Danger close parents guide

Antibiotics are excessive when antibiotics are used when they are not needed. Antibiotics are one of the great advances in medicine. But over-deciphering them has led to resistant bacteria (bacteria that are more difficult to treat). Some microbes that were once very sensitive to antibiotics became more and more resistant. It can cause more serious infections such as pneumococcal infections (pneumonia, ear infections, sinus infections and meningitis), skin infections and tuberculosis. What are antibiotics treated for? Two main types of microbes can make people sick: bacteria and viruses. They can cause diseases with similar symptoms, but they multiply and spread diseases in different ways: Bacteria of living organisms existing as single cells. Bacteria are everywhere, and most of them do no harm, and in some cases are beneficial. But some bacteria are harmful and cause diseases by invading the body, multiplying and interfering with normal processes in the body. Antibiotics work against bacteria because they kill these living organisms, stopping their growth and reproduction. Viruses, on the other hand, are not alive. Viruses grow and multiply only after they have invaded other living cells. The body's immune system may fight some viruses before they cause illness, but others (such as colds) should simply run their course. Antibiotics do not work against viruses. Why are antibiotics rewritten? Doctors prescribe antibiotics for various reasons. Sometimes they prescribe them when they are unsure if the disease is caused by bacteria or virus or wait for the test results. Thus, some patients can wait for an antibiotic prescription and even ask their doctor for it. For example, strep throat is a bacterial infection, but most sore throats are due to viruses, allergies, or other things that antibiotics cannot treat. But many people with a sore throat will go to the doctor expecting - and getting - a prescription for antibiotics that they don't need. Taking antibiotics for colds and other viral diseases doesn't work - and it can create bacteria that are harder to kill. Taking antibiotics too often or for the wrong reasons can change bacteria so much that antibiotics don't work against them. This is called bacterial resistance or antibiotic resistance. Some bacteria are now resistant to even the most powerful antibiotics available. Antibiotic resistance is a growing problem. The Centers for Disease Control and Prevention (CDC) calls it one of the most pressing public health problems in the world. This is particularly worrying in low-income and developing countries. This is because: Health care providers there often lack fast, useful diagnostics that can determine which diseases are caused by bacteria and which are not. Many of these areas have only recently gained wide access to antibiotics. Lack of clean water, poor sanitation and limited vaccine vaccine But unfortunately, Dr. Diamond's research found Forgotten Infant Syndrome, where a parent sort of on autopilot completes tasks as usual because of memory loss, you can forget that the child is in the car. It's akin to putting coffee on top of your car before you walk in and accidentally leave-with the coffee left spilled behind. This is how a fully responsible, loving parent can make a devastating mistake. On top of that, stress, and let's not forget sleep deprivation, which many new parents experience- can exacerbate things. This affects how our prefrontal cortex functions and makes it more likely we will do something out of habit, Dr Diamond told Parents.com earlier. After reviewing the cases of dozens of parents who inadvertently left their child in the car, he found that something in their routine was a little different that day. Once you've gone from point A to point B enough times, you can do it without thinking, said Dr Diamond. You may not even remember the trip. But it's common to drive past the store and go home. When your partner says: Where is the milk? You feel excited because you remember the conversation, but for some reason you came home, not. The temperature inside the car rises faster than you think - the temperature of the car can rise by 20 degrees in 10 minutes. Cracking car windows does not cool things or slow down car heating. Never leave your child unattended in the car, even if it's not that hot; children were hit by heatstroke in 57-degree weather. Children's bodies are heated three to five times faster than adults, according to the National Highway Traffic Safety Administration. By blocking your car and keeping the keys safe the kids so they can't accidentally hit without you. Remember that it's not just negligent parents who leave their kids in hot cars. It is better to be safe than to regret and get into the routine of over-checking before you get out of your car. © copyright. All rights are reserved. The highest incidence of burns occurs in the kitchen, with one-year-olds at the greatest risk of injury through burns, a new study shows. How do we let this happen? January 19, 2005 - Most parents know that a kitchen can be a dangerous place for children. However, a new study from 1997 to 2002 found that an estimated 17,237 burns were treated by children aged five and under, with one year most at risk. How do parents let this happen? According to a study by Kitchen Scalds and thermal burns in children five and younger, which appeared in the January issue of Pediatrics, the high frequency of scalding among may be due to the fact that their motor skills development outpaces their cognitive development, so that they can grab on to something without understanding the associated risks of injury. The study also argues that children, especially toddlers, can reach hot liquid on elevated surfaces (think boiling soup on the stove, or even coffee on the kitchen table), but their parents or caregivers do not recognize either the dangers or the consequences. Unlike the dangers associated with motor vehicles or poisons, parents are not so vigilant in their kitchens. Among the study's other findings: Scalds were about twice as likely as thermal burns, and resulted in significantly more hospitalizations one-year-old accounted for the largest percentage for each burn More boys were injured in both types of burns Two models accounted for half of all scalded injuries: reached and pulled the pot off the stove or other elevated surface, and, grabbed, canceled, or spilled pot on themselves, the thermal burns were primarily caused by the touching of the hot water. Grease takes second place To prevent such injuries, parents should use intervention strategies that have been around for decades, including: Turn the pots on the stoves so that the handles face to the wall Place the hot drinks in the center of the table, out of reach of the toddler Remove the tablecloths from the tables Keep the children out of the kitchen while cooking Avoid drinking hot drinks with the baby Place the guard in front of the stove To prevent your child from reaching it if your child gets a minor burn, the Centers for Disease Control and Prevention (CDC) recommends: Keep the burned area under cool running water for 15 minutes. DO NOT apply ointment or oil. Cover the area with dry gauze. Don't pop blisters. See your doctor if burns occur on the face, arms, genitals, legs, or for any burn on the baby. If the burn is severe, the CDC suggests: There are one person calling 911 or a local emergency number while another person runs cool water over the burned area. Don't use ice. DO NOT put ointment or

lubricant on the burn and do not try to remove pieces of tissue from the burnt area. DO NOT break blisters. DON'T give the victim nothing to eat or drink. DO lift the burnt limbs to minimize swelling. The kitchen is a room filled with dangers, but it is a place where family activities are concentrated. What do you do to keep your children safe in the kitchen? Share your tips and stories on our bulletin board below: Basics of Kitchen Safety: Minimize the risks that ambulance doctors want you to know
