC, Oligometastatic, Radiotherapy

**P.3.01 ADVANCED NSCLC**

**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P.3.01-70 META-ANALYSIS OF METFORMIN IN COMBINATION WITH PLATINUM CHEMOTHERAPY IN ADVANCED NON-SQUAMOUS NON-SMALL CELL LUNG CANCER**

K. Marrone1, A. Parikh2, D. Becker3, J. Brahmer4, D. Ettinger1, B. Levy4
1Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore/MD/US, 2Mt. Sinai Hospital, New York/US, 3NYU School of Medicine, New York/US, 4Johns Hopkins Sidney Kimmel Cancer Center, Washington DC/US

**Background:** Metformin has been shown to have a variety of insulin-dependent and – independent antitumor effects, primarily through cellular growth inhibition via the AMP-activated protein kinase (AMPK) pathway and the IGF1-insulin axis. Two prospective trials evaluating metformin with platinum doublet chemotherapy +/- bevacizumab have demonstrated competitive outcomes in non-diabetic, chemotherapy-naïve advanced non-small cell lung cancer (NSCLC) patients. Outcomes in KRAS-mutated NSCLC, an area of interest due to potential co-occurring LKB1 mutations, an AMPK pathway upstream kinase, is currently unknown. **Method:** This meta-analysis is of two phase II study treatment arms (NCT02019979, NCT01578551), evaluating the use of concurrent metformin and platinum-based doublet chemotherapy +/- bevacizumab. Patient’s demograhic, molecular and adverse event (AE) profiles were summarized with descriptive statistics. Kaplan-Meier curves for progression free survival (PFS) and overall survival (OS) were generated for all patients, as well as known KRAS and EGFR mutation subsets.

**Result:** 33 non-squamous NSCLC patients were treated; 60% were female and the median age was 64 (Range: 37-77). The most common AE was neutropenia (Grade 3-4: 30%). No patients required study treatment cessation due to metformin-related toxicity. Across all patients, mPFS was 6 months (95% CI: 1.36-7.96); mOS was 14.83 months (95% CI: 8.25-19.99). In KRAS-mutated patients (n=13), mPFS was 7.21 months; mOS was 17.46 months. In EGFR-mutated patients (n=7), mPFS was 6.57 months; mOS was 13.25 months.

**Conclusion:** Combination metformin and chemotherapy +/- bevacizumab was safe and well-tolerated in advanced, chemotherapy-naïve non-squamous NSCLC across two phase II clinical trials. Metformin appeared particularly effective in KRAS-mutated NSCLC. Data for LKB1 status was unknown for a majority of patients, but may be an important co-mechanism for benefit. Metformin appeared to underperform in the EGFR subset, perhaps due to lack of TKI use. Given the tolerability, low cost and activity observed in NSCLC, further investigation into metformin’s antitumor effects in molecularly defined subsets is needed.

**Keywords:** combination therapies, metformin, KRAS

**P.3.01-71 RESULTS OF EXTENDED RESECTION IN T4 NON-SMALL CELL LUNG CANCER**

T. Matsunaga1, K. Suzuki2, K. Takamochi3, S. Oh3
1General Thoracic Surgery, Juntendo University School of Medicine, Tokyo/JP, 2General Thoracic Surgery, Juntendo University Hospital, Tokyo/JP, 3Department of General Thoracic Surgery, Juntendo University School of Medicine, Tokyo/JP

**Background:** The strategy for T4 non-small cell lung cancer remains controversies. Extended resection carried a high mortality rate and high advances in surgical technique was needed. However, extended resection may improve survival in selected patients. **Method:** Between 2000 and 2019, 41 patients with ptT4 non-small cell lung cancer, undergoing extended mediastinal resection, were selected. Patients with pulmonary metastasis were excluded. The type of extended resection was carina in 11 (27%), superior vena cava in 9 (22%), the aorta in 6 (15%), esophagus in 2 (5%), left atrium in 7 (17%) and mediastinal tissue in 4 (10%). We investigated the results of surgical resection and over-all survival. **Result:** There were p-stage IIIA in 26 and p-stage IIIB in 15. In histology, squamous cell carcinoma was observed in 22, adenocarcinoma in nine, pleomorphic carcinoma in four and others in six. The median of in-hospital days was 17d, that of operative time was 302m, and that of hospital death was 2%. The rate of intra-operative bleeding was 470cc. The rate of in-10% bed mortality was 10%. Pneumonecctomy was performed in 22 (54%) and bronchoplasty was did in 18 (44%). The rate of morbidity was 66% and that of reoperation was 17%, 30-day mortality was 5%, 90-day mortality was 7% and in-hospital death was 2%. The median follow-up time was 34 months and...
overall 3- and 5-year survival was 57% and 39%. Significant prognostic factors were complete resection (p-value=0.0485) and smoking status (p-value=0.0488) in univariate analysis. Multivariate analysis did not reveal significant prognostic factors. **Conclusion:** Surgical resection for T4 lung cancer was feasible in this study. But, the frequency of morbidity and reoperation was high because of high rate of pneumonectomy and mediastinal extended resection. So, we need to care for patients after operation, intensively.

**Keywords:** extended resection, non-small cell lung cancer, T4

**P3.01 ADVANCED NSCLC**  
**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.01-72 PULMONARY RESECTION IN A PRONE POSITION FOR LUNG CANCER INVADING THE SPINE: TWO CASES REPORT**  
Thoracic Surgery, Okayama University Hospital, Okayama/JP

**Background:** The prone position is usually not selected for pulmonary resection. The intraoperative body position is an important issue in surgery for non-small cell lung cancer (NSCLC) invading the spine because the standard intraoperative body position for vertebralctomy is a prone position, while that for pulmonary resection is a lateral decubitus position. Intraoperative changes in body position are correlated with disadvantages such as the risks of infection and nerve injury. We have previously reported significantly favorable clinical outcome of induction chemoradiotherapy (ICRT) followed by surgery among patients with clinical T3 or T4 locally advanced NSCLC, compared with initial surgery. ICRT can prevent cancer cell microresidues at local sites and to eradicate micrometastatic disease at distant sites. **Method:** Case 1: A 60-year-old man was found to have adenocarcinoma of the right lung with invasion of the adjacent chest wall and vertebral bodies from Th3 to Th5 and his clinical stage (UICC 7th edition) was diagnosed as c-stage IIIa (ct4N0M0). Case 2: A 63-year-old man was found to have squamous cell carcinoma of the left lung with invasion of the adjacent chest wall and vertebral bodies from Th3 to Th5 and his clinical stage (UICC 7th edition) was diagnosed as c-stage IIIa (ct4N1M0). They were treated with ICRT consisting of two cycles of cisplatin plus docetaxel with concurrent radiotherapy of total 46 Gy. **Result:** They both obtained moderate decrease in tumor size at 3.2 and 3.6 days and the rate of pain (30% and 50%). No statistical differences in success rates (talc, 75.9%, MINO + OK-432, 85.1%), period of drainage tube insertion (p-value=0.0498) in univariate analysis. Multivariate analysis did not reveal significant factors. **Conclusion:** We retrospectively assessed 73 patients with NSCLC invading the spine. We assessed the difference in success rates according to the pathology of the disease or chemotherapy. **Result:** Of the 73 patients, 51 were men and 22 were women, the median age was 75 years (range 47-98). The rate of fever was significantly low in the talc group, although no statistical difference was observed in the success rate (talc, 75.9%, MINO + OK-432, 85.1%), period of drainage tube insertion (3.2 and 3.6 days) and the rate of pain (30% and 50%). No statistical difference according to the pathology of the disease or chemotherapy was observed. **Conclusion:** Thus, we can perform pleurodesis in patients with talc less invasively than with MINO + OK-432.

**Keywords:** pleurodesis, malignant pleural effusion

---

**P3.01-73 TALC VERSUS MINOCYCLINE AND OK-432 PLEURODESIS FOR MALIGNANT PLEURAL EFFUSION**  
Respiratory Medicine, Fujieda Municipal General Hospital, Fujieda/JP

**Background:** Globally, talc pleurodesis is the standard treatment for malignant pleural effusion. In Japan, a combination of minocycline (MINO) and OK-432 has been commonly used for treating pleurodesis of malignant pleural effusion: however, data comparing talc and MINO + OK-432 are insufficient. To compare the success rates and adverse events of talc and MINO + OK-432. **Method:** We retrospectively assessed 73 patients receiving pleurodesis for malignant pleural effusion (lung cancer, 60; malignant mesothelioma, 3; others, 10) for the first time between January 2010 and January 2017 at our hospital. We assessed the rates of fever, pain, after drug administration and success of pleurodesis. Moreover, we assessed the difference in success rates according to the pathology of the disease or chemotherapy. **Result:** Of the 73 patients, 51 were men and 22 were women, the median age was 75 years (range 47-98). The rate of fever was significantly low in the talc group, although no statistical difference was observed in the success rate (talc, 75.9%, MINO + OK-432, 85.1%), period of drainage tube insertion (3.2 and 3.6 days) and the rate of pain (30% and 50%). No statistical difference according to the pathology of the disease or chemotherapy was observed. **Conclusion:** Thus, we can perform pleurodesis in patients with talc less invasively than with MINO + OK-432.

**Keywords:** pleurodesis, malignant pleural effusion

**P3.01-74 CLINICAL AND RADIOLOGICAL PREDICTORS OF EFFICACY TO NIVOLUMAB IN NSCLC: A MULTI-INSTITUTIONAL, RETROSPECTIVE COHORT STUDY**  
R. Moor, K. Roberts, R. Ladwa, K. Miles, K. O’Byrne  
Medical Oncology, Princess Alexandra Hospital, Brisbane/QLD/AU

**Background:** Identification of sub-populations of patients with a greater likelihood of response to anti-programmed death-1 (PD1) inhibitors, in non-small cell lung cancer (NSCLC) would enable treatment to be directed to those most likely to benefit, thereby increasing efficacy and cost effectiveness. The relationship, however, between clinical and radiological parameters with efficacy of single agent Nivolumab remains unclear in advanced NSCLC. **Method:** A retrospective analysis was conducted on patients who received second-line Nivolumab following progression after platinum based chemotherapy for advanced NSCLC on a Compassionate Access Program across seven oncology institutions in Queensland, Australia. ECOG Performance status (PS), immune related adverse events (IrAEs), and baseline CT texture analysis (as a surrogate for tumour heterogeneity) were assessed. The endpoints were overall survival (OS), progression free survival (PFS) and objective response rate (ORR). An institutional ethical approval was obtained. **Result:** Two hundred and fourteen patients were enrolled over two years, median age 67 (range 42 to 84 years). PS 0-1 (64 %); PS 2-3 (36%). The median OS was 8.9 months (95% CI, 6.6 to 11.67). 13.3 months in PS 0-1 patients and 4.5 months in PS 2-3 patients. At 1 year, the OS rate was 42%; 55% in patients with PS 0-1 and 19% in PS 2-3 patients. ORR was recorded in 23% of patients (50/214), an additional 27% (58/214) had stable disease. Toxicity data was available for 90% of patients (N=194). The presence of IrAEs of any grade occurred in 36% of patients and was associated with a longer median PFS of 5.9 months versus 2.3 months in patients with no immune toxicity (P value <0.01, 95% CI). In patients with irAE the ORR was 32% versus 18%, 1 year OS 59% versus 29% in those without any immune mediated toxicity. CT texture analysis findings (N=47) were consistent with increased tumour heterogeneity showed significantly longer PFS (median NR versus 1.5 months, Hazard Ratio: 2.05, p=0.018). **Conclusion:** We found Nivolumab had clinically significant long-term benefits in the treatment of locally advanced and metastatic NSCLC with 12 month survival rates in keeping with clinical trials in PS 0-1 patients. An ECOG PS 0/1, the development of IrAEs and increased tumour heterogeneity by CT texture analysis was associated with a significantly longer PFS and increased clinical benefit in this cohort. The combination of these clinical and radiological parameters may identify subgroups of patients benefitting from this therapy.

**Keywords:** immune related adverse events, CT Texture Analysis, Nivolumab

**P3.01-75 RELAY+: AN EXPLORATORY STUDY OF GEFITINIB WITH RAMCIRU MB IN UNTREATED PATIENTS WITH EGFＲ MUTATION-POSITIVE METASTATIC NSCLC**  
M. Nishio1, K. Nishio1, K. Suzukawa2, Y. Omori3, S. Enatsu1, C. Visseren-Grul1, K. Nakagawa2  
1Department of Thoracic Medical Oncology, The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo/JP, 2Department Genome Biology, Kindai University School of Medicine, Osaka/JP, 3 Eli Lilly and Company, Kobe/JP, 4 Eli Lilly and Company, Utrecht/NL, 5 Medical Oncology, Kindai University, Osaka/JP

**Background:** RELAY is a randomized, double-blind phase 1b/3 study investigating the efficacy and safety of the addition of ramucirumab (a human IgG1 monoclonal antibody that binds to Vascular Endothelial Growth Factor (VEGF) Receptor 2) to erlotinib (an EGFR TKI) in treatment-
naive EGFR-mutant metastatic NSCLC. Results from the Phase Ib cohort showed that combining ramucirumab with erlotinib was safe with encouraging clinical activity and a median PFS of 17.1mo (Reck et al., Clinical Lung Cancer 2017). While enrolment for the RELAY Phase 3 cohort has been completed, the RELAY+ cohort was recently added to explore the safety and efficacy of the combination of ramucirumab with gefitinib, a frequently used EGFR TKI in East Asia. Results from the gefitinib cohort are presented in Period 1 and harbors the T790M mutation (Period 2). The trial is planned to be conducted in Japan, Taiwan and South-Korea and is currently open for enrollment. Approximately 80 patients will be enrolled. In Period 1 patients will receive ramucirumab (10mg/kg) every two weeks and gefitinib (250mg orally) until disease progression, unacceptable toxicity or other withdrawal criteria are met. The study objectives are to determine the 1-yr PFS rate, safety and patient reported outcomes (Lung Cancer Symptom Scale and EQ-5D-3L). In Period 2 the efficacy and safety of ramucirumab plus gefitinib in patients whose disease progressed in Period 1 will be explored. Both RELAY+ and RELAY patients will be enrolled in a liquid biopsy exploratory substudy. C.DNA (circulating tumor DNA) from plasma samples will be used for ddPCR (droplet digital PCR) and NGS (Next Generation Sequencing) to characterize mechanisms of acquired resistance and to test the hypothesis if the addition of ramucirumab to an EGFR TKI delays or modifies the emergence of EGFR TKI resistance. Conclusion: Section not applicable. Keywords: Section not applicable.

Keywords: Metastatic NSCLC, ramucirumab, RELAY+

P3.01-76 CLINICAL BACKGROUND AND RESPONSE TO CHEMOTHERAPY IN NSCLC PATIENTS WITH MET EXON14 SKIPPING MUTATION OR HIGH MET GENE COPY NUMBER

Department of Thoracic Oncology, National Kyushu Cancer Center, Fukuoka/JP

Background: MET exon14 skipping mutation (SM) and high gene copy number (HGCN) are present in 3%–4% and < 1% of NSCLCs, respectively. We conducted a retrospective analysis of patients with both MET gene alterations. Method: We collected the clinicopathological data of NSCLC patients with MET gene alteration. The response to chemotherapy was evaluated according to RECIST v1.1. Result: Systemic chemotherapy was given to 10 patients: SM (n=5) and HGCN (n=5). The median age was 67.5 (range 41–77) years. Thirty percent of the patients were female and 40% were never smokers. The most common histology was adenocarcinoma (40%), followed by pulmonary sarcomatoid carcinoma (20%). The tumor PD-L1 expression was >50% in 57% (4/7) of cases. PD-1/PD-L1 doublet, MET inhibitor, immunotherapy (I-1), I-1+ chemotherapy were given to 6, 8, 2 and 1 patients. The overall response rate was 50%, 83%, 0% and 1% respectively. And major histology was poorly differentiated non-small cell lung cancer in both TPS ≥1% and TPS ≥50% group. Conclusion: The concordance correlation coefficient was 0.826 (95% confidence interval: 0.736–0.916). Conclusion: In Korean lung cancer patients, PD-L1 positive group defined as TPS ≥1% was older than negative group. And major histology was poorly differentiated non-small cell lung cancer in both TPS ≥1% and 50% groups. And our results showed a high correlation between PD-L1 IHC expression data analyzed between immunohistochemical assays. Method: We retrospectively reviewed the clinical and pathologic data of pathologically proven lung cancer patients, and collected 267 cases of formalin-fixed, paraffin-embedded tissue sample from single institution. PD-L1 expression was detected by qualitative immunohistochemical assay using Monoclonal Mouse Anti-PD-L1, Clone 22C3. PD-L1 protein expression is determined by using Tumor Proportion Score (TPS), which is the percentage of viable tumor cells showing partial or complete membrane staining. We categorized according to the percentage of TPS; more than 1% or more than 50%. Among 267 patients, 34 were analyzed by both 22C3 and SP263 assays. The results were compared between IHC assays. Result: A total of 267 patients were enrolled and major histologic types were adenocarcinoma (69.3%). The majority was smoker (67.4%) and clinical stage IV (60.7%). Thirty one (11.6%) cases of EGFR mutation and 17 (6.4%) cases of ALK FISH positive were included. The patients who showed TPS ≥1% and 50% were 116 (42%) and 58 (21%), respectively. More than 1% of TPS group was consisted of adenocarcinoma (67.8%), squamous cell carcinoma (29.6%), and small cell carcinoma (1.5%) histology. And more than 50% of TPS group was squamous cell carcinoma (72.4%), non-small cell lung cancer (22%). More than 1% of TPS group was significantly older than less than 1% of TPS group (64.83 ± 9.38 vs. 61.73 ± 10.78 years, p=0.014). The rate of poorly differentiated pathology was significantly higher in TPS ≥1% group (40.8% vs. 28.5%) and TPS ≥50% group (53.2% vs. 27.2%). There was no difference in smoking, EGFR mutation, ALK rearrangement status or biopsy site. More than 34 patients analyzed by both 22C3 and SP263, 27 patients showed positive by both 22C3 and SP263, at the cut-off of 1% higher. The concordance correlation coefficient was 0.826 (95% confidence interval: 0.736–0.916). Conclusion: In Korean lung cancer patients, PD-L1 positive group defined as TPS ≥1% was older than negative group. And major histology was poorly differentiated non-small cell lung cancer in both TPS ≥1% and 50% groups. And our results showed a high correlation between PD-L1 IHC expression data analyzed by 22C3 and SP263 assays.

P3.01-78 THE CYTOLOGY SAMPLES AND PLASMA SPECIMENS WERE FEASIBLE FOR THE EGFR MOLECULAR TESTING.

T. Ohira, W. Hamanaka, Y. Shimada, S. Maehara, J. Maeda, M. Hagiwara, M. Kakhiana, T. Okano, N. Kajiwara, N. Ikeda

Thoracic Surgery, Tokyo Medical University, Tokyo/JP

Background: EGFR mutation detection with real-time PCR is standard method to identify eligible patients for EGFR-TKI treatments in daily routine practice. Since liquid biopsies (tissue-free biopsies) are mainly used as the sample materials for testing. However, the biopsy samples sometimes have a certain limitation in their volume and so the cytology specimens are chosen for EGFR testing instead. Plasma has also become an option especially in EGFR-TKI resistant cases which often have difficulties to obtain the adequate tumor yield. In this study, we evaluated the feasibilities of using cytology samples and plasma specimens for the EGFR molecular testing. Method: atients provided written informed consent for use of the squamous cell carcinoma were participated in this prospective research. Cytology samples were obtained from biopsy and cells were suspended into liquid-based cytology (LBC) media. Tumor contents in the samples were confirmed with Papanicolaou stained slides. Plasma samples were also collected from patients shortly before the tissue biopsy. EGFR mutation test by cobas EGFR Mutation Test v2. Also, EGFR testing result of tissue specimens of the patients corresponded were collected from the medical records measured by cobas EGFR Mutation Test v2 as reference. The feasibilities of both cytology and plasma specimens were evaluated comparing with the tissue samples. Result: One-hundred fifty-eight patients were registered to this study. Among those patients, 77 patients with matched set of samples were enrolled to this study. EGFR mutation rates in tissue, cytology, and plasma samples were 29.9%, 28.5%, and 25.8%, respectively. Overall agreement rate of the cytology specimens and the plasma specimens against the tissue samples were 87.0 and 75.3%, respectively. All eight 9790M mutation positive cases were perfectly matched between tissue and cytology specimens. Conclusion: The results suggested that tissue specimen is the most suitable sample for detecting mutations. Since high specificities were confirmed in both cytology and plasma specimens, the results are reliable as long as the call is positive. Choosing cytology or plasma specimens for EGFR testing can be the considerations for the patients who have difficulties in collecting tissue samples in the real world setting.

P3.01-77 CLINICAL CHARACTERISTICS OF KOREAN LUNG CANCER PATIENTS WITH PROGRAMMED DEATH-LIGAND 1 EXPRESSION

I. Oh1, H. Park2, C. Park1, Y. Kim3, S. Song3, S. Kim4, Y-D. Cho2

1Internal Medicine, Chonnam National University Medical School, Hwasun Hospital, Hwasun, Jeonnam/KR. 2Department of Thoracic and Cardiovascular Surgery, Chonnam National University Hwasun Hospital, Jeonnam/KR. 3Department of Pathology, Chonnam National University Hospital, Gwangju/KR

Background: Programmed death-ligand 1 (PD-L1) is a transmembrane protein that binds to the programmed death-1 (PD-1) receptor and anti-PD-1 therapy enables the immune response against tumors. The aim of this study was to assess the clinical and pathological characteristics of PD-L1 positive lung cancer patients in Korea. And we examined correlation

P3.01 ADVANCED NSCLC

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30
**P3.01 ADVANCED NSCLC**

**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.01-79 INTRACEREBRAL EFFICACY OF IMMUNE CHECK-POINT INHIBITORS IN NSCLC PATIENTS WITH BRAIN METASTASES**

F.Ohyanagi, J. Shihara, F. Kudo, Y. Mizushima, H. Ota, S. Koyama
Division of Pulmonary Medicine, Clinical Department of Internal Medicine, Jichi Medical University Saitama Medical Center, Saitama City/JP

**Background:** The brain is a common site of metastatic disease in patients with non-small cell lung cancer (NSCLC). Approximately 30–50% of patients will develop brain metastases during the course of treatment. Several immune check-point inhibitors (ICIs) have shown efficacy against non–small-cell-lung-cancers (NSCLCs) and approved in second-line setting. However, regarding ICIs intracerebral efficacy and tolerability in NSCLC patients with active brain metastases (BMs) remains unknown.

**Method:** We reviewed the medical charts of 49 patients with advanced NSCLC treated with ICIs between January 2016 and March 2018. The intracranial activity of ICIs in patients with brain metastases was assessed by brain magnetic resonance imaging (MRI) using RECIST v. 1.1 criteria. The primary endpoint was intracerebral objective response rate (iORR). Secondary endpoints included intracerebral control rate, intracerebral and general progression-free survival (PFS), overall survival (OS) and tolerance.

**Result:** Ten NSCLC patients with BMs were identified. The median age of patients was 61 years (range 44–80 years) and the majority of patients were male (n = 9; 90%). All patients were pretreated with stereoradiosurgery (n = 7) or whole brain radiation therapy (n = 3). All but one patients received prior systemic treatment for NSCLC. Three patients received two prior lines of systemic therapy. Two patients were treated with pembrolizumab. Median follow-up was 5.7 (95% CI: 2.7–8.4) months. iORR and extracerebral objective response rate were, respectively, 0% (95% CI: 0.25–0.5%) and 20% (95% CI: 2.5–55.6%). Intracerebral control rate was 60% (95% CI: 26.2–87.8%). Median intracerebral and general PFS lasted 1.8 (95% CI: 0.9–7.1) and 2.8 (95% CI: 1.8–4.6) months, respectively. Median OS was 8.9 (95% CI: 4.9–not reached) months. No neurological adverse events occurred. Conclusion: ICIs might have the efficacy and favorable safety profile in NSCLC patients with BMs.

**Keywords:** NSCLC, immune check-point inhibitors, Brain metastasis

**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.01-80 RETROSPECTIVE ANALYSIS OF THE IMPACT OF EGFR T790M MUTATION DETECTION BY RE-BIOPSY IN PATIENTS WITH NSCLC HARBORING EGFR MUTATIONS.**

N. Okura1, T. Yamada1, A. Yoshimura2, T. Takeda2, Y. Kubota2, S. Shiota3, O. Hirota4, J. Hiranuma1, J. Uchino1, K. Takayama1
1Pulmonary Medicine, Graduate School of Medical Science, Kyorio Prefectural University of Medicine, Kyoto/JP
2Uji-Takushukii Medical Center, Uji/JP
3Japanese Red Cross Kyoto Daishi Hospital, Kyoto/JP
4Otsu City Hospital, Otsu/JP

**Background:** EGFR-TKIs show a good response to most patients with advanced non-small cell lung cancer (NSCLC) harboring EGFR activating mutations. However, it ultimately becomes the acquired resistance to EGFR-TKIs after various periods. We currently attempt to detect EGFR-T790M mutation by re-biopsy that half of acquired resistances to them, because the third generation EGFR-TKI osimertinib had an effective response against the refractory tumors with EGFR-T790M mutations. However, the re-biopsy from tumors is relatively invasive and some cases are impossible to perform them. Therefore, it is a critical issue to select the population with EGFR-T790M mutations. In this study, we analyzed the refractory cases to initial EGFR-TKIs with successful re-biopsy samples to disclose these clinical questions.

**Method:** 78 advanced NSCLC patients with EGFR mutations who achieved successful re-biopsy samples after the resistance to initial EGFR-TKI treatment are enrolled at five institutions in Japan. We validated for the association between the emergence of EGFR-T790M mutation and their profiles, such as clinical outcomes with EGFR-TKI treatment and EGFR activating mutation status.

**Result:** 78 advanced NSCLC patients with EGFR mutations. 29 cases were EGFR-T790M positive and 39 were negative in the re-biopsy samples. Of EGFR-T790M positive patients, 2 cases achieved a complete response (CR), 33 a partial response (PR), and 4 stable disease (SD). In contrast, 1 patient experienced a CR, 19 a PR, 18 SD, and 3 progressive disease (PD) in T790M negative patients. The objective response rate was higher in patients with T790M positive mutations than in those with T790M negative mutations (89.7% versus 51.2%, p < 0.01). There were no difference between each patients in progression free survival and time to failure treated with initial EGFR-TKIs. Conclusion: The response to initial EGFR-TKI treatment might be one of good predictors for emerging of refractory tumors with EGFR-T790M mutations. Further experiments are needed to identify them.

**Keywords:** EGFR-TKI, T790M

**P3.01-81 LONG-TERM OUTCOME OF SURGICALLY RESECTED UNSUSPECTED N2 LUNG ADENOCARCINOMA.**

Department of Thoracic and Cardiovascular Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR

**Background:** This study was performed to assess the long-term outcome of lung adenocarcinoma in patients without clinical suspicion of mediastinal lymph node involvement and whose tumors were finally proven to be pathologic N2. **Method:** This is a retrospective study of a prospective lung cancer database at our institution from January 2004 to December 2014. We retrospectively reviewed the medical records of 299 patients with unsuspected pathologic N2 disease. **Result:** The median follow-up time was 51.5 months (range, 1.1 to 172.3 months). The median recurrence-free survival (RFS) was 25.3 months and the 1-year, 3-year, and 5-year RFS rates were 78.2%, 41.0%, and 29.5%. The median overall survival (OS) was 75.2 months and the 1-year, 3-year, and 5-year OS rates were 92.6%, 85.9%, and 62.7%, respectively. The most common type of resection was lobectomy (88.6%). Adjuvant therapy was administered in 255 patients (85.3%). N2 involvement was single station without N1 involvement (“skip” metastasis, N2a1) in 73 (24.4%), single station with N1 involvement (N2a2) in 148 (49.5%), and N2 at multiple stations (N2b) in 78 (26.1%). The median RFS and 5-year RFS rate of N2a1 were 42.9 months and 44.8%. The median and 5-year OS and OS rate of N2a1 were 86.2 months and 69.0%. In multivariate analysis, N2a1, low T-stage, and adjuvant therapy were significantly associated with a longer RFS, whereas pneumonectomy was significantly associated with a worse RFS. Conclusion: The long-term outcome of unsuspected pN2 group of patients with lung adenocarcinoma was better than expected. Especially, when the RFS and OS of pN2a1 group of patients were similar to the those of N1 group of patients reported for survival in our group. Therefore, resection of properly staged unexpected pathologic N2 lung adenocarcinoma is reasonable and should not be avoided if a complete resection without pneumonectomy can be done.

**Keywords:** N2, Adenocarcinoma, locally advanced

**P3.01 ADVANCED NSCLC**

**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.01-82 SURVIVAL IMPACT OF SURGERY IN THE TREATMENT OF STAGE IIIB-IVA NON-SMALL CELL LUNG CANCER.**

J.Y. Park, S.H. Jang, H.I. Kim, J. Kim, S. Park, Y.I. Hwang, K. Jung
Pulmonary, Allergy and Critical Care Medicine, Hallym University Sacred Heart Hospital, Anyang/KR

**Background:** Surgery is usually not indicated in far advanced stage non-small cell lung cancer (NSCLC), but a few recent clinical trials demonstrated aggressive local therapy such as (chemo)radiotherapy before surgical resection improved survival outcomes in oligometastatic NSCLC. This study aimed to evaluate survival impact of cytoreductive surgery in stage IIIB-IVA (based on the 8th TNM classification) NSCLC in the era of effective anticancer drugs. **Method:** Patients with stage IIIB, IIC or IVA NSCLC was recruited from the Hallym Lung Cancer Registry for this retrospective analysis. Other eligibility criteria were ECOG performance 0-1, age under 85 years old and good adherence to lung cancer treatment. **Result:** A total of 203 patients were analyzed. All the patients received adequate staging of their disease courses. Twenty-two patients (10.8%) received cytoreductive surgery. Significantly better overall survival (OS) was observed in surgery group compared with non-surgery group; Kaplan-Meier estimation for OS was 33.1 months (95% CI, 15.6–50.6) vs. 16.6 months [14.0–19.2] (p = 0.007). The Cox proportional hazard ratio (HR) for death was 0.528 [0.290–0.961] (p = 0.037) in surgery group when it was analyzed with covariates such as age, sex, performance, histology, stage, and smoking status. ECOG performance 0 and adenocarcinoma histology were also revealed as independent favorable prognostic factors for OS (HR 0.660 [0.474–0.919], p = 0.014 and HR 0.481 [0.328–0.707], p < 0.001, respectively). Table. Cox proportional hazard ratio for death (See next page).
**P3.01-84 THE ASSOCIATION OF CDKN2A GENE MUTATION WITH CLINICOPATHOLOGICAL FEATURES AND PROGNOSIS IN ADVANCED LUNG CANCER PATIENTS**

L. Xu, X. Qu, X. He, H. Zhou, Y. Liu

Medical Oncology, The First Hospital of China Medical University, Shenyang/CN

**Background:** The cell cycle–dependent kinase inhibitor gene (CDKN2A) is a tumor suppressor gene and encodes two kinds of cell cycle inhibitor proteins p16INK4a and p14ARF to regulate cell cycle. The aim of this study was to evaluate the association of CDKN2A gene mutation with clinicopathological features and prognosis in Chinese advanced lung cancer patients.

**Method:** CDKN2A gene mutation was screened in tumor specimens using second generation sequencing technology. The correlation between CDKN2A gene mutation and clinicopathological characteristics was analyzed by Spearman's correlation. The overall survival (OS) and progression free survival (PFS) were analyzed by using the Kaplan–Meier method and compared by the log-rank test. The Cox model was used to study the single factors and multiple factors. Statistical data was obtained by using SPSS for Windows version 20.0. P values < 0.05 were considered to indicate statistically significant results.

**Result:** CDKN2A gene mutation was 4.57 % (10/219) in lung cancer patients. Patients harboring CDKN2A mutation were more commonly observed in squamous carcinoma patients (P=0.002). Most of patients with CDKN2A gene mutation were progression disease (PD) in the assessment of first-line treatment efficacy, while the patients without CDKN2A mutation were disease control rate (DCR) (P = 0.011). The OS in patients with CDKN2A gene mutation was 19.1 months compared to 42.8 months in patients without mutation (P = 0.010). The PFS in patients with CDKN2A mutation was 3.5 months compared to 9.7 months in patients without mutation (P = 0.000). In addition, multi-factor analysis showed that CDKN2A gene mutation (HR=2.385, P = 0.025), age 60 years or older (HR=1.588, P = 0.027) were significant risk factor for the survival of lung cancer patients.

**Conclusion:** CDKN2A gene mutation had an important influence on the clinicopathological features and prognosis of Chinese advanced lung cancer patients. The patients with CDKN2A gene mutation had more poor survival.

**Keywords:** Prognosis, lung cancer, CDKN2A

**P3.01-83 USE OF BLOOD OUTGROWTH ENDOTHELIAL CELLS AS A CELLULAR CARRIER FOR ONCOLYTIC VESICULAR STOMATITIS VIRUS IN PRECLINICAL MODELS OF NSCLC**

M. Patel¹, B. Jacobson², Y. Jin², R. Kratzke²

¹Hematology/oncology/transplant, University of Minnesota, Minneapolis/Min/US.
²Medicine, University of Minnesota, Minneapolis/Min/US

**Background:** Oncolytic virus therapy has demonstrated efficacy in numerous tumor models including non-small cell lung cancer. One of the limitations of viral therapy for metastatic lung cancer is that systemic administration can be hindered by complement and antiviral immunity. Thus, we investigated the possibility of using ex- vivo infected blood outgrowth endothelial cells with tumor-homing properties to deliver oncolytic VSV-IFNβ in preclinical models of NSCLC.

**Method:** BOECs were obtained from either human donors or C57Bl/6 mice. Cells were confirmed to maintain the BOEC phenotype and growth characteristics. Indiana strains of VSV were engineered to produce GFP or IFNβ and were titered on Vero cells using either plaque assay or limiting dilution assay. Human NSCLC cell lines, H2009 and H2030 were used for in vitro assays. A549 expressing firefly luciferase cells were used to induce lung metastasis in NOD/SCID mice and treated with BOECs, VSV-IFNβ, or BOECs-infected with VSV-IFNβ. Additionally, syngeneic murine adenocarcinoma cell line, LM2 was used in vivo in A/J mice (n=5). Result: BOEC cells were able to home to metastatic LM2 lung tumors and were retained there for up to 72 hours post-infusion. BOEC cells were retained within lung tumors of mice bearing tumors, but there were none detected in lungs of mice without lung tumors. Both human and murine BOECs could be infected and lysed by VSV-GFP and VSV-IFNβ, respectively. Co-culture experiments showed near complete lysis of H2009 cells using infected BOECs. Both H2009 and H2030 cells were lysed efficiently by infected BOECs while naked VSV was completely inhibited in the presence and absence of neutralizing antibodies. Using Firefly luciferase-expressing A549 cells, metastatic lung tumors were induced in NOD/SCID mice. Compared to BOEC alone and PBS-treated mice, VSV-IFNβ-infected BOECs resulted in superior antitumor efficiency as measured by luciferase activity (p<0.02). Infected BOECs resulted in superior survival of mice compared to VSV-IFNβ alone (n=10, p<0.05). Using immune competent A/J mice, infected BOECs trended toward improved antitumor efficacy to BOEC alone and intravenous VSV-IFNβ treatment (n=5, p=0.09). Replicating virus was recovered only from lungs of infected BOEC treated mice.

**Conclusion:** BOECs can be used as cellular carrier for systemic delivery of oncolytic VSV-IFNβ. For clinical translation, the use of cellular carriers might be an effective method of virotherapy for metastatic NSCLC.

**Keywords:** Oncolytic virotherapy, BOEC, NSCLC

**P3.01-85 REAL-WORLD GEFTINIB 1ST LINE TREATMENT OF PATIENTS WITH ADVANCED NSCLC AND EGFR MUTATIONS - SERBIAN SINGLE CENTER EXPERIENCE**

D. Radosavljevic, J. Spasic, M. Ristic, N. Nikolic, N. Stanic, F. Djordjevic, D. Gavrilovic

Clinic for Medical Oncology, Institute for Oncology and Radiology of Serbia, Belgrade/RS

**Background:** Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKI) revealed their efficacy in advanced non-small cell lung cancer (NSCLC), in patients with EGFR mutated tumors, in large scale of clinical trials. Here we present data from clinical practice, patient characteristics and clinical outcome of consecutive patients treated with gefitinib in first-line setting at the Institute for Oncology and Radiology of Serbia between 2011-2016.

**Method:** Previously untreated patients with lung adenocarcinoma in stages IIB and IV and PS 0 or 1 have been included by institutional multidisciplinary tumor board and selected for molecular EGFR testing since 2011. Patients with activating EGFR mutations (9.5%) received gefitinib, at that time the only approved EGFR TKI for the first line treatment Result: Sixty consecutive patients were included in this analysis. M/F ratio was 21/39, median age 60 years, non-smokers 48%, PS 0/1, 85%, metastatic sites (more than 5% of patients) were lungs and pleura in 40%, bones in 27%, liver in 15%, pericardium in 10%, brain in 7% of patients. Only one metastatic site was present in 56% of patients, two sites in 35% and three sites in 6%. Del19 and L858R were detected in 82% of patients (del19 55% and L858R 27%) and uncommon mutations in 18%. Median duration of gefitinib treatment was 8 months, median follow-up 12.5 months. Partial response (PR) was achieved in 33% of patients, stable disease (SD) in 47%, progressive disease (PD) in 18%. Type of progression was a new lesion(s) in 20% of patients, progression of existing lesion(s) in 42% and both in 10%. Second-line treatment was administered to 38% of patients, and 63% were dead at the time of analysis. Median overall survival was 19 months, median progression-free survival 12 months. In patients with PR median OS was 26 months, in SD patients 22 months and in PD patients only 5 months. No statistically significant differences were shown in OS with regards to age, gender,

P3.01-86 TREATMENT OUTCOMES WITH REDUCED FREQUENCY OF NIVOLUMAB DOING AS SECOND-LINE THERAPY IN PATIENTS WITH ADVANCED NSCLC
S. Rehman1, A. Miller1, A. Meagher1, H. Chen2, G. Dy1
1Roswell Park Cancer Institute, Buffalo, Ny/Us, 2Medicine, Roswell Park Cancer Institute, Buffalo/Ny/Us

Background: Nivolumab (Nivo) was approved as second-line therapy in 2015 for patients (pts) with advanced NSCLC. The optimal effective interval between doses is not well-established. We want to evaluate the effect of reduced dose density on the efficacy and safety of Nivolumab.

Method: This is a single-institution, IRB approved retrospective review of stage IIIB/IV NSCLC who received Nivo after prior platinum-based chemotherapy in the second line setting or beyond between April 2015-June 2018. Characteristics of pts who received Nivo 240mg every 4 (q) weeks vs longer, reasons for alternate dosing and their treatment outcomes are described.

Result: Out of 181 pts with NSCLC who received Nivo during this time frame, 32 pts (18Male:14 Female) received an alternate dose schedule (median q 4 weeks, range q 3-12 weeks). Median age was 65 years. Majority were former smokers (62%) and had adenocarcinoma (81%). 17 pts started on a regular schedule q 2 weeks and then switched to an alternate schedule, the remaining 15 pts started on an alternate schedule. 28% (39/32) patients were on an alternate schedule due to adverse event. Median expected total cumulative dose (240mg/no. of expected doses until disease progression or death) per pt is 4032mg (range 480 -15840). Median actual cumulative dose (240mg/actual no. of doses) received per pt is 1920mg (range 480 - 10560). This represents a median of 52% of the expected total cumulative dose received. Objective response rate (CR+PR) in the entire cohort was 66%. Median progression-free survival (PFS) from start of alternate schedule is 17.1 months (95% CI 5.2 - not reached), 6-month PFS is 65% (95% CI 46%-79%) starting from when alternate schedule of Nivo was begun. We will present updated toxicity and treatment outcomes in the meeting. Conclusion: Nivolumab 240mg administered at q 4 weeks or longer is feasible. Further investigation is needed to optimize patient selection for alternate dosing schedule.

Background: Pembrolizumab, an anti-PD-1 antibody, showed a clear advantage compared with chemotherapy in the advanced non-small cell lung cancer selected by histological PD-L1 expression in response to PD-L1 blockade therapy. We conduct a retrospective study on Pembrolizumab in advanced non-small cell lung cancer in our institution from March 2017 to February 2018.

Result: The median age was 70.0 (37 - 87) years. Male/female : 10/41. Median follow-up duration was 6.4 months [4.1 - 8.5]. The ECOG-PS was 0/1/2/3 : 20/24/5/2. The histologic type was adenocarcinoma/squamous cell carcinoma/non-small cell carcinoma/pleomorphic carcinoma : 23/6/3/9. PD-L1 total proportion score was 5/10/25/50/75/100. ORR was 33.3% and DCR was 62.7%. Median PFS time was 8.9 months and median OS time was not reached. The most common all-causality adverse events were fatigue (6/34), Pr/SD/PD/NE : 17/15/15/4, ORR was 33.3% and proportion score was 1%-49%.

Background: Long survivors (LS) in non-small-cell lung cancer (NSCLC), defined as an overall survival (OS) greater than 2 years, are less than 10% in most series. Classical prognosis factors include stage, weight loss and smoking, but there are other factors whose influence on the evolution of these patients is uncertain. Recently, different drugs targeted against EGFR, ALK and ROS 1 reach OS longer than 2 years in a limited number of patients (less than 20%). Immunotherapy in NSCLC has demonstrated very promising results with LS compared to chemotherapy in first and second line setting. In this study, we have focused in the analysis of LS patients with advanced NSCLC EGFR wt (wild type) and ALK nt (non-translocated), defined as those with OS greater than 36 months, in 8 hospitals in Madrid. Method: In this serie, first of all, we will try to make a clinical, histopathological and immunologicial characterization collecting data from clinical reports according to a previously defined information. In a second step, we will carry out a genetic analysis of these patient samples comparing to an opposite extreme short survivors (SS) samples (OS less than 9 months) from same centers. We used a NGS method of RNA-seq technology with the idea of identify differentiating profiles of gene expression between the two opposite populations with a later confirmation by RT-PCR in the rest of the tissue samples and liquid biopsy.

Conclusion: We have obtained a differential transcriptome expression between samples from 6 LS and 6 SS, resulting 13 overexpressed and 42 under-expressed genes in LS comparing to SS transcriptome expression. Some of the genes involved in this profile belong to different families and cellular pathways: Secretin receptor, Surfactant Protein, Trefoil Factor 1, Serpin Family, Ca bindings protein channel and Toll like Receptor family. A further confirmation of this profile is carrying on by RT-PCR in the rest of the samples and liquid biopsy from the rest of the patients included in the study. Conclusion: We present the first data from a genetic analysis of a LS population with NSCLC EGFR wt (wild type) and ALK nt (non-translocated), obtaining a differential RNA profile

Background: The high proportion of patients with N2 disease after surgery is a challenge for clinicians. The role of upfront surgery versus neoadjuvant chemotherapy followed by surgery is not yet confirmed.

Method: From March 2017 to February 2018, we retrospectively reviewed a total of 51 patients who received a neoadjuvant regimen followed by upfront surgery in our institution.

Result: The median age was 69 years (range 42-78). The histologic type was adenocarcinoma/squamous cell carcinoma/non-small cell carcinoma/other: 21/21/3/6. PD-L1 total proportion score was 0/15/70/100. ORR was 12% and DCR was 44%. Median PFS time was 3.1 months and median OS time was 8.6 months. The most common all-causality adverse events were fatigue (5/10), Pr/SD/PD/NE : 11/3/4/5, ORR was 12% and proportion score was 0%-50%.

Conclusion: Upfront surgery in N2 non-small cell lung cancer is a valid treatment option with an acceptable profile of toxicity.
Background: Non-small cell lung cancer (NSCLC) patients with ipsilateral mediastinal nodal metastases (N2) had poor prognosis. Although definitive chemoradiation was frequently used as a standard care for clinical N2 NSCLC, surgery can be a preferred treatment option in selected patients with upfront surgery plus adjuvant treatment or neoadjuvant treatment followed by surgery. Before starting a prospective study in our institution, we checked a treatment outcome of pathologic N2 NSCLC patients treated by upfront surgery or neoadjuvant treatment approach.

Method: The present study evaluated 21 patients with pathologic N2 NSCLC at St. Vincent hospital from February 2007 to September 2017. Patient with upfront surgery or neoadjuvant treatment followed by surgery was included, and pathologic N2 was confirmed before surgery in neoadjuvant group. Taxane and platinum was used as a neoadjuvant treatment or post-operative therapy in both group. Chemotherapy alone or combined with radiotherapy was conducted. Disease free survival (DFS) and overall survival (OS) was evaluated and Kaplan-Meier survival analysis was used for these analyses.

Result: Eleven (52%) underwent upfront surgery, and 10 patients (48%) underwent neoadjuvant treatment followed by surgery. Clinical T1N2, T2N2 and T3N2 were 4 (19%), 11 (52%) and 6 (29%), respectively. Baseline characteristics did not show significant difference in these two groups. Upfront surgery group received post-operative treatment including chemotherapy alone (n=7), radiotherapy alone (n=2) or chemoradiotherapy (n=1). Neoadjuvant group received chemoradiotherapy (n=3) or chemotherapy alone (n=10). Regarding DFS, there are no significant differences between upfront surgery group and neoadjuvant group (median DFS, 10.0 months vs. 15.1 months, P=0.925). For OS, 5-year disease free survival rate were 90% and 30%, respectively. In addition, OS did not show significant differences between two groups (median OS, 79.5 months vs. 47.7 months, P=0.295). Five year overall survival rate was 90% and 50%, respectively. In upfront surgery group, 4 of 7 patients did complete chemotherapy schedule due to adverse event. But, 9 of 10 patients had a completion of chemotherapy in neoadjuvant group.

Conclusion: There are no significant survival differences between upfront surgery group and neoadjuvant treatment group, but both strategies can be effective treatment option for selected pathologic N2 NSCLC. Further studied need to be done for these patients, and currently our institution are preparing clinical trials in a prospective manner.

Background: Previous studies demonstrated that EGFR-tyrosine-kinase inhibitors (EGFR-TKIs) can have antitumor effects even after disease progression during EGFR-TKI treatment. In this phase II study (NCT01301), we assessed the safety and efficacy of continuing EGFR-TKIs beyond progressive disease followed by the addition of cisplatin (CDDP), pemetrexed (PEM) and bevacizumab (Bev) in patients with EGFR mutation-positive advanced NSCLC with acquired resistance to first-line EGFR-TKIs.

Method: Eligible patients were aged at least 20 years with first-line EGFR-TKI treatment failure and were confirmed to have acquired resistance to first-line EGFR-TKIs. Patients received CDDP 75 mg/m² as a neoadjuvant treatment or post-operative therapy in both group. Chemotherapy alone or combined with radiotherapy was used as a neoadjuvant treatment or post-operative therapy in both group. Chemotherapy alone or combined with radiotherapy was conducted. Disease free survival (DFS) and overall survival (OS) was evaluated and Kaplan-Meier survival analysis was used for these analyses.

Result: Eleven (52%) underwent upfront surgery, and 10 patients (48%) underwent neoadjuvant treatment followed by surgery. Clinical T1N2, T2N2 and T3N2 were 4 (19%), 11 (52%) and 6 (29%), respectively. Baseline characteristics did not show significant difference in these two groups. Upfront surgery group received post-operative treatment including chemotherapy alone (n=7), radiotherapy alone (n=2) or chemoradiotherapy (n=1). Neoadjuvant group received chemoradiotherapy (n=3) or chemotherapy alone (n=10). Regarding DFS, there are no significant differences between upfront surgery group and neoadjuvant group (median DFS, 10.0 months vs. 15.1 months, P=0.925). For OS, 5-year disease free survival rate were 90% and 30%, respectively. In addition, OS did not show significant differences between two groups (median OS, 79.5 months vs. 47.7 months, P=0.295). Five year overall survival rate was 90% and 50%, respectively. In upfront surgery group, 4 of 7 patients did complete chemotherapy schedule due to adverse event. But, 9 of 10 patients had a completion of chemotherapy in neoadjuvant group.

Conclusion: There are no significant survival differences between upfront surgery group and neoadjuvant treatment group, but both strategies can be effective treatment option for selected pathologic N2 NSCLC. Further studied need to be done for these patients, and currently our institution are preparing clinical trials in a prospective manner.

Background: The Advanced Non-Small Lung Holistic Registry (ANCHoR) is established to examine the real-world impact of immunotherapy on choice of treatment, clinical outcomes, and patient reported outcomes of patients with Stage IV NSCLC. Method: Stage IV NSCLC patients diagnosed or initiating treatment at MD Anderson from January 1, 2017 are enrolled in the ongoing ANCHoR study. Their demographic, clinicopathological, molecular, and treatment data were populated in a prospective database. Treatment patterns by line and PD-L1 status were summarized in this interim analysis. Result: At the time of data cut off (Dec 31, 2017) 182 patients were enrolled in the registry, of which 150 were tested for PD-L1. Number of patients initiating first-, second-, and third-line treatment were 163, 42 and 7, respectively. Of the 30 patients not tested for PD-L1, 10 did not have enough tissue and 8 had actionable mutations.

Conclusion: The emergence of immunotherapy has had a dramatic impact on the first-line treatment of patient with advanced NSCLC. As of December, 2017 up to 41% of patient received immunotherapy either singly (23%) or in combination with chemotherapy. Only 40% of the patients now receive chemotherapy alone. There has been a dramatic decrease in the use of chemotherapy with an anti-angiogenesis agent (1.23%). In our dataset 16% of the patients were eligible for targeted therapy as initial treatment.

P3.01 ADVANCED NSCLC

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.01-92 BLOOD TEST PARAMETERS AS PROGNOSTIC FACTORS IN EGFR-MUTATED NON-SMALL CELL LUNG CANCER TREATED WITH TKIS

J. Spasic, N. Stanic, F. Djordjevic, V. Jokic, D. Radosavljevic
Clinic for Medical Oncology, Institute for Oncology and Radiology of Serbia, Belgrade/RS

Background: Systemic inflammation is an important factor contributing to tumor progression. High neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR) are markers of host inflammation which association with worse overall survival (OS) in non-small cell lung cancer (NSCLC) has been shown in various studies. However, there are few studies investigating the association of these, and other haematological parameters of inflammation with prognosis of EGFR mutated NSCLC treated with tyrosine-kinase inhibitors (TKIs).

We therefore examined the association between various blood test parameters and prognosis in this group of patients.

Method: This retrospective analysis included 74 consecutive advanced lung adenocarcinoma patients of caucasian descent, stage IIIB or IV, treated with EGFR TKIs in the first line at the institute for oncology and radiology of Serbia within a five year period. The analysed haematological parameters were derived from the absolute differential counts of a complete blood count (CBC) taken within one week of TKI therapy as initial treatment. Parameters included in this analysis were NLR, PLR, lymphocyte-to-monocyte ratio (LMR), mean platelet volume (MPV), lymphocyte-to-white blood cell ratio (LWR) and neutrophil-to-white blood cell ratio (NWR). Cut-off values were determined using ROC curves. Correlation between each haematological parameter and progression-free survival (PFS) and OS was examined by Kaplan-Meier method and Cox regression analysis. The analysis was a fixed effects model using the Mantel-Haenszel (MH) method.

Conclusion: Of all studied parameters, low LWR (< 0.14) was associated with a shorter PFS in this group (95% CI: 0.138 – 0.623; p = 0.001). Low LWR (< 0.14) was associated with a shorter OS (18.0 months, 95% CI: 8.1) and low LWR (< 0.14) was associated with shorter OS (18.0 months, 95% CI: 8.1). Low LWR (< 0.14) was associated with a shorter OS (18.0 months, 95% CI: 8.1). Low LWR (< 0.14) was associated with a shorter OS (18.0 months, 95% CI: 8.1).

P3.01 ADVANCED NSCLC

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.01-93 OSIMERTINIB-RELATED HEMATOLOGICAL AND PULMONARY TOXICITIES IN ADVANCED NSCLC PATIENTS: COMBINED ANALYSIS OF PHASE III TRIALS

S. Swarup, K. Thein, S. Ball, M. Quirch, Y. Vorakunthada, A. Sultan, F. Hardwicke, L. Tijani, S. Awasthi
Hematology Oncology, Texas Tech University Health Sciences Center, Lubbock/TX/US

Background: In both epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) sensitizing and EGFR T790M resistance mutations in patients with advanced non-small-cell lung cancer (NSCLC), osimertinib, a third-generation and irreversible oral EGFR-TKI, has been shown to improve survival in studies. We performed a systematic review and meta-analysis of phase III randomized controlled trials (RCT) to determine the risk of hematological and pulmonary toxicities among patients with advanced NSCLC treated with osimertinib.

Method: We undertook a comprehensive literature search using MEDLINE, EMBASE databases and meeting abstracts from inception through March 2018. Phase III RCTs that mention hematological and pulmonary toxicities as adverse effects were incorporated in the analysis. The primary meta-analytic approach was a fixed effects model using the Mantel-Haenszel (MH) method.

Conclusion: We calculated the estimated pooled risk ratio (RR) with 95% confidence interval (CI). RR: A total of 971 patients with advanced NSCLC from two phase III studies were eligible for analysis. The study arm used osimertinib while the control arm utilized either chemotherapy (carboplatin/cisplatin+pemetrexed) or standard EGFR-TKIs (gefitinib or erlotinib). The randomization ratio was 1:1 in the FLAURA study and 2:1 in the AURA3 study. Osimertinib was utilized in T790M-positive advanced NSCLC after prior first-line EGFR-TKIs in the AURA3 study (n = 556) and as first-line treatment in the FLAURA study (n = 415). The RR of all-grade side effects were as follows: anemia, 0.594 (95% CI: 0.433 – 0.814; p = 0.001); cough, 1.122 (95% CI: 0.829 – 1.520; p = 0.455); dyspnea, 1.143 (95% CI: 0.784 – 1.666; p = 0.487); and ILD, 2.378 (95% CI: 0.984 – 5.744; p = 0.054). The RR of high-grade adverse effects were as follows: anemia, 0.175 (95% CI: 0.072 – 0.425, p < 0.001); neutropenia, 0.293 (95% CI: 0.138 – 0.623; p = 0.001); thrombocytopenia, 0.183 (95% CI: 0.060 – 0.564, p = 0.003); pneumonia, 1.237 (95% CI: 0.442 – 3.459; p = 0.685); dyspnea, 0.895 (95% CI: 1.192 – 4.175; p = 0.888); and ILD, 1.238 (95% CI: 0.404 – 3.789; p = 0.708).

Conclusion: Our meta-analysis demonstrated that patients on osimertinib experienced a significant decrease in the risk of hematological toxicities, compared to control arm. Moreover, no increase in the risk of pulmonary toxicities was noted in the osimertinib group.

Keywords: osimertinib, toxicity, meta-analysis
Keywords: method: kinase inhibitors (TKIs) but also displaying a highly variable prognosis. We analyzed for efficacy and safety endpoints. Result: The bevacizumab-based group had the highest percentage of partial response/PR (32.3% vs. 22.8% for pemetrexed and 20.0% for other treatments) and a significantly lower incidence of progressive disease/PD (35.9%, 30.17%, and 50.48%, for pemetrexed, bevacizumab-based, and other, respectively; p < 0.0001). Bevacizumab-based regimens achieved a better overall survival (OS) rate (measured at the end of treatment) (pemetrexed 29.6%, bevacizumab-based 35.7%, and other treatments 8.9%; p < 0.0001). However, median OS was not improved (10 months, 12 months, and 13 months for pemetrexed, bevacizumab-based, and other treatments, respectively; p=0.007). A significantly higher incidence of cough (p = 0.001) and hemoptysis (p < 0.0001) in the bevacizumab-based arm, pain in the pemetrexed arm (p = 0.007), and alopecia in the other treatments arm (p < 0.0001) was observed during treatment. A significantly higher incidence of hemoptysis in the bevacizumab-based arm (p < 0.0001) and alopecia in the other treatments arm (p < 0.0001) was seen at the end of first-line treatment. Conclusion: Bevacizumab-based regimens resulted in improved treatment response and short-term survival rate, but not in improved OS. An increased, albeit acceptable, toxicity was also observed among bevacizumab-treated patients as compared to those treated with pemetrexed monotherapy.

P3.01 ADVANCED NSCLC WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.01-95 SAFETY AND EFFICACY OF FIRST-LINE Pemetrexed Versus Bevacizumab-containing Regimens in advanced NON-SMALL CELL LUNG CANCER

National and Kapodistrian University of Athens, Athens/GR

Background: Previous trial data have documented the efficacy of first-line bevacizumab-based regimens, including bevacizumab-pemetrexed combinations in advanced non-small cell lung cancer (NSCLC). We herein aimed to further assess the safety and efficacy of pemetrexed monotherapy versus bevacizumab-containing or other chemotherapy regimens in a real-world NSCLC population. Method: The medical records of 753 patients with advanced-stage non-squamous NSCLC, treated with bevacizumab-based regimens, pemetrexed monotherapy, or other treatments, as first-line therapy, were retrospectively reviewed and analyzed for efficacy and safety endpoints. Result: The bevacizumab-based group had the highest percentage of partial response/PR (32.3% vs. 22.8% for pemetrexed and 20.0% for other treatments) and a significantly lower incidence of progressive disease/PD (35.9%, 30.17%, and 50.48%, for pemetrexed, bevacizumab-based, and other, respectively; p < 0.0001). Bevacizumab-based regimens achieved a better overall survival (OS) rate (measured at the end of treatment) (pemetrexed 29.6%, bevacizumab-based 35.7%, and other treatments 8.9%; p < 0.0001). However, median OS was not improved (10 months, 12 months, and 13 months for pemetrexed, bevacizumab-based, and other treatments, respectively; p=0.007). A significantly higher incidence of cough (p = 0.001) and hemoptysis (p < 0.0001) in the bevacizumab-based arm, pain in the pemetrexed arm (p = 0.007), and alopecia in the other treatments arm (p < 0.0001) was observed during treatment. A significantly higher incidence of hemoptysis in the bevacizumab-based arm (p < 0.0001) and alopecia in the other treatments arm (p < 0.0001) was seen at the end of first-line treatment. Conclusion: Bevacizumab-based regimens resulted in improved treatment response and short-term survival rate, but not in improved OS. An increased, albeit acceptable, toxicity was also observed among bevacizumab-treated patients as compared to those treated with pemetrexed monotherapy.

P3.01-96 CLINICAL CHARACTERISTICS OF NON–SMALL CELL LUNG CANCER HARBORING MUTATIONS IN EXON 20 OF EGFR OR HER2

M. Takeda1, K. Sakai1, H. Hayashi1, K. Tanaka1, J. Tanizaki1, T. Takahama1, K. Haratani1, K. Nishio1, K. Nakagawa1
1Department of Medical Oncology, Kindai University Faculty of Medicine, Osaka-Sayama/JP; 2Department of Genome Biology, Kinki University School of Medicine, Osaka-Sayama/JP

Background: Unlike common epidermal growth factor receptor gene (EGFR) mutations that confer sensitivity to tyrosine kinase inhibitors (TKIs) in non–small cell lung cancer (NSCLC), mutations in exon 20 of either EGFR or the human EGFR2 gene (HER2) are associated with insensitivity to EGFR-TKIs, with treatment options for patients with such mutations being limited. Method: Clinical characteristics, outcome of EGFR–TKI or nivolumab treatment, and the presence of coexisting mutations were reviewed for NSCLC patients with exon-20 mutations of EGFR or HER2 as detected by routine application of an amplicon-based next-generation sequencing panel. Result: Between July 2013 and June 2017, 206 patients with pathologically confirmed lung cancer were screened for genetic alterations including HER2 and EGFR mutations. Ten patients harbored HER2 exon-20 insertions (one of whom also carried an exon-19 deletion of EGFR), and 12 patients harbored EGFR exon-20 mutations. Five of the 13 patients with EGFR mutations were treated with EGFR-TKIs, two of whom manifested a partial response, two stable disease, and one progressive disease. Among the 54 patients treated with nivolumab, one patient manifested a partial response, three stable disease, and three progressive disease, with most (86%) of these patients discontinuing treatment as a result of disease progression within 4 months of PD. The H1047R mutation in PIK3CA detected in one patient was the only actionable mutation coexisting with the exon-20 mutations of EGFR or HER2. Conclusion: Potentially actionable mutations thus rarely coexist with exon-20 mutations of EGFR or HER2, and EGFR-TKIs and nivolumab show limited efficacy in patients with such exon-20 mutations.

Keywords: EGFR, HER2, Nivolumab

P3.01 ADVANCED NSCLC WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.01-97 WHICH IS BETTER PROGNOSTIC FACTOR, PS, INFLAMMATORY MARKER, OR PD-L1 EXPRESSION IN TREATING NSCLC WITH NIVOLUMAB; A RETROSPECTIVE ANALYSIS

A. Tamiya1, Y. Taniguchi2, Y. Inagaki3, N. Sajo1, Y. Naoki1, K. Otsuka3, K. Okishio1, T. Kasai1, S. Atagi4

National Hospital Organization Kinki-Chuo Chest Medical Center, Saka/JP

Background: Although nivolumab showed the significantly longer overall survival (OS) compared with standard second-line therapy using docetaxel for both squamous and non-squamous non-small cell lung cancer (NSCLC) based on two phase III randomized controlled trials, PD-L1 expression alone is not yet an adequate biomarker in treating NSCLC patients with nivolumab. This single institute retrospective study aimed to analyze which biomarker or pretreatment patients’ status were more associated with outcomes in NSCLC patients treated with nivolumab. Method: We retrospectively reviewed the medical records of all patients with previously treated advanced NSCLC who received nivolumab between December 2015 and May 2016 in our institute. And we confirmed PD-L1 expression in the patients who were able to examine PD-L1 expression alone is not yet an adequate biomarker in treating NSCLC. Results: Of 206 patients with pathologically confirmed lung cancer, 139 patients with NSCLC were reviewed for NSCLC patients with exon-20 mutations of EGFR or HER2, and 12 patients harbored HER2 exon-20 insertions (one of whom also carried an exon-19 deletion of EGFR), and 12 patients harbored EGFR exon-20 mutations. Five of the 13 patients with EGFR mutations were treated with EGFR-TKIs, two of whom manifested a partial response, two stable disease, and one progressive disease. Among the 54 patients treated with nivolumab, one patient manifested a partial response, three stable disease, and three progressive disease, with most (86%) of these patients discontinuing treatment as a result of disease progression within 4 months of PD. The H1047R mutation in PIK3CA detected in one patient was the only actionable mutation coexisting with the exon-20 mutations of EGFR or HER2. Conclusion: Potentially actionable mutations thus rarely coexist with exon-20 mutations of EGFR or HER2, and EGFR-TKIs and nivolumab show limited efficacy in patients with such exon-20 mutations.

**P3.01-99 EFFECT OF PEMBROLIZUMAB ON PATIENTS HARBORING UNCOMMON EPIDERMAL GROWTH FACTOR RECEPTOR MUTATIONS**

Y. Taniguchi1, A. Tamiya1, Y. Inagaki1, N. Saijo1, Y. Naoki1, K. Otsuka1, K. Nakao2, K. Okishii1, S. Atagi1

1Internal Medicine, National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai/JP, 2Department of Internal Medicine, National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai/JP, 3Clinical Research Center, National Hospital Organization Kinki-Kyushu Chest Medical Center, Sakai/JP

**Background:** The characteristics of non-small cell lung carcinoma (NSCLC) patients harboring uncommon epidermal growth factor receptor (EGFR) mutations differ from those of patients with common EGFR mutations. For example, male smokers were more common among patients with uncommon mutations. The efficacies of non-afatinib treatment strategies for patients harboring uncommon EGFR mutations are uncertain. The efficacy of immune checkpoint inhibitors (ICIs) in advanced NSCLC patients with EGFR mutations is limited. Furthermore, the efficacy of ICIs in patients harboring uncommon EGFR mutations is unknown.

**Method:** We retrospectively reviewed five NSCLC cases with uncommon EGFR mutations and high program death (PD)-ligand (L1) expression (> 50%) on tumor cells that were treated with the ICI pembrolizumab in our institute from April 2017 to April 2018. We collected data including sex, age, performance status, smoking history, PD-L1 expression, EGFR mutations status and clinical outcome.

**Result:** Four cases were male, median age was 68 (45–78), 4 cases were former/current smokers, 1 case was stage IIIC, 2 cases were stage IVa and 2 cases were stage IVb, 4 cases had G719X and 1 case had both exon 19 deletion and T790M. Four cases were treated with pembrolizumab as first line treatment and 1 case were treated as second line treatment after afatinib. Median number of pembrolizumab doses were 4 (1-7) and best responses were 2 partial response (PR), 2 stable disease (SD) and 1 progressive disease (PD). As adverse events, 1 case had grade 3 colitis and 1 case had grade 1 pneumonitis.

**Conclusion:** Four patients with the G719X mutation were male former/current smokers and were effectively treated (PR of PD) with pembrolizumab. However, one patient with both common mutation and de novo T790M did not respond to pembrolizumab (PD). ICI-based treatments for patients harboring uncommon EGFR mutations may be one of the treatment option.

**Keywords:** Non-small cell lung carcinoma, immune checkpoint inhibitor, epidermal growth factor receptor mutation

**P3.01-100 RISK OF GASTROINTESTINAL AND HEPATIC TOXICITIES IN PATIENTS WITH ADVANCED NON-SMALL-CELL LUNG CANCER TREATED WITH OSIMERTINIB**

K. Thein1, S. Swarup1, S. Baill1, M. Quirch2, M. Sakai2, F. Hardwicke1, S. Awasthi1, L. Tijani1

1Hematology Oncology, Texas Tech University Health Sciences Center, Lubbock/TX/US, 2Internal Medicine, Texas Tech University Health Sciences Center, Lubbock/TX/US

**Background:** Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) are the standard first-line therapy in patients with advanced non-small-cell lung cancer (NSCLC) who harbors EGFR mutation. The presence of T790M point mutation, later, mediates the resistance to first-generation and second-generation EGFR-TKIs. Osimertinib, an oral third-generation EGFR-TKI, targets both EGFR-TKI sensitizing and EGFR T790M resistance mutations. We undertook a systematic review and combined analysis of two phase III randomized controlled trials (RCT) to determine the risk of gastrointestinal and hepatic toxicities among patients with advanced NSCLC treated with osimertinib.

**Method:** We conducted a comprehensive literature search using MEDLINE, EMBASE databases and meeting abstracts from inception through March 2018. Phase III RCTs that mention diarrhea, nausea, vomiting, stomatitis and elevated aspartate aminotransferase (AST) or alanine aminotransferase (ALT) as adverse effects were incorporated in the analysis. Mantel-Haenszel (MH) method was used to calculate the estimated pooled risk ratio (RR) with 95% confidence interval (CI). Fixed effects model was applied.

**Result:** Two phase III RCTs with a total of 971 patients with advanced NSCLC were included in the analysis. Studies compared osimertinib vs carboplatin/cisplatin + pemetrexed and osimertinib vs gefitinib/erlotinib. The randomization ratio was 1:1 in the FLAURA study and 2:1 in the AURA3 study. Osimertinib was utilized in T790M-positive advanced NSCLC after prior first-line EGFR-TKIs in the AURA3 study (n = 556) and as first-line treatment in the FLAURA study (n = 415). The RR of all-grade side effects were as follows: diarrhea, 1.305 (95% CI: 0.920 – 1.836, p < 0.0001); nausea, 0.480 (95% CI: 0.378 – 0.611; p < 0.0001); vomiting, 0.783 (95% CI: 0.561 – 1.092; p = 0.149); stomatitis, 1.262 (95% CI: 0.980 – 1.626, p = 0.071); elevated AST, 0.397 (95% CI: 0.277 – 0.569; p < 0.0001); and elevated ALT, 0.312 (95% CI: 0.212 – 0.458; p < 0.0001). The RR of high-grade side effects were as follows: diarrhea, 0.912 (95% CI: 0.354 – 2.347, p = 0.849); vomiting, 0.135 (95% CI: 0.022 – 0.831; p = 0.311); stomatitis, 0.532 (95% CI: 0.124 – 2.293, p = 0.397); elevated AST, 0.396 (95% CI: 0.196 – 0.797; p = 0.031) and elevated ALT, 0.112 (95% CI: 0.034 – 0.372; p < 0.0001).

**Conclusion:** Patients on osimertinib noted a significant increase in the risk of all-grade diarrhea. Nevertheless, the risk of developing any-grade nausea, all grades of elevated AST/ALT and high-grade vomiting, was significantly reduced in osimertinib arm, favoring osimertinib.

**P3.01-101 A RETROSPECTIVE STUDY OF LUNG CANCER THAT HAS PROGRESSED TO BRAIN METASTASIS ALONE**

Osaka Medical College Hospital, Osaka/JP

**Background:** There is no consensus whether systemic therapy is needed after local treatment of lung cancer that has progressed to brain metastasis alone. To clarify the effect of treatment differences on patient survival, we conducted a retrospective study of treatment outcomes in patients with lung cancer that progressed to brain metastasis alone.

**Method:** The study included patients diagnosed with lung cancer at our hospital between January 2011 and December 2016 and those with disease progression to brain metastasis alone by December 2017. We divided the patients according to the treatment administered and compared their characteristics and survival.

**Result:** This study included 26 patients. Among them, 7 patients were followed up after local treatment (FU) and 19 patients received systemic therapy after local treatment (ST). The patient characteristics were as follows: median age (years): FU, 71 and ST, 68; sex (male/female): FU, 5/2 and ST, 8/11; disease stage at diagnosis (I/II/III/IV/postoperative recurrence): FU, 3/0/3/1/0 and ST, 0/1/7/9/2; and histology (small cell lung cancer/non-small cell lung cancer): FU, 1/6 and ST, 6/13. There were no significant differences in survival between the two groups (median progression-free survival [PFS]: months), FU vs. ST–9 vs. 5, P=0.581; median overall survival [months], FU vs. ST–26 vs. 13, P=0.856). Analysis of prognosis showed significant differences in disease stage at diagnosis based on univariate Cox analysis of PFS (I–III vs. IV or postoperative recurrence; hazard ratio, 3.440; 95% confidence interval, 1.16-10.22; P=0.026).

**Conclusion:** In patients with lung cancer that has progressed to brain metastasis alone, administration of systemic therapy may not be necessary until further disease progression after local treatment.

---

**P3.01-102 POTENTIAL PREDICTORS OF UNEXPECTED READMISSION AFTER LUNG RESECTION**

S. Uchida, Y. Yoshida, K. Asakura, K. Nakagawa, S. Watanabe

Department of Thoracic Surgery, National Cancer Center Hospital, Tokyo/JP

**Background:** Postoperative unexpected readmissions are sentinel events that negatively impact patients. Previous analyses of risk factors of unexpected readmission after lung resection have identified several predictive factors. However, both the operative procedures and perioperative care can vary between institutions. The current study aimed to investigate the incidence levels and potential predictors of unexpected readmission after lung cancer surgery at our institution. Method: Patients who underwent lung resection for primary lung cancers between January 2016 and December 2017 at our institution were enrolled in this study. Operative procedures included pneumonectomy, lobectomy, segmentectomy, and wedge resection. Pleural biopsy and unresectable cases were excluded from this study. Unexpected readmissions were defined as an unscheduled readmission after surgery to our hospital. All patients were examined at our outpatient clinic within 14 days after initial discharge. Thirty-day readmission rates and diagnoses were edulated. Univariate analysis was performed to identify perioperative

1Zhejiang Cancer Hospital, Hangzhou/CN, 2Fujian Cancer Hospital, Fuzhou/CN, 3Jining Hospital, Nanjing/CN, 4Department of Respiratory Medicine, Nanjing Military General Hospital, Nanjing/CN

Background: The most frequent epidermal growth factor receptor (EGFR) mutations of lung cancer include exon 19 in deletion and the exon 21 L858R mutation. And EGFR-tyrosine kinase inhibitor (TKI) as the standard first-line treatment show better response to classical sensitizing EGFR mutations. With the development of detection methods, some uncommon genomic mutation events such as exon 18-25 kinase domain duplications (KDD) and EGFR rearrangements (EGFR-RAD51 or EGFR-PURB) are found. We reported a case of crizotinib resistant non-small cell lung cancer (NSCLC) and the efficacy of erlotinib fusion to this type fusion of NSCLC patients. Method: A 48-year-old male diagnosed with adenocarcinoma (IV, T1N2M1), who was shown to have EGFR fusion by next generation sequencing. Result: The patient with right lung tumor and multiple brain metastases NSCLC. Histological examination of surgical specimens from the brain tumor showed lung adenocarcinoma metastasis. By using next generation sequencing assay, we found that tumor had EGFR-RAD51 fusion rather than the most common kind of EGFR mutations. Then the patient experienced a remarkable tumor response to erlotinib. Considering this rare EGFR fusion and remarkable response to TKI treatment, we conclude that the incidence of EGFR fusions in NSCLC patients should be attentive. NSCLC patients with EGFR-RAD51 fusion gene response to treatment with EGFR inhibitor treatment. Conclusion: With the guidance of precise diagnosis, it is important that we should realize other rare EGFR gene mutations and novel diagnostic method.

Background: Albumin-bound paclitaxel (nab-PC) could benefit advanced non-small cell lung cancer (NSCLC) either in first line or second line. However, the safety and efficacy in Chinese elderly patients remains unclear. In this study, we retrospectively analyzed the efficacy and safety of nab-pc in Chinese elderly patients (≥65 year old) from a single cancer center. Method: We retrospectively collected data from 75 patients who were treated with weekly nab-paclitaxel (125 or 130 mg/m2, d1) from January 2010 to December 31, 2017 in Peking University Cancer Hospital. Among which, 33 patients were non-squamous NSCLC, and 42 patients were squamous NSCLC. Twelve of these patients received nab-paclitaxel as first line treatment (7 of which were combined with carboplatin) and 63 patients received single nab-paclitaxel as latter line treatment. Result: s: Sixty-eight out of 75 patients were available for efficacy evaluation, the overall objective response rate (ORR) was 13.1 (10/68), disease control rate (DCR) were 69.3% (52/75), median progression free survival (PFS) was 5.2 months and overall survival was 12.2 months in the entire population. For first-line and latter line setting subgroup, the ORR, DCR, PFS and OS were 18.2% and 14.0%; 90.9% and 73.7%; 6.7 months and 5.0 months; 17.7 months and 12.2 months, respectively. For the patients over 70 years old, the PFS significantly longer compared with patient <70 years old (6.3 months vs. 3.7 months p = 0.021; the same trend was observed in OS, however the difference was not significant (13.3 months vs. 10.0 months, p = 0.089). For all patients the most common toxicity was neutropenia (37.3%, n = 28), anemia (40%, n = 30) fatigue (18.7%, n = 14) and Peripheral neuritis (17.3%, n = 13) which were all manageable, and the incidence of grade 3 was 13.3% (10/75), no grade 4 AEs were found and no AEs related death. Totally 7 patients discontinued treatment because of AEs. And the incidence of AEs was not different among subgroups of patients defined with age (65≤ age <70, 70≤ age <75 and age ≥75). Conclusion: The efficacy of nab-paclitaxel in Chinese elderly patients was desirable. The toxicity was tolerable and manageable. Patients over 70 may benefit more from nab-paclitaxel. Prospective clinical trials are expected to further confirm the results.

P3.01-106 REAL-WORLD DATA TO EVALUATE THE CLINICAL BENEFIT OF NGS FOR DIRECTING LUNG ADENOCARCINOMA TREATMENT

Z. Wang1, B. Lu1, G. Liu1, T. Xu1, M. Yuan2, R. Chen2, X. Xia1
1Cancer Medical Center, The Second Affiliated Hospital of Nanjing Medical University, Nanjing/CN, 2Geneplus-Beijing, Beijing/CN

Background: Since mid-2017, multiple NGS-based companion diagnostic tests have been approved in NSCLC to select patients eligible for targeted therapy and immunotherapy. Here, we retrospectively analyzed the benefit of NGS for advanced lung adenocarcinoma in routine clinical practice. Method: From 2016 to 2018, the samples taken from 9 lung adenocarcinoma patients were sent to Geneplus-Beijing Institute for genetic testing. Mutation profiles were analyzed using hybridization capture based NGS, which enables the simultaneous detection of single-nucleotide variants, insertions/deletions, rearrangements, and copy-number alterations of at least 59 genes (range 59 – 1021 genes). The tumor response was evaluated using RECIST v1.1. Result: Six tumor tissue samples, two blood samples and one pleural effusion sample were analyzed (Table 1). No actionable mutation was detected in patient 1 and then he left hospital without additional treatment. The KRAS mutation present in patient 2 suggested that he might be resistant to EGFR-TKIs. Therefore, he received chemotherapy. According to the genetic testing results, all the other patients received EGFR-TKIs and the disease control rate was 100% at the 2nd month. Apart from EGFR T790M mutation, EGFR amplification was present in patient 8 with disease progression following gefitinib therapy. She received osimertinib and achieved PR at the 2nd month. The response has maintained for over 7 months up to now, which made us reconsidering the controversial correlation between EGFR amplification and EGFR-TKI effectiveness. Rare EGFR mutation and MET amplification were detected in patient 9, and then he was treated with icotinib. The best response was SD at the 4th month. However, he died of pulmonary embolism or cerebral infarction, making the duration of response 4 months.

P3.01-107 CORRELATION STUDY OF BONE METASTASIS AND CHOLESTEROL LEVEL IN PATIENTS WITH LUNG ADENOCARCINOMA
Y. Wang
1Thoracic Surgery, The 4th Hospital of Hebei Medical University, Shijiazhuang/CN

Background: To explore the correlation between bone metastasis and laboratory examination such as cholesterol level in patients with lung adenocarcinoma. Method: Medical records were studied for patients who were admitted into this high-volume institution from Jan 1, 2017 to the present. 114 patients diagnosed and treated as esophageal squamous cell carcinoma and bone metastasis were retrospectively analyzed for the present study. Along with them were 114 patients without bone metastasis in the control group. Result: There was no significant statistical difference between groups with respect to neutrophils count, lymphocyte count, monocyte count, bilirubin, calcium ion, phosphorus, or blood sugar. Univariable analysis found that total cholesterol levels (OR: 0.230; 95% CI: 0.064–0.822; P=0.024) and triglyceride levels (OR: 0.001; 95% CI: 0.000–0.201; P=0.012) , and Multivariate analysis indicated that triglyceride levels (OR: 0.001; 95% CI: 0.000–0.327; P=0.020) were independently associated with development of bone metastasis in patients with lung adenocarcinoma. Conclusion: Triglyceride levels were independently associated with the development of bone metastasis in patients with lung adenocarcinoma.

Keywords: triglyceride, bone metastasis, lung adenocarcinoma

P3.01-080 ONCOLOGIST TREATMENT CONSIDERATIONS AND SELECTION IN EGFR M+ NSCLC
T. Wehler1, B. Fischer3, S. Reisig3, V. Hirsh4
1Evangelisches Krankenhaus Hamm, Hamm/NR, 2Kantonspital, Munich/DE, 3Boehringer Ingelheim, Ingehelm Am Rhein/DE, 4Department of Medical Oncology, Mollig University, Royal Victoria Hospital, Montreal/CA

Background: The treatment landscape for EGFR M+ stage IIIb/IV NSCLC has significantly changed in the past few years: at the end of 2015, 3rd generation TKI osimertinib was approved for the treatment of EGFR T790M+ NSCLC, and in 2018, osimertinib was approved for the first-line treatment of EGFR M+ patients. As such, there is much debate amongst oncologists around which TKI to prescribe to patients first, now that more targeted treatments are available. The aim of this study was to assess current attitudes towards decision making for TKI sequencing to determine what matters most when selecting a treatment and what challenges oncologists face. Method: A representative online survey was conducted with 310 HCPs (Oncologists, Pulmonologists, Respiratory Surgeons and Internal Respiratory Specialists) across four countries (China, Germany, Japan and USA) between April 2018 and May 2018. Result: For all four countries and irrespective of treatment line, increasing overall survival (OS), followed by increasing quality of life (QoL) emerged as the most important treatment ambitions when prescribing TKIs. However, examination of treatment goals in the first-line setting revealed that clinically meaningful OS stands out for the US, Germany, and Japan. In contrast for China, offering a clinically meaningful progression-free survival (PFS), OS, and improved health related QoL appear to be of equal importance. Predictability of treatment outcome in first-line therapy was also a relevant influence on treatment choice. This included a predictable pattern of resistance to TKIs for the majority of patients, efficacy in specific EGFR M+ subtypes, availability in flexible dose adjustment and if a compound was part of a sequence of targeted treatments which may delay time to chemotherapy. In terms of the sequencing of TKIs, 55% strongly prefer a treatment sequence offering maximum time on targeted therapies. Furthermore, there is a strong need across all countries for information on potential resistance mutations before changing current treatment practice – and over a third (36%) of all HCPs agreed that they do not feel they have all the data required to make informed decisions on how to sequence EGFR M+ NSCLC treatments. Conclusion: The study confirms that increasing survival time across treatment lines is the overarching ambition when using TKIs in EGFR M+ NSCLC together with increasing QoL. In order to overcome uncertainties regarding the appropriate treatment decisions for patients EGFR M+ NSCLC, HCPs require more information about the possible impact of treatment sequencing on extending survival.

Keywords: sequencing, treatment, TKIs

P3.01-010 REAL-WORLD PATIENT-REPORTED OUTCOME ASSESSMENT OF PATIENTS WITH METASTATIC NON-SMALL CELL LUNG CANCER
L. Williams1, S. Dibaji2, S. Chandwani3, V. Vaghani4, Q. Shi5, M. Hirschmann5, L.L. Landry1, E. Roarty1, J. Zhang1, W. Rinsurnogkawong5, J. Lewis5, T. Burke6, C. Cleeiland7, J. Lee8, J.A. Jack A. Roth9, S. Swisher10, J. Heymach11, G. Simon12

Background: Patient-Reported Outcomes (PROs) provide information on patient treatment experience. We have established a real-world Advanced Non-Small Cell Lung Holistic Registry (ANCHOR) to understand how the advent of immunotherapy impacts treatment choice, clinical outcomes, and PROs of metastatic non-small cell lung cancer (mNSCLC). The aim of this analysis is to report early results of baseline symptom status and quality of life among mNSCLC patients using the MD Anderson Symptom Inventory lung cancer module (MDASI-LC) and EuroQol-5D 5-level version (EQ-5D-5L). Method: During 2017, patients with mNSCLC at a single institution were enrolled in ANCHOR and completed the PRO questionnaires at clinic visits. MDASI-LC consists of thirteen core and three lung cancer-specific symptom severity questions, and six interference items rated on 0-10 scales (0 = no symptom or interference, 10 = the most imaginable symptom or complete interference). EQ-5D-5L captures five health state dimensions: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression rated on a five-level scale (1= no problems, 5 = extreme problems). A single visual analogue scale (VAS) on EQ-5D-5L records patient self-rated health between “best imaginable” (100) and “worst imaginable” (0) health state. Descriptive statistics for PRO scores at baseline are summarized. Result: Forty-two patients completed baseline PROs before the start of therapy. Mean patient age was 63 years and 45% were males. For MDASI-LC, the mean scores for the core symptom, lung cancer-specific symptom, and interference subscales at baseline were 2.2 (standard deviation [SD] = 2.80), 2.1 (SD = 2.80), and 2.8 (SD = 3.10), respectively. Fatigue was the most severe symptom reported at baseline (mean = 4.1, SD = 3.01), followed by shortness of breath (mean = 3.2, SD = 2.81) and pain (mean = 3.19, SD = 3.00). The highest percentages of patients reporting moderate to severe symptom levels (score of ≥5) were 38% for fatigue, 33% for pain, 31% for drowsiness, 29% for shortness of breath and disturbed sleep, and 26% coughing. For EQ-5D-5L, 91% of patient reported problems with self-care, 81% with mobility, 48% with usual activity and anxiety, and 33% with pain. Mean EQ-5D VAS was 73.9 (SD = 18.2). Conclusion: Prior to the start of treatment, fatigue, pain, drowsiness, disturbed sleep, and coughing were the most severe symptoms reported, with fatigue, shortness of breath, and pain being the most severe. Additional follow up will confirm and expand these findings and will also allow us to examine change in PROs after first-line treatment is administered.

P3.01-101 DEFINING AGGRESSIVE DISEASE IN PATIENTS WITH ADVANCED NSCLC RECEIVING SECOND-LINE TREATMENT: A SYSTEMATIC REVIEW
K. Winfree1, C. Ainsworth2, A. Njue2, C. Molife1, M. Lyal1, M. Jen3, M. Bitton4, A. Heyes5, D. Carbone6
1Eli Lilly and Company, Indianapolis/US, 2RTI Health Solutions, Manchester/GB, 3Eli Lilly and Company, London/GB, 4Ohio State University, Columbus/OH/US, 5Medical Oncology, The Ohio State Wexner Medical Center, Columbus/OH/US

Background: Recent randomized clinical trials (RCTs) have explored survival benefits of second-line treatments (2LTs) in patients who have rapidly progressed and/or are refractory to first-line treatments, and these trials have determined an existing unmet need for these patients with aggressive non-small cell lung cancer (NSCLC). However, specific characterization of aggressive NSCLC is lacking, thus a
systematic literature review was conducted to explore the definitions of aggressive NSCLC. **Method:** We systematically searched Medline, Embase, Bioscience Information Service, the Cochrane Library, and abstracts from scientific meetings (through October 2017) to identify RCTs reporting the efficacy and/or safety of select 2LTs in patients with advanced NSCLC who have characteristics associated with aggressive disease (AD). Six potential overarching categorizations of these characteristics (based on expert clinical opinion) were explored: (1) refractory and/or progressive disease as best response to prior treatment, (2) rapid progression, (3) short duration on previous treatment, (4) high tumor burden or size, (5) short duration since start of last treatment, and (6) high symptom burden. **Result:** The 14 identified studies had one or more subgroups within five of the six categorizations (11, 2, 1, 2, and 4 studies presented subgroups within categories 1-5, respectively). No RCTs presenting a subgroup of patients for category 6 were identified. Within each category, the identified subgroup definitions (15, 4, 3, 2, and 7 different definitions within categories 1-5, respectively). Reporting of whether a subgroup was prespecified or not was also often unclear; 6 studies indicated that subgroup analyses of patients with AD characteristics were planned. Moreover, baseline characteristics for the subgroup of patients with AD were often not reported. **Conclusion:** Definitions of AD varied, both across the identified studies of 2LTs and within the predetermined categorizations, with refractory being the most frequent followed by short duration since last start of treatment. With the emerging clinical importance of AD, more standard use of these definitions within RCTs may allow for greater comparison treatments. With the emerging clinical importance of AD, more standard use of these definitions within RCTs may allow for greater comparison treatments. With the emerging clinical importance of AD, more standard use of these definitions within RCTs may allow for greater comparison treatments. **Keywords:** Second-line treatment, aggressive disease, advanced NSCLC

**Background:** Subsequent therapies confound the ability to discern the effect of firstline chemotherapy on overall survival (OS). Therefore, the objective of our study was to determine the relationships between progression-free survival (PFS) or post-progression survival (PPS) and OS after first-line EGFR-TKI treatment in, using individual level data.

**Method:** Between April 2008 and December 2015, we analyzed 68 cases of elderly patients with NSCLC harboring sensitive EGFR mutations treated with first-line EGFR-TKI. The relationships between PFS and OS with OS were analyzed at an individual level.

**Result:** PFS was more closely associated with OS ($R^2 = 0.54$) compared to PPS ($R^2 = 0.48$), based on linear regression. Best response at first-line treatment, PS at the end of first-line treatment and administration of EGFR-TKI rechallenge were significantly linked to the PPS. **Conclusion:** PFS has a stronger impact on OS than PPS. This study, it might be possible to evaluate if for patients with NSCLC mutations treated with first-line EGFR-TKI. Fluenced by treatments subsequent to first-line chemotherapy; however, this remains to be verified with prospective studies.

**P3.01-112 THE PROGNOSIS OF LUNG CANCER PATIENTS WITH UNEXPECTED MALIGNANT PLEURAL EFFUSION AND WITHOUT PLEURAL DISSEMINATION DETECTED AT THORACOTOMY**

T. Yamamichi1, M. Harada2, A. Asakawa1, M. Okui1, H. Horio1

1Thoracic Surgery, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo/JP, 2Thoracic Surgery, Tokyo Medical University Hospital, Tokyo/JP

**Background:** Generally, primary lung cancer patients with malignant pleural effusion are not candidate for surgery. But in cases, we have no chance but to perform the surgery for biopsy, prevention for obstructive pneumonitis. We analyzed the surgery for lung cancer patients with unexpected malignant pleural effusion retrospectively. **Method:** We retrospectively reviewed the patients with unexpected malignant pleural effusion and without pleural dissemination detected at thoracotomy underwent surgery in our hospital from 2003 to 2017. Pleural effusion was almost small amount (<50ml), and we included the cases that pleural effusion was malignant in the final report however it was suspicious in immediate report. Patient demographics, comorbidities, findings, surgical approach, number of lymph nodes harvested, overall survival were evaluated retrospectively. Overall survival were analyzed with the Kaplan–Meier method and prognostic factors were analyzed with the Cox proportional hazards model. **Result:** 24 patients underwent resection for NSCLC. The median age was 71 years old (55-79 years old) and 7 cases were male. Pleural effusions of all patients were taken before resection and submitted for rapid diagnosis. The reason we performed surgery was because we judged that we could perform surgery because of pulmonary nodeodis nalysis and prevention of obstructive pneumonitis and so on. Surgical procedures were lobectomy in 15 cases, segmentectomy in 1, wedge resection in 8. The median size of resected nodule was 2.7cm (1.1cm-10.0cm). Histological types of lung cancer were adenocarcinoma in 21 cases, squamous cell carcinoma, adenosquamous carcinoma and small cell carcinoma each in 1. There was no surgical-related death or severe complications. The median follow-up time was 40 months and median survival was 66 months. At 5 years after pulmonary resection, 9 patients (38%) were dead. 5-year survival was 59.7% and 70.0% at cT1-2N0 patients, respectively. In a previous report, 5-year survival on resected stage I patients was almost 75%, and it is almost as good prognosis as our cT1-2N0 patients. Univariate analysis of gender, age, lymph node dissection, pathological findings (PL, ly, v, histology), surgical procedure and Brinkman Index were performed. In a previous report, 5-year survival on resected stage I patients was almost 75%, and it is almost as good prognosis as our cT1-2N0 patients. **Conclusion:** The prognostics of surgery for lung cancer patients with unexpected malignant pleural effusion and without pleural dissemination may be not better than expected and PL0 or 1 was thought as a prognostic factor. Thus, subsequent analysis should be performed to identify patients who could benefit from surgery.

**Background:** Previous results of CTONG1506 study showed that gene aberration test rate was increasing in Chinese NSCLC patients and first-line treatment was standardized accordingly. This survey further described one year survival of patients with different gene aberration status and under different first-line treatments. **Method:** CTONG1506 was a two-year series cross-sectional study. Patients with advanced non-squamous NSCLC who were admitted from August to March 2015 and 2016 and who received first-line anti-cancer treatment at one of 12 tertiary hospitals across China were included. Data extracted from medical charts were entered in medical record abstract forms, which were collated for analysis. Survival information was collected one year after patients were admitted to hospital. One year survival rate and its 95% confidence interval were analysed by Kaplan–Meier method. **Result:** A total of 707 patients were analysed, with mean age of 61 years, 56.7% were male. Among the 487 patients who had survival data, 192 were EGR- mutation positive (86 mutated in exon 19 [one year survival rate 0.90, 95% CI: 0.81-0.94] and 88 mutated in exon 21 [one year survival rate 0.84, 95% CI: 0.75-0.90]), 27 patients were ALK positive and
164 patients were EGFR and ALK wild type. Most EGFR mutation positive patients (128/192) received tyrosine kinase inhibitors (TKIs) as first-line treatment and most EGFR wild type patients (155/175) received first-line chemotherapy (Chemo). Pemetrexed was the most common non-platinum chemotherapy-backbone agent (120/155) in platinum doublet regimens. One year survival rates are shown in the table.

**Conclusion:** This nationwide real world study of tertiary hospitals in China revealed that a majority (>75%) advanced nonsquamous NSCLC patients survived more than one year and was comparable to well-controlled clinical trial results, indicating survival benefits by gene aberration status guided standard of care. This result may be further validated by our on-going two-year survey.

**P3.01-115 LIPOSOMAL PACLITAXEL VERSUS GEMCITABINE: WHICH IS BETTER?**

L. Pan¹, L. Lan², X. Zhou³

¹Department of Respiration, Southwest Hospital of Third Military Medical University, Chongqing/CN, ²The First Affiliated Hospital of Third Military Medical University, Chongqing/CN

**Background:** Lung cancer tends to metastasize to lymph nodes in the early stage. The liposomal Paclitaxel (LP) injection has less side effects and higher uptake. It is also characterized as being able to target organs with rich reticuloendothelial system and keeping a high concentration for a long time. We assume that LP injection has a better curative effect against NSCLC with regional lymph node metastasis. **Method:** Patients divide to 58 for LP and 56 for Gemcitabine plus cisplatin (GP). These patients have good comparability in gender, age, ECOG points, pathological pattern, TNM staging and chemotherapy cycles. 21 days as a single cycle. Each patient finished at least 2 cycles. Estimation was carried on within one week when they have finished the chemotherapy. Chemotherapy continues if the result turns out CR+PR+SD. Surgical treatment would be suggested if the stage of cancer decreases and the lesions of NSCLC turn technically removable. Then continue chemotherapy after surgery, 4 to 6 cycles in total. **Result:** The alleviation rate of lymph nodes metastasis in LP group is significantly higher. The disease control rate of lymph nodes metastasis is 96.55% vs. 92.857%, p=0.38. The alleviation rate of squamous cell carcinoma and the disease control rate is not statistically significant. The alleviation and disease control rate of primary tumor in LP and GP group does not have statistical significance. And among LA patients, it is the same trend.

**Keywords:** Non-small-cell lung carcinoma, lymph node metastasis, liposomal Paclitaxel

---

**P3.01-114 DISSOCIATION OF HEART AND GREAT VESSELS FOR LONG TRACHEAL TUMORS AND LUNG CANCER INVADED TRACHEA: THE CHINESE EXPERIENCE.**

Q. Zhou

Lung Cancer Center, West China Hospital, Sichuan University, Chengdu/CN

**Background:** The length limit of tracheal resection is less than five centimeters. Up to now, there is no any report about resection of more than five centimeters for tracheal tumors. We created a new technique and successfully remove 124 tracheal tumors more than 5 cm in length and 52 lung cancer invaded trachea through dissociation heart and great vessels. Here, we report the results of 176 patients surgically treated in series. **Method:** All patients were given general anesthesia and single cavity endotracheal intubation. After thoracotomy, the right pericardium was totally excised, the heart, inferior vena cava, superior vena cava, ascending aorta and innominate artery were dissociated. Then, thoracic trachea, left and right main bronchus were dissociated; the proximal and distal end of trachea, or left and right main bronchus, or left main bronchus and right middle trunk bronchus were cut off. Fallowing, the distal end of trachea was anastomosed to the proximal end of trachea, or anastomosed to the left and right main bronchus, or anastomosed to the left main bronchus and right middle trunk bronchus with 3-0 micro Joe lines. Finally, the pulmonary artery sleeve reconstruction was performed, and resection and reconstruction of SVC was performed. **Result:** There were 124 patients with tracheal tumor over than 5 cm in length and 52 patients with lung cancer invaded trachea. The length of trachea tumor was 5.5 cm to 10.9 cm. 5 tracheal tumor involved SVC and combined with SVCS. The trachea length invaded by the cancer was 4.5 cm-7.0 cm in the 52 patients with lung cancer. Of the 52 cases, 10 cancer invaded right main pulmonary artery, 22 cancer involved right main pulmonary artery and SVC. The operative procedures included: (1) resection and reconstruction of trachea, or combined with carina in 124 cases, and combined with resection and reconstruction of SVC in 5 cases in the tracheal tumor group; (2) Sleeve right upper lobectomy combined with resection and reconstruction of trachea and carina in 52 cases, combined with sleeve pulmonary artery in 10 cases, combined with sleeve pulmonary artery, and resection and reconstruction of SVC in 32 cases of lung cancer group. There were 5 operative death in this series. The 1-, 3-, 5- and 10-year survival were 71.2%, 54.3%, 33.1% and 22.5%. **Conclusion:** We pioneered a new technique and treated 124 tracheal tumor more than 5 cm in length and 52 lung cancer invaded trachea in the world.

**P3.01-116 RANDOMIZED CLINICAL TRIAL ON THREE DIFFERENT PLATINUM BASED CHEMOTHERAPY IN ADVANCED NSCLC IN BANGLADESHIPOPULATION**

F. Begum¹, N. Khatun², P. Akhtar¹, A.S.M. Chowdhury³, M. Rahman⁴, Q. Chowdhury⁵

¹Medical Oncology, National Institute of Cancer Research and Hospital, Dhaka/BD, ²Biochemistry and Biotechnology, University of Science & Technology Chittagong (Ustc), Chittagong/BD, ³Oncology, Bangladesh Specialized Hospital Ltd., Dhaka/BD, ⁴Radiation Oncology, Ahsania Mission Cancer and General Hospital, Dhaka/BD

**Background:** Lung cancer constitutes the major mortality in the world and incidence of the disease varies considerably among different ethnic population throughout the world. Palliative chemotherapy has been a
choice in advance Non-Small Cell Lung Cancer (NSCLC) due to better result. The primary objective of the study was to evaluate the response and toxicity of three different platinum based regimens in Bangladeshi people.

**Method:** This Randomized Clinical Trial (RCT) was carried out in the Department of Medical Oncology at National Institute of Cancer Research & Hospital (NICRH), Mohakhali, Dhaka. Patients were enrolled from January 2012 for one year. Total 90 patients with above 18 years of age, both sexes presented with histologically confirmed stage IIIA, IIIB & IV NSCLC were enrolled and randomized (1:1:1) in to three arms. Cumulatively 26 patients were lost to follow up. Chemotherapy was given in 21 days interval (4-6 cycles). Toxicities were measured on Day 1, 7, 14, 21, 28, 42, 3 months and on 6 months. Median follow up period was 6 months. Survival data was estimated by Kaplan-Meier method.

**Result:** Significant G-1/2 HB was found in Day7 in TP (16.67%) and (10.52%) arm and in 6 months EP (31.58%) & TP (29.17%). WBC G-1/2 toxicity was found in EP (31.58%) & TP (20.83%) arm at 6 months. Similarly, in case of neutropenia and thrombocytopenia, GP arm was found to be significantly less toxic than TP and EP arm at 6 months. Response rate and survival data are provided in table 1.

**Conclusion:** In locally advanced or metastatic NSCLC response rate of platinum based combination therapy was satisfactory with increased survival than other reference trials along with lower G1/2 toxicity in GP arm followed by TP and EP in Bangladeshi Ethnic population.

**Keywords:** Bangladeshi, NSCLC, chemotherapy

**P3.03-01 BRAF V600 AND NON-V600 MUTATIONS IN CHINESE LUNG CANCER**

Y. Gao,1 R. Chang1, J. Huan,1 Y. Xiao1, Y. Liu1, Y. Zhou1, L. Li1, Y. Cheng1, C. Zhang,1 P. Dai,1 Y. Guan2, X. Yi2, X. Yang1

1Department of Thoracic Surgery, Xiangya Hospital of Central South University, Changsha/CA, 2Geneplus-Beijing, Beijing/CA

**Background:** BRAF gene mutation, especially V600E, was frequently mutated in cancer. Vemurafenib and dabrafenib has already been approved in melanoma as well as NSCLC and preclinical studies have demonstrated promising results in non-V600 NSCLC. But the best treatment for BRAF mutated NSCLC still remains unresolved. Various studies have employed single cell (sc) RNA-seq approaches to investigate the heterogeneity among individual cells directly isolated from resected surgical human lung cancer tissue. The aim of our work is to identify new biomarkers indicating early stage versus late stage of lung cancer patients. As an initiative step, the current study presents a profile of differentially expressed genes (DEG) of single cells of lung cancer tissues collected from diverse lung cancer patients. The study presents the validation of DEGs by qPCR.

**Method:** Tumours resected from lung cancer patients were prepared for scRNA-seq. Microfluidic single cell (Cl (Fluidigm), was used to capture individual cells. Full-length cDNAs (FL-cDNA) were synthesized in the system. Next-generation sequencing (illuminia) of FL-cDNA libraries generated sequence reads from transcriptions of single and bulk cells, respectively. Following read mapping, DEGs were selected by >2x fold-change difference in normalized expression values. qPCR was employed to validate the transcriptional changes in selected DEGs comparing expression values resulting from scRNA-seq and bulk RNA-seq. Both gene set enrichment and signaling pathway analyses were used to identify mechanism of action for validated DEG-encoding molecules.

**Result:** Raw scRNA-seq datasets were processed for read mapping. More than 1 million processed reads per single-cell FL-cDNA library were used for DEG selection. We examined standard deviation of normalized expression value per selected DEG to characterize transcriptomic features of individual tumour cells. We identified a minimum of a dozen DEGs showing certain fold-change differences in each stage of lung cancers. Selected DEGs were validated by qPCR whereby unique patterns of gene expression at specific stages were confirmed. The human lung tumour datasets with late stage diagnosis contributes to poor outcomes. The advent of scRNA-seq allows for the identification of differential gene expression and stage-specific markers that can be used to improve our understanding of complex intratumour heterogeneity in lung cancers. For the future, our discoveries will lead to the development of targeted therapies based on validated DEGs, ultimately allowing for early diagnosis, treatment and improved lung cancer survivorship.

**Keywords:** Lung cancers, gene expression profiling, Single cell RNA sequencing

**P3.03-02 SINGLE-CELL RNA-SEQ IN HUMAN LUNG CANCER**

J. Kim1, Z. Xu1, P. Marignani2

1Biochemistry & Molecular Biology, Dalhousie University, Halifax/NS/CA, 2Dalhousie University, Halifax/CA

**Background:** Lung cancer has the highest mortality amongst cancers primarily due to delay of diagnosis. Until recently, the focus on genomic and transcriptomic characterization of lung cancers has guided to the diagnosis and treatments of the cancers. Although RNA sequencing (RNA-seq) has been used for transcriptome profiling in cancer research, the majority of studies have employed single cell (sc) RNA-seq approaches for investigation of the heterogeneity among individual cells directly isolated from resected surgical human lung cancer tissue. The aim of our work is to identify new biomarkers indicating early stage versus late stage of lung cancer patients. As an initiative step, the current study presents a profile of differentially expressed genes (DEG) of single cells of lung cancer tissues collected from diverse lung cancer patients. The study presents the validation of DEGs by qPCR.

**Method:** Tumours resected from lung cancer patients were prepared for scRNA-seq. Microfluidic single cell (Cl (Fluidigm), was used to capture individual cells. Full-length cDNAs (FL-cDNA) were synthesized in the system. Next-generation sequencing (illuminia) of FL-cDNA libraries generated sequence reads from transcriptions of single and bulk cells, respectively. Following read mapping, DEGs were selected by >2x fold-change difference in normalized expression values. qPCR was employed to validate the transcriptional changes in selected DEGs comparing expression values resulting from scRNA-seq and bulk RNA-seq. Both gene set enrichment and signaling pathway analyses were used to identify mechanism of action for validated DEG-encoding molecules.

**Result:** Raw scRNA-seq datasets were processed for read mapping. More than 1 million processed reads per single-cell FL-cDNA library were used for DEG selection. We examined standard deviation of normalized expression value per selected DEG to characterize transcriptomic features of individual tumour cells. We identified a minimum of a dozen DEGs showing certain fold-change differences in each stage of lung cancers. Selected DEGs were validated by qPCR whereby unique patterns of gene expression at specific stages were confirmed. The human lung tumour datasets with late stage diagnosis contributes to poor outcomes. The advent of scRNA-seq allows for the identification of differential gene expression and stage-specific markers that can be used to improve our understanding of complex intratumour heterogeneity in lung cancers. For the future, our discoveries will lead to the development of targeted therapies based on validated DEGs, ultimately allowing for early diagnosis, treatment and improved lung cancer survivorship.

**P3.03-03 DIFFERENTIAL MICROBIOTA FEATURES IN LUNG TUMOR AND ADJACENT NORMAL TISSUES IN LUNG CANCER PATIENTS**

Q. Mao1, J. Hu2

1Thoracic Surgery, Jiangsu Cancer Hospital, Nanjing/CN, 2Genetics and Genomic Science, Icahn School of Medicine at Mount Sinai, New York/US

**Background:** Emerging evidence has demonstrated the link between the host microbiota and varied malignancies, including colorectal, gastric, hepatocellular, and pancreatic cancers. However, for lung cancer, one of the leading cause of the cancer-related morbidity and mortality worldwide, the interplay between the lung cancer and the lung microbiome has yet not been well investigated. In this study, we surveyed and compared the microbiota composition and diversity in paired tumor and adjacent normal tissues to test whether any tumor specific microbial features can be identified in tumor tissues.

**Method:** We surveyed the microbiota composition of 55 lung tumor and 55 paired adjacent normal tissue samples using bacterial 16S sequencing protocol. The microbiota diversity was further analyzed using QIIME pipeline. The differential taxa feature by tumor status was selected using LEfSe method. Result: We observed diversified microbiota in lung tissue samples. The dominant phyla include Proteobacteria, Firmicutes, Bacteroidetes and Actinobacteria. The overall microbiota similarity in paired tumor and adjacent tissues was significantly higher than unpaired (p<0.01). Compared to adjacent normal tissues, the tumor tissues showed significantly lower alpha diversity (p=0.05) but no difference in beta diversity (PERMANOVA test, p-value=0.27). At taxa level, dominant species showing increased abundance in tumor tissues include Propionibacterium and Enterobacteriaceae. Conclusion: In conclusion, our study demonstrated...
and compared the lung microbiota diversity and composition in paired tumor and adjacent normal tissues. Compared to non-tumor tissues, the reduction of potential pro-inflammatory microbial families/genus in tumor tissues suggest the possible link between the tumor microbiota to the immunosuppression tumor microenvironment.

**Background:** In patients with lung cancer, infections of the lower respiratory tract are often complicated, while it is not known whether ciliary function will be maintained in lung cancer lesion bronchi. We reported the newly developed simple method to evaluate patients bronchial mucociliary movement using bronchoscopy sample. To evaluate human bronchial ciliary movement in the patients with lung cancer, the ciliary beat frequency (CBF) and amplitude (CBA) and drug reaction of bronchodilator were examined by our method using bronchoscope sample which collected in the transbronchial biopsy for the diagnosis.

**Method:** Objective: Fifty eight patients with lung cancer were enrolled who had met the following eligibility criteria. 1) necessity of lung lesion bronchus. Method: When the bronchoscopy was performed in the patients with respiratory disease, bronchial lavage to the transbronchial biopsy site was examined to collect peripheral bronchial epithelial cells. After ciliary motion were observed to identify with microscopy, the ciliary beat were captured again. By software analysis, frequency and amplitude of the ciliary movement was measured. Result: There were cases in which epithelial cells could not be collected, 50 of 58 cases were able to analyze ciliary function. Ciliary epithelium in the patients with lung cancer was confirmed in the amplitude of 4 - 8μm and frequency of 5 - 20bps. It was observed that ciliary movement is significantly activated by inhale bronchodilator, from 6.6 to 8.4 beat per second as frequency, and from 6.0 to 6.5 micrometer as amplitude. Conclusion: Even in lung cancer lesion bronchus of the patients, ciliary function was maintained and it was shown that ciliary function will be activated by drug stimulation.

**P3.03-05 COMPARATIVE TRANSCRIPTOMIC ANALYSIS OF LUNG-I iPSC, NSCLC, AND SCLC: POTENTIAL IMPLICATIONS FOR iPSC MODELING OF LUNG CANCER**

V. Shukla, K. Mcloughlin, J. Gao, Y. Wang, J. Hong, M. Zhang, L. Gesumaria, H. Chen, D. Schrump

Thoracic and Gastrointestinal Oncology Branch, National Cancer Institute, Bethesda/MD/US

**Background:** In addition to having broad applicability as cellular therapy in regenerative medicine, transplantation and oncology, induced pluripotent stem cells (iPSC) may be useful models for studying a variety of benign and malignant diseases. Presently, limited information is available pertaining to the potential utility of iPSC for investigating epigenetic mechanisms of pulmonary carcinogenesis. **Method:** In the present study, RNA- seq techniques were used to examine gene expression profiles in 2 lung-iPSC (Lu-iPSC) cloned from normal human small airway epithelial cells (SAEC). 10 SCLC lines, and 10 NSCLC lines relative to SAEC. **Result:** Using criteria of 2 fold change and FDR< 0.05, 6318, 12051, and 6504 genes were differentially expressed in Lu-iPSC, SCLC, and NSCLC lines, respectively. A substantial number of differentially expressed genes (44% total) in Lu-iPSC were unique to these cells. Approximately 1/3rd of genes differentially regulated in Lu-iPSC were modulated in a histology specific manner. 1515 genes representing 24%, 12%, and 23% of differentially expressed genes in Lu-iPSC, SCLC, and NSCLC lines, respectively, were commonly regulated across Lu-iPSC, SCLC and NSCLC. Top canonical pathways included cell cycle control of chromosomal replication and mitotic roles of Polo-like kinases (up-regulated), and granuloctysis and roles of surviving in tumor microenvironment.

**P3.03-06 DIFFERENTIALLY EXPRESSED MICRORNAS IN LUNG ADENOCARCINOMA INVERT EFFECTS OF COPY NUMBER ABERATIONS OF PROGNOSTIC GENES**

1Krembil Research Institute, University Health Network, Toronto/CA, 2Krembil Research Institute, University Health Network, Toronto/ON/CA, 3University Health Network, Toronto/CA, 4British Columbia Cancer Research Centre, Vancouver/CA, 5Princess Margaret Cancer Centre, Toronto/CA, 6Tao Laboratory, University Health Network, Toronto/ON/CA, 7Data Science Discovery Centre for Chronic Diseases, Krembil Research Institute, Toronto/CA

**Background:** Significant associations between chromosomal copy number aberrations (CNAs) and differential gene expression have been found across many cancers. However, significantly downregulated genes have been often found to reside within chromosomal regions with increased number of copies and vice versa, creating a paradoxical signal. This phenomenon was usually ignored as a noise, but can potentially be a consequence of interference of other regulatory mechanisms controlling mRNA transcription. **Method:** To explore existence of such paradoxes in lung adenocarcinoma (LUAD), we performed integrative analysis of 1,937 tumour and normal tissue samples, comprising copy number aberrations, gene expression and microRNA expression studies and conducted meta-analysis of 9 microRNA expression studies. **Result:** We identified and validated 75 “paradoxical” genes whose differential expression consistently contrasted with aberrations in copy number or expression, and these, 41 genes (p < 0.001) are prognostic and form a clinically relevant signature. Interestingly, differential expression of 19 microRNAs that are frequently deregulated in LUAD, explains observed paradoxes. **Conclusion:** Our results show that deregulation of paradoxical genes is crucial in LUAD and their expression pattern is maintained epigenetically, defying gene copy number status. Our work highlights importance of large integrative analysis of diverse biological data and the need to examine phenomena that contrast the established knowledge.

Background: EGFR mutation is one of the most common driver gene mutations in non-small cell lung cancer (NSCLC) patients, especially in adenocarcinoma. Increasing numbers of rare alterations of EGFR such as kinase domain duplication and fusion have been identified with the clinical applications of next generation sequencing (NGS). However, co-occurring genomic alterations of EGFR have not been fully understood in Chinese lung adenocarcinoma patients. Method: FFPE tumor and matched blood samples of 989 Chinese patients with confirmed histology subtype of adenocarcinoma, consisting of 503 males and 486 females with a median age of 60 years, were collected for NGS-based 450 cancer genes panel assay. Genomic alterations including single nucleotide variations (SNV), short and long insertions/deletions (Indel), copy number variations (CNV) and gene rearrangements in selected genes were assessed. Result: About 57% of Chinese lung adenocarcinoma patients harbored at least one EGFR genomic alteration, which was mainly composed of patient with SNVs and Indels (74%), both gene amplifications and SNVs/Indels (23%), gene amplifications only (2.7%) and gene rearrangements only (0.5%). 20% of patients with SNVs and Indels in EGFR carried more than one EGFR mutations. Moreover, EGFR gene rearrangement was mutually exclusive with other types of genomic alterations. Exon 19 deletions and L858R substitution were the most frequent EGFR mutations. Moreover, EGFR gene rearrangement was mutually exclusive with other types of genomic alterations. Exon 19 deletions and L858R substitution were the most frequent EGFR mutations. About 38% of Chinese lung adenocarcinoma patients harbored more than one EGFR-gene activating mutation. In total, 232 protein coding genes show differential expression in Chinese lung adenocarcinoma patients compared to normal lung tissue. Conclusion: About 38% of Chinese lung adenocarcinoma patients harbored more than one EGFR-gene activating mutation. Our results demonstrated that decreased ESR2 gene mutation correlated with poor overall survival in non-small-cell lung cancer patients. ESR2 gene mutation may define a subset of patients with lung cancer appropriate for investigational therapeutic strategies.

Background: The KIT gene activation of the gene depends on ligand binding with stem cell factor, which enables the phosphorylation of substrate proteins. Subsequently, certain signal transduction pathways are activated, which stimulate important cellular functions, such as proliferation and apoptosis. Mutations in KIT that cause autophosphorylation without the presence of the ligand lead to uncontrolled cell proliferation, which eventually induces tumor development. The aim of this study is to investigate mutations and prognosis of NSCLC harboring KIT mutations. Method: A total of 402 patients with non-small-cell lung cancer were recruited between July 2012 and December 2015. The status of KIT gene with co-occurring mutation. Briefly, patients with (n=4) or without (n=10) co-occurring KIT mutations had a median OS of 4.5 months and 23.0 months respectively (P=0.63); patients with (n=6) or without (n=8) co-occurring TP53 mutations had a median OS of 15.0 months and 23.0 months respectively (P=0.47); patients with (n=2) or without (n=12) co-occurring HER2 mutations had a median OS of 14.4 months and 23.0 months respectively (P=0.01); patients with (n=2) or without (n=12) co-occurring RAS mutations had a median OS of 14.5 months and 23.0 months respectively (P=0.26). Conclusion: HER2 accompanied mutations might play a worse prognosis in KIT gene mutation NSCLC. We report different mutations than those previously reported, which emphasizes the importance of personalized medicine that could be empowered by the use of bioinformatics tools in the diagnostic process and therapeutic approaches.

Background: A number of studies have documented that estrogen receptor alpha (ESR1) may play an important role in the development of breast cancer. While the genetic variability of ESR1 mutation NSCLC patients is unclear. The aim of this study is to investigate mutations and prognosis of NSCLC harboring ESR1 mutations. Method: A total of 501 patients with non-small-cell lung cancer were recruited between July 2012 and December 2015. The status of ESR1 mutations and kinase receptor fusions revealed that 1.1% (6 of 559) of EGFR mutated Chinese NSCLC patients harbored both EGFR mutations and known druggable kinase receptor fusions including ROS1, RET and NTRK. Treatment for these patients received EGFR-TKIs as the standard treatment. One patient achieved partial response for 10 months and two achieved stable disease for 5 and 4 months, respectively. Conclusion: About 38% of Chinese lung adenocarcinoma patients harbored more than one EGFR-gene activating mutation. In total, 232 protein coding genes show differential expression in Chinese lung adenocarcinoma patients compared to normal lung tissue. Because the phosphorylation of substrate proteins. Subsequently, certain signal transduction pathways are activated, which stimulate important cellular functions, such as proliferation and apoptosis. Mutations in ESR1 that cause autophosphorylation without the presence of the ligand lead to uncontrolled cell proliferation, which eventually induces tumor development. The aim of this study is to investigate mutations and prognosis of NSCLC harboring ESR1 mutations. P3.03-07 TRANSCRIPTOMIC DIFFERENCES BETWEEN EARLY AND LATE STAGE LUNG ADENOCARCINOMA
D. Yue1, B. Zhang1, R. Lin2, N. Li2, T. Wang1, L. Gao1, C. Chen1, C. Wang1
1Lung Cancer Department, Tianjin Medical University Cancer Institute and Hospital, Tianjin/CN, 2Repugene Technology Inc., Hangzhou/CN

Background: Early and late stage lung adenocarcinoma patients differ significantly in overall survival. The tumor progression to advanced stage is driven by tumor genomic variation and the resulted abnormal gene expression profiles. A thorough study of molecular expression profiles between early and late stage lung adenocarcinoma will greatly contribute to the understanding of progression mechanism and biomarker discovery. Method: We used RNA-seq to investigate the gene expression differences of 17 fresh frozen tissue samples, which were collected from 7 early (IA) and 10 late stage (IIIA, 3; IIIB, 2; IV, 5) lung adenocarcinoma patients. Result: In total, 232 protein coding genes show differential expression levels between early and late stage subgroups. Gene functional
Background: Cancer immunotherapy has made a big advance on benefit for cure the patients from malignancy. Recent hypothesis indicates that the crosstalk between cancer cells and tumor microenvironment can regulate the innate and adaptive immune system drives immunosuppressive condition for the immune escape of cancer cells.

Method: Using genome-wide microarray and RNA-sequencing analysis, the immune-related gene profiling has been identified in the lung cancer stem cells (CSCs). The CSCs-condition medium was collected from the CSCs or CSCs/CAF co-culture system to treat and analyze the functional responses of the tumor-associated macrophage (TAM)/M2 macrophage and T cells populations. The flow cytometry and Q-PCR were used to validate the markers and related gene expression. Result: We found that the immune-modulation of human lung cancer stem cells (CSCs) could be enriched in multiple KEGG pathways: pancreatic secretion, metabolic addiction, neuroactive ligand-receptor interaction, circadian entrainment, amphetamine addiction, and serotonergic synapse. The majority of pathway enriched DE genes (16 of 24) are translated into transmembrane proteins, such as AADC2 (high in early) and GRIN2B (high in late) etc., with no correlation between expression level and cancer stage. For cancer driver genes, ALK and NTRK2 show higher expression levels in late stage than in early stage. ERBB4 shows lower expression level in the late stage. We also identified a group of kinet family genes (ESR1, KRT6B, KRT14, and KRT16) with higher expression level in the late stage lung adenocarcinomas. Interestingly, keratin expression level distinguishes the subgroups of solid tumors in other cancer types. Through ERBB2, PIK3CA, and TP53 were not identified as differentially expressed genes, their expression variations in the late-stage samples are significantly larger than those in the early stage, which could be a result of regulatory network change along the progression of tumor. Furthermore, 79 non-coding RNA were identified as DE "genes". Among them, four previously studied ncRNA prognostic markers: MIR31HG, DRAIC, LUCAT1, and LINC00261 were also identified as DE "genes" with consistent expression-stage relationship comparing with the previous report. Two other ncRNA, VLDLR-AS1 and LINCO01919, are highly expressed in early stage samples and may serve as potential prognostic markers for lung adenocarcinoma. Conclusion: This study investigated the gene expression differences between early and late stage lung adenocarcinomas and identified differential expressed coding genes and non-coding genes, which will provide potential target information for the diagnosis and clinical intervention of lung adenocarcinoma patients.

Keywords: lung adenocarcinoma, transcriptome, Gene Expression

Result:

Data is mean +/- stderr, *p<0.05 and **p<0.01 with respect to control (n=4-6, ANOVA). (B) Effect of MYOF expression of Erlotinib IC50. (A) Effect of cyclic strain on Erlotinib sensitivity as measured by IC50. Data is mean +/- std err, *p<0.01 and **p<0.001 with respect to control (n=4-6, ANOVA).
Conclusion: Low levels of cyclic strain in the lung tumor microenvironment lead to increased Erlotinib resistance and exposure to physiologic levels of cyclic strain initiates EGFR signaling and increases Erlotinib sensitivity. This highlights the need for modeling and characterizing the mechanics of the lung tumor microenvironment to investigate how cyclic strain and MYOF expression influence chemosensitivity to other cancer therapeutics.

P3.03-13 DOWNREGULATION OF MIRNA-506 MEDIATES EGFR-TKI RESISTANCE THROUGH INDUCING SONIC HEDGEHOG SIGNALING IN NON- SMALL-CELL LUNG CANCER CELL LINES

I. Haque1, M. Sharma2, A. Godwin3, C. Huang3

1. Division of Molecular Pathology, University of Kansas Medical Center, Kansas City/ KS/US, 2. Kansas City VA Medical Center, Kansas City/US, 3. Division of Hematology/ oncology, University of Kansas Medical Center, Westwood/KS/US

Background: Lung cancer is the leading cause of cancer related mortality among both women and men in the United States and worldwide. Epidermal Growth Factor Receptor (EGFR) mutation predicts response to a tyrosine kinase inhibitor (TKI) of EGFR in approximately 25% of patients. All ANSCCL patients with EGFR mutation eventually develop resistance to EGFR-TKI. The mechanism of resistance is not fully elucidated but majority of the cases is related to emergence of clones with T790M mutation in EGFR, and amplification of MET. Recently, increasing numbers of miRNAs, non-coding RNAs are correlated with the drug resistance indicating that miRNAs may serve as novel targets and/or promising predictive biomarkers for anti-EGFR therapy. In this study, we investigated the role of miRNA-506 in the regulation of Sonic Hedgehog (SHh) in TKI- resistant lung cancer cell lines. Method: To generate cell lines resistant to EGFR TKI, HCC4006 cells were exposed to increasing concentrations of erlotinib over 6 months with increasing concentration up to 20 μM. The resistant clones (designated HCC4006 ER1 to HCC4006 ER4), following expansion from single cell. Cell viability was measured by crystal violet staining assay. The expression of miRNA in parental and resistant clones was checked by real-time qRT-PCR. The mRNA and protein expression level of SHh signaling was determined by real-time qRT-PCR and Western blot. Invasive/migratory ability of parental and resistant clones was measured by Boyden chamber assays. EMT and stemness markers were evaluated by Western blot. Single-cell suspensions from pre-treated cells were re-suspended at a density of 500 cells/ml mammocult media in ultralow attachment dishes. Number as well as the size of the tumorsphere/ spheroids in specified experimental set-up was monitored and recorded alternate day for 8-10 days. Result: The studies demonstrated that miR-506 was downregulated in resistant clone as compared to parental cell lines which promotes significantly the invasive/migratory ability and EMT of lung cancer cells through induction of Shh. Interestingly, ectopic expression of miR-506 in these resistant cells inhibits Shh signaling and thus reprograms EMT, EGFR-TKI resistance and stemness. Conclusion: Our data suggest that miR-506 downregulation and induction of Shh are associated with resistance to EGFR-TKI. miR-506 interference and inhibition of Shh pathway are potential therapeutic strategy to reverse resistance to EGFR-TKI in NSCLC with EGFR mutation.

P3.03-14 DOWNREGULATION OF FOXM1 INHIBITS TUMOR PROLIFERATION, COLONY FORMATION AND SPHEROID FORMATION OF NON- SMALL-CELL LUNG CANCER

Y. Otaki1, P. Yenerali1, B. Gao1, M. Peyton1, K. Avila1, L. Girard2, L.S. Li2, A. Basa2, K. Huffman1, B. Timmons1, H. Park1, D. Debi, J. Minna2

1. Hamon Center for Therapeutic Oncology Research, University of Texas Southwestern Medical Center, Dallas/US, 2. Hamon Center for Therapeutic Oncology Research and the Simmons Comprehensive Cancer Center, Dallas/US

Background: Forkhead box protein M1 (FOXM1) is a member of the forkhead superfamily of transcription factors. It plays numerous critical roles in cancer development and progression, such as the regulation of G2/M transition of cell cycle, anti-apoptosis, DNA damage repair, invasion, and drug resistance. In a pan-cancer meta-analysis of mRNA expression signatures from ~18,000 human tumors with overall survival outcomes across 39 malignancies, over expression of the FOXM1 was a major predictor of adverse outcomes and appeared anti-correlated with tumor immune cell populations (Nat Med. 2015;21(8):938-945). Thus, we examined the prognostic and biological role of FOXM1 in non-small cell lung cancer (NSCLC). Method: We examined the prognostic impact of FOXM1 expression in lung cancer patients using a genomic database (UTSW “Lung Cancer Explorer” and KM-Plotter). We also assessed the expression of FOXM1 in NSCLC lines, and human bronchial epithelial cells (HBECs), and assessed the association between FOXM1 and cell cycle related genes in RNA-seq data. We examined the effect of the downregulation of FOXM1 on tumor proliferation and colony formation of lung adenocarcinoma cell lines by short hairpin RNA (Tet-pLKO-FOXM1- shRNA), and the effect of the downregulation of FOXM1 on 3D spheroid formation in spheroid-forming cells using Nunclon Sphera.

Result: High FOXM1 expression correlated with poor prognosis in NSCLC patients who underwent surgical resection, especially adenocarcinoma. FOXM1 expression correlated with resistance to chemotherapy in NSCLC cell lines and was much higher than normal lung epithelial cells. The expression level of FOXM1 was significantly correlated with cell cycle regulator genes such as CCNB1, CCNA2, and PLK2 in both tissue samples (Lung cancer explorer) and cell lines (our data). shRNA mediated reduction of FOXM1 expression significantly inhibited tumor cell proliferation and colony formation of NSCLC cells. Additionally, in the 3D spheroid formation assay, FOXM1 knockdown altered spheroid morphology. Conclusion: FOXM1 was over expressed in NSCLC compared to normal lung epithelial cells, and high tumor FOXM1 expression was prognostic of poor survival in patients with NSCLC who underwent surgical resection, especially in patients with adenocarcinoma. FOXM1 expression correlated with the expression of regulators of the G2/M transition, and functional knockdown studies demonstrate an important role in tumor proliferation, colony formation, and 3D spheroid formation. Overall, our results suggest that FOXM1 has important roles in NSCLC growth, while data from other groups using “CIBERSORT” analyses suggest a possible role for FOXM1 in tumor immune cells infiltration, collectively indicating that FOXM1 is a potential target for the treatment of lung cancer adenocarcinoma.

P3.03-15 LUNG CANCER REGULATION OF GLUCOSE METABOLIC STRESS RESPONSE

L. Roisman1, T. Feinberg2, M. Ilozue3, N. Peled4

1. Cancer Institute, Soroka University Medical Center, Beer-Sheva/IL, 2. Maccabi Healthcare Services, Rehovot/IL, 3. Rabin Medical Center, Petach Tiqwa/IL

Background: Cancer cells have altered metabolism in order to accommodate for the increased metabolic needs required for oncogenic transformation, proliferation, development and survival. The metabolic profile observed in cancer cells often includes increased consumption of glucose and glutamine, increased glycolysis, changes in the use of metabolic enzyme isoforms, and increased secretion of lactate. In order to better understand this hallmark of cancer, we studied the regulation of pathways by microRNAs (miRNA) expression profile under normal or cancer different lung cancer cell lines. Two different NSCLC adenocarcinoma cell lines were tested in the study, A549, which is highly glycolytic (HG) and H358, which is low glycolytic (LG). Sequencing was performed using illumina TruSeq RNA library preparation kit v2 with illumina HiSeq 2500 sequencer using single-end 50bp protocol. Cell were analysed in two different conditions, under 24h of normal glucose concentration and under 24h glucose starvation. Samples were prepared in duplicates from the initial step of cell culturing summarizing to a total of eight samples. Differential expression analysis was performed using EdgeR algorithm with an adjusted p-value > 0.05 and a log2 fold ≥ 1.5. Result: An opposite regulation profile was observed for miRNA of cells that are highly glycolytic (HG), A549, in comparison with low glycolytic, H358 cells. The former expressed 42 downregulated miRNAs from which 39 miRNAs were unique. Only 2 upregulated miRNAs, miR324 and miR616, were found significant in this cohort but they are also upregulated in the latter group. In comparison, from the 20 upregulated miRNAs found in high-glycolytic group from which 18 were unique to lower glycolytic cell line. Lower glycolytic cell lines show 4 downregulated miRNAs from which only one miRNA, miR205 was significantly uniquely downregulated, moreover, miR205HG, which is miR205 host gene, is also found significantly downregulated, suggesting the strong involvement of miR205 in glucose metabolic stress response.

Conclusion: Under glucose metabolic stress, miR205 and miR205HG are uniquely downregulated in low glycolytic NSCLC adenocarcinoma cell line.

Keywords: Glucose stress, Metabolic, miRNA
α was additionally applied to analyze the distribution patterns of nAChRs might contribute to patient survival. The immunohistochemistry Method:

Background:

... 

α7nAChR expression. In addition, nicotine was able to increase α7nAChR expression in both H157 and H157N cells. Anti-α7nAChR antibody suppressed cell grow in only H157N cells despite of nicotine treatment with or without. Long term nicotine exposure might change the dependence of α7nAChR signaling in squamous lung cancer cells. Conclusion: Our results suggested that α7nAChR might play roles in squamous lung cancer and in female lung cancer, mRNA and protein levels of α7nAChR appear to represent a tumor suppressive or an oncogenic role, respectively. The exact roles and underlying mechanisms of the α7nAChR related signaling demand further investigations in particular squamous lung cancer patients with smoking history.

Tumor growth and metastasis by modifying the stromal collagen matrix. **Method:** Primary CAFs (CAF094) isolated from a NSCLC resection specimen and immortalized with hTERT were infected with full length LOXL1 (LOXL1 overexpression), LOXL1 shRNA (LOXL1 knockdown) or with their respective controls, using a lentiviral system. To investigate the impact of LOXL1 on collagen matrix reorganization, we allowed CAFs expressing different levels of LOXL1 to contract collagen matrices. Contracted collagen matrices have then been submitted to second harmonic generation to analyze collagen fibers. We established the role of LOXL1 in lung carcinoma invasion and growth using an in vitro organotypic model and an in vivo xenograft model, respectively. **Result:** LOXL1-overexpressing CAFs embedded in collagen lattices displayed greater ability to reorganize the collagen matrix than those with lower LOXL1 expression. Furthermore, analysis of the collagen matrix demonstrated that LOXL1 contributed to more linear and dense collagen fibers organization. As a consequence of collagen matrix reorganization, invasion of the lung adenocarcinoma H460 cell line significantly increased in an organotypic model in presence of LOXL1-overexpressing CAFs. Moreover, we showed that loss of LOXL1 in mice inhibited subcutaneous growth of the lung adenocarcinoma H460 cell line compared to the mouse wild-type counterparts. **Conclusion:** We demonstrated that overexpression of LOXL1 in NSCLC tumor stroma results in an increased of tumor growth and invasion, due to a change in the matrix reorganization. Thus, LOXL1 appears as an interesting target to improve the outcome of lung cancer.

**P3.03-21 CXCR4 OVEREXPRESSION IS ASSOCIATED WITH POOR SURVIVAL OUTCOME AFTER RECURRENCE IN EARLY STAGE NON-SMALL CELL LUNG CANCER PATIENTS**

A. Fung¹, K. Kopciuk², M. Dean³, A. D’silva⁴, S. Ottsuka¹, A. Klimekovic¹, D. Haö¹, D. Morris⁵, G. Bebb⁶

¹University of Calgary, Calgary/AB/CA, ²Mathematics & Statistics, University of Calgary, Calgary/AB/CA, ³Medical Oncology, University of Calgary, Calgary/AB/CA, ⁴University of Calgary & Tom Baker Cancer Centre, Calgary/AB/CA, ⁵Medical Oncology, Tom Baker Cancer Centre, Calgary/AB/CA, ⁶OncoLabs, Tbcc Translational Labs, University of Calgary, Calgary/AB/CA

**Background:** Overexpression of CXCR4 is associated with poor outcomes for patients with advanced non-small cell lung cancer (NSCLC). Studies suggest a gender specific difference in outcomes of stage IV NSCLC patients, with shorter survival in females with high expression of CXCR4. The current study evaluates the association between CXCR4 expression and gender, time to recurrence, and survival in early stage NSCLC patients. **Method:** Patient characteristics, clinical variables and outcome data were obtained from the Glans-Look Lung Cancer database for stage I-III NSCLC patients diagnosed between 2003-2006 at the Tom Baker Cancer Centre. Tissue microarrays were created from surgical or biopsy specimens, and CXCR4 expression was evaluated using quantitative fluorescent immunohistochemistry. CXCR4 expression and outcome data were analyzed using a Cox proportional hazards and multi-state model. **Result:** 230 patients with stage I-III NSCLC were identified, and 181 patients had corresponding tissue for CXCR4 analysis. Early stage NSCLC patients with CXCR4 overexpression had worse overall survival compared to those with low CXCR4 expression (p<0.05). No gender specific difference was observed. Time to recurrence did not correlate with CXCR4 expression, and there was no association with the site of recurrence (local versus distant). However, high CXCR4 expression was associated with increased risk of death after recurrence (p<0.05). **Conclusion:** Early stage lung cancer patients with high CXCR4 expression have worse survival outcomes, particularly after recurrence of disease. The role of CXCR4 as a prognostic marker in NSCLC patients who have recurred should be further elucidated.

**P3.03-22 IL-1β AS A NEW EARLY PREDICTIVE BIOMARKER FOR NON-SMALL CELL LUNG CANCERS OUTCOME**

University of Ferrara, Ferrara/IT

**Background:** Lung cancer is the first cause of cancer mortality worldwide. Patients diagnosed with early stage disease (stage I) have been considered to have a reasonably favourable prognosis. Unfortunately, up to 40% early stage cases of all non-small cell lung cancers (NSCLCs) have a poor prognosis. Recent studies have suggested that combined modality treatment of NSCLC may improve survival in selected patients. One of the most critical questions in choosing the appropriate use of combined therapy is determining which patients might benefit from the more aggressive treatment. Recent data have enhanced the idea that inflammation is a critical component of tumour progression. It is now becoming clear that the tumour microenvironment is largely orchestrated by inflammatory cells and it is an indispensable participant in the carcinogenesis. In particular, IL-1β is a pleiotropic pro-inflammatory cytokine and its up-regulation is closely associated with various cancers. Chronic inflammation (sustained by overactivation of IL-1β system) is a crucial event in carcinogenesis and tumor progression and there is evidence that plasma IL-1β level is higher in patients with advanced cancers. Our goal is to determine whether IL-1β expression might be associated with NSCLCs patients` clinical outcome. **Method:** Patients diagnosed with lung cancer stage I and treated with potentially curative resection during 2012 were recruited for this study. Tissue samples (tumor masses including peri-tumoral stroma and lungs) were collected during surgery, embedded in paraffin and processed for immunohistochemistry (IHC). IHC was performed by ABC procedure. Adjacent sections were incubated for 1 h at room temperature with monoclonal antibody against human IL-1β. **Result:** In our randomized experiment 35 patients with NSCLC whose tumor was resected or biopsied were enrolled during 2012 and followed up for 5 years through 2017. Our preliminary results showed that patients with high levels of IL-1β in the peritumoral area, revealed by IHC, present a poor prognosis and a reduced overall survival. **Conclusion:** This retrospective analysis of
patients with stage I NSCLCs who had received standard surgery resulted in statistically significant improvement in overall survival in patients with a low release of IL-1β in the tumor microenvironment. This data defines a new role for IL-1β as a predictive biomarker of NSCLCs tumor behavior that can be used to better profile the use of treatments and improve patients’ outcome.

P3.03-23 A PROPSITY SCORE MATCHING COHORT STUDY ON PROGNOSIS OF THE DIVERSITY OF MUC1 EXPRESSION IN PATIENTS WITH LUNG ADENOCARCINOMA

C. Gu1, Z. Shilie2, L. Zhao2, T. Guo3, P. Wang1
1The First Affiliated Hospital of Dalian Medical University, Dalian/CN, 2Department of Thoracic Surgery, The First Affiliated Hospital of Dalian Medical University, Dalian/CN

Background: To probe the expression of MUC1 (Mucin-1) in lung adenocarcinoma tissues, and estimate the relationship between the expression level of MUC1 and prognosis or clinical pathological factors in patients with lung adenocarcinoma simultaneously, so as to establish personal therapeutic strategies and forecast prognosis.

Method: A retrospective analysis was originally conducted on 182 lung adenocarcinoma patients who underwent surgical resection collected from July 2007 and September 2010 at the First Affiliated Hospital of Dalian Medical University. None of the patients received neoadjuvant therapy. Each tumor was reevaluated according to the current adenocarcinoma classification based on HE stains. Additional immunohistochemical staining for MUC1(Mucin-1) was used in selected cases. Cox proportional hazard regression model was used for univariate analysis. The confounding parameters were compromised by propensity score matching (PSM). Result: Among 182 patients with lung adenocarcinoma, 107 patients were MUC1 low expressed, 44 patients were MUC1 moderate expressed 33 patients were MUC1 high expressed. We found the expression of MUC1 was significantly different in gender (p<0.014), smoking history (p=0.009), T stage (p=0.019), N stage (p=0.015), clinical stage (p=0.024) and the WHO classification of tumors of the lung adenocarcinoma (p=0.002). But we found all above differences among groups were no significance after PSM. Lung adenocarcinoma patients with high MUC1 expression, poorly differentiated and high pTNM stage had early relapse than the other (P<0.05), no matter took PSM.

Univariate analysis of clinical pathologic factors on disease-free survival risk.

P3.03-24 INCORPORATION OF A MOLECULAR PROGNOSTIC CLASSIFIER IMPROVES CONVENTIONAL NON-SMALL CELL LUNG CANCER STAGING

G. Haro1, J. Kratz1, N. Cook1, J. He1, S. Van Den Eeden4, G. Woodard4, M. GuDens1, T. Jahan1, K. Jones1, I. Kim1, B. He1, D. Jablons1, M. Mann4
1University of California, San Francisco/CA/US, 2Department of Epidemiology, Brigham and Women’s Hospital, Boston/MA/US, 3Department of Cardiothoracic Surgery, the First Affiliated Hospital of Guangzhou Medical College, State Key Laboratory of Respiratory Disease, Guangzhou/CN, 4Kaiser Permanente Department of Research, Oakland/CA

Background: Despite significant advancements in the understanding of the molecular genetics of tumor biology, the 8th Edition of Non-Small Cell Lung Cancer (NSCLC) staging adopted in 2018 remains dependent upon tumor size, nodal spread, and metastasis. The survival of patients with early stage NSCLC remains poor and further improvement in staging is needed to better inform adjuvant therapy. In this study, we explored the integration of a clinically validated, molecular prognostic classifier into conventional staging.

Method: A novel staging system, TNMB (“B” indicating Biology), that integrates a 14-gene molecular prognostic classifier with the 8th Edition is being developed using 332 patients with non-squamous NSCLC resected at the University of California, San Francisco (UCSF). TNMB was subsequently validated on a separate multi-institutional international cohort of 1,373 patients. Reclassification metrics were evaluated from adoption of TNMB and the 8th Edition. Result: Adoption of TNMB improved prognostication of overall survival significantly more than adoption of the 8th Edition. TNMB resulted in Net Reclassification Improvement of 0.33 (95% CI 0.24-0.41), relative Integrated Discrimination Improvement of 22.1% (95% CI 8.8-35.3%), and Reclassification Calibration Statistic from 36 to 18 (P-Value 0.03 to 0.73). In contrast, the 8th Edition resulted in no change in Net Reclassification Improvement 0.03 (95% CI 0.00-0.06) or relative Integrated Discrimination Improvement 2.5% (95% CI 17.6-12.4%) and resulted in Reclassification Calibration Statistic from 134 to 22 (P-Value <0.01)

TNMB had distinct separation of survival by stage and larger range of survival between early and late stages compared to conventional staging.

P3.03-25 SQUAMOUS CELL CARCINOMA-ASSOCIATED BRONCHIAL DYSPLASIAS DEMONSTRATE ALTERED T-HELPER LYMPHOCYTE DIFFERENTIATION

D. Merrick\(^1\), E. Donald\(^1\), Y. Miller\(^1\), R. Keith\(^1\), M. Ghosh\(^2\), D. Aisner\(^1\), K. Jordan\(^2\), W. Franklin\(^1\), J. Degregori\(^1\)

\(^1\)Pathology, Mail Stop 8104, University of Colorado, Anschutz Medical Campus, Aurora/CO/US, \(^2\)Research, National Jewish Health, Denver/CO/US.

**Background:** Persistent bronchial dysplasia (BD) is associated with an increased risk for development of invasive squamous cell carcinoma and demonstrates altered polarization of inflammatory cell subsets by gene expression analysis as compared to BD that regresses. We hypothesized that a decrease in the T-helper 1 (Th1) to T-helper 2 (Th2) lymphocyte ratio would be associated with progression to invasive squamous cell carcinoma (SCC). **Method:** vectRA 7-color multispectral staining was applied to formalin fixed paraffin embedded (FFPE) persistent (N=12) and regressive (N=10) BD that also included four biopsies from patients that subsequently developed SCC (3 persistent and 1 regressive, 2 from the actual site of progression). inForm (Perkin-Elmer) image analysis software was used to enumerate cells that showed double positivity for Tbet-CD4 (Th1) and GATA3-CD4 (Th2) and the ratios of the percentage of Th1 and Th2 cells amongst all CD4 positive cells were calculated from multiple lesional fields for each BD (dysplastic epithelium and underlying stroma). DNA extracted from the full remaining FFPE tissue of four of these cases was used to find the proportion of different cells in the tumor microenvironment and to calculate an immunescore. All samples were sequenced employing the Oncomine Comprehensive v3 NGS panel (ThermoFisher) and the number of somatic mutations and variant allele frequencies (VAF) were determined using a threshold of at least 200 total reads and 25 variant reads per variant identified. **Result:** A decreased Th1:Th2 ratio was seen in SCC-associated BD as compared to BD from patients that did not develop lung cancer (p=0.04; ratio = 0.04 vs. 0.68, respectively). No significant difference was seen in persistent versus regressive BD groups. There was an inverse correlation between Th1:Th2 ratios and mutational load (\(r^2=0.21\)) and VAF (\(r^2=0.28\)) although the small number of specimens precluded identification of a statistically significant relationship. **Conclusion:** A decreased Th1:Th2 ratio is associated with BD from subjects that progress to SCC suggesting that alterations in T-helper lymphocyte differentiation may contribute to progression. A potential inverse relationship between Th1:Th2 ratios and mutational load or mutant clonal expansion (increased VAF) will require further study. **Keywords:** Immunoprevention, bronchial dysplasia, progression of premalignancy

P3.03-26 TUMOR IMMUNE MICROENVIRONMENT IN NSCLC IS PREDICTIVE OF PROGNOSIS AFTER SURGERY

A. Øijer\(^1\), A. Halvorsen\(^1\), O. Lindgjærde\(^1\), S. Solberg\(^2\), O. Brustugun\(^2\), A. Helland\(^1\)

\(^1\)Department of Cancer Genetics, Institute for Cancer Research –Ous-Radiumhospital, Oslo/NO, \(^2\)Department of Cardiothoracic Surgery, Ous-Rikshospitalet, Oslo/NO.

**Background:** To investigate the tumor microenvironment in NSCLC and try to understand more about how, and why, it differs in histological and expression subtypes of NSCLC. **Method:** Samples were collected from 399 patients who underwent surgery for stage I-IV NSCLC at Oslo university hospital 2006-16. Gene expression was assessed by using Agilent microarray on samples from adenosarcomas (n=184) and squamous cell carcinomas (n=183) separately. RNA sequencing was performed of 32 samples. Of these 53 % (n=17) were adenosarcomas (AD) and 47 % (n=15) were squamous cell carcinomas (SCC). Xcell(1) was used to find the proportion of different cells in the tumor microenvironment and to calculate an immunescore. All samples were assigned a gene expression subtype by using previously described nearest centroid classifiers for AD and SCC respectively (2, 3) **Result:** For AD we found significant differences in progression free survival (PFS)

Background: Molecular profiling is considered standard of care in advanced NSCLC. Identification of drugable molecular alterations may enhance the percentage of patients suitable for personalized treatment.
Method: From 04/2014 to 03/2017, 602 newly diagnosed, advanced NSCLC patients (pts) were enrolled in SAFIR02-Lung trial (NCT02117167). Molecular profile provided information on copy number alterations and mutations on 71 oncogenes and tumor suppressor genes. The profile was performed for 420 pts (70%) on archival tissue or frozen tissue collected from a new biopsy performed before the 3rd cycle (tissue or liquid) of chemotherapy. The frequency of BRCAl mutation (mut) was assessed and clinicopathologic data collected. A homologous recombinant deficiency (HRD) score was performed on the copy number variations (CNV) data and the germline status was based on blood analysis. The BRCAlshare database of 254 was the reference for the variants classification. Result: 18 pts were identified with BRCAl alterations. BRCAl variants of unknown significance were detected in 11 pts (2.6%). Response to chemotherapy according to RECIST 1.1 by investigator was: 6 stable disease (SD), 1 partial response, and 4 progressive disease (PD). CNV profile was evaluable for HRD in 6 out of 11 pts, with 50% positive. Seven pts (1.7%) were identified with deleterious BRCAl-mut. 2 pts (0.5%) harboured germline BRCAl2-mut (1 with breast cancer familiar history). Both pts had SD to chemotherapy. Somatic BRCAl-mut was identified in 5 pts (1.2%, 2 BRCAl1- and 3 BRCAl2-mut). All were male, 100% adenocarcinoma, 75% smokers of 40 pack/year, 1 pt with familial cancer history, and 80% of pts had bone metastases. Response to chemotherapy was: 4 SD, and 1 PD. Three of 7 corresponding CNV profiles were evaluable for HRD score analysis with 100% positive.

P3.03-28 LKB1 MUTATION STATUS IS ASSOCIATED WITH POOR RADIATION OUTCOME IN PATIENTS WITH NON-SMALL CELL LUNG CANCER
S. Pittideatthaiboon1, A. Cobo2, A. Poteete2, F. Zhang3, D. Lui4, W. Rinssurongkawong5, J. Heymach6
1Division of Medical Oncology, Department of Medicine, Faculty of Medicine, Chulalongkorn University/king Chulalongkorn Memorial Hospital, Bangkok/TH, 2Departments of Thoracic/head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston/TX/US, 3Department of Biostatistics, The University of Texas MD Anderson Cancer Center, Houston/TX/US, 4The University of Texas MD Anderson Cancer Center, Houston/TX/US, 5Thoracic/head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston/ TX/US

Background: Previously, we reported that the upregulation of the NRF2/ KEAP1 pathway in non-small cell lung cancers (NSCLC) bearing co-mutations in KRAS and LKB1 is critical to maintain redox homeostasis which contribute to radiation resistance in these tumors. Here, we explore the role of the LKB1 mutation as a potential predictor radiation outcome in NSCLC.
Method: We retrospectively analyzed the patients undergoing definitive treatment for newly diagnosed NSCLC who were enrolled in the prospectively collected MD Anderson Lung Cancer Moon Shot GEMINI database according to LKB1 mutation status. Cox regression analysis and log-rank tests were used to correlate with radiation outcomes according to LKB1 mutation status and/or KRAS mutation subgroup. We then investigated the mechanisms of radiation resistance in these tumors in preclinical models. Result: Of the 173 patients with stage III NSCLC treated with definitive radiotherapy, with or without chemotherapy were analyzed according to LKB1 mutation status demonstrated that LKB1 mutation had statistically significantly higher rate of loco-regional recurrence, and shorter disease-free survival than in patients with wild type LKB1 (P= 0.013 and P = 0.037, respectively). Moreover, additional loss of either LKB1 or TP53 in KRAS-mutant tumors renders these tumors higher loco-regional recurrence after radiation (P interaction = 0.045). We identified that LKB1 loss is associated with radio-resistance in part by KEAP1/NRF2 pathway activation. Re-expression of LKB1 or NRF2 pathway suppression (via KEAP1 expression) enhanced radiotherapy sensitivity in vivo.

Figure 1. LKB1 mutation status predicts loco-regional failure after radiation in patients with stage III NSCLC.
Background: Although EGFReencoded NSCLC occurs mainly in non-smoking patients, most series report 20–35% of cases in current or previous smokers. Expression profile of EGFReencoded NSCLC in smokers has not been reported. Method: Surgically resected primary EGFRexons 19, 20 and 21 mutated NSCLC tumors from 106 patients were molecuarily profiled by whole exome sequencing using the Illumina HiSeq2000 platform. Alignment and variant discovery analysis was performed according to the CuffLink analyses workflow. 74 sequenced to a minimum coverage of 65.1x. Demographics and outcomes were compared for smokers and non-smokers (non-S), and by mutation profile. Result: Among 53 non-smokers and 21 smokers (5 current/recent within 10 years), 70% were male, 51% non-Asian ethnicity, 58.1% had EGFRexon 19. Of the 74 patients, 51% were stage I, 19% stage II and 30% stage III. Smoking was associated with male sex (p=0.011) and non-Asian ethnicity (p=0.00002) but not age, stage or EGFRexon (3.47±2.7 (I), 3.9±2.5 (II), 3.95±2.5 (III)) in non-S (p=0.11), the strongest prognostic factor for OS and DFS was stage (I, II, III+) (p<0.0001 for each compared to stage I). Smoking history did not have a significant effect on survival: HR 1.61 (CI 0.78–3.32, p=0.2) or probability of relapse: HR 0.9 (CI 0.46–1.77, p=0.77). Smoking within 10 years of NSCLC diagnosis was not associated with worse survival. Multivariate “driver” mutations in patients harboring EGFR exon 19, 20 and 21 mutations or a combination of both in circulation. Four patients displayed a single mutation or a combination of both in circulation. Two patients displayed presence of the respective mutations in both plasma and tumor. Conclusion: Stage remains the strongest prognostic factor for survival and probability of relapse in completely resected EGFReencoded NSCLC. EGFR tumors appear to have an effect on survival outcomes, unlike smoking status, and this effect may be greater in patients older than 65 years.

Keywords: EGFR, NSCLC, TMB
received first-line treatment with pembrolizumab alone or in combination with platinum doublet chemotherapy at the Dana-Farber Cancer Institute were enrolled in this study. Plasma collected from patients prior to starting therapy and again at 3 and 3 weeks after starting therapy was analyzed by NGS using enhanced tagged-amplicon sequencing of hotspots and coding regions from 36 genes (InVisionSeq). The trends of the ctDNA allele frequency were correlated with radiographic responses to therapy. Result: Serial plasma samples were collected on 21 patients with the following characteristics: 67% female, median age 62, 90% adenocarcinoma, 10% squamous cell carcinoma. Pembrolizumab was administered as monotherapy to 18 (86%) patients and in combination with platinum/peemetrexed in 3 (14%) patients for a median of 6 cycles. Among the 8 (38%) patients with no detectable ctDNA at baseline, 5 patients who maintained no detectable ctDNA during serial analyses responded to treatment, and 3 patients with emergence of ctDNA within the first 6 weeks of treatment initiation experienced progressive disease. In the 13 (62%) patients with detectable ctDNA at baseline, radiographic responses were preceded by earlier changes in ctDNA allele frequency. Six of 7 patients with >50% decreases in ctDNA allele fraction responded to treatment while 4 of 6 patients with progressive disease had increases in ctDNA within 6 weeks. Conclusion: In advanced NSCLC treated with first-line immunotherapy, rapid decreases and clearance of ctDNA correlated with clinical benefit, while increasing or newly detectable ctDNA allele was indicative of progressing disease. The results suggest a potential role for ctDNA as an early pharmacodynamic biomarker of response or resistance to immunotherapies.

P3.04-03 ASSOCIATION OF FUNCTIONAL POLYMORPHISM IN CTLA-4 GENE WITH SURVIVAL IN NON-SMALL CELL LUNG CANCER: A BRAZILIAN STUDY
J. Machado-Rugolo1, A. Fabro1, E. Cuestas2, V. De Sa1, C. Rainho1, M. Nagai1, V. Capelo2, M. Balancin1
1Pathology, University of São Paulo, São Paulo/BR, 2Pathology, University of São Paulo, Ribeirão Preto/BR

Background: Blockade of immune checkpoints with monoclonal antibodies has recently emerged as a novel therapy against cancer. Cytotoxic T Lymphocyte Antigen-4 (CTLA-4) is a potent immunoregulatory molecule which regulate T-cell activation and proliferation. The most studied +49A/G polymorphism (rs231775) of the CTLA-4 gene has been associated with several autoimmune diseases and cancer. This study aimed to investigate the relationship between +49A/G polymorphism can predict the prognosis of patients with early stage non-small cell lung cancer (NSCLC) after surgical resection in Brazilian population. Method: Genomic DNA (gDNA) was extracted from formalin-fixed paraffin-embedded NSCLC tissue using the QIAamp DNA Mini Kit (Qiagen, Valencia, USA) following the manufacturer’s recommendations. The CTLA-4 gene was customized in a amplicon-based assay for targeted resequencing by TruSeq Custom Amplicon v1.5kit (TSCA, Illumina) on an Illumina MiSeq instrument (Illumina, San Diego, CA, USA). SNPs with minor allele frequency (MAF) of 0.05 or higher were included. X2 test was used to assess the association between CTLA-4 49A/G SNP and categorical clinicopathologic parameters. The overall survival (OS) estimates were calculated using the Kaplan-Meier method. p < 0.05 was considered as statistically significant. Result: Seventy-five patients with diagnosed NSCLC have been enrolled into this study. According to the pathological reports, the samples included adenocarcinoma (AC, n=52), adenosquamous carcinoma (ASC, n=5), squamous cell carcinoma (SCC, n=15) and large cell carcinoma (LCC, n=3). The CTLA-4 +49A/G genotype frequencies in NSCLC patients were detected with the following disposition: the frequencies of AA, AG and GG genotype were 53.3% (40/75), 33.3% (25/75) and 13.3% (10/75), respectively. We observed that patients with the GG-genotype of CTLA-4 rs231775 had longer OS compared with patients with AG and AA genotypes. This study suggests that CTLA-4 +49A/G could potentially be used as a prognostic biomarker.

P3.04-04 PROGNOSTIC VALUE OF MHC-I, PD-L1 AND CD8+ TILS EXPRESSIONS IN PATIENTS WITH SURGICALLY RESECTED NON-SMALL CELL LUNG CANCER
X. Ding, J. Cui, X. Wang
Cancer Center, the First Hospital of Jilin University, Changchun/CN

Background: Lung cancer is the most commonly diagnosed cancer and also the leading cause of cancer death globally. Chemotherapy showed limited improvement in the survival of surgically resected non-small cell lung cancer (NSCLC) patients. There was no effective prognostic indicators in surgically resected NSCLC. The expression levels of tumor surface molecules, such as major histocompatibility complex class I (MHC-I), programmed cell death-ligand 1 (PD-L1) and CD8+ tumor infiltrating lymphocytes (TILs) were detected in this study to investigate the potential prognostic markers in the patients with surgically resected NSCLC. Method: Tissue of 125 patients with surgically resected NSCLC were obtained from the First Hospital of Jilin University. MHC-I, PD-L1 and CD8+ TILs expressions were detected with immunohistochemistry. The association between their expression levels and patients’ prognosis was analyzed by SPSS 17.0 software (SPSS, Chicago, IL). Result: MHC-I was down-expressed, PD-L1 was up-regulated in NSCLC compared with the adjacent tissues. CD8+ TILs could be seen in tumor stroma and nest. With univariate analysis, we found that the down-expression of MHC-I had an association with poor relapse-free survival (RFS) and overall survival (OS) (P = 0.007 and P = 0.001). RFS and OS in PD-L1− group tended to be longer than that of PD-L1+ group, but the difference was not significant (P > 0.05). Based on the distribution of CD8+ TILs, patients were divided into three groups: immune-inflamed group, immune-excluded group and immune-desert group. RFS and OS of patients with the immune-inflamed phenotype (CD8+ inflamed) were longer than patients with the immune-excluded and immune-desert phenotype (CD8+/CD8 inflamed) (P = 0.013 and P = 0.015). Besides, patients were divided into four subgroups based on the PD-L1 and CD8+ TILs expression: PD-L1+/CD8+ inflamed, PD-L1+/CD8+ non-inflamed, PD-L1−/CD8+ inflamed and PD-L1−/CD8+ non-inflamed. Statistical differences were achieved both in RFS and OS (P = 0.012 and P = 0.032). RFS and OS in patients with PD-L1+/CD8+ inflamed and PD-L1−/CD8+ inflamed were longer than patients with PD-L1−/CD8+ non-inflamed and PD-L1+/CD8+ non-inflamed expressed the worst RFS and OS. With multivariate analysis, we found that MHC-I and CD8+ TILs might be independent prognostic factors in surgically resected NSCLC. Conclusion: MHC-I and CD8+ TILs expression had a close association with patients prognosis in this study. The combination of PD-L1 and CD8+ TILs, instead of PD-L1 alone, suggested impressive prognostic values in NSCLC patients. It worth further study to confirm the clinical value of MHC-I, PD-L1 and CD8+ TILs expressions in the patients with surgically resected NSCLC.

P3.04-05 PROGRAMMED DEATH-LIGAND 1 OF CYTOLOGY SPECIMENS AS A PROMISING METHOD FOR MAKER EVALUATION IN PATIENTS OF NON-SMALL CELL LUNG CANCER
Z. Dong
Shanghai Pulmonary Hospital, Shanghai/CN

Background: Measuring programmed death-ligand 1 (PD-L1) expression has been commonly used to classify the promising patients for immunotherapy. PD-L1 heterogeneous expression has been elucidated within the tumor. Therefore, we questioned whether small tissue samples, such as cytology samples, sufficiently represented PD-L1 expression in non-small cell lung cancer (NSCLC). Method: Paired cytological cell block and surgical resection before systemic therapy was assessed. PD-L1 expression was quantified by using both 28-B and SP142 assays. Feasibility of PD-L1 expression in cell blocks was compared with that in matched surgical resection with various cutoffs. Result: A total of 112 pairs of specimens were collected at the time of initial diagnosis, including 79(63.2%) adenocarcinomas and 28(25.0%) squamous cell carcinomas. PD-L1 expression showed fair to substantial concordance between cytology specimens and surgical resection for both antibodies' staining (Conclusion: PD-L1 expression of cytology specimens with high tumor cells showed concordance with surgical resection. These findings suggested that cytology specimens might be adequate representative for PD-L1 expression of patients with NSCLC.

P3.04-06 PROGNOSTIC SIGNIFICANCE OF SERUM CXCL12 LEVEL IN PATIENTS WITH SURGICAL RESECTED LUNG ADENOCARCINOMA
J. Hung, W. Hsu
Taipei Veterans General Hospital and National Yang-Ming University, Taipei/TW

Background: Lung cancer is the leading cause of cancer-related death in the world. Cytokines are a heterogeneous group of soluble small polypeptides or glycoproteins. The tumor microenvironment is rich in cytokines and other inflammatory mediators that influence immunosuppression, cancer cells growth, tissue remodeling and angiogenesis. In this study, we determined the prognostic value of selected cytokines or chemokines in patients with lung adenocarcinoma.

Method: Sixty-three patients undergoing surgical resection for lung adenocarcinoma were enrolled in this study. A total of 63 serum samples from these patients were used for study. The levels of cytokines/chemokines in these serum samples were determined by cytokine bead array according to manufacturer's instruction. The following cytokines/chemokines have been examined, including interleukin-1b (IL-1b), IL-6, IL-8, IL-10, CXCL9, CXCL10, CXCL12, CCL19, CCL21, and CCL25.

Result: With a median follow-up time of 62.3 months (range, 0.7 to 94.1 months), the 5-year overall survival rate was 88.1%. To determine the expression of cytokines/chemokines in lung adenocarcinoma serum samples, cytokometric bead array was performed in 63 lung adenocarcinoma serum samples. Univariate analysis indicated that stage II and III (vs. stage I) (P = 0.016) was a significant prognostic factor for worse overall survival. Poor differentiation (P = 0.062) and CXCL12 overexpression (P = 0.052) tended to be significant prognostic factors for worse overall survival. IL-1b, IL-6, IL-8, IL-10, CXCL9, CXCL10, CXCL12, CCL19, CCL21, and CCL25 were not significant prognostic factors for overall survival. The advanced stage (II and III vs. I) (hazard ratio [HR], 7.775; 95% confidence interval [CI], 1.243 to 48.618; P = 0.028), poor differentiation (HR, 7.995; 95% CI, 1.092 to 58.547; P = 0.041) and CXCL12 overexpression (HR, 7.307; 95% CI, 1.163 to 45.889; P = 0.034) were still significant prognostic factors for worse overall survival in multivariate analysis. Male sex (P = 0.007) was significantly associated with CXCL12 overexpression. Conclusion: CXCL12 overexpression was a significant prognostic factor for worse overall survival in patients with surgical resected lung adenocarcinoma. Male sex was significantly associated with CXCL12 overexpression. CXCL12 overexpression has the potential to be used as a predictor of worse outcome in lung adenocarcinoma patients after surgical resection.

P3.04-07 CORRELATION BETWEEN PD-L1 EXPRESSION AND EXPRESSION OF CDK4 AND SPOP IN NON-SMALL CELL LUNG CANCER
M. Inoue, J. Yoshiida, S. Oka, Y. Honda, D. Yasuda
Chest Surgery, Shimaneoki City Hospital, Shimaneoki/JP

Background: Immunotherapy that targets programmed cell death protein 1 (PD-1) and programmed cell death-ligand 1 (PD-L1) has emerged as a novel treatment modality for cancers. Clinical trials have reported durable responses and long-term remissions using PD-1/PD-L1 inhibitors, and the expression level of PD-L1 at the tumor cells was correlated with a response to PD-L1/PD-L1 inhibitors. However these inhibitors are reported that PD-L1 expression can be regulated at both transcriptional and post-translational levels, such as cyclinD-CDK4 and the cullin 3-SPOP complex, which is determined by cytokine bead array.

Method: We investigated CDK4, CDK6 and SPOP expression of lung cancer, and CD4 and CD8 expression of tumor-infiltrating lymphocytes (TILs) by immunohistochemistry of 36 non-small cell lung cancers, those had an operation or chemotherapy from March 2007 to January 2018 and analyzed PD-L1 expression. The staining intensity of CDK4, CDK6 and SPOP was scored as 0 (negative), 1 (weak), 2 (medium), and 3 (strong). Extent of staining was scored as 0 (0-10%), 1 (11-25%), 2 (26-50%), 3 (51-75%), and 4 (76-100%) according to the percentages of the positive staining areas in relation to the whole cancer area. For CD4 and CD8+ cell, a maximum numbers of stained cell were counted semi-quantitatively in high-powered fields for the scoring as 1-4. The observed protein expression levels and TILs counts were analyzed for correlation to PD-L1 expression, clinicopathological parameters and the responses of PD-1 inhibitors.

Result: PD-L1 expression was observed in 15 (48%) patients of lung cancer, 8 (26%) of low expression and 7 (23%) of high expression. Positive expression rates of SPOP and CDK4 were 56.3% and 76.3%, respectively. The positive rate of SPOP (p = 0.67), CDK4 (p = 0.16) and CDK6 (p = 0.37) in PD-L1 positive group was lower than that of PD-L1 negative group, but significant. CD8+ cell count was positive relation to PD-L1 expression.

Conclusion: Our data supported previous findings that inhibition of CDK4 and CDK6 increases PD-L1 protein levels and SPOP-deficiency correlated with increased PD-L1 protein abundance.

Keywords: PD-L1, SPOP, CDK4

P3.04-08 IDENTIFYING RESISTANCE TO IMMUNE CHECKPOINT INHIBITORSBY SCREENING FOR PD-L1 AND MHC I EXPRESSION ON CTCs IN PTS WITH NSCLC
T. Leal†, J. Schehr‡, A. Kaminski‡, T. Campbell§, A. Traynor¶, J. Lang†
†Medicine/oncology, University of Wisconsin Carbone Cancer Center, Madison/US, ‡Medicine/oncology, University of Wisconsin, Madison/WI/US, §Medicine/oncology, University of Wisconsin Carbone Cancer Center, Madison/WI/US

Background: PD-L1 expression on tumor predicts benefit to immune checkpoint inhibitors (ICIs) in patients with advanced NSCLC. However, there is no significant number of patients whose tumor test positive for PD-L1 expression that do not derive benefit from ICIs, suggesting the existence of intrinsic resistance mechanisms. PD-L1 blockade aims to trigger tumor cell recognition and lysis by CD8+ T cells, but this process requires concurrent expression of MHC I by tumor cells. Recently, MHC I negativity was observed in 49% of patients with lung carcinoma, and correlated with a lack of CD8+ T cell infiltration, emphasizing the importance of screening for MHC I in combination with PD-L1. Method: For the purposes of both screening and the detection of acquired resistance, we developed a minimally invasive diagnostic test using Circulating Tumor Cells (CTCs). CTCs were captured and stained on the ExtractMax system (Gilion, Inc.) with Exclusion-Based Sample Processing (ESP) technology (Salus Discovery, LLC). With automation, the ExtractMax simplifies complex multi-step procedures, reduces variability, and ensures gentle manipulation of rare cell targets for optimal yield and viability.

Result: A range of PD-L1 and MHC I expression levels were detected on CTCs captured from a cohort of patients with NSCLC, with two patients showing no MHC I expression and all others with heterogeneous expression of MHC I. PD-L1 expression was variable across all samples tested with subset of patients with PD-L1 positive CTCs but MHC I negative, suggesting intrinsic resistance to PD-L1 targeted therapies.

Conclusion: This data supports the feasibility of using an automated CTC processing system to detect and monitor PD-L1 and MHC I expression in patients with NSCLC. Ongoing efforts include expanding this patient cohort in larger clinical trials and transitioning this test into a clinical laboratory testing facility for regulatory approval and use as a clinically actionable diagnostic tool.

**Background:** T cells can recognize peptides encoded by mutated genes. Assessed the repertoire features of TCR is vital for us to understand immune behavior and immune response. However, detailed characterization of the peripheral blood T cell receptor (TCR) repertoire, its interaction with the surrounding tumor microenvironment, has been insufficiently studied. **Method:** We used deep sequencing of rearranged genes in TCR gamma (TCRγ) to profile the basic characteristics of T cells in peripheral blood samples of 37 treat-naïve EGFR wild-type lung cancer patients. The study was carried out on patients with metastatic non-small cell lung cancer (mNSCLC) to identify clinical and laboratory factors associated with response to ICI.

**Result:** Data showed that healthy donors had more TCR clonotypes and higher diversity while patients represented with restricted TCR repertoire. Interestingly, TCR repertoire was associated with TP53 mutation status, tumor volume, rapid progression and squamous cell carcinoma antigen (SCC) level in patients, but not with metastasis. Patients with TP53 mutation had fewer clonotypes (p=0.011), lower diversity (p=0.006) and higher clonality (p=0.054), while those with larger tumor volume and rapid progression following chemotherapy had fewer clonotypes (p=0.046 and p=0.011, respectively) in peripheral blood. Peripheral blood TCR repertoire was not significant correlated with brain metastasis or bone metastasis. Additionally, co-linearity was positive correlation with SCC Concentration (p=0.024; R=0.48, n=22).

**Conclusion:** Our study profoundly provides new knowledge about the T cells among treat-naïve EGFR wild-type lung cancer patients and provides new insight into the TCR repertoire associated with clinical presentation in lung cancer patients. And the TCR repertoire in peripheral blood samples before treatment may be used as a predictor of rapid progression in lung cancer patients treated with chemotherapy.

Overall median (m) PFS and mOS were 3.93 months (mo) and 20.7 mo respectively. Baseline absolute neutrophil count (ANC) ≥ 7500/µL and neutrophil to lymphocyte ratio (NLR) ≥5 correlate with worse PFS (3.3 mo vs 5.5 mo, p=0.04 and 2.8 mo vs 5.4 mo, p=0.006 respectively) and OS (15.6 mo vs 34.9 mo p=0.02 and 16.7 vs 34.9 mo p=0.004, respectively). Poor OS and PFS were persist at week 2 in pts with NLR ≥5 (HR=0.3, p=0.0001 for OS and PFS), this was not significant at week 4. Also, baseline derived neutrophil to lymphocyte ratio (dNLR) >3 correlate with worse PFS (p=0.01) and OS (p=0.016). Absolute lymphocyte count (ALC) ≥1000/µL at baseline and week 2 confer higher PFS (5.3 mo vs 3.1 mo, p=0.05) and a trend in OS. Interestingly, week-4 absolute monocytic count (AMC) ≥1000/µL imply a poor PFS and this was not observed at baseline and week 2. Low, absolute eosinophil count (AEC) <50/µL correlate with worse PFS (p=0.031). Finally, pts with lymphocyte monocyte ratio (LMR) ≥1.5 at baseline, week 2 and 4 correlate with better survival. Table 1 Univariate analysis of peripheral blood biomarker and survival outcome in NSCLC patients treated with immunotherapy.

P3.04-13 PD-L1-GENE EXPRESSION BY NCOUNTER CORRELATES WITH PD-L1 PROTEIN EXPRESSION IN ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC)
C. Cabrera1, C. Agudó1, C. Teixidó1, L. Pare1, J. Castellvi2, L. López3, E. Marin4, X. Bernal5, D. Martínez1, A. Giménez-Capitán2, N. Vinolas1, Z. Yeste1, N. Baixeras1, R. Roman2, M. Molina-Vila2, N. Reguart1
1Hospital Clinic. Translational Genomics and Targeted Therapeutics in Solid Tumors, Institut D Investigacions Biomediques August Pi i Sunyer (Idibaps), Barcelona/ES, 2Laboratory of Oncology/pangaea Oncology, Hospital Universitario Quiron Dexeus, Barcelona/ES, 3Translational Genomics and Targeted Therapeutics in Solid Tumors Lab August Pi i Sunyer Biomedical Research Institute (Idibaps), Barcelona/ES, 4Pathology, Hospital de La Santa Creu i Sant Pau, Barcelona/ES, 5Hospital de Granollers, Granollers/ES

Background: PD-L1 immunohistochemistry (IHC) staining is a Food and Drug Administration-approved marker to identify patients for immunotherapy treatment in advanced non-small cell lung cancer (NSCLC). However, several antibodies and cut-off criteria have been used and pathological evaluation involves a certain degree of subjectivity. Multiplexed technologies can be of help in this setting and provide an objective measurement of PD-L1 levels. Method: A 7-gene ‘immune signature’ comprising CD4, CD8, PD-1, PD-L1, IFNG, GZMM and FOXP3 was incorporated into our routine clinical practice as part of a customized nCounter panel (NanoString Technologies), which simultaneously screens for gene fusions (ALK, ROS1, RET and NTRK1), MET overexpression and MET exon 14-skipping mutations. Formalin-fixed paraffin embedded (FFPE) samples from advanced NSCLC patients were analyzed with the panel and compared with PD-L1 IHC evaluation on tumor cells, using 22C3 clone antibody. Result: Since 2017, a total of 296 FFPE samples have been analyzed with the nCounter panel. PD-L1 IHC has been performed in 113 FFPE samples, as requested by the oncologist. All samples were evaluable for nCounter and IHC (100%). By IHC, 48/113 samples (42.5%) were scored as negative for PD-L1 protein expression, whereas 65/113 (57.5%) were evaluated as positive. Of those, 39 presented moderate (≥1-49%) and 26 (23%) high PD-L1 staining (≥50%). Using an appropriate cut-off value, the levels of PD-L1 mRNA, as determined by the nCounter panel, closely correlated the PD-L1 IHC evaluation, with a 78% of concordance and a 0.554 Cohen’s kappa (confidence interval 95% 0.400–0.709). Conclusion: PD-L1 mRNA expression closely correlates with PD-L1 protein expression. Clinical validation is warranted to determine if nCounter can be an alternative to IHC for PD-L1 evaluation.

Keywords: IHC, nCounter, PD-L1

P3.04-14 TMB AND IMMUNE CHECKPOINT INHIBITOR GENE EXPRESSION ARE UNRELATED IN NSCLC PATIENTS
C. Szeto1, R. Parulkar2, C. Garner3, S. Reddy4
1R&d, Nantomics, Llc, Santa Cruz/CA/US, 2R&d, Nantomics Llc, Santa Cruz/CA/US, 3Nantomics, Culver City/CA/US, 4Oncology, Nant Health, Culver City/CA/US

Background: Tumor Mutation Burden (TMB) is an emerging biomarker for response to immune checkpoint inhibitor therapy (ICT). PDL1 is still the only companion diagnostic test for ICT. We sought to examine the relationship between TMB based on whole exome sequencing (WES) data and ICT gene expression.

Method: Retrospective analysis of a database from a commercial DNA tumor:normal and RNAseq platform was carried out. 112 samples were identified with tumor and normal DNA sequencing (WGS or WES) and RNA sequencing. A “high” vs “low” mutation burden was defined with a threshold of 200 exonic non-synonymous mutations. ICT gene expression of 12 checkpoint markers (CTLA4, IDO, FOXP3, LAG3, TIGIT, VEGFA, VEGFC, VEGFB, PDL2, PDL1, OX40, & TIM3) were analyzed for tissue-specific enrichment and within the TMB high and low categories. Immune-cell infiltration was estimated using RNA deconvolution based on known immune cell marker genes (Bindea et al 2013).

Result: 52 of the 112 patients had high TMB based on the defined threshold. ICT gene expression was not significantly different in the TMB high and low groups and none of the 12 ICT markers showed a significant correlation with TMB. Age and gender did not affect TMB.

Conclusion: Quantitative TMB may be a marker of ICT efficacy independent of ICT gene expression.

Keywords: immuno-oncology, checkpoints, TMB
Background: Tumor cells evade immunosurveillance by expression of immune checkpoint proteins PD-L1, IDO, and TIM3, even when tumor-infiltrating lymphocytes (TILs) are present. Combination of checkpoint inhibitors Pembrolizumab (PD-L1) and Epacadostat (IDO) failed to show synergy in melanoma. Yet there are several candidate targets versus checkpoint inhibition and rational selection of which combinations to explore is lacking. In particular, which checkpoints to target when PD-L1 is not expressed is largely unexplored. The purpose of this study was to assess the expression of 12 immune-checkpoint genes in lung cancer patients with high and low expression of PD-L1.

Method: Retrospective review of deep whole transcriptomic sequencing (RNA-Seq) (~200x10^6 reads per tumor) on 1467 unselected clinical cases from NanHealth. 112 NSCLC cases were categorized as PD-L1-low and PD-L1-high by median splitting. Expression and co-expression of 12 checkpoint markers (CTLA4, IDO, FOXP3, LG3, TIM3, VEGFA, VEGFC, VEGFB, PD-L2, PD-L1, OX40, & TIM3) were analyzed for tissue-specific enrichment and within PD-L1-defined categories. Immune-cell infiltration was estimated using RNA deconvolution based on known immune cell marker genes (Bindea et al 2013). Result: CTLA, TIM3 and FOXP3 showed high correlations across all 112 samples as well as within the PD-L1 low and high expression groups and differential expression across the two groups, with higher expression of the markers among the PD-L1 high expression group versus the low group. Within the PD-L1 high expression group, the expression of markers LG3, TIM3, OX40, FOXP3, CTLA4 and TIM3 was both higher and more highly correlated with each other (R=0.72, p=3.85x10^-10). Conclusion: PD-L1 is a primary driver of immune suppression, however when PD-L1 is low there may be some differential role for IDO or TIM3. Combination IDO and Tim3 should be considered in PD-L1 low patients.

Keywords: nCounter, PD-L1, Immune genes
Background: The value of combination therapy with immune checkpoint inhibitors (ICI) for patients with solid tumors remains unclear. We conducted a meta-analysis to evaluate the combination therapy with immune checkpoint inhibitor (ICI) for patients with solid tumors. Method: Pub-med, EMBASE, Cochrane Library and ClinicalTrials.gov website were searched for eligible randomized controlled trials (RCTs). The selection criteria were defined according to the PICOS (population, intervention, comparison, outcome and study design) framework. We assessed overall response rate (ORR), progression free survival (PFS), overall survival (OS) and grade 3 or 4 adverse effects (AEs). Pooled hazard ratio (HR) for survival outcomes (PFS and OS) and pooled risk ratio (RR) for dichotomous data (ORR and AEs) were calculated. Result: 17 RCTs with 6,166 patients were included in this meta-analysis. The combination therapy of ICI was significantly associated with improvement of ORR (RR = 1.56 [95% CI 1.24, 1.96], P = 0.0001), PFS (HR = 0.69 [95% CI 0.59, 0.81], P < 0.0001) and OS (HR = 0.76 [95% CI 0.67, 0.87], P < 0.0001) in solid tumor. In subgroup analyses, combination ICI therapy obviously prolonged OS in melanoma patients (HR = 0.64 [95% CI 0.57, 0.73], P < 0.0001, RR = 0.66) but not in SCLC (HR = 1.04 [95% CI 0.82, 1.08], P = 0.40) and NSCLC (HR = 0.92 [95% CI 0.79, 1.07], P = 0.26) patients. As for toxicity, there was an increased risk of fatigue, rash, diarrhea and increased transaminases with combination ICI therapy. Conclusion: In conclusion, our meta-analysis found that combination ICI showed significant benefits in ORR, PFS and OS for patients with solid tumors. Both of combination of ICI with chemoradiotherapy and dual ICI were effective and relatively safe. Melanoma patients got definite survival benefit from combination ICI therapy. There was also a tendency of improved survival for SCLC and NSCLC patients.

P3.04-18 THE EFFICACY AND SAFETY OF SOLID TUMORS COMBINATION THERAPY WITH IMMUNE CHECKPOINT INHIBITOR: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Peng, Y. Weng, Y. Yao, Q. Song
Department of Oncology, Renmin Hospital of Wuhan University, Wuhan/CN

Background: The efficacy and safety of immune checkpoint inhibitors (ICIs) for patients with solid tumors remains unclear. We conducted a meta-analysis to evaluate the combination therapy with immune checkpoint inhibitor (ICI) for patients with solid tumors.

Method: Pub-med, EMBASE, Cochrane Library and ClinicalTrials.gov website were searched for eligible randomized controlled trials (RCTs). The selection criteria were defined according to the PICOS (population, intervention, comparison, outcome and study design) framework. We assessed overall response rate (ORR), progression free survival (PFS), overall survival (OS) and grade 3 or 4 adverse effects (AEs). Pooled hazard ratio (HR) for survival outcomes (PFS and OS) and pooled risk ratio (RR) for dichotomous data (ORR and AEs) with 95% CI were calculated.

Result: 17 RCTs with 6,166 patients were included in this meta-analysis. The combination therapy of ICI was significantly associated with improvement of ORR (RR = 1.56 [95% CI 1.24, 1.96], P = 0.0001), PFS (HR = 0.69 [95% CI 0.59, 0.81], P < 0.0001) and OS (HR = 0.76 [95% CI 0.67, 0.87], P < 0.0001) in solid tumors. In subgroup analyses, combination ICI therapy obviously prolonged OS in melanoma patients (HR = 0.64 [95% CI 0.57, 0.73], P < 0.0001, RR = 0.66) but not in SCLC (HR = 1.04 [95% CI 0.82, 1.08], P = 0.40) and NSCLC (HR = 0.92 [95% CI 0.79, 1.07], P = 0.26) patients. As for toxicity, there was an increased risk of fatigue, rash, diarrhea and increased transaminases with combination ICI therapy.

Conclusion: In conclusion, our meta-analysis found that combination ICI showed significant benefits in ORR, PFS and OS for patients with solid tumors. Both of combination of ICI with chemoradiotherapy and dual ICI were effective and relatively safe. Melanoma patients got definite survival benefit from combination ICI therapy. There was also a tendency of improved survival for SCLC and NSCLC patients.

P3.04-20 CORRELATION OF IMMUNE-RELATED ADVERSE EVENTS AND RESPONSE FROM IMMUNE CHECKPOINT INHIBITORS IN PATIENTS WITH ADVANCED NSCLC

M. Sung1, A. Zer2, P. Walla3, L. Khoda1, M. Maganti1, C. Labbe1, F. Shepherd4, P. Bradbury4, G. Liu5, N. Leigh1
1Princess Margaret Cancer Centre, Toronto/ON/CA, 2Thoracic Cancer Service, Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, 3Division of Respiratory and Thoracic Surgery, Institut Universitaire de Cardiologie Et de Pneumologie de Quebec, Quebec City/QC/CA

Background: Immune checkpoint inhibitors (ICIs) are associated with a unique set of toxicities termed immune-related adverse events (irAEs). The association between response to ICI therapy and development of irAEs has been documented in various cancer types. Method: Stage IV non-small cell lung cancer (NSCLC) patients treated with ICIs at the Princess Margaret Cancer Centre between 2013 and 2016 were followed for treatment response, treatment duration, survival, and toxicity. The relationship between treatment outcomes and occurrence of irAEs was examined. Result: A total of 97 advanced NSCLC patients were followed. Most patients (81%) received anti-PD-1 agents, 17% received anti-PD-L1 agents, and 2% received combination anti-PD-L1 plus anti-CTLA-4 therapy. Median follow up for the cohort was 5.1 months (0.3-38.1 months) from treatment start. Demographic and tumour characteristics were balanced between the groups. irAEs occurred in half of patients (51%) on ICIs and grade ≥3 irAEs in 7%. The most commonly observed irAEs were arthralgia (13%), diarrhea/colitis (12%), and skin rash (11%). Discontinuation of treatment due to irAEs occurred in 10% of patients, half of whom experienced grade ≥3 irAEs. The overall response rate to ICIs was 23%, with the majority occurring by week 8 of treatment (16/22). Response was non-evaluable in one patient and this was excluded from response analysis. Patients with grade ≥3 irAEs were more likely to have response to treatment compared to those with grade I/II irAEs and no irAEs (67% vs 17% vs 23%, p = 0.035). Table 1. Smoking status was not associated with response rate or frequency of irAEs. Median survival was not reached in those with grade ≥3 irAEs, 15.7 months in those with grade I/II irAEs, and 7.4 months in those with no irAE (p = 0.16). Duration of treatment did not differ significantly among the groups.

Conclusion: The occurrence of grade ≥3 irAEs may be associated with treatment response in advanced NSCLC patients undergoing ICI therapy.

Keywords: immune related adverse event, immune checkpoint inhibitor, lung cancer
Background: Immune checkpoint inhibitors (ICIs) targeting PD-1/L1 have shifted the treatment paradigm of advanced non-small cell lung cancer (NSCLC), but responses are often heterogeneous and temporary. Several landmark publications have confirmed the dominant role of gut microbiome in modulating tumor responses to ICIs, suggesting the predictive value of antibiotics (ATB) in patients treated with anti-PD-(L)1 antibody. However, more evidence is needed to comprehensively reveal the association between ATB usage and ICIs therapeutic response in NSCLC, especially in Chinese populations.

Method: We retrospectively reviewed the medical records of patients with advanced/metastatic NSCLC who received anti-PD-(L)1 based therapies at our hospital. Detailed clinicopathologic characteristics, response data and ATB usage were collected for all patients. The patients receiving ATB within one month around the first administration of ICIs (defined as ATB-treated) were compared to those without (ATB-untreated). Result: 109 cases receiving anti-PD-(L)1 based therapies and underwent response evaluation were identified. 65 (59.3%) of them received monotherapy and 44 received combination therapies including anti-PD-(L)1 plus anti-angiogenesis/chemotherapy. 35 (32.1%) patients had been prescribed ATB 60 days before or during the course of ICIs treatment, and 20 (18.3%) were categorized as ATB-treated group. The most commonly administered ATB were β-lactam inhibitors, fluoroquinolones and macrolides. No major statistical differences in baseline clinicopathologic features were observed between ATB-treated and -untreated groups. The objective response rates (ORR) to ICIs in two groups were 65% and 82%, respectively. ATB treatment was significantly associated with shorter progression-free survival (PFS) (median 3.73 vs 9.3 m, p<0.001), and also tended to be associated with primary disease progression (35% vs 18%, p=0.087). The overall survival (OS) (median 31.9 vs 37.6 m, p=0.74) was similar in two groups, but ATB appeared to be related to decreased duration of survival from ICIs treatment start to death (median 6.07 vs 26.9 m, p=0.002). In multivariable analysis, ATB treatment was markedly associated with poorer ORR and survival to ICIs after adjusting for prior line treatment setting, ICI regimens, numbers of ICI-related toxicity and clinical characteristics. Conclusion: ATB usage was a predictor for decreased clinical benefit from anti-PD-(L)1 Immunotherapies in Chinese NSCLC patients. More comprehensive understanding of the interaction between gut microbiome and ATB is still in urgent need. Furthermore, modulating ATB-related gut microbiome dysbiosis may enhance response to anti-PD-(L1) immunotherapies.

Keywords: Antibiotics, non-small cell lung cancer, anti-PD(L1) immunotherapy

Background: Patients with mutant EGFR (EGFRm) non-small cell lung cancer (NSCLC) have a limited chance of benefiting from treatment with programmed death-1 inhibitors. EGFRm activation leads to overexpression of CD73 and may provide a mechanism of immune evasion. CD73 is a cell surface enzyme which catalyzes the enzymatic production of adenosine from ATP. CD73 activity is regulated by the A2A receptor (A2AR). Azd4635 is a potent, selective A2AR antagonist that inhibits this signaling pathway. However, more evidence is needed to comprehensively reveal the immunomodulatory effects of CD73 inhibition. This phase Ib/2 study will evaluate the antitumor activity of azd4635 in combination with atezolizumab in subjects with EGFRm NSCLC.

Method: A multi-arm, open-label, multicenter, phase 1b/2 study (NCT03381274) consisting of 2 parts. In Part 1, the safety and tolerability of azd4635 in combination with either osimertinib (Arm A) or AZD4635 (Arm B) will be evaluated, and a recommended phase 2 dose for each combination will be identified. In Part 2, the safety, tolerability, and preliminary antitumor activity will be evaluated. In Part 2, the primary objective of antitumor activity will be assessed by objective response according to RECIST v1.1. Key secondary objectives include additional evaluation of clinical activity, the pharmacokinetic profiles of azd4635 and osimertinib, and the evaluation of azd4635 immunomodulatory effects. Additional treatment arms may be added as the study progresses. The study is open for enrollment and recruitment is ongoing. In Part 2, a planned enrollment of up to approximately 98 patients.

Result: As of June 2018, 27 patients with NSCLC were treated across all dose levels. In 20 patients treated with the highest dose of azd4635 (70 mg/kg) combined with osimertinib, one patient achieved a partial response and two had stable disease. In 11 patients treated with the highest dose of azd4635 (35 mg/kg) combined with AZD4635, no responses were observed. In the safety analyses, the most common adverse events were fatigue, nausea, and diarrhea. No dose-limiting toxicities were observed.

Conclusion: Azd4635 is well tolerated in combination with either osimertinib or AZD4635. Further evaluation of this combination is warranted.

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.04-25 EMPOWER-LUNG 3: A PHASE 3 STUDY OF CEMIPLIMAB, IPIPLUMAB AND CHEMOTHERAPY IN ADVANCED NSCLC WITH PD-L1 <50%  
N. Rizvi1, S. Lee2, P. Curtis3, W. Caldwel4, B. Gao5, P. Rietschel6  
1Columbia University Medical Center, New York/NY/US, 2Regeneron Pharmaceuticals, Inc., Tarrytown/NY/US  

Background: Immune checkpoint inhibitors have shown clinical activity in multiple tumor types, including NSCLC, which accounts for 80–85% of all lung cancers. Median progression-free survival (PFS) with platinum-based doublet chemotherapy ranges from 2.7–6.4 months. Cemiplimab (REGN2810), a human monoclonal antibody to PD-1, has exhibited antitumor activity and safety in a phase 1 trial of advanced malignancies including NSCLC. Recognizing that NSCLC tumors express PD-L1, combining cemiplimab with other immunotherapies and/or chemotherapy has the potential for a synergistic effect in patients with advanced NSCLC. 

Method: EMPOWER-lung 3 (16113) is a randomized (1:1:1), open-label, global, phase 3 study of the efficacy and safety of combinations of cemiplimab, ipilimumab, and platinum-based doublet chemotherapy vs pembrolizumab monotherapy in the first-line treatment of patients with stage IIIIB or stage IV squamous or non-squamous NSCLC with tumors expressing PD-L1 ≥50% (EudraCT 2017-001041-27). Patients who have received prior systemic treatment for their advanced disease will be excluded. Patients will be stratified by histology and randomized into three study arms: Arm A: standard of care pembrolizumab monotherapy for 108 weeks; Arm B: cemiplimab every 3 weeks (Q3W) for up to 108 weeks plus ipilimumab 50mg every 6 weeks (Q6W) (4 doses); Arm C: cemiplimab Q3W for up to 108 weeks plus platinumdoublet Q2W (2 doses) and ipilimumab 50mg Q6W (4 doses). The primary objective is to evaluate PFS. Key secondary objectives include overall survival and overall response rates. Assuming a median PFS of 10 months for patients treated with pembrolizumab monotherapy and a median PFS of 15 months for patients treated with each of the cemiplimab combination therapies, 585 patients are needed to obtain sufficient PFS events for the analysis of PFS with 90% power to detect statistical significance for each of cemiplimab combination vs pembrolizumab monotherapy comparison. This study is open for enrollment with the first patient’s first visit planned for Q3 2018 and the last patient’s last visit planned for Q1 2023.

Conclusion: Section not applicable  

Keywords: cemiplimab, Anti-PD-1, REGN2810

P3.04-26 EMPOWER-LUNG 4: A PHASE 2 STUDY OF CEMIPLIMAB PLUS IPIPLUMAB IN THE SECOND-LINE TREATMENT OF ADVANCED NSCLC WITH PD-L1 <50%  
N. Rizvi1, S. Lee2, P. Curtis3, W. Caldwel4, B. Gao5, P. Rietschel6  
1Columbia University Medical Center, New York/NY/US, 2Regeneron Pharmaceuticals, Inc., Tarrytown/NY/US  

Background: Immune therapies have been investigated as potential therapeutic approaches to improve survival and quality of life in patients with advanced NSCLC. With monotherapy PD-1 blockade, the greatest benefit was seen in patients with tumor proportion score (TPS) of PD-L1 immunoreactivity of ≥50%. Patients with TPS <50% will likely require a combination approach. Cemiplimab (REGN2810), a human monoclonal antibody to PD-1, has exhibited antitumor activity and safety in a phase 1 trial of advanced malignancies including NSCLC. Combination of cemiplimab with other therapies may improve overall response rate (ORR) in patients with advanced NSCLC whose tumor have TPS <50%. 

Method: EMPOWER-lung 4 (1763) is a randomized (1:1:1), open-label, global, phase 2 trial of the efficacy and safety of high-dose (HD) vs standard-dose (SD) cemiplimab in combination with ipilimumab vs SD cemiplimab in the second-line treatment of patients ≥18 years old with advanced NSCLC with tumors expressing PD-L1 ≥50% (NCT03430063). Patients will be stratified by histology and PD-L1 expression level (<1% vs 1–49%), and randomized to Arm A: SD cemiplimab every 3 weeks (Q3W); Arm B: HD cemiplimab Q3W in combination with ipilimumab 50 mg every 6 weeks (up to 4 doses); or Arm C: HD cemiplimab Q3W. Patients will receive cemiplimab for up to 108 weeks or until progression. The primary objective is to evaluate ORR (complete response + partial response) based on RECIST v1.1 assessed by blinded, independent review committee. Key secondary objectives include the assessment of overall survival, progression-free survival, and safety/tolerability of the study drugs. Assuming an ORR of 10% in Arm A and 30% in each of Arm B and Arm C, 201 patients (67 per Arm) will yield an 80% power to detect a statistically significant difference for HD or SD cemiplimab in combination with ipilimumab vs SD cemiplimab. This study is open for enrollment with the first patient’s first visit planned for Q2 2018 and the last patient’s last visit planned for Q4 2021. 

Result: Section not applicable  
Conclusion: Section not applicable  

Keywords: Anti-PD-1, cemiplimab, REGN2810
month x 6 with or without daily oral metronomic cy/cel. The primary endpoint was serologic response to a panel of purified CG as well as carbohydrate antigens assessed in a blinded manner by ELISA or glycan array techniques, respectively, 1 month after the 6th vaccination. Immune subsets were assessed in peripheral blood (p-values uncorrected for multiple comparisons). Standard of care imaging studies were obtained at baseline and 1 month after the 3rd and 6th vaccinations unless otherwise clinically indicated. **Result:** All patients exhibited local inflammatory responses and flu-like symptoms lasting 72-96 hours following vaccinations. There were no dose limiting treatment related toxicities. 14 patients (67%) completed all six vaccinations; 7 patients were removed from study early due to disease recurrence. 8 of 14 patients (4: vaccine alone and 4: vaccine and cy/cel; 57%) exhibited serologic responses to NY-ESO-1. One patient developed antibodies to GAGE7; several patients exhibited reactivity to XAGE and MAGE-C2. Additional serologic responses were observed against Muc1, Muc1Tn, and LSTc. Vaccine therapy decreased percent Tregs (p=0.067), PD-1 expression on Tregs (p=0.023), PD-L1 expression on CD14+ monocytes (p=0.0089), PD-L1 expression on classical monocytes (p=0.0159), and PD-L1 expression on intermediate monocytes (p= 0.0031). Cy/cel did not increase immune responses or enhance vaccine-induced alterations in peripheral immune subsets. **Conclusion:** H1299 lysate vaccines with Iscomatrix™ induce immune responses to CG and oncofetal antigens commonly expressed in lung cancers, and modulate peripheral immune subsets in a manner that may enhance antitumor immunity. These findings support further evaluation of the vaccine in combination with epigenetic agents and immune checkpoint inhibitors for lung cancer therapy.

**P3.04 IMMUNOONCOLOGY**  
**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.04-28 CAN IPILIMUMAB RESTORE IMMUNE RESPONSE IN ADVANCED NSCLC AFTER PROGRESSION ON ANTI PD1/PDL1 AGENTS?**

M. Sternschuss1, N. Peled2, E. Dudnik3, O. Rotem4, A. Zer4

1Davidoff Cancer Center, Robin Medical Center, Beilinson Campus, Petah Tikva/IL, 2Director of the Cancer Center, Soroka Medical Center, Beer Sheva/IL, 3Thoracic Cancer Service, Davidoff Cancer Center, Robin Medical Center, Petach Tiqwa/IL, 4Thoracic Cancer Unit, Davidoff Cancer Institute, Robin Medical Center, Affiliated To the Sackler Faculty of Medicine, Petah Tikva/IL

**Background:** Anti PD1/PDL1 agents play a crucial part in the treatment of NSCLC demonstrating improved overall response rate (ORR) and overall survival. While anti CTLA4 alone did not show significant single agent activity, a phase 1 study evaluating the combination with anti PD1 suggests improved ORR. Evidence is scarce regarding subsequent treatment with immune checkpoint inhibitors (ICI) after progression on anti PD1/PDL1. A recent study in melanoma patients reported lack of benefit from the addition of Ipilimumab after progression on anti PD1. **Method:** All off-label Ipilimumab administrations in a single tertiary center were retrieved through the institutional review board records. 21 patients with advanced NSCLC were allocated during 2017. Clinical data were retrieved retrospectively. Disease control was define as partial response (PR) or stable disease (SD).

**Result:** Of 21 patients who were treated with a combination of anti PD1 agent and Ipilimumab, in 15 Ipilimumab was initiated after confirmed progression on anti PD1/PDL1 alone. Patients’ characteristics are described in table 1. The overall disease control rate was 33.3% (n=9); 3 patients with PR and 2 patients with SD, 3 of whom had previously responded to anti PD1. Immune related AE rate was 40% (n=6); 2 patients had grade 3 AE and one patient died of pneumonitis. While the median time to progression was 2 months, 4 of the 5 responding patients are still stable after median 4 months follow up (range 1-15).

**P3.04 IMMUNOONCOLOGY**  
**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.04-29 EFFICACY OF RE-TREATMENT WITH IMMUNE CHECKPOINT INHIBITORS IN PATIENTS WITH PRETREATED ADVANCED NON-SMALL CELL LUNG CARCINOMA**

Department of Medical Oncology, Kindai University Faculty of Medicine, Osaka-Sayama/JP

**Background:** The majority of NSCLC patients treated with immune-checkpoint inhibitors (ICI) develop acquired resistance. Conventional cytotoxic chemotherapy remains the treatment of choice for those patients. There are case reports on re-administration of ICIs for advanced NSCLC; however, these case series are difficult to draw definitive conclusions. We therefore retrospectively reviewed the efficacy of retreatment with ICI in our hospital. **Method:** Patients with pathologically confirmed advanced NSCLC who were treated with ICI in Kindai University hospital were retrospectively reviewed from December 2015 to July 2017. Among 212 NSCLC patients treated with ICIs, 10 patients (4.7 %) were retreated with ICI. **Result:** Number of patients treated with Nivolumab, Pembrolizumab and Atezolizumab were four, five and one, respectively. The best response of initial treatment with ICIs among 10 patients were five partial response (PR), two stable disease (SD) and three progressive disease (PD). Whereas, three patients (30%) showed SD and the others (70%) had PD to ICI retreatment. No severe adverse events attributable to the ICIs were noted. **Conclusion:** In the limited number of retrospective study, we could not find good responders for retreatment with ICIs. Best
overall response during the previous treatment period is not related to the efficacy of retreatment with ICIs. At present, former responder to ICI therapy may not be the proper candidate for ICI re-challenge treatment strategy. Further biomarker analysis and treatment strategy is warranted for the patients and physicians to retreat with ICIs.

**Keywords:** Retreatment, non small cell lung cancer, immune checkpoint inhibitor

**P3.07-01 TELEPHONE PREASSESSMENT CLINIC INCORPORATING HOLISTIC NEEDS**

**V. Beattie, P. Shepherd, M. Guerin**

Thoracic Medicine, Aintree Hospital, Liverpool/GB

**Background:** Approximately 44,000 people are diagnosed with Lung Cancer in the United Kingdom (CRUK, 2012). In Liverpool we serve a population of 330,000. As health care providers we constantly look to new models of care to aid earlier diagnosis. Introduction of a new referral system into the diagnostic service at our hospital including; pre planned investigations prior to first outpatient appointment, it was identified that some pre planned investigations were inappropriate for some patients due to unknown performance status and co-morbidities. There was an increase in patients failing to attend outpatient appointments. The Lung CNS team looked provide intervention to provide patients with early and key worker support with the aim of enhancing and reducing the lung cancer pathway.

**Method:** In 2016 a pre assessment proforma was developed. CT scan reports and referrals are assessed by Lead Lung Physician and appropriate referrals forwarded to Lung CNS. Lung CNS team contact patients via telephone and a pre assessment proforma completed. Patients informed of date of outpatient appointment need for investigations and explanation provided of what to expect. Holistic needs assessment undertaken to enable any concerns to be raised and allow early intervention by the specialist team with an aim of improving symptoms and performance status prior to commencing a treatment pathway.

**Result:** Initial audit results looking at case studies, failure to attend rates and patient satisfaction met our objectives. There has been a reduction in failure of patients attending investigations; reduction in cancelation of pre booked investigations; provides early rapport between Lung CNS and patient/carer with earlier recognition of symptoms and earlier access to urgent treatments; allows health education prior to first outpatient appointment including: smoking cessation, exercise and nutrition.

**Conclusion:** This work has been an opportunity to demonstrate a positive impact on the patient pathway by streamlining complexities in the pre diagnostic phase. Whilst it had a marked impact on the Lung CNS job plan it accommodates a growing demand on a constrained service. A Lung Cancer Support Physician and appropriate referrals forwarded to Lung CNS. Lung CNS team contact patients via telephone and a pre assessment proforma completed. Patients informed of date of outpatient appointment need for investigations and explanation provided of what to expect. Holistic needs assessment undertaken to enable any concerns to be raised and allow early intervention by the specialist team with an aim of improving symptoms and performance status prior to commencing a treatment pathway.

**P3.07-02 EXPECTATIONS, STANDARDS AND PERFORMANCE FRAMEWORK TO SUPPORT THE LUNG CANCER SUPPORT NURSE IN LUNG FOUNDATION AUSTRALIA**

**V. Brunelli, C. Mulvihill, J. Kerr, H. Allan**

1Institute of Health and Biomedical Innovation, Queensland University of Technology, Red Hill/AU; 2Lung Foundation Australia, Milton/QLDAU

**Background:** A project initiated by Lung Foundation Australia (LFA) in 2015 entitled, Nurse-Led Lung Cancer Support Service commenced with four key objectives and limited other structure. A Lung Cancer Support Nurse (LCSN) was appointed to implement the project. To succeed, the LCSN required role definition. Given the novelty of the LCSN role in LFA and the scarcity of practice guidelines relative to similar roles in other settings, standards and performance framework (the framework) was developed. The framework supports the LCSN role with a theoretically sound, contextually relevant, empirically informed, “living” document where activity is captured, evaluated and used to inform practice and improve consumer outcomes.

**Method:** Key questions directed an extensive literature search: 1) What structural features are required in a practice framework to meet LCSN, consumer and organisation needs? 2) How might a framework function to meet these needs in a real time and ongoing manner? Ritchie and Spencer’s (1994) concept of Framework, which dictates the use of a tool such as Excel spreadsheet, inspired the “physical” construction of this framework. The approach offers practical, analytical and visual utilities to the data corpus. The key four pillars within the framework represent LCSN practice expectations, standards and performance. Data entered relevant to these areas of practice directly relate to the four key objectives of the project and an additional six objectives, defined as the role has evolved due to input from consumer demand. As descriptive data are entered into the framework, they are evaluated against key lung cancer nursing literature for appropriateness of scope and purpose of the role. As activity data are entered, they are evaluated against organisation, practitioner and consumer driven indicators to ensure needs are met and improvements made.

**Result:** The framework is contextualised to the role and setting and in doing so is intricately linked to the business of the organisation, LCSN practice and consumer outcomes. The framework offers the organisation an infrastructure, benchmarking and service development document. The framework provides the LCSN an ability to create a work environment that supports excellence in all aspects of practice, including scope of practice and decision-making, and capabilities development. In collaboration with consumers, the framework defines clear expectations about the engagement required by the LCSN to meet needs and improve outcomes.

**Conclusion:** The framework is an empowering tool for the LCSN, LFA leadership team and consumers. Its potential applicability to other roles and settings furthermore makes the framework a valuable body of work.

**Keywords:** lung cancer nurse role definition, lung cancer nurse practice development, practice framework

**P3.07-03 LUNG CANCER CLINICAL NURSE SPECIALIST & PALLIATIVE CARE NURSE SPECIALIST – A DUAL ROLE**

**K. Clayton, A. Byatte, N. Barnett, C. Guerin**

1Respiratory Medicine, East Cheshire NHS Trust, L/G, 2Respiratory Medicine, East Cheshire NHS Trust, Macclesfield/GB

**Background:** The majority of Lung cancer diagnoses are advanced at presentation. There have been advances in treatment over the last 5 years, with new therapies developed enabling improved prognosis for palliative patients. In the UK, just 20% of Stage 4 NSCLC will survive to one year. (CRUK2018). At East Cheshire in 2017, 66.1% of patients were non-curative on diagnosis, of these 42% were referred directly to specialist palliative care (SPC). Ferrel et al (2015) reported significant improvements in QOL, symptoms, and reduced distress for palliative NSCLC patients. While El et al (2014) suggested that palliative care providers need to become front-line team members, who provide a high-quality service in order to facilitate early integration of palliative care.

At East Cheshire NHS Trust, England, the Lung Cancer CNS has a dual role as Community SPC nurse. This ensures patients are supported from pre-diagnosis through treatment, living with and beyond, then onto end of life care with the same keyworker.

**Method:** The Lung CNS is present in clinic pre-diagnosis and at MT when management plans are formulated. Patients who are referred directly for SPC due to frailty or co-morbidities that exclude them from anti-cancer treatment, a dedicated key worker/CNS. The CNS is present when bad news is broken to the patient and carers. They co-ordinate all services required for the patient and arrange follow up: either hospital inpatient review, a further nurse-led clinic appointment or a home visit. The CNS will discuss and organise advanced care planning ensuring patient wishes are met.

**Result:** This model of working has been evaluated with excellent feedback. Carer response has been very positive: a patient’s wife said “thank you for being there when we heard the bad news and for being there at end of life. Having one person who knew the journey throughout has been very reassuring.” Another patient’s daughter stated “having the guidance of the CNS from diagnosis to death, for my father was invaluable in ensuring his wishes were fulfilled.” The Commissioners of Quality Care (CQC) in January 2018 rated care at the end of life in the community as outstanding.

**Conclusion:** The service at East Cheshire offers a novel model of working for patients and carers. The same key worker being present throughout has a positive impact on their lives. Further research is required to fully understand the impact of the role on the quality of life and especially on prognosis.

**Keywords:** Palliative, lung cancer, Nurse Specialist
P3.07-05 RECEIVING A DIAGNOSIS OF MESOTHELIOMA (RADIO MESO): RECOMMENDATIONS FOR PRACTICE TO IMPROVE THE PATIENT EXPERIENCE

B. Taylor1, A. Tod1, H. Ball2, L. Darlison2, H. Stanley3, C. Warnock3
1School of Nursing and Midwifery, The University of Sheffield, Sheffield/GB, 2Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield/GB

Background: Communicating a diagnosis of mesothelioma is complex and highly skilled1, 2. If done badly, ‘it can cause long lasting distress, confusion and resentment’1 . Receiving A DIagnosis Of MESO thelioma (RADIO Meso) is a qualitative research project designed to identify ways to improve patient and family carer experience of receiving a mesothelioma diagnosis by generating evidence based recommendations for practice. This abstract provides an overview of the findings and a summary of recommendations. Method: The study utilised a descriptive qualitative approach. Individual telephone interviews were conducted with people who had experience of giving or receiving a diagnosis of mesothelioma. This included patients, family carers (N=16) and health care professionals (N=16). Two separate focus groups were also carried out with patients and carers (N=27) and mesothelioma nurse specialists (N=15). A national web-based consultation with staff and patients/ family carers was then undertaken. Interview recruitment and the consultation were conducted via electronic mailshots and social media run by Mesothelioma UK, the National Lung Cancer Forum for Nurses and British Thoracic Oncology Group. Interview data was collected between January and December 2017. Consultation data was collected between January and March 2018. Framework analysis methods were used.

Result: The findings provide an in-depth understanding of patient, family carer and staff experiences of receiving a mesothelioma diagnosis. A number of patient centred requirements to improve this experience were identified. These requirements form the basis of the recommendations developed and refined through consultation. The recommendations highlight the importance of providing consistency and continuity in terms of who the patient sees and what is said on the diagnostic journey. The recommendations also emphasise the value in health professional’s decisions and what is said to the patient on the diagnostic journey. Recommendations for both mesothelioma diagnosis and communication, a patient-centred approach, a quiet and private environment to facilitate communication, sufficient time to address patient and family concerns, access to good quality information resources, and effective partnerships for timely referrals to specialist services. Participants indicated that the involvement of the Clinical Nurse Specialist enhanced diagnostic experience. Conclusion: The study provides unique insight into the mesothelioma diagnostic experience. The recommendations will be launched by Mesothelioma UK on 1st May 2018. These will help inform health professional’s decisions and practice regarding the communication of a mesothelioma diagnosis and improve patient experience. The goal is to make the patient feel like the most important person in the room, and at the centre of the communication process.

Keywords: diagnosis, recommendations, qualitative
P3.07-07 MULTIDISCIPLINARY SUPPORTIVE CARE ASSESSMENT IN LUNG CANCER – A CASE STUDY EXAMPLE
F. Dickinson1, C. Childs1, R. White1, P. Labuc1
1Physiotherapy, Guy’s and St Thomas’ NHS Foundation Trust, London/GB, 2Guys and St Thomas’ NHS Foundation Trust, London/GB

Background: Although many patients report positively on their experience of cancer care, their Supportive Care (SC) needs may not be met for several reasons, including services not being universally available, poor recognition of needs and poor inter-professional communication (NICE, 2004). Guys and St Thomas’ NHS Foundation Trust has a dedicated SC service for lung cancer patients consisting of specialist Dietetics, Occupational Therapy (OT), Physiotherapy (PT) and Speech and Language Therapy (SLT). Here we describe a complex case study requiring extensive multimodal SC interventions.

Method: Patient X was a 46 year old female with adenocarcinoma of the left lung T4N3M1b diagnosed August 2017. She presented with shortness of breath, chest wall pain, dysphagia, dyspnoea, anorexia and weight loss. She received 3 cycles of first line chemotherapy, 3 cycles of 2nd line Pembrolizumab and a single fraction of stereotactic radiotherapy for brain metastases. She died in January 2018.

Result: On initial dietician assessment the patient had lost 16.5% of her body weight over the previous 4 months. Dysphagia and anorexia resulted in her only maintaining puréed textures and liquids resulting in a significant nutritional deficit. She received dietary counselling and oral nutritional supplements to optimise her intake and minimise further weight loss. She received PT and OT intervention for fatigue, reduced mobility, deconditioning and reduced occupational performance within the clinic, including education regarding strengthening exercises, fatigue and breathlessness management. She was referred on to community services to progress her rehabilitation and assess equipment needs within the home setting. SLT provided assessment and management of oropharyngeal dysphagia and dysphonia. She was supported to use a left head turn swallow strategy to reduce the risk of aspiration. In addition vocal hygiene advice and education was provided, aiming to prevent vocal strain.

Conclusion: Patient X benefited from assessment and intervention by a range of SC therapists which may have prevented aspiration pneumonia, minimising her weight loss and increased her functional independence thus having a significant impact on her quality of life. In many centres access to SC services may result in a high appointment burden and non-specialist intervention. Providing these services as part of one stop clinic prevented additional appointments and ensured effective communication between the MDT, so that medical and supportive goals were aligned. It can be argued this should be gold standard care for all lung cancer patients. To support this argument more robust clinical outcomes and patient experience data needs to be collected.

Keywords: Multidisciplinary, holistic, supportive

P3.07-08 PAIN MANAGEMENT IN LUNG CANCER
A. El Meziane1, H. Laarej2
1Centre Commercial Nadia Im. 4 Apt1, Cheikh Khalife Ibn Zayd Hospital, Casablanca/MA, 2Respiratoire Unit, Hospital Cheikh Khalifa, Casablanca/MA

Background: Lung cancer is one of the most prevalent cancers worldwide and pain is its most common symptom. Pain can be brought about by several causes including local invasion of chest structures, metastatic disease or can also be a consequence of treatment. An active multidisciplinary approach is required to manage pain in patients with lung cancer.

Method: It is a cross-sectional study of 166 patients with lung cancer. We used the BPI ‘Brief pain inventory’ to assess pain prevalence, intensity and impact on quality of life. Adequacy of pain management was evaluated by the Pain Management Index (PMI).

Result: We interviewed 166 patients with bronchogenic carcinoma: 163 men and 3 women, 116 with adenocarcinoma and 50 with epidermoid carcinoma. 80 (42.2%) of our patients have pain. Among them, 7 report low pain and 73 moderate to severe pain (91%). 149 (89,7%) patients have metastasis. The association between the intensity of pain and metastasis was statistically significant (p<0,001). 21 patients (26.2%) are treated with antalgic. 18 with the second level and 3 with the third level. The Pain Management Index (PMI) is negative in 63 patients (81.2%). There is also a stastically significant correlation between the intensity of pain and the degradation of each quality of life parameter.

Conclusion: Pain management still remains a challenge. This deficiency is due to the inadequate medical training and the unavailability of most third level of analgesics in ambulatory prescription.
Method: The research was a single site, mixed methods study, including a survey and interviews of patients. • A survey to identify and understand what people have experienced in terms of on-going support to enhance their recovery. • Interviews to improve understanding of the patient and family experience • To generate initial recommendations through analysis of survey and interview data. 100 invites were sent out to those who met the eligibility criteria; 34 completed the questionnaire and 17 agreed to be interviewed. Results: Understanding of the recovery package was lacking • There was a mixed response of positive and negative comments related to the various health professionals involved in The Recovery Package • Health and wellbeing programmes were welcomed • An individualised exercise and rehabilitation programme would be preferable • 70% surveyed wanted to know more about The Recovery Package

Conclusion: For The Recovery Package to be effective it needs to be managed and maintained by all health care professionals involved in the patient pathway. Patients and carers need to be made aware of what is available locally and nationally to enhance their recovery and quality of life. Implementing a dedicated rehabilitation programme to promote the enhanced physical recovery and to address psycho-social needs of people living with and beyond lung cancer is required.

Keywords: survivorship, recovery package, quality of life

P3.07-11 SURVIVORSHIP AFTER LUNG CANCER SURGERY – SOLACE – A MACMILLAN FUNDED PROJECT

C. Merriman1, J. Canavan2, J. Mitchell1, E. Belcher3, D. Stavroulias4, F. Di Chiara4

1Thoracic Surgery, Oxford University Hospitals, Oxford/Gb, 2Oxford University Hospitals NHS Foundation Trust, Oxford/Gb, 3Thoracic Surgery, Oxford University Hospitals NHS Trust, Oxford/Gb

Background: Lung cancer remains the leading cause of cancer related death worldwide. Surgery is the mainstay of curative therapy for lung cancer. However, 75% of patients present over the age of 65yrs, many with co-morbidities which impact on the resection rate. Post treatment many cancer survivors experience fatigue, reduced physical capacity and quality of life. We have established a Macmillan funded service at our institution. Our aim is to optimise the patient pre-operatively, encourage self-management post operatively and extend the role of recovery beyond the immediate post-operative period and establish survivorship as the goal. Method: Each referred patient is offered a key worker and a tailored pre and post operative programme based on individual needs, which may incorporate some or all of the following: opportunity to discuss concerns, education regarding their condition, smoking cessation, healthy eating, pre and post-operative exercises. Baseline and follow up data is collected regarding the patient’s current health status, respiratory parameters and qualitative data about patient experiences. Result: 249 patients (as of March 2018) have been referred since the service was established in September 2016. The level of contact these patients have received is summarised below:

<table>
<thead>
<tr>
<th>Level of Intervention</th>
<th>Numbers of patients</th>
</tr>
</thead>
<tbody>
<tr>
<td>Level 1 – No direct involvement with patient, advice via telephone or email provided</td>
<td>37</td>
</tr>
<tr>
<td>Level 2 – Single face to face consultation, to assess requirements and receive information, advice and referral to another health profession</td>
<td>93</td>
</tr>
<tr>
<td>Level 3 – More than one intervention involving advice on specific issues, for example provided with home exercise DVDs</td>
<td>90</td>
</tr>
<tr>
<td>Level 4 – Multiple contacts with the patient and/or carer over a long term period. Of these patients 16 attended pre-operative exercise classes</td>
<td>29</td>
</tr>
</tbody>
</table>

212 (85%) of patients met with either the ANP or ATP, 56% of those engaged in further support. Early evaluation of the project indicates that there are challenges in gaining patient engagement with the exercise classes. The reasons are multifactorial and include patients perceiving their current level of activity is sufficient and the need for multiple attendances (time, cost and difficulty parking) acting as deterrents. A home based exercise programme and exercise DVD is offered to address this challenge. Conclusion: The project has had a positive start; changes have been made based on our early experiences. Work continues to develop the service; ensuring patients receive a tailored programme to meet their needs.

Keywords: Service Development, survivorship, Surgery

P3.07-12 IMPROVING CARDIAC TAMPONADE OUTCOMES THROUGH LESS INVASIVE INTERVENTIONS AND EARLIER RECOGNITION

K. Murphy

Nursing Evidence-Based Practice, Memorial Sloan Kettering Cancer Center, New York City/NY/US

Background: Oncology patients are at increased risk for developing pericardial effusions due to disease processes or treatment regimens. Approximately 20% of cancer patients have pericardial involvement. At one large NCI-Designated Cancer Center, emergent pericardial drainages and windows are increasing; some leading to poor outcomes. Seventy-three percent of the emergent cases were pericardial windows compared to 28% being less invasive pericardial drainages. A workgroup including Critical Care, Cardiology, Thoracic Surgery and Nursing was formed to improve workflows and earlier recognition of pericardial effusions and cardiac tamponade. Method: The team reviewed current workflows and barriers that hindered early recognition and intervention for patients with pericardial effusions. Guidelines were developed to aid in early recognition and treatment. An exhaustive literature search was completed and an education program was developed for nurses encompassing information on malignant and non-malignant pericardial effusions and cardiac tamponade using an interactive case study format. Highly impacted areas such as the Operating Room, recovery areas, emergency department and thoracic surgery/step-down unit were targeted. The program included information on risk factors, signs and symptoms, interventions and the new workflow. In addition to nurse training, implementation included training more LIP/PAs to complete bedside echocardiograms and establishing a new escalation workflow.

Result: In July 2017, the education program for nursing was initiated and the revised workflows were enacted. Over the first 6 months, 173 nurses were trained. Since implementation, the total number of emergent pericardial windows reduced by 55%, with a shift to less invasive measures for emergent drainage to be utilized. This improved workflow has led to providing patients with less invasive procedures, as well as cost avoidance of more than $15,000 in direct hospital costs to date. Final presentation will include the training program curriculum and workflow algorithms, as well as pre- and post-metrics. Conclusion: Not only is early identification of pericardial effusions and cardiac tamponade critical to patient outcomes, but there is a significant cost difference to third payers and hospitals for these procedures. On average, pericardial windows cost 5-7 times the cost of a pericardiocentesis. Nurses have an important role in patient assessment and identification which can not only improve patient outcomes but aid in financial sustainability for organizations. Other organizations can implement similar collaborative response teams and educational programs for high risk, low volume patient situations where response time is paramount to patient outcomes.

Keywords: outcomes, nursing, cost
**P3.07-13 NON-ONCLOGY PROVIDER IMMUNOTHERAPY NEEDS ASSESSMENT**

E. Nguyen1, L. Dobre2

1Cancer Center, St. Joseph Hospital, Orange/CA/US, 2Oncology Research - the Center for Cancer Prevention and Treatment, St. Joseph Hospital, Orange/CA/US

**Background:** It is critical for non-oncology providers such as the emergency department, internal medicine, and critical care, to have accurate, up-to-date information on new cancer treatments such as immunotherapy (IO), and have means to properly identify immunotherapy-related adverse effects (IrAEs). IoS have a distinct side effect (SE) profile from standard cancer treatments such as surgery, chemotherapy and radiation therapy. With a subclass of IO are checkpoint inhibitors (CIs). Common CI SE are dermatologic toxicities such as pruritus and rash, experienced by half of patients receiving Cis (Davies, 2016). Gastrointestinal toxicities such as abdominal pain, nausea/ diarrhea, can develop into colitis. The risk of intestinal perforation is high in patients with colitis from immunotherapy due to tissue damage from autoimmunity (Kroschinsky et al., 2017). Also, a cough and shortness of breath can advance into immune-mediated pneumonitis, which is most common in patients treated with surgery and radiation to the lungs (Doyle, 2016). In October 2017 IASLC released the first published guidelines, followed in February 2018 by the National Comprehensive Cancer Network guidelines. Through this project we are actively raising awareness and education of these guidelines at our community hospital.

**Method:** A needs assessment survey was given to St. Joseph Hospital Emergency Care providers and Sepsis work group at their department staff meeting in 2017. In April 2018, this same survey was given to Hospitalists. A one page pre in-service survey was administered, followed a brief in-service, and a post in-service survey immediately followed. The pre and post survey was used to evaluate effectiveness of teaching. Sample size: 30 non-oncology providers Data from 2017 and 2018 surveys will be collated to evaluate knowledge deficits, effectiveness of teaching, and implementation of IO patient identification card. Knowledge of IO SE management was measured with an identical pre and post in-service survey. The survey contained 5 items measuring the individual’s current knowledge/comfort with managing immunotherapy side effects for oncology patients receiving immunotherapy who are evaluated in St. Joseph Hospital. Result: Data analysis ongoing using SPSS- Preliminary results identified a gap. Conclusion: The field of oncology and treatment of advance malignancies is growing at a fast pace, the oncology team will need to coordinate and educate other organ-specific specialties through educational programs and algorithms for the management of these AE. Consequently, we need to assess the most constructive framework that can aid in the understanding and adoption of these newly published guidelines for the broader immune-oncology multidisciplinary team.

**Keywords:** non-oncology provider, Immunotherapy, IRAE management

**P3.08 OLIGOMETASTATIC NSCLC**

**P3.08-01 TREATMENT OUTCOMES IN OLIGOMETASTATIC DISEASE OF NON SMALL CELL LUNG CANCER: A SINGLE CENTER EXPERIENCE**

P. Akın Kabalak1, D. Kızılgöz2, Ü. Yılmaz2, T. İnal Cengiz1, E. Tunc3, S. Yaman4, E. Gultan4

**Background:** Even if oligometastatic disease is staged as 4, survival rates are higher when curative approaches are performed for both primary tumour and metastasis. We analysed our institution data of oligometastatic disease. **Method:** 52 NSCLC patients with limited metastasis were retrospectively analysed. All treatment modalities (surgery, CRT, supportive-care, palliative chemotherapy) were compared in terms of survival. Curative treatment was defined as surgery or CRT (concurrent or sequential). **Result:** Median overall survival (OS) was 35.2(24.1 to 55.3) months vs. 27.4 months, p<0.05). Progression free survival (PFS) was 29.4(15.9 to 42.9) months vs. 27.4 months, p<0.05). Survival after first progression (SAFP) was 15.6(2.8 to 8.3) months. Patients performed metastasectomy had higher SAFP rates than others with significance (20.07±3.8 months vs. 7.9±1.7 months p=0.046). Adenocarcinoma was related better SAFP than non-adenocarcinoma group (32±4 vs 8±1.5, p=0.002). The 1- and 2-year OS were 67% and 50.4%, respectively. Among curative treatment group, while patients under age 65 (n=25) had 31 months OS, patients above 65 (n=13) had 22 months (p=0.88).

(See next page)
Conclusion: Our study revealed that in well-selected NSCLC patients with limited metastasis survival rates can reach up to 3 years even in geriatric population. And clinical N staging and co-morbidity are well known prognostic factors.

Keywords: Chemoradiotherapy, non-small cell lung cancer, Oligometastasis
P3.08-02 OLIGOMETASTATIC NON SMALL CELL LUNG CANCER PATIENTS TREATED WITH STEREOTACTIC BODY RADIOTHERAPY (SBRT), A SINGLE INSTITUTION EXPERIENCE

D. Franceschini1, F. De Rose1, G. Radicioni2, E. Toska1, L. Faraci2, G. Carta1, M. Scorsetti1
1Radiotherapy and Radiosurgery, Humanitas Clinical and Research Center, Rozzano Milano/IT; 2Radioterapia, Università Federico II, Naples/IT

Background: Oligometastatic disease is an intermediate state between localized and widespread diffuse disease. By definition, this state is amenable to local ablative approaches, like Stereotactic Body Radiation Therapy (SBRT), with curative intent. Method: Patients treated with SBRT for oligometastatic NSCLC (max 5 active lesions in max 3 different organs) between January 2014 and December 2015 in the Radiotherapy and Radiosurgery department of the Humanitas Clinical and Research Hospital were retrospectively analyzed. Primary endpoint of the study was local control (LC); overall survival (OS), disease metastases free survival (DMFS) and progression free survival (PFS) were analyzed as well. LC and survival times were calculated from the first day of SBRT. Best local response (BLR) was defined according to RECIST criteria. Result: 83 patients were included in the study. Patients received different RT schedules according to number, site and size of the metastases. Treatment was generally well tolerated, no acute or late G3-4 toxicity was recorded. Complete response, partial response or stable disease were recorded in 30 (35%), 40 (47%) and 14 (16%) patients respectively. One patient had a local progression at first evaluation, while other 16 (19%) patients experienced local relapse during follow up. Actuarial local control time at 6, 12 and 24 months was 91.73%, 84.95% and 77.82% respectively. Distant progression was recorded in 64 patients (75%), in most cases (64 patients, 84%) patients progressed again in an oligometastatic way. Actuarial DMFS at 6, 12 and 24 months was 60.97%, 36.9% and 23.36% respectively. Actuarial PFS at 6, 12 and 24 months was 60.1%, 37% and 22% respectively. With a median follow up time of 20 months (range 4.9-49.9), 33 patients (39%) were still alive, in 8 cases with no evidence of disease. Actuarial median overall survival (OS) was 24.5 months, OS at 6, 12 and 24 months was 97.6%, 81.6% and 50.2%. At univariable analysis type of oligometastases (p=0.015) and BLR (p=0.000) were found to be correlated with LC. Previous local ablative treatments (p=0.04, p=0.033), site of the irradiated lesion(s) (p=0.0016, p=0.0026), adjuvant medical therapies (p=0.0278, p=0.023) and BLR (p=0.011, p=0.018) correlated with DMFS and PFS. Site of irradiated lesion (p=0.000), RT BED (p=0.0019) and BLR (p=0.000) were statistically correlated with OS. Conclusion: SBRT for oligometastatic NSCLC is safe and effective. Local response is strongly correlated with patients’ prognosis, underlying the relevance of local control also in a metastatic setting.

Keywords: Oligometastases, Stereotactic body radiation therapy, non small cell lung cancer

P3.08-03 STEREOTACTIC RADIOTHERAPY OF LUNG CANCER WITH SYNCHRONOUS BILATERAL NODULI OR OLIGOMETASTATIC DISEASE

1Institute of Clinical Research, University of Southern Denmark, Odense C/DK; 2Department of Oncology, Odense University Hospital, Odense/DK; 3Academy of Geriatric Research, Odense University Hospital, Odense/DK; 4Laboratory of Radiation Physics, Odense University Hospital, Odense/DK

Background: Stereotactic radiotherapy (SBRT) is an efficient treatment for early stages of inoperable NSCLC. This retrospective study compares the outcomes of patients diagnosed with either bilateral disease (BilatD) or oligometastatic disease (OligoD) prior to SBRT of the lung lesions Method: All cases of lung cancer treated with SBRT are prospectively recorded at our institution. We treated 75 patients with histological or cytological verified lung cancer 2009-2017 with IMRT or VMAT to a central dose 45–66 Gy in 3 fractions (F) for peripheral located tumors and 45 Gy-80 Gy/5-10F for centrally located tumors. BilatD was seen at the time of SBRT in 44 patients. In 35 patients, SBRT was used to treat simultaneous lesions in the 2 lungs, and in 9 patients SBRT was combined with surgical resection of a lesion in the other lung. OligoD was seen in 31 patients.

Result: The median, 1, 2, 3, and 4 year overall survival was 65 mo., 79%, 64%, 56%, and 56% in BilatD and 12.3 mo., 55%, 34%, 29% and 29 % in OligoD (p=0.01).

P3.08 OLIGOMETASTATIC NSCLC

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.08-04 OMEGA, A RANDOMIZED TRIAL OF LOCAL ABLATIVE THERAPY VS. CONVENTIONAL TREATMENT IN OLIGOMETASTATIC NSCLC - TRIAL IN PROGRESS

M. Infante1, E. Bria2, S. Novello3, U. Pastorino4, L. Buffoni5, M. Scorsetti6, M. Alloisio7, A. Ardizzoni8, S. Santo9, S. Pilotto10, F. Facciolo11, D. Giannarelli12
1University and Hospital Trust - Ospedale Borgo Trento, Verona/IT; 2Division of Medical Oncology, Università Cattolica Del Sacro Cuore, Fondazione Policlinico Universitario A. Gemelli, Rome/IT; 3Department of Oncology, University of Turin, Aou San Luigi, Orbassano/IT; 4Thoracic Surgery, Fondazione IRCCS Istituto Nazionale Tumori, Milan/IT; 5Medical Oncology, Ospedale S. Giovanni Battista Molinette, Turin/IT; 6Radiotherapy and Radiosurgery, Universitaria Clinical and Research Center,
Background: A recent randomized phase 2 study has shown that local ablative therapy in addition to systemic treatment was superior to maintenance therapy in prolonging disease-free survival in NSCLC patients harboring up to three metastatic sites. Oligometastatic lung cancer (OM-NSCLC) seems thus to be associated with a better prognosis than usual Stage IV non-small cell lung cancer when radical local therapy of all metastatic sites is administered but the impact of such an approach on overall survival and quality of life remains unclear.

Method: A consortium of tertiary referral centres involved in Lung Cancer management at the national level was established with the aim of setting up a randomized trial addressing this issue. Result: A randomized trial of local ablative therapy vs standard treatment. Balancing between study arms will be performed according to synchronous vs. metachronous presentation, Number of oligometastases, nodal status and Oncogene-addiction or PDL-1 expression. Primary outcome will be Overall Survival (O2) from randomization. The sample size is set to 195 patients. Inclusion criteria include adequate performance status, primary tumor controlled or controllable staging with whole-body FDG PET scan and brain MRI, fit to receive at least 3 cycles of platinum-based double chemotherapy, or immunotherapy or targeted agents according to molecular profile. Exclusion criteria include cerebral oligometastasis alone (will receive local therapy in any case), metastasis in sites where normal radiotherapy constraints cannot be met, multiple solid nodules in the absence of extrapulmonary metastasis, prior malignant tumor with some exceptions, relevant co-morbidities that would significantly reduce life expectancy on their own. Disease state and life status assessed on a 2-monthly basis by physical examination, whole-body CT scan plus repeat PET-scan if needed and Brain MRI if brain metastasis at enrolment. Toxicity and adverse events will be assessed according to NCI-Common Terminology Criteria. Quality of life will be assessed at randomization and after six months by the SF36/QLCCS. Conclusion: There is a need to perform randomized controlled trials with overall survival as main endpoint to confirm whether local ablative therapy indeed has a role in the management of oligometastatic lung cancer. The Omega trial will try to respond to such a need.

P3.08-06 LONG-TERM SURVIVAL FOR BRAIN-ONLY OLIGOMETASTATIC NSCLC PATIENTS TREATED WITH ABLATIVE THERAPY (AT): PROGNOSTIC FACTORS

C. Salvador Coloma1, C. Escoín2, D. Lorente1, J. Mendez1, O. Juan-Vidal1
1 Medical Oncology. Hospital Universitari i Politécnic La Fe, Valencia/ES; 2 Hospital de La Ribera, Valencia/ES

Background: Although brain metastasis (BM) have been associated with poor prognosis, brain-only oligometastatic (BOO-NSCLC) patients represent a special population for whom CAT may represent a reasonable therapeutic approach. Method: Retrospective cohort with BOO-NSCLC (defined as ≥ 1 metastases in brain as only metastatic site) treated between 2010-2018 at Hospital La Fe. Recursive Partitioning Analysis (RPA) group-score was calculated Result: 67 patients were identified (Table-1). Median-overall survival (mOS) was 20.2 months (95%CI:11.5-28.9). RPA-group score was associated with OS (HR:5.7;p<0.001). mOS was not reached in RPA-I 16.2 m (95%CI:8.3-24.1) in RPA-II and 4.5 m (IC95%:2.2-6.8) in RPA-III. Other factors associated with OS in univariable analysis were: radical treatment of the primary tumor (HR:2.6;p<0.005); radical treatment of the BM (HR:5.6;p<0.001); lymph node involvement (HR:2.17;p=0.031). Radical treatment in both primary and BM was associated with an increased mOS (HR:2.62;p<0.001). In the multivariable model, only RPA-group (HR:1.8 CI95%:2.8-12.7:p<0.0001), radical treatment of BM (HR:1.7;CI95%:2.4-13.1:p<0.0001) and lymph node involvement (HR:0.82;CI95%:1.1-4.9;p<0.03) were associated with an improved survival (Table-2). </table>

Conclusion: A radical approach in patients with stage-IV NSCLC with a limited number of BM may achieve long-term disease control in a subgroup of patients. Patients with RPA-I and II, one-BM, radical treatment, and N0-N1 have improved OS and may be suitable for this approach.

**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.08-08 OUTCOMES OF PULMONARY METASTASECTOMY IN BREAST CANCER: PROGNOSIS BASED ON THE METASTATIC LUNG TUMOR STUDY GROUP OF JAPAN**

M. Endoh¹, S. Shiono¹, N. Matsutani², S. Okumura³, N. Ikeda³, I. Yoshino⁴, J. Nakajima⁵, M. Kawamura²

1General Thoracic Surgery, Yamagata Prefectural Central Hospital, Yamagata/JP, 2Department of Surgery, Teikyo University, School of Medicine, Tokyo/JP, 3General Thoracic Surgery, Cancer Institute Hospital, Tokyo/JP, 4Department of Surgery, Tokyo Medical University, Tokyo/JP, 5General Thoracic Surgery, Chiba University Graduate School of Medicine, Chiba/JP, 6Department of Thoracic Surgery, The University of Tokyo Graduate School of Medicine, Tokyo/JP

**Background:** Although pulmonary metastasectomy is a common treatment in other primary cancers, its role in patients with primary breast cancer is still controversial. The purpose of this study was to analyze a Japanese multi-center database to assess the prognostic factors and indications of metastasectomy in breast cancer. **Method:** Data of 387 patients with histologically proven pulmonary metastases from breast cancer have been prospectively enrolled in the Metastatic Lung Tumor Study Group of Japan between December 1982 and March 2017. Those with inadequate information about perioperative data, surgery for biopsy, male or non–epithelial malignancies were excluded. A total of 253 female with invasive breast carcinoma between 1982 and 2017 constituted the study population, and their clinical and prognostic data were retrospectively analyzed. **Result:** The median follow-up period was 5.4 (range, 0–24) years. The mean age of patients was 56 (range, 32–82) years, the median disease-free interval was 4.8 (range, 0–31)
years, pulmonary metastasis (215 solitary, 38 multiple) was treated with surgery, namely, wedge resection (n = 113, 45%), segmentectomy (n = 112, 29.5%), and pneumonectomy (n = 2, 0.8%). Nodal metastases were found in 56 (22%) patients. There were 24 (9%) patients with incomplete resection. Additional treatments after metastasectomy were performed in 141 patients (56%). Recurrence after pulmonary metastasectomy developed in 98 of 229 (43%) patients without incomplete resection, namely, intrathoracic lesion (n = 21, 23%), distant metastasis (n = 47, 51%), and unknown (n = 25, 27%). The 5-year and 10-year survival rates after pulmonary metastasectomy were 66% and 52%, respectively, and the median survival period was 10 years. In the univariate analysis, early treatment period (p < 0.01), short disease-free interval (<3 years; p < 0.01), large tumor size (>2 cm; p < 0.01), surgical procedure (lobectomy and pneumonectomy; p = 0.01), intrathoracic nodal metastasis (p < 0.01), and incomplete resection (p < 0.05) were shown to be associated with poor survival. Multivariate analysis revealed that only short disease-free interval (<3 years; p < 0.01) was significantly worse prognostic factor in 253 patients. Conclusion: The main poor prognostic factor was disease-free interval (<3 years). However, complete resection of metastases was not a significant prognostic factor. The efficacy of pulmonary metastasectomy in breast cancer is still controversial. For pulmonary metastasis from breast cancer, pulmonary metastasectomy is considered to be optional treatment.

P3.08 OLIGOMETASTATIC NSCLC

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.08-09 SURGICAL RESECTION OF PULMONARY OLIGO-RECURRENCE OF NON-SMALL CELL LUNG CANCER

Chest Surgery, Hyogo Cancer Center, Akashi/JP

Background: The concept of oligo-recurrence, which is theoretically curable by definitive local therapy, has been proposed in several cancers. But the efficacy of surgical resection for pulmonary oligo-recurrence of lung cancer is unclear. The aim of this study was to investigate the efficacy of surgical resection of pulmonary oligo-recurrence of non–small-cell lung cancer (NSCLC). Method: We retrospectively analyzed the data on 21 patients who underwent lung resection for pulmonary oligo-recurrence in our institution, between 2000 and 2016. We evaluated independent risk factors for progression-free survival after pulmonary resection. Result: There were 14 men and 7 women with median age of 71 years [interquartile range (IQR), 65–72]. The median follow-up time was 48.8 months [IQR, 17.2–69.2]. Previous therapies for NSCLC were resections in 16 (76.2%) patients, stereotactic radiosurgery for brain metastasis in 9 (42.9%), chemotherapy in 2 (9.5%), chemoradiation therapy in 2 (9.5%) and chemotherapy (ALK-TKI) in 1 (4.8%). Median progression-free interval between previous therapy and pulmonary resection of oligo-recurrence was 28.0 months [IQR, 16.0–40.0]. Histopathology was adenocarcinoma in 18 (85.9%) patients, squamous cell carcinoma, adenosquamous carcinoma and large cell neuroendocrine carcinoma in 1 (4.7 %). Surgical procedures were wedge resection in 11 patients, segmentectomy in 3, lobectomy in 5 and pneumonectomy in 2. There were no perioperative deaths. Three-year overall survival and progression-free survival was 68.6% and 59.3%. Postoperative recurrence occurred in 8 (38.1%) patients (local; 4, distant; 4). Univariate analyses identified progression-free survival as independent risk factor for progression-free survival after surgical resection. Conclusion: Surgical resection of pulmonary oligo-recurrence of NSCLC is feasible and the postoperative survival is acceptable. But there are highly selective patients in our study, further study is needed for curative intent treatment.

P3.08 OLIGOMETASTATIC NSCLC

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.08-10 A RETROSPECTIVE STUDY OF OLIGO-RECURRENCE IN PATIENTS WITH RESECTED NON-SMALL CELL LUNG CANCER

T. Nakagawa1, S. Kudo1, S. Takashima1, H. Iwai1, H. Suzuki1, Y. Minamiya1
1Thoracic Surgery, Omagari Kosei Medical Center, Daisen, Akita/JP, 2Thoracic Surgery, Akita University Graduate School of Medicine, Akita/JP

Background: In recent years, local therapy has been shown to be a first-line treatment for patients with postoperative oligo-recurrence of non-small-cell lung cancer (NSCLC). The aim of this study was to clarify the clinical features and outcomes of patients with postoperative oligo-recurrence of NSCLC. Method: Of 230 patients with resected NSCLC, between 2008 and 2016, 80 patients who developed recurrence were included in this study. Oligo-recurrence was defined as 1 to 3 loco-regional or distant recurrent lesions restricted to a single organ. Other recurrences were classified as poly-recurrence. Second primary lung cancers and synchronous lesions were excluded. Definitive local therapy (DLT) included surgery, stereotactic radiotherapy, and radiotherapy performed with curative intent. Result: Oligo-recurrence was identified in 26 (44%) patients, mainly as single recurrence (n = 19, 73%) in regional lymph nodes, lung, brain, bone, or adrenal gland. The pathological stage was IA in 7 patients, IB in 7, IIA in 4, IIB in 1, and IIIA in 7. Histology was adenocarcinoma in 18, squamous cell carcinoma in 6, adenosquamous carcinoma in 1, and large cell neuroendocrine carcinoma (LCNEC) in 1. Epidermal growth factor receptor (EGFR) mutation was positive in 3, and anaplastic lymphoma kinase (ALK) mutation was positive in 3, and 10 were unknown. Sixteen (62%) of the 26 patients first received DLT, and 9 (35%) received systemic chemotherapy including EGFR and ALK-tyrosine kinase inhibitors (TKIs). For patients (lung in 3, adrenal gland in 1) underwent surgical resection, and the remaining 12 patients received stereotactic radiotherapy and radiotherapy. The three-year post-recurrence survival (PRS) after DLT and after systemic chemotherapy was 79.0% and 75.0%, respectively. Neither recurrence location nor initial treatment by DLT or systemic chemotherapy affected PRS in oligo-recurrence patients. There was no significant difference in the time to recurrence of oligo-recurrence patients compared with poly-recurrence (median time to recurrence: 1.49 years vs. 3.2 years, p = 0.09). The entire population of oligo-recurrence patients had better PRS than those with poly-recurrence (5-year PRS: 67.9% vs. 9.0%, p < 0.01). Conclusion: Oligo-recurrence of NSCLC is not uncommon. For oligo-recurrence, DLT or systemic chemotherapy should be given because it improves prognosis.

Keywords: oligo-recurrence, tyrosine kinase inhibitors (TKIs), NSCLC

P3.08-11 DIFFERENCES IN EVALUATIONS OF EARLY THORAX CT’S IN FOCUS ON EARLY THORAX CT’S POST LUNG STEREOTACTIC BODY RADIOTHERAPY (SBRT)

F. Oner Dinçbaş, M. Dagedelen, E. Sedef
Radiation Oncology, Istanbul University Cerrahpasa Medical Faculty, Istanbul/TR

Background: Radiological changes after lung SBRT reflect variety and diversity compared to the changes after irradiation with other radiotherapy techniques. This leads to confusion in evaluating treatment response and changes in lungs, especially for the physicians who are not aware of the radiological changes after SBRT. Our study has aimed to compare evaluations of clinicians with various expertise on post SBRT early thorax CT images of patients with early lung cancer or pulmonary metastasis. Method: Posttreatment CT scans from 19 patients and 20 lesions treated with lung SBRT during 2015–2017 were reviewed retrospectively. Thorax CT within 3 months after SBRT was evaluated individually by 8 physicians from radiology, radiation oncology, nuclear medicine and chest disease. Two physicians were chosen from each department. One senior and one junior 2 physicians were assessed the CT images. The physicians were blinded to the original CT reports and they assessed CT scans independently. The evaluations were compared with evaluation of the radiation oncologist who was experienced in thoracic radiology and applied SBRT. Four choices were provided to physicians who were asked to choose one:0, Stable; 1, Regression; 2, Progression; 3, Reactive changes due to SBRT. CT images were reviewed through ExtremePacsPacs Software version 4.2 programme. Coherence coefficients of the evaluations were calculated by the Cohen-kappa test. Result: SBRT was applied to 6 patients with stage 1 lung cancer, 10 with stage 4 lung cancer and 3 pulmonary metastasis. One patient received SBRT for 2 nodules in different lobes in the ipsilateral lung. The median SBRT dose was 55 Gy(32-60)/3-10 fractions and biological effective dose (BED) was 115, 56 Gy(48-180). When we took into account all CT scans during the whole follow-up period, all lesions had complete or partial response. When the evaluations were compared with the radiation oncologist, the strongest coherence coefficient was found with the senior radiation oncologist(s: 0.72). The Kappa coefficients between the junior radiation oncologist, junior nuclear medicine physicians and the reference physician were 0.61, 0.55 respectively. The compliances were lower for the other physicians(0.48, 0.48, 0.45, 0.37). It was observed that such non-conformity was caused by misinterpretation of RT changes and not confused with progression. Conclusion: Early radiological changes after lung SBRT can be observed in different forms and misunderstood by physicians from different specializations and the acute changes are confused with progression, mostly. Although our study was conducted with a small number of patients, findings support this argument.
Therefore, radiation oncologists who apply SBRT have to be aware of these radiological changes and evaluate accurately by themselves.

P3.08-12 LONG-TERM OUTCOME AFTER ADRENALECTOMY FOR ISOLATED ADRENAL METASTASIS IN OTHERWISE OPERABLE PATIENTS WITH NSCLC - TWO INSTITUTIONS STUDY
D. Petrov¹, A. Semkova¹, D. Djuric², E. Naseva³, G. Yankov³, S. Shumarova⁴, G. Todorov⁴
¹Thoracic Surgery Department, Saint Sophia University Hospital for Active Treatment of Pulmonary Diseases, Sofia/BG; ²2 Thoracic Surgery Department, Institute for Lung Diseases, Novi Sad/RS, ³Faculty of Public Health, Medical University Sofia, Sofia/BG; ⁴L. Stanishev Department of Surgery, Umah “Alexandrovskaya”, Sofia/BG

Background: Isolated adrenal metastasis (IAM) from non-small cell lung cancer (NSCLC) is a rare event and the management in such patients remains controversial. Our objective is to evaluate the long-term outcome after resection of IAM in operable NSCLC patients as a part of multimodality treatment. Method: Twelve patients (mean age 58.4 years) underwent adrenalectomy for NSCLC IAM. IAMs were synchronous (7) and metachronous (5), of them were contralateral and 8 ipsilateral. Adrenalectomy and metachronous (5), 4 of them were contralateral and 8 ipsilateral. Mean progression free survival (PFS) time is 25.1 months (95% CI 19.9-32.7) in 1 patient from this subset. In the last case REA was performed at a first stage, followed by right lower lobectomy. The mean interval between the lung resection and the adrenalectomy was 6 months. All patients were followed up for a mean period of 42 months. The survival was studied by Kaplan-Meier method. Log-Rank test for comparisons was applied. Result: There was no perioperative mortality. The mean overall survival (OS) time is 42.0 months (95% CI 33.8-50.3). One-year and 3-years OS rate is 90.8% and 64.6%, respectively. Six patients are still alive until the last follow-up, four of them are with progression. One of the patients underwent radio- and immunotherapy with good response for local recurrence 20 months after left upper lobectomy. Brain metastases were found in one patient 2 years after initial surgery, which were treated by stereotactic radiosurgery. No patients had local recurrence 2 years after adrenalectomy. Conclusion: Long term survival is possible after resection of IAM in carefully selected NSCLC patients with early locoregional stages without involvement of mediastinal lymph nodes.

Keywords: NSCLC, oligometastasis

P3.08-13 STEREOTACTIC BODY RADIOTHERAPY (SBRT) FOR OLIGOMETASTATIC LUNG NODULES: A SINGLE INSTITUTION SERIES
R. Wegner¹, N. Ahmed¹, S. Hasan², L. Schumacher², A. Colonias²
¹Radiation Oncology, Allegheny Health Network Cancer Institute, Pittsburgh/US; ²Radiation Oncology, Allegheny Health Network Cancer Institute, Pittsburgh/PA/US; ³Cardiothoracic Surgery, Allegheny Health Network, Pittsburgh/PA/US

Background: Lung metastases from a primary extrapulmonary malignancy often represent widespread metastatic disease. There are circumstances, however, where disease may truly be limited. For patients that cannot undergo surgical metastectomy, SBRT represents a non-invasive option. Herein, we report the results of using lung SBRT to treat limited lung lesions from extrapulmonary malignancies. Method: We retrospectively reviewed outcomes in 44 patients with 50 lung nodules treated with SBRT. Fifty percent of the patients were male and median age was 64 (38-86). The median number of nodules was 1 (1-3) and almost all patients had oligometastatic disease (90%). Thirty-four percent of patients had extrathoracic disease. Primary malignancies included bladder (2%), breast (14%), endometrial (7%), Ewing sarcoma (2%), cholangiocarcinoma (2%), colon cancer (30%), small bowel (2%), head and neck (14%), renal cell (5%), and thyroid (2%). Seventy-five percent of patients had systemic therapy prior to any lung SBRT. Result: As above, 50 lung nodules were treated with SBRT in 44 patients. Median dose was 48 Gy (36-54 Gy) in 5 fractions (3-8). This dosing scheme yielded a median BED10 of 100 Gy (60-105 Gy). Follow-up imaging was available for review in 96% of nodules. Median follow-up from SBRT was 17.5 months (1-68). One year local control was 82%. BED_Y>72 Gy predicted improved local control (90% vs 57% at 1 year). Local control was inversely related to SUV on pre treatment PET/CT using a cut off of 4. If lesions had SUV>4.0 local control was 67% compared to 92% at one year. One year overall survival from SBRT was 66%. There was no difference in OS if patients had extrathoracic disease. Forty-six percent of patients had distant failure at 6 months. There was no acute or late grade 3 or higher toxicity. Conclusion: Lung SBRT is an effective and safe tool for treatment of limited lung metastases. Dose selection remains important for local control, and lesions with increased SUV show higher predilection for local failure.

Keywords: SBRT, lung metastases, oligometastatic

P3.08-14 LONG-TERM SURVIVAL FOLLOWING SURGICAL RESECTION OF ISOLATED BRAIN METASTASIS IN NON- small cell lung cancer
C. Yen, W. Wu
N.92, Mackay Memorial Hospital, Taipei City/TW

Background: Lung cancer is one of the leading causes of death all over the world and the prevalence is still growing. About half of the patients are diagnosed with stage IV disease at presentation with the most common sites of distal metastasis including the brain, liver, adrenal glands, and bones. Brain metastases remain a significant problem in patients with lung cancer. Surgical resection of metastasis limited to brain had been recommended by guidelines. However, few patients received metastasectomy of brain metastasis and the benefit of such intervention is unclear. So, we reviewed such patients of a medical center to see if those patients achieved long term survival after operation. Method: All patients of non-small cell lung cancer with brain metastasis diagnosed in 2011/1/1 to 2017/12/31 from a medical center were reviewed. The characteristics of the patients, local control rate, survival time after diagnosis of brain metastasis, EGFR status and surgical complications were recorded. The survival rate was calculated using Kaplan-Meier model. Result: We identified 276 patients diagnosed with non-small cell lung cancer with brain metastasis. Of these, 24 patients received metastasectomy of brain metastasis. 22 of the 24 patients had metastasis limited to brain. 2 patients were excluded due to loss of follow up within one month after surgery. 20 patients were included in the analysis, of which 19 were adenocarcinoma, 1 was sarcomatoid carcinoma and 16 of them had solitary brain metastasis. 2 with 2 lesions and 2 with 4 lesions. The average size of brain mass was 3.67 cm (range 0.5 cm to 7.4 cm, standard deviation 1.78 cm). To the date of our data collection (2018/4/30), 8 of them were dead, 4 were censored and 8 were still alive with regular follow up. The median survival after diagnosis of brain metastasis was 40.3 months. The 3 year and 5 year survival rate were 72% and 24% respectively. Recurrence of brain metastasis was documented in 2 patients only. One patient died 26 days after operation due to intracranial hemorrhage. No cognitive function impairment or wound infection leading to prolonged hospitalization was recorded after operation Conclusion: For non-small cell lung cancer patient with isolated brain metastasis, surgical resection of brain metastasis is likely to lead to long term survival with acceptable risk. Randomized case control study is needed to determine the best treatment strategy for this group of patients. Keywords: Brain metastasis, non-small cell lung cancer, metastasectomy
P3.08-15 LUNG SQUAMOUS CELL CARCINOMA WITH SOLITARY OCULAR METASTASIS, SUCCESSFUL TREATMENT: AN INTERESTING AND RARE CASE REPORT
K. Ma, X. Wang, Y. Guo, Y. Xu
The First Hospital of Jilin University, Changchun/CN

Background: The incidence of ocular metastases from lung cancer is reported to be 0.1%-7% according to the international literature. Adenocarcinoma and small-cell lung cancer occupied the most proportion. Lung squamous cell carcinoma with solitary symptomatic ocular metastasis as the initial manifestation who accepted the multidisciplinary team (MDT) treatment has never been reported.

Method: In the diagnosis of intracranial disease, ophthalmofundoscopy and optical coherence tomography can be used for follow-up observation and evaluation of therapeutic effects. Whole body PET -CT imaging can be used to identify the primary cancer and determine the disease staging. Result: A 62-year-old woman presented to ophthalmology of hospital with a 1-week history of left eye pain, blurred vision. The ophthalmologist performed ophthalmofundoscopy and optical coherence tomography on the patient(Fig.1A). The ophthalmologist initial diagnosis is metastatic carcinoma to the eye. The diagnostic work was completed with PET-CT which confirmed the central lung cancer in the lower lobe of the right lung with ocular metastasis. After multiple disciplinary team consultations, including surgery, internal medicine, ophthalmology, radiotherapy and imaging department, the patient underwent the right lower lobe resection and lymph node dissection in December 2016. Postoperative pathology diagnose the right lung-squamous-cell carcinoma staged T2aN1. In January 2017, the patient reviewed the eye examination and indicated that the ocular lesions were enlarged. The patient received 4 courses of gemcitabine plus cisplatin regimen chemotherapy. The eye symptoms disappeared completely after 4 courses(Fig.2B). The progression-free time was 11.9 months. There’re 16.5 months for the patients has been followed up(March, 2018) from surgery, and the lesion of ocular was still controlled very well without any specific ocular treatment.

Conclusion: It’s the first report of a rare case with solitary ocular metastasis as the initial manifestation of lung squamous cell carcinoma. The successful treatment of this case was reported to provide a new therapeutic reference for clinicians to encounter similar cases in the future.

Keywords: Lung Squamous cell carcinoma, rare case, solitary ocular metastasis

P3.08-16 PROGNOSTIC VALUE OF PD-L1 EXPRESSION AND CORRELATION BETWEEN PRIMARY TISSUE AND BRAIN METASTASES IN OLIGOMETASTATIC NSCLC
V. Krishnan1, K. Imame1, L. Gaboury1, R. Albadine1, D. Tran-Thanh1, C. Gauvin2, N. Blais1, B. Routy3, M. Tehef1, M. Florescu2
1Pathology, CHUM, Montreal/CA, 2Faculté de Médecine, Université de Montréal, Montréal/CA, 3Hematology and Medical Oncology, Centre Hospitalier de L’Université de Montréal, Montreal/CA

Background: Immunotherapy with anti-PD-1/PD-L1 agents in first-line metastatic non-small cell lung cancer (NSCLC) is chosen based on tumor cell PD-L1 expression. However, the incidence and prognostic value of PD-L1 expression in NSCLC patients with oligometastatic brain disease has never been characterized.

Method: We retrospectively analyzed in our SARDO clinical database NSCLC patients with only 1-3 brain metastases (oligometastatic) treated in our University Health Care Center CHUM from 2007-2014. Samples were stained with SP263 (Ventana) antibody against PD-L1. A membranous staining of ≥25% was considered positive, and scoring was performed by an experienced pathologist. Kaplan-Meier survival curves of all clinical data were performed in SPSS 25.

Result: In our cohort of 39 oligometastatic NSCLC patients treated before 2014, none received immunotherapy. A total of 49 specimens (biopsy or surgical) from either the primary or metastatic site were adequate and included in the study. In 10 cases, both primary and metastatic tissue were available for correlation. Overall PD-L1 positivity was 40.8% (20/49), with a positivity of 54.5% (12/22) in primary site samples and 29.8% (8/27) in metastatic tissue. Correlation of PD-L1 status between primary and metastatic site was adequate and included in the study. In 10 cases, both primary and metastatic tissue were available for correlation. Overall PD-L1 positivity was 40.8% (20/49), with a positivity of 54.5% (12/22) in primary site samples and 29.8% (8/27) in metastatic tissue. Correlation of PD-L1 status between primary and metastatic site was adequate and included in the study. In 10 cases, both primary and metastatic tissue were available for correlation. Overall PD-L1 positivity was 40.8% (20/49), with a positivity of 54.5% (12/22) in primary site samples and 29.8% (8/27) in metastatic tissue.

Conclusion: Correlation of PD-L1 status between primary and metastatic site was adequate and included in the study. In 10 cases, both primary and metastatic tissue were available for correlation. Overall PD-L1 positivity was 40.8% (20/49), with a positivity of 54.5% (12/22) in primary site samples and 29.8% (8/27) in metastatic tissue.

P3.08-17 PAEDIATRIC MOTION MANAGEMENT SOLUTIONS FOR PARTICLE THERAPY BASED THORACIC STEREOTACTIC ABLATIVE BODY RADIOTherAPY (SABR)
A. Kent1, N. Hardcastle1, T. Kron2, G. Wheeler1, F. Hegi-Johnson1
1Radiation Oncology, Peter MacCallum Cancer Centre, Melbourne/AU, 2Physical Sciences, Peter MacCallum Cancer Centre, Melbourne/AU

Background: We have recently developed a paediatric protocol for the treatment of pulmonary metastases using Stereotactic Ablative Body Radiotherapy (SABR). In thoracic SABR the treatment is commonly planned to the internal target volume, which encompasses the gross tumour and excursion of the tumour in space. Particle therapy has been shown to be beneficial in paediatric patients, but unfortunately, most systems do not have respiratory motion management thereby limiting their utility in thoracic patients. We model the implementation of strategies such as ventilation using CPAP or deep inspiration breath hold (DIBH). The purpose of this study was to establish the benefit seen in a prospectively evaluated paediatric cohort to inform clinical trials.

Method: Patients Two patients with a single lesion, and one patient with 3 lesions were volumed. Average age was 12 years (range 6 to 16), prescription dose was 24 Gy in one fraction. Clinical volumes were...
based on the Maximum Intensity Projection (MIP) and this ITV covered all motion seen on 10 phases of respiratory binning. The test dataset was classified on the maximum exhale dataset (ME), as this was the most stable respiratory phase. 5 mm was added to create the PTV.

Dynamic conformal arc (DCAT) was used for planning using 6MV photons with 3 to 5 arcs. Result: Reduction in radiotherapy target volumes: Exhale scans resulted in a reduction in the radiotherapy target volumes for all lesions with the average standard deviation of the PTV being 3.85 ± 2.52 cc and 2.51 ± 1.35cc for MIP vs. ME scans respectively. Reduction in dose to lung and heart: V5 Gy (%) was also reduced from a mean of 6.0±4.10% vs. 1.7±1.73% for MIP vs. ME scans respectively. For the 2 patients with lesions near the heart the mean heart dose was also reduced from 2.35±0.78 Gy vs. 1.8±0.28 Gy for the MIP vs. ME scans respectively.

The maximum reduction was seen for patient 3; PTV was reduced from 8.2 to 4.9 cc, the V5 Gy (%) was reduced from 10 to 4.9% and the mean heart dose decreased from 2.9 to 2.0 Gy. Conclusion: Respiratory motion management strategies such as DIBH and CPAP may be suitable for paediatric patients who are old enough to comply with these strategies, and who do not require general anaesthesia. As in adult patients, the implementation of these strategies reduces the radiotherapy target volume, and results in lower doses to critical normal organs such as the lung and heart.

Keywords: Pulmonary stereotactic ablative body radiotherapy, Paediatric, Respiratory motion management

P3.08-18 CHANGING RESISTANCE MECHANISMS IN REBIOPIES OF ALK-POSITIVE NSCLC DURING MULTIPLE LINES OF THERAPY: ALK/ BRAF-MUTATIONS FOLLOWED BY EMT

E. Urbanska1, L. Melchior2, K. De Stricker3, J. B. Sarenson1, E. Santoni Rugli2
1Dept. Oncology, University of Copenhagen, Rigshospitalet, Finsens Center, Copenhagen/DK, 2Pathology Department, University of Copenhagen, Pathology Department, Copenhagen/DK

Background: 4-7% of NSCLC patients harbor the oncogenic ALK-rearrangements and may obtain clinical benefit from different ALK-inhibitors. Despite long remissions, resistance inevitably appears in alternative dosing forms. We present a case of a 38-year-old male with metastatic ALK-positive NSCLC. The patient received four consecutive ALK-TKIs and two lines of chemotherapy in-between. Significant clinical benefit was observed during different ALK-TKIs, as well as resistant ALK- and BRAF-mutations, and rapid progression shortly before death associated with phenotypical changes related to epithelial-mesenchymal transition (EMT).

Method: The diagnostic biopsy from cervical lymph nodes showed ALK-positive adenocarcinoma–metastasis with ALK variant 2 of EML4-ALK rearrangement. To identify TKI-resistance mechanisms during treatment, 4 rebiopsies from new metastatic lesions were analyzed histologically and by IHC, FISH and NG5. Additionally, two liquid biopsies were performed. Result: The treatment was initiated by Crizotinib in 2010; the 1st rebiopsy from new hepatic metastases showed a new p.C1156Y-mutation. The patient then received Cisplatin/Vinorelbine, progressed after two cycles and received 3rd line Ceritinib. The 2nd rebiopsy from new metastasis appearing 8 months later displayed persistence of ALK-fusion and p.C1156Y, but also new p.D1203N ALK- and p.V600E BRAF-mutations. Therapy was changed to 4th line Alectinib. A 3rd rebiopsy taken 4 months later from progressing sites revealed persisting ALK-fusion without p.C1156Y and p.D1203N mutations, and still p.V600E BRAF-mutation. No mutations were detected in plasma cfDNA 3 months later. Due to mixed response Pemetrexed was added and the patient had progression for a year. At subsequent progression a 4th rebiopsy from new lesions revealed maintained ALK-fusion without any ALK- or BRAF-mutations. Histology (expression of spindle cells and IHC (strong positivity for the mesenchymal marker Vimentin, loss of the epithelial marker E-cadherin)) revealed phenotypical changes related to EMT. A liquid biopsy did not show any DNA-mutations either. Meanwhile, 6th line Lorlatinib was initiated without any response. The patient died shortly before initial diagnosis. Conclusion: Following the treatment course of this case we observed heterogeneous and transitional mechanisms of resistance to different ALK-TKIs, such as secondary ALK-mutations, BRAF-mutation, and phenotypical changes consistent with EMT. This resistance heterogeneity suggests a continuously changing state of the disease. Sequential use of different ALK-TKIs and combination therapies may allow long responses with satisfactory quality of life, however phenotypical EMT-related changes remain a significant hurdle for TKI-based therapy that may explain lack of response to 3rd generation’s ALK-TKI, despite preserved ALK-positive status of the tumor.

Keywords: ALK-positive NSCLC, resistance mechanisms, EMT

P3.09-01 PDL1 PROFILE OF FILIPINO LUNG ADENOCARCINOMA PATIENTS SHOW MODERATE POSITIVITY AND LOW EGFR CORRELATION

F. H. Heraldel1, M. T. Barzaga2, N. Tan-Liu1, M. S. Angeles1, S. Bernal1
1Biochemistry and Molecular Biology, University of the Philippines - Manila, Manila/ PH, 2Pathology, Lung Center of the Philippines, Quezon/PN, 3Molecular Diagnostics, Na Cellular Therapeutics Lab, Lung Center of the Philippines, Quezon/PN, 4Institute of Personalized Molecular Medicine, the Medical City, Mandaluyong/PN

Background: The recent approval of anti-PD1 or PDL1 immunotherapy based on promising clinical trial results ushers in the accelerated adoption of pertinent companion diagnostics to make available the relevant therapy to cancer patients. The Lung Center of the Philippines established a routine immunohistochemistry-based diagnostic for PDL1 in collaboration with pharmaceutical companies to address the existing gap of diagnostic information for the lung adenocarcinoma in terms of who and to what extent, this subset of population may benefit from this new targeted therapy. This study aims to report the PDL1 profile of Filipino lung adenocarcinoma patients and evaluate its possible correlation with EGFR mutation. Method: Tumor block samples from 345 Filipino lung adenocarcinoma patients were processed for PDL1 testing using the Ventana PD1 Assay. Samples with positive results were subjected to Cobas EGFR mutation testing. Result: One hundred forty-two samples (i.e., 41.2%) were positive for the PD1 markers. Majority of the samples tested were males (i.e., 62-65% males vs. 33-38% females) with ages ranging from 64-66 years for both males and females. From a subset of eleven PD1 positive samples, only three showed positive EGFR mutations (i.e., 27.3%) with two, showing L858R mutation and one T790M mutation. Conclusion: Moderate prevalence of the PD1 markers were shown by Filipino lung adenocarcinoma patients suggesting that a moderate population could potentially benefit from anti-PD1 or PDL1 immunotherapy. Meanwhile, the low presence of EGFR mutation detected from the subset of PDL1 positive samples suggest a possibly mutually exclusive pattern for these biomarkers consistent with those reported in other studies. Albeit preliminary, co-EGFR testing could provide rationalization of clinical response and an alternative therapeutic targeting for this subset of patients.

Background: PD-L1 expression level evaluated by immunohistochemistry plays an important role in immunotherapy for many malignancies including non-small cell carcinoma of the lung (NSCLC). Adoptions in terms of personalized molecular medicine usher in the accelerated adoption of pertinent companion diagnostics to make available the relevant therapy to cancer patients. The Lung Center of the Philippines established a routine immunohistochemistry-based diagnostic for PDL1 in collaboration with pharmaceutical companies to address the existing gap of diagnostic information for the lung adenocarcinoma in terms of who and to what extent, this subset of population may benefit from this new targeted therapy. This study aims to report the PDL1 profile of Filipino lung adenocarcinoma patients and evaluate its possible correlation with EGFR mutation. Method: Tumor block samples from 345 Filipino lung adenocarcinoma patients were processed for PDL1 testing using the Ventana PD1 Assay. Samples with positive results were subjected to Cobas EGFR mutation testing. Result: One hundred forty-two samples (i.e., 41.2%) were positive for the PD1 markers. P3.09 PATHOLOGY WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30
adequate tumor cellularity and 17 (6.5%) samples with no or less than 100 viable tumor cells (all cell blocks). The majority of samples (n=216) were tissue blocks/cell blocks, followed by core biopsies (n=42) and other biopsies, such as shave biopsy (n=8). No (<1%) PD-L1 expression was detected in 12% (1-4%) expression in PD-L1 patients with two different antibodies. The two antibodies were used to determine the suitability of PD-L1 expression in lung tumors, including SSC, ADC, and SCLC. The method for assessing PD-L1 expression was based on tissue blocks and core biopsies. The authors concluded that the results showed that the lung microbiome of lung cancer patients altered significantly compared with healthy individuals. However, the association between microbial dysbiosis and lung cancer is not clearly understood, future studies involving larger cohorts and metagenomics, or metabolomics, may elucidate the correlations between gut microbiota and lung cancer development.

P3.09-04 ASSESSMENT OF PD-L1 EXPRESSION IN CYTOTOLOGY SAMPLES: AN ANALYSIS OF 263 CONSECUTIVE NSCLC BIOPSYs.

P. Illei, A. Rajgarah
Pathology, Johns Hopkins University School of Medicine, Baltimore/MD/US

Background: FDA approved anti-PD1 therapy can be considered for first-line use in advanced NSCLC with high (≥50%) PD-L1 expression. FDA approval was based on resection and core biopsy specimen, thus excluding most cytology samples. Since the majority of lung cancer patients are diagnosed with advanced stage disease and therefore are not candidates for surgical resection, bronchoscopic biopsies targeting N1 or N2 lymph nodes and/or the primary tumor are often the first biopsies these patients are subjected to. There is a great clinical need to determine the suitability of cytology specimen in the assessment of PD-L1 expression of NSCLC since often these are the only tissue samples available in advanced stage lung cancer. Method: PD-L1 immunohistochemistry was performed using the 22C3 antibody (Dako) on a Ventana automated platform on 263 consecutive cytology samples in a 14 month period. The assay was cross validated with the FDA approved companion diagnostic test. The samples included 216 cell blocks of fine needle aspirates of various sites, 10% of body cavity effusions, and 42 core biopsies of various organs (20 gauge cores). Tissue blocks (majority) or cell blocks were made from the aspirates followed by fixation in 10% buffered formalin. After fixation the tissue blocks, cell blocks, and core biopsies were subjected to routine tissue processing. Result: There were 246 (93.5%) samples with adequate tumor cellularity and 17 (6.5%) samples with no or less than 100 viable tumor cells (all cell blocks). The majority of samples (n=216) were tissue blocks/cell blocks, followed by core biopsies (n=42) and other biopsies, such as shave biopsy (n=8). No (<1%) PD-L1 expression was detected in 12% (1-4%) expression in PD-L1 patients with two different antibodies. The two antibodies were used to determine the suitability of PD-L1 expression in lung tumors, including SSC, ADC, and SCLC. The method for assessing PD-L1 expression was based on tissue blocks and core biopsies. The authors concluded that the results showed that the lung microbiome of lung cancer patients altered significantly compared with healthy individuals. However, the association between microbial dysbiosis and lung cancer is not clearly understood, future studies involving larger cohorts and metagenomics, or metabolomics, may elucidate the correlations between gut microbiota and lung cancer development.

P3.09-05 SIGNIFICANCE OF THE EXPRESSION OF PD-L1/PD-1 BY TUMORAL AND IMMUNE CELLS IN NON-SMALL-CELL LUNG CANCER.

C. Orta- Villalongí, L. De Petris1, L. Kis1, A. Yoshikawa2, H. Ngoc3, A. Roden4, J. Fukuk1a, A. Montero5
1Pathology, Karolinska University Hospital, Stockholm/SE, 2Department of Oncology and Pathology, Karolinska Institute, Stockholm/SE, 3Nagasaki University Hospital, Nagasaki/JP, 4Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester/MN/US, 5Cellular Pathology, Wythenshawe Hospital, Manchester NHS Foundation Trust, Wthenshawe/GB

Background: Non-Small Cell Lung Cancer (NSCLC) accounts for approximately 85% of all cases of lung cancer, including adenocarcinoma, squamous cell carcinoma and large cell carcinoma. There is solid evidence that demonstrates the existence of anti-tumor adaptive T-cell mediated immunity activation in lung tumors, indicating that lung cancers are immunogenic. PD-L1 and PD-1 expression level in lung cancers may be a predictive biomarker for the use of PD1/PD-L1 inhibitors. However, the reproducibility of PD-L1 staining using different antibodies and platforms is still a matter of debate. We assessed whether PD-L1 expression in non-small cell lung cancer is associated with specific clinical features or survival using four different antibodies and if the expression of PD-L1 in TILs correlates with the expression of PD-L1 in same group of cells. Method: PD-L1 and PD-1 status was assessed with IHC (AB clone SP142 and SP263 - Ventana, 22C3, 28-8 – Dako and PD-1) on archival FFPE surgical tumor specimens, arrayed on tissue microarrays (TMAs) with duplicate 1 mm cores, from Karolinska University Hospital. All patients (n = 598) underwent curative surgery between 1987 and 2015. The following cases were excluded from survival analysis (n = 89): R1 resection, early post-operative mortality, adjuvant cheemo- or radiotherapy. PD-L1 staining was scored as positive if present in >1% of tumor cells, independently of staining intensity. Result: Patient and tumor characteristics were as follows. Median age (QQR): 68 years (27-89); gender: male/female 54%/46%; histology: squamous-cell carcinoma (SCC)/Non-squamous (N-Sq)-NSCLC/carcinoid 219 (32%)/394 (58%)/45(7%); p-stage: IA/IB/IIB/IIB/IIB 50%/26%/10%/2%/0.2%. PD-L1 28-8 was positive in 11% of cases, Pearson Chi-square p<0.0001. PD-L1 positivity 22C3/SP263/SP142 was 10%/13%/3%. All carcinoids were negative for PD-L1. In NSCLC, PD-L1 positivity for each antibody was associated with tumor size (T1/T2-4; Fisher’s exact test, p<0.001) and grade of differentiation (G1, G2 and G3; p=0.0002). Statistically significant association between PD-L1 expression and OS was only observed using the clone SP263 (log-rank p=0.013). PD-1 expression in TILs correlates with those of PD-L1 (clone 28-8). Conclusion: In this surgical series, the clone SP142 showed less PD-L1 expression in the tumor cells. PD-L1 status was associated with tumor size, grading and only the clone SP263 showed association between its expression and survival ratio. PD-1 expression in TILs correlates with those of PD-L1. P3.09-06 THE LINK BETWEEN TUMOR PROMOTING FIBROUS MICROENVIRONMENT AND IMMUNOSUPPRESSIVE MICROENVIRONMENT IN STAGE I Lung ADENOCARCINOMA

T. Tsuboi 1, G. Ishii 7
1Division of Thoracic Surgery, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa/JP, 7Department of Pathology, Exploratory Oncology Research & Clinical Trial Center (Epoc), National Cancer Center Hospital East, Kashiwa/JP, 5Department of Pathology, Exploratory Oncology Research & Clinical Trial Center (Epoc), National Cancer Center Hospital, Kashiwa/JP, 6Division of Pathology, Exploratory Oncology Research & Clinical Trial Center (Epoc), National Cancer Center Hospital, Chuo/JP

Background: Podoplanin-positive cancer-associated fibroblasts (PDPN (+)CAFs) play an important role in cancer progression in non-small-cell lung cancer (NSCLC). The aim of this study is to clarify the correlation between fibroin microenvironment containing PDPN (+) CAFs and immune microenvironment. Method: 174 cases with stage I primary lung adenocarcinoma were analyzed in this study. We evaluated PDPN (+) CAFs and immune-related cells: CD 204-positive tumor-associated macrophages (CD204 (+) TAMs), CD 8-positive T cells and FOXP 3-positive T cells in cancer stroma by immunohistochemical staining method. By analyzing the gene expression profiles of lung adenocarcinoma (n=442), we compared the expression level of immune-regulatory cytokines between PDPN expression-high group and PDPN expression-low group. Results: Presence of PDPN (+) CAFs was a risk factor for recurrence (P=0.012). The number of CD204 (+) TAMs was significantly higher in PDPN (+) CAFs cases than in PDPN (+) CAFs cases (P<0.001). Furthermore, CD8 (+)/FOXP3 (+) T cell ratio was significantly lower in PDPN (+) CAFs cases (P=0.027). Within the same tumor, the number of CD 204 (+) TAMs was significantly higher in PDPN (+) CAFs area than in PDPN (-) CAFs area (P<0.001). Moreover, CD8 (+)/FOXP3 (+) T cell ratio tend to be lower in PDPN (+) CAFs area than in PDPN (-) CAFs area (P=0.062). Microarray analysis revealed PDPN expression-high group had significant higher levels of M-CSF, a cytokine inducing M2 macrophage polarization, and TGFβ1, IDO, VEGFA and galectin 1; immunosuppressive cytokines. Conclusion: The current results revealed that lung adenocarcinoma with PDPN (+) CAFs is typified by an immunosuppressive microenvironment, suggesting the close link between tumor promoting fibroin microenvironment and immune microenvironment.

P3.09-07 IMMUNOHISTOCHEMICAL EXPRESSION OF PROGRAMMED DEATH-LIGAND 1 IN DIABETIC PATIENTS VS NON-DIABETICS WITH NON-SMALL-CELL LUNG CANCER

M. Zaleski 1, S. Sharzehei 1, R. Voland 2, J. Varlotto 3, N. Rassaei 4, Y. Liu 4
1Pathology, Penn State Health M.S. Hershey Medical Center, Hershey/US, 2University of Wisconsin, Madison/US, 3Radiation Oncology, University of Massachusetts, Sudbury/MA/US, 4Penn State Hershey Medical Center, Hershey/US

Background: Immunohistochemical (IHC) expression of programmed death-ligand 1 (PD-L1) serves as a predictive biomarker to select a subgroup of patients who may benefit from immunotherapy. Diabetes mellitus type 2 (DM2) has been shown to be present in approximately 20-25% of lung cancer patients and adversely affects lung cancer outcome. Yet, there are no established studies which investigate potential differences in PD-L1 expression in this group of patients. Method: To investigate expression of PD-L1 in DM2 patients compared to non-DM2 patients, we assembled a retrospective cohort of 79 surgically-resected NSCLC cases (39-adenocarcinoma, 40-squamous cell carcinoma) without previous malignancies or pre-operative radiation. Clinical data were obtained by chart review. Patients with DM2 had HbA1c levels of 7.5-7.7. Histologic slides were methodically reviewed. PD-L1 (DAKO 22C3) immunohistochemistry was performed on slides with the maximum amount of viable tumor. Tumor positive score (TPS) was evaluated based on IASLC guidelines as follows: 0: no staining, 1: <1%; 2: 1-4%; and 3: >4%. Immunoreactivity was compared using Chi-square and Fisher’s exact tests. Results: Of the 79 cases of NSCLC, 40 (50.6%) were patients with DM2, and consisted of 20 (50%) adenocarcinoma, and 20 (50%) squamous cell carcinoma. Non-DM2 patients showed a relatively equal TPS distribution from 0 to more than 50%; however, DM2 group largely showed TPS of less than 50% (P=0.0319 Chi-square test); (P=0.0347 Fisher’s exact test). Conclusion: DM2 patients were less likely to have PD-L1 >50%, and therefore they may be less likely to respond to PD-L1 inhibition alone in the adjuvant setting. These findings are in accordance with the literature that supports a worse prognosis, tendency for co-morbidities, and known immunologic defects for DM2 patients with NSCLC.

P3.09-08 TUMOR HETEROGENEITY AND MOLECULAR PROFILE OF NSCLC IN THAI POPULATION

1Department of Medicine, Faculty of Medicine Ramathibodi Hospital, Bangkok/TH, 2Pathology, Ramathibodi Hospital, Bangkok/TH, 3Ramathibodi Hospital, Bangkok/TH, 4Phramongkutklao Hospital, Bangkok/TH, 5Rajavithi Hospital, Bangkok/TH, 6Medical Oncology Unit, Department of Internal Medicine, Ramathibodi Hospital, Bangkok/TH

Background: Oncogenic driven mutation is the key to develop targeted therapy in lung cancer. Different ethnicity and tumor heterogeneity affect the prevalence of molecular alteration. This study aimed to explore the unique molecular profile of lung adenocarcinoma in Thai population. Method: We studied 166 lung adenocarcinoma patients' molecular profile using Next Generation Sequencing (NGS) on 45 genes lung cancer panel (Ion Torrent system). Variants from NGS with coverage of higher than 1000X and cut off at 2% alternate variant frequency were considered positive. We validated the positive mutation of EGFR, BRAF, and KRAS by Real-Time PCR using the Amoy DX kit. Results: This study found 68%(113/166) of EGFR mutation, 9.6%(16/166) of V600E, 32.5%(54/166) of KRAS mutation, 9%(15/166) of MET exon14 splice site, 4.8%(8/166) of AKT mutation (E17K), 2.4%(4/166) of ROS1 mutation, 0.6%(1/166) of PIK3CA mutation (H1047R), and 0.6%(1/166) of PTEN mutation. Furthermore, we also found 40 patients (24.1%) who had more than one mutation in each person. We further validated the positive results by Real-Time PCR. Thirteen patients were obtained tissue from different organs and some with different period of time. T790M usually develop later in EGFR-positive patients who failed 1st or 2nd generation EGFR-TKI. Two patients (patient 5&9) who had lung surgery different lobe in same operation, had different mutation in tissues and one patient (patient 13) who obtained tissue from lung and pleural effusion cell block in different period of time had totally different mutation (Table1).

**Conclusion:** Thai populations have unique molecular alteration compared to the other ethnicities, especially, higher of BRAF V600E and MET exon14 splice site. Our population also has high co-mutation prevalence. Tumor heterogeneity is needed to explore in the larger cohort.

**Keywords:** molecular alteration in lung cancer
**PREVALENCE OF EPIDERMAL GROWTH FACTOR RECEPTOR MUTATION IN NON-SMALL CELL CARCINOMA LUNGS AT A CANCER CENTER IN NEPAL**

**Background:** Mutations in the epidermal growth factor receptor (EGFR) gene are commonly observed in non-small-cell lung cancer (NSCLC), particularly in adenocarcinoma (AC). The prevalence of EGFR mutations in different parts of the world is well documented but there is lack of information for patients in Nepal. This study aims at exploring the proportion of EGFR mutation among Nepalese patients with NSCLC/AC.

**Method:** A retrospective study was conducted in patients with all lung primary lesions diagnosed as NSCLC/AC and treated at Nepal Cancer Hospital and Research Center from March, 2015 till Feb, 2018. The related information on age, gender, histomorphological diagnosis, geographic distribution, ethnicity and EGFR mutational analysis were collected from the Department of Pathology and Laboratory Medicine at Nepal Cancer Hospital and Research Center, Nepal and were analyzed.

**Result:** Total 106 cases of primary malignant lung lesions diagnosed as NSCLC/AC were evaluated for EGFR mutational analysis. 3%, 12% and 86% were well, moderately and poorly differentiated NSCLC/AC respectively. 21% metastasized to lymphnodes, bone, liver and others and 8% had local invasion into pleura. EGFR mutation were seen in 36%(38 out of 106) of NSCLC/AC, most common in exon 19(55%) followed by exon 21(37%), exon 20(5%) and both exon 19&20(3%). There was no mutation found in exon 18. Malignancies were predominant in males (M: F=3:1) with median age 66years. However, EGFR mutation were predominant in female (M:F=0:6:1). Most of the patients were from Brahman/Chei community(42%) followed by Newar(30%), Tarai Madhesi(11%), Janajati(10%), Dalit(6%) and Tamang(1%). Despite of being second in population for NSCLC/AC Newars had the most number of EGFR mutation of 16% followed by 10%, 5% and 3% in Brahman/Cheuri, Janajati, Tarai Madhesi and Dalit respectively. Most of the patients were from central Nepal(32%), West Nepal(19%) and East Nepal(33%) followed by Newar(32%) and other mutations in 6%. Most of them were female from Newar community from central part of Nepal. Though rare, mutation in both the exons 19 and 20 were also observed. To our knowledge this is the first report in Nepalese population about EGFR mutation. A detailed population base and multicentric studies are recommended to know about the actual prevalence of EGFR mutation and it’s types in the Nepalese lung cancer patients.

**Conclusion:** EGFR mutation in lung cancer in our center was more than one third(36%) which is relatively high when compared to other parts of the world. Most of them were female from Newar community from central part of Nepal. Though rare, mutation in both the exons 19 and 20 were also observed. To our knowledge this is the first report in Nepalese population about EGFR mutation. A detailed population base and multicentric studies are recommended to know about the actual prevalence of EGFR mutation and it’s types in the Nepalese lung cancer patients.

**Background:** Detecting cfDNA in the liquid biopsy has become a promising method to explore the genetic landscape of tumor heterogeneity. We developed a pilot-study to find the suitable cutoff of variant frequencies detected from liquid biopsy by NGS to track tumor-associated mutations in NSCLC patients.

**Method:** Ninety-four samples (24 early-stage NSCLC, 70 late-stage NSCLC) were collected from Ramathibodi Hospital, Thailand. Profiling cfDNA using Ion Proton NGS platform. Overall average base coverage depth from NGS was 10,000x. all variants selected have read depths >10x in order to reach 0.1% sensitivity. Each of selected variants has threshold variant quality (QUAL) >20. Droplet digital PCR (ddPCR) was performed for EGFR-mutation testing to determine the appropriated cutoff variant frequency from NGS.

**Result:** In early-stage NSCLC, a minimum-threshold variant frequencies at 0.1% could detect EGFR exon19 deletion in all samples (24,100%), with BRAF (12.50%), KRAS (21.87.5%) and other mutations in AKT1, MET, PIK3CA, PTEN, ROS1 (14.58%). None of these mutations identified when using conventional level cutoff at 3% (Table1). ddPCR observed EGFR-mutations in 2 early-stage cases only (8.3%). In late-stage NSCLC, 64 (91.4%) cases were observed multiple mutations, suggesting tumor heterogeneity. At 0.1% cutoff in NGS, Thirty-six (52.9%) cases of EGFR-mutations in NGS and ddPCR were identical. Thirteen (18.6%) samples showed partial discrepancies in the mutations. Interestingly, NGS found EGFR-mutations in 20 (28.6%) samples which ddPCR failed to detect. 12 of them contained T790M. Only one sample (1.4%) using 0.1% cutoff was unable to detect EGFR-mutation. Higher variant allele frequencies were found in EGFR-positive detected by ddPCR compared to not-detected by ddPCR.

**Conclusion:** Detecting variant frequencies at 0.1% could reveal more hidden tumor-associated mutations compared to variant frequency cutoff at 3%. With a careful validation, profiling cfDNA using NGS can be a crucial method to accurately select treatment for NSCLC patients in the future.

**Keywords:** liquid biopsy, cfDNA, NGS
P3.09 PATHOLOGY
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.09-11 GENOMIC ORGANIZATION AT LARGE SCALES (GOALS) WITHIN NUCLEI AND CELL SOCIOLOGY FOR PREDICTING LUNG CANCER OUTCOMES
C. Macaulay1, M. Guillaud1, K. Enfield1, Z. Xu1, S. Lam1, W. Lam1, P. Gallagher2
1Integrative Oncology, British Columbia Cancer Agency Research Centre, Vancouver/ BC/CA. 2Integrative Oncology, BC Cancer Agency Cancer Research Centre, Vancouver/ BC/CA

Background: Accurate prediction of the biological aggressiveness of lung cancers in patients from limited material could have utility with respect to patient treatment planning. We examined the hypothesis that the quantification of large scale DNA organization or GOALS within the nucleus combined with tumour microenvironment as quantified by cell sociology (which cells types are adjacent which cell types) could predict patient outcomes. Method: Tissue (TMA cores) from patients with poor outcomes (lung cancer mortality within 24 months) and good outcomes (5+ year survivors) was stained using a stochiometric DNA stain (Feulgen-Thionin). High resolution brightfield imaging of 29 cores was performed using multiple wavelengths and spectral unmixing used to retrieve the DNA concentration at every pixel. In house software was used to automatically segment all the nuclei within each core, calculate 100+ features for each nucleus and classify each nucleus as epithelial, stromal or immune in origin. Further each nucleus was scored as coming from a patient with poor or good outcome. For each TMA core the percentage of these cell categories was tabulated as well as cell-cell association frequencies (for example the frequently an epithelial cell predicted to have come from a patient with good outcome was found next to a stromal cell predicted to come from a patient with poor outcome). Cell percentages and cell-cell interaction frequencies were used to predict patient outcome. Result: Many of the individually calculated features had a statistically significant association with patient outcome. Four+ features could predict patient outcome with 79% accuracy, 15+ different pairs of features could predict patient outcome with greater than 85% accuracy. Epithelial- stromal cell interactions and stromal cell – immune cell interactions were particularly predictive of outcome suggesting that microenvironment cell - tumour cell interactions predict future biological activity.

Conclusion: This pilot study suggests that GOALS and cell sociology could predict patient outcomes.

P3.09-12 MOLECULAR AND IMMUNOHISTOCHEMICAL CORRELATES OF RB1 INACTIVATION IN SMALL CELL LUNG CARCINOMA
N. Mahadevan, L. Sholl, D. Hwang
Pathology, Brigham and Women’s Hospital, Boston/MA/US

Background: Retinoblastoma (RB1) is a critical negative regulator of cell cycle progression, and serves as a tumor suppressor gene that is inactivated in many tumor types, including small cell lung carcinoma (SCLC). Because biallelic inactivation of RB1 has been observed in virtually all SCLC, loss of RB1 expression in the correct context is considered highly suggestive of SCLC or SCLC-like neuroendocrine carcinomas. However, the relationship between the genomic inactivation of RB1 and expression in SCLC has yet to be fully defined. Here, we characterize the genetic and immunohistochemical correlates of RB1 inactivation in SCLC. Method: SCLC (n=57), and combined SCLC cases with a non-neuroendocrine component (CSCCLC; n=5), that had undergone targeted next generation sequencing (NGS) (Oncopanel, 309-447 genes) were retrospectively identified. Designation of the molecular mechanism of RB1 inactivation was pursued by integrative analysis of RB1 variant type, variant allele fraction, and heterozygosity of the RB1 locus. RB1 protein status was interrogated in a subset of SCLC (n=25, 19 with biallelic inactivation) and CSCCLC (n=2) by immunohistochemistry (IHC). Result: 77% (44/57) of SCLC showed biallelic inactivation of RB1 by NGS, most commonly through a loss-of-function (LOF) variant and associated loss of RB1 protein expression (LOP) (65%). The most common molecular mechanism of RB1 genetic inactivation in these cases were nonsense (32%), frameshift (25%), and splice site (23%) variants, respectively. RB1 protein expression was lost in 89% (17/19) of SCLC with biallelic RB1 inactivation; the two remaining cases harbored RB1 splice site variants and displayed weak, patchy RB1 expression. Additionally, 80% (5/6) of SCLC without molecular evidence of RB1 biallelic inactivation showed loss of RB1 expression. Overall, 60% (3/5) of SCLC harboring splice site variants retained weak RB1 expression. 60% (3/5) of CSCCLC showed molecular RB1 inactivation in all tumor cells. While one CSCCLC showed loss of RB1 expression in both histologic components, the other tumor, which harbored a RB1 splice site variant, retained strong RB1 expression. Conclusion: Genetic inactivation of RB1 in SCLC may not be identified in ~20% of cases via targeted NGS. While most SCLC with biallelic RB1 inactivation show loss of RB1 expression, retention of weak RB1 expression in SCLC does occur and may be associated with RB1 splice site variants. While additional investigation is needed to interrogate the functional and clinical significance of retained RB1 expression in SCLC, these data suggest that genetic RB1 inactivation does not always result in loss of protein expression, which may have implications for disease classification.

Keywords: small cell lung carcinoma, next generation sequencing, retinoblastoma (RB1)

P3.09-13 MOLECULAR PROFILING SUGGESTS THE DIFFERENT MECHANISMS AMONG LOCAL INVASIVENESS IN RESECTED HUMAN LUNG ADENOCARCINOMA
Thoracic Surgery, Graduate School of Medicine, Kyoto University, Kyoto/JP

Background: Local invasive factors are pathologically defined as pleural or lymphovascular invasion in lung cancer. Accumulating evidences have shown that these factors are associated with metastatic activity finally leading to poor survival of the patients. Here we examined the correlations of cancer-progressive molecular markers with local invasiveness in resected human adenocarcinoma. Method: Clinical samples were obtained from the 256 cases of lung adenocarcinoma which were consecutively operated to treat from January 2001 to December 2007 in our institution. Pathological stage distribution of the cases by TNM classification was below: 1A: 118, 1B: 71, 2A: 22, 2B: 4, 3A: 23, 3B: 1, 4: 17. Tissue microarrays were immunohistochemically (IHC) stained. The previously published IHC data of molecular markers and DNA mutation data of EGFR and K-ras using our same cohorts were integrated. These markers included TP53, E-cadherin, vimentin, TWIST, CD133, CD44, Aldehyde dehydrogenase (ALDH), Carbonic anhydrase (CA)-9, Lactate dehydrogenase (LDH)-A, Glucose transporter (GLUT)-1, Hypoxia inducible factor (HIF) 1α, Ubiquitin C-terminal hydrolase (UCH)-L1, Gsr2, GEP100, Arf6, AMAP1, EPHB4L5, phosphorylated receptor tyrosine kinases (EGFR, HER2, Cmet, VEGFR2). Statistical analyses were performed by chi-square test or log-rank test. For survival data analyses,
Conclusion: The pivotal markers were different among the types of local invasiveness. Pathways commonly used in local invasiveness, nodal and distant metastases were suggested to be EMT, glycolysis, hypoxia-related.

Keywords: lung adenocarcinoma, molecular marker, local invasiveness

Notch1, 2, and 3. Result: Immunohistochemical study of lung tissues revealed that NOTCH2 was detected in bronchiolar epithelial cells and was often colocalized with CC10, and that adenocarcinoma tissues were more positively stained than those of squamous cell carcinoma and small cell carcinoma tissues. In human lung cancer cell lines the expression of NOTCH2 was similar to that of NOTCH1 and preferentially detected in non-small cell lung carcinoma (NSCLC) cell lines. Knockdown experiments of the Notch2 gene in NSCLC cell lines showed no significant changes in the expression of molecules associated with cell differentiation, proliferation, apoptosis, and motility. The effects of Notch2 gene knockdown could have been masked by concomitant Notch1 activation, as indicated by an increase in the intracellular domain of NOTCH1. Additionally, the transient transfection of the N2ICD gene induced CC10 expression in an adenocarcinoma cell line.

Conclusion: The present study revealed that Notch2 is important in Club cell differentiation in normal lungs and in adenocarcinoma. We also determined that Notch1 and Notch2 are covariant, and the balance of the expression of Notch receptors could determine the biological behaviors of lung cancer cells.

Background: Little is known about the pathogenesis or genetic profiles of idiopathic pulmonary fibrosis (IPF) associated non-small cell lung cancer (NSCLC). This study was performed to investigate the genetic profiles of IPF associated NSCLC and to explore the possibility of defining potential therapeutic targets by using next-generation sequencing (NGS).  

Method: The Oncomine Comprehensive Assay v3 (OCAv3) from Thermo Fisher was used to detect clinically relevant single nucleotide variants (SNVs), insertions/deletions (INDELs), copy number variations (CNVs), and gene fusions from 161 unique cancer-related genes. Result: Surgically resected tumor specimens from 18 patients with IPF associated NSCLC (adenocarcinoma, n=9; squamous cell carcinoma, n=9) were collected. A total of 61 gene mutations was identified by targeted NGS and a median number of mutated genes per patient was 5 (range, 2–26). None of these SNVs, INDELs, CNVs, or gene fusions from 18 patients with IPF associated NSCLC showed high frequency of mutations (gene frequency >5%).  

Conclusion: This study demonstrated novel genetic profiles of IPF associated NSCLC using NGS. Keywords: idiopathic pulmonary fibrosis (IPF), non-small cell lung cancer (NSCLC), next-generation sequencing (NGS)

P3.09-16 TRANSCRIPTOME PROFILING FOR SUBTYPING NSCLC: OFF THE BEATEN PATH(OLOGIST)  
L. Petersen1, A. D’silva1, M. Dean2, M. Konno3, Y. Ilnytskyy4, O. Kovalchuk4, G. Bebb1  
1Oncology, University of Calgary, Calgary/CA, 2Oncology, University of Calgary, Calgary/AB/CA, 3Health Services, Calgary/AB/CA, 4Biological Sciences, University of Lethbridge, Lethbridge/AB/CA  

Background: Histopathological distinction between non-small cell lung cancer subtypes is still relevant in the age of targeted therapy due to the relatively low number of patients with actionable molecular alterations such as EGFR mutations or ALK rearrangements in squamous cell carcinomas. In addition, for patients without these alterations, the choice of most effective chemotherapy regimen is often based upon gene fusions from a limited list of fusions.  

Method: The statistical method used was the multiple regression logistic model. Result: 146 men and 60 women out of 206 samples were tested for EGFR expression. Twenty-one men and sixteen women expressing EGFR positive. Activating kinase–domain mutations in EGFR were identified in 45 pts (21, 95%): exon 19 deletion = 23, L858R = 7, exon 20 insertion = 11, other = 4. EGFR alterations were associated with gender (p=0.044), women showed more alterations of the genes. Age and smoking habit of patients did not show significant association (p=0.757 and p=0.547, respectively).  

Conclusion: Our results showed a comparable frequency in EGFR mutations and gene fusion ALK in relation to the data published in western population. These results allow a proper diagnosis to provide pts with the most adequate therapy.

P3.09-17 MOLECULAR PROFILE IN LUNG ADENOCARCINOMA: AN AMO CENTER STUDY IN CORDOB A, ARGENTINA  
N. Pianik1, V. Bengio2, M. Canigiani1, P. Díaz3  
1Internal Medicine Department, Cordoba University, Cordoba, Argentina, 2Pathology, Cordoba Hospital, Cordoba, Argentina, 3Molecular Biology, Cordoba University, Cordoba, Argentina

Background: Substantial advances have been made in the understanding of the biology of NSCLC in relation to characterization of molecular abnormalities such as activations of oncogenes by mutations, translocations and amplifications, which are being used as molecular targets and predictive biomarkers. Molecular analysis of NSCLC, adenocarcinoma (AC) is now the standard of care for therapy selection Method: We determined the frequency of molecular alterations in EGFR and gene fusion ALK in our Caucasian and Hispanic populations to decide the adequate treatment. 206 small biopsies and resection specimens of 103 different institutions of Cordoba were studied during a period (2014 - 2018). In addition to Histopathology Type, we analyzed immunohistochemistry (IHC) characteristics and molecular profiles and Several clinical variables were studied. Different tests were performed to detect alterations of EGFR and fusion gene EML4-ALK expression, with the aim to identify our own profile and define a possible therapeutic option. EGFR mutation was studied by therascreen kit, PCR, in order to detect genetic alterations in exons 18, 19, 20 and 21. ALK translocations were analyzed by FISH (Vysis- Break Apart, Abbott) and IHC (Cis D5F3, ventana, Roche). We correlated the molecular profile with different clinical variables (age, gender, and tobacco habits). The statistical method used was the multiple regression logistic model. Result: 146 men and 60 women out of 206 samples were tested for EGFR expression. Twenty-one men and sixteen women expressing EGFR positive. Activating kinase–domain mutations in EGFR were identified in 45 pts (21, 95%): exon 19 deletion = 23, L858R = 7, exon 20 insertion = 11, other = 4. EGFR alterations were associated with gender (p=0.044), women showed more alterations of the genes. Age and smoking habit of patients did not show significant association (p=0.757 and p=0.547, respectively).  

Conclusion: Our results showed a comparable frequency in EGFR mutations and gene fusion ALK in relation to the data published in western population. These results allow a proper diagnosis to provide pts with the most adequate therapy.

P3.09-18 IDENTIFICATION OF MET EXON 14 SKIPPING MUTATIONS BY FUSIONPLEX™ SOLID TUMOR PANEL  
L. Tafe, S. Dehavergt, J. Kilbourn, D. Green, J. Peterson, F. De Abreu  
Department of Pathology, Dartmouth-Hitchcock Medical Center, Lebanon/NH/US

Background: MET exon 14 skipping (METex14), or splice site mutation, results in the deletion of the juxtamembrane domain of MET, leading to increased MET receptor pathway signaling. Non-small cell lung cancer (NSCLC) patients with METex14 mutations are eligible for therapy with MET inhibitors like crizotinib. METex14 mutations are diverse and complex and can be challenging to detect by targeted DNA NGS assays alone. The Archer FusionPlex™ Solid Tumor Panel use anchored multiplex PCR chemistry to detect fusions and other mutations including oncogenic isoforms in 53 genes associated with solid tumors. Method: In July 2016, we implemented the FusionPlex test in our clinical laboratory for routine testing of NSCLC. RNA is extracted from FFPE tissue using the AllPrep DNA/RNA FFPE Kit and RNA quantity is assessed using the Qubit HS RNA Assay, and RNA quality is assessed using the PreSeq RNA QC Kit. cDNA synthesis and library preparation were performed according to the manufacturer’s recommendations. Libraries are quantified using the KAPA Library Quantification Kit, diluted to 4 nM, pooled and sequenced on
the Illumina MiSeq System. Data analysis is performed using the Archer Analysis platform (v4.0.11). MET exon 14 isoforms were confirmed by an orthogonal method (DNA NGS assay and/or melt curve analysis).

Result: Since July 2016, samples from 275 NSCLC patients were successfully sequenced. Six (2.2%) MET oncogenic isoforms, consistent with MET exon 14 skipping mutations, were identified and subsequently confirmed. All six patients were female with an age range of 61-82 years. Two presented with stage I disease, two stage II, one stage III and one stage IV. To date, none of the patients have been treated with MET inhibitor therapy.

Conclusion: The FusionPlex Solid Tumor NGS panel can be routinely performed in the clinical laboratory to optimize detection of MET exon 14 mutations as well as other clinically actionable gene fusions.

Keywords: MET exon 14 skipping mutations; FusionPlex Assay; Next Generation Sequencing

Figure 1. Sequencing data reads detecting a MET exon 14 skipping mutation.
**Background:** Liquid biopsy is the new non-invasive technology to explore the molecular profile. We evaluate molecular alteration from matched tissue and liquid specimen in NSCLC patients using NGS. **Method:** A total of 61 matched tumors and cfDNA in NSCLC patients were retrieved for DNA extraction. All qualified samples were analyzed by using Next Generation Sequencing (NGS) with Gene Read Qiagen Lung Cancer Panel sequencing 45 Genes on Ion Torrent system. Variants from NGS with coverage of higher than 1000X of tissues and 10000X of liquid biopsy, cutoff at 3% variant frequency were considered positive. Each detected mutation was validated by the different method. **Results:** The average time from sample QC to MiSeq loading was 10 hours. Including 40-hour instrument run time and data processing and analysis, the sample-to-answer time was less than three days. Library pooling experiments evaluated sample run capacity, coverage uniformity, and variant call accuracy from FFPE TNA and DNA. For example, a single pool of 8 RNA and 16 DNA libraries was run in only 2 days. Library pooling of samples and multiplexing of libraries allow for genetic analysis of multiple tumors and blood samples in all samples. Result: This study found 59.0% and 19.7% of EGFR mutation, 14.75% and 8.20% of KRAS mutation in tissues and cfDNA, respectively. Moreover, we found 3.29% of BRAF V600E, 1.64% of MET exon14 splice site, and 1.64% of ROS1 mutation in tissue NGS and also confirmed by the other techniques, but there was none of these mutations in the blood sample. Looking at EGFR-mutation detected by different techniques, higher sensitivity, specificity, positive-predictive value, negative-predictive values, and concordant rate were found in tissue NGS and liquid ddPCR compared with liquid NGS at cutoff 3% of variant frequency detection, when the gold standard for validation was ARMS-PCR in tissue testing (Table 1).

**Conclusion:** Using tissue for molecular profile testing is still being the gold standard testing. Liquid biopsy is less invasive, but in our study, liquid NGS performed less sensitivity, specificity, PPV, NPV, and concordance rate compared with tissue NGS. We need to explore more for proper cutoff of variant allele frequency to develop more sensitivity and specificity of liquid NGS.

**Keywords:** lung cancer, liquid biopsy, NGS
Background: Primary mucoepidermoid carcinoma of the lung is a rarely reported neoplasm. Synchronous primary malignancies of the lung comprising mucoepidermoid carcinoma and conventional adenocarcinoma are highly unusual neoplasm. Method: Case Report: A 75-year-old female presented with left-sided pleuritic chest pain and cough. CT scan of the chest showed a 3.5 cm mass over the lower lobe. Result: Microscopic examination revealed the tumor comprised two different histologic components of adenocarcinoma and mucoepidermoid carcinoma. This unique combination of lung malignancies showed characteristic morphologic and immunohistochemical features. Molecular differentiation and genetic mutation analysis would be a valuable tool for the diagnosis of primary lung malignancy with two different histologic types. Conclusion: Herein, we present a rare case of mixed mucoepidermoid carcinoma and adenocarcinoma of the lung. In this work, we discuss the clinicopathological features of previously reported mixed mucoepidermoid carcinoma and adenocarcinoma of the lung and with its mutation by molecular and genetic analysis.

Keywords: Mucoepidermoid, Adenocarcinoma, lung cancer

P3.09-22 CORRELATION BETWEEN MAXIMUM TUMOUR DIAMETER MEASUREMENT ON CT-SCAN AND HISTOPATHOLOGICAL SPECIMEN: AN INDIAN EXPERIENCE

M. Gowda1, B. Bansal1, V. Kumar1, S. Deo1, S. Bhorival1, D. Jain1, P. Malik2, S. Jee Bharati3, S. Kumar4
1Surgical Oncology, All India Institute of Medical Sciences, New Delhi, New Delhi/IN, 2Surgical Oncology, Bra-arch, All India Institute of Medical Sciences, New Delhi/IN, 3Pathology, All India Institute of Medical Sciences, New Delhi/IN, 4Medical Oncology, All India Institute of Medical Sciences, New Delhi/IN

Background: Lung cancer is staged according to TNM classification, which encodes the anatomic extent of the disease. This is the most important prognostic factor in patients diagnosed with lung cancer. CT scan is a basic imaging modality used for pre-treatment tumour staging (I-T staging). Each centimetre increase in size leads to worsening of prognosis. Adjuvant treatment decisions are based upon the final histopathological tumour size. Accurate clinical and pathologic correlation of prognosis. Adjuvant treatment decisions are based upon the final histopathological tumour size. Accurate clinical and pathologic correlation has been an important focus of research in many cancers. The objective of our study is to use for any discordance with respect to tumour size calculated by CT scan and final histopathological specimen in patients of our study is to see for any discordance with respect to tumour size calculated by CT scan and final histopathological specimen. Method: A total of 109 patients with lung cancer who underwent both surgical material offers a very high percentage of positive results, close to the histological one. But in the tumor size less than 1.0cm, the establishing of the histological type is more difficult by cytological examination. Despite this, the cytology may be extremely useful in diagnosis of the small peripheral tumors. The cytological characteristics of small peripheral adenocarcinoma were little reference to the differentiation at the cellular level. Our findings indicated that the presence of several nucleoli and granular chromatin densely are the factors of adenocarcinoma.

Keywords: ground-glass opacity cytology reproducibility

P3.09-23 ACCURACY AND REPRODUCIBILITY OF TOUCH IMPRINT CYTOLOGY IN RESPECTED LUNG CANCERS

General Thoracic Surgery, Tokyo Medical University, Tokyo/JP

Background: With the development of high-resolution computed tomography (CT), small-sized tumors showing ground-glass opacity (GGO) on chest CT images has been more frequently encountered. However, methods such as the transbronchial biopsy and the computed tomography-guided fine-needle aspiration cytology are limited in their ability to diagnose such small lung tumors. We evaluated about the association of the cytological features with the histological examination using the surgically resected specimen. Method: 169 patients, age between 31–87 years old, who showed radiological signs of peripheral lung tumors less than 3.0cm in diameter on CT images underwent surgical resection at our institution between 2015 and 2016. The histological examination was performed on surgical specimen, fixed with 10% formalin and stain with Hematoxylin–Eosin. The cytological examination was performed on stamps from surgical material by Papanicolaou staining. The morphological features were compared both histopathological diagnosis and cytological diagnosis of imprint cytology derived from the resected specimen. Interobserver reproducibility was assessed by Kappa coefficient providing a measure for agreement beyond chance. Result: By histologically (in the 169 cases), the diagnostic of lung cancer was given with the establishing of the histological type. In 139 cases (82.2%) of the cases diagnosed as adenocarcinoma, in 25 cases (14.8%) squamous cell carcinoma, in 3cases (1.7%) lung adenocarcinoma, and one case each of adenosquamous carcinoma and pleomorphic carcinoma. There was 86.3% (146 of 169 cases) agreement with a K statisticvalue of 0.65. Obtained kappa values from imprint cytology showed good (from 0.60 to 0.8) for detection of epithelial cell abnormalities indicating high observer diagnostic reproducibility. Conclusion: This kappa statistic method allows assessment of the diagnostic quality of a respiratory cytology. Imprint cytology for small peripheral lung cancer is a useful method for evaluating tumors. Our data indicate the fact that the cytological examination on imprints from surgical material offers a very high percentage of positive results, close to the histological one. But in the tumor size less than 1.0cm, the establishing of the histological type of lung cancer is more difficult by cytological examination. Despite this, the cytology may be extremely useful in diagnosis of the small peripheral tumors. The cytological characteristics of small peripheral adenocarcinoma were little reference to the differentiation at the cellular level. Our findings indicated that the presence of several nucleoli and granular chromatin densely are the factors of adenocarcinoma.

P3.09-24 THE CONCORDANCE OF HISTOLOGICAL DIAGNOSIS FROM TRANSBRONCHIAL BIOPSY AND RESECTED SPECIMEN OF LUNG CANCERS

Y. Kidokoro1, T. Haruki2, Y. Nozaka1, W. Fujiwara3, T. Miyamoto3, Y. Suzuki2, Y. Taniguchi2, M. Kodani5, Y. Umekita6, H. Nakamura1
1Division of General Thoracic Surgery, Tottori University Hospital, Yonago/JP, 2General Thoracic Surgery, Tottori University Hospital, Yonago/JP, 3Department of Surgery, Division of General Thoracic Surgery, Tottori University, Faculty of Medicine, Tottori/JP, 4Division of Organ Pathology, Tottori University, Yonago/JP, 5Medical Oncology and Molecular Respiratory, Tottori University, Yonago/JP, 6Department of Pathology, Division of Organ Pathology, Tottori University, Faculty of Medicine, Tottori/JP

Background: In resected samples, the histological diagnosis of lung cancer is made after the association of histological features, which was the established histologic type of lung cancer. However, in many cases, the histological diagnosis is made before the resection and the follow-up treatment is based on the information obtained at the biopsy examination. Method: A total of 653 patients with primary lung cancer were operated on in our hospital between January 2013 to March 2018. Among them there were 438 patients who underwent bronchoscopy examination, and 364 patients (83.1%) were diagnosed preoperatively as lung cancer. We retrospectively reviewed 316 patients who underwent both transbronchial biopsy (TBB)
then surgical resection for primary lung cancer between January 2013 to March 2018. We compared diagnosed histological types, examined the accuracy of preoperative diagnosis by TBB, and evaluated the concordance between those two kinds of specimens. Result: In 302 of the 316 patients (95%), the histological types of lung cancer diagnosed from TBB matched those from resection specimens (κ = 0.878). Care facilities were the highest in adenocarcinoma (243/252; 99%), followed by squamous cell carcinoma (52/55; 95%). On the other hand, it was only 50% in neuroendocrine carcinoma (small cell carcinoma and LCNEC ± combined with adenocarcinoma / squamous cell carcinoma). Due to histological heterogeneity, 6 of 14 patients were diagnosed with different types of postoperative diagnosis, and four were due to the inconsistency of immunohistochemical (IHC) staining between biopsy and resected specimens. Conclusion: We considered that lung cancer has not only histological heterogeneity but also IHC heterogeneity. If larger samples are taken, the preoperative diagnosis of histological type could be more reliable.

Keywords: transbronchial biopsy, resected specimen, Concordance

P3.09-05 SURVIVAL ANALYSIS IN YOUNG ADULTS WITH LUNG CARCINOMA
J. Nicolau1, M.A. Koike Folgueira1, R. Roela1, S. Maistro1, M.L. Katayama2, J. Eluf Neto1, C. Luizaga3, K. Ribeiro4, G. De Castro, Jr.1
1Oncology. Centro de Investigación Translacional En Oncología (Cito). Instituto Do Cancer Do Estado de Sao Paulo (Itesp). Hospital Das Clinicas HCFMUSP. Facultade de Medicina, Universidade de Sao Paulo. Sao Paulo/BR. 2Fundacao Onccentro Do Estado de Sao Paulo (Fosp). Sao Paulo/BR

Background: Lung cancer is uncommon in young adults and there is no consensus about its behavior in this age group. The aim of this study was to compare clinical and pathological characteristics and median overall survival in young adults (<40 years) and older adults (intermediate: 41-65 years and elderly: >65 years) with lung carcinoma. Method: A retrospective cohort study including information from 21,285 lung cancer cases (ICD – O: C34) diagnosed in the period 2000 – 2009 was performed. Cases were retrieved from the hospital based cancer registries in the state of Sao Paulo, Brazil. Study variables included sex, histological type, cancer staging based on the TNM System, status in the last follow-up, date of diagnosis and date of death. For 1,410 patients, who were initially considered lost to follow-up, a consultation was made through Brazilian databases, such as national registry of deceased, registry of living individuals and voting status in political elections (Brazilian compulsory voting system). After this search, 202 patients remained as loss of follow-up (1.02%). Survival analysis was performed by Kaplan-Meier curve and log-rank tests. Result: Among 21,285 patients, 19,900 were further analyzed, after exclusion of patients diagnosed with malignant neoplasms without specification, carcinoid and neuroendocrine tumors and in situ carcinomas. Most patients were diagnosed with adenocarcinoma (49.5%) or squamous cell carcinoma (27.67%) in advanced stage (clinical stages III and IV) (80.26%). Young adults were 542 patients (2.72%), intermediate adults were 10,661 (53.57%) and elderly people were 8,697 (43.70%). Adenocarcinoma was the most prevalent histological type in all age groups (63.09%, young adults vs 49.85%, intermediate adults vs 48.33%, elderly patients) and squamous cell carcinoma was the second most prevalent (14.02%, young adults vs 25.71%, intermediate adults vs 30.93%, elderly patients). In all age groups, most patients presented metastatic disease (stage IV: 58.85%, young vs 51.18%, intermediate vs 43.14%, elderly adults). Median overall survival was significantly different among age groups: young adults, 9 months (CI 95%: 7.71-10.28); intermediate adults, 8 months (CI 95%: 7.74-8.25) and elderly patients, 7 months (CI 95%: 6.73-7.26)<p-value>0.001. Conclusion: Most young adults were diagnosed with adenocarcinoma in advanced stage. Although still very troublesome, our results indicated median overall survival was longer in young adults than in older adults.

P3.09-26 CONCORDANCE OF SURGICAL RESECTIONS AND FINE NEEDLE BIOPSY-DERIVED CELL BLOCK SECTIONS FOR PD-L1 22C3 IMMUNOHISTOCHEMISTRY
University Health Network, Toronto/CA

Background: A significant proportion of lung cancer patients presents at an advanced disease stage. Diagnosis and treatment in these patients is frequently based on small tissue samples such as fine needle biopsies. Eligibility for pembrolizumab immunotherapy requires assessment of the PD-L1 expression. Data on the concordance of PD-L1 assessment by immunohistochemistry between quantitatively limited samples, in particular cytology specimens, and resections are scant. We studied PD-L1 in formalin-fixed paraffin-embedded (FFPE) cell block sections of CT-guided transthoracic fine needle biopsies in comparison with the subsequent resection specimens of the primary lung tumors.

Method: Paired specimens of fine needle biopsy-derived cell blocks and subsequent lung tumor resections of the same anatomic site were obtained from the archives of the Department of Pathology, University Health Network. Cell blocks were produced from normal saline needle rinse fluids fixed with a final concentration of 10% neutral-buffered formalin and processed using the Histogel method for paraffin-embedding. Cytology samples treated with alcohol-based fixatives were not included. Cell block sections were reviewed for a minimum of 100 tumor cells. Cases below the positivity threshold were excluded. Staining was performed using the 22C3 pharmDxTM assay (Agilent). All cell block and representative tumor sections were assessed by three observers (1 expert pulmonary pathologist, 2 cytopathologists). Tumor proportion score (TPS) were recorded and a final TPS was determined using the mean between expert and second closest observer. Cases close to the ≥50% cut-off underwent multiphase microscope review. Pearson, intraclass correlation coefficients and test parameters were calculated using standard statistical methods. Result: 43 paired cases were informative. Mean interval between biopsy and resection was 1.5 months (range 0-4). TPS of cell blocks and resections showed positive correlation (Pearson: 0.8; range 0.78 - 0.84 for individual observers). Intraclass correlation coefficients were 0.97 (cell blocks) and 0.92 (resections). 10/43 (23%) cell blocks and 9 (21%) resections were positive at TPS≥50%. 21/43 (49%) cell blocks and 19 (44%) resections were positive at TPS≥1%. Sensitivity, Specificity, PPV, NPV and accuracy were 78/74, 91/71, 70/67, 94/77 and 88/72% for the ≥50% cut-off, respectively. Conclusion: Cytology FFPE cell block sections showed strong positive correlation with resection specimens of the same anatomic site for PD-L1 assessment using the 22C3 pharmDxTM immunohistochemistry assay. Reliability between observers was excellent. Test parameters, in particular for the ≥50% cut-off value, were deemed acceptable for clinical use. Selected side review of cases with discordant scores indicated tumor heterogeneity as cause.

P3.09-27 HISTOPATHOLOGIC PARAMETERS DEFINE FEATURES OF TREATMENT RESPONSE TO NEOADJUVANT CHEMOTHERAPY IN NON-SMALL CELL LUNG CANCER
1Pathology, Division of Pathology and Laboratory Medicine, The University of Texas MD Anderson Cancer Center, Houston/US, 2Department of Thoracic/head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, Tex/TX/US, 3Department of Thoracic/head and Neck Medical Oncology, MD Anderson Cancer Center, Houston/US, 4Anatomical Pathology, The University of Texas MD Anderson Cancer Center, Houston/TX/US, 5Thoracic and Cardiovascular Surgery, MD Anderson Cancer Center, Houston/TX/US, 6Melanoma Medical Oncology, MD Anderson Cancer Center, Houston/TX/US, 7Thoracic/head and Neck Medical Oncology, MD Anderson, Houston/TX/US, 8Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston/TX/US, 9Thoracic/head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston/TX/US, 10Thoracic and Cardiovascular Surgery, UT MD Anderson Cancer Center, Houston/TX/US

Background: Previous studies indicate that neoadjuvant chemotherapy improves survival in patients with loco-regionally advanced non-small cell lung cancer (NSCLC). The amount of residual viable tumor has been associated with long-term overall survival. This histopathologic
measure has potential to become a standard method for evaluation of the effectiveness of neoadjuvant therapy regimens. However, adequate comparison of chemotherapy-treated and untreated lung cancers is lacking. We analyzed histopathologic characteristics of resected NSCLC with and without prior neoadjuvant chemotherapy. Method: Histopathologic assessment was performed of specimens obtained from patients enrolled on the immunogenomic lung cancer study (ICON), which integrates clinical, pathologic, immune, genomic and outcome data from surgically resected NSCLC. Cases included material from 10 patients who underwent neoadjuvant chemotherapy and 10 patients treated with primary surgery (adenocarcinoma, n=5; squamous cell carcinoma, n=5; for each cohort). Hematoxylin and eosin-stained tumor sections (mean, 6; range, 3-10) were evaluated and semiquantitatively scored for parameters commonly attributed to treatment response. The percentage of viable tumor was estimated by comparison to the proportion of fibrosis and necrosis on each slide. Additional parameters analyzed included the presence of inflammation, tertiary lymphoid structures (TLS), macrophages, lymphovascular invasion (LVI), cholesterol clefts, giant cells and neovascularization (score 0-3). For each patient, the results for all slides were averaged to determine a mean value. P values were calculated using the Mann–Whitney test. Result: All histopathologic parameters typically associated with treatment response could also be identified in untreated specimens, albeit in different proportions. Compared to the untreated cohort, samples after chemotherapy were characterized by lower proportion of viable tumor (42.4% vs 67.7%, p=0.04) and higher degrees of fibrosis (46.6% vs 26.6%, p=0.08), and necrosis (11.0 % vs 5.6%, p=0.35). Among the additional parameters, similar scores were seen for inflammation (1.54 vs 1.46, p=0.60), TLS (1.00 vs 0.80, p=0.47), LVI (0.16 vs 0.23, p=0.62), and neovascularization (both 0) while macrophages (0.94 vs 0.12, p=0.20), cholesterol clefts (0.92 vs 0.13, p=0.03) and giant cells (0.80 vs 0.40, p=0.17) were more common among the neoadjuvant cohort. Conclusion: Histopathologic variables commonly associated with chemotherapy treatment response can also be identified in treatment naive lung cancers. However, the amount of viable tumor, fibrosis and cholesterol clefts are parameters strongly associated with neoadjuvant therapy. These results highlight the importance of assessing the type and extent of treatment response. Analysis of larger patient cohorts will reveal potential prognostic value in primary tumors, chemotherapy-treated, and eventually immunotherapy-treated tumors.

P3.11-01 METHYLATION MARKERS THAT CORRELATE WITH OCCULT LYMPH NODE METASTASES OF NSCLC AND A PRELIMINARY PREDICTION MODEL

W. Liang1, J. Tao2, Z. Jiang2, J. Sun2, J. Fan2, J. He3

1The First Affiliated Hospital of Guangzhou Medical University; China State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, Guangzhou/CN, 2Anchordx Medical Co., Ltd., Guangzhou/CN, 3Department of Thoracic Surgery, The First Affiliated Hospital of Guangzhou Medical University; State Key Laboratory of Respiratory Disease; National Clinical Research Center of Respiratory Disease, Guangzhou/CN

Background: Lymph node (LN) metastasis status is the most important prognostic factor before surgery, while the invasive biopsy fails to be widely used. Therefore, more precise and non-invasive methods are warranted to determine the lymph node status preoperatively and lead to appropriate treatment strategy. Methylation alteration is an optimal measure has potential to become a standard method for evaluation of the effectiveness of neoadjuvant therapy regimens. However, adequate comparison of chemotherapy-treated and untreated lung cancers is lacking. We analyzed histopathologic characteristics of resected NSCLC with and without prior neoadjuvant chemotherapy. Method: Histopathologic assessment was performed of specimens obtained from patients enrolled on the immunogenomic lung cancer study (ICON), which integrates clinical, pathologic, immune, genomic and outcome data from surgically resected NSCLC. Cases included material from 10 patients who underwent neoadjuvant chemotherapy and 10 patients treated with primary surgery (adenocarcinoma, n=5; squamous cell carcinoma, n=5; for each cohort). Hematoxylin and eosin-stained tumor sections (mean, 6; range, 3-10) were evaluated and semiquantitatively scored for parameters commonly attributed to treatment response. The percentage of viable tumor was estimated by comparison to the proportion of fibrosis and necrosis on each slide. Additional parameters analyzed included the presence of inflammation, tertiary lymphoid structures (TLS), macrophages, lymphovascular invasion (LVI), cholesterol clefts, giant cells and neovascularization (score 0-3). For each patient, the results for all slides were averaged to determine a mean value. P values were calculated using the Mann–Whitney test. Result: All histopathologic parameters typically associated with treatment response could also be identified in untreated specimens, albeit in different proportions. Compared to the untreated cohort, samples after chemotherapy were characterized by lower proportion of viable tumor (42.4% vs 67.7%, p=0.04) and higher degrees of fibrosis (46.6% vs 26.6%, p=0.08), and necrosis (11.0 % vs 5.6%, p=0.35). Among the additional parameters, similar scores were seen for inflammation (1.54 vs 1.46, p=0.60), TLS (1.00 vs 0.80, p=0.47), LVI (0.16 vs 0.23, p=0.62), and neovascularization (both 0) while macrophages (0.94 vs 0.12, p=0.20), cholesterol clefts (0.92 vs 0.13, p=0.03) and giant cells (0.80 vs 0.40, p=0.17) were more common among the neoadjuvant cohort. Conclusion: Histopathologic variables commonly associated with chemotherapy treatment response can also be identified in treatment naive lung cancers. However, the amount of viable tumor, fibrosis and cholesterol clefts are parameters strongly associated with neoadjuvant therapy. These results highlight the importance of assessing the type and extent of treatment response. Analysis of larger patient cohorts will reveal potential prognostic value in primary tumors, chemotherapy-treated, and eventually immunotherapy-treated tumors.

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.11-02 LUNG CANCER SCREENING IN A HIGH INCIDENCE POPULATION: RESULTS OF LOW-DOSE CT SCREENINGS IN A NORTHERN KENTUCKY COMMUNITY HEALTHCARE SYSTEM

R. Calhoun1, G. Turner1, G. Schmitt1, M. Gieske1, E. Krasik1, V. Williams1, S. Brown2, M. Lockwood3, E. Burns1, A. Snow1

1St. Elizabeth Healthcare, Edgewood/KY/US, 2St Elizabeth Physicians, Crestview Hills/KY/US, 3St. Elizabeth Physicians, Lakeside Park/KY/US

Background: The National Lung Screening Trial (NLST) demonstrated that low-dose CT screening increases lung cancer-related survival in at-risk patients. In the U.S., Kentucky has the highest rate of lung cancer, worst historical survival rates and could benefit greatly from a robust screening program. However, concerns have been raised that lung cancer screening performed broadly in the community may not replicate NLST results. Here we evaluate the initial 3 years of a Northern Kentucky community healthcare system lung cancer screening program. Method: Medical records related to screening low-dose CTs performed in the St. Elizabeth Healthcare System from January 1, 2015 through February 28, 2018 were retrospectively reviewed. Statistical significance was calculated using a two-sample t-test (p <0.05). Result: Overall, 3,496 low-dose CTs were completed. Screenings increased annually, with 218 performed in 2015, 716 in 2016, 1,933 in 2017 and 629 through February 2018. Incidences of interventions resulting from screening findings were tallied (Table 1). Screenings produced a shift to an earlier stage at diagnosis (Figure 1). Table 1

P3.11 SCREENING AND EARLY DETECTION
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.11-03 IMPLEMENTING LUNG CANCER SCREENING IN CANADA: EVIDENCE ON ADHERENCE AND BUDGET IMPACT FROM THE PAN-CANADIAN EARLY DETECTION STUDY
S. Cressman1, S. Peacock1, A. Tremblay2, C. Ho3, M. Tammemagi4, S. Lam1
1Cancer Control Research, The British Columbia Cancer Agency, Vancouver/BC/CA, 2University of Calgary, Calgary/CA, 3Medical Oncology, BC Cancer, Vancouver/BC/CA, 4Brock University, St. Catharines/CA

Background: High-risk lung cancer screening has favourable cost-effectiveness ratios; making it an attractive intervention for lung cancer control. Relatively little is known, however, about the implementation of lung cancer screening in universal health care systems. To address this, we characterize screening adherence rates in the Pan-Canadian Early Detection of Lung Cancer Study (PanCan) and prepare a budget impact analysis for Canada. Method: We retrospectively characterized screening adherence to short-term (first-year) and long-term (year-four) annual screening rounds in the PanCan study and explored association with socio-demographic and screening characteristics with logistic regression models and Mann-Whitney rank sum and Chi square likelihood tests. We did a four-year budget impact analysis using published utilization rates for screening-related and incidental healthcare resources, smoking cessation, opportunistic screening and projected market dynamics for entrant treatments in Canada. Result: The PanCan study screened 2537 participants with a baseline LDCT exam; of these, 2254 (88.9%) adhered to the second annual screening exam and 1,762 (69.5%) adhered to the year four exam. After adjusting for lung cancer incidences and other-cancer mortality, we found significant associations between self-reported “current smoker” status and lower, second annual scan adherence rates (p<0.05); while variables related to the delivery of the intervention—such as the use of screening autofluorescence bronchoscopy and finding a lung nodule on the baseline LDCT—were significantly associated with greater adherence (p<0.05). Adherence to year-four screening exams was positively associated with age, family history of lung cancer, baseline quality of life and prior screening exam adherence (all p<0.05). Non-adherence was significantly associated with participants who had greater than 100 pack-years of smoking history and a lower level of formal education (p<0.05). Compared to participants who adhered to their scheduled, year-four annual screening exams, non-adherent participants had a higher predicted risk of developing lung cancer at baseline (p<0.05). The budget impact analysis indicates that the incremental program costs for screening an estimated 257,914 eligible, high-risk, non-adherent participants who were at the highest risk of developing lung cancer, were to uncertainty around the cost to treat actionable incidental findings and the adoption of entrant systemic therapy drugs. Conclusion: Study participants who were at the highest risk of developing lung cancer, were the least likely to adhere to screening. Using risk selection would enable affordable programs; however, programs may be compromised by barriers to participation for individuals who are at the greatest risk of developing lung cancer.

Keywords: high-risk screening, Cost-effectiveness, Screening Implementation

P3.11 SCREENING AND EARLY DETECTION
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.11-04 TRENDS AND BARRIERS IN LUNG CANCER SCREENING IMPLEMENTATION ACROSS THE UNITED STATES.
A. Criswell1, A. Ciupek2, A. Copeland3, J. King4

Background: In 2010, the National Lung Screening Trial was halted after showing a 20% reduction in mortality for high risk individuals when three years of annual lung cancer screening was performed by low dose computed tomography (NEJM, 2011). Many questions remained about whether screening could be properly implemented in non-academic, community settings. Lung Cancer Alliance developed a National Framework for Excellence in Lung Cancer Screening and Continuum of Care in 2012 and began a nationwide network dedicated to responsible lung cancer screening. The Screening Center of Excellence (SCHOE) designation requires a center to ensure shared decision-making, comply with best practice standards, work with a multidisciplinary care team, deliver or refer for smoking cessation, provide results in a timely manner, and meet technical specifications set by the American College of Radiology. Our aim is to promote high-quality, responsible lung cancer screening throughout the United States, including in community settings where most lung cancer is diagnosed. Method: From 2012 through 2017, over 500 centers were designated as SCHOEs. These centers represented 42 states and more than 60% were from community/non-academic centers. High-risk individuals who come to the Lung Cancer Alliance website or contact the organization by phone to find a screening center are directed to a SCHOE. A data collection effort in 2017, being repeated in 2018, collected comprehensive information about the state of lung cancer screening and care at the SCHOEs. Nearly 70% of SCHOEs responded to the 2017 survey. Result: The SCHOE program data shows that screening is being performed widely across the United States, including in non-academic centers. For centers who were able to provide numbers of screenings performed and diagnoses, we identified a clear trend in diagnosis of Stage 1 lung cancer, indicating these screenings are able to find lung cancer early. We also identified a number of implementation challenges around referral patterns, insurance and billing, and determining appropriate risk criteria. Rates of adherence to annual scans and recommended follow-up varied widely across different institutions indicating a lack of focus for future implementation research. Conclusion: We have shown that a patient advocacy group working with medical professionals can help deliver high quality care to a broad population. Data collection from the SCHOEs provides a snapshot of the state of lung cancer screening in the United States that underscores the success of screening and the importance of early detection but also identifies barriers in implementation that still need to be addressed.

Keywords: implementation, Screening, LDCT

P3.11 SCREENING AND EARLY DETECTION
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.11-05 USE OF ELECTRONIC MEDICAL RECORD (EMR)-EMBEDDED CLINICAL DECISION SUPPORT TOOLS IMPROVES LUNG CANCER SCREENING RATES
J. Doty1, L. Lackey2, J. Ersek2, D. Howard2, A. Clary2
1Atrium Health Pulmonary Care, Atrium Health, Charlotte/NC/US, 2Atrium Health, Charlotte/NC/US, 3Levine Cancer Institute, Charlotte/NC/US

Background: Atrium Health (AH) is a large, community-based healthcare system serving approximately 1.1 million primary care patients in the southeastern United States. In this region lung cancer incidence, death rates and rate of advanced stage of disease at diagnosis are among the highest in the nation. Previous work demonstrated that primary care providers in our region were not aware of lung cancer screening eligibility requirements. AH aimed to improve lung cancer outcomes for our patients by integrating new clinical decision support tools within our electronic medical record (EMR) to increase referral rates to our lung cancer screening program. Method: We collaborated with the AH Information and Analytics Services team to embed new clinical decision support tools within the EMR simplifying identification of patients eligible
for lung cancer screening. We first revised the smoking history section of the EMR with data fields to record the number of years a patient smoked, the average packs consumed per day and the specific quit date for former smokers. A health maintenance alert (HMA) was then designed which would appear in a conspicuous location in the charts of patients aged 55 to 77 with a 30 pack/year smoking history who were active smokers or former smokers with quit dates within the last 15 years. Result: Since integration of the decision support tools into the EMR, over 22,000 patients in our system who meet eligibility criteria have been identified. Lung cancer screening referrals in the first quarter of 2018 increased by almost 500% compared to quarter 1 2017.

Conclusion: Clinical decision support tools embedded into the EMR have increased lung cancer screening rates among AH patients.

Keywords: clinical decision support tool, lung cancer screening, health maintenance alert

P3.11-06 IMPROVING LUNG CANCER SCREENING COMPLETION RATES IN A PRIMARY CARE PRACTICE IN LARGE URBAN ACADEMIC MEDICAL CENTER
L. Dowling1, L. Zimmerman1, P. Shah1, L. Powell2, D. Dunham2
1Cancer Center, Rush University Medical Center, Chicago/IL/US, 2Rush University Medical Center, Chicago/IL/US

Background: Despite implementation of a physician-facing electronic health record (EHR) best practice alert (BPA) with robust medical decision making and documentation, only 7.3% of eligible patients (85 of 1170) throughout the institution completed a low-dose CT (LDCT) for lung cancer screening in 6 months (May 1st to November 1, 2017). The objective is to improve lung cancer screening by: 1. Describing primary care referral patterns and status among eligible patients 2. Identifying system, patient and provider-level barriers to referral and completion 3. Developing and testing targeted interventions Success will be measured by reducing number of eligible patients overdue for screening by 50% in the next 6 months. Method: An Epic EHR report identified patients with an overdue lung cancer screening BPA within one practice representing approximately 40% of primary care (16,000 visits in 6 months). Through chart review, we quantified number of patients at different points of the referral pathway. New interventions were developed for the most common categories of patients overdue for screening: Those with orders that had not scheduled the exam and those with no order and no documentation of why in the EHR. Lung Cancer Screening Coordinators contacted patients with current orders and began scheduling LDCT exams. (Intervention 1). Division leadership, medical directors, primary care providers (PCP), and the practice nurse manager were engaged to design an intervention to address patients with no LDCT order (Intervention 2) Result: The total number of LDCTs performed in the first 12 weeks after starting the intervention was almost equal to the performed in the 6 month baseline period. (12 vs 14). The percentage of patients overdue with orders increased from 28% to 37.5%. Only 7 of the original 18 with orders not scheduled remained in that category at 12 weeks. The percentage of patients overdue with no order and no documentation decreased from 65.3% to 51.3%. Fifteen of 41 with no order and no reason documented (36.5%) were newly identified at 12 weeks, i.e. not identified by the baseline query. The most significant limitation to measuring 12-week outcomes is that patients have not yet completed their scheduled PCP appointments and LDCT appointments.

Conclusion: Multiple challenges were identified at system, patient and provider levels: 1. The BPA lacks specificity. 2. This patient subpopulation has a high prevalence of comorbidities and chronic conditions. 3. PCPs expressed skepticism regarding evidence for lung cancer screening, perceived lack of benefit for some patients and competing demands.

Keywords: LDCT, lung cancer screening best practice alert (BPA), lung cancer screening
restricted to 55-77 years to match CMS re-imbursement criteria. **Result:** Of the 50,421 patient charts analyzed, 2,720 (5%) met eligibility criteria for LCS with a low cut-off level of 30 pack years. **Conclusion:** While our sample size is small, we can optimize use of the BPA and provide patients with better health management.

**Keywords:** low dose computed tomography (LDCT), smoking documentation, lung cancer screening

**P3.11 SCREENING AND EARLY DETECTION**

**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.11-09 SHARED DECISION MAKING: A DECISION AID FOR THE PRIMARY PRACTITIONER**

**F. Grannis**

**Surgery, City of Hope National Medical Center, Duarte/US**

**Background:** Lung cancer (LC) remains the number one cancer killer of both men and women. Despite general agreement that computerized tomographic (CT) lung cancer screening (LCS) is safe and effective, with first-dollar insurance coverage available from CMS, uptake of LCS among those at risk is currently less than 5%. Centers for Medicare and Medicaid Services (CMS) mandates shared decision making (SDM) using decision aids (DA) providing specific information. Only half of primary care practitioners (PCPs) know USPSTF guidelines and identify multiple barriers to guideline adherence. Although half of PCPs know how to work-up positive results, most prefer to refer such patients to specialists. Compounding these problems, existing DAs provide inaccurate and difficult to understand information. PCPs require accurate information to fulfill their obligation to patients in SDM. **Method:** Research and clinical results from the prospective, international, multi-institutional cohort research project, International Early Lung Cancer Action Project (IELCAP) and National Comprehensive Cancer Network (NCCN) over 20 years was reviewed and distilled into content aimed to provide accurate, up-to-date information for PCPs to use in answering patient questions during SDM consultation. Information is summarized in “stick figure” graphics. **Result:** Multiple current LCS DAs provide gratuitously inaccurate information, e.g. that only 21% with LC in LCS survive 5-years. IELCAP and NCCN research results show that cancer detection rate with adherence to annual CT screening is 12.5% (1 in 8) decade in both NCCN risk groups 1 and 2. Baseline false positive rate is 10% at baseline screen; 5% during annual repeat screens. More than 80% of LC are early-stage. 10-year actuarial LC survival exceeds 80%. With guideline adherence, 10% of false positives have biopsy or surgical removal of a benign nodule and overtreatment of slow-growing, pre-invasive LC is avoidable. Screen-detected LC are increasingly treated with minimally invasive operations, often with sublobar resection, with equivalent cure rates and lower morbidity. Operative mortality is less than 1%. Radiation therapy is available for treatment of early-stage LC in patients with increased surgical risk. Radiation exposure is small; there is no evidence of substantial risk of radiation carcinogenesis in adults receiving LCS. **Conclusion:** A new DA, reflecting results in LCS from IELCAP and NCCN centers provides PCPs with accurate information for SDM sessions with patients at risk of LC. PCPs providing accurate, coherent information to patients can play a major role in prevention of many thousands of unnecessary LC deaths.

**Keywords:** lung cancer screening; shared decision making; decision aid

---

**P3.11-10 LUNG CANCER SCREENING SHARED DECISION MAKING: DECISION-AID FOR THE PATIENT**

**F. Grannis**, **S. Ross**

**Surgery, City of Hope National Medical Center, Duarte/US; Icahn School of Medicine at Mount Sinai, International Early Lung Cancer Action Program, New York City/NY/US**

**Background:** Despite general agreement in the U.S. that lung cancer screening (LCS) is effective and safe, with availability of insurance coverage for those at high-risk, screening uptake is less than 5%. Patients in Medicare and Medicaid (CMS) must participate in “shared decision making” (SDM) with a primary care giver and a “decision-aid” (DA) used. A major potential contributor to this low uptake is the lack of a detailed history. The majority of patients, 38,197 (76%), had incomplete smoking history documentation. Out of the patients with incomplete smoking history documentation, many charts were missing documentation of smoking history in pack year, and/or the number of years it has been since the patient quit smoking. **Conclusion:** Data identifies a key weakness in electronic health record documentation of smoking history at RUMC and ROPH. Since the BPA for lung cancer screening only triggers with a documented smoking history of greater than 30 pack years, patients who may be eligible for lung cancer screening are not being identified. By advocating for more thorough documentation of patient smoking history, we can optimize use of the BPA and provide patients with better health management.

**Keywords:** low dose computed tomography (LDCT), smoking documentation, lung cancer screening

**P3.11 SCREENING AND EARLY DETECTION**

**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.11-11 IMPROVING TIMELINESS OF LUNG CANCER DIAGNOSTIC SERVICES WITH THE IMPLEMENTATION OF COORDINATED CARE VIA A “NAVIGATION DAY”**

**1Faculty of Medicine, University of Ottawa, Ottawa/ON/CA; 2Ottawa Hospital Research Institute, The Ottawa Hospital, Ottawa/ON/CA; 3Agnes Cancer Assessment Clinic, The Ottawa Hospital, Ottawa/ON/CA; 4Division of Radiation Oncology, The Ottawa Hospital, Ottawa/ON/CA; 5Division of Gynecologic Oncology, The Ottawa Hospital, Ottawa/ON/CA; 6Division of Thoracic Surgery, The Ottawa Hospital, Ottawa/ON/CA**

**Background:** Lung cancer patients often experience stressful wait times and delays through the diagnostic phase of care. In an effort to streamline this process, a multidisciplinary team at The Ottawa Hospital (TOH) created a “Navigation Day” whereby patients and their family partake in a day-long visit and receive concurrent coordinated testing. At the Navigation Day, patients have testing for LC—a decision to social work, access to specialist care for symptom control, and same day appointments via dedicated test slots for positron emission tomography–computed tomography (PET-CT) scans, pulmonary function tests (PFTs) and/or magnetic resonance imaging (MRI) of the head. We evaluated the impact of this program on patient satisfaction and timely diagnostic and treatment decisions. **Method:** Patients with a suspicion of lung cancer on chest CT who were referred during three time periods relative to the implementation of Navigation Day were included: one year pre-launch, one year post-launch, and two years post-launch. Mean wait times for PET, PFT, and/or MRI tests were calculated for each time period. To specifically assess the impact of dedicated slots on wait times, patients within each time period were stratified according to whether they underwent their test on the same day or a different day from their Navigation Day. Student’s t-test and ANOVA were used to assess for significance. Patient satisfaction was measured by examining provincially-collected data from a standardized survey used by all diagnostic assessment programs in Ontario, and data from program-specific feedback surveys distributed at TOH. **Result:** At one year post-launch, mean wait times improved from 15.5 to 9.2 days for PET (p<0.0001, t-test), from 15.7 to 9.6 days for PFT (p<0.0001), and from 16.0 to 10.2 days for MRI (p<0.0001). These improvements were sustained at two years post-launch, and MRI wait time improved even further from 10.2 to 6.6 days (p<0.0001, t-test). The patients who underwent tests within a dedicated slot experienced the shortest wait times for all tests, at 5.8 days for PET, 5.8 days for PFT, and 6.3 days for MRI (p<0.0001, ANOVA). Wait time dispersion also improved by 11.2%
P3.11-12 COMPARISON OF CANCER SCREENING ADHERENCE ACCORDING TO SMOKING STATUS: KOREA NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY 2010-2012

Y.S. Kim1, J. Park1, E.Y. Kim2, H.Y. Lee3, H.K. Ahn4, S.M. Kang1, I. Park1
1Internal Medicine, Gachon University Gil Medical Center, Incheon/KR, 2Radiology, Gachon University Gil Medical Center, Incheon/KR

Background: Smokers who are aged 55 to 74 years with 30 pack-years or more of smoking-history are regarded as high risk subjects for lung cancer, and recent study revealed lung cancer screening with low-dose CT (LDCT) could reduce lung cancer mortality of high-risk individuals. The purpose of this study was to compare the general medical checkups and cancer screening practice pattern according to self-reported smoking status. Method: Using a representative dataset from the Korea National Health and Nutrition Examination Survey (KNHANES) IV from 2010 to 2012, we compared the adherence of general medical checkups and cancer screening practice of Korean adults (55-74 years) according to self-reported smoking status; heavy smokers (≥30PY), non-heavy smokers (<30PY), and never-smokers. Socio-demographic factors (gender, age group, education, marital status, income, insurance status), health-related lifestyle behavior (drinking status, exercise), and comorbidities (HTN, DM, hyperlipidemia, and self-reported health status) were also collected. Result: For the 5,480 respondents, the weighted prevalence of heavy smokers, non-heavy smokers, and never-smokers was 19.3%, 23.5%, and 57.2%, respectively. The overall screening rate was 70.7% (health), 59.1% (stomach cancer), 58.1% (colorectal cancer), 59.1% (breast cancer), and 48.8% (cervical cancer). The screening rates for colorectal cancer are lower in heavy smokers compared with never-smokers even after adjusting covariates (OR=0.71, 95% CI=0.52-0.95). The adherence of general medical checkups and other cancer screening practice of heavy smokers, non-heavy smokers, and never-smokers was 19.3%, 23.5%, and 57.2%, respectively. There was no significant difference in the adherence of general medical checkups and other cancer screening between heavy smokers and non-heavy smokers, however, no difference was observed in the adherence of general medical checkups and other cancer screening between heavy smokers and never-smokers. This finding provides a better understanding of the screening practice adherence for this population.

Keywords: lung cancer, Screening, smoking

P3.11-13 LIVERPOOL IDENTIFIES THE HARD TO REACH POPULATION AT RISK OF DEVELOPING LUNG CANCER.

M. Ledson1, E. Gaynor1, S. Grundy1, S. Hill2, D. Fidade3, S. Mason1, S. Duffy4, J. Field4
1Liverpool Heart & Chest, Liverpool/GB, 2Ropewalks General Practice, Liverpool/GB

Background: The Liverpool Healthy Lung Programme (LHLP) is an initiative aimed at improving respiratory health and diagnosing respiratory disease at a more treatable stage, taken by the Liverpool Clinical Commissioning Group (CCG) working with communities across Liverpool. Liverpool has one of the highest respiratory mortality rates in England, with double the national lung cancer incidence, particularly in lower socioeconomic groups. The Liverpool Healthy Lung Programme was initiated in response to both the clinical problem and the health inequalities. Method: General practice records targeted ever-smokers and subjects with chronic obstructive pulmonary disease (COPD), 58-70y and were invited for 45-minute lung health check. Positive lifestyle messages were promoted; 5-year personal lung cancer risk calculated (www.MyLungRisk.org using LLP2 risk model). Those who trigger the 5% threshold were offered a LDCT-scan. Spirometry was used to assess lung function (FEV1/FVC); those with abnormal results referred for potentially definitive diagnosis of COPD. Smoking advice and referrals to smoking cessation clinics were provided. Patients CT detected nodules were managed, based on BACR recommendations. Results: During the 2 years following the implementation of Navigation Day, Conclusion: Implementation of a Navigation Day significantly improved timeliness of diagnostic services (PET, PFT, and MRI) for potential lung cancer patients. This program represents an innovative service delivery model for other lung cancer care centers.

Keywords: lung cancer, timeliness, Diagnostic services

P3.11-14 LOW RATES OF LUNG CANCER SCREENING AMONG DOCTORS IN MEXICO

O. Macedo-Pérez1, S. Campos-Gomez2, M. Enríquez-Aceves3, F. Talavera-Caro4, I. Lyra-González5, K. Campos-Peralta6, E. Jiménez-Fuentes7
1Thoracic Tumors Unit, Instituto Nacional de Cancerología, Mexico City/MX, 2Dep of Medical Oncology, Centro Oncológico Estatal de Toluca, Hospital de Leon, Issste, Leon/MX, 3Thoracic Tumors Clinic, Instituto Nacional de Cancerología, Mexico City/MX

Background: Lung cancer represents the leading cause of death from cancer worldwide and in Mexico. Most patients are diagnosed in advanced stages at the time of diagnosis and treatment in these cases is palliative. Lung cancer screening with low-radiation exposure tomography has shown to reduce mortality due to early detection of the disease in high-risk individuals. In Mexico more than 80% of patients are diagnosed in the metastatic stage. Our objective is to know the frequency of screening for lung cancer among pneumologists, thoracic surgeons and oncologists in Mexico and the reasons why they do not. Method: Transversal, descriptive study, carried-out during the international congress of pneumology and thoracic surgery from April 2-6, 2018, in Guanajuato, Mexico. A survey was conducted in Mexican doctors from different specialties and different public and private institutions, they were questioned if they consider screening for lung cancer useful, if they do it, if the screening can be applied to Mexico and what are the barriers that it finds not to do it. The data were emptied into a database in the SPSS v23 system and descriptive statistics were made for the analysis. Result: A total of 147 specialist doctors were interviewed, 49% were oncologists, 43% were pneumologists and 8% were chest surgeons. Despite the fact that 86% considered screening to be useful, only 36% performed it within their daily clinical practice. The main barriers they found to implement screening in our country were due to multiple factors according with response of 70% of physicians where lack of CT scan and qualified personnel to interpret image results were the most prevalent. The remaining 30% considered only one factor as the most important where the lack of infrastructure (CT scan) was the most prevalent in 14% of the answers. Conclusion: Although the specialists in prevention, diagnosis and treatment of lung cancer in Mexico are aware of the usefulness of screening for lung cancer, the frequency of implementation is low, mainly due to lack of appropriate infrastructure and trained personnel. It is necessary to implement public health policies to promote screening in the majority of patients who meet the high-risk criteria to increase early diagnosis and subsequently improve survival outcomes in this population.

Keywords: diagnosis in latin-america, Screening, Early Detection
Based multi-faceted interventions are required to empower highly lung cancer manage their lung health in the short term. Fixation on the difficult life circumstances and stigma, individuals who are high risk for Conclusion: the importance of earlier diagnosis. Multi-faceted interventions were cancer symptoms, modify negative lung cancer beliefs and highlight Focus groups caring responsibilities, anticipated refusal of treatment for lung cancer, deterred help seeking. Some participants, particularly those without 'treatable' chest infections led to denial of symptoms of 'inevitable and infections) leading to avoidance of longer term health (lung cancer), and social housing. Key themes were: fixation on short term health (chest infections) leading to avoidance of longer term health (lung cancer), and the the importance of the relationship with their healthcare professional to facilitate or deter help seeking. Focusing on detecting and managing 'treatable' chest infections led to denial of symptoms of 'inevitable and incurable' lung cancer. For example, participants normalised haemoptysis. Being judged by healthcare professionals and unworthy of medical help because of residence in a disadvantaged area or smoking habit deterred help seeking. Some participants, particularly those without caring responsibilities, anticipated refusal of treatment for lung cancer, with some contemplating suicide. Focus group intervention content included information to raise awareness of lung cancer symptoms, modify negative lung cancer beliefs and highlight the importance of earlier diagnosis. Multi-faceted interventions were suggested, including talks and stands led by a trained, non-judgemental facilitator. Conclusion: In the context of difficult life circumstances and stigma, individuals who are high risk for lung cancer manage their lung health in the short term. Fixation on the treatment and detection of immediate health concerns may lead to avoidance and denial of important lung cancer symptoms. Community based multi-faceted interventions are required to empower highly deprived individuals to seek timely help, using a non-judgmental and welcoming approach. Keywords: Intervention Development, symptom presentation, early diagnosis

P3.11 SCREENING AND EARLY DETECTION WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.11-17 GENDER COMPARISON IN LUNG CANCER SCREENING
S. Randhawa1, S. Serra2, G. Ma3, V. Dísea4, L. Kaiser5, C. Erkmen2
1Thoracic Surgery, Einstein Medical Center, Philadelphia/PA/US; 2Thoracic Surgery, Temple University Hospital, Philadelphia/PA/US

Background: Persistent underrepresentation of females in lung cancer screening (LCS) trials has raised concerns regarding the accurate perception of differences between the sexes and its generalizability. We examined a balanced cohort of men and women undergoing LCS with the hypothesis that gender does not affect the ability of LCS to successfully detect early-stage lung cancer. Method: In an urban, academic medical center, we prospectively collected data on patients referred for LCS from June 2015 to May 2017. We compared age, ethnicity, level of education and smoking history and outcomes of LDCT between men and women. We also measured treatment and complications. Result: Two hundred and thirty-six patients underwent LCS. 115 (48.7%) were females and 121 (51.3%) were males. Age did not significantly differ between females (63.9±15.56; p=0.019). There was no gender difference amongst the distribution of ethnicity, education or smoking history and outcomes of LDCT between men and women. We also measured treatment and complications. Result: Two hundred and thirty-six patients underwent LCS. 115 (48.7%) were females and 121 (51.3%) were males. There were no significant differences in the distribution of LDCT results. 41 (35.7%) females and 56 (46.3%) males diagnosed with Lung-RADs 1, 57 (49.6%) females and 48 (39.7%) males with Lung-RADs 2, 5 (4.3%) females and 6 (4.9%) males with Lung-RADs 3 and 8 (6.8%) females and 7 (5.8%) males with Lung-RADs 4 (p=0.542). Three females and 2 males were diagnosed with lung cancer. 4 patients (2 females and 2 males) were treated with surgery and 1 female underwent radiation therapy, all without complications or death.

P3.11-15 LUNG CANCER SYMPTOM PERCEPTION AND INTERVENTION PREFERENCES IN THE UK'S MOST DEPRIVED COMMUNITIES: A QUALITATIVE STUDY
G. Mccutchan1, J. Hiscock2, P. Murchie3, K. Hood4, R. Neal5, S. Thomas6, A.M. Thomas7, G. Newton8, K. Brain9
1School of Medicine, Division of Population Medicine, Cardiff/GB; 2Bangor University, Bangor/GB; 3Aberdeen University, Aberdeen/GB; 4Cardiff University, Cardiff/GB; 5Leeds University, Leeds/GB; 6Public Health Wales, Cwm Taf/GB

Background: People at highest risk for lung cancer- current or former smokers, aged over 40 years, with serious lung comorbidity and living in areas of deprivation- are more likely to prolong presenting to a GP with symptoms, leading to advanced stage diagnosis. This qualitative study sought to understand the influences on early presentation with lung cancer symptoms and intervention preferences in a sample of high risk, highly deprived individuals. Method: Semi-structured interviews were conducted with 37 high risk participants recruited purposively according to age, lung comorbidity and smoking status from primary care practices in deprived areas of England, Scotland and Wales. A lung symptom attribution task was used to explore symptom interpretations, symptom presentation and beliefs surrounding lung cancer, underpinned by Leventhal’s Common Sense model. Four focus groups with members of the public and local stakeholders (healthcare professionals and community partners) were conducted to explore intervention preferences. Data were analysed using Framework method. Result: Interviews All participants resided in the most deprived quintile and most were unemployed or seeking benefits, and/or rented social housing. Key themes were: fixation on short term health (chest infections) leading to avoidance of longer term health (lung cancer), and the the importance of the relationship with their healthcare professional to facilitate or deter help seeking. Focusing on detecting and managing 'treatable' chest infections led to denial of symptoms of 'inevitable and incurable' lung cancer. For example, participants normalised haemoptysis. Being judged by healthcare professionals and unworthy of medical help because of residence in a disadvantaged area or smoking habit deterred help seeking. Some participants, particularly those without caring responsibilities, anticipated refusal of treatment for lung cancer, with some contemplating suicide. Focus group Suggesting for Community based multi-faceted interventions are required to empower highly deprived individuals to seek timely help, using a non-judgmental and welcoming approach. Keywords: Intervention Development, symptom presentation, early diagnosis

P3.11 SCREENING AND EARLY DETECTION WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.11-16 COMPARATIVE ANALYSIS OF HEALTH-CARE RESOURCES AND ECONOMIC COSTS OF LUNG CANCER PATIENTS TREATED MEDICALLY OR SURGICALLY IN CATALUNYA
A. Guirao1, L. Mollins1, R. Guzman1, M. Cleries2, E. Vela3, D. Magen4, D. Sanchez2, M. Boada5, J. A. Esplins2, J.M. Borras4, J.M. Argimon4, A. Agustí1
1General Thoracic Surgery, Hospital Clinic of Barcelona, Barcelona/ES; 2Serie Català de Salut, Barcelona/ES; 3General Thoracic Surgery, Hospital Clinic of Barcelona, Barcelona/ES; 4Pla Director D’Oncologia, Departament de Salut. Generalitat de Catalunya, Barcelona/ES; 5Respiratory Institute. Hospital Clinic Barcelona, Barcelona/ES

Background: To contribute to the debate about the cost-benefit ratio of lung cancer computed tomography (CT) screening programs, and to support the implementation of large scale lung ancer (LC) screening programs to increase the number of potential LC patients that can benefit from this treatment. Method: Observational, comparative, retrospective study includes 13.415 patients who were diagnosed of LC between 2014 and 2016 in Catalonia. All of them were treated medically or surgically. We obtain information from the data bases of the “Health attention system.” of the following variables (both before and after LC diagnosis): vital status and autonomy level, drug dispensation, radiotherapy sessions, use of health-care resources, day-hospital visits, hospitalization events, use of nursing homes, non-urgent sanitary transport, monthly and annual costs (€) per patient (and 3 year/survival) Variables were compared between the group medical treatment vs. the group surgical treatment using unpaired parametric tests. Since this is an observational study, no formal calculation of sample size was pretended. Yet, post-hoc results identified a cohort of 13.415 participants, which should be enough for descriptive purposes. Result: 3 year/Survival after LC diagnosis was much higher in surgical patients (78.9% vs 23.3%) (p<0.001). Surgically treated patients achieve a higher level of autonomy earlier before diagnosis. The monthly rate of total drug dispensation, cancer drugs, radiotherapy sessions, opioid and analgesic dispensation before and after LC diagnosis were much higher in medical patients. The rate of dispensation of ansiolitic, sedatives and anti-depressives were similar in both groups. Hospitalization events were slightly higher in the surgical group. There were no significant differences between groups in the rate of primary care or hospital outpatient clinic visits. The use of Health-care resources and non-emergency sanitary transport peaked before diagnosis to a larger extend in medical patients. The average annual cost of medical and surgical patients one year after LC diagnosis and treatment was 67% higher in medical patients (17.495 vs. 10.447 €). Conclusion: Surgical treatment of LC offers better clinical outcomes and is cost-efficient. These arguments support the implementation of large scale LC screening programs to increase the number of potential LC patients that can benefit from this treatment. Keywords: Screening, Early stages, survival

P3.11 SCREENING AND EARLY DETECTION WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30
Conclusion: Our study of LCS demonstrates the equal participation of men and women. Gender did not impact early detection and successful treatment of lung cancer. This is an opportunity to advocate for enhanced female participation in LCS research to provide meaningful guidance to women and their physicians.

Keywords: lung cancer screening, Low Dose CT Scan, gender comparison

P3.11 SCREENING AND EARLY DETECTION
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.11-18 IMPLEMENTING ONE STOP LUNG CLINIC TO IMPROVE DIAGNOSTIC TIMELINESS IN LUNG CANCER PATIENTS IN THE NORTH OF ENGLAND
S. Robinson¹, V. Dudzevicius², R. Sathyamurthy², R. Mustafa², R. Hartley², G. Andrijevskiene³, K. Linkin³, T. Jasper³, J. Hughes⁴, S. Fenwick⁴, H. Sircus⁴, A. Charles⁴, C. Taylor¹, K. Hartley³, G. Andrijevskiene³, K. Linkin³, T. Jasper³, J. Hughes⁴, S. Fenwick⁴, H. Sircus⁴, A. Charles⁴, C. Taylor¹

Background: Employing just one modification (early use of endobronchial ultrasound) has been shown to improve survival in a randomised controlled trial (Navani et al. Lancet Respir Med 2015). A new innovation set out to implement One Stop lung clinic to reduce diagnostic times as a part of the Macmillan Integrated Cancer Care Programme on the Lung Cancer Pathway mapping started in 2014, which pre-dates the National Optimal Lung Cancer Pathway. The aim of the study was to demonstrate shorter time to diagnosis for patients with suspected lung cancer referred from general practice on a ‘2 week wait’ referral pathway in the UK. Method: Data relating to diagnostic intervals of the patient’s attending One Stop clinic collected and interim analysis performed. The diagnostic intervals were analysed using descriptive analysis to establish the timeliness of intervals from first seen to diagnosis and discussion at the Multi-Disciplinary Team (MDT) meeting. Result: 33 patients attended One Stop clinic and received a CT and then either bronchoscopy, endobronchial ultrasound or pleural aspiration on the same day. 48% (n=15) of patients were diagnosed with a primary lung cancer, 16% (n=5) - with other malignancies including myeloma, lymphoma and colorectal cancer and 32% (n=10) - with non-malignant conditions. The diagnostic intervals from first seen in a lung clinic to diagnosis were in range between 9 and 37 days. 39% (n=13) of patients attending the clinic were worked up for the lung MDT discussion within 9 days, 24% (n=8) of patients - within 16 days, 6% (n=2) of patients - within 23 days. In 9% (n=3) of the cases the work up took 30 days or over, 15% (n=5) were taken off the pathway and 6% (n=2) - were referred for best supportive care. Conclusion: Diagnostic intervals for a cohort of patients attending the clinic were shorter in comparison to England’s National Cancer Standard of 31 days from referral to diagnosis. It is argued that One Stop clinic which involves a CT, then either a bronchoscopy, endobronchial ultrasound or pleural aspiration completed all on the same day reduces the time to diagnosis and improves organisational performance.

Interventions for expediting earlier diagnosis of lung cancer need to focus on the compliance of diagnostic services to be all aligned in a rapid one stop environment to improve the earlier diagnosis of lung cancer.

Keywords: earlier diagnosis, lung cancer
Conclusion: Results from the National Lung Screening Trial support current guidelines to screen high-risk smokers annually for lung cancer with low-dose computed tomography (LDCT) in the United States. Monitoring the screening process, including repeat screening and follow-up, is important to ensure the benefits of screening outweigh its harms. We examined early patterns and predictors of adherence to recommended follow-up care after baseline LDCT screening in a large integrated healthcare system. Method: Our cohort study included patients screened for lung cancer during the first year of LDCT screening at selected Kaiser Permanente Northern California facilities, when referrals for screening came directly from primary care physicians (PCPs, instead of dedicated clinician specialists as now implemented). Using electronic administrative and clinical databases, we identified 145 screening-eligible patients who had a baseline LDCT screening exam from July 2014 to June 2015, with continuous health plan enrollment for at least 14 months post-baseline. Adherence to recommended follow-up after the baseline exam was determined here using a two-tier model of classification. We defined adherence as receipt of imaging within 10 to 14 months after a negative exam (i.e., Lung-RADS category 1 or 2) and receipt of imaging or diagnostic evaluation within ±30 days of the recommended follow-up interval after a positive exam (i.e., Lung-RADS category 3 or 4). Among patients with a negative exam, we further examined whether baseline factors, including age, gender, race/ethnicity, prior healthcare utilization, smoking history, and Charlson comorbidity index (CCI), were associated with adherence, using logistic regression.

Result: Of the 145 patients, 61% were male. 71% were of white race, 76% were current smokers, and 72% had a CCI of 0-1. The median age was 66 years. Baseline exam results were negative for 122 patients and positive for 23 patients. All five patients subsequently diagnosed with lung cancer were classified as Lung-RADS category 4 at baseline. Adherence to recommended follow-up was higher after a positive than negative exam – 61% vs 23% – although low overall. Among patients with a negative exam, adherence was suggestively associated with gender and race/ethnicity, with greater adherence in women than men (odds ratio, OR = 2.0; 95% confidence interval, CI: 1.03–3.9). Results were compared to published national standards. Using a broader range of comparison improvements, we found rates were generally similar to published national standards. Adherence to recommended follow-up was higher after a positive than negative exam – 61% vs 23% – although low overall. Among patients with a negative exam, adherence was suggestively associated with gender and race/ethnicity, with greater adherence in women than men (odds ratio, OR = 2.0; 95% confidence interval, CI: 1.03–3.9). Conclusion: Our preliminary results suggest adherence to recommended follow-up is low, particularly after a negative baseline exam due in part to insufficient patient education and shared decision-making about LDCT screening during PCP visits. Further analyses are underway to interpret these results.

Keywords: lung cancer screening, adherence.

P3.11 SCREENING AND EARLY DETECTION
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.11-22 THE PATH TO NATIONAL LUNG CANCER SCREENING PROGRAM IN ISRAEL
S. Shilo1, A. Agbaria1, N. Peled1
1Israel Lung Cancer Foundation, Rehovot/IL, 2Assuta Nazareth, Nazareth/IL, 3Director of the Cancer Center, Soroka Medical Center, Beer Sheva/IL

Background: 2500 people are diagnosed every year with lung cancer and 2000 die from the disease, the leading cause of death in Israel. The prevalence of smoking is 22.5% above 21 years of age, resulting in about 1.2 million smokers overall. The USPSTF found adequate evidence that annual screening for lung cancer with LDCT in a defined population of high-risk persons can prevent a substantial number of lung cancer-related deaths, therefore the Israeli Lung Cancer Foundation (ILCF) decided to advocate for including LC screening program in Israel’s medical services.

Method: The medical services “health basket” in Israel encompasses the entire range of services, drugs, medical equipment and devices that the insured public receives. Every end of year, a health basket committee is appointed to review and approve the new services to be included in the following year health basket. The services are reviewed for their health benefit and then are chosen to fit a limited budget. ILCF have filled twice for the years of 2017 and 2018 to have a national LDCT LC screening program in Israel. Result: LC Screening program was filled in ILCF to the 2017 Health basket committee. The committee decided that there is not enough supporting evidence and did not rank the program high enough to be included in the funding debate. Nevertheless, because the issue was raised, the ministry of health decided to gather a special committee to evaluate LC Screening program. The committee decided that there is enough evidence and recommended to have the program be part of the health system in Israel. For 2018-year, LC Screening program was filled by ILCF and the ministry of health LC Screening committee. This time after an additional appeal the program was ranked to enter the funding debate. Unfortunately, it was excluded from the 2018 health basket. As a result, ILCF appealed to the Israeli high court of justice against the health basket committee claiming that the decision was unreasonable. The appeal is being currently discussed. Conclusion: Change takes a lot of effort and collaboration. Unfortunately, lung cancer screening is not an industrial initiative, thus does not have strong lobbying power. Therefore, it is the duty of patient advocates and leading oncologists, radiologists and pneumologists to raise the flag. Here we present a model of collaboration between a patient organization and leading oncologists and radiologists to incorporate LC screening program in Israel.

Keywords: Screening, advocacy.

P3.11 SCREENING AND EARLY DETECTION
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.11-21 THE DEVELOPMENT OF A ROBUST RADIOLOGY QUALITY ASSURANCE (QA) PROGRAM IN A PROVINCIAL HIGH-LOW RISK LUNG CANCER SCREENING PILOT (HRLCSP)
M. Ang1, H. Schmidt1, R. McCauley1, G. Darling1, D. Langer1, P. Jain1, V. Treister2, M. Tammegam1, S. Flora2
1Cancer Imaging Program, Cancer Care Ontario, Toronto/ON/CA, 2Cancer Care Ontario, Toronto/ON/CA

Background: Lung cancer is the leading cause of cancer death in Ontario, with an estimated 7100 patient deaths occurring in 2016 (Canadian Cancer Society, 2016). Based on results from the National Institute of Health’s National Lung Screening Trial, Cancer Care Ontario (CCO) implemented the HRLCSP in 2017 to determine feasibility of provincial scale roll-out of an organized lung cancer screening program. An integral component of the HRLCSP is to ensure high-quality LDCTs, the ROAQL, site participants and clinical experts collaborated to define and implement quality parameters. Equipment standards were defined in the Radiology QA Program Manual. Peer Review agreement from pilot sites was confirmed. Collaboration with reading radiologists led to tailored educational workshops designed to ensure consistency in the reporting of lung nodules based on the Lung-RADS™ scoring criteria, adapted from the American College of Radiology. Scan interpretation considerations, scoring criteria, and reporting templates were implemented. Annual assessments have ensured compliance across pilot sites. A working group aiming to determine an algorithm to examine incidental findings is being created. LDCT scan Double Read minimums and Peer Review adjudication processes were developed to ensure expert opinion availability with radiologist discrepancies to ensure high quality scan interpretation. Conclusion: The design of the HRLCSP offered opportunities for implementing high quality standards around the LDCT scans. Implementation of a robust quality assurance program can ensure that the radiology component is delivered in a high-quality manner. Radiologist training programs, centre minimum requirements, and standardized reporting can ensure standards remain high. Lessons learned through the development of this comprehensive radiology QA program in the HRLCSP will allow for adoption of high-quality radiology standards on a larger provincial scale.

Keywords: quality, screening, radiology.
P3.11-23 ADHERENCE TO ANNUAL LOW-DOSE CT LUNG CANCER SCREENING AT A LARGE ACADEMIC INSTITUTION
L. Spalluto1, J. Lewis2, K. Sandler3, P. Massion4, R. Dittus4, C. Roumie4
1Radiology and Radiological Sciences, Vanderbilt University Medical Center, Nashville/TN/US, 2Vanderbilt University Medical Center, Nashville/TN/US, 3Division of Allergy, Pulmonary and Critical Care Medicine, Vanderbilt-Ingram Cancer Center, Nashville/TN/US, 4Veteran’s Health Administration-Tennessee Valley Healthcare System Geriatric Research Education Clinical Center, Nashville/US

Background: Annual low-dose computed tomography (LDCT) is standard-of-care in the high-risk population for lung cancer screening. We assessed adherence to annual LDCT screening in a large academic institution. Method: We assembled a retrospective cohort of patients who underwent LDCT between January 1, 2014 and September 30, 2016. We included patients with baseline LungRads 1 or 2 with 12-month follow-up recommendation. We excluded those who died before the time of recommended follow-up. The time interval between the recommended follow-up study date and the actual follow-up study was calculated. Patient adherence at time of due follow-up was defined by this time interval: <=90 days (adherent) and >90 days (non-adherent). Primary analysis was change in adherence over time. Secondary analysis included descriptive statistics of demographics. Result: 395 patients had baseline LDCT screening. We found a persistent, significant increase in adherence: 11% (2/18) in the 1st quarter 2015 and 70% (46/66) in the 3rd quarter 2017 (Pearson’s chi-squared test p=.008). We also identified racial disparity in patients enrolling in our Lung Screening Program (93% white).

Conclusion: Adherence to annual LDCT screening significantly increased from 2015 to 2017. Improvement may be due to changes in national policy and/or implementation of a dedicated program physician director and program coordinator. Future work should address racial disparities and barriers to and facilitators of annual LDCT screening.

P3.11 SCREENING AND EARLY DETECTION
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.11-25 ANALYSIS INDICATES LOW INCREMENTAL COST-EFFECTIVENESS RATIO FOR IMPLEMENTATION OF LUNG CANCER SCREENING IN ITALY

G. Veronesi1, S. Ghislandi2, L. Toschi1, L. Velutti1, M. Sollima1, P. Novelli1, E. Vanni1, E. Dieci1, L. Toschi2, L. Velutti2, M. Solimano2, E. Riboli2, N. Navone2

1Robotic Thoracic Surgery, Humanitas Research Hospital, Rozzano/IT, 2Thoracic Surgery, Humanitas Research Hospital, Rozzano/IT, 3Business Operating Officer, Humanitas Research Hospital, Rozzano/IT, 4Epidemiology, Humanitas University, Rozzano/IT

**Background:** Given the potential of early lung cancer detection to improve survival, accurate assessment of the cost-effectiveness of low-dose computed tomography (LDCT) screening is crucial. We report the results of a cost-effectiveness analysis of screening for Italian persons at high risk of lung cancer from the public payer's perspective. **Method:** The study built on a mathematical decision model to estimate the cost-effectiveness of annual LDCT screening for 5 years in a high-risk population of smokers (at least 30 pack-years) aged 55-79 years. The stage distribution of patients diagnosed as part of the COSMOS screening study was used for the “screening arm,” the stage distribution of patients in the SEER database was used for the “usual care arm.” Treatment costs were determined using detailed individual-level administrative information from our institutional database of lung cancer patients. Lung cancer survival in screened patients was adjusted for lead-time bias assuming a lead-time bias of 2 years. The model estimated expected future life years using survival probabilities according to age, sex, and lung cancer stage (or no lung cancer). Quality-Adjusted Life Years (QALYs) gained and Life Years (LY) gained were estimated. **Result:** The base-case incremental cost for each QALY gained was 4747.57 Euro. The incremental cost-effectiveness ratio (ICER) for each LY gained was 4069 Euro. An extensive sensitivity analysis showed that model outcomes were particularly sensitive to lung cancer prevalence, the sensitivity and specificity of screening, and the lead-time bias assumed. **Conclusion:** Our analysis indicates that LDCT screening is associated with a low ICER of 4069 Euro, meaning that this is the yearly incremental cost of saving the life of a patient, and is lower than the ICER accepted by the Italian government. The implication is that implementation of screening throughout Italy can be achieved at a relatively low cost, a finding which should be taken into account by health policy decision-maker.

**Keywords:** lung cancer screening, Cost-effectiveness, cost-analysis

P3.11-26 RESULTS OF INITIAL LOW-DOSE COMPUTED TOMOGRAPHIC SCREENING FOR LUNG CANCER FROM A SINGLE-INSTITUTION IN CHINA

W. Wang1, M. Zhou2, J. Xie3, M. Ye1, D. Lv1, F. Kong1, H. Yang1

1Radiation Oncology, Laboratory of Cellular and Molecular Radiation Oncology, Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou Hospital, Taizhou/CN, 2Department of Radiology, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou Hospital, Taizhou/CN, 3Department of Thoracic Surgery, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou Hospital, Taizhou/CN

**Background:** Lung cancer screening using low-dose computed tomography (LDCT) has been reported to reduce lung cancer-specific mortality for smokers at high risk in patients of the United States. However, there are very few LDCT screening results from Chinese patients. We here report the screening findings at the initial round of LDCT screening program from a single-institution population-based LDCT screening program for lung cancer. Patients participated LDCT in Taizhou Hospital of Enze Medical Center were eligible. All noncalcified nodules with long-axis diameters of 4mm or greater in the axial plane were considered to be positive for potential lung cancer according to NLST definition. If more than three nodules were found, one dominant nodules were selected for this analysis. **Result:** From July 2017 through December 2017, a total of 8611 participants with LDCT screening were included in this report. A total of 78 participants with history of cancer and 437 participants were follow-up procedures were excluded in this analysis. Of the remaining 8096 participants, the median age was 51 years (range, 16-97 years). A total of 1516 (18.8%) participants were younger than 40 years, 5264 (65.2%) were 40-64 years and 1316 (16.3%) were greater than 64 years. The total proportion of positive nodules was 21.8%, slightly higher in females (535/2258, 23.7%) than males (1233/5838, 21.1%). Lung cancer was diagnosed in 26 participants (0.32%) (11 males and 14 females) of the 1768 positive nodules. The comprehensive demographics of 26 lung cancer patients (included one patients with multiple metastases tumor from pancreas) is shown table 1.

**P3.11-27 LUNG CANCER DIAGNOSED AT AGE 50-54 YEARS: SURVIVAL AS POOR AS OLDER PATIENTS**

P. Yang, L. Luo, Y. Wang, J. Wampfler, D. Li, Y. Wang, S. Stoddard, Y. Yang, H. Xie, D. Midthun

1Health Sciences Research, Mayo Clinic, Rochester/MN/US, 2Division of Epidemiology, Mayo Clinic, Rochester/MN/US, 3Preventive Medicine, School of Public Health and Management, Wenzhou Medical University, Wenzhou/CN, 4Health Sciences Research, Mayo Clinic, Rochester/MN/US, 5Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester/MN/US, 6Hematology and Oncology, Mayo Clinic, Rochester/MN/US

**Background:** The United States Preventive Services Task Force (USPSTF) recommends lung cancer screening with low-dose computed tomography among people aged 55–80 years with a 30-pack year cigarette smoking history and, if stopped smoking, quit within 15 years. We previously identified a prominent subpopulation that would have been too young (i.e., 50–54.9 years) yet otherwise meet the USPSTF criteria and were diagnosed with lung cancer. We assessed survival outcomes in these younger patients compared to those eligible for USPSTF lung cancer screening.

**Method:** We studied two cohorts of 7,390 primary lung cancer patients: a Hospital Cohort from Mayo Clinic Rochester (n=6,554) and a Community Cohort from the Olmsted County population (n=836, Minnesota, USA). All patients were diagnosed between age 50 and 80 years, had >30 pack-year smoking history and had quitted >15 years ago. Two cohorts were analyzed independently to evaluate the impact of younger age (50–54.9 years) on overall survival using Cox Proportional Hazard models by hazard ratio (HR) and 95% confidence interval (CI). Known prognostic factors (age, sex, tumor stage and treatment) were adjusted. To control for age gap, the USPSTF subgroup was subdivided into a 55–69 age subgroup (lower age USPSTF subgroup) and a 70–80 age subgroup (higher age USPSTF subgroup).

**Result:** In both cohorts, the younger age group had at least the same risk of death as patients who met the USPSTF criteria: HR=1.16 for both cohorts; p=0.08 for the Hospital Cohort and p=0.52 for the Community Cohort. Age-stratified analyses did not change the results in either cohort.

**Conclusion:** People who are 50–54.9 years of age and otherwise meet the USPSTF criteria for lung cancer screening have a higher risk of death than the older patients. Benefit of screening in this younger population deserves consideration and further study.

**Keywords:** Screening, Younger age, survival

**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.12-02 DYNAMICS OF DLL3 AND ASCL1 EXPRESSION IN SCLC OVER DISEASE COURSE**

A. Farago, K. Isse, B. Drapkin, V. Kamesan, M. Kem, L. Saunders, S. Quadri, M. Mino-Kenudson

1Massachusetts General Hospital Cancer Center, Boston/MA/US, 2Abbvie Stemcentrx, South San Francisco/CA/US, 3Department of Pathology, Massachusetts General Hospital, Boston/MA/US, 4Abbvie Inc., North Chicago/IL/US

**Background:** SCLC is a high-grade neuroendocrine malignancy highly responsive to first-line therapy, etoposide plus platinum (EP), but increasingly resistant to subsequent lines of treatment. Because SCLC is rarely biopsied following the initial diagnosis, the dynamics of expression of therapeutically relevant biomarkers in relapsed disease are poorly understood. ASCL1 is an oncogenic driver of SCLC and directs transcription of delta-like protein 3 (DLL3), an atypical Notch receptor family ligand involved in neuroendocrine tumorigenesis and the target of the antibody drug conjugate ralituzumab tesirine (Rova-T™). The use of SCLC and DLL3 expression in SCLC patient (pt) tumor biopsies and patient-derived xenografts (PDXs) collected serially from time of diagnosis (pre-treatment) and after progression following ≥1 lines of therapy.

**Method:** Fresh cut, formalin fixed, paraffin embedded tissue from primary SCLC tumors and PDXs was sectioned and stained with mouse monoclonal antibodies against DLL3 (SC16.65) and ASCL1 (SC72.201) on the Dako platform. ASCL1 and DLL3 expression were scored as a percent of positive cells and correlated with each pt’s treatment history.

**Result:** Among biopsies and/or PDXs derived over serial time points, 6 cases had baseline positive DLL3 expression ranging from 15–80% of cells with a mean of 50% pre-EP. All 6 remained positive following progression after EP, with DLL3 expression ranging from 10–100%. Cells with a mean of 66%. Up to 7 serial tissue or PDX samples were available over the course of multiple treatments for 2 pts, and DLL3 and ASCL1 expression remained consistent over time, being strongly positive in 1 case and negative in the other. Among biopsies and PDXs established at matched time points, ASCL1 and DLL3 expression were consistent in 7/7 and 7/8 cases, respectively.

**Conclusion:** ASCL1 and DLL3 expression remain mostly consistent pre- and post- chemotherapy in pts with SCLC, suggesting that expression of these biomarkers in archival tissue likely accurately estimates expression even after intervening treatments. Furthermore, PDXs derived both from biopsies and circulating tumor cells maintain ASCL1 and DLL3 expression that reflect the pt tumor, supporting use of PDXS to model pt tumor biology.

**Keywords:** DLL3, small cell lung cancer, Patient-derived xenograft

P3.12-04 LINCO0173 MODULATES CHEMOSensitivity OF SMALL CELL LUNG CANCER BY BINDING HNRNPA2B1 AND HNRNPI TO REGULATE CHK2 LEVEL
L. Guo, F. Zeng, Q. Wang, S. Liang
Pathology, Zhongshan Hospital, Southern Medical University, Guangzhou/CN

Background: Small-cell lung cancer (SCLC), the most aggressive type of lung cancer, is characterized by high proliferation and invasion, and difficulty in chemotherapeutic treatment. Linc00173, a long non-coding RNA (IncRNA) with length over 200 nucleotides, has been identified to play crucial regulatory roles in cell differentiation, proliferation, migration, invasion and apoptosis. Long intergenic non-protein coding RNA 173 (Linco0173) which was first identified in small cell lung cancer, and was found to be involved in chemoresistance in our previous array analysis. In this study, we aimed to explore the biological role of Linco0173 and its possible molecular mechanism in SCLC chemoresistance.

Method: Linco0173 was examined in 60 SCLC patient samples by reverse transcription-quantitative PCR (RT-qPCR). The functional roles of Linco0173 in SCLC were studied by overexpression and RNA interference approaches in vitro and in vivo. The localization of Linco0173 was studied by separating cytoplasmic and nuclear RNA fractions from SCLC cells. RNA pulldown and mass spectrum experiments were performed to find the RNA-binding proteins that interact with Linco0173. RNA sequencing of RNA-binding proteins-immunoprecipitated RNA and coexpression profiles of Linco0173 and mRNAs were used to identify the gene that was regulated by Linco0173 with the RNA-binding proteins. Result: Linco0173 expression was significantly associated with chemoresistance and the shorter survival time in SCLC patients. Upregulation of Linco0173 promoted the proliferation and cell-cycle progression and also induced multidrug resistance in SCLC cells. Downregulation of Linco0173 expression had opposite effects both in vitro and in vivo. Linco0173 increased the expression of hnRNPA2B1 and hnRNPI in the nucleus and formed an RNA-protein complex, which further bound to the target mRNA of CHK2 that is implicated in cell cycle progression. This interaction made the CHK2 mRNA fragile and decreased its protein level. Conclusion: Linco0173 was first identified to promote proliferation and chemoresistance in SCLC. It interacts directly with hnRNPA2B1 and hnRNPI to regulate levels of CHK2. Overexpression of Linco0173 represents a biomarker of poor prognosis and chemoresistance in SCLC patients.

Keywords: Linco0173, Small cell lung cancer (SCLC), chemoresistance

P3.12-05 THE PATTERN OF PD-L1 EXPRESSION IN THORACIC NEUROENDOCRINE TUMORS
N. Karim1, J. Pathrose2, I. El Desouki3
1Internal Medicine, University of Cincinnati, Cincinnati/OH/US, 2The McMicken College of Arts and Sciences, The University of Cincinnati, Cincinnati/OH/US, 3Internal Medicine, The University of Cincinnati, Cincinnati/OH/US

Background: Immunotherapy has assumed a pivotal role in the treatment of a number of cancers including lung cancer through up-regulation of tumor-specific cytolytic T cell activity. The level of expression of programmed death-ligand 1 (PD-L1) on tumor cells plays an important role in determining the first-line cell-mediated killing in small cell lung cancer (NSCLC) with immunotherapy. Large cell neuroendocrine carcinoma (LCNEC) of the lung has an adverse prognosis, with small numbers of patients suitable for surgical resection at diagnosis. While PD-L1 expression is shown to be an overall negative prognostic factor, it is associated with a positive outcome when PD-1/PD-L1 blocking antibodies are used. In this study, we investigated PD-L1 expression in LCNEC using immunohistochemistry.

Method: Thirty-six patients with LCNEC diagnosed between 2007 and 2013 at the University of Cincinnati Medical Center were included. PD-L1 IHC 22C3 expression was analyzed by immunohistochemistry on formalin fixed, paraffin embedded (FFPE) tissue samples using anti-PD-L1 antibody PD-L1 expression in the tumor cells was evaluated. Immunostaining was quantitated based on staining intensity (0 to 3+) and stained surface area (0-100%). A grade cutoff of PD-L1 of ≤5% was used to decide positive or negative. Result: We found that 11 of 36 patients showed strong expression of PD-L1, whereas only 6 of 36 patients demonstrated PD-L1 expression on the tumor and 3 patients were positive for PD-L1 expression in both tumor and surrounding stromal cells. Conclusion: In conclusion, PD-L1 expression on stromal cells appears to be higher in patients with LCNEC compared to the PD-L1 expression on the tumor cells. Prior studies have shown that patients with small cell lung cancer, another aggressive neuroendocrine tumor, exhibited greater levels of PD-L1 expression on stromal cells and tumor-associated macrophages suggesting a possible alternative predictive marker.

P3.12-06 SLFN11 EXPRESSION AND EFFICACY OF PARP INHIBITOR THERAPY IN EXTENSIVE STAGE SMALL CELL LUNG CANCER: ECOC-ACRIN 2511 STUDY
T. Owonikoko1, S. Dahlberg2, G. Sica3, J. Poirier4, L. Byers5, C. Rudin6, I. Wistuba6, S. Ramalingam4
1Hematology/Medical Oncology, Emory University, Atlanta/Georgia/US, 2Department of Biostatistics, Dana-Farber Cancer Institute, Boston/MA/US, 3Pathology, Emory University, Atlanta/Georgia/US, 4Memorial Sloan Kettering Cancer Center, New York/NY/US, 5Thoracic/Head & Neck Medical Oncology, UT MD Anderson Cancer Center, Houston/TX/US, 6Memorial Sloan Kettering Cancer Center, New York/New York/US, 7Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston/TX/US, 8Medical Oncology, Emory University Winnship Cancer Institute, Atlanta/Georgia/US

Background: Veliparib (V), an oral small molecule inhibitor of poly(ADP-ribose)polymerase (PARP) enhanced cytotoxic chemotherapy in preclinical models of small cell lung cancer (SCLC). The combination of V with cisplatin/etoposide (CE) doublet showed efficacy improvement as first-line therapy of extensive stage SCLC (ES-SCLC) with adjusted PFS HR: 0.63 (-1.3 - 0.9) p=0.01. There was differential treatment effect by strata (adjusted treatment HR comparing CE+V: CE: 0.34; 80% CI: 0.22 - 0.51; 1-sided p<0.001 for male patients with high tumor burden versus adjusted HR: 0.81 80% CI: 0.60 - 1.09; 1-sided p=0.18 for other patients subsets) highlighting the need to identify patient subset most likely to benefit. SLFN11 expression was previously shown to be associated with benefit of V when combined with temozolomide in relapsed SCLC and also predicted benefit of CE in preclinical models. We assessed the utility of SLFN11 as a predictive biomarker in the context of E2511 frontline clinical trial.

Method: Archival tissue samples collected from patients with ES-SCLC enrolled and treated on E2511 study was employed for biomarker analysis looking at SLFN11 expression by immunohistochemistry. The study has 88% power to detect a PFS hazard ratio of 0.5 comparing SLFN11 (+) and (-) patients using a one-sided test at 5% level of significance. There was an imbalance between control and experimental arms in the Male/abnormal LDH stratum (in strata) with respect to Age: p=0.006; malignant pleural effusion: p=0.095 and T stage: p=0.02. Median PFS was 5.6 mos on CE+V (95% CI 3.9 - 6.6 mos) vs. 6.6-11.1 mos on CE (95% CI 6.0 - 11.7 mos); HR=0.76, p=0.39.
Clinical outcome differences based on SLFN11 expression is ongoing and will be presented at the meeting. **Conclusion:** Pending ongoing analysis of correlation of biomarker with clinical outcomes.

**Keywords:** small cell lung cancer; biomarker; SLFN11

**P3.12-07 MICRONA DEREGLATION IN A TYPICAL CARCINOID TUMOR: POTENTIAL ROLE OF IMMUNE RESPONSE AND INVASION IN TUMORIGENESIS.**

A. Seneda1, R. Lopez Lapa1, T. Felix2, C. Oliveira2, É. Hasimoto2, D. Cataneo2, A. Cataneo3, J. De Faveri1, S. Drigo1, P. Dos Reis1

1Department of Surgery and Orthopedics, São Paulo State University (Unesp), Faculty of Medicine, Botucatu, Botucatu, SP/Brazil; 2Department of Genetics, São Paulo State University (Unesp), Faculty of Medicine, Botucatu, Botucatu, SP/Brazil

**Background:** Lung carcinoid tumors comprise an uncommon type of neuroendocrine cancer, and are classified as typical or atypical according to their histological characteristics. Typical carcinoid tumors are more common and usually not associated with metastasis at diagnosis. To date, genetic and epigenetic changes, as well as regulatory mechanisms mediated by non-coding RNAs and their association with the development and progression of lung carcinoid tumors are not understood. Considering that microRNAs (miRNAs) are potent gene expression regulators associated with several cancer types, our goal was to determine global miRNA expression changes in a rare case of typical lung carcinoid tumor and its corresponding metastasis from the same patient. **Method:** RNA was isolated from two fragments of the same tumor and its paired lymph node metastasis, using the RecoverAll Total Nucleic Acid Isolation Kit for FFPE tissues (Ambion/Thermo Fisher), miRNA profiling was performed using the TaqMan Array Human microRNA card A v.3.0 platform (Life Technologies/Thermo Fisher), miRNA expression was analyzed in the Expression Suite software using the global normalization algorithm provided. Furthermore, we applied bioinformatic methods for prediction of miRNA target genes, using microRNA data integration portal, mirDIP, and to determine validated targets in lung tissue as well as molecular pathways, using mirTarBase and TopGene Suite. **Result:** Of the 15 miRNAs were significantly down-regulated (FC>=2 and p<0.01). Pathways identified were enriched for miRNA target genes, and the corresponding lymph node metastasis from the same patient. **Conclusion:** Down-regulated miRNAs may be associated with metastatic progression of typical carcinoid tumors, since a subset of 15 miRNAs were down-regulated in paired primary tumor and metastasis samples. Our results contribute to improve our understanding of miRNA regulation and disease pathogenesis in lung carcinoid tumors.

**Keywords:** Typical carcinoid tumor, MicroRNAs, Bioinformatics

**P3.12-08 THE ROLE OF CONTACTIN 1 ON ACQUIRED RESISTANCE TO PEGYLATED ARGINASE IN SMALL CELL LUNG CANCER**

S. Xu1, S. Yan2, S. K. Lam1, P. N. Cheng2, J. C. Ho1

1Department of Medicine, The University of Hong Kong, Hong Kong SAR/HK; 2Bio-Cancer Treatment International, Hong Kong SAR/HK

**Background:** Small cell lung cancer (SCLC) accounts for about 15% of all lung cancer cases. SCLC is characterized by easy to relapse, and current treatment lacks tumor specificity. Arginine is an important amino acid in human, but some tumors lose the ability to synthesize it. So arginine deprivation has become a targeted therapy in certain tumors. BCT-100 is a pegylated arginase with anticancer activity in arginine auxotrophic tumors, such as human melanoma, hepatocellular carcinoma and acute myeloid leukemia. Contactin 1 (CNTN1) is a cell adhesion molecule which plays an important role in drug resistance. The aim of this study is to determine the effects of CNTN1 on BCT-100 acquired resistance in SCLC. **Method:** BCT-100 resistant (BR) cells, H446-BR cells, H526-BR cells, were developed by incubating with serially increasing concentration of BCT-100 with parental H446 (adherent cell line) and H526 (suspension cell line) cells respectively. Gene chip assay was employed to fish out the potential targeted biomarkers in BR cell lines. MT T assay was used to detect cell viability on BR cell lines. Western blotting was employed to evaluate the protein expression. Knockdown of CNTN1 was performed using specific shRNA. Wound healing assay was used to evaluate the cell migration ability in H446 and H446-BR adherent cell lines. Flow cytometry was applied to detect the response to chemotherapy in BR cells. **Result:** The protein expression of CNTN1 in H446-BR and H526-BR cells was 2.7 folds and 5.3 folds higher than that in parental cells respectively. Cell migration ability in BR cells was stronger than parental cells: wound healing rate was greatly increased from 48.5% to 69.9% in H446-BR cells. Epithelial-mesenchymal transition (EMT) progression and AKT activation were observed in both BR cell lines. Knockdown of CNTN1 re-sensitized BR cells to BCT-100 treatment and reversed the EMT progression via inhibiting AKT pathway. **Conclusion:** Contactin 1 modulates BCT-100 resistance through induction of EMT by activating AKT pathway in SCLC.

**Keywords:** Contactin 1, small cell lung cancer, pegylated arginase (BCT-100)

**P3.12-09 SMAD4 MUTATION CONFERS ACQUIRED NEUROENDOCRINE PHENOTYPE IN TRANSFORMATION OF LUNG ADENOCARCINOMA TO SMALL CELL LUNG CANCER**

J. Zhang1, X. Ding1, L. Zhang2, B. Su3

1Oncology, Shanghai Pulmonary Hospital, Shanghai/CN; 2School of Medicine, Tongji University, Shanghai/CN; 3Pathology, Shanghai Pulmonary Hospital, Shanghai/CN

**Background:** Along with the widely used of EGFR-TKI therapy, transformation from lung adenocarcinoma (LAC) to small cell lung cancer (SCLC) has been recognized and accepted as a reason of drug resistance, but the mechanism remains unclear. **Method:** At first, we detected mutated genes in LAC and SCLC component from 9 combined SCLC cases independently by NGS, and analyzed the gene expression in pairs to find the targeted genes. At then, we knocked out the putative gene in HCC827 cell line by CRISPR/Cas9 to detect the changes of classic neuroendocrine markers (Cga, Syn, CD56). **Result:** A high mutation rate of Smad4 gene is observed in SCLC component from 9 combined SCLC cases (66.7%, 6/9, Figure 1A), which is much higher than that in pure SCLC (1.8%, available on http://www.cbioportal.org) samples. HCC827-Smad4-/- cell line is successfully established (Figure 1B), and by IHC assay, the expression of Syn is obviously enhanced in HCC827-Smad4-/- cells when compared with HCC827-GFP cells (Figure 1C).

(See next page)
Conclusion: The dysfunction of Smad4 protein confers the neuroendocrine phenotype of LAC, which plays a potential role in transformation to SCLC.

Keywords: small cell lung cancer, SMAD4 mutation, transformation

P3.12-10 IMMUNOGENOMIC CHARACTERISTICS OF SCLC AND LCNEC REDEFINED MOLECULAR SUBGROUPS
X. Li1, J. Su1, D. Lu1, J.-. Yang1, W. Zhong1, Y. Wu1, X. Zhang1, J. Hou2
1Guangdong Lung Cancer Institute, Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou/CN, 2School of Medicine, South China University of Technology, Guangzhou/CN

Background: While small-cell lung cancer (SCLC) and large-cell neuroendocrine carcinoma (LCNEC) are distinct classes of high-grade neuroendocrine carcinomas, the differential diagnosis between SCLC and LCNEC remains challenging. In fact SCLC and LCNEC overlap in clinical, histopathologic, cytologic, morphologic and genetic characteristics. Molecular profiling with microarray or next-generation sequencing has provided growing evidence suggesting that both SCLC and LCNEC are biologically heterogeneous and a great part of them are borderline neuroendocrine carcinomas falling between typical SCLC and LCNEC. On account of accumulated knowledge, we speculated that immunogenomically characterizing SCLC and LCNEC collectively as one group, or rather morphologically or cytologically separating SCLC from LCNEC has superior clinical value.

Method: We analyzed gene expression profiles of 44 SCLCs, 56 LCNECs and 25 normal lung samples obtained from Gene Expression Omnibus. Unsupervised and supervised analyses were performed to understand molecular characteristics of samples. Pathway and CIBERSORT analyses were employed to obtain immune landscape of SCLC and LCNEC. Result: Unsupervised clustering with 1189 differentially expressed genes revealed 2 distinct molecular subgroups (G1 and G2) of SCLC and LCNEC, which is not associated with histopathology. Targeted pathway analysis found that G1 was marked by activated IL-17, MAPK and Hippo signaling pathways. In contrast, transcriptional factors, such as ASCL1, INSM1, SOX2, and NKX2-1 were significantly up-regulated in G2, but not in G1. Moreover, in silico analysis of cellular composition and expression of immune genes disclosed unique immunoprofiles for G1 and G2. G1 was characterized by enriched CD4 memory cells, M1 macrophages and activated dendritic cells. While G2 was composed of high fractions of memory B cells and naive CD4 cells. Strikingly, expression of both immunoinhibitors (IL10, PDL1, IDO1) and immunomodulators (OX40L, BAFF, GITR, IL6), as well as MHC class I and II molecules was higher in G1 compared to that in G2. Conclusion: We identified the common intrinsic features and molecular subgroups of SCLC and LCNEC, which are beyond conventional histopathology and better associated with immunogenomics of tumors. Further research is warranted to identify potential clinical implication of SCLC and LCNEC molecular subgroups.

Background: The controversial classification of lung neuroendocrine tumor has been amended a few times since recognised as a separate entity. LCNEC shares clinical features with small cell lung carcinoma (SCLC) and they were both classified as lung neuroendocrine carcinoma according to the 2015 WHO lung primary pathology classification. Numerous studies have revealed barely satisfactory outcomes when it was treated as SCLC. However, the underlying molecular basis for such comparable TMB and CNV status as SCLC, which are significantly higher than carcinoid and atypical carcinoids. Our analysis showed strong staining (H-score ≥ 270). In the 77 SCLC patients cohort, PVR protein expressed predominantly in the membrane of tumor cells, with minimal expression observed on immune cells. PVR expression in the SCLC patient cohort was 82% with an arbitrary H-score cut-off of ≥ 50. Higher PVR expression was found for male patients (P=0.040). The expression of PVR increased the tumor expression from stage I to stage III (P =0.007). SCLC patients who had higher PVR expression demonstrated poor prognosis and the difference was near statistically significant (P=0.050). Using the same cut-off (H-score ≥ 50) in the independent SCLC cohort, the prevalence of high PVR expression was 89% (24/27). In the independent SCLC cohort, TIGIT was found to be expressed membranous or cytoplasm on the immune cells found to be weak to moderate staining. Immune cells with TIGIT staining were typically seen as variable size and aggregated toward the periphery of the tumor. TIGIT protein staining was demonstrated in 20 cases (74%). No association was found between PVR H-score and TIGIT expression by Fisher’s test (p=0.093).

Conclusion: PVR is broadly expressed in SCLC cell lines and tumor tissues. The expression of TIGIT protein was also found in immune cells with TIGIT staining were typically seen as variable size and aggregated toward the periphery of the tumor. TIGIT protein staining was demonstrated in 20 cases (74%). No association was found between PVR H-score and TIGIT expression by Fisher’s test (p=0.093).

Background: The poliovirus receptor (PVR) is an immune checkpoint protein expressed on tumor cells. It has been reported to mediate activation of T cells via CD226 or inhibition through binding to T-cell Ig and ITIM domain (TIGIT). TIGIT competes with CD226 for binding to PVR, and exhibits stronger affinity for PVR. Recently we have found that PVR is highly expressed in SCLC cell lines. Characterizing the expression and significance of the PVR-TIGIT axis in SCLC will help us to better understand the immunology of SCLC and may lead to novel therapeutic strategies to combine checkpoint blocking agents for improved SCLC immunotherapy.

Conclusion: We performed to evaluate PVR protein expression in a TMA of 39 SCLC cell lines and a stage IIA TMA of 77 limited stage SCLC patients with clinical data. We analyzed both PVR and TIGIT in an independent cohort of 27 resected, limited-stage SCLC tumors. Result: Thirty-seven cell lines (95%, 37/39) demonstrated staining for PVR and of those, 4 cell lines (10.3%, 4/39) showed strong staining (H-score ≥ 270). In the 77 SCLC patients cohort, PVR expressed predominantly in the membrane of tumor cells, with minimal expression observed on immune cells. PVR expression in the SCLC patient cohort was 82% with an arbitrary H-score cut-off of ≥ 50. Higher PVR expression was found for male patients (P=0.040). The expression of PVR increased the tumor expression from stage I to stage III (P =0.007). SCLC patients who had higher PVR expression demonstrated poor prognosis and the difference was near statistically significant (P=0.050). Using the same cut-off (H-score ≥ 50) in the independent SCLC cohort, the prevalence of high PVR expression was 89% (24/27). In the independent SCLC cohort, TIGIT was found to be expressed membranous or cytoplasm on the immune cells found to be weak to moderate staining. Immune cells with TIGIT staining were typically seen as variable size and aggregated toward the periphery of the tumor. TIGIT protein staining was demonstrated in 20 cases (74%). No association was found between PVR H-score and TIGIT expression by Fisher’s test (p=0.093).

POSTER SESSION 3
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

SCLC patient cohort was 82% with an arbitrary H-score cut-off of ≥ 50. Higher PVR expression was found for male patients (P=0.040). The expression of PVR increased the tumor expression from stage I to stage III (P =0.007). SCLC patients who had higher PVR expression demonstrated poor prognosis and the difference was near statistically significant (P=0.050). Using the same cut-off (H-score ≥ 50) in the independent SCLC cohort, the prevalence of high PVR expression was 89% (24/27). In the independent SCLC cohort, TIGIT was found to be expressed membranous or cytoplasm on the immune cells found to be weak to moderate staining. Immune cells with TIGIT staining were typically seen as variable size and aggregated toward the periphery of the tumor. TIGIT protein staining was demonstrated in 20 cases (74%). No association was found between PVR H-score and TIGIT expression by Fisher’s test (p=0.093).

Conclusion: PVR is broadly expressed in SCLC cell lines and tumor tissues. The expression of TIGIT protein was also found in SCLC patients with weak to moderate staining. Blockade of the PVR-TIGIT pathway may represent a possible future target to immunotherapy in SCLC patients.

Background: Small cell lung cancer (SCLC) is one of the deadliest malignancies and accounts for nearly 15% of lung cancers. The 5-year survival rate for SCLC is very low. Previous study had revealed the genomic characterization of SCLC in Western patients. However, little is known about that in Chinese SCLC patients. Method: FFPE tumor and matched blood samples of 79 Chinese SCLC patients, including 60 males (median age of 60 years old) and 19 females (median age of 59 years old), were collected for next generation sequencing to detect 450 cancer related genes. All histological diagnoses were confirmed by independent pathologists. Genomic alterations including single nucleotide substitutions (SNV), short and long insertions/deletions (Indel), copy number variation (CNV), and gene rearrangement in selected genes were assessed. Result: The most frequently altered genes in 79 Chinese SCLC patients were TP53 (94.9%), RB1 (83.5%), LRP1B (22.8%), KMT2D (13.9%), NOTCH1 (12.7%), FAM135B (11.4%), FAN1 (11.4%), DPTA (10.1%) and STK24 (10.1%). Four of the patients harbored EGFR alterations including one EGFR fusion. Copy number variation analysis revealed that the most frequent variations occurred in the long arm of chromosome 13, including amplifications of STK24, FGFR1, IRS2 and TNSF13B (10.1%, 8/79) and deletion of RB1 and BRCA2 (59.5%, 47/79, located at 13q31-13q34) and deletion of RB1 and BRCA2 (59.5%, 47/79, located at 13q31-13q34). Compared to the previously reported 25 mutational frequency in Western cohort reported previously, 31.6% (25/79) of our patients exhibited alterations in NOTCH1 signaling pathway related genes (NOTCH1, NOTCH2, NOTCH3, NOTCH4, EP300 and CREBBP). Around 15.2% (12/79) patients had PIK3/AKT/mTOR signaling pathway alterations (PIK3CA, MTOR, PTEN, and TSC2). Homologous Recombination Deficiency (HRD) related genes altered in 17.7% (14/79) patients, suggesting the potential clinical benefits from PARP inhibitors. The genomic alterations of FGFR family members occurred in 25.3% (20/79) of patients. Other targetable genes included KIT (7.6%, n = 6), PDGFR (5.1%, n = 4) and DDR2 (2.5%, n = 2). Conclusion: In this study, we characterized the genomic alteration profile of Chinese SCLC patients. Our discovery of CNV in the long arm of chromosome 13 might be helpful in understanding the pathogenesis of SCLC. Consistent with previous report, high mutation rates of TP53 and RB1 are the most important genomic features of SCLC [PMID: 26168399]. In addition, we identified several targetable variations including HRD, FGFR family, KIT, PDGFR and DDR2, which might provide potential targeted therapy options for SCLC patients. Further association analyses of these genomic alterations with clinical features in SCLC are still needed.

shows patient distribution according to clinical variables and stage (8th TNM), as well as HR for multivariate survival analysis. Many pts (48%) were classified to stage I-III disease, while the rest had stage IV. Pts with stage I-III were treated with Surgery (n=13), Radiotherapy+ Chemotherapy (CT) (n=80) or Stereotactic body radiation (n=7). The patients who were diagnosed with stage IV disease were treated with palliative CT or did not receive any oncological therapy. In pts that did not perform PET/CT, the majority (87%) were treated with CT or did not receive treatment. The percentage of pts diagnosed with M1b-disease was slightly higher in those who performed a PET/CT vs those who did not (7% vs 3%, respectively).

Multivariate analysis with PS, Age, Gender, Stage for those patients who performed PET/CT.

Conclusion: The 8th TNM edition has a strong prognostic impact in SCLC. Incorporating a PET/CT scan in the diagnostic workup of SCLC is relevant to distinguish potentially curable pts (stages I-III) from pts with stage IV disease, and may be of value to indentify single extra-thoracic metastases (M1b cases).

P3.13 TARGETED THERAPY
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.13-01 DETECTING ALK REARRANGEMENTS IN NSCLC PATIENTS: IHC, FISH OR NGS FUSION?
A. Addeo, A. Friedlander, C. Py, P. Dietrich
Hug, Genève/Cv

Background: Rearrangements of the anaplastic lymphoma kinase (ALK) gene in non-small cell lung cancer (NSCLC) represent a novel molecular target in a small subset of patients. Although ALK rearrangements are usually assessed by immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH), molecular approaches have recently emerged as relevant alternatives in routine laboratories. Previous studies that compared FISH and IHC considered FISH the gold standard, although there are emerging data on ALK fusion variants that question the role of FISH.

Method: Here, we report our personal experience with the use of the IHC, FISH and next-generation sequencing (NGS) analyses in a group of ALK rearranged NSCLC patients treated within our institution. Result: A total of 13 patients with NSCLC were positive for ALK rearrangements on IHC and was subsequently tested with FISH. Interestingly 5 out of 13 patients were negative on FISH but all the patients received first line ALK inhibitors. The response rate (RR) was 79% (10/13), the progression free survival (PFS) was 19 months for the total population. Among the non-responders 2/13 were FISH negative but 1/13 was IHC and FISH positive. We are going to retrospectively perform NGS analyses to further assess the role of NGS fusion in the context of ALK patients.

Conclusion: Our study suggests that IHC is a valid, quick and reliable assay for the detection of ALK gene rearrangements. It also shows that FISH should not be considered the gold standard on its own for the detection of ALK gene rearrangements. We are going to present the data on NGS fusion in this group of patients at the next conference (WLLC November 2018) with the view of seeing if NGS fusion could and should be a valid alternative and replace FISH as the gold standard.

Keywords: ALK, IHC, NGS fusion

P3.13-02 LYMPHOCYTIC PLEURAL EFFUSION DUE TO CRIZOTINIB USAGE: FIRST CASE IN LITERATURE
P. Akın Kabala, Ü. Yılmaz, S. Kavurgaci, D. Kızılgöz, T. İnal Cengiz, Ş. Yaman
Chest Disease, Ankara Atatürk Chest Disease and Thoracic Surgery Training and Research Hospital, Ankara/TR

Background: Crizotinib is an ALK inhibitor and used for treatment in advanced stages lung adenocarcinoma patients with ALK (+). Most common side effects are: gastrointestinal disorder and visual side effects. Drugs are one of the reasons of effusion. For accurate diagnosis patients’ drug history should be questioned in details. To the best of our knowledge pleural effusion due to crizotinib treatment does not exist in current literature.

Method: 41 years old female patient’s admitted to outpatient clinic with chest pain. There was a right hilar lesion and pleural effusion on right hemithorax (Figure 1A). Thorax tomography revealed 5 cm mass lesion in right middle lobe. Transthoracic needle aspiration biopsy reported as adenocarcinoma. Tissue was positive for ALK-rearrangement and first line crizotinib initiated. In the third month of treatment bilateral pleural effusion more in the right was occurred (Figure 1B and 1C). Primary lesion was regressed (Figure 1D). Efusion on left hemithorax was serous and exudate. Any malignant cells were observed. There were lymphocytic cell predominance. Others reasons were excluded. Crizotinib treatment was interrupted, in 15th day of crizotinib free initiation fluid’s amount decreased. To increase the rate of recovery methylprednisolone 40 mg/day is added. Result: Crizotinib started again with frequent clinical, radiological follow-up. Fluid’s amount did not increase when steroid dose was tapered. While patient take 16 mg/day crizotinib, it has been seen that left pleural fluid disappeared and right pleural thickening appeared due to talc pleurodesis (Figure 1E and 1F).

P3.13 TARGETED THERAPY
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30
P3.13-02 REAL-WORLD ANAPLASTIC LYMPHOMA KINASE TESTING PRACTICES: RESULTS FROM A SURVEY IN THE UNITED STATES
K. Bloom1, S. Sudarsanam2, H. Hwang1, F. Racke1, S. Astrow3, M. Moran5, M. Chiolda4, J. Sheng1, J. Ramage4, J. Mardekian6, A. J. Iafrate7

1Clariant Diagnostic Services, Inc., Also Viejo/CA/US, 2Phenopath Plc, Seattle/WA/US, 3Quest Diagnostics Nichols Institute, San Juan Capistrano/CA/US, 4Kite Pharma, Inc., Santa Monica/CA/US, 5Cancer Genetics, Inc., Los Angeles/CA/US, 6JPhi Oncology, New York/NY/US, 7Massachusetts General Hospital, Boston/MA/US

Background: Anaplastic lymphoma kinase (ALK) translocation is a clinically validated predictive biomarker in multiple cancer types including non-small cell lung cancer, and widespread adoption of diagnostic assays permits a review of test performance. This analysis presents ALK and epidermal growth factor receptor (EGFR) testing rates, expediency, and results from 4 large national laboratories. Method: Deidentified data from January 2013 to December 2015 were compiled from 40 states and Washington DC and included in the final analysis. ALK status was evaluated with the Vysis ALK Break Apart FISH Probe Kit; EGFR status was evaluated by therascreen EGFR RRQ PCR Kit; cobas EGFR Mutation Test, or Sanger sequencing. Results: From the most recent conclusive test were used. Collection to order (time from date of biopsy to date of biomarker test order), order to results (time from date of biomarker test order to date of available results), and overall turnaround times (collection to order + order to results) were evaluated. Results were analyzed by laboratories and regions (Northeast, South, and Midwest). Results were summarized with descriptive statistics. Results: 5 of 50,992 ALK+ and 50,023 patients were tested for both ALK and EGFR, 9035 had results for ALK only, and 969 for EGFR only patients. The rates of ALK and EGFR were compared to known rates of positive patients with advanced NSCLC. Conclusion: Our data suggest that the majority of laboratories are performing ALK and EGFR testing rates of 1% to 7% of non-small-cell lung cancers (NSCLCs). Crizotinib, an ALK inhibitor, is highly potent and selective third generation ALK tyrosine kinase inhibitor (TKI) with known activity against most resistance mutations. In a phase 1 study, lorlatinib showed intracranial and systemic activity in ROS1-positive and ALK-positive patients with advanced NSCLC. Result: Thus far, we treated 6 ALK- and 4 ROS1-negative patients with lorlatinib in a compassionate use program. Best response was complete remission in two of our patients. One ROS1-positive patient with CNS metastases has now ongoing complete response for 27 months; the other patient with a ALK-positive NSCLC with CNS metastasis has now been treated with lorlatinib for 16 months. Three patients showed a partial response with an ongoing progression free survival of respectively 3, 5 and 8 months. Two of our patients (one ALK-positive and one ROS1-positive NSCLC) showed progressive disease as best response. In three patients response data is not yet available. There were no significant side effect apart from hypercholesterolemia, which occurred in four of our patients. Conclusion: Lorlatinib shows promise in the treatment of ROS1-positive and ALK-positive patients with advanced NSCLC.

Keywords: Anaplastic lymphoma kinase, ROS proto-oncogene 1, lorlatinib

P3.13-03-04 LORLATINIB IN ANAPLASTIC LYMPHOMA KINASE AND PROTO-ONCOGENE TYROSINE-PROTEIN KINASE ROS-POSITIVE NON-SMALL CELL LUNG CANCER
M. Paats, J. Minnema-Luiting, R. Cornelissen, J. Aerts
Pulmonary Medicine, Erasmus MC, Rotterdam/NL

Background: In this case series we present ten patients with anaplastic lymphoma kinase (ALK)-rearranged or ROS proto-oncogene 1 (ROS1)-rearranged non-small-cell lung cancer (NSCLC) treated with lorlatinib. Method: Lorlatinib is highly potent and selective third generation ALK and ROS1 tyrosine kinase inhibitor (TKI) with known activity against most resistance mutations. In a phase 1 study, lorlatinib showed intracranial and systemic activity in ROS1-positive and ALK-positive patients with advanced NSCLC. Result: Thus far, we treated 6 ALK- and 4 ROS1-negative patients with lorlatinib in a compassionate use program. Best response was complete remission in two of our patients. One ROS1-positive patient with CNS metastases has now ongoing complete response for 27 months; the other patient with a ALK-positive NSCLC with CNS metastasis has now been treated with lorlatinib for 16 months. Three patients showed a partial response with an ongoing progression free survival of respectively 3, 5 and 8 months. Two of our patients (one ALK-positive and one ROS1-positive NSCLC) showed progressive disease as best response. In three patients response data is not yet available. There were no significant side effect apart from hypercholesterolemia, which occurred in four of our patients. Conclusion: Lorlatinib shows promise in the treatment of ROS1-positive and ALK-positive patients with advanced NSCLC.

P3.13-05 USE OF CRIZOTINIB IN A PATIENT WITH A ROS MUTATION CAUSING ELEVATED CPK AND RESULTING IN DOSE LIMITING: CASE REPORT
B.M. Luz, A.C. Vasconcelos, C. Santos, R. Aragão
Clinical Oncology, Imp. Recife/BR

Background: The use of target therapy in lung cancer has changing the story of this disease. However, the toxicity sometimes can be a challenge. Method: We report a clinical case in a patient with advanced lung cancer with mutation in ROS 1 that had an excellent response with Crizotinib, but developed high levels of CPK. Result: Man, 75y, with an adenocarcinoma of the right lung with lesions in pleura. Tumor was assessed for EGFR mutation and ALK translocation, but were not found. We started chemotherapy with Carboplatin and Pemetrexed with partial response and, after four cycles, we continued treatment with Pemetrexed isolated. After thirteen cycles, he had bone progression and the chemotherapy was changed to Docetaxel. After that, he was submitted to three more lines of chemotherapy and immunotherapy with Nivolumab. After four years of metastatic disease, a new bone progression with a sternal mass. new biopsy was made and found a mutation in the ROS 1 gene. He was very symptomatic, limited performance status (ecog 4) and was admitted in the hospital. We started treatment with Crizotinib 250 mg twice daily and he had a dramatic response. After two months, ECOG was one and a PET-CT showed almost a complete response. However, the patient started cramps in the abdomen and laboratory showed a CPK of 4500 u/l. the dose of the Crizotinib was adjusted to 250mg/day and the levels of cpk started to fall. We tried to reintroduce the full dose, but the levels of CPK increases to 4800 u/l again. So, we reduced the dose with maintenance of response and better tolerability.

P3.13-06 ANALYSIS OF ALK REARRANGEMENT NON-SMALL CELL LUNG CANCER CELL BLOCKS FROM PLEURAL EFFUSION

inhibitor, has been demonstrated to provide dramatic clinical benefits in ALK rearrangement advanced NSCLC. The aim of this study is to investigate the clinical value of ALK rearrangement NSCLC blocks cell from pleural effusion. Method: Two hundred and fifteen cases of ALK rearrangement non-small cell lung cancer (NSCLC) blocks cell from pleural effusion. Four hundred and four cases of tissues were detected by reverse transcription polymerase chain reaction (RT-PCR) method. The consistency of ALK rearrangement was examined in 74 cases of patients with tissues and cell blocks. Result: ALK rearrangement was found in 26 of 215 cell blocks (positive detection rate of 12.09%), ALK rearrangement was detected in 25 of 404 tissue blocks (positive detection rate of 6.19%). There were 67 cases in the 74 (90.54%) cases had the same consistency as tissue block. ALK rearrangement was detected in 11 of 74 (14.86%) cell blocks, and 14 of 74 (19.22%) tissue blocks. Conclusion: The rate of ALK rearrangement in cell blocks of NSCLC is higher than in matched tissue blocks. The patients with malignant pleural effusion are likely to tend ALK rearrangement.

Keywords: non-small cell lung cancer, cell block, ALK

P3.13-07 THE EFFECT OF CRIZOTINIB IN PATIENTS OF NON SMALL CELL LUNG CANCER WITH BRAIN METASTASES: A RETROSPECTIVE ANALYSIS
J. Zhang
State Key Laboratory of Respiratory Disease, the First Affiliated Hospital of Guangzhou Medical University, National Clinical Research Center for Respiratory Disease, Guangzhou/ CN

Background: Crizotinib is a tyrosine kinase inhibitor targeting the anaplastic lymphoma kinase gene (ALK) and exhibited a prominent effect in treating ALK-positive non-small cell lung cancer (NSCLC). This retrospective study aimed to evaluate therapeutic effects of crizotinib in patients with brain metastasis from ALK-positive NSCLC. Method: Patients diagnosed with BM from ALK-positive NSCLC from November 2010 to October 2015 and treated initially by crizotinib were enrolled and reviewed. The median and 95% confidence interval (CI) of the intracranial and whole-body progression-free survival (PFS) and the overall survival (OS) were calculated by Kaplan-Meier method with diagnosed lung adenocarcinoma. And the candidate prognostic factor of the survivals was checked by a log-rank test. Result: Totally 41 patients were eligible for analysis. The median whole-body PFS, intracranial PFS and OS were 8.00 (95% CI, 6.99-9.01) and 8.00 (95%, CI 6.99-9.01) and 23.0 (95% CI, 15.8-30.2) months, respectively. Compared with multiple BM, single BM seemed to lead to a better OS when crizotinib was administered (P = 0.029). Totally 5 patients (12.2%) developed crizotinib-related adverse events. Except 1 patient terminated crizotinib treatment because of interstitial pneumonia, the other 4 cases exhibited only adverse events of grade 1. Conclusion: Crizotinib could bring an ideal control on BM from ALK-positive NSCLC and were well tolerated. It might be a feasible treatment for patients with this kind of disease.

Keywords: ALK-positive NSCLC, brain metastasis, crizotinib, survival

P3.13-08 ASSESSMENT OF EGFR GENE MUTATIONS IN CF-DNA IN MONITORING OF RESPONSE TO EGFR TKIS IN PATIENTS WITH LUNG ADENOCARCINOMA
M. Nicóś1, K. Wojas-Krawczyk2, P. Krawczyk2, I. Chmielewska3, M. Nicoś1, K. Wojas-Krawczyk2, P. Krawczyk2, I. Chmielewska3, M. Nicoś1, K. Wojas-Krawczyk2, P. Krawczyk2, I. Chmielewska3
1Pneumonology, Oncology and Allergology, Medical University of Lublin, Lublin/ PL, 2Department of Pneumonology, Oncology and Allergology, Medical University of Lublin, Lublin/PL, 3Institute of Genetics and Immunology, Gemm LCC, Lublin/PL, 4Independent Public Provincial Hospital Named Jan Boży in Lublin, Lublin/PL, 5Oncology, Poznan University of Medical Science, Poznan/PL, 6Department of Pulmonology and Pulmonary Oncology, Mazovian Specialist Hospital in Radom, Radom/PL, 7Department of Forensic Medicine, Medical University of Lublin/Lub.

Background: Molecular analysis of cf-DNA in NSCLC patients enables overall and monitoring of EGFR mutations. It allows for detection of the acquired resistance for 1st and 2nd generation of EGFR-TKIs caused Thr790Met substitution. The third generation of EGFR-TKIs (osimertinib) could overcome the resistance in patients with Thr790Met mutation. Method: The studied group included 23 Caucasian patients (8 male and 15 female, median age 63 (40-80) with diagnosis of adenocarcinoma and with EGFR mutations detected in tumor samples. Blood samples were collected before administration of EGFR-TKIs in all patients, and re-collected repeatedly from 10 patients during therapy. EGFR mutations and content of mutated cf-DNA were analyzed using ctEGFR Mutation Analysis Kit (Entrogen, USA) in Rotor-Gene Real-Time PCR device (Qiagen, Germany). Result: Analysis of EGFR activating mutations in cf-DNA showed 82.61% concordance/sensitivity (19/23) with tumor samples. The mean content of mutated cf-DNA was 7.44% and it was significantly lower (p<0.000035) than in tumor samples (34.54%). Concentration of mutated cf-DNA positively correlated with advanced stage of the disease. Monitoring of EGFR status in cf-DNA showed reduction and stabilization of mutant DNA content with the emergence of response to EGFR-TKIS treatment. Primary Thr790Met substitution was undetectable in cf-DNA and in tumor samples. Acquired resistance in Thr790Met mechanism during EGFR-TKIs treatment was detected only in one patient (1/10). This patient responded to osimertinib therapy. Conclusion: Analysis of EGFR mutations in cf-DNA shows lower sensitivity than in DNA isolated from tumor samples. Multiple evaluations of EGFR status may be useful in monitoring of therapy and allows for early detection of acquired resistance.

P3.13-09 ALTER-0303 STUDY: TUMOR MUTATION INDEX (TMI) FOR CLINICAL RESPONSE TO ANLOTINIB IN ADVANCED NSCLC PATIENTS AT 3RD LINE
B. Han1, J. Lu1, W. Zhang1, B. Yan1, L. Zhang1, J. Qian1, B. Zhang1, S. Wang2
1Shanghai Chest Hospital, Shanghai/ CN, 2Department of Pulmonary Medicine, Shanghai Chest Hospital, Shanghai/ CN

Background: Anlotinib is an effective multi-targeted receptor tyrosin kinase inhibitor (TKI) for refractory advanced Non-Small Cell Lung Cancer (NSCLC) therapy at 3rd line. ALTER-0303 clinical trial has been revealed that Anlotinib significantly prolongs progression free survival (PFS). Anlotinib: 5.37 months vs Placebo: 1.40 months and overall survival (OS; Anlotinib: 9.63 months vs Placebo: 6.30 months) with the objective response rate (ORR) of 9.18% and the disease control rate (DCR) of 80.95%. Here, we sought to understand the gene mutation determinants for clinical response to Anlotinib via next generation sequencing (NGS) upon cell-free DNA (cfDNA) and circulating tumor DNA (ctDNA) at baseline. Method: Totally 437 advanced NSCLC patients enrolled in ALTER-0303 study, and 294 patients received Anlotinib therapy. Of the 294 patients, 80 patients were analyzed in the present study. Capture-based targeted ultradope sequencing was performed to obtain germine and somatic mutations in cfDNA and ctDNA. Response analyses upon discovery cohort (n = 62) and validation cohort (n = 80) were performed by use of germine and somatic (G-S) mutation burden, somatic mutation burden, nonsynonymous mutation burden, and unfavorable somatic mutation score (UMS), respectively. Based on the above independent biomarkers and their subtype factors, tumor mutation index (TMI) was developed, and then used for response analysis. Result: Our data indicated that the patients harbouring less mutations are better response to Anlotinib therapy (G-S mutation burden, cutoff = 4000). Median PFS: 210 days vs 131 days; p = 0.0056; somatic mutation burden, cutoff = 800. Median PFS: 210 days vs 130 days; p = 0.0052; nonsynonymous mutation burden, cutoff = 50. Median PFS: 210 days vs 130 days; p = 0.0155; UMS, cutoff = 1. Median PFS: 210 days vs 131 days: p = 0.0016). TMI is an effective biomarker for Anlotinib responsive stratification (Median PFS: 210 days vs 126 days; p = 0.0008; AUC = 0.76, 95% CI: 0.62 to 0.89) upon discovery cohort and validation cohort (Median PFS: 210 days vs 127 days; p = 0.0006). Lastly, integrative analysis of TMI and IDH1 mutation suggested a more promising result for Anlotinib responsive stratification upon validation cohort (Median PFS: 244 days vs 87 days; p < 0.0001; AUC = 0.90, 95% CI: 0.82 to 0.97). Conclusion: This study provide a biomarker of TMI to stratify Anlotinib underlying responders, that may improve clinical outcome for Anlotinib therapy on refractory advanced NSCLC patients at 3rd line. Clinical trial information: NCT02388919.

Keywords: NSCLC, Anlotinib, Responsive biomarker
P3.13-10 FACTORS ASSOCIATED WITH LONG-TERM SURVIVAL OF STAGE IV NSCLC PATIENTS ON FIRST-LINE EGFR-TARGETING THERAPY

A. Gibson1, A. D’silva2, R. Todor1, A. Elegbede3, S. Otsuka1, G. Bebb3, D. Hao4
1Oncology, University of Calgary, Calgary/CA, 2Oncology, University of Calgary, Calgary/AB/CA, 3Medicine, University of Calgary and Alberta Health Services, Calgary/CA

Background: To determine factors associated with long term survival in Stage IV, non-small cell lung cancer (NSCLC) patients receiving EGFR-targeting agents (EGFR-TA) as systemic anti-cancer treatment in the first-line setting at a Canadian tertiary cancer centre. Method: Retrospective analysis was conducted on patients diagnosed with Stage IV (AJCC 7th edition) NSCLC between 1999 and 2014, and receiving EGFR-TA as first-line treatment. Demographic, clinical, histopathological, treatment and outcome data was extracted from the large, population-based institutional Glass-Look Lung Cancer Database. Long-term survivors (LTS) were defined as those surviving ≥ 18 months post EGFR-TA initiation. Correlates of survival were investigated via univariate analysis, Kaplan-Meier analysis using the log-rank test, and multivariate Cox regression. Result: We identified 117 eligible patients. Median age was 65 (IQR 54.5-74) years, 61% female, 91% adenocarcinoma, 60% never smoking history, and 80% were identified as EGFR-mutant (remainder were unstaged and accessed EGFR-TA before routine testing was performed). Most common ethnicity (by place of birth) was North American (47%), followed by Asian (37%). 21% survived ≥18 months post-EGFR-TA initiation, with a median overall survival (mOS) of 46 vs. 13 months in those surviving < 18 months post-EGFR-TA initiation (p < 0.001). LTS were more likely to be over the age of 65 years at diagnosis (76% vs. 46%, p = 0.012), receive palliative radiation therapy (72% vs. 27%, p < 0.001), and possess Asian ethnicity (60% vs. 30%, p = 0.044), although impact of age and radiation therapy did not retain prognostic significance in multivariate analysis. Conclusion: older age and radiation therapy did not retain prognostic significance in multivariate analysis after controlling for other measured confounders; Asian ethnicity was retained as a favorable prognostic factor for survival [HR: 0.5, 95% CI (0.3-0.8), p = 0.005]). Patients with Asian ethnicity revealed no significant demographic or clinical characteristics (notably gender, smoking status and EGFR mutation type) between LTS and non-LTS, with the exception of age. Asian LTS were significantly more likely to be ≥ 65 years of age at diagnosis (87% vs. 32%, p < 0.001), a factor which retained significance as a favorable prognostic factor in multivariate analysis [HR: 0.3, 95% CI (0.2-0.7), p < 0.004].

*Del 19 and T790M
Conclusion: In our group of patients with advanced NSCLC treated with gefitinib or erlotinib for over 5 years the treatment was safe and effective. The NGS analysis of the available samples were retrospectively done to assess the specific genetic features of these long-term responders.

Keywords: erlotinib, gefitinib, long-term treatment

P3.13-12 A LUNG ADENOCARCINOMA WITH CONCOMITANT EGFR AND DE NOVO MET AMPLIFICATION RESPONSE WELL TO COMBINATION OF TKI AND BEVACIZUMAB

Q. Chu, J. Jiang, S. Huang, P. Zhang, Y. Chen
Department of Oncology, Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, Wuhan/CN

Background: Patients with NSCLC who are carrying concomitant de novo EGFR and MET amplification were commonly reported to have poor response to therapy. Here, we presented a case of a patient harboring concomitant de novo MET and EGFR, who obtained favorable response to combinatorial therapy of TKI and bevacizumab. Method: We presented a lung adenocarcinoma patient harboring dual EGFR-MET alterations, and evaluated his response to combinatorial therapy of TKI and bevacizumab. In vitro experiments were performed in HCCB27(EGFR-19del) and HCCB27-GR (EGFR-19del+MET amplification) cells to validate the effect of bevacizumab on MET pathway. Result: A 44-year-old male stage IV lung adenocarcinoma with left lung tumor was detected harboring of EGFR-19del and MET amplification using PCR and FISH. The patient was treated with erlotinib+bevacizumab and achieved partial response (PR) with a PFS of 13 months. After PD, NGS performed on both tissue and plasma biopsies revealed that the patients obtained first-generation resistant mutation EGFR-T790M, concomitant with EGFR-19del. The patient was treated with osimertinib+bevacizumab and achieved PR. He developed PD again with a PFS of 10.2 months, and repeated biopsies sequencing identified concomitant EGFR-19del and MET amplification. Then, the patient was treated with crizotinib+bevacizumab and the best curative effect was stable disease. Four months later, he developed PD and the third biopsy still revealed positive EGFR-19del and MET amplification. The patient received osimertinib+crizotinib+bevacizumab and achieved PR one month after treatment initiation. Here, in this study confirms that rare mutations have been increasingly seen due to the employment of improved sensitivity genetic techniques, like NGS. Furthermore, reveals two rare examples of rapid clinical response to afatinib in patients harboring EGFR exon 20 insertions. Finally, despite it could be an option for management of this broadly unknown situation, it suggests caution because of the short-lasting benefit in some.

Keywords: exon 20 insertions, EGFR, Afatinib

P3.13-14 IDENTIFICATION OF NOVEL MUTATIONS BY HIGH-THROUGHPUT SEQUENCING IN T790M WILDTYPE/CMET UNAMPLIFIED NSCLC WITH ACQUIRED RESISTANCE TO EGFR TKIS

C. Li, B. Zhang, C. Wang
Department of Lung Cancer, Tianjin Medical University Cancer Institute and Hospital, Tianjin/CN

Background: Lung cancer remains the leading cause of cancer-related death worldwide. Though most patients with EGFR activating mutations are sensitive to EGFR tyrosine kinase inhibitors (TKIs), tumors will inevitably acquire resistance to first generation EGFR TKIs. EGFR T790M mutation and cMET amplification are common mechanisms. Further study is needed to explore unknown genomic alterations contributing to drug resistance. Method: In the screening period of ASTRIS (D5160C00022) study of single center, tumor and blood samples from 69 stage IIIB-IV NSCLC patients defined as acquired resistance to first generation EGFR TKIs (Gefitinib, Erlotinib or Ectotinib) were collected. The cobas® and Droplet digital PCR (ddPCR) were used to detect T790M mutations in tumor samples and plasma ctDNA. cMET amplification were evaluated by Fluorescence in situ Hybridization (FISH). Exome sequencing were performed in four T790M wildtype/cMET unamplified samples. Result: The T790M mutation rate of FFPE tissue cobas, plasma cobas and plasma ddPCR testing were 54.5%, 21.3% and 30.4% respectively. Taking all testing methods into account, the T790M positive rate was 52.2%. In 21 samples which tumor re-biopsy was performed, 14 were T790M positive (66.7%). cMET amplification were identified in 3 out of 7 T790M negative samples. Exome sequencing in 4 T790M wildtype/cMET unamplified samples and paired white blood cells identified a cohort of candidate key mutated genes including BRAF, FGFR1, PKA1, PCKT, PEMp4 and SOX3. Conclusion: EGFR T790M mutation and cMET amplification are main mechanisms leading to EGFR TKI resistant in lung adenocarcinoma. These key mutated genes identified in the present study would need further functional study validation.

P3.13-13 AFTINIB IN LUNG ADENOCARCINOMA HARBORING DE NOVO EGFR EXON 20 INSERTIONS.

M. Costa1, J. Lewgoy2
1Oncology, Oswaldo Cruz Hospital, Sao Paulo/BR, 2Oncology, Hospital Do Cancer Mâe de Deus, Porto Alegre/BR

Background: NSCLC, particularly adenocarcinoma, has been successfully treated with upfront targeted therapies according to respective oncogenic mutations in a tailor-made model. EGFR-TK inhibitors (TKi) have exhibited major responses, improving PFS, RR and even mOS (a subset treated with afatinib). This drug has emerged as the best option for those with uncommon mutations, but until now is broadly unknown its action in exon 20 mutations, which accounts for nearly 3% of all and, classically, is associated to worse response to 1st generation TKi. Method: Here, in this retrospective analysis, is reported the past medical history and clinical outcomes of two patients who presented with de novo EGFR exon 20 insertions: D770_N771insSVD and Ser768_Asp770dup. The patient were treated in two different Cancer Centers in Brazil and the mutations were identified with Next Generation Sequencing (NGS) by illumina HiSeqs of Foundation Medicine (FM) and the other by a local certified laboratory using Ion Torrent-PGM Thermo Fischer v5.0. Analysis were performed in tissue samples extracted from FFPE. The follow-up was obtained from electronic charts. Result: Patient 1: never-smoker 66 y/o lady, without comorbidities. presented 12 mo ago with dry cough, thoracic pain and -10% of weight. CT scan revealed extensive ground-glass infiltration area and multiple bilateral pulmonary nodules. Lung biopsy pointed out a mod. differentiated adenocarcinoma of predominantly lepidic pattern (IHC: AE1/2+, CK20-, CK7+, Napsin A+, TTF1+). With this, rtPCR (Cobas Mu test v.2) detected an exon 20 insertion, thus ineligible to upfront EGFR-TKI. However, was chosen to re-analyze it using NGS (FM). After a TAT of only 2 weeks, we retrieved the result which showed a poorly described mutation: EGFR exon 20 insertion D770_N771insSVD. Afatinib 30mg/day was started and, only three days after the initiation, the patient decreased the dry cough and fatigue. CT scans showed stable disease after 45 days of continuous use. Patient 2 had a more extensive past medical history: 1L chemo, followed by nivolumab and docetaxel. Lastly, NGS revealed an uncommon EGFR exon 20 insertion (Ser768_Asp770dup). Rapid clinical improvement was observed (less fatigue and dyspnea), but occurred liver progression in the first control, 4w after initiation. Conclusion: This study confirms that rare mutations have been increasingly seen due to the employment of improved sensitivity genetic techniques, like NGS. Furthermore, reveals two rare examples of rapid clinical response to afatinib in patients harboring EGFR exon 20 insertions. Finally, despite it could be an option for management of this broadly unknown situation, it suggests caution because of the short-lasting benefit in some.

P3.13 TARGETED THERAPY
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30
P3.13-15 FIRST-LINE AFATINIB DOSE INITIATION AND ADJUSTMENT IN PATIENTS WITH EGFR MUTANT ADVANCED NON-SMALL CELL LUNG CANCER
C. Liam1, G. Ho2, C. Chai3, A. Bt Alip2, Y. Pang1
1Department of Pulmonary Medicine, All India Institute of Medical Sciences, Bhubaneswar, India, 2Department of Oncology, Faculty of Medicine, University of Malaya, Kuala Lumpur, MY, 3Department of Medicine, University Malaysia Sarawak, Kota Samarahan, MY

Background: The recommended starting dose of afatinib is 40mg od with 20mg, 30mg and 50mg tablets available for dose adjustment. Method: This is a retrospective observational study of starting dose, dose adjustment and optimal dose of first-line afatinib in patients with EGFR mutant advanced non-small cell lung cancer in University Malaya Medical Center from 1st December 2014 to 30th April 2018. Result: Of 22 patients on first-line afatinib, the starting dose was 40 mg od in 12 patients and 30 mg od in 10 patients (Figure 1). Among the 12 patients started on afatinib 40mg od, 4 (33.3%) did not require dose adjustment, 4 (33.3%) needed dose reduction to 30mg od, 2 (16.7%) needed dose reduction to 20mg od, and 2 (16.7%) had dose escalation to 50mg od. Among 10 patients started on afatinib 30mg od, 6 (60%) did not require dose adjustment, 1 (10%) needed dose reduction to 25mg od and 3 (30%) had dose escalation to 40mg od. Dose reduction was to reduce the cost of treatment in 1 patient and to reduce drug-related side-effects in the rest. Dose escalation was exclusively to improve disease control. The overall response rate and disease control rate was 80% (8/10) and 90% (9/10) in patients who did not require dose adjustment; while the respective rates were 85.7% (6/7) and 100% (7/7) in patients who had dose reduction. The optimal dose of afatinib defined by good disease control and tolerable side-effects was 50mg od in 9.1% (2/22), 40mg od in 31.8% (7/22), 30mg od in 31.8% (7/22), 25mg od in 13.6% (3/22) and 20mg od in 13.6% (3/22) of patients. Conclusion: We suggest starting afatinib at 30mg od and adjust the dose accordingly because dose adjustment is not required in most cases on this starting dose and it is the commonest optimal dose.

P3.13-16 CONCOMITANT EML4-ALK REARRANGEMENT AND EGFR MUTATION IN NON-SMALL CELL LUNG CANCER PATIENTS: DATA FROM EASTERN INDIAN HOSPITAL
P. Mohapatra1, S. Bhuniya1, M. Panigrahi1, S. Patra1, P. Mishra1, S. Purkait1, S. Dasmajumdar1, S. Mohakud1, S. Naik1, S. Sahoo1, S. Jagaty1, S. Mohankudo1, Y. Dhanurdhar1, S. Panigrahi1, M. Rahman1, D. Muduly1
1Pulmonary Medicine, All India Institute of Medical Sciences, Bhubaneswar, India, 2Pathology, All India Institute of Medical Sciences, Bhubaneswar, India, 3Radiotherapy, All India Institute of Medical Sciences, Bhubaneswar, India

Background: Clinical guidelines recommend routine testing for genetic mutations in all adenocarcinoma of lung, including ALK EML4 gene rearrangement. The coexistence of EGFR mutations and EML4-ALK rearrangements have been described as extremely rare. Perhaps this is due to its low prevalence and the sensitivity of available diagnostic modalities. All India Institute of Medical Sciences, Bhubaneswar, is an upcoming institute of national importance situated in eastern India. No report on EGFR mutation and EML4-ALK rearrangement has been published so far from this region of India. Method: We retrospectively analysed the available data of patients from June 2014 to April 2018. Genetic testing was done from tissue block specimens immediately after establishing the histology. EGFR mutation analysis were done using commercially available Real Time PCR and ALK-positivity was assessed with immunohistochemistry (IHC) by VENTANA ALK (D5F3) CDx Assay. We investigated the course of disease with the efficacy of targeted therapy in EGFR/ALK co-altered NSCLCs Result: Out of 251 NSCLC cases, 198 had adenocarcinoma and only four patients (1.6%) had concomitant EGFR/ALK co-alterations. Of the EGFR mutations, two were positive for Exon 19 and other two were positive for Exon 21. Mean age for Exon 19 and Exon 21 positive patients were 40 and 63 respectively. All four patients were male and had advanced stages of lung cancer. Mutation in all the four patients were detected from initial tissue biopsy and they were negative for ROS1. Three patients had received platinum based doublet regimen followed by EGFR-TKI and one patient received Erlotinib. None had received Crizotinib yet. Conclusion: The coexistence of EGFR mutations and EML4-ALK rearrangements is low but higher than other geographical areas. Since the two alterations may coexist from the beginning of diagnosis, future perspective in management could be finding potential efficacy of a double inhibition of both ALK and EGFR mutations.

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.13-17 A RETROSPECTIVE STUDY: CENTRAL NERVOUS SYSTEM RESPONSE TO OSIMERTINIB IN PATIENTS WITH ADVANCED NSCLC
Y. Mu, P. Xing, X. Hao, Y. Wang, J. Li
National Cancer Center/Ranker Hospital Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Background: Central nervous system (CNS) metastases are common in patients with non-small-cell lung cancer (NSCLC). More than 30% of patients who progress during or after treatment with epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKIs) have CNS metastases. Osimertinib, a third-generation EGFR-TKI, has been demonstrated promising intracranial efficacy in patients with advanced NSCLC from several large scale randomized control trials. We aimed to explore clinical impact of osimertinib for patients with CNS metastases, advanced NSCLC in real world setting. Method: Patients with advanced NSCLC who received osimertinib after progression of prior EGFR-TKIs and CNS metastases on baseline brain scan were retrospectively collected from Cancer Hospital Chinese Academy of Medical Sciences. Primary outcome was objective response rate (ORR) and secondary objectives were disease control rate (DCR), progression-free survival (PFS), time to tumor response, median best percentage change from baseline in CNS target lesion (TL) size and safety. Result: Between Apr 1, 2017, and Dec 30, 2017, 22 patients met selection criteria, 15 with ≥1 measurable CNS lesion (RECIST 1.1) were included in CNS evaluable for response (cEFR) set. The median duration of follow-up was 6.5 months. For overall 22 patients, ORR and DCR were 40.9% and 86.4%, respectively, with median PFS of 8.5 months (95% CI 4.1, 13.0). Of 15 patients in cEFR set, CNS ORR was 53.3% with complete responses reported in 3 patients (20.0%). Median best percentage change from baseline in CNS TL size was -40% (range: -100% ~ +60%) and median time to CNS tumor response was 1.3 months. CNS DCR was 80.0%. Median CNS PFS was not reached. Safety profile was acceptable and no new unexpected findings were found.

Figure 1. Waterfall plot for best percentage change in CNS target lesion

Conclusion: This real world analysis further confirmed that osimertinib was indeed demonstrated clinically meaningful efficacy against CNS metastases in Chinese patients with advanced NSCLC.

Keywords: central nervous system, non-small cell lung cancer, Osimertinib

P3.13-18 MECHANISMS OF ACQUIRED RESISTANCE TO AFAFABIN CLARIFIED WITH LIQUID BIOPSY
Internal Medicine, Saga University, Saga/JP

Background: While the elucidation of the mechanisms of acquired resistance to 1st and 3rd generation EGFR-TKI progressed, there have been few clinical investigations into the mechanisms of acquired resistance to 2nd generation EGFR-TKI, afatinib. Method: We analyzed 20 patients with advanced lung adenocarcinoma who acquired resistance to afatinib including EGFR-TKI re-challenge. We examined EGFR T790M, C797S, BRAF V600E, MET amplification by MBP-QP method and droplet digital PCR using ctDNA and re-biopsy samples at pre and post afatinib treatment. Result: Just before afatinib treatment, 15 patients were T790M negative, and 5 were positive with ctDNA. Among T790M negative patients, 40.0% (6/15) turned to positive at PD to afatinib. T790M positive patients showed synchronous change of T790M allele frequency with treatment efficacy of afatinib. C797S was not detected just before afatinib treatment, and it appeared in 3 patients with very low level of allele frequency. Two of 3 patients were both C797S and T790M positive, who achieved PR to osimertinib. However, PFS with these patients was a trend shorter than T790M only. BRAF V600E was detected in one patient at PD to afatinib. MET amplification was never detected in this study. Conclusion: T790M was related with acquired resistance to afatinib like 1st generation EGFR-TKI, but the frequency is relatively lower. The influence of C797S for resistance to afatinib would be less than T790M, but existence of C797S possibly causes shorter PFS of osimertinib.

Keywords: afatinib, Acquired resistance, T790M

P3.13 TARGETED THERAPY
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.13-19 SURGERY FOR IIIB LUNG ADENOCARCINOMA AFTER RESPONSE TO ERLOTINIB, SURVIVAL AND MANAGEMENT OF POSTOPERATIVE OLIGOPROGRESSIONS
D. Petrov1, G. Yankov2, M. Atanassova3, A. Semkov2, S. Bichev2
1Thoracic Surgery Department, Saint Sophia University Hospital for Active Treatment of Pulmonary Diseases, Sofia/BG, 2Central Hospital, Plovdiv/BG, 3National Genetic Laboratory, Sofia/BG

Background: Down-staging of epidermal growth factor receptor (EGFR) activating mutation-positive (EGFR M+) advanced non-small-cell lung cancer (NSCLC) after first-line EGFR tyrosine kinase inhibitor (TKI) therapy may lead to primary tumor resection. Unfortunately, most patients’ disease will progress postoperatively even with the use of adjuvant TKI therapy due to EGFR M+ resistance. Osimertinib, a third-generation inhibitor of EGFR T790M mutation, is with reduced toxicity profile as compared to non-selective EGFR TKI. Our aim is to assess a survival benefit of salvage lung resection in Stage IIIB lung adenocarcinoma after response to TKI and a management of oligoprogressions in the postoperative period. Method: A Caucasian age 56 female lung adenocarcinoma patient (ECOG PS-0) was initially staged as cT3aN3M0 on October 10, 2015, Pretreatment biopsy specimens from ipsilateral scalene lymph node harbored EGFR mutation (exon 19 E746–T751insI deletions). After six months of first-line treatment with erlotinib150 mg/daily, which patient tolerated very well, a FDG–PET scan showed a 21/16 mm formation of the left upper lobe with SUV-2, without other abnormalities, down-staging with cT1cN0M0. Radical left upper lobectomy with 20 negative dissected mediastinal lymph nodes was carried out (May 17, 2016). Postoperative pathomorphological and mutational studies of residual tumor revealed adenocarcinoma and EGFR exon 19 mutation. Result: Adjuvant erlotinib therapy was started for 3 months. Four months after its discontinuation by patient decision a 3 cm left supraclavicular mass (SUV 2.0 on FDG–PET) was diagnosed and totally resected. Adenocarcinoma involvements of 3 lymph nodes, as well as EGFR exon 19 mutation, were confirmed. The patient continued on erlotinib, but after 6 months on FDG–PET scan 2 left cervical lymph nodes (SUV 4.6 and 6.1 on FDG–PET) were diagnosed. Systematic left cervical dissection was performed with resection of four metastatic lymph nodes. Again adenocarcinoma histology was confirmed, but EGFR T790M mutation was identified as well. Three months later, even without signs of residual tumor mass on computerized tomography scan, Osimertinib therapy in dose 80 mg orally once daily was administered. The last follow-up FDG–PET scan revealed no signs of progression (April 30, 2018). The patient is with ECOG PS-0 and perfect quality of life without drug-related adverse events. Conclusion: Radical surgery of oligoprogression following salvage surgery for Stage IIIB (EGFR M+) lung adenocarcinoma after response to TKI, while continuing to use TKIs (specifically osimertinib in EGFR T790M mutation), can result in prolonged overall survival. The pending question is whether the EGFR-TKI therapy can be discontinued in these patients.

Keywords: adenocarcinoma, target therapy

P3.13 TARGETED THERAPY
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30
BACKGROUND: The frequency of the EGFR mutation in pulmonary adenocarcinoma varies between 15-40% depending on population reported. Study descriptive, observational, retrospective and multicentric was conducted to determine the frequency of this mutation in public and private centers service in Mexico. Method: They were selected patients with diagnosed of pulmonary adenocarcinoma between January 2011 and January 2016 from three oncology centers, two private centers (ABC Medical Center and the Spanish Hospital) and one public (National Institute of Respiratory Diseases). The total sample was 328 patients, subdivided by the presence or not of EGFR mutations. The primary objective was the mutation in EGFR and the secondary the type of mutation, frequency by sex, type of treatment and clinical stage at the time of diagnosis. Result: The sample was formed by 136 (41%) men and 195 (59%) women, the average age of diagnosis was 62.4 years, the clinical stage in 75.7% was IV at the time of diagnosis. The total frequency of the EGFR mutation was 42.7% (140 patients), the most prevalent being Del19 (66.4%) and L858R (30%). These mutations were present in 113 patients of INER (34.5%) and by both private centers was 27 patients (8.2%), this difference was significant when comparing hospital types (public vs. private, p=0.033). Men showed a protective factor for the EGFR mutation compared to women with HR 0.88 (p=0.028), there were differences between the possibility of presenting the EGFR mutation in patients with lung cancer, with less possibility of presenting it if medical attention was done in a private medium compared to the public medium with a HR 0.81 (p=0.001). Conclusion: There is a significant difference in the frequency of mutations in EGFR between the public and private hospital, probably generated with ethnic, genetic, environmental and social differences between the two populations.

Background: To date, the phenomenon of EGFR co-mutated with other genes in untreated NSCLC patients was common, which might be the reason of EGFR-TKI primary resistance. In our previous research, samples from 81 NSCLC Chinese patients were tested with next-generation sequencing (NGS) based targeted panel assay. 49% (40/81) patients had EGFR mutations, the top-ranked co-mutant genes were TP53 (35%, 28/81) and cell cycle pathway related genes (19%, 15/81). Clinical data indicated that antiangiogenic drug combination with EGFR-TKI might reverse EGFR-TKI acquired resistance. Apatinib is a new antiangiogenic drug targeting vascular endothelial growth factor receptor 2 (VEGFR2), and Icotinib is a potent and specific EGFR-TKI, which were both made in China. In this study, we aim to assess the efficacy and safety of Apatinib plus Icotinib as first-line therapy for EGFR co-mutations NSCLC in Chinese patients, and compare the differences of curative effect among EGFR co-mutant subgroups. Method: This single-arm, open-label, the exploratory study will recruit 50 Chinese patients with stage IIIB/IV NSCLC who have never received any anti-tumor treatment previously. Tumor tissue and matched blood of each patient will be collected for NGS-based 450 cancer related genes panel assay, designed to comprehensively assess EGFR mutation and co-mutations. Meanwhile, ctDNA extracted from blood samples will be collected for NGS-based 329 cancer related gene before treatment as baseline, and every 2 months after treatment until disease progression. To evaluate the evolution of genomic variation and effects of drug efficacy. The analysis of genomic alterations including single base substitution, short and long insertions/deletions, copy number variations, gene rearrangement in selected genes and also tumor mutation burden (TMB) calculated at different NGS-based somatic substitutions and indels per megabase. Patients with EGFR-sensitizing mutations accompanied with other genomic alterations will receive Apatinib 250mg, qd, po and Icotinib 150mg, tid, po until disease progression, or unacceptable toxicity. The primary endpoint of this study is progression free survival (PFS), and the secondary endpoints include objective response rate (ORR), disease control rate (DCR), overall survival (OS), quality of life (QOL) and drug-safety. Result: Not applicable

Conclusion: Not applicable

Keywords: afatinib, first-line, re-challenge

P3.13-22 REAL WORLD STUDY OF AFATINIB IN FIRST-LINE OR RE-CHALLENGE SETTING FOR PATIENTS WITH EGFR MUTANT NON-SMALL CELL LUNG CANCER.

H. Tanaka1, K. Taima1, M. Itoha1, Y. Ishiokai1, K. Babai1, S. Shiraorii1, H. Tanakai1, H. Nakagawa1, T. Morimoto1, Y. Hasegawa1, H. Yasugahira1, K. Okudera1, S. Takana2i, T. Sasa1

Background: Afatinib is the second generation epidermal growth factor receptor (EGFR) - tyrosine kinase inhibitor (TKI) for mutant non-small cell lung cancer (NSCLC), and approved in Japan in 2014. This study evaluated clinical outcomes of afatinib in real world practice. Method: Patients who received afatinib for advanced EGFR-mutant NSCLC in 5 institutions in Aomori, Japan from October 2014 to January 2017 were included into the analyses. Result: In total, 128 patients were analyzed. Seventy-six patients received afatinib as first-line setting and 52 as re-challenge setting (i.e., prior first generation TKIs used and third generation TKI were not adapted). In first-line setting, patient characteristics were as follows: a median age 68 yrs (42-88 yrs), 67% female, and 88.1% PS 0/1. The median progression-free survival (PFS) was 17.8 months (95% CI: 13.7-21.5 months). The overall survival (OS) was 39.5 months (95% CI: 34.4- not reached). There was no difference in median PFS and OS according to age (< 74, 75 +). Though 58 patients (76.3%) had to reduce the dose due to adverse events, it did not affect its efficacy in terms of OS (39.5 months in the reduction group vs. not yet reached in the no reduction group) (P=0.37). Moreover, the reduction group showed even longer PFS than the no reduction group. (18.0 months in the no reduction group vs. 7.9 months in the reduction group) (P=0.016). The response rate (RR) was 64% (CR/PR/SD/PD/NE: 1/48/16/1/10). Twenty-eight patients among 48 who had PD underwent re-biopsy, and 16 patients (51.7%) were T799M positive. In re-challenge setting, patient characteristics were as follows: a median age 65 yrs (37-90 yrs), 78% female, and 90.3% PS 0/1. The median PFS was 8.0 months (95% CI: 4.9-9.5 months). The RR was 24% (CR/PR/SD/PD/NE: 1/12/29/6/4). Most common adverse events leading to dose modification and treatment discontinuation were diarrhea, paronychia, and oral mucositis in both settings. Interstitial lung disease occurred in 5.4% (7/128). Conclusion: In the real practice in Japan, afatinib in first-line and re-challenge settings showed comparable or better efficacy compared with previous clinical trials.

Keywords: afatinib, first-line, re-challenge

P3.13-23 EGFR-TKIS COMBINED HYDROXYCAMPTOTHECIN IMPROVED OUTCOMES IN EGFR-MUTANT NSCLC PATIENTS WHO HARBORING PERICARDIAL EFFUSION.

X. Wang1, J. Yao2, R. Guo1, X. Lu1
1Department of Oncology, The First Affiliated Hospital of Nanjing Medical University, Nanjing/CN, 2Department of Oncology, First Affiliated Hospital of Nanjing Medical University, Nanjing/CN

Background: Pericardial perfusion of hydroxycamptothecin (PCPH) is the effective treatment for malignant pericardial effusion (MPCE). Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) have shown greater efficacy in clinical trials than chemotherapy in patients with EGFR-mutant non-small cell lung cancer (NSCLC), but little
Our results indicate that the 507-gene decentralized system provides accurate results for the determination of TMB across a broad range of mutation burdens, and detects clinically relevant genetic alterations important in NSCLC.

Keywords: Tumor mutation burden, next-generation sequencing, Decentralized Solution

P3.13-26 OUTCOMES OF PATIENTS WITH METASTATIC LUNG CANCER PRESENTED IN A MULTIDISCIPLINARY MOLECULAR TUMOR BOARD

L. Chu1, K. Kelly1, D. Gandara1, P. Lara1, A. Borowsky2, F. Meyers1, J. McPherson1, R. Erlich4, N. Almog5, A. Schrock5, S. Ali1, J. Ross1, V. Miller1, A. Heilmann1, J. Riess1

Background: With the adoption of broad genomic profiling, interpretation of genomic data in NSCLC has become increasingly complex. Approved targeted therapies against oncogenic driver mutations have improved clinical outcomes for patients with lung cancers harbor these genomic alterations. However, for other patients, the benefit of broad genomic sequencing is not fully proven. Multidisciplinary molecular tumor boards (MTB) may improve clinical outcomes by appropriately matching targeted treatments. Method: We retrospectively reviewed clinical, pathologic, and molecular data of metastatic lung cancer patients presented at the UC Davis MTB from January 2016 through May 2017. Genomic alterations were identified by hybrid capture-based comprehensive genomic profiling
to a median coverage depth of >500X for 315 cancer-related genes (FoundationOne®). Result: Out of 48 patients presented, 19 (39.6%) had lung cancer. Fourteen patients (73.7%) had adenocarcinoma, 1 squamous, 2 neuroendocrine, and 1 mixed histology. Seventeen patients were available for follow-up. Median number of prior treatments was 2 (range: 0-7) and median number of prior targeted therapies was 2 (range: 0-5). On average, each tumor sample had 5.3 genomic alterations (range 2 – 14). Every sample had 1 actionable mutation, in that matched targeted therapy was available in the form of an FDA-approved drug for NSCLC, FDA-approved drug in another tumor type, or genomically informed clinical trial. Tumors harbored an EGFR mutation (N=7), HER2 amplification (N=2), BRAF V600E (N=2), or mutation in BRCA1 (N=1), KIT (N=1), or PTPCH1 (N=1). All 7 patients with an EGFR mutation had previously received EGFR-targeted therapy, six with progressive disease (PD) on prior EGFR-TKI. Thirteen patients (76.5%) received targeted therapy, including FDA-approved therapy for NSCLC (N=4), FDA-approved therapy for another tumor type (N=6), or a genomically informed clinical trial (N=3). The other four patients were either on an immunotherapy clinical trial (N=2) or could not tolerate treatment (N=2). Out of the 13 patients who received targeted therapy, 4 patients had a partial response (31%) (3 EGFR, 1 BRAF V600E), all other patients had stable disease or PD. Median PFS on MTB-selected treatment was 4.8 months (range: 2.2 – 75% 10.7 months). Conclusion: MTB at an academic medical center matched a high percentage of patients to either a targeted treatment or clinical trials with targeted therapies or immunotherapy. A subset of patients had clinical benefit to targeted therapies in this pretreated or clinical trials with targeted therapies or immunotherapy. A subset matched a high percentage of patients to a targeted treatment.

P3.13 TARGETED THERAPY
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.13-27 CLINICAL OUTCOMES OF PATIENTS WITH LUNG ADENOCARCINOMA HARBORING CONCOMITANT DRIVER MUTATIONS IN A BRAZILIAN CANCER CENTER
M. Costa, M. Santos, C. Teixeira, J. Tabacoff
Oncology, Oswaldo Cruz Hospital, Sao Paulo/BR

Background: NSCLC, particularly adenocarcinoma, has been successfully treated with upfront targeted therapies according to respective oncogenic mutations in a tailor-made model. It has led to improvement in oncological outcomes (CO) and QoL, however, some evidences suggest that the occurrence of concomitant driver mutations (OCMD) is responsible for poorer results than expected. Questions, thus, have emerged regarding the best strategy to this population. Method: In this retrospective study, we reviewed lung cancer patients treated in our institution in the last four years in order to identify the OCMD. The vast majority of patients performed Next Generation Sequencing (NGS) using Illumina HiSeqs of Foundation Medicine (FM). The f/u was obtained from our electronic charts. Result: From apr/14 to apr/18, 5 patients were eligible for this analysis, 2M / 3F, mean 59y/o. Patient 1: treated with crizotinib because of MET amplification harboring concomitantly ATM deletion exon 11-50. Died after pneumonia before first radiologic evaluation. Patient 2: osimertinib for EGFR T790M harboring BRCA2 c1528G>T. Derived partial response (PR) with PD after 9 mo. Patient 3: immunotherapy because of TMB 18 & PD-L1 e PD-L2 amplification, harboring STK11 Q159R c2 as well. Curiously, the previous report of PD-L1 (22C3) by IHC had been negative. Still in PR, lasting 14 mo. Germline analysis (to Peutz-Jeghers) will soon be performed. By FM, Everolimus or Temsirolimus were suggested. Patient 4: crizotinib and alectinib for ALK-EML4 fusion harboring concomitantly BRCA2 S1074R. Had PR lasting 9 mo and only 6 mo respectively. Curiously, previous FISH had not identified the translocation. Patient 5: treated with crizotinib because of ALK-EML4 translocation harboring concomitantly Kras mutation. This is a condition and, until recently, de novo rearrangements of ALK was thought to be mutually exclusive to Kras. Not surprisingly, and in line with some reports of literature, the patient experienced rapid progression, saw already in the first control in 6 weeks. Conclusion: This study confirms that the OCMD has been increasingly seen due to the employment of improved sensitivity genetic techniques, like NGS. Additionally, provides the clinical outcomes of patients with lung adenocarcinoma harboring more than one of those mutations, which is broadly unknown yet. Finally, previous reports suggest that, particularly, patients with concomitant ALK fusion and Kras mutation carry poorer results with anti-ALK than expected. This study reinforces this observation and argues that the best management of these patients is still to be clarified.

Keywords: KRAS, concomitant driver mutations, ALK

P3.13-28 HETEROGENEITY, PREVALENCE AND PROGNOSTIC SIGNIFICANCE OF PD-L1 EXPRESSION IN EARLY RESECTED NSCLC
1 Oncology, University of Calgary, Calgary/AB/CA, 2Translational Laboratories, Alberta Health Services, Calgary/AB/CA, 3Mathematics & Statistics, University of Calgary, Calgary/AB/CA

Background: The interaction between the programmed death protein-1 receptor (PD1) and its membrane-bound ligand (PDL1) is one mechanism by which tumor cells evade the immune system. Cancer immunotherapies target this interaction by blocking the function of either protein, allowing for T-cell activation and destruction of the tumor. Because PDL1 expression in tumor is used to identify patients who might benefit from immune-modulating treatment, its detection plays a key role in clinical recommendations. Our objectives are to assess the prevalence of PD1 expression in early stage non-small cell lung cancer (NSCLC) patients, determine its association with clinical outcomes using the Glans-Look Research (GLR) database (Calgary, AB), and validate these findings using a cohort from the Manitoba Tumor Bank (MTB).

Method: A tissue microarray (TMA) was built using pre-treatment resected and biopsy tissue samples from 459 GLR database patients with early stage NSCLC, diagnosed between 2003 and 2010. Cell lines expressing varying levels of PD1 were generated, embedded into Histogel® and co-mounted onto the GLR and MBTB arrays. Fluorescence immunohistochemistry was performed using anti-PD1 E1L3N (Cell Signaling Technology), and PD1 expression was evaluated as percent-positive and intensity scores in the cytoplasmic compartment of tumor and stromal cells using HALO™ automated image analysis software. Cell line PD1 intensity scores served as on-slide reference standards to normalize PD1 expression in patient specimens using R Programming software. PD1-percent-positive tumor scores were generated to assess the cut-points of ≥50%(“PD1-strong”), ≥1%-to-49%(“PD1-weak”), and <1%(“PD1-negative”), indicated by the FDA-approved companion diagnostic anti-PD1 22C3 (Dako) for pembrolizumab. Clinicopathological outcomes were analyzed, and overall survival was assessed using the Kaplan-Meier method and compared using the log-rank test.

Result: Preliminary analyses indicate PD1-weak/negative GLR patients with adenocarcinoma experienced higher median OS (3.50yrs) compared to PD1-strong patients (1.91yrs) (p=0.0043). This trend was not significant over all histologies, or when using mean scores. The opposite trend was found with the MTB cohort (2.52yrs vs. 1.76yrs OS, PD1-strong vs. PD1-weak/negative maximum scores, p=0.0410). Conclusion: Variations across datasets illustrate the difficulty in harmonizing PD1 testing. Heterogeneity of protein expression, TMA sampling error, and differences between study cohorts can translate into variable correlations between PD1-positivity and survival estimates. Increased survivorship in GLR adenocarcinoma patients with PD1-weak/negative staining could challenge the notion of using PD1 as a prognostic biomarker. Comparisons between the E1L3N and 22C3 anti-PD1 assays will be performed and discussed. Further outcome findings will be presented and discussed.
**Background:** Non-small cell lung cancer is the most prevalent type of lung cancer, and one of its subtype, squamous cell carcinoma has limited targeted therapeutic options in comparison with adenocarcinoma. For this reason, we established the patient-derived xenograft models of primary lung cancer and then focused on the SCC PDX models to be used for the discovery of target mutations through the molecular profiling of lung tumors and their association of therapeutic responses.

**Method:** PDX models were established using the tissues of patients who underwent surgery as primary lung cancer at Samsung Medical Center during the period between October, 2014 and September, 2017. Briefly, tumor tissues from patients were subcutaneously engrafted and passaged two more times in NOD-scid-IL2Rnull mouse. Then we are analyzing histological characteristics and molecular profiles of established SCC PDX by whole exome sequencing and whole transcriptome sequencing.

**Result:**

### Mutation profiles of squamous cell carcinoma Patient Tumors and their PDX models

</table>
rare case of a squamous cell carcinoma with a driver mutation in a current smoking, and maybe justified by the fact that the tumor had an adenosquamous component. If the patient wasn’t tested for driver mutations, she would never received an target therapy. Thus, maybe we should assessed all non small lung cancers for the driver mutations.

Keywords: driver mutation in scc lung cancer, target therapy

P3.13 TARGETED THERAPY
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.13-30 DRIVER MUTATION IN HEAVY SMOKER PATIENT WITH SQUAMOUS CELL CARCINOMA METASTATIC LUNG CANCER: CASE REPORT
B.M. Luz, A.C. Vasconcelos, C. Santos, R. Aragao
Clinical Oncology, Imip, Recife/BR

Background: Nowadays, guidelines recommend to assess the presence of a driver mutation in tumors that contains an element of adenocarcinoma regardless of the clinical characteristics of the patient or squamous cell carcinoma in a patient that never smoked. Method: We reported a clinical case of a patient that had a squamous cell carcinoma with a driver mutation in EGFR, despite the fact that he was a heavy smoker, the case occurred in our service in the northeast of Brazil. Result: Woman, 63 years old, current smoking, presented in a public health service in Brazil with history of cough and dyspnea 3 months earlier. In the investigation, CTS showed mass hilar in the right lung and enlarged lymphonodes in the mediastinum IPSI and contralateral, but there was no evidence of secondary lesios in other organs. She was submitted to a core biopsy CT guided that confirmed squamous cell carcinoma. The planned treatment was radiotherapy and concomitant chemotherapy. As in our service the time to start the radiotheraphy is about 3 months, we started a platin based chemotherapy and made sequencial radiotherapy. After that, she was submitted to a core biopsy CT that showed partial response in the lung and lymphnodes, but there was evidence of bone metastatis in the sacrum and left iliac. In our service, there was a trial in which all patients diagnosed with lung cancer had it’s tissue avaliated for driver mutation, and we received the results with a driver mutation in exon 19 of EGFR. So, we started a treatment with Erlotinib with a great response and, now, after 9 months, it’s still respondint. Conclusion: This case represent a rare case of a squamous cell carcinoma with a driver mutation in a current smoking, and maybe justified by the fact that the tumor had an adenosquamous component. If the patient wasn’t tested for driver mutations, she would never received an target therapy. Thus, maybe we should assessed all non small lung cancers for the driver mutations.

P3.13-31 CREATING A PRECISION MEDICINE PIPELINE FOR LUNG CANCERS.

P. Marignani1, J. Kim1, W. Greer2, Z. Xu3
1Biochemistry and Molecular Biology, Dalhousie University Tupper Medical Building 9FL, Halifax/CA, 2Pathology, Dalhousie University and QEII Health Sciences Centre, Halifax/NS/CA

Background: The vision of High Mortality Cancer Precision Medicine Pipeline (HMCPMP) is to improve high mortality cancer outcomes. Our mission of HMCPMP is to establish precision medicine pipelines for high mortality cancers that start with the patient and ends with precise treatments for the patient based on their lung cancer’s unique molecular profile. HMCPMP leverages expertise areas of i) single-cell gene-discovery that allows for the identification of new barcodes and therefore new targets, ii) animal models that recapitulate human cancers, and patient-derived xenographs that allow for pre-clinical trials in mouse models to test novel drugs and drug development, iii) immunology and

Conclusion: In PDX models of 49 patients, successful lung SCC PDX engraftment and identical histomorphology was achieved. And the 30 sets of exome sequencing analyses showed that the somatic mutations were relatively preserved. Among them, some interesting targetable mutations including BRAF(V600E) were identified. We identified consistency of transcriptome profiles of PDX models during the passages.

Keywords: Patient derived Xenograft, Squamous cell lung cancer, molecular profiling
cancer stem cell biology to explore the role the immune system and stem cell niche impact tumourigenesis, iv) single-cell fluidics/3D organ systems that allow for understanding the heterogeneity of cancers and v) data mining that allows for better treatment choices and the discovery of new treatment options based on their lung cancer’s barcodes. **Method:** We have created a patient-centered precision medicine pipeline that moves resected lung cancers from the surgical suite to banking, through to single cell molecular diagnostics to validation (Figure 1). **Result:** Single-cell genomic profiling of resected lung cancers were prepared using a microfluidics platform Fluidigm C1 followed by transcriptome sequencing per single cell. We identified differentially expressed genes (DEGs) for stage, sex, and smoking status, followed by validation by quantitative PCR. We are currently pursuing new barcodes that differentially express genes that allow for understanding the heterogeneity of cancers and vi) data mining that allows for better treatment choices and vii) single-cell fluidics/3D organ systems that allow for understanding the heterogeneity of cancers and viii) single-cell fluidics/3D organ systems that allow for understanding the heterogeneity of cancers.

**Conclusion:** The significance of HMCPMP research is improved health, survivorship, and quality of life for people living with lung cancer. Although the economics of lung cancer are important and likely drivers of federal, provincial and regional research initiative, HMCPMP considers the human when faced with the diagnosis of lung cancer. **Keywords:** precision medicine, early stage lung cancer, single cell genomics

**P3.13-32 DRUG SENSITIVITY OF LUNG ADENOCARCINOMA TOWARDS INDUCERS OF EPIGENETIC MODIFICATIONS**

I. Moneke1, S. Dhamija2, A. Becker2, M. Jung3, A. Hauser3, M. Luebbert4, B. Passlick1, S. Diederichs1

1Department of Thoracic Surgery, Medical Center - University of Freiburg, Freiburg/DE, 2Department of Thoracic Surgery, Division of Cancer Research, Medical Center - University of Freiburg, Freiburg/DE, 3Pharmacology, University of Freiburg, Freiburg/DE, 4Hematology and Oncology, Medical Center - University of Freiburg, Freiburg/DE, 5German Cancer Research Center, Division of RNA Biology and Cancer, Heidelberg/DE

**Background:** Over the last decade, epigenetic regulation of gene expression emerged as a central mechanism in tumorigenesis and metastasis. In contrast to DNA mutations, epigenetic modifications are reversible and therefore suitable targets for pharmacological therapy. To understand which patients will benefit the most from which drug regime remains a challenge in everyday clinical practice. The aim of this study is to characterize the tumor drug sensitivity and epigenetic modifications on a molecular level induced by different compounds, in order to improve tumor-specific treatment for patients. **Method:** We tested a total of 40 epigenetically active compounds (partly known and partly unknown/unpublished) in two different concentrations in 56 lung adenocarcinoma cell lines and 3 control cell lines for cell viability. **Result:** The resulting 14000 data points were split according to sensitivity of the tumor cells to the compounds into three different groups (high sensitivity: < 25% viable cells, medium sensitivity: 25%-75% viable cells and low sensitivity: >75% viable cells). Six compounds showed broad effectiveness with high sensitivity in more than half of the cell lines while 15 compounds inhibited proliferation in only a few cell lines and are therefore of special interest for the discovery of new predictive biomarkers. The remaining compounds did not show high sensitivity in any cell line. Notably, we found that different compounds targeting the class of histone acetyltransferases (HAT) can have very different impacts on the survival of the tumor cells, and that the epigenetic modification of opposing mechanisms (e.g. HAT- and HDAC-inhibitors) may give rise to similar results. **Conclusion:** Taken together, we demonstrate the differential effectivity of drugs inducing epigenetic modifications in lung adenocarcinoma cells in vitro. By combining the sensitivity data with molecular profiles of RNA and protein expression which we have generated, we are identifying molecular determinants for the individual sensitivity of the tumor to the respective drugs, which could be further developed in vivo into predictive biomarkers for drug response. **Keywords:** lung adenocarcinoma cell lines, Drug sensitivity, Epigenetic modifications

---

**P3.13-33 LUNG ADENOCARCINOMA HARBORING RET FUSION AND DRAMATIC RESPONSE TO COMBINATION OF VANDETANIB (VAN) AND EVEROLIMUS (EVE): A CASE REPORT FROM BRAZIL**

I. Figueiredo1, R. Nishimoto2, S. Castro1, C. Haddad1

1Oncology, Bp - A Beneficencia Portuguesa de Sao Paulo, Sao Paulo/BR, 2Oncology, Associação Beneficente Bom Samaritano, Maringa/BR

**Background:** The identification of oncogene addicted NSCLC and the development of target therapies lead to improvement in survival rates and quality of life. In addition to other drugable targets such as EGFR mutation and ALK translocation, RET fusion has been shown to be an oncogenic driver in 1 to 2% of patients with NSCLC. **Method:** Here we report a 23-year old never-smoker male patient (Pt) diagnosed with lung adenocarcinoma, metastatic to lymph nodes, bones, and lungs. Tumor biopsy was performed during broncoscopy. Tissue molecular testing was negative for EGFR (cobas) and ALK (FISH), and PDL-1 tumor proportional score (22C3) was 5%. Pt presented rapid disease progression after one cycle of cisplatin and pemetrexed, with pleural effusion and respiratory distress. Since initial tissue biopsy paraffin had been exhausted, next generation sequencing in cell-free tumor circulating DNA in plasma was performed (Guardant360). CDCK6-RET fusion and TP53 mutation (T256i) were identified. **Conclusion:** Based on promising activity of the combination
of VAN with EVE previously reported, and the lack of clinical trials in this setting in Brazil, Pt started oral target therapy with VAN 300 mg and EVE 10 mg daily. He had univocal clinical improvement over the following weeks, with discontinuation of pain medications and relief of respiratory symptoms. After 30 days on treatment, restaging CT scans demonstrated a dramatic response. Adverse events were grade (G) 1 cutaneous rash, G1 stomatitis, and G1 G1 pneumonitis that resolved rapidly with EVE temporary discontinuation. He remained without disease progression at 4+ months. After 5 months, he presented pneumonitis recurrence with respiratory failure. VAN is a multi-targeted tyrosine kinase inhibitor of EGFR, VEGFR and RET, with limited activity in RET-rearranged NSCLC phase 2 trial. However, the concurrent inhibition of RET and the mammalian target of rapamycin (mTOR) has shown promising activity for RET-rearranged tumors in preclinical models. Among the 6 evaluable NSCLC patients with RET fusions treated with VAN and EVE in phase I trial, 5 achieved partial responses (83%) and 1 stable disease (16%). In particular, it has been suggested that CCDC6-RET subtype shows higher sensitivity to VAN. Conclusion: This case report corroborates the promising activity of combination of VAN and EVE in RET-rearranged NSCLC.

P3.13 TARGETED THERAPY
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.13-34 RET GENE, A NEW CHOICE FOR NSCLC
Y. Wang, K. Ma, Y. Xu
The First Bethune Hospital of Jilin University, Changchun/ CN

Background: RET gene, accounting for 1-2% of non-small cell lung cancer (NSCLC), has been reported as a novel target molecule which has been reported that could not coexist with other gene mutations such as P, EGFR, BRAF, MEK1, HER2 and ALK. The emerging targeted agents Cabozantinib and Vandetanib have been recommended by NCCN guidelines for non-small cell lung cancer with RET fusion, based on a series of clinical trials. Method: We presented a case of lung adenocarcinoma with KIF5B/RET fusion. The patient was a 50-year-old, male, non-smoker, diagnosed as left upper lobe adenocarcinoma lung cancer. We performed a radical resection of pulmonary carcinoma for two years ago. Subsequently, he completed four cycles of chemotherapy with gemcitabine and cisplatin. However, half years later, pleural metastasis made him have to receive systemic treatment but no chemotherapy due to his worse tolerance. We then performed a gene examination with the PCR method using the intraoperative specimen, and finally found positive KIF5B/RET fusion gene. From then on June 10, 2017, he started to take cabozantinib (140 mg orally, once daily) for about nine months. His disease sustained SD during that period (please see Figure 1). No serious adverse events (AEs) except rash (II grade) occurred in the whole treatment process. Conclusion: We found that the RET gene is a new alternative for lung adenocarcinoma patients without common mutations such as EGFR, ALK, ROS1 and SOI. This case report supports a useful reference for the therapy of lung adenocarcinoma patients with RET mutation and may provide a new choice for this kind of NSCLC patients.

P3.13-35 ANTITUMOR EFFECT OF NERATINIB TARGETING HER2-ALTERED LUNG CANCER
Y. Ogoshi
Okayama University Graduate School of Medicine, Okayama/IP

Background: Human epidermal growth factor receptor 2 (HER2) plays an important role in the pathogenesis of various cancers. HER2 alterations have been suggested to be a therapeutic target in non-small-cell lung cancer (NSCLC), as in breast and gastric cancers. However, the benefit of HER2-targeted therapy is much less defined. The aim of the study is to investigate the antitumor effect of neratinib, an irreversible pan-HER tyrosine kinase inhibitor (TKI), in NSCLC cells harboring HER2 alterations. Method: We examined the sensitivity of neratinib against normal bronchial epithelial cells BEAS-2B which ectopically overexpressing wild-type or mutant HER2. Human CDKNAs encoding full-length HER2 (wild-type or mutants A775insYVMA, G776VC, G776LC, P780insGSP, V659E, G660D, and S310F) were cotransfected into the pCDH-FLAG expression vector, and observed the antitumor activity of neratinib in several NSCLC cell lines harboring HER2 alteration in vitro and in vivo experiments, and investigated the association between their genetic alterations and sensitivity to neratinib treatment. Result: BEAS-2B cells ectopically overexpressing wild-type HER2 or mutants (A775insYVMA, G776VC, G776LC, P780insGSP, V659E, G660D, and S310F) showed constitutive auto phosphorylation of HER2 and activation of downstream signaling by Western blotting. These BEAS-2B cells were sensitive to neratinib, but insensitive to erlotinib, a first generation EGFR-TKI. Neratinib significantly inhibited the growth of HER2-altered (H2170, Calu-3, and H1781) NSCLC cell lines with an average IC50 value of 0.00347μL, 0.0428μL, and 0.0119μL. Neratinib administration showed strong antitumor effect on tumor growth in mouse xenograft model using HER2-altered lung cancer cell lines. Conclusion: Our study strongly suggests that neratinib is a promising therapeutic option for the treatment of HER2-altered NSCLC.

P3.15-01 LONG-TERM OUTCOMES OF PULMONARY METASTASECTOMY: A 12-YEAR DUAL CENTRE EXPERIENCE
N. Yaftan1, P. Antippa2, F. Cheung3, G. Wright3
1Department of Surgery, University of Melbourne, Parkville/VIC/AU, 2Cardiothoracic Surgery, Royal Melbourne Hospital, Parkville/AU, 3Cardiothoracic Surgery, St Vincent’s Hospital, Fitzroy/AU

Background: Pulmonary metastases are a common site of spread for many cancers. We describe the long-term outcomes of surgical resection of pulmonary metastases at two major cancer centres. Method: The study institutions thoracic surgery databases were searched for all patients who underwent pulmonary metastasectomy between 2005 and 2017. Result: There were a total of 489 patients who underwent pulmonary metastasectomy. Mean age at time of surgery was 45.6 ± 11.6 years. There were a total of 658 operations performed with 105 (21.5%) patients having repeat pulmonary metastasectomy. Of these patients 68 (64.8%) had 1 repeat operation, 20 (19.0%) had 2 repeat operations, 11 (10.5%) had 3 repeat operations, 2 (1.9%) had 4 repeat operations and 4 (3.8%) had 5 repeat operations. The most common primary lesions were colorectal cancer (CRC) in 35.3% (173/489) of patients, melanoma in 23.7% (116/489) of patients, melanoma in 16.2% (79/489) patients, renal cell carcinoma (RCC) in 7.2% (35/489) of patients and germ cell carcinoma (GCC) in 4.5% (22/489) of patients. Other cancers accounted for the remaining 13.1% (64/489) of patients. Mean follow-up was 41.2 ± 1.6 months and was complete for 91.8% of patients. Survival was 85.6% (95% CI: 81.9 – 88.3%) at 1-year, 45.2% (95% CI: 39.7 – 50.5%) at 5-years and 27.8% (95% CI: 21.2 – 34.6%) at 10-years follow-up (figure 1). On univariate Cox regression analysis CRC (p = 0.027) and GCC (p = 0.016) were associated with improved survival while melanoma (p = 0.039) was a risk factor for mortality. On multivariate Cox regression analysis CRC (p = 0.025) and GCC (p = 0.011) were associated with improved survival.

Conclusion: Pulmonary metastasis is associated with survival of less than 30% at 10 years follow-up. CRC and GCC cancers were associated with better long-term mortality while melanoma was associated with worse long-term mortality.

Keywords: metastasis, metastasectomy, Surgery
P3.15-02 CARBOPLATIN DOSE CALCULATED USING DIFFERENT FORMULA FOR EGFR AND THEIR COMPARISON WITH ACTUAL DOSE ADMINISTERED IN LUNG CANCER PATIENTS

D. Behera1, V. Muthu1, K. Prasad1, N. Singh2
1Pulmonary Medicine, Postgraduate Institute of Medical Education and Research (Pigimer), Chandigarh/IN, 2Pulmonary Medicine, Pigimer, Chandigarh/IN

Background: Carboplatin dosage for chemotherapy is usually estimated using AUC-based dosing. Several equations are available for estimating GFR(eGFR); including Cockcroft-Gault, Chronic Kidney Disease Epidemiology Collaboration(CKD-EPI), and a recent equation(1). However, while calculating dosage of carboplatin, several factors other than estimated-GFR[including performance status(PS), vial package strengths] merit consideration. Do we require high degree of precision in eGFR and how does each of these equation perform in real-life settings? Method: We performed a retrospective audit of lung cancer patients undergoing first-line chemotherapy at our centre, with the aim of determining discrepancies between actual doses of carboplatin administered versus those calculated using different equations. Calvert formula was used to calculate carboplatin dose, with the eGFR being obtained from Cockcroft-Gault, CKD-EPI and the Janowitz-equation.

Result: 77 subjects received carboplatin-based chemotherapy(Jan-Aug 2017). Dosage calculated by Cockcroft-Gault based GFR and manufacturer’s recommendation had significant variation as compared to new equation-based dose. However, the actual administered doses were lower than both Cockcroft-Gault-based and manufacturer’s recommended doses. Significant proportion(n=48, 62.3%) had >20 absolutePE of carboplatin dose as compared to reference standard. Carboplatin dose PE(actual administered, calculated as per Cockcroft-Gault, CKD-EPI equation and manufacturer’s recommendation) were plotted against the reference standard as waterfall chart(Figure 1A-D). All, except six(7.8%) patients(none of them were>20% higher than the predicted), received doses: that calculated from the reference. Conclusion: Actual carboplatin administered is lower than the predicted in majority(irrespective of equation used for eGFR). Hence the probability of administering a potentially toxic dose, owing to incorrect eGFR might be negligible. Thus, using more accurate equations/measuring GFR may not be required.

Keywords: Chemotherapy; carboplatin; kidney function

P3.15-03 CAPTURING THE PATIENT EXPERIENCE FOR THE TREATMENT OF EGFR EXON 20 MUTATIONS IN NON-SMALL CELL LUNG CANCER

J. Bell1, L. Roberts2, M. Jean-Baptiste2, D. Revicki2, G. Salvatore1, S. Li1, A. Galaznik1

Background: Non-small cell lung cancer (NSCLC) accounts for 80−85% of new lung cancer cases, which presents as metastatic disease 40−50% of the time. The prevalence of NSCLC patients with a mutation in the epidermal growth factor receptor (EGFR) varies by ethnicity, ranging from 15−50%, and EGFR exon 20 insertion mutations specifically account for 7−12% of all EGFR mutations. Health-related quality of life (HRQOL) was widely used, as generic measures may lack the sensitivity required to demonstrate clinical change related to new therapies. Assessments of disease-specific patient-reported outcomes (PROs) play an important role in clinical trials to evaluate the benefits of new treatments on HRQOL and in making treatment decisions for patients. This study aimed to better understand the overall symptom experience and HRQOL impact from the perspective of NSCLC EGFR exon 20 patients to evaluate the effectiveness of new treatments. Method: A targeted literature review was conducted in Embase and Medline (2007−2017) to identify PROs used in previous NSCLC studies for evidence of content coverage. Interviews with expert clinicians were conducted to explore the clinical perspective on treatment and observed patient experience. Following approval from an independent review board, semi-structured qualitative interviews were conducted with NSCLC patients identified through the International Cancer Advocacy Network. Result: Five oncologists were interviewed, reporting a wide range of NSCLC symptoms, notably shortness of breath, chest pain, bone/other pain, and substantial emotional impacts. Ten patient interviews were conducted (median age
ETOILE educational program. Ninety-six percent of the patients were 2016, 94 patients (66% were men, median age : 59 years), entered the Method:
its impact on patients.

Quality of life. Outpatients' treatments are now very common, giving them managing their treatments, symptoms in order to improve their access for patients and their family to an educational program to help Background:

L. Bigay-Gamé
DEDICATED TO NON-SMALL CELL LUNG CANCER PATIENTS TO
manage their symptoms and adapt the food, 86% to take care of them and to have better information about all helps that can be provided. For 72% of the patients, the educational program permits to manage their stress and help their relatives throughout the disease and treatment trajectory. Conclusion: Providing a tailored educational program is important for patients with advanced NSCLC throughout the disease trajectory even if the disease prognosis remain poor for many patients. Our experience shows that an educational program dedicated to NSCLC patients is feasible and useful.

P3.15-05 PATIENT REPORTED OUTCOMES (PROS) AS PERFORMANCE MEASURES AFTER SURGERY FOR LUNG CANCER
M. Brønserud1, M. Iachina2, A. Green3, M. Grønvold4, E. Jakobsen5
1Institute of Clinical Research, University of Southern Denmark, Odense C/DK, 2Center for Clinical Epidemiology and Research Unit of Clinical Epidemiology, Odense University Hospital, Odense/DK, 3Odense Patient Data Exploratory Network (Open), Odense C/DK, 4Research Unit, Department of Palliative Medicine, Bispebjerg Hospital, Copenhagen Nv/DK, 5The Danish Lung Cancer Registry, Department of Thoracic Surgery, Odense University Hospital, Odense C/DK

Background: In Denmark and other countries, quality in lung cancer care is measured using performance indicators from clinical registries. The registries and the indicators are based on data from professionals taking care of patients and their treatment. What is missing in this quality measurement, however, is the patients’ perspective. The objective of this study was to examine if patient reported outcomes (PROs) from patients with lung cancer could be used in performance measurement after surgery. Would it be feasible to use PROs in benchmarking, comparing treatment quality in different regions of Denmark? Method: All patients registered in the Danish Lung Cancer Registry (DLCR) from 1 October 2013 until 30 September 2015, who received curatively intended surgical treatment, were eligible(N=1,718). They were asked to complete the European Organisation for Research and Treatment of Cancer (EORTC) QLQ-C30 questionnaire six months after surgery. From the questionnaire we chose the global health score (GHS) and role functioning (RF) as indicators, and the threshold for good performance was set to 65 points (on a scale 0-100 where 100 is the best). Information about the patients’ socioeconomic position was obtained from Statistics Denmark. Results were compared between the five regions within Denmark, using the patients’ home address. Patient characteristics of the five groups were compared using t-tests and chi squared tests. Result: Of 1,615 patients alive six months after surgery, questionnaires were completed by 999 patients (61.9%). Patient characteristics of the five groups differed significantly in e.g. performance status, cancer stage, and income. There were difference in GHS between groups, but mean RF varied significantly (see table).

Global health score (GHS) and Role functioning (RF) for the five regions

Conclusion: In a population with lung cancer receiving surgery, it may be feasible to use PROs for benchmarking. The next step in our study is to examine whether differences in GHS and RF are a consequence of different outcomes, or of different patient populations.

P3.15-06 CAPILLARY LEAK SYNDROME IN A PRIMARY LUNG ADENOCARCINOMA PATIENT WITH THROMBOCYTOPENIA FROM INTERLEUKIN-11 TREATMENT

H. Chen¹, Y. Zhu¹, K. Du¹, X. Li¹, L. Wu¹, W. Wang¹, C. Xu¹, M. Fang²
¹Zhejiang Rongjun Hospital, Jiaxing/CN, ²Zhejiang Cancer Hospital, Hangzhou/CN.

Background: Capillary leak syndrome (CLS) is an uncommon complication characterized by generalized edema and hypotension. We report a 62-year-old male patient with lung and liver metastasis who had undergone liver radiofrequency ablation. Method: He was treated with interleukin (IL)-11 (3 mg per day) because of chemotherapy induced thrombocytopenia. Result: After 9 days of therapy, the patient complained of abdominal distension and with bilateral edema of all four extremities. Chest computed tomography and B ultrasound of the abdomen showed pleural effusions and ascites. IL-11 was then discontinued. Fluid resuscitation was performed, fresh frozen plasma and packed red blood cells were transfused, and methylprednisolone therapy was administered. The patient had recovered after 12 days of treatment. Conclusion: This case report demonstrates that patients with lung cancer can develop this rare form of CLS after treatment with IL-11. The manifestation of IL-11-induced CLS indicates that it may be a severe side effect of IL-11 treatment in cancer.

Keywords: lung cancer, capillary leak syndrome, interleukin-11

P3.15-07 A LITERATURE REVIEW AND ASSESSMENT OF LUNG CANCER QUALITY INDICATORS

K. Chiew¹, B. Jalaludin², P. Sundaresan¹, S. Vinod³
¹Sydney West Cancer Network, Westmead/AU, ²Epidemiology Department, South Western Sydney Local Health District, Liverpool/AU, ³Liverpool Cancer Therapy Centre, Liverpool Hospital, Liverpool/AU

Background: Quality indicators (QIs) are used to assess various aspects of the quality of healthcare services received by patients in the “real-world”. They provide a measurement tool to be utilised in care settings to develop standards or benchmarks, identify variations in care, guide performance improvement, monitor changes over time and promote accountability. The management of lung cancer is complex and rapidly evolving. Care often involves multidisciplinary assessment and management with multimodality treatment that requires a comprehensive and co-ordinated approach. Evaluating the quality of care received in “real-world” everyday care is crucial for optimising health outcomes for lung cancer patients. We reviewed quality indicators in lung cancer and assessed their utility. Method: A medline search was conducted using the search terms “quality indicators” and “lung neoplasms” and grey literature using a web search of government and relevant health organisations. Full-text review was performed to include only articles that fulfilled inclusion criteria of original research that developed or applied specific QIs related to the care of lung cancer patients. Data was collected on the characteristics, frequency, use and testing for each indicator. Result: A total of 43 articles or reports were analysed. These included 295 distinct QIs, the most frequently reported indicators were related to surgery (n=66), then symptom assessment and management (n=43) and diagnosis and staging (n=38). There were fewer indicators related to systemic therapy (n=30), radiotherapy (n=17) or combined treatments (n=10). Analysis of the characteristics of process and structure QIs was undertaken and classified as meeting all ideal or a minimum set of desirable characteristics for QIs. Of these 60 met the minimum set and only five the ideal characteristics. These included 12 related to diagnosis and staging, four to pre-treatment assessment, five to surgery, 12 to systemic treatment, six to radiotherapy, three to combined treatment, three non-specific to treatment, three to symptom assessment, 11 to supportive care and one to palliative care. Conclusion: A wide range of quality indicators have been developed and used in lung cancer. The most frequent are treatment related and surgical based, which only reflects a small proportion of all lung cancer patients. In order to assess their usefulness, we classified QIs according to fulfilling accepted desirable characteristics. We present these as the most useful for implementation as quality metrics. QIs must also be feasible and relevant, which must be tailored to the health service for application. Conclusion: This real world data preliminarily profile patients’ experiences over a short period after lung resection. Compared to OS, MIS did not show a significant advantage in symptom severity, but related to better functioning on daily living. Additional recruitments and follow-up will expand patients’ perceptions to the full trajectory of recovering from lung resection.

P3.15-08 PATIENT-REPORTED OUTCOMES (PROS) IN PATIENTS WITH LUNG RESECTION: OPEN VERSUS MINIMAL INVASIVE SURGERY

W. Dai¹, Q. Shi², X. Peng¹, X. Yang¹, Q. Li¹
¹Department of Thoracic Surgery, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, school of Medicine, University of Electronic Science and Technology of China, Chengdu/CN, ²Symptom Research, University of Texas MD Anderson Cancer Center, Houston/US

Background: A novel and cutting-edge indicator to evaluate the quality of surgery, e.g. minimal invasive surgery (MIS). Patient-Reported Outcomes (PROs) has not been implemented in patients with lung resection in the real world. This study aims to profile PRO-measured symptom burden in patients with lung resection of either open surgery (OS) or MIS. Method: We conducted a prospective study on lung resection patients from November 22, 2017 to April 23, 2018. MD Anderson Symptom Inventory-lung cancer module (MDASI-LC) was used to assess the severity of perioperative symptoms and how they interfered with daily functioning. MDASI-LC was administered on the pre-operation day and daily after surgery up to the day of discharge. Trajectories of symptom severity and interference were compared between OS and MIS via mixed effects models. Result: Among 78 lung resection patients, 22 received OS and 56 received MIS. Most of the resection types were lobectomies (74.4%). All patients completed pre-operation assessment and the missing rate after surgery was less than 10%. There were no statistically significant differences between OS and MIS in pre-operation variables including age, BMI, hemoglobin, neutrophil ratio, platelets and creatinine. Within the first week after surgery, the most severe symptoms were pain, cough, fatigue, disturbed sleep and dry mouth for OS patients and pain, fatigue, cough, disturbed sleep and shortness of breath for MIS patients. MIS patients reported better physiological functioning (walking, general activity and work) than did OS patients in the first 7 days post surgery (p=0.013). Among patients with MIS, those with stage II-IV reported more severe fatigue than did stage I patients over the hospitalization (p=0.018).

P3.15-09 ARE LUNG CANCER PATIENTS RECEIVING EDUCATION MATERIALS? THE HEALTHCARE PROVIDER PERSPECTIVE ON DISTRIBUTION GAPS AND POSSIBLE SOLUTIONS
U. Basu Roy1, A. Ferris2, M. Jacobson1, K. Haskins2
1Research and Policy, Lungevity Foundation, Bethesda/MD/US, 2Lungevity Foundation, Bethesda/US, 3Lungevity Foundation, Chicago/IL/US

Background: While new treatments for lung cancer bring new hope, they can also make understanding a lung cancer diagnosis and making treatment decisions a challenge for both patients and caregivers. Education is imperative to understanding the diagnosis and making informed treatment decisions. However, many patients and their caregivers report that they do not receive materials from their doctors. We fielded a study of healthcare providers (HCP) to understand their attitudes and practices on disseminating patient education for lung cancer.

Method: We conducted an IRB-approved sequential mixed-method study of 216 HCPs (130 oncologists, 52 pulmonologists, and 34 nurse navigators/clinic or hospital administrators) from academic research centers, community cancer centers, and private practice to get a full and broad picture of education for lung cancer patients based on the specific role each HCP group plays in the treatment journey. The quantitative survey was followed by a qualitative interview of five HCPs to contextualize the survey findings. Questions of the study delved into perception, usage, distribution, and development of education materials.

Result: Of the HCPs surveyed, surprisingly only 75% report that lung cancer educational materials are distributed. Nurse navigators/clinic administrators were more likely to distribute patient education materials than oncologists and pulmonologists (p<0.05). Notably, there is a discrepancy in who actually does the distributing: nurse navigators and community cancer center administrators say oncologists most often distribute them (80%), while oncologists and pulmonologists claim they only distribute some of the time (56%). Information format also was reported as a factor in distribution; HCPs are interested in information that can be both electronic and printable (79% of HCPs report that they distribute information via printed resources, and 59% of them still prefer printed materials, given the choice). Overall, community cancer center administrators say oncologists most often distribute these materials.

Conclusion: Distribution practices for educational materials are not standard and tend to be subject to the HCP’s own discretion, leading to inconsistent delivery of materials. In-depth interviews with HCPs suggest possible solutions, including: better patient-to-patient education, availability of multiple formats of education materials for distribution, and white-labeling of materials to allow re-branding to an HCP’s unique practice setting.

P3.15-10 SURVIVAL IMPACT OF PERIPHERAL BLOOD RATIOS IN LUNG CANCER ACCORDING CLINICAL STAGE
C. Flores1, A. Aguilar2, D. Enriquez1, L.A. Mas Lopez1, J. Schwarz1, C. Vallesjos1
1Dirección Científica Y Académica, Oncosalud - Auna, Lima/PE, 2Dirección Científica Y Académica, Oncosalud - Auna, Lima/PE

Background: Lung cancer represents one of the most frequent and lethal neoplasms in many regions, where most patients are still diagnosed as advanced disease, and many biomarkers have been studied unsuccessfully. Peripheral blood ratios as Neutrophil-to-lymphocyte ratio (NLR), Monocyte-to-lymphocyte ratio (MLR) and Platelets-to-lymphocyte ratio (PLR) have been studied as potential biomarkers of systemic inflammation but cut-off values are still difficult to establish. We explored the survival impact of different cut-off values according clinical stages in lung cancer. Method: We analyzed medical records of 193 patients with lung cancer treated at ONCOSALUD – AUNA 2011-2014. Peripheral blood data was obtained retrospectively from the first medical visit and we calculated optimal cut-off values using the clinically selected rank statistics according every clinical stage (CS). Overall survival (OS) was evaluated using Kaplan-Meier method and survival curves comparison was performed using log-rank test or Breslow. Result: Median age was 67 years (range: 34-88), 51% were women and 71.5% had 0-1 ECOG scale. The 9.8, 11.4, 18 and 60% were CS I, II, III and IV. The most common metastatic sites were brain, bones, cervical and subcarinal nodes. Patients with CS I and II underwent to lobectomy, and 59% of II and most III-IV CS received chemotherapy. The median follow-up was 4.9years, median OS was 1.4years (95%CI: 1.1-1.9) and 2 and 5years OS were 42% and 25%, respectively. The next table shows survival impact of blood ratios according CS. Optimal cut-off values were different according every CS of lung cancer, however in the IV CS group the cut-off of 2.6 and 0.31 for NLR and MLR showed significant survival impact on OS.

Conclusion: Our results suggest that exists different cut-off values for blood ratios according every clinical stage that needs to be explored among larger population data-bases to confirm it. In advanced disease, NLR and MLR show significant survival impact in this study.

P3.15-11 ASSOCIATION BETWEEN PERIPHERAL BLOOD RATIOS AND CLINICAL STAGE DISEASE IN LUNG CANCER
C. Flores, D. Enriquez, A. Aguilar, L.A. Mas Lopez, C. Vallesjos
Dirección Científica Y Académica, Oncosalud - Auna, Lima/PE

Background: Many attempts have been described to establish peripheral blood ratios as systemic immune biomarkers in lung cancer, unfortunately they are still not considered because of lack accuracy and sensibility. In this study, we explore and correlate clinical stages to median values of peripheral blood ratios as Neutrophil-to-lymphocyte ratio (NLR), Monocyte-to-lymphocyte ratio (MLR) and Platelets-to-lymphocyte ratio (PLR) among patients with lung cancer. Method: Retrospectively, we review clinical and laboratory data from 193 patients with lung cancer treated at Oncosalud – AUNA from 2011 to 2014. The laboratory data (hemoglobin, leukocytes, neutrophil, lymphocyte and monocyte) were collected from blood routine test obtained from the first clinic visit. The median (range) and mean (± SD) of the ratios were determined according every clinical stage and compared using the U Mann Whitney test. Result: Median age was 67 years, and 63 (34-79), 64 (37-83), 69 (44-88) and 67 (38-86) years in I, II, III and IV CS, respectively. In early disease (I-II), female patients were slightly more frequent that men. Median hemoglobin was 13.6, 12.4, 13.7 and 12.7 gr/dl for I, II, III and IV CS, respectively. Peripheral blood levels (leukocytes, lymphocytes, monocytes and platelets) show a slightly higher level among patients with advanced disease. Median NLR, MLR and PLR are described in the following table, there was a significant difference between early and advanced disease (III and IV CS) for NLR and MLR.

(See next page)
Conclusion: These results suggest that there are higher levels of peripheral blood ratios related to advanced disease; but larger studies are needed to confirm it. Only NLR and MLR showed differences between early and advanced disease.

P3.15-12 SURVIVAL IMPACT OF PATIENT ENROLLMENT IN ANTE NEOPLASTIC DRUG TRIALS FOR STAGE IV NON-SMALL CELL LUNG CANCER (NSCLC)
B. Goulart1, E. Silgard1, K. Stricker2, K. Eaton2, R. Martins2
1 Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle/WA/US. 2Seattle Cancer Care Alliance, Seattle/WA/US

Background: Patient enrollment in antineoplastic drug trials (ADT) is essential for the development of effective therapies in stage IV NSCLC. An open question is whether NSCLC patients derive a survival benefit from enrollment. We hypothesized that patient enrollment in ADT is associated with longer overall survival (OS) because of access to novel therapies and closer follow up, compared with no ADT enrollment.

Method: We reviewed electronic medical records of 193 patients diagnosed with biopsy-proven, stage IV NSCLC between 01/01/2007 and 12/31/2014, who received treatments at the Seattle Cancer Care Alliance. Other inclusion criteria were age ≥ 18 and receipt of ≥ 1 antineoplastic agent within 180 days from diagnosis. We abstracted patient clinical characteristics, tumor histology, EGFR and ALK mutation status, receipt of chemotherapy, targeted therapies, and immunotherapy up to 5 consecutive lines, participation in ADTs, and OS from diagnosis to death. We fitted multivariate Cox regression models to estimate the risk-adjusted effect of ADT participation on survival, compared with no trial participation.

Result: Patients’ mean age was 63.4; 53.9% were female. 28.5% were never smokers; 75.1% had ECOG PS of 0-1; 95.3% had non-squamous histology; 27.5% had brain metastases; 20.7% and 4.1% had EGFR+ and ALK+ NSCLC. Fifty-three (27.5%) enrolled in ≥ 1 ADT, of whom 17 (32.0%) received trial drug(s) that later became FDA approved, and 44 (83.0%) and 13 (24.5%) enrolled in phases I/II or III trials. Adjusting for ECOG PS, smoking, EGFR mutation status, type of first line therapy, and number of treatment lines, participation in ≥ 1 ADT was associated with a hazard ratio for death of 0.62 (P = 0.02; Table 1).

Conclusion: Participation in therapeutic trials is associated with longer OS in NSCLC. Besides supporting drug development, trial enrollment may improve patient outcomes. Efforts should focus on increasing patient enrollment in drug trials.

Keywords: Trials, survival, outcomes
malignant pleural mesothelioma (MPM). Recurrence of MPE is common, and symptoms significantly impact on people’s daily lives. No ideal treatment strategy for MPE currently exists. However, there are four main treatment options aimed at relieving symptoms and improving quality of life. These include aspiration, thoracoscopy with pleurodesis, bedside pleurodesis and indwelling pleural catheter. Choosing which option is best depends on many factors and making decisions can be challenging in pressured clinical environments. This project aimed to develop a support tool to help this decision making process for people with MPE. **Method:** Pleural teams from three sites in the UK undertook a creative co-production (CC-P) approach led by the translational knowledge into action (TK2A) team of the NIHR Research Collaboration and Leadership in Applied Health Research and Care Yorkshire and Humber. The geographical distance between the three sites and the ill-health of service users meant a novel distributed model of CC-P was used. This comprised of three locally run workshops with clinicians, patients and carers that were designed and structured by the TK2A CC-P experts. This was followed by a joint national workshop with representatives from all stakeholder groups to consider findings and outputs from local meetings. The design team worked with participants to develop outputs included patient timelines and personas. These were used as the basis to develop and test visible and tangible prototype ideas. **Result:** Some key messages emerged that informed prototype development. Understanding and managing their pleural effusion was the priority for patients, not their overall cancer journey. Preferred methods for receiving information were varied but visual and graph approaches were favoured. The main influences on people’s decisions about their MPE treatment were personal aspects of their situation (how active they were or that support was at home). The design team developed a first prototype (i.e. a video representing a web-based support tool) to help people identify personal priorities and guide shared treatment decisions. This requires further development before implementation into practice. **Conclusion:** The creative co-production distributed model of co-production used in this project overcame many of the barriers to traditional co-production methods such as power, language and time. They allowed specialist pleural teams and service users to work together to create a patient-facing decision support tool owned by those who will use it.

**P3.15-15 ALI COULD BE A ONE OF PROGNOSTIC SURVIVAL FACTOR FOR NON-SMALL CELL LUNG CANCER PATIENTS**

Y. Hamamoto
Pulmonary Medicine, National Hospital Organization West Saitama Central Hospital, Saitama, JP

**Background:** Patients with terminal non-small cell lung cancer become greatly concerned about where they will die. And the Advanced Lung Cancer Inflammation Index (ALI, body mass index × albumin/neutrophil-to-lymphocyte ratio) has been demonstrated to be a prognostic factor of survival in some solid cancers. We examined the survival times of such patients according to their place of death, i.e., whether they died at home, at a hospice, or at hospital and analysis with ALI. **Method:** A retrospective cohort study of patients who were followed from their first chemotherapy session for non-small cell lung cancer until death was performed. Specifically, the study compared four groups, those that died at home, at a hospice, at hospital or alive. The study was based on mortality data from the single institution National Hospital in Japan, for the period between April 2010 and December 2015. **Result:** Among the 313 patients recruited, 214 were analyzed in this study; 90, 49, and 75 received hospice, home-based, and hospital-based palliative care, respectively. The patients who died at a hospice exhibited significantly longer survival than those that died at hospital (estimated median survival time, 420 days [95% confidence interval (CI), 325–612 days] vs. 252 days [95% CI, 201–316 days]; P<0.0001), and the patients that died at home also demonstrated significantly longer survival than those that died at hospital (estimated median survival time, 420 days [95% CI, 325–612 days] vs. 341 days [95% CI, 293–460 days]; P<0.0001). No significant difference in survival was detected between the patients that died at home and those that died at a hospice. At the time of data cut-off, ALI could be one of prognostic survival factor.

**P3.15-16 MANAGEMENT OF PATIENTS WITH ALK-TRANSLOCATED NSCLC: A SIMULATION-BASED ASSESSMENT OF MEDICAL ONCOLOGISTS’ PRACTICE DECISIONS**

T. Herrmann1, M. Warters2, C. Cason1, E. Van Laar2
1Medscape Education, Fort Sam Houston/TX/US; 2Medscape Education, New York/US

**Background:** The past several years have witnessed unparalleled changes in treatment for patients with ALK-translocated NSCLC. The objective of this study was to assess oncologists’ confidence regarding the use of ALK tyrosine kinase inhibitors in the management of NSCLC and the impact of virtual patient simulation on narrowing gaps in clinical practices. **Method:** A CME certified virtual patient simulation (VPS) was made available via a website dedicated to continuous professional development. The VPS consisted of 2 cases presented in a platform that allows oncologists to assess the patients and make diagnostic and therapeutic decisions supported by an extensive database of diagnostic and treatment possibilities matching the scope and depth of actual practice. Clinical decisions were analyzed using a sophisticated decision engine, and instantaneous clinical guidance (CG) employing up-to-date evidence-base and faculty recommendations was provided after each decision. Oncologists were able to revise each decision post-CG, if desired. Rationales for clinical decisions were also collected in real time. Data were collected between 08/01/2017 and 10/31/2017. **Result:** At the time of assessment, 178 oncologists had fulfilled the participation criteria for completing the simulation. Assessment of their practice choices revealed: in a patient with newly diagnosed NSCLC, up to 30% of oncologists did not order testing for a tumor’s ALK translocation status. Moreover, only 37% ordered the appropriate therapeutic regimen. CG led to a 3% improvement in testing and 20% increase in evidence-based treatment (P=0.003). The primary rationales for the selected treatment differed based on the chosen regimen, disease control (26%) for continued treatment with crizotinib, better efficacy profile for the patient (24%) with use of ceritinib, and recommended by guidelines (25%) for alectinib. A majority of oncologists initially ordered side effect counseling in each case. CG resulted in a 18% (P=0.014) increase in the case for progression on crizotinib. **Conclusion:** This study, using an immersive VPS, provided insights into oncologists’ real world practices, and the rationales behind their treatment landscape and uncovered a lack of clarity about identification of the most appropriate regimen for patients with ALK-translocated NSCLC. Our findings demonstrate a continued need to educate oncologists about how to select and prescribe treatment for these patients.

**Keywords:** NSCLC, ALK-translocated
comorbidities, physical functioning, fatigue, pain interference). Variables significant in bivariate analysis (p<.05) were included in multivariate regression analysis. Result: The regression analysis, age (OR: 1.070, 95% CI: 1.016-1.126, p = 0.01), BMI (OR: 0.840, 95% CI: 0.738-0.956, p = 0.008), and female (OR: 0.142, 95% CI: 0.055-0.366, p < 0.001) were also statistically significant.

Conclusion: A total of 124 patients who were diagnosed with lung cancer at one tertiary academic hospital underwent bone mineral density test. Result: Among the 124 patients, 40 (32.3%) showed osteoporosis. Alcohol history, smoking history, lung cancer histology, lung cancer stage, bone metastasis, and comorbidity (hypertension, diabetes, coronary artery disease, cerebrovascular accident, and chronic obstructive pulmonary disease) did not differ significantly among the osteoporosis and normal group. In univariate analysis, age (p = 0.025), BMI (p = 0.028), and female (p < 0.001) were statistically significant. In multivariate logistic regression analysis, age (OR: 1.070, 95% CI: 1.016-1.126, p = 0.01), BMI (OR: 0.840, 95% CI: 0.738-0.956, p = 0.008), and female (OR: 0.142, 95% CI: 0.055-0.366, p < 0.001) were also statistically significant.

Conclusion: One-third of lung cancer patients were diagnosed with osteoporosis at a high rate after age 60. However, the risk factors affecting osteoporosis of lung cancer patients. Physicians should be aware of screening bone marrow density of lung cancer patients with old age, low BMI and female group. Studies on the effect of calcium supply and bisphosphonate treatment on bone metastasis and fracture in these osteoporosis patients are underway.

Keywords: osteoporosis, Female, lung cancer

P3.15-18 COMPARISON OF PAIN CONTROL EFFECTS AND SIDE EFFECTS EARLY AFTER VATS LOBECTOMY BETWEEN IV-PCA, EPIDURAL-PCA AND ON-Q

J. Jung, S. Haam, J. Park
Department of Thoracic and Cardiovascular Surgery, Ajou University School of Medicine, Suwon/KR

Background: Video-Assisted-Thoracic Surgery (VATS) is widely used as a standard surgical treatment in non-small cell lung cancer (NSCLC), the postoperative pain is reduced rather than before, but postoperative pain management is still important because the pain is in itself and can cause other respiratory complications. So we compared the pain control effects and side effects of intravenous (IV) patient-controlled analgesia (PCA), epidural PCA, and continuous local anesthesia infusion (On-Q), the most commonly used pain management modalities after VATS lobectomy. Method: Total 94 patients who underwent VATs lobectomy in this center with NSCLC from January 2014 to August 2015 were analyzed. Of these 94 patients, 28 had epidural PCA, 36 had IV-PCA, and 30 had On-Q for postoperative pain management. The degree of pain was assessed by NPSI (numeric pain intensity scale), and we analyze NPSI from immediate postoperative period to 48 hours after operation by postoperative day. The incidence of side effects associated with pain control devices and early discontinuation due to side effects were analyzed in patients with each device. The mean value of NPSI on the day of surgery was 6.04 ± 2.56 in the epidural PCA group, 4.75 ± 2.35 in the IV-PCA group, and 5.27 ± 1.87 in the On-Q group and there was no statistically significant difference. NPSI values were decreased in all three groups until 48 hours postoperatively with there was no statistically significant difference between groups. The incidence of side effects related to pain control devices up to 48 hours after operation was the highest in the IV-PCA group (36.1%, 13/36), in the epidural PCA group (35.7%, 10/28) and in the On-Q group (10.0%, 3/30) and there was statistically significance (p=0.032). The rate of early discontinuation of the pain control device due to side effects was 33.3% (12/36) in the IV-PCA group, 25.0% (7/28) in the epidural PCA group, and 6.7% (2/30) in the On-Q group (p = 0.032). Conclusion: The effects of pain control after VATs lobectomy in NSCLC patients were not significantly different in epidural-PCA, IV-PCA, and On-Q but On-Q was superior in terms of side effects and early discontinuation of pain control devices. Continuous extrapleural infusion of local anesthetic via On-Q has less systemic side effects and higher procedural stability than PCA. Therefore, On-Q may be sufficient to replace PCA in pain control after VATs lobectomy in NSCLC patients.

Keywords: NSCLC, Pain control, VATS

P3.15-19 RISK FACTORS FOR OSTEOPOROSIS IN LUNG CANCER PATIENTS

Korea University College of Medicine, Seoul (Korea University Guro Hospital)/KR

Background: Bone related disease is increasingly a problem as lung cancer patients are usually older and the survival rate is increasing. Also cancer patients with multiple chronic comorbidities are at risk of osteoporosis (1-score of ≥ 2.5). The purpose of the study is to investigated the risk factors that attribute to osteoporosis of patients with lung cancer. Method: We retrospectively investigated the incidence of osteoporosis of lung cancer patients from March, 2017 to April 2018. A total of 124 patients who were diagnosed with lung cancer at one tertiary academic hospital underwent bone mineral density test. Result: Among the 124 patients, 40 (32.3%) showed osteoporosis. Alcohol history, smoking history, lung cancer histology, lung cancer stage, bone metastasis, and comorbidity (hypertension, diabetes, coronary artery disease, cerebrovascular accident, and chronic obstructive pulmonary disease) did not differ significantly among the osteoporosis and normal group. In univariate analysis, age (p = 0.025), BMI (p = 0.028), and female (p < 0.001) were statistically significant. In multivariate logistic regression analysis, age (OR: 1.070, 95% CI: 1.016-1.126, p = 0.01), BMI (OR: 0.840, 95% CI: 0.738-0.956, p = 0.008), and female (OR: 0.142, 95% CI: 0.055-0.366, p < 0.001) were also statistically significant.

Conclusion: One-third of lung cancer patients were diagnosed with osteoporosis at a high rate after age 60. However, the risk factors affecting osteoporosis of lung cancer patients. Physicians should be aware of screening bone marrow density of lung cancer patients with old age, low BMI and female group. Studies on the effect of calcium supply and bisphosphonate treatment on bone metastasis and fracture in these osteoporosis patients are underway.

Keywords: osteoporosis, Female, lung cancer
prominent adverse event in both groups. **Conclusion:** Palliative sedation is effective way of controlling intractable symptoms. Most common reason for palliative sedation was progressive dyspnea in lung cancer for both groups. 30–30 mg/24-hour IV MaM starting dose well tolerated and highly effective dose. 15/15 mg dose increment can be done if needed.

**Keywords:** lung cancer, palliative sedation, immediate or elective, intractable symptom

**P3.15-21 REAL-WORLD EXPERIENCE OF FIRST-LINE AFATINIB TREATMENT IN PATIENTS WITH EGFR MUTANT ADVANCED NON-SMALL CELL LUNG CANCER**

C. Liam1, G. Ho2, C. Chai3, A. Bt Alip2, Y. Pang1

1Department of Medicine, Faculty of Medicine, University of Malaya, Kuala Lumpur/MY, 2Department of Oncology, Faculty of Medicine, University of Malaya, Kuala Lumpur/MY, 3Department of Medicine, Faculty of Medicine and Health Science, University Malaysia Sarawak, Kota Samarahan/MY

**Background:** Published reports of first-line afatinib treatment efficacy, side-effects and resistance mechanism in the real-world setting are lacking.

**Method:** A retrospective observational study of patients with EGFR mutant advanced non-small cell lung cancer (NSCLC) receiving first-line afatinib in University Malaya Medical Center from 1st December 2014 to 30th April 2018. **Result:** Twenty-two out of 33 patients on first-line afatinib were eligible for analysis. The patients’ demographic and clinical characteristics are as shown in Table 1. The mPFS was 14.3 months, overall response rate was 86.3% (19/22) and disease control rate was 95.5% (21/22). The median time-to-treatment failure was 16.2 months. The median overall survival has not been reached but 12-month survival rate was 81.8% (18/22). A patient with exon 20 T790M mutation had received treatment for 23.3 months without disease progression (PD).

**Conclusion:** Overall response rate was 86.3% (19/22) and disease control rate was 95.5% (21/22). The median time-to-treatment failure was 16.2 months. The median overall survival has not been reached but 12-month survival rate was 81.8% (18/22). A patient with exon 20 T790M mutation had received treatment for 23.3 months without disease progression (PD).

**P3.15-23 DATA MINING THE INTERNET AND CROWDSOURCING IN GUIDING PATIENT DECISION-MAKING**

S. Pathak1, C. Sit2

1Caregiver To Nsclc Patient, Calgary/CA, 2Lung Cancer Canada, Toronto/ON/CA

**Background:** The internet, through social media, blogs and forums, has enabled patients to share experiences and outcomes. Data mining and crowdsourcing is a methodological approach to gather the individual experiences within these platforms and convert them into Real World Evidence (RWE) that can help patients make decisions, especially in the case of new treatments or treatments in trial. This abstract is a case study of how this methodology was used to inform the decision between Whole Brain Radiation (WBR) vs. osimertinib in treating brain metastasis in EGFR+, T790M, NSCLC – at a time when the results to an open label...
investigations and treatments faster by multidisciplinary team (MDT) established in October 2014, aims to help the patients accessing all investigations and osimertinib were accessible from the search. Conversations with patients of the same genetic profiles, metastasis and treatments were selected. The user profiles detailed clinical RWE, which increased the trust factor of the data. Information was obtained from April to June 2016 with data points beginning in 2014. When reviewing the 66 self-reported cases, it was found that osimertinib was effective in patients with brain metastases in 36% of patients while 4% had no response. Quality of life and side effects were other fields that were explored. This evidence influenced the patient to choose osimertinib instead of WBR to treat her lung cancer. Conclusion: The Internet offers opportunities to source evidence and help patients to make informed treatment decisions before starting the treatment which may affect treatment outcomes. Datamining and crowdsourcing is a methodological system that gathers individual self-reported results from the Internet and converts it into credible RWE. For this patient, it increased the trustworthiness of the information and helped decrease anxiety about the treatment decision. Used appropriately, it has the potential to inform treatment decisions, help predict outcomes, and be a tool for post marketing surveillance that can be used to inform health technology assessment.

Conclusion: The study reveals that there is high prevalence of depression among lung cancer patients in developing country. The results of this study show that depression is common and has been associated with increased morbidity and mortality. Method: The study was conducted in 79 patients diagnosed with advanced stage lung cancer attending medical oncology department of B. P. Koirala Memorial Cancer Hospital, Nepal. A set of questionnaire was used to interview and collect the data. Beck’s Depression Inventory (BDI-II) and its Nepali translated transcript was used to assess the depressive symptoms of patient. Based on score, depression was classified as Minimal depression, Mild Depression, Moderate Depression and Severe Depression. Verbal consent was taken before each interview to address the rights of the patient. Result: This study revealed lung cancer was predominant in male patients (55.7%). Patients age ranged from 42 to 81 years with mean age 65.59 years. Among the 31 patients evaluated only 45/79 (57%) patients were aware of their disease status. 34 patients were unknown about their diagnosis. All the patients evaluated were found to be depressed in several degrees. 11/79 (13.9%) of the patients had minimal, 27/70 (34.2%) had mild, 12/79 (32.3%) had moderate and 29/79 (36.7%) had severe forms of depression. Depression was common in patients with stages II and III. Interestingly most of patients who were explained about their disease status had moderate to severe depression but those patients who were unknown about their disease status tend to have minimal to mild depression (table 1). The association between awareness of disease status and severity of depression was statistically significant.
2 weeks to date at our centre. Evidence of PD-L1 expression was not present in either of the patients. All were within the ECOG performance status ≤2, and none of them were on systemic corticosteroids or immunosuppressive therapy. First case: a 48-year-old male, adenocarcinoma lung with brain metastases, TTF-1 positive and EGFR negative, was treated initially with craniotomy followed by whole brain irradiation. 4 cycles of pemetrexed/carboplatin followed by 6 cycles of maintenance pemetrexed were given but the disease progressed. Then he completed 4 cycles of docetaxel which again resulted with progressive disease (PD). Now he is on nivolumab, 6 cycles completed to date. Second case: A 62-year-old female, adenocarcinoma lung with contralateral lung metastases, EGFR and ALK negative, was treated initially with craniotomy followed by whole brain irradiation. 4 cycles of pemetrexed/carboplatin followed by 6 cycles of maintenance pemetrexed/cisplatin. As the disease progressed, 4 cycles of docetaxel/carboplatin were given which again showed PD. Now he is on nivolumab, cycle-6 completed to date. Third case: A 75-year-old male, squamous cell esophageal cancer at lower 3rd, was non-surgical and non-chemo candidate because of uncontrolled diabetes and significant cardiac comorbidity. Nivolumab was started, and received 2 cycles. Result: In the first and second cases, ‘stable disease’ was achieved with no serious immune-mediated reactions over the period of nivolumab therapy. When evaluated with Common Terminology Criteria for Adverse Events (CTCAE version 4.03), only grade-1 elevated creatinine was seen in both patients. There was no reported toxicity of endocrinopathy, enterocolitis, intestinal perforation, hemorrhage, neuropathy, pneumonitis, hepatitis or dermatitis. In the third case, patient developed, 7 days after cycle-2, grade-3 diarrhea along with hematemesis and hematochezia. On arrival at our emergency department, he was found to be life-threatening grade-4 enterocolitis and he died before undergoing any intervention. Conclusion: Nivolumab may delay disease progression with minimal toxicity but may sometimes be associated with severe immune-related events. Practice should be done with caution and prompt action is warranted once toxicity has developed in order to prevent fatality.

Keywords: Nivolumab, lung cancer, esophageal cancer

P3.15 INITIAL RESPONSE TO FIRST LINE TREATMENT IS THE BEST PREDICTOR OF THE PATIENT SURVIVAL IN ADVANCED NSCLC

N. Turhal, S. Orscelik, G. Taktakoglu
Medical Oncology, Anadolu Medical Center, Kocaeli/TR

Background: Although most of the NSCLC patients are treated according to the standard guidelines, the patients who present in routine clinical practice usually have inferior performance status, in comparison to the patients registered in the clinical trials. Also in comparison, the frequency and thoroughness of the tests and procedures the clinical trial patients subjected are more intense as well. The oncologist practising in community needs simpler ways and means to assess patients' disease history and their reliability. Method: We searched among 5130 patients treated in our clinic since 2006 to find 678 lung cancer patients of all stages and pathology. Of these, 171 advanced stage NSCLC patients that were treated primarily under our supervision are selected for the calculations. The other histologies and the patients seen once or twice for a second opinion are excluded. The common patients characteristics including age, gender, stage, date of diagnosis, the date of progression, the site and the number of metastasis etc. are all recorded. Result: The median age of the patients were 62, 23% were female, and the median overall survival was 18 months. The majority did not receive any targeted immunotherapy because either it did not exist back then or they had access problems in more recent times. We did then univariate/multivariate analysis of survival according to the age, gender, site of metastasis, platin vs non-platin based treatment and response to first line of chemotherapy. From these, only the response to first line of therapy appeared as a statistically significant variable, 23 vs 14 months with p=0.0001. In over 90% of the patients, the radiological findings were in line with clinical picture. Conclusion: Although more complex and costly measures exist to predict the overall survival of the NSCLC patients, in our experience the clinical responsiveness to first line of chemotherapy most precisely predicted the overall survival. This simple measure may help the healthcare professionals to understand the disease course of the patients and manage their needs in more proper fashion.

Keywords: lung cancer, survival, chemotherapy

P3.15-28 PROGNOSTIC NUTRITIONAL INDEX FOR PREDICTING POSTOPERATIVE COMPLICATIONS AFTER SURGERY THORACIC TUMOR INVOLVING THE NEIGHBORING STRUCTURES

I. Watanabe, A. Hattori, K. Takamochi, S. Oh, K. Suzuki
Departments of General Thoracic Surgery, Juntendo University School of Medicine, Toyono -Chome, Bunkyo-Ku, Tokyo/JP

Background: The prognostic nutritional index (PNI), which is scored based on laboratory data of albumin and lymphocyte count, predicts postoperative complications in various types of malignancies. This study aimed to assess the risk factors of postoperative complications, especially the preoperative immune nutritional condition as estimated with the PNI, after surgical treatment of patients for thoracic tumor involving the neighboring structures. Method: From July 2008 to December 2015, 39 patients with resected thoracic tumor involving the neighboring structures were retrospectively analyzed and the relationship between the preoperative PNI and postoperative complications was evaluated. There were 119 men and 40 women with a median age of 61 years (range 21–88 years). Invading neighboring structures, including chest wall, superior sulcus, diaphragm, tracheal carina, left atrium, superior vena cava, aorta, and vertebrae were performed when possible in patients with locally advanced disease. Result: Multivariate logistic regression analysis revealed that the preoperative PNI was a significant independent predictor of postoperative complications of Clavien-Dindo Grade ≥II (odds ratio: 3.87, p=0.0489). Using receiver-operating characteristics curve analysis predicting postoperative complications, we established cut-off values 46 (Area Under the Curve: 0.62) for the PNI. Patients were divided into two groups according to the preoperative PNI: high (≥46; n=95 (59.7%)), low (<46, n=64 (40.3%)). The incidence of postoperative complications of Grade ≥II and Grade ≥III was higher in the low PNI groups than in the high PNI groups (p=0.019 and p=0.009, respectively). The incidence of pneumonia and the length of postoperative hospital stay were significantly higher in the low PNI groups than in the high PNI groups. However, the 30 day mortality (1.88%) and 90 day mortality (4.40%) were not correlation with PNI. Conclusion: The preoperative PNI might be a useful marker to predict the risk of postoperative complications after surgery for thoracic tumor involving the neighboring structures. We have to intensive attention to the low PNI patients in the perioperative management.

P3.15-29 DEFINING THE SYMPTOM BURDEN OF NON-SMALL CELL LUNG CANCER

M. Whisenant1, L. Williams1, V. Vaghanii, 2 Q. Shi3, A. Garcia Gonzalez4, S. Haq2, C. Cleeland1, J. Zhang4, J. Heymacht1, G. Simon1
1Symptom Research. The University of Texas MD Anderson Cancer Center, Houston/TX/US, 2Thoracic Head & Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston/TX/US, 3Thoracic/Head and Neck Medical Oncology. The University of Texas MD Anderson Cancer Center, Houston/TX/US, 4Thoracic Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston/TX/US

Background: Symptom burden is disease and treatment symptom severity and its impact on daily functioning. Symptom monitoring has demonstrated improved cancer patient outcomes, including quality of life, resource utilization, ability to continue treatment, and survival. The use of disease-specific patient-reported outcomes (PRO) measures facilitates individualized symptom monitoring and management. The purpose of this study was to describe symptom experience from the patient perspective and identify key symptoms for a PRO measure of NSCLC symptom burden. Method: Patients with NSCLC described their symptom experience in single qualitative interviews. Content analysis was used to define the content for a PRO measure of NSCLC symptom burden. Result: Mean age of the 40 patients interviewed was 66.1 years (standard deviation = 10.9). 60.0% were male, 77.5% were white, and 56.4% had stage IV disease. Content analysis found a total of 32 symptoms, 6 reported by ≥ 20% of participants (Table 1). Symptoms varied based on treatment modality (chemotherapy versus radiation therapy), but not stage of disease. Numbrness or tingling and sore mouth were described only by patients who had received chemotherapy. Patients volunteered ways in which symptoms impacted daily activities and relationships. (See next page)
### Table 1. Patient quotes from qualitative interviews describing the 6 most common symptoms (reported by ≥ 20% of participants)

</table>

**Conclusion:** Patients with NSCLC experience numerous symptoms related to disease and treatment. Shortness of breath, cough, distress, fatigue, pain, and constipation were commonly reported symptoms, suggesting that clinicians should routinely and proactively monitor the presence and severity of these symptoms in NSCLC clinical care. In patients receiving chemotherapy, attention to specific treatment-related symptoms, including symptoms of neuropathy and sore mouth, is needed. While stage of disease does not produce unique symptoms, the severity of the symptoms may possibly vary by stage of disease. Clinicians should also be aware that symptoms result in interference with daily activities, relationships, life plans, treatment adherence, and mood.

**Keywords:** non-small cell lung cancer, symptoms, qualitative

---

**Background:** Treatment strategies for metastatic non-small cell lung cancer (NSCLC) are evolving rapidly. Real-world evidence (RWE) of treatment patterns and outcomes can further our understanding of the impact of novel therapies. In this population-based study, we investigated treatments and outcomes for stage IV NSCLC in a large Canadian province.

**Method:** Patients diagnosed with de novo stage IV NSCLC from April 1, 2010 to March 31, 2015 were identified. Baseline characteristics, treatments, and outcomes were analyzed. We classified treatments targeting EGFR, EML4–ALK, and ROS1 as targeted therapy and intravenous checkpoint inhibitors as immunotherapy.

**Result:** A total of 6,438 patients were identified with NSCLC, of whom 3,606 (56%) had de novo stage IV disease. The median age of diagnosis was 69 years (range 20–100) and 52.4% were male. The median age among those who received targeted therapy and immunotherapy was 63 (27–90) and 61 (37–72) years, respectively, and 41.8% and 61.8% were male, respectively. First line treatments were: 5.7% targeted agents (n = 204), 1% immunotherapy (n = 1), 19.5% palliative chemotherapy (n = 703), 6.8% palliative radiotherapy (n = 246), and 74.8% received supportive care only (n = 2,698). Most frequent subsequent treatments in 2L included: 30.7% targeted agents (n = 125), 1.7% immunotherapies (n = 7), 67.6% palliative chemotherapy (n = 275), 32.2% palliative radiotherapy (n = 131). Median overall survival (mOS) for the whole cohort was 3.8 months (0–not reached [NR]). MOS with targeted therapies was 18 months (1.4–NR), chemotherapy was 9.4 months (1.1–NR) and supportive care only had a mOS of 2.5 months (0–NR) (Figure 1). About 1.0% of patients (n = 34) received immunotherapy at any line.

**Conclusion:** Survival benefit was dependent on type of treatment received, with a trend towards improved survival with newer agents.

**Keywords:** NSCLC, metastatic, outcomes

---

**Background:** Advanced anaplastic lymphoma kinase (ALK) fusion-positive non-small cell lung cancers (NSCLCs) are effectively treated with ALK tyrosine kinase inhibitors (TKIs). However, clinical outcomes and acquired resistance were unclear. This study was to show the clinical outcomes and resistance mechanisms of crizotinib in ALK-Positive Non-Small Cell Lung Cancer (NSCLC) Method: From Feb 2, 2013 to Mar 10, 2018, 2360 patients in Hunan Cancer Hospital were enrolled in this project. We identified 90 ALK-positive NSCLC patients which were detected by Ventana (Roche) and Nex-generation sequencing with known ALK variants were selected for target patients. ALK resistance mutations and clinical outcomes on Crizotinib were retrospectively evaluated according to ALK variant and detection methods. Subgroups of brain metastasis, multiple gene mutation, uncommon rearrangement and concomitant mutation and dual rearrangement were also been evaluated. Nomograms for predicting survival in ALK-Positive NSCLC was also been built. Result: Section not applicable Conclusion: Section not applicable

**Keywords:** resistance mechanisms, ALK-Positive Non-Small Cell Lung Cancer, Better Clinical Outcomes
P3.16-01 A MULTIOMIC STUDY REVEALS BTG2 AS A RELIABLE PROGNOSTIC MARKER FOR EARLY-STAGE NON-CELL LUNG CANCER

D. Christiani1, L. Su1, R. Zhang1, E. Loehrer2, M. Lanuti3, N. Diao1, N. Aoi1, F. Chen1
1Environmental and Occupational Medicine and Epidemiology Program, Harvard School of Public Health, Boston/MA/US, 2Environmental Health, Epidemiology, Harvard School of Public Health, Boston/MA/US, 3Thoracic Surgery, Massachusetts General Hospital, Boston/MA/US, 4Biostatistics, Nanjing Medical University, Nanjing/China

Background: B-cell translocation gene 2 (BTG2), which functions as a tumor suppressor gene, has been reported to be involved in several cancers. However, the role has focused on its role in lung cancer progression or prognosis. We aimed to investigate the role of BTG2 in early-stage non-small cell lung cancer (NSCLC) survival.

Patients and Methods: This study included 1,230 early-stage (I, II) surgically treated NSCLC patients with methylation and expression data from five international cohorts. We built a prognostic model based on BTG2 methylation. Then, we explored BTG2 expression and NSCLC survival in 3,038 cases, including the above-mentioned cohorts as well as 17 extended public datasets by meta-analysis. Further, we integrated the clinical information, expression, and methylation to build an integration model and evaluated its prediction ability using C-index.

Result: Three risk Cpg probes (cg01798157, cg06373167, cg23371584) were associated with overall survival. The prognostic model based on methylation could distinguish patient survival in the four cohorts (hazard ratio (HR), range 1.51 to 2.21) and the independent validation set (HR = 1.85). In the expression analysis, BTG2 acted as a tumor-suppress gene in each cohort (HR range, 0.28 to 0.68). A meta-analysis showed high BTG2 expression was associated with better survival (HR = 0.61, 95% CI: 0.54-0.68). The three Cpg probes were all negatively correlated with BTG2 expression. Further, the integration model based on BTG2 methylation, expression, and clinical information showed a better prediction ability in the training set and validation set.

Conclusion: The methylation and prognostic signatures based on BTG2 are stable and reliable biomarkers for early-stage NSCLC. They may have new applications for appropriate clinical adjuvant trials and personalized treatments in the future.

P3.16-02 PHASE III STUDY OF CANAKINUMAB (ACZ885) AS ADJUVANT THERAPY IN PATIENTS WITH SURGERYALLY RESECTED NSCLC

E. Garon1, A. Ardizzoni2, F. Barlesi1, B. C. Cho1, P. De Marchi1, Y. Goto4, S. Lu1, L. Páez-Ares2, D. Spigel6, M. Thomas10, P. Cazorla Arratia11, J. Baum7, Y. Lai2, C. Zheng1, J. C. Yang1
1David Geffen School of Medicine at UCLA/US, 2UCLan Research Institute, Clitheroe/L/UK, 3University of British Columbia, Vancouver/CA/Canada, 4University of Cincinnati College of Medicine, Cincinnati/OH/US, 5University of Alabama at Birmingham, Birmingham/AL/US, 6University of Texas MD Anderson Cancer Center, Houston/TX/US, 7University of Pennsylvania, Philadelphia/PA/US, 8National Cancer Institute, Bethesda/MD/US, 9Thoracic Oncology Group, University of Colorado, Aurora/CO/US, 10Thoracic Surgery, Tohoku University, Sendai/JP, 11Thoracic Surgery, University of California, Los Angeles/LA/US

Background: Preclinical and clinical data suggest that cytokines such as interleukin (IL)-1β can promote angiogenesis and tumor growth, and are essential to tumor invasiveness. Canakinumab (ACZ885) is a high-affinity human IgGx anti-IL-1β monoclonal antibody approved for patients with various IL-1-driven auto-inflammatory diseases. In the Phase III Canakinumab Anti-Inflammatory Thrombosis Outcomes Study (CANTOS) in patients with coronary artery disease, IL-1β was associated with reduced cardiovascular events. IL-1β may play a significant role in the incidence of fatal and non-fatal lung cancer in patients with increased high-sensitivity C-reactive protein levels.

ACZ885 T2301 (NCT03447769) is evaluating the efficacy and safety of adjutant canakinumab versus placebo in patients with surgically resected non-small cell lung cancer (NSCLC).

Method: This Phase III, randomized, double-blind, placebo-controlled study is enrolling patients (≥18 years, Eastern Cooperative Oncology Group Performance Status ≤1) with completely resected (RO) American Joint Committee on Cancer (AJCC)/Union for International Cancer Control (UICC) V.8 stages II–IIB and III and N2 NSCLC, who have completed standard-of-care adjuvant treatments, including cisplatin-based chemotherapy and thoracic radiation therapy (if applicable). Prior treatment with neoadjuvant chemotherapy or radiotherapy is not permitted. Approximately 1500 patients will be randomized 1:1 to receive canakinumab (200 mg every 3 weeks [Q3W], subcutaneous [s.c.]) or placebo (Q3W, s.c.) for 21 cycles for 18 cycles or until disease recurrence, unacceptable toxicity, treatment discontinuation at the discretion of the investigator or patient, death, or loss to follow-up. Following baseline screening, imaging will be performed every 12 weeks for the first year (treatment phase) following Cycle 1 Day 1, then every 26 weeks during Years 2 and 3, and annually during Years 4 and 5 (post-treatment surveillance phase).

Result: Randomization will be stratified by AJCC/UICC v.8 stage, tumor histology, and region. The primary objective is to compare disease-free survival (DFS) in the canakinumab versus placebo arms, as determined by local investigator assessment. Secondary objectives include a comparison of the two treatment groups with respect to overall survival (key secondary objective), lung cancer-specific survival, safety, pharmacokinetics and immunogenicity of canakinumab, and patient-reported outcomes.

Keywords: Canakinumab, ADJUVANT, NSCLC

P3.16-03 UNCOMMON EGFR MUTATIONS AS A WORSE PROGNOSTIC FACTOR FOR SURGERICALLY RESECTED LUNG ADENOCARCINOMA

K. Hayasaka1, S. Shiono1, Y. Matsumura2, H. Suzuki3, N. Yanagawa4, J. Abe5, M. Sagawa6, A. Sakurada7, M. Katahira8, S. Takahashi5, M. Endoh9, Y. Okada10
1Department of Thoracic Surgery, Yamagata Prefectural Central Hospital, Yamagata/JP, 2Thoracic Surgery, Yamagata Prefectural Central Hospital, Yamagata/JP, 3Pathology, Yamagata Prefectural Central Hospital, Yamagata/JP, 4Thoracic Surgery, Miyagi Cancer Center, Natori/JP, 5Department of Endoscopy, Tohoku Medical and Pharmaceutical University, Sendai/JP, 6Thoracic Surgery, Institute of Development, Aging and Cancer, Tohoku University, Sendai/JP

Background: The characteristics and prognosis of patients with lung adenocarcinoma harboring uncommon epidermal growth factor receptor (EGFR) mutations have not been clarified. Here, we examined whether the presence of uncommon EGFR mutations is a prognostic factor for patients treated surgically.

Method: In this multi-institutional retrospective cohort study, clinicopathological data were collected from 1,463 patients who underwent complete surgical resection for lung adenocarcinoma between 2005 and 2012 at five institutions and were examined for EGFR mutation status. Differences in postoperative survival (OS) and recurrence-free survival (RFS) according to EGFR mutation status were evaluated.

Result: Of 1,031 eligible patients, 500 (48.5%), 497 (48.2%), and 34 (3.3%) had wild-type EGFR (WT), common EGFR mutations (CMs), and uncommon EGFR mutations (UCMs), respectively. In the UCM group, 19 patients had a single mutation, including exon 18 L851Q (n = 7), exon 20 T790M (n = 6), or exon 21 L861Q (n = 5), and 15 patients had compound mutations. The clinicopathological characteristics were not significantly different between the CM and UCM groups. The 5-year OS rates in the WT, CM, and UCM groups were 76.3%, 88.6%, and 68.4%, respectively. OS was significantly shorter in the UCM than CM group (p = 0.011), although no significant difference was observed between the UCM and WT groups (p = 0.83). The 5-year RFS rates in the WT, CM, and UCM groups were 63.7%, 74.5%, and 58.1% respectively. RFS was significantly shorter in the UCM than CM group (p = 0.006), although no significant difference was observed between the UCM and WT groups (p = 0.41). The use of EGFR–tyrosine kinase inhibitors after recurrence did not affect the prognosis with respect to EGFR mutation type. Among the patients with single mutations in the UCM group, patients harboring T790M were younger, more likely to be males and smokers, and more likely to have a larger tumor size, lymph node metastasis, pleural invasion, and lymphovascular invasion, compared with those harboring G719X or L861Q. T790M was also associated with shorter OS and RFS; the 3-year OS rates were 50.0%, 83.3%, and 100% and the 3-year RFS rates were 16.7%, 71.4%, and 80.0% for patients harboring T790M, G719X, and L861Q, respectively.

Conclusion: Among patients with surgically resected lung adenocarcinoma, OS and RFS were significantly short in these with UCMs compared with CMs, implying that UCMs may be a worse prognostic factor.

Keywords: Surgery, Prognosis, uncommon EGFR mutation
P3.16-04 COMPARISON OF 2D AND 3D CONSOLIDATION TO TUMOR RATIOS TO PREDICT LESS INVASIVE LUNG ADENOCARCINOMA
T. Ikeda, J. Nakano
Sakaide Citizen Hospital, Sakaide/JP

Background: Increases in lung cancer screening with computed tomography have led to more frequent detection of lesions like early stage lung adenocarcinomas. Patients with a ground-glass nodules (GGN) dominant small lesion have an excellent prognosis after complete resection. The consolidation to tumor diameter ratio (d-CTR) is a widely utilized 2D radiological parameter, and lesions with d-CTR > 0.5 are candidates for segmentectomy instead of lobectomy. However, the radiological and pathological features of an adenocarcinoma can be contradictory. Some lesions diagnosed as a pure GGN may actually be invasive adenocarcinomas. The purpose of this study was to compare 2D and 3D parameters of lesions to identify less invasive pathological Stage I adenocarcinoma.

Method: We retrospectively evaluated 42 lesions from 41 patients who underwent curative resection for pathological Stage I adenocarcinoma from May 2016 to December 2017 at Sakaide citizen hospital. We defined Adenocarcinoma in situ and minimally invasive adenocarcinoma as less invasive histological subtypes. Besides, we defined lesions exhibiting lymphatic or vascular invasion as invasive lesions. The 2D parameter was the d-CTR. The 3D parameter was the volume ratio of the solid part to the whole tumor (v-CTR). We used a cut-off value of 0.5 for the 2D parameter, and then cubed that value to obtain a cut-off of 0.125 for the 3D parameter.

Result: There were 29 (69.1%) invasive histological subtypes lesions, 8 (19.0%) lymphatic invasion lesions and 11 (26.2%) vascular invasion lesions. There were 20 (47.6%) lesions with d-CTR > 0.5, compared to the 22 with d-CTR < 0.5, which were significantly more likely to be less invasive histological subtypes (p = 0.0001). When we compared with v-CTR > 0.125, the 20 lesions with d-CTR > 0.5 and 12 (28.6%) lesions v-CTR > 0.125. The 20 lesions with d-CTR > 0.5, compared to the 22 with d-CTR < 0.5, were significantly more likely to be less invasive histological subtypes (p = 0.0001), or exhibit no vascular invasion (p = 0.0005). In multivariate analysis, having a d-CTR > 0.5 was a significant predictive factor for less invasive lesions. Similarly, the 12 lesions with v-CTR > 0.125, compared to the 30 with v-CTR < 0.125, were more likely to be less invasive histological subtypes (p = 0.0001), exhibit no lymphatic invasion (p = 0.0001), or exhibit no vascular invasion (p = 0.0014). However, the 8 lesions with v-CTR < 0.125, despite having d-CTR < 0.5, all had invasive histological subtypes (p = 0.0009).

Conclusion: The values d-CTR > 0.5 and v-CTR > 0.125 could be predicted factor of less invasive lesions in early-stage lung adenocarcinomas. Furthermore, the study suggested that the 3D CTR parameter for making these predictions.

P3.16-06 DOES COMPREHENSIVE MUTATION ANALYSIS ADD PROGNOSTIC VALUE IN RESECTED EARLY STAGE LUNG ADENOCARCINOMA?

P. Kneueritz1, D. Carbone2, L. Luo3, D. D’souza4, S. Moffatt-Brice5, R. Merritt1
1Division of Thoracic Surgery. The Ohio State Wexner Medical Center, Columbus/OH/US, 2Division of Thoracic Surgery. The Ohio State University Wexner Medical Center, Columbus/US

Background: Recent efforts have been directed to enhance staging of non-small cell lung cancer by including common or targetable mutations. However, the predictive value of isolated mutations has been inconsistent between studies, possibly related to mutation interactions, confounding, and heterogeneous patient cohorts. We sought to determine the prognostic role of common mutations in resected early stage lung adenocarcinoma patients.

Method: Lung cancer mutation panel (PULMOL) using next generation sequencing was routinely obtained on tumors of 317 patients who underwent lobectomy and mediastinal lymphadenectomy for stage I-II adenocarcinoma from 2011-2017. Frequency of mutations was determined, and association with disease-free survival (DFS) and overall survival (OS) following complete resection were calculated. Result: Of 248 (78%) patients at least one mutation, 20% had two or more detected mutations. KRAS and EGFR genes were most frequently affected, in 39% and 24% of patients. EGFR mutations were almost exclusively seen in KRAS-negative patients, except for nine KRAS+/EGFR+ patients, TP53 mutation was the most common co-existing mutation in 59% of cases. Other frequent mutations were MET (6%), BRAF (5%), HRAS (4%), and ALK rearrangement (3%). KRAS mutation, and presence of two or more mutations were the only molecular predictors of decreased DFS and OS in univariate analysis. Kaplan-Meier plot with Logrank test was performed for KRAS+ and KRAS- for disease-free survival and Kaplan-Meier plot with Logrank test was performed for KRAS+ and KRAS- for overall survival. Conclusion: Routine mutation analysis may yield important prognostic information in patients with completely resected early stage lung adenocarcinoma and may enhance staging when accounting for other known prognostic factors. KRAS mutation was the strongest predictor of worse survival. The prognostic value of EGFR should be further explored in KRAS-negative tumors.

Background: Brain metastases are common in non-small cell lung cancers (NSCLC) with activating EGFR mutations (EGFRm), occurring in 44%-63% of patients. To date, there are no known clinical or molecular factors to predict the risk of brain metastases in these patients.

Method: In this retrospective single-institution study, we identified 106 patients with EGFRm NSCLC who underwent surgery for primary lung tumor. Clinical and demographic data was collected from electronic records. Whole Exome Sequencing (WES) of the primary tumor was performed utilizing the Agilent SureSelect Exome v6+COSMIC baits followed by sequencing on the Illumina HiSeq2500 platform. Development of brain metastases was correlated with clinical/pathologic features, EGFR mutation type, co-mutation of EGFR and other frequently mutated genes; and non-synonymous tumor mutation burden (TMB). Statistical analysis used Fisher exact test for categorical variables, Mann-Whitney test for continuous variables of association with the risk of developing brain metastases, and Gray’s test for the probability of brain metastases and Gray’s test for the probability of brain metastases over time.

Result: Of 106 patients who underwent surgical resection of primary EGFRm NSCLC, WES was successful for 73: 51 (70%) females, 52 (71%) never smokers, 38 (52%) stage I, 14 (19%) stage II and 21 (28%) stage III; 42 (57%) EGFR exon 19 mutation, 30 (41%) exon 21, 1(1%) Exon 20 insertion mutation. Twenty-five patients (34%) developed brain metastases. Patients with brain metastases were younger (median age 61 vs. 65 years, p=0.021), had more advanced stages (p=0.012), with a trend towards higher rates in females (p=0.066). One patient with brain metastases had de-novo EGFR T790M mutation in the primary tumor. No difference was seen regarding smoking history, EGFR mutation type, TP53 co-mutation, and median TMB. The 5-year probability of brain metastases increased with increasing stage (14% stage I; 43% stage II, [HR=3.00], 44% stage III, [HR=3.13], p=0.01), and a trend towards higher probability among females (33% vs. 19%; HR=3.99 for males, p=0.074), and younger patients (37% <65 years vs. 15% >65, HR=0.37 in older patients, p=0.042). There was no difference in probability of brain metastases based on smoking history, ethnicity, EGFR type (33% exon 19 vs. 22% exon 21, p=0.28), TP53 co-mutation (31% vs. 27% without TP53, p=0.59), or TMB (24% TMB≥2.87 vs. 32% TMB<2.87, p=0.37 for non-synonymous mutations/Mb, p=0.99). Conclusion: While our findings suggest that younger age, advanced stage, and female sex may be associated with the development of BM in EGFRm NSCLC, we could identify no molecular predictor of BM based on EGFR subtype, TP53 co-mutation or TMB.

P3.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30
P3.16-08 BASELINE QUALITY OF LIFE IS INFLUENCED BY THE DURATION OF ABSTINENCE FROM SMOKING IN CANDIDATES TO LUNG CANCER SURGERY
C. Pomplii, G. Velikova, K. Franks, J. Robson, S. Dixon, M. Callister, A. Brunelli
1 Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, GB, 2 Clinical Oncology, St James’s University Hospital, Leeds, GB, 3 Department of Respiratory Medicine, Leeds Teaching Hospitals, Leeds, GB, 4 St James University Hospital, Leeds, GB, 5 Thoracic Surgery, St. James’s University Hospital, Leeds, GB

Background: The optimal interval of smoking cessation before Non-Small Cell Lung Cancer (NSCLC) surgery is still unknown. The objective of this study is to evaluate the influence of smoking cessation on the preoperative quality of life (QoL) of surgical NSCLC patients. Method: 266 consecutive ever smokers (133 females) with a pack year history ≥20 undergoing lung resections for NSCLC and with complete preoperative QoL data were analysed. The EORTC QoL summary score was calculated (SumS) as the average of the individual functional and reversed symptom scales (excluding Global-Health and Financial-Impact scales). The following smoking-related variables were tested for a possible association with SumS: age when the patient quit smoking and months elapsed from smoking cessation (for current smokers a value of 0 was used). These variables were entered as independent predictors in a stepwise multivariable regression analysis along with several patient-related baseline factors. Result: 108 patients were current smokers, 158 were ex smokers (quit at least 1 month before surgery). We found no difference of preoperative QoL SumS between current smokers and ex smokers (81.5 vs. 83.0, p = 0.66). Amongst the 158 ex-smokers, 69 quit smoking before the age of 60. Their SumS was similar to the one of those who quit older (84.2 vs. 82.0, p = 0.30). A linear regression showed a significant association between the duration of abstinence from smoke and their QoL SumS (coefficient 0.02, SE 0.009, p = 0.03). When the analysis was adjusted for other confounders using a multivariable regression analysis, the duration of abstinence from smoking (p = 0.001-0.001-longer time better QoL) remained independently associated with SumS along with performance score. Figure 1: Lowess Curve plotting SumS against the months elapsed from the time quit smoking. Conclusion: Patients should be counselled to stop smoking prior surgery independently as the QoL has expected to increase.

P3.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.16-09 HIGH PREOPERATIVE D-DIMER LEVEL PREDICTS EARLY RECURRENTENCE AFTER SURGERY FOR NON-SMALL CELL LUNG CANCER
General Thoracic Surgery, Chiba University Graduate School of Medicine, Inohana, Chuo-Ku Chiba-Shi, Chiba, JP

Background: Carcinoma cells often affect the coagulation and fibrinolysis among cancer patients. Plasma dimerized plasmin fragment D (D-dimer) has been reported as the prognostic marker of various type of malignancies. For non-small cell lung cancer (NSCLC) patients, significance of D-dimer levels still remains unclear. Method: Two hundreds and thirty five patients with NSCLC who underwent radical surgery between April 2015 and March 2017 were retrospectively reviewed. We divided two groups including 1) high D-dimer (over 1.0ug/ml) group (hDD group, n=47), and 2) normal D-dimer group (nDD group, n=188). The clinical characteristics, tumor CT findings, pathological findings, and clinical outcomes were analyzed. Result: The mean D-dimer level was 2.49±2.58 among hDD group. The hDD group had the characteristic of 1) male gender, 2) elder patients, 3) larger tumor size (p=0.0011), 4) pure solid appearance (p=0.0203). The hDD group showed worse overall survival (OS), disease free survival (DFS), and disease specific survival (DSS) than nDD group (Figure 1-A, B, C; log-rank test, p<0.0001, =0.0007, =0.0003, retrospectively) and these findings were also observed only for the p-Stage IA cases. Interestingly patients with granul glass attenuation-dominant nodule were not affected by D-dimer level with favor prognosis. Pathology showed more frequent vessel involvement (v+) in hDD group (p=0.033), but there was no significant difference for histology or histological subtypes of adenocarcinoma.

Keywords: D-dimer, NSCLC, Prognosis

Figure 1: Kaplan-Meier survival curves of postoperative overall survival (A), disease-free survival (B), and disease-specific survival (C) by preoperative D-dimer level. Conclusion: The preoperative D-dimer level predicts the postoperative early recurrence and poor prognosis in the patients with NSCLC with pure solid appearance on chest CT.
P3.16-10 RADIOMIC FEATURES ON CT ARE PROGNOSTIC OF RECURRENCE AS WELL AS PREDICTIVE OF ADDED BENEFIT OF ADJUVANT CHEMOTHERAPY IN ES-NSCLC

P. Vaidya1, K. Bera2, P. Fu3, S. Ganesan4, A. Khunger5, P. Patil6, V. Velcheti7, A. Madabhushi1

1Biomedical Engineering, Case Western Reserve University, Cleveland/US, 2Department of Biomedical Engineering, Case Western Reserve University, Cleveland/OH/US, 3Biostatistics, Case Western Reserve University, Cleveland/OH/US, 4Oncology, Cleveland Clinic, Cleveland/US, 5Cleveland Clinic, Cleveland/OH/US, 6Yokohama City University, Yokohama/JP, 7Taussig Cancer Institute, Cleveland Clinic, Cleveland/OH/US

Background: Early-stage non-small cell lung cancer (ES-NSCLC) accounts for approximately 40% of NSCLC cases, with 5-year survival rates varying between 31-49%. The decision to offer adjuvant chemotherapy for these patients is primarily dependent on several clinical and visual radiographic factors as there is a lack of biomarkers which can accurately stratify and predict disease risk. Method: Retrospective chart review between 2005-14 yielded 315 ES-NSCLC patients who underwent surgery with the primary tumor having relapsed in 75 cases. From the entire cohort, 74 underwent adjuvant chemotherapy. This cohort was randomly divided into a training (N=60) and validation (N=255). A total of 248 intratumoral (IT) and peritumoral (PT) radiomic textural features were extracted for every patient. The most stable, significant and uncorrelated features were selected from training cohort using LASSO Cox-regression model. Performance of imaging features was evaluated using hazard ratio (HR) and concordance index (CI). Linear Discriminant Classifier (LDA) was trained using top imaging features and performance of predicted labels was assessed using Kaplan-Meier survival curves and log-rank test. Result: Top nine radiomic textural features (from the Haralick, Laws, Gabor texture families) included a combination of four IT and five PT from 0-12mm distance outside the nodule. The features were prognostic of recurrence (N=255, CI=0.66, HR =1.8, p=0.05). To evaluate the predictive model, subset analysis was performed on the test set. The imaging feature based classifier was able to identify low and high risk groups in the surgery alone setting (N=181, CI=0.73, HR=4.4, p<0.005), potentially identifying patients who might have benefitted from adjuvant chemotherapy. Meanwhile, in the group of patients who received adjuvant chemotherapy following surgery, the classifier did not identify any difference between high and low risk groups (N=74, CI=0.69, HR=1, p>0.05). Conclusion: We identified radiomic features from within and outside lung nodule that were prognostic of recurrence and also predictive of added benefit of adjuvant chemotherapy in ES-NSCLC.

Background: The prognostic significance of epidermal growth factor receptor (EGFR) mutations in resectable lung adenocarcinoma is not well defined. We evaluated the influence of EGFR mutation status on postoperative recurrence timing with the use of event dynamics. Method: A total of 644 patients with lung adenocarcinoma who underwent complete resection and examined for EGFR mutation status between 2008 and 2015 were studied. Disease-free survival (DFS) were calculated using the Kaplan-Meier method and compared between EGFR mutation-positive patients (n=322) and EGFR wild-type patients (n=322). Event dynamics, based on the hazard rate, were evaluated and only first events (distant metastases or local recurrence) were considered. Result: There was no statistical significance in recurrence rate (9.9% versus 14.6%; p=0.09) between EGFR mutation-positive patients and EGFR wild-type patients. In patients with pathological stage I, DFS was significantly better in the EGFR mutant group than the wild-type group (p=0.009), whereas the EGFR mutant group had an inferior DFS compared with the wild-type group among patients with pathological stage II or higher (p=0.110). The resulting hazard rate curves indicated that the recurrence risk pattern was definitely correlated with EGFR mutation status, with an early highest peak during the first year for EGFR wild-type patients and a late maximum peak in the fifth year for EGFR mutation-positive patients.

radiotherapy (SABR) offers a promising alternative to these groups of or nonoperative options may be indicated, Stereotactic ablative surgical candidates, lesser minimal invasive pulmonary resections for all operable NSCLC. In most patients who are not operable Background: Cardiothoracic Department, Wellington Regional Hospital, Wellington/NZ P. Balakrishnan STAGE NON-SMALL CELL LUNG CANCER (NSCLC) – A REVIEW STEREOTACTIC BODY RADIOTHERAPY IN PATIENTS WITH EARLY P3.16-12 STANDARD CONVENTIONAL LOBECTOMY VS STEREOTACTIC BODY RADIOTHERAPY IN PATIENTS WITH EARLY STAGE NON-SMALL CELL LUNG CANCER (NSCLC) – A REVIEW P. Balakrishnan Cardiothoracic Department, Wellington Regional Hospital, Wellington/NZ Background: Lobectomy is the standard of care surgical treatment for all operable NSCLC. In most patients who are not operable surgical candidates, lesser minimal invasive pulmonary resections or nonoperative options may be indicated, Stereotactic ablative radiotherapy (SABR) offers a promising alternative to these groups of unhealthy patients. In this review, we look into various published studies & articles in various databases, to evaluate the survival outcomes, cost-effectiveness, complications & evidence-based conceptualizations behind both treatment modalities in these studies via a summarized review. Method: A extensive literature search was performed using MEDLINE, OVID & PUBMED search databases in the last 10 years. A retrospective review & meta-analysis of these papers were conducted using matched-pair analyses & propensity matched scoring & standard statistical analysis. A total of 21 papers were reviewed & a meta-analysis of these survival outcomes were compared between the standard conventional Lobectomy with the newer SABR treatment arm in early lung cancer patients. Result: Pending - applying for late-breaking abstract Conclusion: Pending - applying for late breaking abstract Keywords: NSCLC, lobectomy, SABR P3.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30 P3.16-13 LONG-TERM OUTCOMES OF STEREOTACTIC BODY RADIATION THERAPY FOR STAGE I NON-SMALL CELL LUNG CANCER IN PATIENTS LESS THAN 70 YEARS OF AGE Z. Chen, T. Akita, Y. Maehara, R. Saito, S. Aoki, K. Marino, T. Komiyama, H. Onishi Department of Radiology, University of Yamanashi Hospital, Chuo, Yamanashi/JP Background: We retrospectively analyzed the treatment outcome of stereotactic body radiotherapy (SBRT) for stage I non-small cell lung cancer (NSCLC) in patients less than 70 years of age. Method: We retrospectively analyzed patients with stage I (ct1-2aNOMO) NSCLC, treated with SBRT between 2000 and 2014. 43 consecutively treated patients less than 70 years of age were identified. Staging was reassessed by UICC 7th. Both biopsy-proven and clinically diagnosed stage I NSCLC were included. Overall survival (OS), cause-specific survival (CSS), local control rate (LCR), regional lymph node control rate (RLNCR), and distant control rate (DCR) were calculated and compared between subsets of patients. Kaplan-Meier estimates were used for survival analysis and evaluated by the log-rank test. Common Terminology Criteria for Adverse Events (CTCAE) v4.0 scales were recorded during follow-ups and utilized for toxicity assessments. Result: For the 43 patients included, median age was 65 years (Range: 50–69 years), median Karnofsky performance status was 100 (Range: 80–100), and median follow-up time was 58 months (Range: 7–193 months). Median prescription dose was 48 Gy in 4 fractions (Range: 48–70 Gy in 4–10 fractions). The rates for OS and CSS at 5 years were 63.8% and 91.5%, respectively. The 5-year LCR, RLNCR, and DCR were 92.4%, 91.7%, 78.7%, respectively. In the subsets analysis, patients were subcategorized into Group Ia and Group Ib, according to the T-stage, or subcategorized into Operable group and Inoperable group. Although there was no significant between the groups, Group Ia, and Operable group showed a better result in OS, but not in other parameters. Regarding treatment toxicity, severe (grade 3 or above) radiation pneumonitis occurred in 6.8% of the cases, and no other toxicities of Grade 2 or above were observed. Conclusion: SBRT for stage I NSCLC in patients less than 70 years of age yielded good long-term survival outcomes with acceptable toxicity. Keywords: lung cancer, SBRT, Younger patient P3.16-14 SBRT IN EARLY STAGES OF LUNG CANCER L. Fernández Fornos, S. Miranda Labajos, D. Esposito, P. Dorado Rodríguez, M.D. Ruiz Sánchez, D. Planes Meseguer, A. Pomares Arias, E. García Miragall Oncología Radioterápica, Hospital General Universitario de Elche, Elche/ES Background: We present the experience in our department with SBRT in early stages of lung cancer. Method: Between April 2012 and January 2018, 59 patients with 65 different locations underwent to SBRT in early stages of lung cancer (51 men and 8 woman, with a median age of 76 years). 44 patients had histological confirmation (22 adenocarcinomas, 13 squamous cell carcinomas, 1 adenosquamous and 1 typical carcinoid). There was not histological confirmation in 15 patients. In all patients, PET-CT was used for the diagnosis. The T-stage classification (8th edition of the TNM Classification), was the following: T1a (6), T1b (24), T1c (16), T2a (10), T2b (6), T3 (3). The treatment planning was made using vacuum body fixation and abdominal compression to reduce intrafractional organ motion. We made five CTS planning in all patients: 3 free breathing, inhalation and exhalation, the internal target volume (ITV) was delineated based on the fusion of five CTS. The planning target volume
**Kinetic Energy Distribution for Gated Technique at Lung Ablative Body Radiotherapy (SABR)**

**K. Li**

Radiation Oncology, John R Marsh Cancer Center, Hagerstown/US

**Background:** Gated technique could be applied for lowering the dose spillage of motion target stereotactic body radiotherapy. There are three clinical steps in gated therapy. The first is the target delineation with 4DCT, the second is the localization for region of interested based on selected gated window and CBCT images, and the third is the gated delivery. At current clinical scale, radiation and target formed six combinations, which were determined by motion and static state of both radiation and target at the condition of with and without gated approach. In this study, the kinetic energy distribution for phased targets were evaluated based on gated radiotherapy procedure.

**Method:** A Patient with tumor adjointed to the heart was selected to simulate a gated lung SABR case with 9 co-plane beams. The prescription was 50 Gy in 5 fractions. The internal target volume (ITV) based on window size was selected to be 20% to 60% of breathing cycle phase. And this fixed radiation beam aperture was determined by the sum of target from phases at 20%, 30%, 40%, 50% and 60%. The dosimetric characteristics of these individual targets, their sum, and overlap region were described with coverage level, conformity index, homogeneity index, and kinetic energy distribution was defined to be the product of mean dose and prescribed target volumes (PTVs) at different phase window sizes. The ranges of these energy distributions were compared with static target with static radiation beam. **Result:** For image sets at phase 20%, 30%, 40%, 50%, 60%, sum of these phase and overlap region, the ITVVs were 12.8cc, 14.2cc, 14.4cc, 16.2cc, 13.7cc, 25cc and 6.5cc; their corresponding prescription dose coverage were 96.6%, 98.2%, 96.1%, 96.3%, 97.9%, 95% and 99.3%; their corresponding conformity indexes were 1.0 Gy, and reduction in heart V5Gy of 10.3%, with p-values

**Keywords:** SBRT, Cardiac sparing, Cardiac toxicity

**Conclusion:** Cardiac sparing is feasible for early stage NSCLC patients treated with SBRT, without compromising target coverage, and with minimal increase in mean lung dose. As cardiac exposure is associated with increased mortality, cardiac sparing has the potential to increase survival, and should be considered for all early stage NSCLC patients treated with radiotherapy. This data will need to be confirmed in a larger, prospective cohort.

**P3.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.16-18 MODERN RADIOThERAPY INCREASES PATIENT ACCESS TO CURATIVE INTENT RADIOThERAPY IN NON-SMALL CELL LUNG CANCER**

**Northern Ireland Cancer Centre, Belfast/GB**

**Background:** Technical developments in the delivery of radiotherapy such as image-guided radiotherapy (IGRT) and intensity modulated radiotherapy (IMRT) have permitted the introduction of advanced radiation techniques such stereotactic ablative radiotherapy (SABR). These new techniques have the advantage of more accurate localisation of the tumour and reduced irradiation of normal tissues. In our centre, we have implemented a range of new techniques to deliver IGRT (such as PET/CT and 4-dimensional CT planning, and cone beam CT during treatment delivery). We postulate that using the advanced techniques increases the access to curative intent radiotherapy treatment of lung cancer. We seek to assess the access rates to curative intent thoracic radiotherapy.

**Method:** Using our institutional lung radiotherapy database we analysed the data recording intent of treatment with reference to the stage and performance status (PS) of all patients with stage 1-3 non-small cell lung cancer (NSCLC) in 2007 and compared this to the same population receiving radiotherapy during 2017 and up to April 2018. Result: In 2007, 217 patients with stages 1-3 NSCLC received any radiotherapy compared to 218 patients for the 2017/2018 cohort. Within the 2017/2018 cohort 96% of patients (n=94) received radical radiotherapy compared to 28% of patients in 2007 (n=26). Of the 94 patients receiving radical treatment in 2017/2018, 61% received SABR. This increase was largely due to the introduction of SABR. In those patients with stage 3 disease, overall fewer patients received any radiotherapy in 2017/2018 compared to 2007, however the number of patients receiving curative intent radiotherapy increased from 20 (13% of all stage 3 patients) to 44 (37%). Of note in those patients receiving curative intent radiotherapy there was an increase in access for patients with poorer PS, with only 7% of patients with a PS ≥2 in 2007 receiving curative intent radiotherapy compared with 42% of patients in 2017/2018. Conclusion: In our series, we report an increase in the proportion of patients with NSCLC receiving curative intent radiotherapy. Furthermore, more patients with a poorer performance status received curative intent radiotherapy. We suggest that the introduction of advanced radiotherapy techniques has permitted the curative intent treatment of patients who were previously treated with a palliative approach to management.

**P3.16-19 CLINICAL OUTCOMES OF STEREOTACTIC BODY RADIATION THERAPY FOR T2N0M0 NON-SMALL CELL LUNG CANCER**

**Y. Zhu1, C. Jiang1, W. Chen1, Q. Lin2, X. Sun1, K. Shao2, H. Wu2, Y. Xu3**

1First Clinical Medical School, Wenzhou Medical University, Wenzhou/ CN, 2The Hospital of Armed Police Corps of Zhejiang Province, Jiaxing/CN, 3Zhejiang Cancer Hospital, Hangzhou/CN

**Background:** For patients with inoperable stage I non-small cell lung cancer (NSCLC), stereotactic body radiation therapy (SBRT) is considered standard. However, the effectiveness and safety of SBRT specifically for T2N0M0 NSCLC remains controversial. This retrospective study investigated the safety and efficacy of SBRT in T2N0M0 NSCLC. **Method:** The medical records of 29 patients with T2N0M0 NSCLC treated with SBRT were reviewed. The overall, progression-free, and cause-specific survival rates were determined. **Result:** The mean follow-up was 20.1 months. At years 1, 2, and 3, the overall survival rates were 93.1, 93.1, and 89.7%, respectively; the progression-free survival rates were 96.6, 96.6, and 93.1%; the progression-free survival rates were 75.9, 65.5, and 62.1%; the local control rates were 100, 96.6, and 96.6%; the regional control was 86.2, 79.3, and 75.9%; and distant control was 89.7, 82.8, and 79.3%. Twenty patients (69.0%) developed symptoms of grade 1 toxicity: dyspnea, chest pain, fatigue, cough, esophagitis, or pneumonia. Among these, 5 patients suffered grade ≥2 therapy-associated pneumonitis, and one patient experienced grade 4 adverse pulmonary effects. **Conclusion:** SBRT was efficient and safe for patients with inoperable T2N0M0 NSCLC, imposing tolerable toxicities. These results warrant a prospective study to develop the multidisciplinary criteria for SBRT in T2N0M0 NSCLC.

**P3.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.16-20 FEASIBILITY OF LIMITED RESECTION FOR PERIPHERAL SMALL-SIZED NON-SMALL CELL LUNG CANCER ACCORDING TO FDG ACCUMULATION AND IMAGING FINDINGS**

**M. Aragaki, K. Kaga, Y. Hida, T. Kato, R. Chiba, Y. Motohashi, Y. Matsui**

Department of Cardiovascular and Thoracic Surgery, Hokkaido University Graduate School of Medicine, Sapporo, Hokkaido/JP

**Background:** With the progress of diagnostic imaging modalities, such as CT and FDG-PET, the number of resectable lung cancer, particularly small peripheral lung cancer, is increasing. We focused on the SUVmax of FDG-PET as a prognostic factor for lung cancer and established criteria for limited resection on the basis of CT findings and SUVmax. Since 2007, we continuously monitored the recurrence and prognosis of non-small cell lung cancers (NSCLCs) resected using our criteria. Here, we report the results of this study. **Method:** Between December 2007 and December 2015, 611 consecutive patients underwent surgery for NSCLC at our institution. Of these, 73 patients with CT staging T<3N<0M0 with promising limited resection (partial resection or segmentectomy) were enrolled. The criteria for undergoing limited resection were as follows: ① tumor SUVmax of ≥0.75 and ② tumor SUVmax of ≤1.5. GGO ratio was calculated using the following equation: GGO ratio=(maximum diameter of the tumor – (maximum diameter of tumor consolidation)) / (maximum diameter of the tumor). The group that met our criteria and underwent limited resection was designated as intended limited resection group (ILR group), and the group subjected to limited surgery without meeting the criteria treated as control group. **Result:** The study included 35 men and 38 women with a median age of 65 (range, 36–84) years. In total, 51 patients who met our criteria were included in the ILR group, and 21 patients who did not meet the criteria were included in the control group. The control group was selected for limited resection on the basis of complications, pulmonary hypofunction, and heart failure. Regarding surgical approach, in the ILR group, 19 patients underwent partial resection and 32 underwent segmentectomy; in the control group, 13 patients underwent partial resection and 8 underwent segmentectomy. According to our criteria, no relapsed cases were reported in the ILR group. Moreover, the 5-year overall survival rates of the ILR and control groups were 100% and 60.5%, respectively, and the disease-free survival rates were 100% and 56.0%, respectively, indicating a significant difference (P < 0.001). In the control group, 6 patients showed the recurrence of lung cancer. **Conclusion:** In this study, we analyzed the feasibility of our criteria for performing limited resection on the basis of CT findings and SUVmax. In the ILR group, no relapsed cases were reported, suggesting that our criteria may be useful in determining patient’s eligibility for undergoing reduction surgery.

**P3.16-21 ROBOTIC THORACIC SURGERY IN LUNG CANCER RESECTION – A COMPREHENSIVE REVIEW**

**P. Balakrishnan**

Cardiothoracic Department, Wellington Regional Hospital, Wellington/NZ

**Background:** Minimally invasive VATS thoracic surgery is currently the gold standard approach for most thoracic procedures. It has come along way since major maximally invasive thoracotomy approaches.
Minimally invasive thoracic procedures indefinitely has its distinctive positive outcomes & other secondary benefits to patients & surgeons. Introduction of robotic technique into thoracic surgery has brought huge advantage to patients & surgeons as well as maximised treatment modalities more efficiently. In the review, we will look into the state of art robotic thoracic surgeries available, feasibility, outcomes, accessibility & costs and the pitfalls. Methods: A extensive literature search was performed using MEDLINE, OVID & PUBMED search databases in the last 10 years. A retrospective review & meta-analysis of these papers were conducted using matched-pair analyses & propensity matched scoring standard statistical analysis. A total of 43 papers were reviewed & a meta-analysis of these studies in terms of feasibility, outcomes, accessibility & costs and the pitfalls were looked into. A summary review into the current state of robotic thoracic surgery, with the its current limitations and future adaptations were also looked into. Results: pending data collection & interpretation. Applied late-breaking abstract Conclusion: pending - applied late-breaking abstract

P3.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.16-22 WEDGE RESECTION FOR SMALL PULMONARY LESIONS WITH PREOPERATIVE BRONCHOSCOPIC BARIUM MARKING T. Furuya, T. Li, S. Toda Department of Thoracic Surgery, Osu City Hospital, Shiga/JP

Background: Barium marking is one of the various types of preoperative marking used with minimal pulmonary lesions. We evaluated the safety and efficacy of wedge resection for small pulmonary lesions after using preoperative bronchoscopic barium marking. Method: A retrospective study was conducted for patients who underwent barium marking before surgery between January 2009 and January 2018. Lesions were localized in advance by chest computed tomography (CT); then, a catheter was inserted into a bronchus close to the lesion under bronchoscopic guidance. Small amounts of barium sulfate (0.1-2 ml) was injected under fluoroscopic guidance. During surgery, the lung surface was observed with a thoracoscope to check color change by barium. In case of the absence of clear identification by visual inspection, the lung was palpated to search for the barium marker. Once the barium was detected, a grasping forcep was used to hold the lesion and barium en bloc, and a wedge resection was performed with stapling devices. Result: We retrospectively investigated 29 lesions in 29 patients who underwent barium marking before surgery. Five lesions were solid nodules with a longest diameter of 0.5–1.4 cm (mean, 0.9 cm). Eight lesions were partially solid nodules with an overall longest diameter of 0.8–2.2 cm (mean, 1.3 cm) and solid longest diameter of 0.3–0.8 cm (mean, 0.5 cm). Sixteen lesions were pure ground-glass nodules (GGNs) with an overall longest diameter of 0.7–1.7 cm (mean, 1 cm). The only complication of marking was mild pneumothorax that did not require drainage in 1 patient. On performing CT after barium marking, the distance between marked barium and the lesion was 0.0–3.7 cm (mean, 0.9 cm). The period between marking and surgery was 5–33 days (median, 15 days). We performed wedge resection in all cases, and all lesions were resected completely. Pathological results showed adenocarcinoma in situ in 20 patients, primary lung adenocarcinoma in 4, metastatic pulmonary tumor in 3. Inflammatory pulmonary nodule in 1, and an intrapulmonary lymph nodule in 1. All margins were pathologically negative. The only postoperative complication was arrhythmia that required an anti-arrhythmic drug in 1 patient. Conclusion: Wedge resection for small pulmonary nodules after using preoperative bronchoscopic barium marking was safely conducted with satisfactory outcomes.

P3.16-24 PROGNOSTIC VALUE OF POSITIVE LYMPH NODE RATIO IN NON-SMALL CELL LUNG CANCER J. He, H. Pan Thoracic Surgery, Guangzhou Medical University First Affiliated Hospital, Guangzhou/CN

Background: Previous studies had shown the importance of lymph node (LN) resection in TN NSCLC and recommended no less than 16 LN for those with high-grade sarcomas was significantly lower than that for low-grade sarcomas. Tumor size and age of patient were not prognostic. Result: Surgery is important in the treatment of most sarcomas. Resection was the primary treatment in 28 cases (87%). All patients were treated by multimodal treatment, chemoradiation therapy and surgery. Local recurrence developed in 25%. Metastases occurred in 15 (46%) of the cases (metachronous in 12, synchronous in 3) and were more common in patients with high-grade disease than in those with low-grade disease. Overall 5-year survival was 60%. Five-year survival rate for those with high-grade sarcomas was significantly lower than that for low-grade sarcomas. Tumor size and age of patient were not prognostic. Conclusion: Additional treatments, including chemotherapy and radiation therapy, may be administered before and/or after surgery. Thoracic wall soft-tissue sarcomas are best controlled by wide surgical resection.

Keywords: sarcoma, Soft tissue, chest wall resection

P3.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

Background: Soft tissues include muscle, fat, blood vessels, nerves, tendons and joint linings (synovial tissue). Cancerous tumors (sarcomas) of the soft tissue are rare, but there are many types. Because soft tissue sarcomas depend on the type, size, grade, stage and location of the tumor, as well as a person's age and general health. Classification from grade are low, midle, high differentiations. Aim of Study: Our objective was to introduce a patient diagnosed with neglected giant soft tissue chest wall liposarcoma. Method: Records of 32 patients admitted to our institution from January 2004 to July 2017 were treated in our clinic A patient with the initials K.B bored 17/06/1950. He was admitted to our hospital in thoracal surgery at 19.09.2012 with diagnosis : soft tissue tumor left chest wall. Patient without other diseases. We did all necessary examinations , CT, MRI and determined the extent of tissue tumor. Result: Ages ranged from 13 to 86 years (median, 38 years); the ratio of male to female patients was 3.1. The initial complaint was mass or pain in 98% of the cases. Histologic types were as follows: desmoid tumor (n = 5), 15%; liposarcoma (n = 7), 21%; rhadomyosarcoma (n = 6), 18%; fibrosarcoma (n = 4, 12%); malignant peripheral nerve tumor (n = 3, 9%); malignant fibrous histiocytoma (n = 1, 3%); tenosynovial sarcoma (n = 1, 3%); hemangioendothelioma (n = 2, 6%); alveolar soft part sarcoma (n = 2, 6%); and other types (lymphoma) (n = 2, 5%). Resection was the primary treatment in 28 cases (87%). All patients were treated by multimodal treatment, chemoradiation therapy and surgery. Local recurrence developed in 25%. Metastases occurred in 15 (46%) of the cases (metachronous in 12, synchronous in 3) and were more common in patients with high-grade disease than in those with low-grade disease. Overall 5-year survival was 60%. Five-year survival rate for those with high-grade sarcomas was significantly lower than that for low-grade sarcomas. Tumor size and age of patient were not prognostic.

P3.16-26 ANATOMIC SEGMENTECTOMY IN STAGE I NON-_SMALL-CELL LUNG CANCER REVEALS EQUIVALENT LONG-TERM OUTCOMES COMPARED TO LOBECTOMY
A. Hoda1, K. Sinn1, T. Stork1, A. Steindl1, G. Lang1, S. Taghavi1, T. Klikovits1, W. Klepetko2
1Thoracic Surgery, Medical University of Vienna, Vienna/AUT, 2Division of Thoracic Surgery, Medical University Vienna, Vienna/AUT

Background: Lobectomy represents the preferred surgical procedure for patients with early stage non-small cell lung cancer (NSCLC). The choice for the right surgical procedure for stage I patients remains controversial. Aim of our study is to analyze short term and long term outcome of patients undergoing anatomic segmentectomy compared to lobectomy. Method: In this retrospective cohort study we included all patients with stage I NSCLC undergoing anatomic segmentectomy or lobectomy from 2006 until 2013 at your institution. A Propensity Score analysis was carried out with respect to age, gender, cardiovascular comorbidities, lung function (FEV1 >60%) and histology (adenocarcinoma vs squamous cell carcinoma). Overall survival and disease free survival as well as morbidity were endpoints of the study Result: In total, 385 patients with peripheral located stage I NSCLC who neither underwent neoadjuvant nor adjuvant treatment were identified in our database. After applying propensity core matching, 47 patients underwent anatomic segmentectomy and lobectomy was performed in 47 patients. Of those 94 patients, 76 (81%), were in stage IA and 18 (19%) in stage IB. Adenocarcinoma was the histology in 67 (71%) patients and 27 (29%) patients had squamous cell lung cancer. 25 (27%) patients were operated by VATS and 69 (73%) patients underwent thoracotomy. In all patients, the postoperative complication rate was 11.7% and mean hospital stay was 9 days. There were no significant differences with regard to postoperative morbidity, 30- and 90-day mortality between the anatomic segmentectomy group and lobectomy group. 3- and 5-year overall survival (OS) were 79% vs. 84% and 69% vs. 76%, respectively. There was no significant difference between both groups regarding overall survival (p=0.302) and disease free survival (p=0.603). Interestingly, there was no significant difference in OS and disease free survival in both groups when tumor size was bigger than 2 cm (p = 0.728 and p = 0.432). Conclusion: The benefit of lobectomy over anatomic segmentectomy in patients with stage I NSCLC is still not clear. In our cohort, oncologic short- and long-term outcome of anatomic segmentectomy was comparable to outcome after lobectomy. However, the results of prospective randomized studies are warranted to clarify the value of sublobar resections for stage I NSCLC.

Keywords: Surgery, sublobar resection, lobectomy

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.16-25 IMPACT OF DIABETES MELLITUS ON SURVIVAL OUTCOME IN PATIENTS WITH PATHOLOGICAL STAGE IA NON-_SMALL-CELL LUNG CANCER
Department of General Thoracic Surgery, Juntendo University School of Medicine, Tokyo/JP

Background: The aim of this study was to investigate the impact of diabetes mellitus (DM) on prognosis of non-small cell lung cancer (NSCLC) patients with pathological stage IA. Method: A retrospective study was performed on 506 patients with pathological stage IA in NSCLC, who underwent complete resection between 2008 and 2012. We investigated the clinicopathological features and prognosis of patients with DM (DM group: N = 62) and those without (non-DM group: N = 444) retrospectively. Median follow-up period was 5.2 years. Result: The DM group consisted of more males, high serum CEA level, history of smoking and heart disease, vascular invasion and lymphatic permeation than the non-DM group. DM patients tended to have worse overall survival, disease specific survival (DSS), recurrence free survival (RFS) and disease specific survival (DSS) rate in the DM group (5-year OS rate, 76.0%; 5-year RFS rate, 90.6%; 5-year DSS rate 97.6%) (p = 0.001, p = 0.014; respectively). The univariate and multivariate analyses revealed that DM was an independent prognostic factor for RFS and OS (P = 0.027 and P = 0.020, respectively). There was no significant difference regarding OS and DSS rate in both groups when tumor size was bigger than 2 cm (p = 0.728 and p = 0.432). Conclusion: The benefit of lobectomy over anatomic segmentectomy in patients with stage I NSCLC is still not clear. In our cohort, oncologic short- and long-term outcome of anatomic segmentectomy was comparable to outcome after lobectomy. However, the results of prospective randomized studies are warranted to clarify the value of sublobar resections for stage I NSCLC.

P3.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.16-27 CLINICAL OUTCOME OF PREOPERATIVE INTERVENTION BRONCHOSCOPY FOLLOWED BY SURGERY
Y. Kato1, K. Furukawa2, R. Amemiya3, H. Furumoto2, S. Shigefuku2, N. Ikeda4
1Thoracic Surgery, Kanto Central Hospital, Tokyo/JP, 2Thoracic Surgery, Tokyo Medical University Ibaraki Medical Center, Ibaraki/JP, 3Thoracic Surgery, Tokyo Medical University Hospital, Tokyo/JP, 4Tokyo Medical University Hospital, Tokyo/JP

Background: The report of patients with respiratory disease who could receive surgery after bronchial intervention (IBV) is relatively rare. We still experience patients with advanced lung cancer that develops with severe dysplasia and bleeding. To assess the usefulness intervention bronchoscopy combined with surgery. Method: We experienced a total of 5 lung cancer patients treated by surgery after IBV at Tokyo Medical University Ibaraki Medical Center. Chief complaint were severe dysplasia in 4 cases and bronchial bleeding in one case. The lesions were located at central bronchus in 4 cases. Histological types were 2 squamous cell carcinomas, 1 adenocarcinoma, 1 large cell carcinoma, and 1 pleomorphic carcinoma. Endobronchial snare & argon plasma coagulation (APC) were firstly performed in 2 cases, airway stentings using Dumon stent or Dumen-Y stent in 2 cases, and endobronchial Watanabe spigot (EWS) in 1 case. We evaluated the clinical outcome retrospectively. Result: 4 cases with obstructive lesions were treated by endobronchial snare and APC, and the other 2 cases were used bronchial stent. EWS was used to occlude the bronchi in the purpose of stopping blood aspiration in advanced adenocarcinoma case. After reducing the massive bleeding using EWS, we could perform salvage surgery. Performance status improved from 2 and 3 to 1 in all patients. All cases showed their symptom improvements after IBV, and were examined full staging (cT4NOMO) and checked operative risk. Thereafter, we could undergo...
salvage surgery (lobectomy: 2, bi-lobectomy: 1, pneumonectomy: 1, tracheoplasty: 1, carinoplasty: 1). Mean time of IVB followed by surgery was 11.7 days. Overall survival was 22.5 months (4-107.2 months). 5 years survival was 50%, and recurrent rate was 40% (2/5), respectively. **Conclusion:** IVB followed by surgery is useful modality, and we should realize that there are some patients who can be treated by surgery after IVB because of improvements of their conditions. Also, IVB can be effective for reducing performance status.

**P3.16-28 SURGERY OF STAGE I NON-SMALL CELL LUNG CANCER IN PATIENTS AGED 70 YEARS OR OLDER**

Q. Kawamata

Surgery, Chonmichi Municipal Hospital, Chonmichi/JP

**Background:** Non-small cell lung cancer (NSCLC) is a typical disease of the elderly patients, and is becoming increasingly. Surgical resection is standard treatment for early-stage NSCLC. The strong predictor of long-term survival for lung cancer is reported to be age. We evaluate the influence of age for stage I non-small cell lung cancer in elderly patients 70 years or older.

**Method:** 156 cases with stage I (UICC 8th) non-small cell lung cancer aged 70 years or more who underwent surgery at our hospital between 2007 and 2016 were studied. The patients’ medical records were reviewed with age, gender, type of operation, postoperative morbidity, postoperative mortality and survival results. **Result:** There were 89 male and 67 female. The average ages were 78.2 years (range, 70-90 years). The 5-year survival of all patients was 75.7%. Two groups were compared: patients aged 70 to 79 years, patients aged 80 years or more. At pathologic analysis, 74.5% and 70.7% were stage IA, 25.5% and 29.3% were stage IB. Procedure performed was lobectomy in 52.1% and 39.7%, segmentectomy in 40.8% and 39.7%, and wedge resection in 71% and 20.7%. Postoperative complications were documented in 12 patients (12.2%) and 11 patients (19.0%) without any difference in two groups. The 30-day mortality was 0.6%, and the 90-day mortality was 0.6%. No case died for lung cancer and 14 cases (male 11) died for other disease in 5 years after lung resection in 79-79 years. The 5-year survival was 81.3%. 3 cases died for lung cancer and 12 cases (male 8) died for other disease within 5 years after lung resection in 80 years or more.

**Conclusion:** A total of 770 patients were included for study, 14 (1.8%) were non-small cell lung cancer, elderly, Prognosis

**P3.16-29 PREDICTION OF LYMPH NODE METASTASES IN CLINICAL T1ANOMO NON-SMALL CELL LUNG CANCER**

T. Tsai1, C. Liu2

1Division of Thoracic Surgery, Department of Surgery, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei/TW. 2Thoracic Surgery, Far Eastern Memorial Hospital, New Taipei City/TW

**Background:** Lung cancer with smaller tumor size is now frequently being detected because of prevalent use of computed tomography (CT) as a screening tool for pulmonary lesions. A small group of clinical T1N0M0 NSCLC have a worse prognosis than what they are expected to be, and nodal upstaging after surgery is a main reason. Prediction of the pathologic nodal upstaging is important. In our study, we aim to reappraise the prediction factors of nodal metastases in clinical T1N0M0 (AJCC 7th edition for lung cancer) NSCLC. **Method:** Cases of cT1aN0M0 NSCLC after surgical resections in National Taiwan University Hospital from 2011 to 2015 were retrospectively reviewed. The prediction factors of interest are tumor size, tumor ground glass opacity (GGO) percentage in chest CT, and preoperative serum carcinoembryonic antigen (CEA) level. Logistic regression model was done to find predictive factors for nodal upstaging. **Result:** A total of 770 patients were included for study, 14 (1.8%) were found to have pN0 (nodal upstaging) after pulmonary resection. Larger tumor size, less tumor GGO percentage, and higher preoperative serum CEA level are significant predictors for nodal upstaging. In pathology, less.

**Background:** Radical mediastinal lymphadenectomy is an essential part of lung cancer surgery. The purpose of preoperative mediastinal staging is to identify patients who benefit from induction treatment. However, even in early stage lung cancer some patients present with N1 or N2 disease only intra- or even post-operatively. Accordingly, this study aims to evaluate the impact of different surgical approaches and tumor size on the rate of nodal upstaging. **Method:** We performed an analysis of our prospectively collected database from January 2016 (for robotic assisted surgery January 2015) to March 2018 and nodal upstaging with regard to surgical approach and T status in all patients with early stage T1-2 NSCLC undergoing primary resection with curative intent. **Result:** A total of 452 T1 or T2 stage NSCLC patients were operated with curative intention. Upstaging occurred in 65 cases (14.4%), from which 43 (9.5%) patients had pN1 and 22 (4.9%) had pN2 disease. Staging was performed according to ESTS guidelines. 366 patients (81%) were preoperatively evaluated by PET/CT and/or EBUS. 293 patients received PET/CT and 169 of them had an additional EBUS. 73 patients received EBUS based on conventional staging without PET/CT. There was a significant difference (p=0.01) in upstaging between T1 and T2 tumors (10.5% (7%/3.5%)N2) and 19.4% (12.8%/6.6%)N2), respectively. A stratification based on the surgical approach is shown in Table 1.

(See next page)
P3.16-31 YOUNGER PATIENTS OPERATED FOR LUNG CANCER HAVE BETTER OVERALL SURVIVAL
T. Marjanski, R. Dziedzic, D. Davoodi, S. Josefszon, W. Ryzman
Department of Thoracic Surgery, Medical University of Gdańsk, Gdańsk/PL

Background: Median age of patients diagnosed with lung cancer is 63 years. Incidence of lung cancer in population of patients younger than 50 years of age is relatively low. The aim of this study was to compare the clinical outcomes of patients with early lung cancer onset (ELCO, onset before the age of 50) and late lung cancer onset (LLCO, onset after the age of 50).

Method: We have retrospectively analyzed the prospectively collected data of 1517 patients with Lung cancer treated in a Thoracic Surgery Department in the years 2007-2015. Patients were divided into two groups, group I - 78 patients with ELCO and group II - 1439 patients with LLCO. We have compared overall survival in unmatched and matched population. In order to reduce potential selection bias we performed a propensity-score matched analysis (based on exact matching – by sex, pTNM, type of operation, pathological diagnosis and Charlson Comorbidity Index). The latter analysis was performed in 65 ELCO patients with 453 LLCO patients.

Result: In the unmatched population we found no differences in gender, pTNM and type of surgery performed. Younger patients were also more likely to have typical carcinoid (23.1% vs 2.6%, p<0.05, OR 11.06 95%CI 5.695-21.380) and mucoepidermoid tumours (2.6% vs 0.3%, p<0.05, OR 0.455 95%CI 0.256-0.799). Older patients were more likely to have squamous cell lung carcinoma (39.7% vs 23.1%, p<0.05, OR 0.455 95%CI 0.256-0.799). Older patients more were likely to be smokers (82% vs 59%, p<0.05 OR 0.316, 95%CI 0.192-0.519). Median Charlson Comorbidity Index in younger population was 0 and in the older population was 1 (p<0.05). Five-year survival in ELCO group was 71.9% vs. 58.7% in LLCO group (p=0.008). The propensity score-matched analysis showed that younger patients had better survival rates compared to older patients (p<0.001 HR=0.559, 95%CI 0.360-0.865). Five-year survival in patients with ELCO was 77.6% comparing to 61.5% in LLCO patients (p=0.011).

Conclusion: Irrespective of the surgical approach the rate of N1 upstaging is significantly higher in patients with T2 tumors compared to T1 tumors. The rate of mediastinal upstaging is comparable in both groups. The distribution between T1 and T2 tumors needs to be taken into account when analyzing upstaging rates in primary lung cancer surgery.

Keywords: upstaging, lung cancer surgery, radical mediastinal lymphadenectomy.

P3.16-32 A STUDY OF POSTOPERATIVE RECURRENCE IN PATHOLOGICAL STAGE 1 NON-SMALL CELL LUNG CANCER PATIENTS
K. Mizuno1, M. Kuriyama2, M. Morishita3, Y. Araki2, A. Ishihara2, H. Maeda4
1Department of Thoracic Surgery, Nagoya City East Medical Center, Nagoya/JP, 2Department of Thoracic Surgery, Nagoya City East Medical Center, Nagoya/JP

Background: Even in pathological stage 1 non-small cell lung cancer, there are some cases in which recurrence occurs after surgical treatment. The prognosis of the recurrent cases is poor despite the early stage of their disease. An analysis of the clinicopathological factors of these recurrent cases may help improve the prognosis.

Method: A total of 199 patients underwent surgical treatment for primary lung cancer from July 2010 to December 2017 in our hospital. We retrospectively analyzed the clinicopathological factors of 131 patients (65.8%) with pathological stage 1 disease. To compare the clinical data, we divided the 131 patients into 2 groups depending on the presence of recurrence. Group A was recurrent cases and group B non-recurrence cases. For the statistical analysis, the t-test, F-test, and chi-squared test were used.

Result: Group A included 19 cases and group B 112 cases. The mean age was 71.3±5.4 years in group A and 70.7±8.0 years in group B (p=0.75). The procedures performed in group A were lobectomy in 14, segmentectomy in 2, and wedge resection in 3, while those performed in group B were lobectomy in 83, segmentectomy in 18, and wedge resection in 11 (p=0.13). The mean tumor size was 2.5±0.9 cm in group A and 2.0±0.9 cm in group B (p=0.05). In group A, pathologic T factor 1a was found in 0 patients, 1b in 3, 1c in 6, and 2a in 10. In group B, 1a was found in 17 patients, 1b in 48, 1c in 23, and 2a in 24 (p<0.05). Pleural lymphatic invasion (ly+) and venous invasion (v+) were found in 6 and 10 patients in group A and 14 and 17 patients in group B, respectively (p<0.05, p<0.01). The mean survival time after the operation was 1185.8±557.0 days in group A and 1034.3±736.0 days in group B (p=0.39).

Conclusion: The mean tumor size and pT outcomes showed significant differences between the two groups. Furthermore, ly+ and v+ indicate a high malignant potential and may be considered predictors of a poor prognosis in patients with early-stage lung carcinoma.

Keywords: recurrence, pathological stage 1 non-small cell lung cancer, postoperative adjuvant therapy.

P3.16-33 CHARACTERISTICS AND RISK FACTORS OF RECURRENCE AFTER SEGMENTECTOMY IN PATIENTS WITH CLINICAL STAGE I NON-SMALL CELL LUNG CANCER
A. Nakamura1, Y. Shimizu1, T. Goto1, S. Sato1, T. Koike2, M. Tsuchida2
1Thoracic and Cardiovascular Surgery, Niigata University, Niigata/JP, 2Thoracic and Cardiovascular Surgery, Niigata University Graduate School of Medical and Dental Sciences, Niigata/JP

Background: Although lobectomy is the standard surgical procedure for operable non–small cell lung cancer (NSCLC), sometimes we performed segmentectomy for compromised patients, and patients with small-sized NSCLC and adequate pulmonary function for curative intent. The aim of this study was to investigate first recurrence sites and risk factors of recurrence in NSCLC patients who underwent segmentectomy.

Method: We retrospectively reviewed 136 patients with clinical stage I NSCLC (the 7th edition of the TNM classification) who underwent segmentectomy at Niigata University Medical and Dental Hospital between 2000 and 2016. We investigated first recurrence site to classify as intrathoracic or extrathoracic recurrence. The significant demographic, clinical, and pathologic factors identified with the log rank test in univariate analyses were analyzed with the Cox proportional hazards regression model to examine independent predictors for recurrence in multivariate analysis. For the significant predictor, we determined optimal cutoff points by receiver operating characteristic (ROC) analysis and Youden’s Index.

Result: Of the 136 patients in this study, 81 were male and 55 were...
female, and the median age was 71 years (range, 41 to 86 years). During the median follow-up period of 1568 days (range, 15 to 6584 days), recurrence was observed in 11 patients. Intraoperative recurrence was developed only in 4 patients, including 2 patients with surgical resection margin recurrence. The 5- and 10-year recurrence-free probabilities were 89.7% and 89.7%, respectively. Solid tumor component size on computed tomography (CT) was identified as an independent significant predictor (hazard ratio [HR], 3.459). To illustrate ROC curve and use Youden's index, the optimal cutoff points were determined as 1.5 cm for solid component size on CT. Conclusion: In the study, the NSCLC patients with solid component of larger than 1.5 cm on CT had a higher risk for postoperative recurrence after segmentectomy. However, it is still unknown whether these patients could be cured by lobectomy, because many of the patients with postoperative recurrence had extrathoracic recurrence.

Keywords: segmentectomy, recurrence

P3.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.16-34 THE IMPACT OF PREOPERATIVE EXERCISE THERAPY ON THE SURGICAL OUTCOMES OF PATIENTS WITH LUNG CANCER AND COPD: A SYSTEMATIC REVIEW AND META-ANALYSIS

W. Nan1, X. Li1, S. Li1, S. Yan1, Y. Wang1, X. Wang1, A. Siho2, Y. Yang1
1Department of Thoracic Surgery II, Peking University Cancer Hospital & Institute, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing/CN, 2Department of Surgery, The University of Hong Kong, Hong Kong/CN

Background: Although isolated studies have looked at the impact of preoperative exercise on patients with lung cancer and chronic obstructive pulmonary disease (COPD), a comprehensive meta-analysis of the available data has hitherto been lacking. Method: Articles were searched from PubMed, Embase, and Cochrane library, with the following criteria: lung cancer patients with or without COPD; undergoing resection; receiving preoperative exercise training. Key outcomes were analyzed using meta-analysis. Result: Seven studies containing 404 participants were included. Patients receiving preoperative exercise training had a lower incidence of postoperative pulmonary complications (PPCs) (Odds Ratio [OR] 0.35, 95% Confidence Interval [CI] 0.21 to 0.59) and shorter length of hospital stay (Standard Mean Difference −1.02 days, 95% CI −1.31 to −0.74 days). Exceptionally, incidence of pneumonia remained unchanged. Patients with COPD could not obviously benefit from exercise training to reduce PPCs/OR 0.44, 95% CI 0.18 to 1.08) but still might achieve faster recovery. No significant difference in pulmonary function was observed between the two groups. However, 6-minutes walking distance and VO2 peak were significantly improved after exercise training. Conclusion: Preoperative exercise training might not reduce PPCs for COPD patients undergoing lung cancer resection, but still facilitate faster recovery. Muscle capacity was strengthened after rehabilitation, which emphasized the possible mechanism of the protocol design.

Keywords: Preoperative exercise, lung cancer, copd

P3.16 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.16-35 STAIR CLIMBING EXERCISE MAY AMELIORATE PULMONARY FUNCTION IMPAIRMENT IN PATIENTS AT ONE MONTH AFTER LUNG CANCER RESECTION

Y. Wang, S. Yan, X. Wang, X. Li, S. Li, Y. Yang, W. Nan
Department of Thoracic Surgery II, Peking University Cancer Hospital & Institute, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing/CN

Background: Surgical resection remains the primary treatment for patients with localized non-small cell lung cancer (NSCLC). Despite the possibility of a cure, lung resection is associated with an immediate pulmonary function impairment. Stair-climbing test as a reliable indicator of pulmonary function, is often performed preoperatively to select patients. It also has been reported that stair-climbing yielding greater values of VO2 is a more stressful exercise than cycle ergometry. The benefits of this intervention in postoperative patients remain unclear. Thus, this study aimed to evaluate the effects of performance at the postoperative symptom-limited stair climbing exercise on pulmonary function. Method: We retrospectively analyzed 36 consecutive NSCLC patients undergoing video-assisted thoracoscopic surgery lobectomy and systematic mediastinal lymphadenectomy from November 2017 to January 2018. In the postoperative pulmonary rehabilitation program, all patients were suggested to perform symptom-limited stair climbing exercise in addition to routine physiotherapy (walking, incentive spirometry, breathing) from the first day after surgery. Patients were encouraged to climb gradually to the maximum number of floors at a pace of their own choice, and to stop in case of exhaustion, insufferable pain, limiting dyspnea or leg fatigue. A nursing professional was indispensable for the management of chest drains and supervision of any symptoms. Heart rate, pulse oxygen saturation were continuously measured using a portable pulse oximeter. Stair climbing exercise was performed at least twice a day during and after hospital stay. According to their performance of the exercise, patients could be divided into two groups. Stair climbing group completed the exercise training as planned, while routine physiotherapy group was reluctant to stair climbing exercise except for routine physiotherapy. Pulmonary functions were performed on all patients preoperatively and at one month postoperatively. Result: Totally, 25 patients (15 in stair climbing group and 10 in routine physiotherapy group) were included in the final analysis. The average preoperative and postoperative FEV1 for patients in two groups were 2.69±0.83 L vs. 3.08±0.72 L (p=0.244) and 2.08±0.72 L vs. 2.23±0.60 L (p=0.592), respectively. The difference in FEV1 decline between stair climbing group and routine physiotherapy group was significant (0.61±0.26 L vs. 0.84 ± 0.23 L, p=0.032). Conclusion: This study suggested that symptom-limited stair climbing as a more stressful exercise performed postoperatively in patients may ameliorate pulmonary function impairment at one month after lung resection. Prospective randomized controlled trials are therefore warranted.

Keywords: lung cancer, Pulmonary Function, stair climbing

Background: Survival benefit of adjuvant chemotherapy (AC) of patients with intrapulmonary lymph node (IPLN) metastasis (level 12–14) needs investigation. We evaluated the impact of AC on patients whose metastatic nodes were limited to intrapulmonary levels after systematic dissection of N1 nodes. Method: First, 155 consecutive cases of lung cancer confirmed as pathologic N1 were collected and evaluated. Patients received systematic dissection of N2 and N1 nodes. For patients with IPI metastasis, survival outcomes were compared between those receiving AC and those not receiving AC. Result: In this group, 112 cases (72.3%) had IPI metastasis and 55 cases (35.5%) had N1 involvement limited to level 13–14 without further disease spread to higher levels. Patients with IPI involvement had a better prognosis than that of patients with hilar–interlobar involvement. For the intrapulmonary N1 group (level 12–14-positive, level 10–11-negative or unknown, n = 112), no survival benefit was found between the AC group and non-AC group (5-year overall survival 54.6±1.6 vs. 50.4±2.4 months, p = 0.177, Figure 1A). However, 76 of 112 cases for whom harvesting of level-10 and level-11 nodes was done did not show cancer involvement in pathology reports (level 12–14-positive, level 10–11 both negative), oncologic outcome in this group was better for patients receiving AC than those not receiving AC (5-year OS: 57.3±1.5 vs. 47.1±3.2 months, p = 0.002, Figure 1B). Similarly, survival benefit of AC didn’t exist in patients with lymph node metastasis to level 13–14 (level 13–14-positive, 10-12-negative or unknown, n=55, Figure 1C), but was found in 38 patients with complete examination of N1 nodes (58.3±1.7 vs. 51.0±4.2 months, p = 0.048, Figure 1D).

(See next page)
Conclusion: Oncologic outcome may be improved by AC for patients with involvement of N1 nodes limited to intrapulmonary levels after complete examination of N1 nodes.

**P3.16-37 COMPARISON OF LONG-TERM OUTCOMES BETWEEN VATS AND OPEN LOBECTOMIES FOR STAGE I NSCLC: PROPENSITY SCORE-MATCHING ANALYSIS**

Dept. Oncology, Immunology and Surgery, Nagoya City University Graduate School of Medical Sciences, Nagoya/JP

**Background:** Video-assisted thoracoscopic surgery (VATS) lobectomy is widely spread for patients with clinical stage I non-small cell lung cancer (NSCLC). The postoperative survival and safety of VATS lobectomy are reported equal or better than those of open lobectomy. **Method:** We retrospectively reviewed the clinical data of 186 patients underwent lobectomy with clinical and pathological stage IA NSCLC from January 2008 to December 2013. Perioperative clinical factors and outcomes of patients with clinical and pathological stage IA NSCLC who underwent lobectomy were compared between VATS (n=63) and thoracotomy (n=123) using a propensity score-matching analysis. **Result:** In the analysis of 61 matched cases, the VATS group showed decreased blood loss and lower value of the C-reactive protein (CRP) at the peak, despite longer operative time. The VATS group demonstrated a significant longer survival, despite greater number of preoperative comorbidities than the thoracotomy group. The 5-year overall survival (OS) of VATS and thoracotomy were 100% and 89% each (log-rank p=0.02). The 5-year disease-free survival (DFS) of VATS and thoracotomy were 100% and 81% in each (log-rank p<0.01). **Conclusion:** The results of this study indicate that VATS has some advantages compared with thoracotomy in early stage lung cancer patients.

**Keywords:** non-small cell lung cancer (NSCLC), Video-assisted thoracoscopic surgery (VATS), lobectomy

**P3.16-38 SYSTEMATIC REVIEW AND META-ANALYSIS OF METHODS TO PREDICT POSTOPERATIVE LUNG FUNCTION FOLLOWING LUNG CANCER RESECTION**

N. Oswald1, J. Halle-Smith1, R. Mehdi2, A. Turner1, B. Naidu1

1University of Birmingham, Birmingham/GB, 2Thoracic Surgery Research, Heartlands Hospital, Birmingham/GB

**Background:** Prediction of postoperative lung function is a critical part of assessment of fitness for lung cancer resection. Multiple techniques of prediction have been reported but formal assessment of the comparative accuracy of these methods has not been performed. **Method:** A systematic review and meta-analysis using the generic inverse variance method was performed according to a prospectively registered strategy (PROSPERO ID:[CRD42017058955]). Extraction of accuracy measures to predict postoperative FEV1, FVC and TLCO was planned; assessment of bias was performed using a preliminary version of the PROBAST tool. **Result:** Searches retrieved 3817 studies, of these 17 met inclusion criteria and passed risk of bias assessment for inclusion in meta-analysis. Most studies measured FEV1. Only 1 study which passed risk of bias assessment reported absolute TLC values. All techniques had a Standard Error range of more than the minimum clinically important difference in FEV1 of 100ml, CT measures of lobar volume and lung tissue density had the lowest range at 207ml. **Conclusion:** Prediction based on the commonly used methods of segment or subsegment counting gives imprecise estimates of postoperative lung function and may lead to patients being turned down for curative resection. More precise methods using CT density and volume are preferable. There is inadequate evidence to justify any prediction technique for postoperative TLC over another.

**Keywords:** Prediction, Surgery, lung function

P3.16-39 WHICH SURGERY FOR GROUND GLASS OPACITY LUNG NODULES?
S. Ricciardi1, A. Nesti2, V. Aprile3, S. Korasidis3, P. Dini4, M. Ambrogi4, M. Lucchi4
1Department of Surgical Medical Molecular Pathology and Critical Care, Division of Thoracic Surgery, University Hospital of Pisa, Pisa, Italy, University of Pisa, Pisa/IT. 2University of Pisa, Pisa/IT. 3Department of Surgical Medical Molecular Pathology and Critical Care, Division of Thoracic Surgery, University Hospital of Pisa, Pisa/IT. 4Department of Surgical Medical Molecular Pathology and Critical Care, Division of Thoracic Surgery, University Hospital of Pisa, Pisa, Italy, University of Pisa, Pisa/IT

Background: Pulmonary ground glass opacity (GGO) nodules represent a significant dilemma in oncology since its diagnosis in clinical practice has increased because of growing application of low-dose computed tomography and screening programme. The aim of this study is to analyse the clinical and pathological features, the overall survival (OS) and Disease Free Interval (DFI) in surgically resected solitary ground glass nodules in order to assess the surgical treatment of choice. Method: We retrospectively analysed 49 patients (M=25/24) with a mean age of 67.7 years (range 40-81) who underwent lung resection for solitary GGO nodules among 570 reviewed CT of patients treated for lung neoplasms between 2010 and 2016. The cohort included 22 pure GGO nodules and 27 part-solid GGOs (also called mixed GGOs). Result: Median maximum diameter of GGOs, defined as the largest axial diameter of the lesion on the lung-window setting, was 17 mm (range,5–30). GGO nodules were removed by wedge resection, segmentectomy, sublobar resections or lobectomy, respectively. Pathology showed minimally invasive adenocarcinoma (MIA), invasive adenocarcinoma (IA) or multifocal adenocarcinoma (MAC) in 9 (18%), 7 (15%) and 3 (6%) cases, respectively. With a median follow up of 47 months the OS and DFI of the entire cohort was 46.3% and 43 months respectively. The histotype (p=0.008), the size of GGO (p=0.014) and the PET-SUV max (p=0.001) were independent prognostic factors of worse survival. Sex, age, previous lung surgery, type of surgical resection and the mediastinal lymph-node evaluation did not impact on OS and DFI. Analysing the 22 pure GGO nodules, we found a 3-year OS and DFI of 98% and 100% respectively, significantly different from 80% and 75% respectively of part-solid GGOs, (log-rank p=0.043 and p=0.011). Conclusion: Our data suggest an individualized approach of tumours presenting as solitary GGO nodules, especially in case of pure GGOs. In our series wedge resections guarantee the same results in terms of OS and DFI when compared to lobectomies. Sublobar resections without mediastinal lymph-nodes evaluation represent the treatment of choice for pure-GGO. More studies are needed to assess its role for part-solid GGO nodules.

P3.16-40 DELAYED CUT-END RECURRENT AFTER WEDGE RESECTION FOR PULMONARY GROUND-GLASS OPACITY ADENOCARCINOMA
K. Sekihara1, J. Yoshida2, M. Oda3, M. Tsuboi2
1Thoracic Surgery, National Cancer Center Hospital East, Kashiwa/JP, 2Thoracic Surgery, National Center for Global Health and Medicine, Shinjuku/JP, 3General Thoracic Surgery Department, National Center for Global Health and Medicine, Shinjuku/JP

Background: Prognosis of surgically resected stage I adenocarcinoma was relatively fair with up to 75% of 5 year disease free survival rate. However, in some cases, in spite of the very small-sized tumor, recurrence as systemic metastasis is found. Solid or micropapillary subtype adenocarcinoma are reported as poor prognostic subtypes, and additional treatment after surgical resection for those subgroup was required to improve survival. We reported that incidence of PD-L1 strong positivity is significantly higher in solid–predominant subtype of adenocarcinoma, PD-L1 inhibitor can be more effective adjuvant treatment modality in this subtype. Method: Design: Open-label, single arm, single center, phase 2 trial. (NCT03254004) Eligibility: The subject must have primary lung adenocarcinoma with stage 1 and less than 4 centimeter, whose tumor should be solid-predominant or microc papillary (~5%) by posturgical pathological examination. Objective: The primary objective of this study is to assess the improvement of disease-free survival rate by adjuvant therapy with pembrolizumab for solid or micropapillary adenocarcinoma with pathologic stage I and tumor size less than 4 cm. The secondary objective is to assess the safety profile of adjuvant pembrolizumab in an adjuvant setting. Treatment: Pembrolizumab 20mg IV infusion every 3 weeks for 12 months until disease progression or prohibitive toxicity. The treatment should be started within 8 weeks after surgery. Statistics: The hypothesis is that adjuvant pembrolizumab will improve 3-year disease-free survival from 65% to 80% in pathologic stage Ia lung adenocarcinoma patients with solid/micropapillary subtypes. Assuming that the subject enrollment period is 1.5 years, follow-up of last registered subject period is 4 years, and the disease free survival period follows the exponential distribution, a significance level 5% (one side) and 63 peoples are required 85% at the power of test. At this time, assuming that the dropout rate is 10%. It is necessary to register 70 subjects Assessment : Chest CT (covering up to both adrenals) will be done every 3 months till 1 year since the study treatment, and then every 4 months afterward till 2 years and thereafter every 6 months till 3 years. Brain MRI and bone scan will be done at 1 year and 2 years since the study treatment. This study is an investigator-initiated trial with support from MSD. Result: Section not applicable Conclusion: Section not applicable

P3.16-42 EARLY STAGE NON-SMALL CELL LUNG CANCER SURVIVAL IN A CHILEAN PRIVATE TEACHING HOSPITAL
F. Suárez1, M. Fica2, V. Linacre3, R. Aparicio2, C. Suárez Cruzat2
1Thoracic Surgery Department, Clínica Santa María, Santiago/CL, 2Thoracic Surgery, Clínica Santa María, Santiago/CL

Background: Lung cancer is the leading cause of cancer death worldwide. The long-term survival is one the most important outcome for therapies in oncology. In early stages, it permits to adequately evaluate the quality of epidermal growth factor receptor (EGFR) gene mutation or echinoderm microtubule-associated protein-like 4 (EMI4) - anaplastic lymphoma kinase (ALK) fusion gene. A negative biopsy speciﬁcally for the second adenocarcinoma also had no EGFR mutation or EML4–ALK fusion gene, however, the lobectomy specimen had EGFR mutation (L858R in exon21).

Conclusion: Small papillary-predominant adenocarcinoma might develop delayed cut-end recurrence more than 5 years after limited resection. Careful follow-up with special attention to the cut-end(S1) is necessary ideally for 10 years.

Keywords: minimally invasive, lung cancer, wedge resection
of the oncological resections of thoracic surgery teams, and in advanced stages it evaluates the quality of the multidisciplinary teams. Screening programs and early diagnosis are the most efficient way to improve survival in lung cancer patients. The results of the surgical treatment in early-stage non-small cell lung cancer of our center is presented.

**Method:** All patients treated by our thoracic surgery team for early-stage non-small cell lung cancer, between June 2010 and December 2017, were entered prospectively and consecutively to a web database. Demographic, clinical and pathological data, as well as every adverse event were recorded. All our patients underwent to an exhaustive staging process. Statistical descriptive analysis of clinical and demographic variables and 5 year overall survival by stage are shown. **Result:** 174 patients were included with median age of 67.7 years old (range 38-86 years), 51.7% female. Adenocarcinoma was the most frequent histology (60.9%). 81% were treated in Stage I and 29% in Stage II. For Stage I patients, the median follow-up time was 50 months (IQR: 23.6 - 70.3), and 5-year overall survival 89.79% (95% CI 82.11-94.29). For Stage II patients, the median follow-up time was 33.6 months (IQR: 16.9 - 56.1), and 5-year OS 63.47% (95% CI 33.2-82.91) Stage Ia and Ib patients had similar 5y OS: Ia 89.26% (95% CI 80.09-94.35) and Ib 91.3% (95% CI 68.98-97.82) **Conclusion:** The epidemiological profile of our patients is similar to that published in most of the series, and adenocarcinoma is the main histology in early stage NSCLC in our center. 5-year overall survival in stage I patients are good compared to other international publications, which we believe is directly related to the exhaustive preoperative and intraoperative study. Correctly assessing the cardiopulmonary capacity of patients allows us to reduce postoperative morbidity and mortality. Accurate staging (imaging, systematic lymph node dissection) allows our group to ensure that stage I patients are actually in stage I, avoiding sub-treating patients who might otherwise require adjuvant therapy.

**P3.16-43 IS SUBLOBAR RESECTION FOR STAGE I INVASIVE ADENOCARCINOMA (≤2-CM) FEASIBLE?**

Y. Terada1, T. Takahashi1, J. Nitadori1, K. Kitano1, K. Nagayama2, M. Anraku1, M. Sato1, A. Shinozaki-Ushiku1, S. Morita1, J. Nakajima1
1Department of Thoracic Surgery, The University of Tokyo Hospital, Tokyo/JP, 2Department of Pathology, The University of Tokyo Hospital, Tokyo/JP

**Background:** Recent studies have reported that sublobar resection is not inferior to lobectomy for small-sized non-invasive adenocarcinoma (ADC); however, the adequacy for small-sized invasive ADC (IAD) remains unclear. The objective of this study was to identify prognostic factors and validate sublobar resection for small-sized IAD. **Method:** We retrospectively reviewed patients with therapy-naïve, pathological stage I (≤2-cm) IAD, who had undergone complete resection from 1998-2015. Each tumor was evaluated by comprehensive histologic subtyping according to the 2015 World Health Organization classification. Overall survival (OS) and recurrence-free survival (RFS) was estimated using the Kaplan-Meier method. **Result:** 179 patients met inclusion criteria. 104 (58%) were male and 75 (42%) were female, with a median age of 68 years; sublobar resection was performed in 35 (20%), and lobectomy or pneumonectomy in 144 (80%). Median pathological tumor size was 1.5 cm, with a median invasive component size of 0.9 cm, and pleural, lymphatic, or vascular invasion in 27 (15%), 25 (14%), and 49 (23%) patients, respectively. In IAD, the elderly patients and ever smokers were likely to undergo sublobar resection (p<0.015, 0.011, respectively). Patients undergoing sublobar resection for IAD had significantly worse prognosis (5-year OS: 59.9%, 90.2%, p<0.0001) and increased risk of local recurrence (5-year RFS: 60.0%, 87.6%, p<0.0001). Multivariable analysis revealed that sublobar resection, age, and sex was an independent risk factor of overall survival and sublobar resection and vascular invasion was an independent risk factor of recurrence for IAD ≤2-cm.

**Conclusion:** Sublobar resection in patients with IAD ≤2-cm was significantly associated with increased risk of recurrence and worse prognosis.

**Keywords:** Adenocarcinoma, sublobar resection

**P3.16-44 ROBOTIC-ASSISTED THORACIC SURGERY FOR EARLY-STAGE NON-SMALL-CELL LUNG CANCER: INITIAL EXPERIENCE IN BRAZIL**

R. Terra1, B. Bibas1, R. Haddad1, J.R. De-Campos1, P.H. Nabuco-De-Araújo1, C.E. Lima2, F. Braga2, L. Lauricella3, P. Pego-Fernandes4
1Thoracic Surgery, Universidade de São Paulo, Faculdade de Medicina, Hospital Das Clínicas, Instituto Do Câncer Do Estado de São Paulo, São Paulo/SP, 2Thoracic Surgery, Hospital das Clínicas, Instituto Do Câncer Do Estado de São Paulo, São Paulo/SP, 3Thoracic Surgery, Universidade de São Paulo, Faculdade de Medicina, Hospital Das Clínicas, Instituto Do Câncer Do Estado de São Paulo, São Paulo/BR, 4Thoracic Surgery, Catholic University of Rio de Janeiro and Hospital Copa Star – Rede D’Or, Rio de Janeiro/BR

**Background:** Robotic approach for anatomic lung resection has brought an innovative development in minimally invasive thoracic surgery. The aim of this was to assess the safety and effectiveness of robot-assisted resection in patients with stage I-II non-small-cell lung cancer (NSCLC) in Brazil. **Method:** Retrospective analysis of prospectively maintained databases of 2 groups of surgeons from São Paulo and Rio de Janeiro,
respectively. We retrieved data regarding demography, diagnosis, operative time, lymphadenectomy, and morbidity of patients undergoing robotic surgery from March 2016 to April 2018. Continuous variables are presented as means and standard deviation. The Shapiro–Wilk test was used for the assessment of normality. Non-parametric data is represented as medians. Categorical variables are presented as absolute numbers and percentage. Alpha error was defined as 5%. Result: 140 consecutive patients were included (80 Males/60 Females). Mean age was 66 ± 9 years old (range:30-85). The majority of patients had adenocarcinoma (n=101;72%), followed by epidermoid (n=29;21%) and carcinoid tumors (n=10;7%). Lobectomy was the most common operation (n=119;85%), followed by anatomic segmentectomies (n=21;15%). Mean overall operative time was 209 ± 80 minutes (214 ± 80 for lobectomies and 167 ± 51 for segmentectomies; p=0.01). Mean number of lymph nodes resected was 12 ± 6, and the mean number of lymph nodes stations sampled was 1. There was no conversion to either VATS or thoracotomy in our series; neither major intraoperative bleeding. Postoperative complications occurred in 30 patients (21%). Prolonged air leak was the most common (n=13;9%) and 7 patients were discharged with a chest tube. Chylothorax occurred in 4 patients (2.8%), but all were treated with dietetic measures. Median length-of-stay was 3 days (IQR:2-6). The overall 30-day mortality was 0.5% (n=1). One patient had a procedure-related death, 25 days after a lobectomy. He developed pneumonia, sepsis and multiple organ failure. 138 patients (98.5%) are still under follow-up. Disease recurrence occurred in 7.8% of patients (n=11). Conclusion: Robot-assisted pulmonary resection is safe, effective and provides good outcomes, even within the context of an initial experience. Further follow-up should provide insight regarding long-term oncologic disease control.

Background: The Lung Cancer Screening Trial demonstrated improved overall survival (OS) and lung cancer specific survival (LCSS), likely due to finding early-stage non-small cell lung cancer (NSCLC). Patients with a past history of lung cancer were excluded from this trial. The purpose of our investigation is to suggest whether long-term surveillance strategies (4 years after surgical resection of the initial primary lung cancer (1LC)) would be beneficial in NSCLC patients by assessing the rates of second lung cancers (2LC) and the LCSS in 1LC as compared to 2LCs when treated surgically. Method: The SEER13/18 database was retrospectively reviewed for years 1998-2013. The 1LC population(N=58,758) consisted of all patients with Stage I-III (A JCC 6th) NSCLC undergoing definitive resection, while the 2LC population (N= 384) consisted of LC patients who developed a 2LC > 48 months after 1LC. Log-rank tests were used to determine the OS/LCSS differences between the 1LC and 2LC in the entire surgical group (EG) and in those having an early-stage tumors (ESR, tumors <4cm with no node involvement). Jointpoint analysis was used to assess changes in rates of 2LCs in correlation with age, resection type, and race. OS in the 1LC and 2LC decreased with divorce, positive nodes, and poor differentiation. Conclusion: Because the rate of 2LCs is increasing and because the OS/LCSS of the 1LC and 2LC are similar in early-stage lesions, we feel that continued surveillance of patients in order to find early-stage disease may be beneficial.

Keywords: Lung cancer; survivorship; second cancers
were used obtained good wound healing at the drain insertion site. **Conclusion:** When air leakage occurs, air evacuation with the only BD drains has both air inner lumen and liquid duct channels for drainage capability. Therefore, we think Coaxial Drains provide proper drainage of both air and fluid after pulmonary resection.

**Keywords:** Coaxial Drain, lung cancer surgery

**Conclusion:** Approximately 30% of NSCLC patients are diagnosed at early stage. Although surgery is curative treatment in early stage, recurrences are frequent. Preoperative SUV max (of primary tumor in PET/CT might be a predictor of postoperative relapse for operated NSCLC.

**Keywords:** PET/CT, SUV-max of primary tumor, Early stage lung cancer
were 70.9%, 55.6%, and 71.2% respectively. No grade 4/5 toxicities were observed, and there were 5 late grade 3 events (2 non-malignant pleural effusions, 2 episodes of hemoptysis, 1 one esophageal stricture) with an estimated rate of 21% at 1 year. UVA revealed worse survival in patients with increasing maximum dose to the esophagus, carina, heart, pulmonary artery, and spinal cord, and increasing mean dose to the esophagus (≥0.05 for each). Patients who received a cumulative point max dose of ≥ 7500 cGy to the esophagus, ≥11620 cGy to the heart, ≥12000 cGy to the pulmonary artery, or ≥3250 mean dose to the esophagus had significantly worse survival than those who did not (all p<0.05). Conclusion: PT re-irradiation is a viable treatment option for patients with thoracic recurrences and offers excellent outcomes with limited toxicity. In this study, we identified dosimetric parameters associated with worse survival that can be used in treatment planning for recurrent disease.

WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.17-03 SURVIVAL AND SIDE EFFECTS IN NON-SMALL CELL LUNG CANCER PATIENTS TREATED WITH COMBINATION OF CHEMOTHERAPY AND CONFORMAL RADIOTHERAPY
S. Crvenkova
Lung Cancer, University Clinic of Radiotherapy and Oncology, Skopje/MK

Background: Combined modality therapy is standard of care for patients with unrespectable locally advanced non-small cell, however, insufficient data are available regarding what is the best combination of chemotherapy and radiotherapy. Method: s: To evaluate the treatment results, study of 85 patients was randomly assigned to one of the two treatment arms. In the sequential arm, 45 patients had previously received sequential chemotherapy with 4 cycles of carboplatin and etoposide followed by conformal radiotherapy (RT). In the second concurrent arm, 40 patients received concomitant chemotherapy of cisplatin and etoposide and conformal RT, followed by two cycles of consolidation chemotherapy of carboplatin and etoposide. We described all phases of the conformal RT. Result: s: From October 2005 to April 2008, 85 patients were enrolled. The median survival was 13 months for the patients in the sequential arm and 19 months for those in the concurrent treatment arm. The differences were statistically significant (log-rank test p=0.0039) Figure 1. The disease-free survival was 9 months in the sequential arm and 16 months in the concurrent treatment group. The differences were statistically significant (log-rank test p=0.0023). Treatment-related toxicities were assessed according RTOG/EORTC criteria. Acute esophagitis and incidence of neutropenia were higher in the concurrent arm. Grade 3 esophagitis was characteristic only for concurrent treatment and it was reason for radiotherapy interruption, but no longer than 7 days.

Conclusion: s: Given the higher toxicity in the concurrent-consolidation schedule, it should be reserved for patients younger than 70 years, with good performance status and minimal weight loss.

Keywords: conformal thoracic radiotherapy, sequential arm, concurrent consolidation arm

There was no significant difference in overall survival (OS) or progression-free survival (PFS) in stage IIIa (N2) NSCLC patients who received neoadjuvant chemotherapy or chemoradiotherapy prior to surgical resection compared to those who received neoadjuvant chemotherapy or chemoradiotherapy prior to radical radiotherapy. There was a significant increase in pathological complete remission in the mediastinal lymph nodes in stage IIIa (N2) NSCLC patients who received neoadjuvant chemoradiotherapy prior to surgical resection compared to those who received neoadjuvant chemotherapy.

Conclusion: In general, North American surgeons are more likely to surgically stage the mediastinum before operation, are less likely to offer surgical treatment when N2 disease is identified preoperatively and are more likely to use induction therapy before resection. In contrast, European surgeons may offer operation as the initial treatment followed by adjuvant therapy in selected cases of N2 disease, and they may perform a more aggressive intraoperative nodal dissection. Neoadjuvant chemotherapy and/or radiotherapy prior to surgical resection do not appear to be clinically superior to neoadjuvant chemotherapy and/or radiotherapy prior to definitive radiotherapy in IIIa (N2) NSCLC patients.

Keywords: be assessed by whether it leads to higher rates of complete resection and evaluated. The potential benefit of preoperative chemoradiotherapy must provide a benchmark against which new treatment regimens can be and long-term survival was promising especially in whom underwent acceptable morbidity and mortality. The complete resectability was high, In selected patients with SST, multimodrity treatment was feasible with chemoradiotherapy, 5-year OS and CSS were both 83.3%. Conclusion: and cancer specific survival (CSS) was 87.5%. In patients with induction Of these one died from cancer relapse in small intestine and the other observation time of 20 M, 8(80%) were alive and 2(20%) were dead. 4(40%), and IIIB(T3N2) in 1(10%) patient(s). Of 8 patients with induction therapy, down stage was obtained in 2(20%); c-T3N1 to yc-T3N0 in 1 and c-T3N2 to yc-T3N0 in 1 patient. Complete resection was achieved in a patients (100%) and pathologic therapeutic response was Ef3,Ef2,Ef1b in 4,3,1 patient(s), respectively. Operative mortality was 0%. With a mean observation time of 20 M, 8(80%) were alive and 2(20%) were dead. Of these one died from cancer relapse in small intestine and the other from diabetes mellitus. Actuarial 5-year overall survival (OS) was 43.8% and cancer specific survival (CSS) was 87.5%. In patients with induction chemoradiotherapy, 5-year OS and CSS were both 83.3%. Conclusion: Induction treated patients with SST, multimodality treatment was feasible with acceptable morbidity and mortality. The complete resectability was high, and long-term survival was promising especially in whom underwent induction chemoradiotherapy followed by surgery. Our results may provide a benchmark against which new treatment regimens can be evaluated. The potential benefit of preoperative chemoradiotherapy must be assessed by whether it leads to higher rates of complete resection and a lower risk of local relapse. Further evaluation and long term follow up would be necessary. Keywords: Chemoradiotherapy, Surgery, superior sulcus tumor.
corresponding tumor SUVmax, tumor T1-weighted (T1w)/T2-weighted (T2w) intensity ratio, tumor T1-enhanced (T1C)/T2w intensity ratio, muscle T1w/T2w intensity ratio and muscle T1C/T2w intensity ratio had been measured and correlated with T stages.

Result: There were 25 patients with T1 disease, 29 with T2 disease, 27 with T3 disease and 20 with T4 disease. All the 101 lung lesions were SUV avid, MRI imaging and (18)F-FDG PET/CT agreed on T stages in all patients (100%). Median SUVmax were 12.4 in T1, 12.4 in T2, 12.9 in T3 and 13.0 in T4 patients, respectively. Patients showed lower T1/T2w ratio values in tumor while higher T1/T2w ratio in muscle area (median tumor T1/T2w ratio: 0.69, median muscle T1/T2w ratio: 2.45, P=0.000). In contrast enhanced MRI, a higher T1C/T2w ratio was observed in tumor as compared to T1/T2w ratio (median tumor T1C/T2w ratio: 2.45, median tumor T1/T2w ratio: 0.69, median muscle T1C/T2w ratio: 3.25, P=0.000). However, tumor T1C/T2w ratio was still lower than muscle T1C/T2w ratio (median tumor T1C/T2w ratio: 2.45, median muscle T1C/T2w ratio: 3.25, P=0.000).

Conclusion: The T1/T2-weighted ratio can improve diagnostic efficacies of primary pulmonary lesions that match hypermetabolic tissues in PET/CT and enables more detailed tissue characterization of lung cancers.

Keywords: magnetic resonance imaging, Primary lung cancer lesion, T1/T2-weighted ratio

---

This is a single institution retrospective study with an observation period from January 2015 to December 2017. The primary endpoint was to investigate mortality, morbidity and short-term outcomes of pulmonary resection, after induction therapy (IT), for NSCLC elderly patients. The secondary endpoint was to identify risk factors for post-operative complications. Inclusion criteria were as follows: patients who received pre-operative chemotherapy (+/- radiation therapy) and subsequent pulmonary resection. The multimodal treatment was established by a multidisciplinary team. Comparisons between two groups were made: patients <70 years (group A) and patients ≥70 years (group B). Categorical variables were analyzed by means of chi-square tests and Multivariable logistic regression was used to identify pre-operative factors associated with overall morbidity. The variables included into the logistic regression model were chosen based on clinical relevance (age, sex, PS, ASA score, mCCI, clinical stage and pneumonectomy).

Result: In the study, 70 patients were included.
patients (male/female = 42/28; adenocarcinoma 58.6% vs squamous-cell carcinoma 33%) underwent pulmonary resection after IT; among these, 26 were aged 70+ (median age 72.5 years; range: 70–80). No significant differences in baseline characteristics as PFTs, PS, ASA score, number of comorbidities, clinical stages. 66 patients were treated with platinum-based chemotherapy. Chemoradiation therapy was used more frequently in group A (25% vs 3.8%; p=0.02). Surgical procedures were similar in both groups, the percentage of pneumonectomies was comparable (15.9% vs 19.2%), while chest wall resections were more frequent in group A (18.2% vs 3.8%). Pathological stages were comparable between the two groups. In-hospital mortality (2.3% vs 0%) and median hospitalization were not different. The percentage of patients who suffered from any complication (36.4% vs 42.3%, p=0.8) and the complication rate (43.1% vs 69.2%, p=0.06) were higher in group B. In group B there was a significantly higher incidence of atrial fibrillation (p=0.049). Despite these findings, the severity of complications was comparable between the two groups. The multivariable analysis demonstrates the absence of any significant factors associated with overall morbidity. Conclusion: Lung resection, for LA-NSCLC after IT, can be performed safely in appropriately selected elderly patients. There is a strong need to standardize the preoperative evaluation in order to reach an effective and tailored multimodal treatment for LA-NSCLC elderly patients.

P3.17 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.17-10 OUTCOME OF SURGICAL RESECTION FOR SUPERIOR SULCUS TUMOR: EXPERIENCE AT A SINGLE INSTITUTION.

S. Omura1, K. Kaseda2, K. Masa1, T. Hishida1, T. Ohtsuka1, H. Asamura1
1Department of Thoracic Surgery, Keio University, School of Medicine, Tokyo/JP; 2Department of Thoracic Surgery, Keio University, School of Medicine, Tokyo/JP

Background: Superior sulcus tumors are some of the most challenging thoracic malignant disease to treat because of their proximity to vital structures at the thoracic inlet. The aim of this study was to investigate the outcome of surgical treatment for the patients with superior sulcus tumor who underwent surgery in our institution. Method: Between 2006 and 2015, 23 patients with non-small cell lung cancer with small or middle-sized of the superior sulcus underwent surgical resection, and their clinical and pathologic data were retrospectively reviewed. Postoperative complications were defined as events of grade 2 or more according to the Clavien-Dindo classification. Overall survival (OS) rates were compared using a log-rank test and survival curves were plotted using the Kaplan–Meier method. Result: Participants comprised 6 men and 2 women, ranging in age from 46 to 76 years (median, 69 years). Median observation period in the survivors was 61.0 months (range, 10–125 months). One patient underwent pneumonectomy with median sternotomy and posterolateral thoracotomy, and all others with posterolateral thoracotomy. One patient underwent combined resection of left innominate vein and chest wall, and all others underwent combined resection of chest wall, respectively. The histologic types were adenocarcinoma, squamous cell carcinoma and large cell carcinoma in 3, 3 and 2 cases, respectively. A complete resection was achieved in seven patients (87.5%), and there was no fatal complication and no postoperative mortality. The 5-year overall survival rate for all the patients was 62.5%. Conclusion: In our institution, 87.5% of patients with superior sulcus tumor could achieve complete resection. There was no postoperative mortality, and no postoperative complication of grade3 or more. Our result indicated that complete resection could impact the overall survival of the patients with superior sulcus tumor, as well as the patients with lung cancer with chest wall invasion except superior sulcus tumor.

P3.17-11 DUO SYNCHRONOUS PRIMARY LUNG TUMOURS MIMICKING A SOLITARY SPICULATED CAVITATORY MASS ON COMPUTED TOMOGRAPHIC IMAGING

K. Ong, A.A. Fazuludeen, D. Aneez
Department of Thoracic Surgery, Department of General Surgery, Tan Tock Sang Hospital, Singapore/SG

Background: Multiple primary lung cancer (MPLC) is a well-established clinical entity with an incidence ranging 1-8%. It is the simultaneous clinical entity with an incidence ranging 1-8%. It is the simultaneous multiple primary lung cancer (MPLC) in a single lesion on computed tomographic (CT) imaging. Method: A 60-year-old Chinese gentleman, smoker, had an incidental finding of 2.4 cm lesion in the right lower zone on chest X-ray. CT of the thorax demonstrated 2.2 x 2.7 x 3.1 cm right lower lobe spiculated soft tissue mass with a small central cavitation and enlarged right hilar and pre-carinal lymph nodes measuring 1.5 x 1.6 cm and 1.8 x 1.8 cm respectively. Positron emission tomography – CT showed 3.1 cm spiculated lung mass in the right lower lobe (max SUV 7.5), with metastatic FDG- avid right hilar node, right tracheo-bronchial node (max SUV 4.8) and right parastrachial node. CT guided biopsy was done and histology showed primary lung adenocarcinoma. Result: The patient underwent completely portal robotic right lower lobectomy with mediastinal lymph node dissection. His recovery was uneventful and was discharged on post-operative day 5. Histological examination revealed R0 resection of two distinctly separate adenocarcinomas measuring 2.3 x 2 x 1.5 cm and 2.5 x 2.5 x 2.2 cm respectively. The former showed acinar (40%), lobular (30%), micropapillary (20%) and solid (10%) growth patterns while the latter showed solid (80%) and acinar (20%) growth patterns. Lymph node stations 2, 4, 7, 9, 10, 11 were dissected and analysed. Stage 7 and 11 nodes were found to contain metastases. Final pathological staging was Stage 3A (pT1N2M0). Subsequently, he underwent adjuvant chemotherapy (Carbo/Amita) following by radiotherapy (50.4Gy/28f). There was no tumour recurrence at the 1 year follow-up. Conclusion: Despite current state of the art imaging modalities for lung cancer, there remains the possibility of MPLC mimicking a solitary cavitory lung lesion during clinical staging.

P3.17-12 PHASE II TRIAL OF ATEZOZULIMAB BEFORE AND AFTER CHEMORADIOATION FOR UNRESECTABLE STAGE III NSCLC (AFT-16): TRIAL IN PROGRESS

1Mayo Clinic Arizona, PhoenixAZ/US; 2Dana Farber Cancer Institute, Boston/US; 3UCSD, San Diego/US; 4The Ohio State University, Columbus/US; 5Alliance Foundation Trials, Boston/US; 6Genentech, Inc, South San Francisco/US; 7Genentech, Inc., South San Francisco/CA/US, 8Duke University, Durham/US; 9Medical University, Chicago/US; 10Duke University, Durham/NC/US

Background: Cure is possible for a substantial majority of stage III NSCLC patients, but most will relapse after conventional chemoradiation (CRT). Combination checkpoint inhibition through PD-L1 blockade at an early stage with CRT may attenuate tumor related immune suppression via depletion of Tregs and clonal expansion of effector T-cells, thereby improving tumor immunogenicity. Further, CRT may reveal hidden antigens that can present additional targets to the reconstituting immune system. Whether anti-PD-L1 therapy before and after CRT will improve outcomes in this setting is the subject of this trial. Method: This phase II single arm Alliance Foundation Trials study (AFT-16, NCT03102242) explores safety and efficacy of atezolizumab before and after definitive CRT. 63 patients with stage III NSCLC, PS 0-1, no active autoimmune disease and no significant organ dysfunction will enroll at 15 Alliance sites. Participants receive 4 cycles of neoadjuvant atezolizumab 1200 mg IV q 21 days with restaging after cycles 2 and 4. Non-progressing patients undergo carboplatin and paclitaxel (C/P) weekly with 60 Gy RT followed by 2 cycles of C/P consolidation and adjuvant atezolizumab to complete one year of therapy. The primary endpoint is disease control rate (CR+PR+SD) after neoadjuvant atezolizumab. Secondary endpoints include ORR, PFS, OS, safety and QoL by the EORTC QLQ-30.

Correlatives include the role of PD-L1 and tumor mutation burden as predictive biomarkers. Tumor tissue is obtained at study entry, and plasma and immune cells are isolated at study entry, post neoadjuvant atezolizumab, post CRT, during adjuvant atezolizumab and at study end.

P3.17-16 ADENOCARCINOMA OR EPIDERMOID? THE IMPORTANCE OF THE HISTOLOGICAL SUBDIVISION
S. Sequero, J. Jurado-Garcia, M. Perez-Garcia, D. Castillo-Barnes
Oncologia, Hospital Campus de La Salud, Avenida Investigacion S/n/ES

Background: Lung cancer is the leading cause of cancer death. Most studies focus on metastatic disease, and the complementary treatment in localized disease has limited evidence. This study aims to highlight the factors that influence the survival of lung cancer in localized phase.

Method: A retrospective study was conducted on 96 patients (14% women and 86% men, median age of 66 years) with localized lung cancer treated in our center between 2009 and 2017. At the end of the data collection, 44 patients had died (46%) but 52 (54%) remained alive until today. All the medical histories were reviewed in order to analyze different parameters related to histology, stage, tumor biology, imaging tests, surgery and treatment. A statistical data analysis software (SPSS) was applied to find statistically significant relationships between the variables.

Result: From the 49 patients with adenocarcinoma, 18 (37% of the total) died with a median overall survival (OS) of 35 months (27-43 months with CI <0.05%). From the 47 epidermoids, 26 died (55% of the total) although with a median OS of 59 months (40-78 months with CI <0.05%). By stages I and II: The median OS for the adenocarcinoma group was 12.33 months (3.6-21 months with CI <0.05%) versus the squamous cell group, with a median of 28.75 months (12.6-57.8 months with CI <0.05%). Between stages III: The median OS in the adenocarcinoma group was 14 months (11.7-16.2 months with CI <0.05%) compared to the squamous group with 22.26 months (15.7-28.8 months with CI <0.05%). The median OS among the patients with some inflammation data was 65.7 months (57-74 months with CI <0.05%).

Conclusion: Adenocarcinomas seem to present a worse prognosis in localized stage, in contrast to metastatic stage. Inflammation seems to play an important role in the evolution of the tumor, regardless of the treatment.

Keywords: adenocarcinoma, epidermoid, global survival

P3.17 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.17-18 TOWARDS INDIVIDUALIZING PATIENT SELECTION IN PROTON THERAPY FOR LUNG CANCER USING THE MODEL-BASED APPROACH
S. Teoh, F. Fiorini, B. George, K. Vallis, F. Van Den Heuvel
University of Oxford, Crick/mrc Oxford Institute for Radiation Oncology Gray Laboratories, Oxford/GB

Background: Intensity modulated proton therapy (IMPT) has the potential to reduce dose to adjacent normal tissue compared to photon therapy. Although dosimetric advantages can be seen, these results need to translate to clinically meaningful benefit. We aim to identify patients who would benefit from IMPT over photon volumetric modulated arc therapy (VMAT) in locally advanced lung cancer using recently published normal tissue complications probabilities (NTCP) models for heart and lung.

Method: VMAT and robust optimised-IMPT plans were assessed to a physical dose of 70Gy in 35 fractions according to RTOG 1308 protocol. Risk estimates of grade 3+ cardiac toxicities and dyspnoea were calculated based on NTCP models which incorporated dose metrics and individual patients’ baseline risk-factors (RF) (cardiac: pre-existing heart disease (HD), lung: patient-reported outcome dyspnoea grade). Risk estimates were calculated and compared based on the pre-treatment patients’ RF and in the hypothetical scenarios where all patients had baseline HD or grade 1 dyspnoea. The difference between the probability estimates of VMAT and IMPT were determined (ANTCP). The models were applied in the different scenarios to ten proxy patients. These patients were retrospectively identified to ensure different anatomical locations (lobes and mediastinal/hilar regions) were represented (GTV median:

Treatment. A statistical data analysis software (SPSS) was applied to search for relationships statistically significant among the variables. For the survival analysis, they used Kaplan-Meier curves and the Log-Rank test. Result: 39 cases of patients in Stage III were collected. The surgery group (with neoadjuvant or adjuvant chemotherapy) covers 21 patients (54%). The group treated with Chemo-Radiotherapy includes 18 patients (46%). For the surgery group, the mean for the DFS is estimated at 51 months (39.5-62.3 months), the median has not yet been reached. The mean DFS in the Chemo-Radiotherapy group is 40.2 months (22.6-57.8 months); the median being 18.2 months (15.75-20.65 months). These differences are statistically significant. The group treated with surgery: median age of 66.5 years, 94% male smokers. The adenocarcinoma represented the 61% of the group compared to the epidermoids, which account for 39%. In 44% of the tumors, signs of inflammatory infiltration were found. The Standard Uptake Value (SUV) average was 11.19 (2-72-18 SUV). The group treated with Chemo-Radiotherapy: median age of 66 years, 95% male smokers, 57% epidermoid tumors versus 43% of adenocarcinomas. Only 14% had signs of histological inflammation. The average SUV was 15.94 (3-48 SUV).

Keywords: surgery, quimio-radiotherapy, disease free survival
allows for tumor localization and response assessment during definitive chemotherapy. However, our experience suggests that tumor volume loss occurs relatively early during treatment; and that greater tumor volume loss during treatment correlates with improved disease control and overall survival. It is not a standard practice to re-simulate patients for smaller target volume; but it is important to note that increased tumor volume and consequent increase in air density could lead to increased radiation dose to the surrounding normal tissue such as the spinal cord. We hypothesize that increased air density secondary to tumor size reduction leads to increased dose to normal tissue including spinal cord, heart, esophagus and normal lung. Method: KV-BCCT images were imported to Eclipse treatment planning system. Primary tumors were re-contoured, and all normal tissue structures were re-adjusted based on the new images. Doses to the spinal cord, esophagus, normal lung, original planning target volume (PTV) as well as the new, smaller, PTV were re-calculated based on the original prescription dose and compared with the original plan by paired t-test. The Acuros XB advanced dose calculation algorithm was used for all patients. Result: Nine patients with greater than 40% target volume reduction after 4 weeks of CRT were analyzed. There is a mean size reduction of 425.1 cc (55.6%) in PTV (p=0.002). Mean dose to the new PTV is 50 cGy (0.8%) less than the prescription dose (average 6088 cGy) (p=0.07). 0.03 cc of PTV receiving the highest dose is 110 cGy (1.8%) less than originally planned. There is no significant dose difference to the normal tissue, including esophagus (D0.03cc, DMean, V50 Gy and V60 Gy), heart (D0.03cc, DMean, V35Gy and V45Gy), ipsilateral lung (DMean, V50Gy, V10 Gy, V20 Gy, V30 Gy) and total lung (DMean, V50Gy, V10 Gy, V20 Gy, V30 Gy). Conclusion: Despite significant primary tumor size reduction, there is no clinically significant difference in dose delivered to the primary tumor or to the radiation sensitive critical organs. Therefore the orinal treatment plan can be safely used.

P3.17-19 FIRST RELAPSE AND SURVIVAL FIVE YEARS AFTER RADICAL RADIOTHERAPY FOR LUNG CANCER.
G. Walls, G. Hanna, C. Rooney, L. Young, J. Harney, R. Eakin, J. McAleese
Cancer Centre Belfast City Hospital. Belfast/GB

Background: Whilst local and distant control rates for both small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC) have been described for the immediate years following curative-intent radiotherapy, the natural history in patients with long-term disease-free survival (DFS) has not been established. Late relapse has been described in limited, small series (e.g. following surgery or SABR) but there is a paucity of data on relapse and survival after radical radiotherapy for all-comers. With improved radiotherapy planning and delivery, systemic therapy personalisation and surveillance strategies, survival rates at five years are improving. We describe the outcomes in patients with at least five years DFS from the completion of radiotherapy with curative intent. Method: Patients with DFS >5 years post-radiotherapy between 1st December 2000 and 1st March 2013 were identified from a prospective database of patients treated with curative-intent radiotherapy at a tertiary centre. Electronic records were interrogated for information pertaining to disease status and cause of death. Result: 680 patients received curative-intent radiotherapy; 503 NSCLC, 176 SCLC. At 5 years, 108 (16%) patients were alive; 66 males, 42 females. Mean age of survivors at treatment 67 years, median ECOG PS 1. SCLC for accounted 32 cases (18% total SCLC); NSCLC for accounted 76 cases (15% total NSCLC). SCLC (n=32 limited-stage) were managed with sequential chemoradiotherapy (n=20), concurrent chemoradiation (n=12). NSCLC (n=37 stage I; n=9 stage II; n=27 stage III; n=3 stage IV) were managed with radiotherapy alone (n=47), sequential chemoradiotherapy (n=19), concurrent chemoradiotherapy (n=7), SABR (n=5). With 80 months total median follow-up 16 (15%) patients surviving 5 years relapsed, 14 NSCLC (2.7% total treated radically), 2 SCLC (1.9% total treated radically). Of 23 patients reaching the 5-year time-point and thereafter developing a further malignancy, 4 were cases of second lung primary. Conclusion: Approximately 1 in 6 patients (all-comers) survived for 5 years after radical radiotherapy. Approximately 1 in 6 patients with 5 year DFS will later go on to relapse, suggesting that such patients should receive active follow-up.

Keywords: late relapse, lung cancer, radical radiotherapy

P3.17-20 IMPACT OF SIGNIFICANT PRIMARY TUMOR SIZE REDUCTION ON RADIAO DOSE TO NORMAL STRUCTURES IN PATIENTS RECEIVING DEFINITIVE CHEMORADIOTHERAPY.

Background: Kilo-voltage cone beam computed tomography (KV-BCCT) allows for tumor localization and response assessment during definitive chemoradiotherapy (CRT) for locally advanced non-small cell lung cancer (LA-NSCLC). Previously we have analyzed patients with LA-NSCLC treated with definitive CRT accompanied with daily CBCT in our department and found that significant primary tumor volume loss occurs relatively early during treatment; and that greater tumor volume loss during treatment correlates with improved disease control and overall survival. It is not a standard practice to re-simulate patients for smaller target volume; but it is important to note that increased tumor volume and consequent increase in air density could lead to increased radiation dose to the surrounding normal tissue such as the spinal cord. We hypothesize that increased air density secondary to tumor size reduction leads to increased dose to normal tissue including spinal cord, heart, esophagus and normal lung. Method: KV-BCCT images were imported to Eclipse treatment planning system. Primary tumors were re-contoured, and all normal tissue structures were re-adjusted based on the new images. Doses to the spinal cord, esophagus, normal lung, original planning target volume (PTV) as well as the new, smaller, PTV were re-calculated based on the original prescription dose and compared with the original plan by paired t-test. The Acuros XB advanced dose calculation algorithm was used for all patients. Result: Nine patients with greater than 40% target volume reduction after 4 weeks of CRT were analyzed. There is a mean size reduction of 425.1 cc (55.6%) in PTV (p=0.002). Mean dose to the new PTV is 50 cGy (0.8%) less than the prescription dose (average 6088 cGy) (p=0.07). 0.03 cc of PTV receiving the highest dose is 110 cGy (1.8%) less than originally planned. There is no significant dose difference to the normal tissue, including esophagus (D0.03cc, DMean, V50 Gy and V60 Gy), heart (D0.03cc, DMean, V35Gy and V45Gy), ipsilateral lung (DMean, V50Gy, V10 Gy, V20 Gy, V30 Gy) and total lung (DMean, V50Gy, V10 Gy, V20 Gy, V30 Gy). Conclusion: Despite significant primary tumor size reduction, there is no clinically significant difference in dose delivered to the primary tumor or to the radiation sensitive critical organs. Therefore the orinal treatment plan can be safely used.

P3.17-21 SURGICAL TREATMENT FOR CENTRALLY LOCATED OR HILAR INVASIVE LOCALY ADVANCED LUNG CANCER.
M. Yamashita1, Y. Makii, R. Sugimoto1, T. Ueno1, S. Toyooka2
1Shikoku Cancer Center, Matsuyama/JP, 2Okayama University Graduate School of Medicine, Okayama/JP

Background: In cases of centrally located or hilar invasive lung cancer (CLHILC), it is quite difficult to decide the treatment strategy whether pneumonecctomy, sleeve-lobectomy and/or pulmonary angioplastics surgery, or lobectomy is necessary or not. Especially in the patients with inadequate pulmonary functions, the treatment strategy is hard to be decided. To clarify the surgical outcomes for CLHILC, we retrospectively investigated our experiences in Setouchi Lung Cancer Study Group (SLCG). Method: In order to show the clinical results of CLHILC, we retrospectively investigated the patients’ medical records from January 2010 to December 2011 in SLCG. The definition of CLHILC; clinical tumor size is more than 3cm (T2 or more) and located in main bronchus or lobar orifice, or hilar nodal invasion is shown around lobar bronchial orifice or pulmonary arterial branch without mediastinal nodal metastasis. That is, the simple lobectomy is not easy or inadequate to complete resection for CLHILC. Result: Ninety-seven patients’ records were collected, the men were 78, the mean age was 67. Twenty-four cases underwent preoperative treatment (induction chemotherapy in 8, induction chemoradiotherapy in 13, and radiotherapy in 3 cases). Except 1 exploratory thoracotomy cases, the surgical procedure was as following; lobectomy in 37, lobectomy with broncho-vascular plasty in 4, bronchoplasty in 11 and pulmonary angioplasty in 16, bilobectomy in 12, and pneumonecctomy in 15 cases. The post-operative complications were occurred in 39 cases (40%), and there were 2 30-days mortal cases. The survival rate was 65% at 3 years and 60% at 5 years. Conclusion: We reviewed CHILC in SLCG Group and showed the surgical procedure variety, the morbidity and survival rate. The pneumonecctomy was performed in 15% and the complicated surgical procedure such as broncho-vascularal plasty were chosen in 30% with acceptable morbidity and mortality.
**P3.CR-02 TO BETTER UNDERSTAND THE ANATOMICAL PROXIMITY OF CARDIAC PLEXUS TO PREVENT LETHAL ARRHYTHMIAS ASSOCIATED WITH LUNG CANCER SURGERY**

K. Fukui, S. Ikeda, T. Yokota, T. Hoshino
Surgical Department of Respiratory Center, Mitsui Memorial Hospital, Tokyo/JP

**Background:** Arrhythmias are known as one of the complications after surgery, and most of them are not lethal. But life-threatening brady and tachy arrhythmias, such as complete heart block and asystole, have been described in the literature, but in reality very rare. **Method:** To consider the relationship between arrhythmias and the involvement of cardiac plexus during lymph node dissection from anatomical viewpoint by presenting two patients who were complicated with life-threatening arrhythmias during and after surgery. **Result:** A 71 year-old Japanese woman had an abnormality in a chest X ray on the annual medical checkup. A CT scan and a bronchoscopic biopsy led to the diagnosis of adenocarcinoma in left lower lobe. CT2aN0M0 StageIIb. A preoperative electrocardiogram showed a heart rate of 55 per minute with normal sinus rhythm, and the echocardiography was normal. The patient underwent a thoracoscopic-assisted left lower lobectomy and lymph node dissection. Post-operatively the patient was noticed to have lower heart rates of 40s, and when the patient sat up on the next morning, the bradycardia progressed to asystole for 10 seconds. CPR was performed and sinus rhythm was resumed. Having a temporary then a permanent pacemaker been implanted, the patient was uneventfully discharged from hospital on postoperative day (POD) 22. The second patient was a 67 year-old Japanese man who presented with bloody sputum. An X ray and a bronchoscopic biopsy led to the diagnosis of squamous cell carcinoma in left lower lobe. CT2bN0M0 StageIia. A preoperative electrocardiogram showed a heart rate of 73 per minute with normal sinus rhythm and the echocardiography was normal. The patient underwent a left lower lobectomy and bilateral mediastinal lymph node dissection through a median sternotomy. During lymph node dissection along the right vagus nerve, the patient’s heart rate and blood pressure dropped suddenly and an electrocardiogram monitor showed ST elevation. These abnormalities returned to normal soon after cardiac massage was performed and a coronary vasodilator was given. A temporary pacing wire was inserted at the end of the surgery. The postoperative course was uneventful and the patient was discharged on POD 11. **Conclusion:** The cause of arrhythmias is probable that cardiac plexus was stimulated inadvertently during lymph nodes dissection around the vagus nerve, considering a role of cardiac plexus from the anatomical viewpoint. It is important to be familiar not only with the course of phrenic, vagus and recurrent laryngeal but also the anatomy of cardiac plexus in lung cancer surgery.

**Keywords:** lung surgery, bradycardia, cardiac plexus

P3.CR-02 SBRT OF LUNG PRIMARY AFTER COMPLETE RESOLUTION OF METASTATIC DISEASE IN CASE OF EGFRMUTATED ADENOCARCINOMA LUNG: A CASE REPORT
S. Majumdar1, S. Dhar1, S. Mishra1, S. Patra2, S. Mohakud1, P. Mohapatra1, D. Paria1

1Radiotherapy, All India Institute of Medical Sciences, Bhubaneswar/IN, 2Pathology, All India Institute of Medical Sciences, Bhubaneswar/IN

Background: Lung cancer accounts for the highest malignancy related mortality among men worldwide. The prognosis of metastatic lung cancer is dismal and as per data from United States of America, the 5-year survival of metastatic lung cancer patients stands at mere 5 percent. Loco-regional management in metastatic lung cancer is not routinely practiced, however exceptions are made in patients who have very good response to systemic treatment. In such cases loco-regional treatment is expected to improve disease free survival. Method: Section Not applicable Result: Fifty-six year old male, known hypertrophic[on thymine supplementation] without any significant history of addiction/ family history presented with chronic non-productive cough and acute breathlessness. On evaluation left lung upper lobe primary mass [adenocarcinoma on histopathology] and left sided pleural and pericardial effusion[malignant on cytology]s well as multiple cervical lymphadenopathy was found on PET-CT. Hundred percent of the primary tumour tissue was found to harbour EGFR mutation while being negative for ALK mutation. After six cycles of chemotherapy with Carboplatin and Pemetrexed combination chemotherapy regimen, the patient was kept on Erlotinib for 9 months. All the metastatic diseases were found to be resolved and primary was shrunk on assessment PET-CT. The patient was advised for SBRT to primary 50Gy in 5 fractions,10Gy per fraction on alternate days over a period of 10 days following which he has been kept on Tab Erlotinib. The patient has a survival of 18 months calculated from the time of diagnosis till compilation of data and is disease free.

Conclusion: High percentage of EGFR mutation can provide very good response to tyrosine kinase inhibitor therapy in case of metastatic adenocarcinoma lung. Partial response at primary with resolution of metastatic disease throws a challenge for use of loco-regional modality of management in tandem with systemic treatment.

P3.CR-03 PULMONARY SPINDLE CELL NEOPLASM - NEOADJUVANT TREATMENT AND RESPONSE
A. Ismail, A. Sultan, K. Thein, S. Swarup, K. Nugent, S. Graham, L. Tijani, F. Hardwicke

Texas Tech University Health Sciences Center, Lubbock/TX/US

Background: Sarcomatoid carcinoma (SC) of the lung comprises a small subset of non-small cell lung cancer (NSCLC) accounting for no more than 3% of all lung tumors. Method: Section not applicable Result: A 66-year-old Caucasian man was seen in the ED for the complaints of shortness of breath, productive cough, and fever. He had a 70 pounds unintentional weight loss over 5 months and generalized weakness. His medical history included COPD, HTN, HLD, and tobacco abuse (108 pack years of smoking). He denied alcohol or illicit drug use. He was treated with antibiotics for COPD exacerbation with symptomatic improvement; however, he had a chest X-ray finding notable for an 8 cm right upper lobe mass (now 4.5 x 1.7 cm instead of 7.9 x 4.7 cm) and a hilar lymph node that measured 1.3 x 1.3 cm (previously measuring 2.3 x 2.9 cm).

Conclusion: We present a patient that received concurrent chemoradiotherapy with initial response on CT imaging. This can provide an acceptable alternative to patients presenting with non-resectable tumors.

Keywords: Neoadjuvant treatment, Spindle cell neoplasm

P3.CR-04 LUNG CANCER WITH CONCURRENT ROS1 REARRANGEMENT AND KRAS MUTATION: A CASE REPORT
Y. Zhu1, C. Xu2, W. Wang3, K. Du1, W. Zhuang1, M. Fang1

1Zhejiang Rongjun Hospital, Jiaxing/CN, 2Fujian Cancer Hospital, Fuzhou/CN, 3Zhejiang Cancer Hospital, Hangzhou/CN

Background: ROS1 rearrangement has recently emerged as a new molecular subtype in non-small cell lung cancer (NSCLC), and is predominantly found in lung adenocarcinomas compared with other oncogenes such as EGFR, KRAS, or ALK. Patients who have both mutations are extremely rare. Method: A 42-year-old female diagnosed with adenocarcinoma (IIIB, T_N_M), who was shown to have ROS1 and KRAS mutations by next generation sequencing. Result: The patient was prescribed oral crizotinib and a CT scan show a partial response in the pulmonary lesions after one month. Unfortunately, a CT scan show progression of the pulmonary lesion after three months. And the patient was treated with the MEK inhibitor, selumetinib (AZD6244), combined with pemetrexed. The patient was alive at now.

Conclusion: We reviewed the literature to determine the frequency of gene mutations in NSCLC patients. A better understanding of the molecular biology of NSCLC with multiple driver genomic aberrations will assist in determining optimal treatment.

Keywords: non-small cell lung cancer, KRAS gene mutation, ROS1 fusion gene

P3.CR-05 THE ROLE OF PATIENT ENGAGEMENT IN IMPROVED OUTCOMES IN LUNG CANCER CARE
A.M. Cerato, C. Sit

Lung Cancer Canada, Toronto/ON/CA

Background: Anne Marie Cerato, the primary author, is the patient in this case study. Lung cancer patients tend to have a high disease burden as many are diagnosed at a late stage and require extensive treatment. As such, they are required to make life-altering decisions during and after treatment. The level of their engagement and participation in that decision-making process can differ greatly thus effecting their quality of care and quality of life. Method: Patient was diagnosed in 2009 with stage 3A adenocarcinoma of the right lung. Treatment decisions were required at three different time points within this patient’s experience (at time of original diagnosis, at recurrence, and at progression). Two different models of engagement were experienced. At diagnosis, the patient as a passive participant model was experienced, and upon recurrence and progression, the patient was an active participant in the decision making process. Result: In the patient as a passive participant model, the patient felt dues to follow prescribed treatment resulting in feelings of isolation, anxiety, anger, and depression. In contrast, the patient was an active participant and involved in the decision making process, the patient felt more in control of their treatment, which resulted in feelings of inclusion, hopefulness, and decreased anxiety.

Conclusion: It is difficult to determine the difference whether or not there was improvement in patient clinical outcomes. However, qualitatively as a result of increased patient engagement and shared decision making, patients experienced improved outcomes as they felt less isolated, anxious, and more involved in their care. As a result of increased patient engagement, this patient explored additional treatment avenues and sought connections with the larger patient community. Clinicians can work with patients to enable or improve engagement and involvement by considering the following recommendations: 1. Patients should be given access to clinical notes, results and reports, and given time to consider the information provided. 2. Patients should be encouraged to ask questions. 3. Connect patients to a lung cancer patient group for additional support. 4. Ensure patients are supported post treatment and through transitions in care.

**P3.CR-06 EFFECT OF PALLIATIVE CARE AND CANCER REHABILITATION ON LUNG CANCER SURVIVORSHIP - PATIENT’S PERSPECTIVE**
S. Kono
Arun, Tokyo/JP

**Background:** Pate et al. (1995) and Bryan et al. (2007) reported that approximately 30% of total cancer deaths are related to poor exercise and nutrition. Though importance of palliative care, cancer rehabilitation and nutritional advice has been recognized, those information tend to be fragmented. Considering the importance of palliative care and cancer rehabilitation in patients’ treatment outcome and survivorship, joint and comprehensive advocacy to strengthen those intervention is necessary.

**Method:** Case study of a 56-year-old Japanese male patient diagnosed with pulmonary adenocarcinoma NSCLC (stage 4) metastases and worked with cancer for 7 years. Result: Various treatment were used including chemotherapy, EGFR Tyrosine kinase inhibitor, and immunotherapy. Bone metastases and brain metastases were observed and palliative radiotherapy and stent were used. Vertebroplasty was considered but not conducted. Irradiation to whole brain was considered but not done. Early introduction of palliative care and cancer rehabilitation helped to improve the patient QOL and enable patient to continue his work.

**Conclusion:** The life of the patient has had its ups and downs. The case shows effect of palliative care and cancer rehabilitation on patient’s QOL and survivorship. More integrated approach of cancer rehabilitation into palliative care and lung cancer treatment need to be explored. It also suggest that more study from patients’ perspective could contribute towards comprehensive understanding and advocacy.

**P3.CR-07 COMPREHENSIVE GENOMIC PROFILES FOR A MEDIASTINAL TUMOR SUSPECTED OF SYNOVIAL SARCOMA: A CASE REPORT**
General Thoracic Surgery, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama/JP

**Background:** Synovial sarcoma (SS) is an aggressive malignant tumor and accounts for 5 to 10% of all soft tissue sarcomas. SS commonly occurs in the deep tissue adjacent to the joints or tendons in the limbs while SS rarely occurs in the mediastinum. Most of SS harbor t(1;18) (p11.2;q11.2), which leads to chimeric fusion of SYT with one of the SSX genes. Furthermore, somatic mutations of cancer-related genes such as RT-PCR, TERT, CDH1, and PTEN have also been reported in the SS even though the frequencies of these genetic alterations were not high. Recently, the comprehensive genomic profile (CGP) using the next-generation sequencing (NGS) is widely used for better understanding of tumor genotypes and it can also provide clinically actionable information to guide treatment decisions for patients. **Method:** In this study, the clinical and histological records of an anterior mediastinal tumor suspected of SS were reviewed, and a reverse transcript polymerase chain reaction (RT-PCR) assay and NGS using a high sensitivity amplicon–based targeted sequencing method incorporating molecular barcodes (a panel designed for hotspots of 47 cancer-related genes) were performed to identify the genetic alterations. **Result:** A 78 years old woman was referred to our hospital because of approximately 9 cm anterior mediastinal tumor. A positron emission tomography showed the high fluorine-18-fluorodeoxyglucose uptake. The patient underwent median sternotomy and resection of the tumor combined with wedge resection of the left upper lobe of lung. Histological examination revealed a monomorphic spindle cell growth and immunohistochemical stains (AE1/AE3, CAM5.2, CD34, CD99, Desmin, Nestin, a-SMA, CDK4, CD56, c-kit, EMA, and S-100) were negative, so the tumor was suspected of SS. We performed a RT-PCR assay for SYT-SSX fusion, however, it was not detected. NGS analysis revealed the presence of hotspot mutations in 4 cancer-related genes (PIK3CA, CDKN2A, PTEN, and MAP2K4). Because the tumor was completely resected, an adjuvant therapy had not been planned and the scheduled medical checkup has been performed. Fortunately, the patient is alive without any recurrence for 5 years. **Conclusion:** The genetic features of a mediastinal tumor suspected of SS, without SYT-SSX fusion, were evaluated by CGP analysis. In case of the rare tumor especially when it occurs in the unusual location and the histological and molecular assessments are not conclusive, a CGP assay may be helpful to reveal the genetic feature of the tumor and to determine the effective targeted drugs.

**P3.CR-08 CLINALLY RELATED PRIMARY ALK REARRANGEMENT ADENOCARCINOMA AND ASSOCIATED METASTATIC LESIONS: A CASE REPORT**
W. Wang1, C. Xu2, Y. Zhu3, Q. Zheng4, W. Zhuang1, Y. Chen5, M. Fang6, G. Chen2
1Zhejiang Cancer Hospital, Hangzhou/CN, 2Fujian Cancer Hospital, Fuzhou/CN, 3Zhejiang Rongjun Hospital, Jiaxing/CN, 4Pathology, Fujian Cancer Hospital, Fuzhou/CN, 5Medical Oncology, Fujian Cancer Hospital, Fuzhou/CN, 6Pathology, Fujian Cancer Hospital, Fuzhou/CN

**Background:** Anaplastic lymphoma kinase (ALK) rearrangement is a driver gene in non-small cell lung cancer (NSCLC). ALK-positive tumors are sensitive to ALK tyrosine kinase inhibitors (TKIs). Detecting key driver genes is crucial to personalized treatment. Different histomorphological patterns have different driver genes. **Method:** A 42-year-old male diagnosed with adenocarcinoma (II), who was shown to have ALK fusion by reverse transcription polymerase chain reaction (RT-PCR).

**Result:** The patient diagnosed with adenocarcinoma, who had different histomorphologies in the primary lung site (mucinous type) and lymph node metastasis (solid type), but had the same genotype, which both presented with an ALK rearrangement, while negative for an EGFR mutation. This histological heterogeneity did not necessarily indicate a genomic difference. **Conclusion:** Genomic analysis may be a supplement of the histological feature of ALK-rearranged tumors. These gene alterations could help patients to choose an appropriate TKI and its impact on the therapeutic responses.

**P3.CR-09 MET-UBE2H FUSION AS A NOVEL MECHANISM OF ACQUIRED EGFR RESISTANCE IN LUNG ADENOCARCINOMA**
WITH “MET FUSION AS A NOVEL MECHANISM OF ACQUIRED EGFR RESISTANCE IN LUNG ADENOCARCINOMA”

**Background:** As we all known, the most common mechanism of acquired resistance to EGFR-TKIs treatment is the development of the EGFR T790M mutation, which occurs almost one half of cases of acquired resistance. Other previously described resistance mechanisms include HER2 amplification, MET amplification, PIK3CA mutation, epithelialmesenchymal transition (EMT), and small cell transformation. **Method:** A 43-year-old female diagnosed with adenocarcinoma including brain and bone metastases, who was shown to have MET fusion after erlotinib acquired resistance by next generation sequencing. **Result:** The patient with left lung tumor. Cytological examination of sequeicms from primary focus show adenocarcinoma. With “A bronchoscopic biopsy specimens from primary focus show adenocarcinoma. By next generation sequencing we found EGFR 19 exon E746_G752delinsV and MET-UBE2H fusion after erlotinib acquired resistance, and the patient experienced a remarkable tumor response to crizotinib remains at 6
months on therapy. **Conclusion:** We report the occurrence of MET-UBE2H fusion along with EGFR 19del at disease progression after treatment with erlotinib. Hence we attribute the emergence of MET-UBE2H fusion as a possible mechanism of acquired resistance to first generation EGFR-TKI in EGFR mutated NSCLC.

**Keywords:** EGFR resistance, MET fusion, non-small cell lung cancer

**P3.CR-10 HIP1-ALK FUSION VARIANT IN NON- small-CELL LUNG CANCER AND RESPONSE TO CRIZOTINIB**

W. Wang¹, C. Xu², Q. Zhang³, W. Zhuang⁴, Y. Zhu⁵, Y. Chen⁶, M. Fang⁷, G. Chen⁷

¹Fujian Cancer Hospital, Fuzhou/CN, ²Zhejiang Cancer Hospital, Hangzhou/CN, ³Pathology, Fujian Cancer Hospital, Fuzhou/CN, ⁴Medical Oncology, Fujian Cancer Hospital, Fuzhou/CN, ⁵Zhejiang Rongjun Hospital, Jiaxing/CN, ⁶Pathology, Fujian Cancer Hospital, Fuzhou/CN

**Background:** Several fusion partners of ALK have been reported in patients with non-small cell lung cancer (NSCLC). And huntingtin interacting protein 1 (HIP1)-ALK is one kind of ALK fusion type. **Method:** We reported a case of HIP1-ALK fusion variant in non-small-cell lung cancer and further reviewed the clinical characteristic and the efficacy of crizotinib to this type fusion of NSCLC patients. **Result:** A 56-year-old Chinese woman with multiple lung metastases NSCLC(T1N0M1, stage IV). Histological examination of the tumor showed lung adenocarcinoma. Ventana (D5F3) ALK IHC assay (Ventana Medical Systems, Roche, Inc) analysis of the left lung tissue revealed the presence of an ALK rearrangement. Then the patient received a remarkable tumor response to crizotinib. By using next generation sequencing assay, we found that tumor had HIP1-ALK (H21; A20) rather than the most common kind of Echinoderm microtubule–associated protein-like 4-anaplastic lymphoma kinase (EML4-ALK). Considering this rare ALK fusion and remarkable response to crizotinib treatment, we conclude that the incidence of HIP1-ALK in NSCLC patients with ALK rearrangement should be attentive. NSCLC patients with HIP1-ALK fusion gene response to treatment with ALK inhibitors. **Conclusion:** With the guidance of precise diagnosis, it is important that we should realize other rare ALK fusions and novel diagnostic method.

**Keywords:** HIP1-ALK, NSCLC, crizotinib

**P3.CR-11 ROS1 FUSION AND MET AMPLIFICATION DUAL DRIVE COEXISTENCE IN LUNG ADENOCARCINOMA AND RESPONSE TO CRIZOTINIB: A CASE REPORT**

C. Xu¹, P. Wang², Z. Song², Q. Zhang², Q. Zhuang⁴, Y. Chen⁵, G. Chen⁵, M. Fang⁴, T. Lv¹, Y. Song²

¹Fujian Cancer Hospital, Fuzhou/CN, ²Zhejiang Cancer Hospital, Hangzhou/CN, ³Pathology, Fujian Cancer Hospital, Fuzhou/CN, ⁴Medical Oncology, Fujian Cancer Hospital, Fuzhou/CN, ⁵Zhejiang Cancer Hospital, Hangzhou/CN, ⁶Jilin Hospital, Nanjing/CN

**Background:** The c-ros oncogene 1 (ROS1) fusion is almost mutually exclusive to MET amplification in non-small cell lung cancer (NSCLC), and it is not seen in the literature for patients to exhibit both fusions. **Method:** A 66-year-old female diagnosed with IV stage adenocarcinoma, who was shown to have ROS1 fusion and MET amplification by fluorescence in situ hybridization (FISH), and verified by next generation sequencing. **Result:** The patient with right lung tumor and brain metastases NSCLC. Histological examination of surgical sepcimens from primary focus show adenocarcinoma. By fluorescence in situ hybridization (FISH), we found ROS1 fusion and MET amplification. Then we verified a novel ROS1 fusion. ZCCHC8-ROS1, and the patient experienced a remarkable tumor response to crizotinib for 6 months (PFS). **Conclusion:** To the best of our knowledge, this is the first case report of a patient with concurrent ROS1 fusion and MET amplification, and ZCCHC8-ROS1. This patient had an excellent response to crizotinib, suggesting that concurrent ROS1 fusion and MET amplification response to crizotinib was less than ROS1 fusion single driver.

**Keywords:** ROS1 fusion, MET amplification, non-small cell lung cancer

**P3.CR-12 A NOVEL ONCOGENIC DRIVER IN A LUNG ADENOCARCINOMA PATIENT HARBORING AN EGFR-KDD AND RESPONSE TO AFATINIB**

C. Xu¹, P. Wang², Q. Zhang³, B. Wu¹, W. Zhuang⁴, Y. Zhu⁵, Y. Chen⁶, M. Fang⁷, G. Chen⁷

¹Fujian Cancer Hospital, Fuzhou/CN, ²Zhejiang Cancer Hospital, Hangzhou/CN, ³Pathology, Fujian Cancer Hospital, Fuzhou/CN, ⁴Medical Oncology, Fujian Cancer Hospital, Fuzhou/CN, ⁵Medical Oncology, Fujian Provincial Cancer Hospital, Fuzhou/CN, ⁶Zhejiang Rongjun Hospital, Jiaxing/CN, ⁷Pathology, Fujian Cancer Hospital, Fuzhou/CN

**Background:** Oncogenic mutations in the epidermal growth factor receptor (EGFR) are found in a subset of patients with non-small cell lung cancer (NSCLC) and serve as important predictive biomarkers in this disease. EGFR exon 18-25 kinase domain duplication (EGFR-KDD) mutations has recently emerged as a new EGFR gene molecular subtype in non-small cell lung cancer(NSCLC) is extremely rare. **Method:** A 59-year-old male diagnosed with adenocarcinoma, who was shown to have gene detected by the next generation sequencing (NGS) and treatment with afatinib. **Result:** Histopathological observations with hematoxylin and eosin staining was shown adenocarcinoma, immunohistochemical staining for the expression of TTF-1, NapsinA and CK7. The gene detected by NGS that found an EGFR-KDD, CTNNB1 p.S37Y and TP53 p.R282W. Our case is the second report EGFR-KDD in Chinese populations. The patient was treated with afatinib therapy. And afatinib therapy showed a good response. **Conclusion:** The cases presented here highlight that adjusting our strategy and using newly available tools, such as comprehensive NGS tests, could prove useful in detecting alternative ways in which the EGFR pathway is altered (and can be targeted) in tumors.

**Keywords:** afatinib, NSCLC, EGFR-KDD

---

**P3.CR-13 DUAL DRIVE COEXISTENCE OF EML4-ALK FUSION AND TPM3-ROS1 FUSION LUNG ADENOCARCINOMA: A CASE REPORT**

Y. Zhu¹, C. Xu², P. Wang², W. Zhuang³, G. Chen⁴, K. Du⁵

¹Zhejiang Rongjun Hospital, Jiaxing/CN, ²Fujian Cancer Hospital, Fuzhou/CN, ³Pathology, Fujian Provincial Cancer Hospital, Fuzhou/CN

**Background:** Recent reports of overlap between ROS1 fusions and other oncogenic driver alterations have still been controversial. We reported a case of concomitant EML4-ALK fusion and TPM3-ROS1 in non-small-cell lung cancer (NSCLC) and further reviewed the clinical characteristic in this type double fusion of NSCLC patients. **Method:** A 47-year-old male diagnosed with adenocarcinoma (IA, T1aN0M0), who was shown to have ALK and ROS1 fusion by next generation sequencing. **Result:** The patient presented with a locally tumor of the left upper lobe with physical examination. He received lung cancer surgery with thoracoscopic. By using next generation sequencing assay, we found that tumor had concomitant EML4-ALK fusion and TPM3-ROS1. No recurrence was observed from a follow-up of 7 months in the case. Considering this rare ALK fusion and ROS1 double rearranged, we conclude that the incidence of this double mutation in NSCLC patients should be attentive. **Conclusion:** With the guidance of precise diagnosis, it is important that we should realize the incidence of concomitant ROS1 fusion and other driver genes including ALK or EGFR. And it should further explore treatment model and provides additional therapeutic options.

**Keywords:** Anaplastic lymphoma kinase, ros1, Concomitant
to the hospital with fevers. Osimertinib was held on admission. Imaging showed a possible pneumonia and she started IV antibiotics. Her fevers subsided and she was discharged on IV antibiotics. She resumed osimertinib upon discharge. The following day, she spiked fevers to 103.9°F. She was admitted to the hospital with fevers and new hypoxia requiring 4 liters of supplemental oxygen. Osimertinib was continued on admission. The results of her infectious workup, including bronchoscopy studies, were negative and she continued to spike high fevers despite broadened coverage for atypicals and fungi. Osimertinib was stopped on hospital day #4 due to QTc prolongation likely from its interaction with other QT prolonging antimicrobials. Given persistently high fevers despite broad antibiotics and a negative infectious workup, Osimertinib-induced pneumonitis became a likely explanation. Anti-microbials were stopped and prednisone 1mg/kg daily was started. She defervesced and had a rapid symptomatic improvement.

**Hospital Admission #1**

![Image](63x474 to 294x621)

Conclusion: Osimertinib toxicity has been investigated in the literature. In the AURA3 trial, pneumonitis resulted in 1/4 reported fatal adverse events. ILD-like events were reported in 10 patients (4%, 9 events were grade 1 or 2, 1 death). The FLUARA trial showed similar findings, with ILD-like adverse events in 11 patients (4%) with 7 “recovered” and 4 “recovering”. There were no reported fatal outcomes from ILD. After stopping Osimertinib during her 2 hospitalizations, our patient defervesced after 4 days and 3 days, respectfully. This correlates with the 48-hour half-life of Osimertinib. Our case demonstrates that determining drug toxicity can be challenging, especially when other etiologies such as infection are more common. For Ms. M, her lack of improvement with anti-microbials coupled with a significant response to steroids makes the case for Osimertinib-induced pneumonitis.

**Hospital Admission #2**

![Image](63x474 to 294x621)

Conclusion: Osimertinib toxicity has been investigated in the literature. In the AURA3 trial, pneumonitis resulted in 1/4 reported fatal adverse events. ILD-like events were reported in 10 patients (4%, 9 events were grade 1 or 2, 1 death). The FLUARA trial showed similar findings, with ILD-like adverse events in 11 patients (4%) with 7 “recovered” and 4 “recovering”. There were no reported fatal outcomes from ILD. After stopping Osimertinib during her 2 hospitalizations, our patient defervesced after 4 days and 3 days, respectfully. This correlates with the 48-hour half-life of Osimertinib. Our case demonstrates that determining drug toxicity can be challenging, especially when other etiologies such as infection are more common. For Ms. M, her lack of improvement with anti-microbials coupled with a significant response to steroids makes the case for Osimertinib-induced pneumonitis.

**P3.CR-15 A SQUAMOUS CELL CARCINOMA DIAGNOSED WHILE ON IMMUNOTHERAPY FOR LUNG ADENOCARCINOMA: A UNIQUE CLINICAL CASE.**

**Medical Oncology, Instituto Português de Oncologia Do Porto, Porto/PT**

**Background:** In the first-line setting, pembrolizumab is used in non-small lung cancer (NSCLC), when the expression of PD-L1 is 50% or more, and the tests for EGFR, BRAF V600E mutations and ALK and ROS1 rearrangements are negative. In this setting, pembrolizumab showed higher response rates, overall survival benefit and fewer adverse events when compared with chemotherapy. Also, there is increasing evidence of the efficacy of immunotherapy in other types of cancer, namely, locally advanced unresectable or metastatic cutaneous squamous cell carcinoma (cSCC). **Method:** A literature and patient clinical information review was performed. **Result:** A 72-years-old man, former smoker (60 pack-year), was admitted to our hospital for treatment of a stage IIIA (cT1N2M0) lung adenocarcinoma, diagnosed in November 2015 following screening exams. Concurrent chemoradiotherapy was administered between 27 th February 2016 and 14 th February 2016 (70Gy in 35 fractions, using Intensity-modulated radiation therapy technic with carbolplatin-paclitaxel duplet) followed by consolidation chemotherapy. Ten months later, a sub-carinal adenopathy recurrence confirmed by biopsy was diagnosed. The tumor was highly positive to PD-L1 (expression over 90%) and showed no predictive mutations/rearrangements of sensitivity to molecular target EGFR, ALK or ROS1 drugs. Radical radiotherapy to the mediastin was administered between 9 th January and 17 th February 2017 (60Gy in 30 fractions, using volumetric modulated arc radiotherapy technic). Metastatacular lung disease was diagnosed 7 months later, with right hilar and mediastinal adenopathies, bilateral pulmonary nodules and right pleural metastasis. Pembrolizumab 200mg every 21 days was initiated in 10 th November 2017 until 20 th March 2018 (7 cycles), due to disease progression and to grade 3 serostomia (CTCAE v4.03). Second-line palliative treatment with platin-pemetrexed duplet was proposed. In January 2018, while on pembrolizumab, the patient noticed an ulcerated and growing lesion in the right ala of the nose. The lesion was surgically removed in 29 th March 2018, with the diagnosis of an invasive cSCC. **Conclusion:** The patient developed a cSCC while on treatment with pembrolizumab for metastatic lung adenocarcinoma. The reason for this does not seem to be associated with immunotherapy as there is no current description in the literature of development of second neoplasia while on immunotherapy. Innate resistance to immunotherapy could be a possible explanation, with unsuccessful reactivation and poor clonal-proliferation of antigen-experienced T cells present in the tumor micro-environment.

**Keywords:** Immuneontherapuy, cutaneous squamous cell carcinoma, lung adenocarcinoma

**P3.CR-16 A CASE OF TOXIC HEPATIC EVENT OCCURRING IN COMBINATION TREATMENT WITH NIVOLUMAB AND ANTI-TUBERCULOSIS IN ADVANCED LUNG CANCER.**

T.H. Kim1, J. Kim2

1Department of Pulmonary and Critical Care Medicine, Bundang CHA Medical Center, CHA University, Gyeonggi-Do/KR. 2Department of Oncology, CHA Bundang Medical Center, CHA University, Gyeonggi-Do/KR

**Background:** Nivolumab, an immune checkpoint inhibitor, has been considered one of the standard treatments for previously treated advanced non-small-cell lung cancer. There is a not well known about the treatment and complications of tuberculosis in advanced lung cancer patients treating with nivolumab. We report a new case, toxic hepatic event occurring in combination treatment with nivolumab and anti-tuberculosis in advanced lung cancer patient. **Method:** The patient was 60-year-old man with advanced lung cancer. He had been treated for lung cancer stage IV by nivolumab for 15 months. Chest computed tomography showed a new developed wedge shaped consolidation in right upper lobe posterior segment. However, there was grossly no interval change of residual tumor less in left upper lobe. Nivolumab treatment was discontinued to confirm metastasis. In bronchoscopic examination, we found endobronchial mass like lesion in right upper lobe anterior segment posterior portion, and bronchoscopic biopsy was done for pathologic diagnosis. The specimen showed chronic granulomatous inflammation with necrosis, suggestive of tuberculosis, but PAS and AFB stains was negative. However, Mycobacterium tuberculosis polymerase chain reaction (TB-PCR) revealed positive finding, so the new consolidative lesion was confirmed as pulmonary tuberculosis infection, not metastasis. The patient began receiving anti-tuberculosis treatment. **Result:** After 1 month anti-tuberculosis treatment, he complained no adverse effect and the laboratory finding was normal range. Thus, he resumed nivolumab treatment. However, abnormalities in liver function tests (LFT) were observed after 2 weeks nivolumab treatment. Anti-tuberculosis medication and nivolumab was discontinued for control the elevated LFT. In further evaluation, he was likely to be drug-induced toxic hepatitis, and no other causative factor was found to affect hepatic function. **Conclusion:** This is the first report of toxic hepatic event occurring in combination treatment with nivolumab and anti-tuberculosis in lung cancer patient. Anti-PD L1 antibody immunotherapy is known to upregulate the immune response against micro-organisms, but the
patient was infected with the pulmonary tuberculosis. Although the mechanism is unknown, nivolumab combination treatment seems to increase the risk of toxic hepatitis in tuberculosis treatment. Thus, we should pay attention to liver function changes in combination treatment with nivolumab and anti-tuberculosis.

P3.CR CASE REPORTS
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.CR-17 AN INTERESTING CASE OF LONG-TERM IMMUNOTHERAPY RESPONSE IN METASTATIC NSCLC
S. Kulkarni1, S. Kazmi2
1Oncology, Western University, Windsor Regional Cancer Program, Windsor/ON/CA, 2Biotechnology, Wajat College of Applied Sciences, Muscat, Oman, Muscat/OM

Background: Immunotherapy has improved survival in advanced non-small cell lung cancer but optimal duration of treatment is unknown. We present a case of metastatic squamous cell carcinoma of lung, who continued to respond, in spite of short exposure to immunotherapy.

Method: A 71 year old male was diagnosed with T2N2M1 squamous cell carcinoma of lung in May, 2012. CT revealed right lung mass 4 cm and left lung lesion 1 cm but no distant metastasis. PET scan revealed FDG-avid lesion in the right lung with SUV of 18.5. Sub carinal lymph node and contralaetral nodule with SUV 3.4. His case was reviewed in Lung MCC and the consensus was to treat as stage 4 due to FDG avid contralaetal lung nodule. Result: He received 4 cycles of carboplatin and gemcitabine from May to July of 2012, with good response. He had progressive disease in October 2012 and received palliative radiation to the chest. He responded well. Further progression was observed on a PET scan to 7.2 cm hypermetabolic lesion in right lung, right hilar and sub carinal lymph nodes. Histopathological study showed persistent hypoxia with atypical cells in the lung. Chemotherapy with taxotere was offered from July to October of 2013. CT scan revealed reduction in size of lesion to 5 cm. In July 2014 CT revealed progressive disease with 9.1 cm right lung mass. Standard of care, Erlotinib was offered from August, 2014 to June, 2015 with good response. Further progression was revealed in July,2015 to 9.3 cm with adrenal metastases. Erlotinib was discontinued. Immunotherapy with Nivolumab was given from September to December of 2015. CT from December,2015 revealed index lesion in the right lung 6.9 cm compared to 9.6 cm. However, the patient developed grade 3 pneumonitis requiring admission to the hospital and was treated with steroids with discontinuation of Nivolumab. The index lesion remained stable on CT in April, 2016. Subsequently he remained stable till progression was observed on CT in May, 2017 to 9.8 cm. Conclusion: The immunotherapy has revolutionized the treatment of lung cancer. Nivolumab was offered to this gentleman as a 4th line of treatment. His exposure to immunotherapy was only 3 months, which achieved a durable response of 18 months. Duration of treatment required to achieve durable response might be different for each patient. More studies are needed to find out the optimal exposure to immunotherapy. This might enable a huge cost saving in a publicly funded health system.

Keywords: Durable response, Immunotherapy

P3.CR CASE REPORTS
WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30

P3.CR-18 CENTRAL NERVOUS SYSTEM ACTIVITY OF CHECKPOINT INHIBITOR IN NON-SMALL-CELL LUNG CANCER
M. Pereira-Lima1, A. Brunetto2, T. Leão1, G. Geib1, T. Rebelatto1, H. Andrade1, C. Escovar3
1Radiation Oncology, Hospital de Clínicas de Porto Alegre, Porto Alegre/BR, 2Medical Oncology, Hospital Mouins de Vento, Porto Alegre/BR, 3Clinical Oncology. Santa Casa de Misericórdia Hospital, Porto Alegre/BR

Background: Data regarding the activity of atezolizumab in the central nervous system (CNS) and its toxicity in combination with radiotherapy in patients with brain metastases (BM) of non-small cell lung cancer (NSCLC) is limited. Most clinical trials adopt strict selection criteria excluding patients with active BM and the blood–brain barrier (BBB) seems responsible for limiting the distribution of agents into the CNS.

Method: Here we present a 51 yr-old female patient with the diagnosis of stage IV NSCLC with an isolated BM (T3 N3 M1b, non-mutated EGFR). She received stereotactic radiosurgery (SRS) to the isolated brain lesion (figure 1) and sequential palliative first-line systemic monotherapy with atezolizumab (1200mg/dose q21d, 15 doses).

Result: Control brain MRI 3-month post SRS showed a new lesion in the thalamus (figure 2) while on atezolizumab. Medical team decided to continue systemic treatment and the repeat brain MRI demonstrated complete response to the new lesion. Additionally, treated lesion showed evidence of pseudoprogression. While on follow-up, the patient continued to respond in the brain for 14 months.

Conclusion: This case reports activity of atezolizumab in CNS. The advent of immunotherapy in the therapeutic algorithm of NSCLC has raised the need to identify patients that could mostly benefit from checkpoint inhibitors.

Keywords: Immunotherapy, brain, Metastases

FIGURE 1. Right frontal lesion treated with SRS. Lesion-based, to a dose of 20 Gy in one fraction. Yellow contour represents the 95% isodose line and blue contour the 5% isodose line.

FIGURE 2. Axial contrast-enhanced T1-weighted MRI sequence at baseline pre SRS. 3, 10 and 13 months of follow up after SRS. At right frontal lesion, treated with SRS is a dose of 20 Gy. During follow up the lesion increased in size as seen in the 10 months MRI, but there was no increase in perfusion and it reduced in the latter MRI, suggesting radiation effect. a) left thalamic lesion (red area), evidenced in the 2 months follow up MRI demonstrating sustained complete response in the subsequent MRI.
**Background:** Despite the significant clinical benefits, checkpoint inhibition is associated with a unique spectrum of immune-related adverse events. It is sometimes difficult to distinguish a rare adverse effect from a cancer progression, so such effects should be reported to be diagnosed in clinical practice. **Method:** A 56-year-old male patient, former smoker, was diagnosed with adenocarcinoma of lung with bone metastasis. He did not have EGFR mutation or ALK translocation, but a PD-L1 expression of 80%. The patient started first-line treatment with Pembrolizumab in January 2018, and it was side effects were followed appropriately. The patient was received Pembrolizumab 2 mg/kg and dexamethaspin with progressive improvement of the symptoms. After 10 days, he received hospital discharge and Pembrolizumab was permanently discontinued. **Conclusion:** Our case demonstrated that the PD-1 blockade has potential life threatening adverse events, with the necessity of suspension. To the best of our knowledge, that is the first case of thromboembolic events related to immunotherapy in a patient with no previous history of thrombophilia or autoimmune disease. **Keywords:** Non Small Cell Lung Cancer, Thromboembolism, Immunotherapy

**P3.CR-20 THE EFFECT OF PEMBROLIZUMAB IN EGFR MUTATED LUNG ADENOCARCINOMA PATIENTS WITH PD-L1 OVEREXPRESSSION: TWO CASES REPORT**

**T. Uenami, M. Ishijima, M. Kanazu, H. Kurebe, R. Edahiro, K. Nishida, Y. Akazawa, Y. Yano, T. Yamaguchi, M. Mori**

**Background:** Recently, the immune checkpoint inhibitor (ICI) pembrolizumab was demonstrated to be superior to platinum doublet chemotherapy in the first-line setting in patients with tumor PD-L1 expression of at least 50%. However, because patients with epidermal growth factor receptor (EGFR) mutations of anaplastic lymphoma kinase (ALK) rearrangements were not included in that study, the efficacy of this agent in lung cancers carrying EGFR mutations could not be determined. **Method:** We retrospectively evaluated the clinical effects of pembrolizumab treatment for EGFR mutated lung adenocarcinoma patients with PD-L1 overexpression. **Result:** Between March 2017 and February 2018, 343 cases were evaluated immunohistochemical analysis of PD-L1 expression by tumor cells according to findings of transbronchial lung biopsies or surgically resected lung specimens at our institution. Of the 343 tumors analyzed, 12 had both TPS of at least 50% and positive for EGFR mutations. Only 2 cases of EGFR mutant NSCLC patients with PD-L1 overexpression treated with pembrolizumab. We described 2 cases of response to pembrolizumab in EGFR mutated lung adenocarcinoma patients with PD-L1 overexpression. Case 1 involved a 75-year-old male, diagnosed with stage IVB lung adenocarcinoma. The tumor was found to have a PD-L1 tumor proportion score (TPS) of almost 100% and was EGFR mutation positive. First line treatment with erlotinib yielded no response. Case 2 involved an 83-year-old female, diagnosed with Stage IVA adenocarcinoma with EGFR mutation, as determined from left pleural effusion cytology. Gefitinib was selected for the initial treatment. The tumor regressed remarkably, but then slightly progressed 11 months later. We performed re-biopsy and the tumor was found to have a PD-L1 TPS of at least 95% and to be harboring the same EGFR mutation as that in the initial biopsy but was negative for T790M. In both cases, second-line therapy was commenced using pembrolizumab after failure of first-line EGFR-TKI therapy. After administering pembrolizumab, both tumors were observed to be reduced on chest radiography. Therefore, pembrolizumab was observed to be effective. **Conclusion:** The cases presented in this report indicate that ICIs are an effective treatment for EGFR mutated lung adenocarcinoma patients with PD-L1 overexpression. **Keywords:** Programmed death-ligand 1, Non-small cell lung cancer, Epidermal growth factor receptor

**P3.CR-21 UTILITY OF THORACOSCOPY IN DIAGNOSIS OF LUNG TUMOUR IN PLEURAL EFFUSION**

**N. Pandhi, N. Kajal, S. Rana**

**Pulmonary Medicine, Government Medical College, Amritsar/N**

**Background:** Papillary adenocarcinoma of the lung is a rare malignancy accounting for 7.4%-12% of the lung adenocarcinomas. A pleural metastasis is often accompanied by a malignant pleural effusion (MPE), can be one of the presentations of this disease. Differential diagnosis of exudative recurrent pleural effusion is often a lengthy process brimming with various snags. Contrary to thoracocentesis and closed pleural biopsy, thoracoscopy allows biopsy with direct visualization. Medical thoracoscopy increases the diagnostic yield in patients with pleural disease especially when thoracocentesis and closed pleural biopsy are non diagnostic. **Method:** We present case of 75 year old female housemaker with complaint of breathlessness and chest pain for the last 3 months. She was a never smoker and did not have any significant personal history. On physical examination and chest xray – a massive pleural effusion was seen on the left side. A chest tube was inserted. Because of unilateral haemorrhagic pleural fluid with an exudative pattern, medical thoracoscopy was performed. We observed a hepatized lung with severe pleural inflammation, medical thoracoscopy was done and biopsy was taken. Because of the family’s low economic status, we could not perform immunohistochemistry. Smear and culture of the pleural fluid were negative for tuberculosis. Cytology of the pleural fluid was positive for malignancy. On histopathology, Sections from the biopsy taken showed a malignant neoplasm with atypical cells arranged in a branching papillary pattern with fibrovascular cores. The stroma are lined by columnar cells with moderate amount of cytoplasm showing nuclear overlapping hyperchromasia and coarse chromat. Few of the nuclei appear optically clear. Invasion into the deeper tissues is seen in the form of different sized angular and malignant glands surrounded by a dense desmoplastic stoma. Areas of necrosis, neutrophilic exudate and hemorrhage were also seen. **Result:** Hence a diagnosis of stage IV papillary type of adenocarcinoma lung was made. And the patient was started on Chemotherapy but unfortunately she expired in the course of treatment. **Conclusion:** High index of suspicion should be kept for the possibility of malignancy in a massive pleural effusion especially when its being refilled – recurrently. Medical thoracoscopy is always helpful in diagnosis and management of these cases as seen in the present case report. In developing nations where interventional pulmonology is still not a routine procedure, by this case report we wish to highlight its importance. **Keywords:** papillary adenocarcinoma, pleural disease, Thoracoscopy

---

**P3.CR-22 PULMONARY TUBERCULOSIS - A CHAMELEON; MIMICKING LUNG CANCER ON IMAGING**

**N. Pandhi, N. Kajal, S. Gupta, S. Rana**

**Pulmonary Medicine, Government Medical College, Amritsar/N**

**Background:** Tuberculosis (TB) often mimics other diseases including malignancy, and has been rightly called a benign imposter. Most common radiographic appearances seen in TB are cavitary, fibroproliferative, exudative, acinar, micro and macronodular and miliary types. The typical presentation of pulmonary tuberculosis is easily recognisable but the disease, a well-known masquerader, can be a source of diagnostic confusion radiologically when the presentation is atypical, especially in the regions in which the tuberculosis is endemic. Tuberculosis may be radiographically revealed as mass formation in the cases clinically and radiographically examined, difficulties may be encountered in the differential diagnosis due to similar constitutional symptoms such as fatigue, breathlessness, , and anorexia both in tuberculosis and carcinoma, and the radiologic appearance is also confusing. **Method:** A 65 year old female patient was referred to our department with a 3 months history
of breathlessness, chest tightness, intermittent non-productive cough and unintended weight loss of 5 kg in the past 2 months. She had no reported fever or any prior medical history. A presumptive diagnosis of lung cancer was made from elsewhere based on her radiological appearance on computed tomography (CT) scan of chest which showed a large peripherally located enhancing solid mass lesion in the posterobasal segment of the middle lobe abutting the pericardium along with multiple nodular opacities. CT guided fine needle aspiration cytology was done from the lesion and it showed acute on chronic inflammation. The next diagnostic step was bronchoscopy with negative results regarding malignancy. The bronchial wash samples were also sent to microbiology with negative results for bacteria, fungi, even negative on direct microscopy but Cartridge based nucleic acid amplification test (CBNAAT) (Polymerase Chain Reaction based) for Mycobacterium tuberculosis provided the diagnosis by showing growth of the Mycobacterium tuberculosis. **Result:** The patient was diagnosed as pulmonary tuberculosis and started on standard anti-TB-therapy and she responded symptomatically as well as with clearing of the lesion, radiologically. **Conclusion:** In conclusion, tuberculosis emerged as a neoformative mass or mass-like radiographic appearance is uncommon and this can be easily confused with the tumoral formations. Differentiation from lung cancer based on imaging findings alone may be challenging and often ambiguous, thereby highlighting the importance of use of interventions like bronchoscopy in suspecting cases.

**Keywords:** bronchoscopy, lung cancer, tuberculosis

**P3.CR CASE REPORTS**

**WEDNESDAY, SEPTEMBER 26, 2018 - 09:45-13:30**

**P3.CR-23 MULTILOBAR ADENOCARCINOMA: A CASE REPORT AND REVIEW OF THE LITERATURE OF PAPILLARY ECCRINE ADENOCARCINOMA PRESENTING WITH RESPIRATORY FAILURE**

J. Turner1, W. Hanna1, J. Dudgey2, S. Baveja1, G. Sneed1, H. Huang2, W. Höhenforst-Schmidt2, P. Zarogoulidis2

1Department of Medicine, University of Tennessee Graduate School of Medicine, Knoxville/TN/US, 2肿瘤科, Shanghai Hospital of Traditional Chinese Medicine, Shanghai/CN

**Background:** Aggressive digital papillary adenocarcinoma (ADPaCa) is a rarely recognized neoplasm of the sweat gland duct that has a high metastatic potential with metastasis seen in the lymph nodes, liver, lungs, and bones. Originally described in 1865, this tumor represents a rare group of sweat gland carcinomas. We report the uncommon presentation of a patient with metastatic eccrine adenocarcinoma and hypoxic respiratory failure with a review of the literature.

**Method:** A 52-year-old Caucasian male was brought to the emergency room by his wife appearing cyanotic and with a saturation of 82%. The respiratory exam demonstrated coarse breath sounds and a well-healed right thoracotomy scar. His extremities demonstrated a prior amputation of the second finger of the left hand. He was subsequently intubated and imaging obtained (Fig. 1).

The wife noted he had a slowly growing lesion on the left second finger approximately 10 years before initial presentation with primary amputation and a diagnosis of papillary eccrine adenocarcinoma. Concurrently, a right upper lobe mass was found and, with his strong history of tobacco abuse, a right upper lobectomy was performed with negative lymph nodes and margins but the pathology consistent with metastatic papillary eccrine adenocarcinoma. He first presented at our facility 3 years later with a chest wall mass and biopsy, again, demonstrated metastatic papillary eccrine adenocarcinoma. Pathology of the mass demonstrated multiple fragments of tissue containing metastatic adenocarcinoma. Immunohistochemistry disclosed these to be tumor cells positive for pancytokeratin, S100, SOX-10, and p63, and negative for TTF-1, CK20, Napsin, and CDX2. In review, with the initial left index finger excision, this was diagnostic of metastatic papillary eccrine adenocarcinoma.

**Result:** Section not applicable. **Conclusion:** Aggressive digital papillary adenocarcinoma is a rare tumor of the eccrine sweat glands with marked metastatic potential often affecting the hands and presenting as a slowly growing mass or cystic lesion.

**Keywords:** Adenocarcinoma, eccrine, metastatic

---

**P3.CR-24 SURGICAL RESECTION OF 30 YEARS' RECURRING PNEUMONIA: 1 CASE OF GIANT BRONCHOPULMONARY SEQUESTRATION**

J. Zhang1, N. Chen2, X. Qiu1

1Lung Cancer Center, China Medical University Lung Cancer Center, the First Hospital of China Medical University, Shenyang/CN, 2Department of Logistic Management, College of Economics and Management, Liaoning University of Traditional Chinese Medicine, Shenyang/CN

**Background:** Bronchopulmonary sequestration is easily omitted or missed diagnosed as recurrent pulmonary infection or pneumonia due to having no specific symptoms. Recurring pulmonary infection is the most common manifestation for bronchopulmonary sequestration. Enhanced CT is useful for diagnosis by revealing clearly the aberrant vessels from aorta to the sequestrated mass. Surgery is the best choice for treatment. Here we report one rare case of giant tumor-like bronchopulmonary sequestration, with three aberrant thicker vessels from descending aorta to the sequestered mass. **Method:** A male aged 38 in Nov 2017, with recurring pneumonia, breath with difficulty, fatigue for more than 30 years, until recently enhanced CT revealed three aberrant thicker vessels from descending aorta to the sequestered mass. **Result:** Standard posterolateral thoracotomy was performed, and severe adhesion closed the thoracic cavity. The normal pulmonary fissure was not existed. Whole left lower lobe became a 20x15x12cm3 solid giant tumor-like mass, with sever inflammatory edema on pulmonary surface, rich lateral wall circulation between the lung and chest wall. Three aberrant thicker vessels 2.5, 1.5, 1.2cm in width were found from descending aorta connecting to the left lower lobe, confirming the diagnosis of bronchopulmonary sequestration. Severe adhesion prevented separating left lower-lobe from diaphragm. Left lower pulmonary vein was first separated, ligated and cut; left lower-lobe bronchus, left lower-lobe arteries branches were then separated, ligated and cut. The widest one of the three aberrant thicker vessels was almost as same as the descending aorta in width. Three vessels were 2.5, 1.5, 1.2cm in width were separated, ligated and then cut, respectively. The patient recovered rapidly. Six months’ follow-up revealed that the patient recovered better than before, pneumonia, dyspnea, and fatigue were all completely disappeared. **Conclusion:** Bronchopulmonary sequestration is less common and easily omitted or missed diagnosed as recurrent pneumonia.
Method:

Section not applicable

Result:

We report a 50 years old lady presented with persistent cough and palpitation, difficult to breathe and got worsen with daily activities since 3 months. There was no fever, no weight loss and normal appetite. The left lung sound was decreased but no rales and wheezing. Chest X-Ray showed mass suspected bulky adipose tissue consistent with mediastinal lipoma. Thoracotomy was performed and 2.8 kilograms intramediastinal mass was removed and pathological evaluation confirmed intramediastinal lipoma. Patient was recovered with minimal symptoms.

Conclusion:

Mediastinal Lipoma is a rare case and usually found in adult without specific symptoms, but could be evaluated by thoracic CT Scan and/or MRI and could be successfully removed by surgical resection.

Keywords: Mesenchymal Tumor, Mediastinal Lipoma, resection
P3.CR-27 SURGICAL TREATMENT OF A RARE CASE OF MEDIASTINAL MASON’S TUMOUR MIMICKING A THYMOHA

A. De Palm\1, M. Lorusso\1, G. De Iaco\1, O. Pizzuto\1, G. Garofalo\1, A. Fiorella\1, E. Maiolino\1, G. Nix\1, M. Schiavone\1, A. Cimmino\1, R. Quercia\1
\1Section of Thoracic Surgery, Department of Emergency and Organ Transplantation, University of Bari “aldo Moro”, Bari/IT. \2Division of Pathology, Department of Emergency and Organ Transplantation, University of Bari “aldo Moro”, Bari/IT

Background: Mason’s tumour or intravascular papillary endothelial hyperplasia (IPEH) is a rare non-malignant pseudotumoral disease, characterized by an exuberant endothelial proliferation usually arising as a reactive process within a normal blood vessel. The pathogenesis of intravascular papillary endothelial hyperplasia is still unclear, but it seems that the exuberant tissue derives from an autocrine stimulation of the endothelial cells due to the action of growth factors (like VEGF) on the type of spindle endothelial cells, with a primary or intravascular form, secondary or mixed form and tertiary or extravascular (rarer) form. Mediastinal localization is exceptional. We report a rare case of antero-superior mediastinal Mason’s tumour mimicking a thymoma, successfully treated with surgery.

Method: A 48-year-old man presented to our institution with computerized tomography (CT) evidence of a 4 x 3 cm antero-superior mediastinal mass, extending up to the right thyroid lobe, resembling a thymoma. Total body 18F-fluorodeoxyglucose positron emission tomography (FDG-PET)/CT revealed a SUV max of 3.5. Despite complaining of a myastheniform syndrome (asthenia and slight palpebral ptosis) laboratory and instrumental evaluation (electromyography) were found to be normal. The patient had previously undergone resection of a right supraclavicular Mason’s tumour and of a sublingual angiomata. After cardio-respiratory function evaluation, through a sternotomy, the patient underwent thymectomy and challenging resection of a hypervascularized mediastinal lesion adjacent to the right upper lobe of the thorax but apparently independent from it, and tenaciously adherent to the right inominate vein.

Result: Postoperative course was uneventful. Histopathology revealed a normal adipose thymic involution and a Mason’s tumour or intravascular papillary endothelial hyperplasia with mediastinal localization. The patient underwent hemocoagulative and genetic tests, as Mason’s tumour may be associated with thrombophilia and genetic syndromes. Conclusion: Mason’s tumour can clinically and radiologically mimic various benign and malignant mediastinal lesions, such as thymomas. The definitive diagnosis can be obtained only with the histological examination, demonstrating the presence of endothelial papillae, with a thin fibrous stroma, protruding into the vessel lumen. To the best of our knowledge, this is the first reported case of surgical treatment of a mediastinal Mason’s tumour. However, surgical resection may be technically difficult due to the intrinsic hypervascularized nature of these pseudotumoral lesions.

Keywords: Surgical treatment, Thymoma, Mason’s tumour

P3.CR-28 SIMULTANEOUS PRESENTATION OF MEDIASTINAL MALIGNANT PERIPHERAL NERVE SHEATH TUMOUR WITHINTRAPONUMARY METASTASIS, AN EXTREMELY RARE CASE

H.V. Kara\1, A. Turma\1, I. Sarbay\1, S. Batur\2
\1Department of Thoracic Surgery, Istanbul University Cerrahpasa Medical Faculty, Istanbul/TR. \2Department of Pathology, Istanbul University Cerrahpasa Medical Faculty, Istanbul/TR

Background: Malignant peripheral nerve sheath tumors (MPNST) are sarcomas originating from the cells constituting the nerve sheaths and occupy 5-10% of all soft tissue sarcomas. MPNSTs may occur in any peripheral nerve. They are often found in the chest wall and the posterior mediastinum. Their simultaneous existence with intrapulmonary metastasis is not commonly seen. Method: In this report, we present a rare patient with Simultaneous presentation MPNST located in the right posterior mediastinum and having contralateral Lung metastasis both treated with minimally invasive surgery. Result: Clinical summary: A 57-year-old woman had no history of smoking had respiratory symptoms sputum and dyspnea. Chest computed tomography revealed a posterior mediastinal solid mass of 55mm on the right hemi thorax also as a 33mm solid mass lesion located on the left upper lobe. She first underwent video assisted thoracoscopic surgery (VATS) resection of the lesion on the right. The histopathological examination revealed malignant peripheral nerve sheath tumor (MPNST). Just after the first intervention she underwent left VATS lingual sparing upper lobectomy . The histopathological examination revealed the lesion as intrapulmonary metastasis of the previous MPNST. Patient did not have any problem related with surgery and discharged quickly in both surgeries. She had a chemotherapy afterwards. Conclusion: Simultaneous presentation of MPNST with lung metastasis are extremely rare clinical cases with very poor prognosis. Our patient is doing well on the 11th months after resection. This may be a good example of the synergic effect of surgery with chemotherapy with successful outcomes.

Keywords: malignant peripheral nerve sheath tumor, Intrapulmonary metastasis, minimally invasive surgery

P3.CR-29 EN-BLOC EXCISION OF INTRAPERICARDIAL THYMOHA USING SINGLE PORT VIDEO-ASSISTED THORACOSCOPIC SURGERY. A RARE CASE

H.V. Kara\1, A. Turma\1, I. Sarbay\1, S. Batur\2
\1Department of Thoracic Surgery, Istanbul University Cerrahpasa Medical Faculty, Istanbul/TR. \2Department of Pathology, Istanbul University Cerrahpasa Medical Faculty, Istanbul/TR

Background: Thymomas are located in the normal location of the thymus in the anterior mediastinum. It is very rare for thymomas to arise primarily intrapericardially. There had been only few reports for this unusual localization. We report a case of a patient with an entirely intrapericardial thymoma. Method: A 76-year-old man with a known human immunodeficiency virus (HIV) positivity and has been under close follow up for the recent 5 years . The patient had a computerized tomography of the thorax due to suspicious mediastinal enlargement. The radiological evaluation revealed an intrapericardial mass of 3x3x2.5 cm dimensions.

Result: We have performed right uniportal videoassisted thoracoscopic surgery( VATS) for the intrapericardial mass resection. Histopathological examination revealed the tumour as type A thymoma, according to the World Health Organization classification (1999). The biopsyed adjacent pericardial tissue in relation with the tumour showed thymic gland. As the patient was evaluated again he did not have any signs of symptoms of myasthenia gravis. The patient was discussed in tumour board and agreed for a local radiation treatment on the site of excision. The patient is in his early post operative period with no clinical problem.

Conclusion: HIV positive patients are in higher risk for opportunistic infections and other tumoral lesions including malignant thymic tumours . Unexpected localization for thymoma might be the question of HIV and needs to be proven with more patients and clinical data.

---

P3.CR-30 PLEURAL DISEASES ON SINGLE LUNG AFTER PNEUMONECTOMY FOR CANCER

N. Motas, M. Davidescu, M. Tetu, O. Rus, V. Manolache, A. Burlacu, T. Horvat, I. Horvat
Thoracic Surgery, Oncology Institute Bucharest, Bucharest/RO

Background: After pneumonectomy for cancer, the residual lung can be affected by pleural disorders, which usually produce severe respiratory distress and impose emergency treatment. Method: Between 2000 and 2016 we identified 11 patients with previous pneumonectomy for cancer, who presented with pleural disease; 9 of them needed emergency treatment. Result: There were 2 cases of pneumo-thorax; one developed in first postoperative day after left pneumonectomy and the second pneumo-thorax developed after CT-guided needle biopsy of a left pulmonary nodule (single left lung after pneumonectomy for cancer) – in both cases the pneumo-thorax needed emergency chest tube drainage. Also, there were 8 cases with liquid pleural effusions – 6 malignant, 1 tuberculous and 1 empyema. We performed 2 thorascopies and 6 chest drain insertions; in one case the patient with persisting left pneumo-thorax presented with right pleural and pericardial effusion, for which a pericardial peumatic left parastramal drainage with ultrasound guidance, and a right pleurotomy, were performed. In another case a left tension loculated pleural effusion needed CT-guided pleural drainage. In 3 cases the diagnosis was performed. Finally, one patient with previous pneumo-thorax presented with left pulmonary nodule and he was prepared for resection. At thoracotomy a pleural entrapment of the inferior lingual segment was found and a decorticating was performed; no pulmonary nodule was found.

Conclusion: Neither intraoperative nor at postoperative CT-scan. The pleural disease developed on single surgical lung (pneumonectomy for cancer) may be malignant or benign, correlated or not with the primary...
malignancy which imposed previous pneumonectomy. In endemic areas for TB specific pleural effusions and pleural retraction may appear and surgical treatment is necessary. Special attention is needed for nodules on single lung proposed for CT-guided biopsy – the pneumothorax on single lung has indication for drainage.

Keywords: pleural disease, single lung, pneumonectomy

P3.CR-31 A CASE OF THYMOMA WITH AUTOIMMUNE HEPATITIS FOLLOWING PREOPERATIVE CHEMOTHERAPY

Division of Thoracic Surgery, Department of Surgery, Kyoto Prefectural University of Medicine, Kyoto/JP

Background: We encountered a case of thymoma with autoimmune hepatitis. Method: A 63-year-old woman was found to have an abnormal finding on chest radiography during a medical checkup, but did not seek further care. She was referred to our hospital one year later when a bilateral hilar abnormality was again found during a checkup. Chest computed tomography (CT) showed a 4.6 x 3.0 x 5.6 cm mass with calcifications in the anterior mediastinum. The tumor invaded the right lung and middle lobe, in association with a 2.0-cm daughter nodule in the head of the main tumor, with multiple pleural seeding lesions in the right thoracic cavity. Although she was asymptomatic, the anti-acetylcholine receptor antibody level was elevated to 33 nmol/L and the soluble IL-2 receptor antibody was elevated to 1,700 U/mL. The mass was diagnosed with CT-guided biopsy as a type-B2 thymic tumor (CT3NOM1a, c-Stage IV). She underwent induction chemotherapy (ADOC, 2 courses). After chemotherapy, abnormal liver enzyme levels (aspartate aminotransferase: 451 U/L, alanine aminotransferase: 529 U/L) were noted on preoperative examination. She was diagnosed with autoimmune hepatitis based on liver biopsy findings and treated with oral prednisolone 30 mg. Result: Surgery was performed after prednisolone dose was gradually decreased to 20 mg. Extended thymectomy and pulmonary wedge resection using median sternotomy were performed. Pleural dissemination was resected using video-assisted thoracoscopic surgery. The pathological findings showed type-B3 thymic carcinoma (pT3NOM1a, p-Stage IV, Masaoka classification IVa). She was placed under observation without any additional treatment. Prednisolone dose has been gradually decreased to 15 mg without exacerbation of liver function. The anti-acetylcholine receptor antibody level decreased after surgery. Conclusion: Autoimmune diseases in association with thymoma are well known, but reports of autoimmune hepatitis are very rare. Autoimmune hepatitis must be considered when acute liver disease is observed.

P3.CR-32 AMYLOID DEPOSITION IN THYMIC EXTRANODAL MARGINAL ZONE LYMPHOMA OF MUCOSA-ASSOCIATED LYMPHOID TISSUE: A CASE REPORT

K.J. Park, D.Y. Kim  
Radiology, Ajou University School of Medicine, Suwon/KR

Background: Extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT) is a rare thymic tumor with a few cases described to date. Amyloid deposition can be unusually associated with MALT lymphoma, and those cases have been reported arising from the lung, soft tissue, ocular adnexa, skin, and aerodigestive tract. To our knowledge, our case is the first report of thymic MALT lymphoma with amyloid deposition. Method: A 35-year-old East Asian male presented with dyspnea on exertion. He did not have any history of autoimmune disease. His CT scan showed a 7.5-cm mass in the anterior mediastinum with extensive conglomerated calcification (Fig 1a and b). Acetylcholine receptor antibody titer was elevated up to 7.83 nmol/L. The mass was removed by median sternotomy and histologically diagnosed as extranodal marginal zone lymphoma of MALT arising from the thymus. Extensive amyloid deposition was noted within the tumor with a positive stain to Congo red, apple-green birefringence on polarized microscopy and binding of antibodies predominantly to kappa light chain.

Keywords: thymoma, amyloid, thymus

Result: Section not applicable Conclusion: We report a case of thymic MALT lymphoma with extensive amyloid deposition. Unusual CT manifestation of extensive calcification can lead to difficulties in differential diagnosis of mediastinal masses.

Keywords: lymphoma, Amyloid, thymus

P3.CR-33 TRICHOPTYSIS, HEMOPTYSIS AND CHEST PAIN: A VERY RARE PRESENTATION OF ANTERIOR MEDIASTINAL TERATOMA IN A YOUNG PATIENT

A. Saidane, B. Dhahri, H. Cherif, H. Aouina  
Charles Nicolle Department Tunisia, University of Medicine Tunisia, Tunis/TN

Background: A 28-year old patient who presented to the Emergency Department for a 2-week history hemoptysis, right chest pain and intermittent sebaceous expectorations. He had such intermittent chest pain for the last 2 months. He had no fever, breathlessness, loss of weight, joint pain or renal symptoms. He had no significant personal or family history of tuberculosis. On examination, he was afebrile. Full clinical examination revealed decreased breath sound in the left lung with a dull-percussion note. Method: 2/Investigations: Laboratory investigations were normal. The coagulation tests were normal. The Tuberculin skin test was negative. The Chest CT-scan revealed a large well-circumscribed anterior mediastinal mass with heterogeneous mixed density (fat, soft tissue and calcifications), in the left hemi-thorax. It also showed intratumoral bleeding associated with a left massive hemomediatinum. This radiological aspect suggested a teratoma. Preoperative labs showed normal carcinoembryonic antigen (CEA), alpha-fetoprotein (AFP), CA-125 and beta-HCG level were normal. Result: 3/Treatment: The multidisciplinary team decision was to perform surgery. A standard postero-lateral thoracotomy was performed in the 5th intercostal space. Immediately upon entering the thoracic cavity, a bulky mediastinal mass was found to have a strong adhesion to the upper left lobe. The mass itself was originating from the thymus and extending down to the left lung. A complete thymectomy with a total removal of the tumor was...
On examination, she was in significant distress due to pain. She was Emergency Department with a 2-month progressively worsening chest pain. She had pneumonia at the age of 2 years. The family history was marked by an allergic rhinitis in the father. On examination, she was afebrile. Full clinical examination revealed decreased breath sound in the left lung and dull-percussion note of the left hemi-thorax. The patient had a computerized tomography of the thorax revealing a bulky tumoral mass measuring 28*19*12cm. The case was reviewed on 2 times. Final pathology showed a well-circumscribed, white- pearly, bulky tumoral mass measuring 28*19*12cm. The case was reviewed on the Multidisciplinary team. The decision was made to proceed with the second surgical time. The patient is currently doing well 6 months after the initial diagnosis.

Background: Thymomas are located in the normal location of the thymus in the anterior mediastinum. It is very rare for thymomas to arise primarily intracardially. There had been few reports for this unusual localization.

Method: We report a case of a patient with an entirely intrapericardial thymoma. A 76-year-old man with a known human immunodeficiency virus (HIV) positivity and has been under close follow up for the recent 5 years. The patient had a computed tomography of the thorax due to suspicious mediastinal enlargement. The radiological evaluation revealed an intrapericardial mass. We have performed right uniportal videoassisted thoracoscopic surgery (VATS) for the intrapericardial mass resection. Pathological evaluation revealed a Type A thymoma with a 3x3x2.5 cm dimensions. He was discharged on the 3rd day of operation. He underwent pericardial irradiation. He has been doing well for 5 months.

Conclusion: Whether unusual localization of thymoma could be attributable to HIV infection remains unknown and needs to be confirmed with case series.

P3.CR-35 A RARE GIANT THORACIC DESMOID TUMOR/A CASE REPORT
A. Saidane, B. Dhaifhir, H. Aouina
Charles Nicolle Department Tunisia, University of Medicine Tunisia, Tunisia/TN

Background: A 43-year-old lady who presented to the Emergency department with a 2-month progressively worsening chest pain associated with dyspnea. There was no remarkable past history. On examination, she was in significant distress due to pain. She was afebrile, Full clinical examination revealed decreased breath sound in the left lung and dull-percussion note of the left hemi-thorax.

Method: A Computed-Tomography Scan (CT) revealed an expansile soft–tissue density mass locating in the left hemi-thorax. The large mass invaded the posterior arches of the 6th and 7th ribs and the 6th and 7th vertebral bodies with an ‘hour-glass’–like extension through the growth of bone including the bone, lymph nodes and the anterior osteolytic lysis. The left lung was compressed. She had a Transthoracic Needle biopsy of the tumor. The histological aspect can be perfectly fitted with a fibromatosis.

Result: After a strict work-up and assessment of the prognosis, that results in establishment of an indication for surgery in 2 times. Final pathology showed a well-circumscribed, white–pearly, bulky tumoral mass measuring 28*19*12cm. The case was reviewed on the Multidisciplinary team. The decision was made to proceed with the second surgical time. The patient is currently doing well 6 months after the initial diagnosis.

Conclusion: To conclude, this case demonstrates the complexities involved in the presentation and the management of these rare tumors. We also underline that surgical treatment is safe and efficient.

P3.CR-37 EXTENSIVE RESECTION FOR INVASIVE ATYPIAL CARCINOID OF THYMUS: 1 CASE REPORT
J. Zhang¹, N. Chen², X. Qiu³
¹Lung Cancer Center, China Medical University Lung Cancer Center, the First Hospital of China Medical University, Shenyang/CN, ²Department of Logistic Management, College of Economics and Management, Liaoning University of Traditional Chinese Medicine, Shenyang/CN

Background: Atypical carcinoid of thymus (ACT) is extremely rare. Patients with ACT usually have no specific symptoms, and mostly are found as mediastinal tumors when taking chest X-ray or CT scanning. ACT is usually aggressive and extensive surgical resection is of first choice, even though chemo-radiation is recommended but showing less effects. Here we report one case of ACT invading adjacent organs and tissues received extensive radically surgical resection.

Method: A male aged 53 in Mar 2018, with chest distress, fatigue for 1 month; chest CT revealed a round 5x4x3cm3 mediastinal tumor sitting on superior vena cava, aortic arch. Thymoma was diagnosed. Heart and lung function test showed normal; there was no contraindication for surgery.
Surgical resection became first of choice. **Result:** Median sternotomy was performed, and the 5x4x3cm³ tumor was confirmed invading into adjacent superior vena cava and left innominate vein, invading aortic adventitia, pericardium, right mediastinal pleural and right upper lobe of the lung. Extensive and radical en block resection was performed including resection and followed plasty of the lateral wall of the superior vena cava and right innominate vein, resection of being-invaded aortic adventitia, pericardium, right mediastinal pleural, right upper lobe of the lung, and resection of the whole thymoma and fat tissues of thymus body and four feet. The surgical resection was evaluated as perfect, being resected completely and radically. Postoperative adjuvant radiation was followed one month later. No chemotherapy was added. The patient is now recovering rapidly and healthily. Long term follow-up is needed to monitor recurrence and metastasis. **Conclusion:** Atypical carcinoid of thymus is extremely rare. Surgical resection is of first choice. Complete en bloc resection of the whole tumor, the whole fat tissues of thymus body and four feet, and adjacent being-invaded organs and tissues, is the key point to avoid recurrence, to cure ACT. (This study was partly supported by Science Foundation of Shenyang City, China, No. F16-206-9-05, 17-230-9-71)

ACME Definition of a Commercial Interest: A commercial interest is any entity producing, marketing, re-selling, or distributing health care goods or services consumed by, or used on, patients. This IASLC CME educational activity was planned and developed to: uphold academic standards to ensure balance, independence, objectivity and scientific rigor; adhere to requirements to protect health information under the Health Insurance Portability and Accountability Act of 1996 (HIPAA); and include a mechanism to inform learners when unapproved or unlabeled uses of therapeutic products or agents are discussed or referenced.

IASLC CME Department assures that the planners/reviewers/authors/faculty/peer reviewers et al. conflicts of interest were identified, reviewed and resolved from all individuals involved in the development or able to influence and control the content of this CME activity. The IASLC CME Department assures that disclosure is given prior to an educational activity being delivered to learners. Any individual who failed or refused to disclose relevant financial relationships was disqualified from this CME activity and removed from all IASLC CME activity presentations.

All commercial relationships and conflicts of interest that are identified are thoroughly vetted by IASLC Ethics Committee, CME Subcommittee and an independent reviewer. COI will be evaluated by the IASLC Board of Directors for fair balance, scientific objectivity of studies utilized in this activity and patient care recommendations. The IASLC CME Department is committed to providing its learners with high-quality CME activities and related materials that promote improvements or quality in health care and not a specific proprietary business interest of a commercial entity.

A conflict of interest (COI) is created and exists when individuals in a position to control the content of CME (or their spouses/partners) have a relevant personal financial relationship within the past 12 months with a commercial interest that produces, markets, re-sells or distributes health care goods or services consumed by, or used on, patients that benefits the individual in any financial amount and therefore may bias their opinions and teachings. This may include receiving a salary, royalty, intellectual property rights, consulting fee, honoraria, ownership interest (e.g., stocks, stock options or other ownership interest, excluding diversified mutual funds) or any other financial benefit. Financial benefits are usually associated with roles such as employment, management position, independent contractor (including contracted research and clinical trials), consulting, speaking and teaching, membership on advisory committees or review panels, board membership and other activities for which remuneration is received or expected.

The intent of this disclosure is not to prevent a speaker with a relevant financial or other relationship from making the presentation, but rather to identify and resolve any conflicts of interest that may control the content of the activity. It is also intended that any potential conflict be identified openly so that the listeners have a full disclosure of the facts and may form their own judgments about the presentation. It remains for the audience to determine whether the speaker’s interests or relationships may influence the presentation with regard to exposition or conclusion.

All other faculty/contributors have reported no commercial affiliation associated with this conference or intent to reference off-label/unapproved uses of products or devices in their presentations. All planning committee members, faculty’s, reviewers, authors et al. identified conflicts of interest pertaining to this activity were resolved prior to the activity.

IASLC 2019
Meetings Schedule

IASLC 19th Lung Cancer
Targeted Therapies Meeting
February 20-23, 2019 | Santa Monica, California
#LCTT19

IASLC Small Cell Lung Cancer Meeting 2019
April 3-5, 2019 | New York, New York
#SCLC19

2019 European Lung Cancer Congress
April 10-13, 2019 | Geneva, Switzerland | #ELCC19

IASLC Mesothelioma Meeting 2019
July 10-12, 2019 | New York, New York | #Meso19

IASLC 20th World Conference on Lung Cancer
September 7-10, 2019 | Barcelona, Spain
#WCLC2019

IASLC North America Conference on Lung Cancer 2019
October 9-12, 2019 | Chicago, Illinois | #NAACL19

IASLC Latin America Conference on Lung Cancer 2019
October 18-19, 2019 | Mexico City, Mexico
#LACLC19
