Vaquitas have unique color patterns. There are distinct black to dark gray lip patches and eye rings; otherwise the body is light brownish-gray with a whitish belly. There is a chin-to-flipper stripe. Calves tend to be somewhat darker than adults.

A photo of several vaquitas killed in totoaba gillnets near El Golfo de Santa Clara in the northern Gulf of California. The animal in front is a 70-cm female calf, and others are adult males (back) and females (middle), each around 135 cm in length. PHOTO: A. ROBLES, COURTESY OF L. ROJAS-BRACHO

In the small number of specimens examined to date, there have been 16–22 pairs of teeth in the upper jaw and 17–20 pairs in the lower jaw.

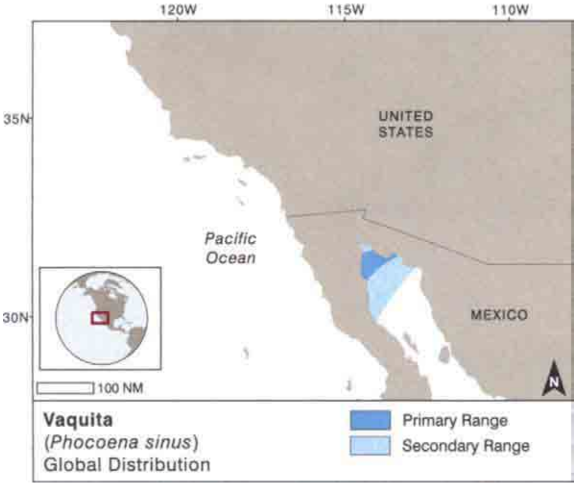
Currently known maximum length is 1.5 m (females) and 1.45 m (males), but very few specimens have been examined. Females are larger than males, as is true in several species of the porpoise family.

Recognizable geographic forms None.

Can be confused with When seen at a distance, the tall dorsal fin of the vaquita must be carefully distinguished from those of bottlenose and long-beaked common dolphins, both of which are common in the vaquita's range. However, the small group size, unique body shape (e.g., no prominent beak), and different behavior will generally allow the vaquita to be easily distinguished.

Distribution The restricted distribution of the vaquita appears to be defined by relatively murky, shallow (< 40 m deep) waters in the northern quarter of the Gulf of California (with a core area of ca. 2,000 km^2, centered at Rocas Consag). This is near the estuary of the Colorado River. However, there are some suggestions that the range traditionally may have extended further south in the Gulf as well. The animals are most commonly seen in the western portion of the upper Gulf, between San Felipe Bay and Rocas Consag.

Ecology and behavior Very little is known of the biology of the vaquita. As is generally true for porpoises, they occur in small groups, most often of about two, although groups of up to 8–10 have been sighted. Sometimes, large numbers of such groups loosely aggregate in a very small area (only several hundred square



meters). They are cryptic and relatively inconspicuous in their behavior, and they do not ride bow waves. Aerial behavior is rare.

Life history parameters appear to be similar to those of other, better-studied species of porpoises. Females reach sexual maturity sometime between 3 and 6 years of age, and males are assumed to be similar. Calving appears to be seasonal, and most calves are apparently born in the spring (i.e., around March). Gestation is about 10–11 months, and females appear to calve about every other year. The maximum known longevity is 21 years.

Feeding and prey Only 34 stomachs have been examined, and the contents indicated opportunistic feeding on a wide array of demersal and benthic fishes, squids, and crustaceans.

Threats and status The vaquita used to be considered the second-most endangered species of cetacean in the world (the first being the baiji). However, with the apparent extinction of the baiji, the vaquita now takes over the dubious distinction of being the most endangered. The only proven (and without a doubt, the main) threat is incidental catches in fisheries, especially various types of gillnets. Estimated mortality from gillnet fishing is at least 39 (and maybe as many as 84) vaquitas per year, which is certainly unsustainable. There are also a number of other potential threats, including habitat changes associated with reduction in freshwater flow to the Gulf, inbreeding depression, and environmental contamination.

The most recent estimate of total abundance for the vaquita was 567 individuals (in 1997). The population has probably been declining since the 1940s, and may be dropping by as much as 15%/year. It is in danger of extinction in the next decade. Conservation of the vaquita is being attempted through the creation of a biosphere reserve and more recently a wildlife refuge that includes waters outside the reserve in the upper Gulf of California, as well as the establishment of an international committee (CIRVA) convened by the Mexican government to recommend protection measures. However, implementation has been slow, and the effectiveness of these measures is still very much in doubt. Despite all this, the habitat of the species appears relatively healthy, and there is still a glimmer of hope for the vaquita.

IUCN status Critically Endangered.

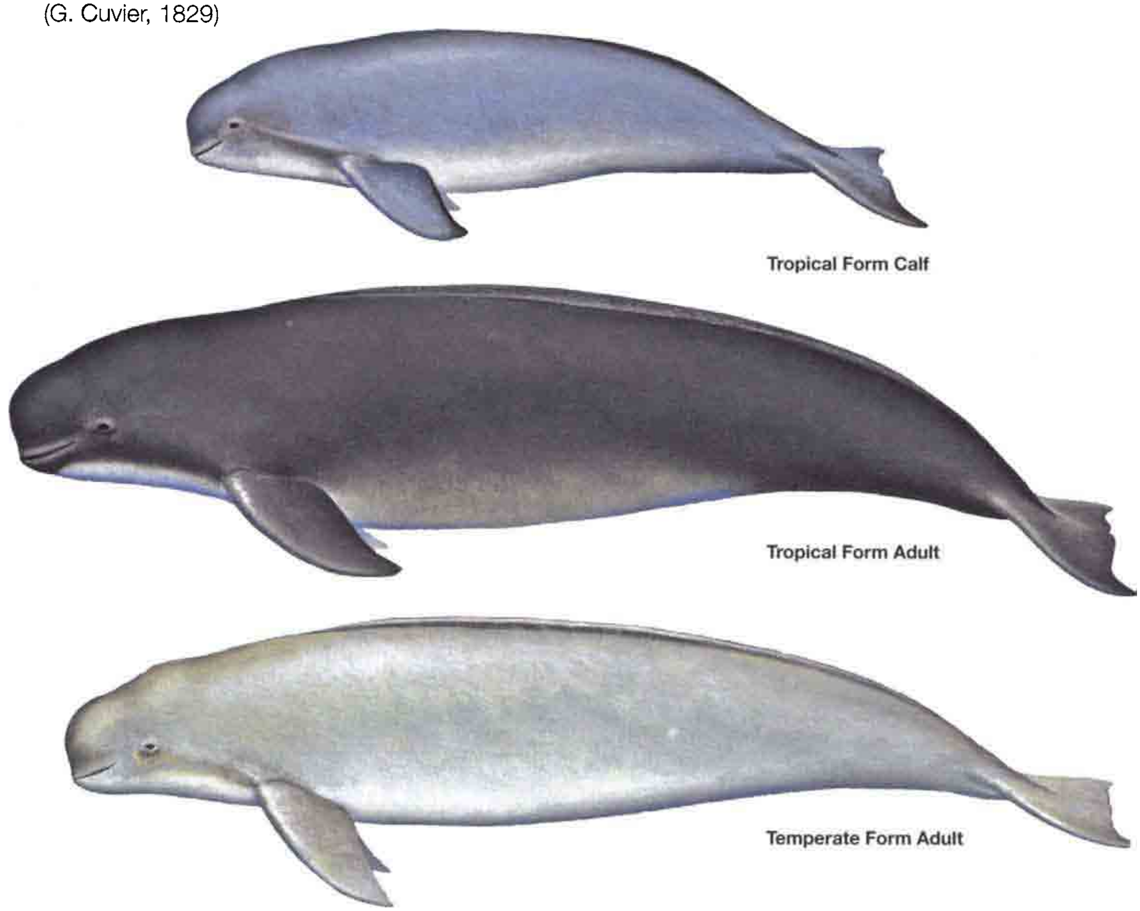
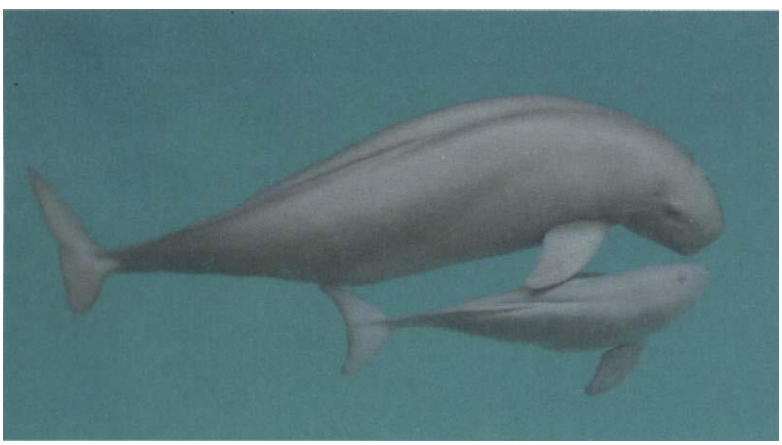
Finless Porpoise—*Neophocaena phocaenoides*

(G. Cuvier, 1829)



Recently-used synonyms *Neomeris (Meomeris) asiaeorientalis, Neophocaena sunameri.*

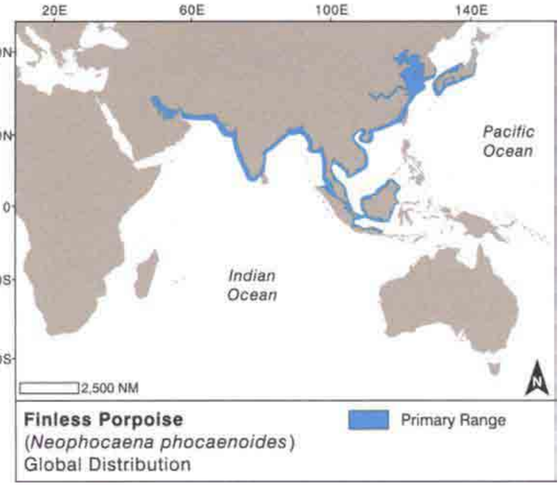
Common names En.—finless porpoise; Sp.—*marsopa lisa o sin aleta*; Fr.—*marsouin aptere*.



These captive finless porpoises are from the Yangtze River and are clearly of the narrow-ridge form; the calf was the first ever born in captivity. PHOTO: COURTESY OF WUHAN INSTITUTE OF HYDROBIOLOGY

Taxonomic information Order Cetacea, Suborder Odontoceti, Family Phocoenidae. Three subspecies are currently recognized: *N. p. phocaenoides* in the Indian Ocean and South China Sea, *N. p. asiaeorientalis* in the Yangtze River, and *N. p. sunameri* from the Taiwan Strait north to northern China and Japan. There is mounting evidence that the two major forms—i.e., the wide-ridge type (*phocaenoides* subspecies) and narrow-ridge type (including *asiaeorientalis* and *sunameri* subspecies)—may actually represent separate species.

Species characteristics As the name implies, finless porpoises have no dorsal fin, and this is their most distinctive characteristic. In some ways, they resemble small, slender beluga whales. The head is beakless; the rounded forehead rises steeply from the snout tip. The body shape, in general, is more slender



than in other porpoises. The bodies of at least some finless porpoises are soft and mushy, and the neck is very flexible. Instead of a dorsal fin, the finless porpoise has an area of small bumps or tubercles on its back, running from just forward of mid-back to the tail stock. This dorsal ridge ranges in width from 0.2 to 12.0 cm. There are narrow-ridge forms in Japan, Korea, and northern China (including the Yangtze River) and wide-ridge forms throughout the remainder of the species' range. The trailing edge of the flukes is concave and the flippers are large, ending in rounded tips. Regional differences in body size and morphology have been documented, with separate stocks recognized based mainly on skull morphology.

The common name that was used in the past, "finless black porpoise," apparently resulted from descriptions of dead animals, after post-mortem darkening. In most areas, finless porpoises are gray in color, often with lighter areas on the throat and around the genitals. The wide-ridge form is light gray at birth, and darkens to dark gray or nearly black as adults. The narrow-ridge form has the reverse pattern: young are dark gray, and lighten as they age. In at least Japan and northern China, the adults are a light creamy gray.

Tooth counts range from 15–22 in each tooth row. The teeth are small and slender.

Adults of this species can reach 2.27 m in length, although animals from most populations are much smaller, rarely exceeding 2.0 m (males tend to be slightly larger than females). Finless porpoises are about 75–85 cm at birth.

Recognizable geographic forms

***Tropical finless porpoise* (N. p. phocaenoides)—**This subspecies occurs in the southern portion of the range, from the Taiwan Strait, south and west to the Persian Gulf. It is characterized by a low and wide dorsal ridge (3.5–12.0 cm wide), lined with 10–25 rows of tubercles. Adults reach lengths of about 171 cm and are dark gray in color, with light areas around the throat. Young animals are much lighter in color.

***Yangtze finless porpoise* (N. p. asiaeorientalis)—**This subspecies occurs throughout the Yangtze River system (and possibly into the estuary). It has a narrow dorsal ridge (0.2–0.8 cm), which originates anterior to mid-length. The ridge rarely exceeds 1.5 cm high and has 1–5 rows of tubercles. Adults reach up to 177 cm, and are uniform dark gray.

***Temperate finless porpoise* (N. p. sunameri)—**This subspecies occurs in temperate waters of northern China

A *phocaenoides*-type finless porpoise stranded in Hong Kong, showing the pattern of the wide dorsal ridge covered with tubercles. This is a juvenile, and adults in this area have much darker gray coloration. PHOTO: S. K. HUNG

(from the Taiwan Strait north), Korea and Japan. The dorsal ridge is narrow (0.2–1.2 cm) and high (1.2–5.5 cm), with 1–10 rows of tubercles. It is the largest of the subspecies, with adults ranging up to 2.27 m long. Coloration of adults is light gray to cream, with newborns much darker (nearly black).

Can be confused with The smooth back of the finless porpoise should make it easy to distinguish from other cetacean species, such as humpback, bottlenose, and Irrawaddy dolphins, baiji, and South Asian river dolphins, which share parts of its range. Finless porpoises are actually most likely to be confused with dugongs, where the two species overlap in tropical and subtropical waters. The double-nostrils on the snout tip, and very different mouth shape should serve to distinguish dugongs.

Distribution The finless porpoise occurs in tropical to warm temperate shallow waters of the Indo–Pacific region. It mostly is found in coastal waters, including shallow bays, mangrove swamps, estuaries, and some large rivers. However, it does occur quite far from shore (up to 240 km) in some areas with shallow water < 200 m deep. The range extends from central Japan and northern China, south and west along the northern rim of the Indian Ocean to the Persian Gulf, including a few estuaries and rivers in the Asian subcontinent. One of the best-known populations (and the only known wholly-freshwater one) is found in the Yangtze River of China, where it ranges up to 1,600 km upstream from the mouth, to near the headwaters in the Three Gorges area.

Ecology and behavior Finless porpoises are generally found as singles, pairs, or in groups of up to 20. However, groups of up to about 50 have been reported in Chinese coastal waters. When such large groups are seen, they are generally opportunistic aggregations of smaller subgroups gathering to take advantage of a productive food source.

Like other porpoises, their behavior tends to be not as energetic and showy as that of dolphins. However, contrary to what their body shape might suggest, they are fast and agile swimmers, often making high-speed sharp turns and rolling on their long axes while chasing down prey. They do not ride bow waves, and in some areas appear to be shy of boats. Mothers have been reported to carry calves on the tubercle area on their backs, but this behavior has not been confirmed. In the Yangtze River, finless porpoises are known to leap from the water and perform "tail stands." However, in other areas, aerial behavior appears to be quite rare. When startled by a powered vessel, they may create splashes as they move quickly away from the boat. Most dives are relatively short, and the longest recorded dive time is only about 4 minutes. In Hong Kong waters, groups of finless porpoises spend about 60% of their time at or near the surface.

Reproduction has been studied in Japanese and Chinese waters. Sexual maturity of both sexes occurs at 3–6 years of age, and 132–150 cm in length. Calving occurs at different times of the year in different regions (most often either spring/summer or winter). These animals appear to live somewhat longer than other species of porpoises, with most populations having a maximum known longevity of 18–25 years. A specimen from the population in southern China was found to have lived to 33 years.

Two finless porpoises taken in fishing nets in the same area of Fujian Province, central China. The animal in front is of the *phocaenoides*-type, with a wide dorsal ridge. The animal behind is of the *asiaeorientalis*-type, with a narrow dorsal ridge. PHOTO: COURTESY OF THE LATE S. LEATHERWOOD

Feeding and prey Small fishes, squids, and crustaceans form the diet of finless porpoises. Some animals have also ingested some plant material, probably incidentally. Common prey species are fishes of the families Apogonidae, Carangidae, Clupeidae, Sparidae, and Engraulidae; cephalopods of the families Loligonidae, Sepiidae, and Octopodidae; and panaeid shrimps.

Threats and status Finless porpoises are not known to be directly killed in large numbers anywhere, but they are often incidentally killed in fishing gear throughout their range. Gillnets appear to represent a particularly serious threat in nearly all areas of the range. However, they are also taken in trawls, rolling hook longlines, beach seines, set nets, stow nets, and traps in certain areas. Significant numbers have also been live-captured in Japan, China, and the Gulf of Thailand. This coastal species also suffers from serious problems of habitat loss and degradation, vessel strikes, and environmental contamination. The Yangtze River population, a unique subspecies, is apparently declining in numbers (although it is not in the serious condition that the baiji is in). Estimates of finless porpoise abundance have only been made for a few areas: Bangladesh (1,400), Hong Kong and surrounding waters (>220), China's Yangtze River (<2,000), and Japanese waters (5,000–10,000). Clearly, the species is not in immediate danger of extinction, and global abundance is probably in the high tens or low hundreds of thousands. However, certain populations (e.g., those in the Yangtze River and the Inland Sea of Japan) are seriously threatened by human activities.

Two finless porpoises surfacing in the Yangtze River of China. The animal on the left shows the narrow dorsal ridge, and the one on the right demonstrates a rare example of aerial behavior. PHOTO: T. PUSSER

IUCN status Endangered (Yangtze River population), Data Deficient (all other populations).

South Asian River Dolphin—*Platanista gangetica*

(Roxburgh, 1801)

Recently-used synonyms *Platanista indi, Platanista minor.*

Common names Ganges subspecies: En.—susu, shushuk, or Ganges River dolphin; Sp.—*platanista del Ganges*; Fr.—*plataniste du Gange*. Indus subspecies: En.—bhulan or Indus River dolphin; Sp.—*platanista del Indus*; Fr.—*plataniste de l'Indus*.

Taxonomic information Order Cetacea, Suborder Odontoceti, Family Platanistidae. Until recently, most marine mammal biologists classified the Ganges and Indus River dolphins as separate species (*Platanista gangetica* and *P. minor*). However, due to the lack of adequate systematic studies, a more taxonomically-conservative view is now favored, with the two forms recognized as subspecies (*P. g. gangetica* in the Ganges/Brahmaputra region, and *P. g. minor* in the Indus). This view is still controversial, and only future studies will reveal the true relationship of these two forms.

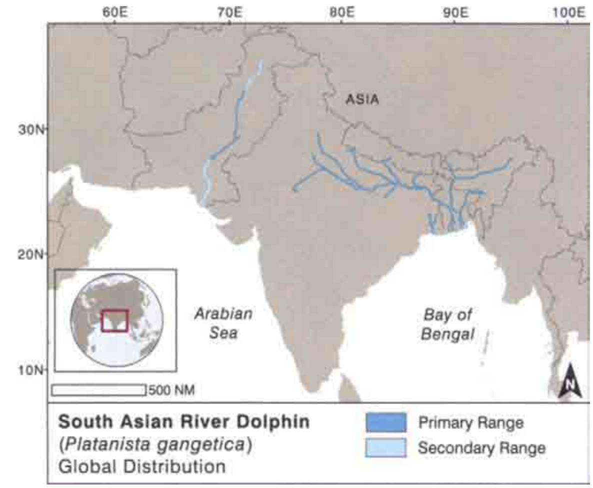
Two bhulans leap out of the water along a riverbank in the Indus River of Pakistan. The animal in front is leaping towards the camera, showing the characteristic ridge on the melon.
PHOTO: G. BRAULIK

Species characteristics The Ganges and Indus river dolphins are very unusual-looking animals. The body is supple and stocky, with a flexible neck, often characterized by a constriction or crease. The long beak is distinct from the steep forehead, but there is no crease between them. The beak is like a pair of forceps, is laterally compressed, and widens at the tip; it tends to be proportionately longer in females than in males. It curves upward and to one side in long-beaked animals. The blowhole, unlike that of most cetaceans, is a slit that runs along the long axis of the animal's body. There is a distinct, but shallow, longitudinal ridge on the melon, ahead of the blowhole. The melon becomes less rounded as animals approach adulthood. The eyes are extremely small slits or pinholes and are located just above the distinctly-upturned corners of the mouth. The external ear is actually larger than the eye, and is located above it (this is unique for odontocetes). The dorsal fin is a low and wide-based triangle about $^2/3$ of the way to the flukes, which are concave along the rear margin. The broad flippers are squared-off at their distal ends, and usually have flat trailing edges, but they are sometimes scalloped. The outlines of the bones of the flipper are visible, which is unusual for cetaceans.

South Asian river dolphins have a relatively simple color pattern (which is consistent with their nearly-blind state). The animals are light brown or brownish-gray, often with a slightly lighter ventral surface. They become increasingly blotchy as they get older. Young animals may have a pinkish cast to the belly.

The 26–39 upper teeth and 26–35 lower teeth are curved. They are sharply pointed in young individuals. The anterior teeth are longer and extend outside of the closed mouth, especially in larger individuals. The teeth may become peg–like from dentine accumulation and wear in older animals. Tooth wear is generally minimal in younger animals.

Female South Asian River dolphin adults are up to 2.6 m and males 2.2 m in length. They can reach weights



of at least 85 kg. Newborns are apparently between 70 and 90 cm long.

Recognizable geographic forms The relationship between Ganges and Indus River dolphins has been controversial, with many authors suggesting that they should be considered separate species. Although the river basins they occur in have been largely separate for millions of years, recent genetic studies found apparently low diversity and little evidence for species-level difference. They are currently considered to be separate subspecies:

***Ganges River dolphin* (*P. g. gangetica*)—**The Ganges River dolphin occurs in the Ganges and Brahmaputra river systems of India, Bangladesh and Nepal (and possibly Bhutan). Female susu adults are up to 2.6 m and males 2.2 m in length. They can reach weights of at least 85 kg.

***Indus River dolphin* (*P. g. minor*)—**The Indus River dolphin is found only in the Indus river system of Pakistan. Bhulans are considered to reach slightly smaller sizes than the maximums of 2.6 m (females) and 2.2 m (males) for susus. However, it is unclear if these differences are real, or simply artifacts of limited sample sizes. No other external differences are known between animals from the two river systems.

Can be confused with Susus can be confused with several other small cetaceans that are found in overlapping areas of the Sundarbans mangrove forest and near the mouths of the Hughly, Karnaphuli and Sangu rivers. They might be confused with Irrawaddy dolphins, finless porpoises, bottlenose dolphins, or Indo-Pacific humpback dolphins. The prominent dorsal fins of bottlenose and humpback dolphins, complete lack of a dorsal fin in finless porpoises, and absence of a beak in Irrawaddy dolphins should make all these species easily distinguishable. Also, adult bottlenose and humpback dolphins are much larger than South Asian river dolphins. Bhulans do not presently overlap in distribution with any other cetacean species.

Distribution The extensive range of the susu includes the Ganges, Brahmaputra–Megna, and Karnaphuli–Sangu river systems and many of their tributaries in India, Bangladesh and Nepal (there is some suggestion that it may possibly extend into Bhutan in the wet season as well, although this has not been confirmed). Susus live not only in the main river channels, but also in seasonal tributaries and appended lakes during the flood season. Though formerly much more widely distributed in the Indus and some of its tributaries, the bhulan's range is now restricted to the middle and lower Indus River. It is centered between Taunsa and Sukkur barrages.

Ecology and behavior As is true for most of the river dolphins, susus and bhulans generally live in small groups of less than 10 individuals, and are most often seen alone or in pairs. Bhulans have occasionally been reported in loose aggregations of up to 30 individuals, defined by common use of clumped resources. Other than the mother/calf bond, affiliations between individuals are thought to be ephemeral. These are active animals, but they do not often engage in leaps. At least in captivity, these dolphins appear to spend much of their time swimming on their sides, and they constantly emit echolocation clicks. This might be related to the fact that they spend time in relatively shallow, turbid waters; however, some of the pools they occur in may be > 30 m in depth. South Asian river dolphins are nearly blind, and can probably only detect light levels, and perhaps direction.

Almost nothing is known of the reproductive biology of this species, except that males reach sexual maturity at about 170 cm and females at slightly longer body lengths. Calving apparently can occur at any time of the year, but for the susu, there may be peaks in

This young bhulan in the Indus River of Pakistan demonstrates the bizarre head and body shape of the species.

A susu surfaces in the Ganges river system of India, bringing its long, slender beak out of the water. PHOTO: J. GOOLD

December to January and March to May. Newborn bhulans have been observed mainly in April and May. Calves are weaned within about one year of birth.

Feeding and prey Susus and bhulans feed on several species of fish and invertebrates (prawns and possibly clams). They apparently do much of their feeding on or near the bottom.

Threats and status South Asian river dolphins have been subjected to direct killing in both the Indus and Ganges/Brahmaputra systems. In addition to use of their meat as human and livetock feed, the oil of susus is used as a fish attractant and for medicinal purposes. Like almost all small cetaceans, they suffer from entanglement in various types of fishing nets, and they are sometimes also killed by vessel strikes. The damaging effects of environmental contaminants, while not sufficiently understood, are probably important threats to these dolphins. Perhaps the most important problem, and one that affects this species to a much greater degree than other riverine cetaceans, is the placement of dams and barrages across rivers in this species' range. These structures artificially fragment populations and reduce available habitat by altering riverine ecology.

The susu has a moderately large range that spans several countries and is apparently not in immediate danger of extinction, probably numbering at least in the low thousands. There are thought to be from 965 to 1,200 bhulans in Pakistan. The bhulan's range is extremely restricted and declining, and the overall population is fragmented into five subpopulations by barrages, making it one of the most endangered types of cetaceans in the world.

IUCN status Endangered.

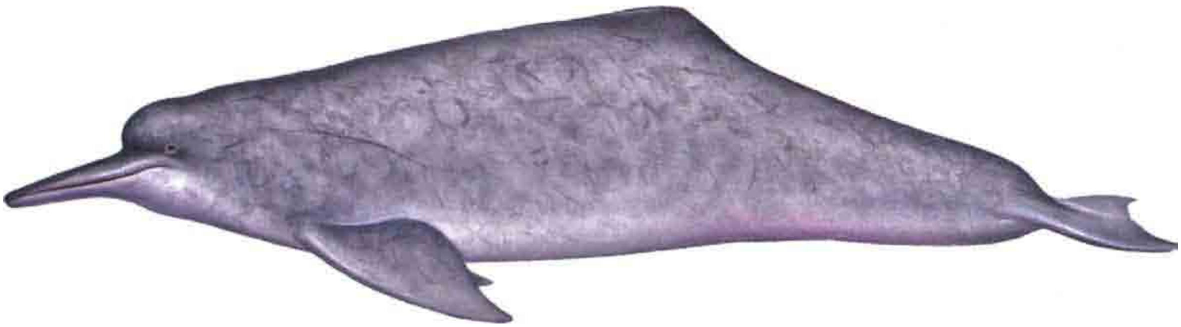
Boto—*Inia geoffrensis*

(Blainville, 1817)



Recently-used synonyms *Inia boliviensis*

Common names En.—Amazon River dolphin or boto; Sp.—*bufeo*; Fr.—*inia*. (Note—boto is the Portuguese name used in Brazil, and although it is not used by locals in Spanish-speaking parts of the range, it has been adopted as the English common name.)

Taxonomic information Order Cetacea, Suborder Odontoceti, Family Iniidae. Three subspecies are currently recognized: *I. g. geoffrensis* in the Amazon River system of Brazil, Peru, and Ecuador, *I. g. boliviensis* in Bolivia, and *I. g. humboldtiana* in the Orinoco basin of Venezuela and Colombia. The validity of these subspecies is questionable, however, and no reliable differences in morphology are known. Recent molecular genetic studies suggest that only the Bolivian dolphins are separate, and those in the remainder of the Amazon and Orinoco systems may not be separate subspecies.

Species characteristics The boto, or Amazon River dolphin, is probably the best-studied and most well-known of the river dolphins. These animals are moderately robust, but extremely flexible (e.g., unfused cervical vertebrae allow great movement of the neck). They have long beaks with a series of bristles, and steep bulbous foreheads, which are capable of changing shape by muscular action. More than any other species of cetecean, botos have visible "cheeks". There is no true dorsal fin, but only a dorsal ridge about 2/3 of the way back from the beak tip that is low and wide-based. The flippers are large and triangular, with blunt tips, and the flukes are broad and triangular, with a concave trailing edge. The eyes are small, but not as small as those of the susu or bhulan.

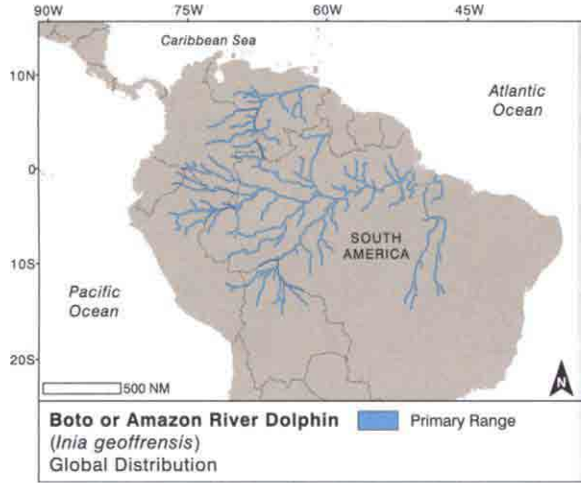
Botos are gray to white/pink above and light below; some individuals are totally pink. In general, young animals are mostly uniform dark gray; they become progressively more pinkish with age (especially in males). The extreme color is so unusual that the boto is often called the pink dolphin. The pink color is thought to result from flushing of blood to the body surface on animals that have lost most of their pigmentation—and is probably not the result of red pigments. Albino botos have been documented.

The mouth is lined with 23–35 stout teeth in each row. This is essentially the only species of cetacean with differentiated teeth; those at the front of the jaw are typically conical, but those near the rear are flanged on the inside (for crushing of hard-bodied prey).

Botos are the largest of the river dolphins. Adult size ranges to 2.3 m (females) or 2.8 m (males). Males can reach maximum weights of 207 kg, about 35% more than females. At birth, botos are about 80 cm long.

Calf/juvenile—1/3 to 3/4 adult length; body color uniformly gray, scarring light to absent.

Two captive botos in unusually clear water. In their natural habitat the water would essentially never be this clear. PHOTO: D. K. CALDWELL, COURTESY S. LEATHERWOOD



Adult female— Adult size (1.6–2.25 m), body grayish-pink, with light to moderate scarring.

Adult male— Large size (2.0–2.5 m), body color mostly pink with dark blotches, moderate to heavy scarring (especially on the trailing edges of the flippers and flukes, which are often ragged), and "cobblestoning" of the skin is common.

Recognizable geographic forms Morphological differences have been proposed for the three subspecies, but the validity of these distinctions are highly questionable. At this point, the three subspecies can only be distinguished based on their locality of origin.

Botos are unmistakable, as the only species that they overlap with (the tucuxi) has a more typical dolphin-like appearance. By comparison, the boto looks primitive. Peruvian Amazon. PHOTO: T. HENNINGSEN

An adult boto, captured from the Amazon river system. Note the bulbous melon, large paddle-shaped flippers, and heavily corrugated body. PHOTO: D. K. CALDWELL, COURTESY S. LEATHERWOOD

Can be confused with The only other dolphin that inhabits the range of the boto is the tucuxi (*Sotalia*). This latter species is much smaller, has a true dorsal fin, and more spritely, dolphin-like movements, making confusion unlikely.

Distribution Botos are endemic to the Amazon and Orinoco drainage basins of South America. Their distribution extends to the upper reaches (impassible falls or rapids) of these rivers and their tributaries in Colombia, Ecuador, Peru, and Bolivia, as well as the lower reaches in Brazil and Venezuela, a total area of about 7 million km^2. They are found widely, not only in the main river channels, but also in smaller tributaries, lakes, and (seasonally) the flooded forest. Botos are especially common at the confluences of river channels, and entrances to lakes. The animals that inhabit the upper Madeira and Beni/Mamore rivers of Bolivia are isolated from those in the Amazon/Orinoco basins.

Ecology and behavior Botos are not highly social. Loose aggregations of up to 12–15 botos have been observed, generally at river bends and confluences, for purposes of mating and feeding. However, most botos are seen singly or in small groups of 2–3 (most pairs are mother and calf).

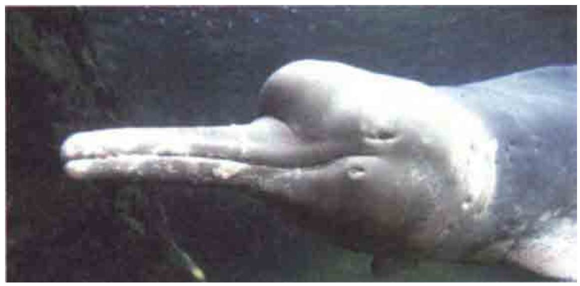
Botos generally move slowly (typically about 1.5–3.2 km/hr), although they are capable of short bursts of up to 22 km/hr. They typically surface at a shallow angle, showing the melon, tip of rostrum, and the dorsal ridge simulteneously. However, they do perform high, arching rolls as well. Their responses to humans can range from shyness to curiosity, although they do not ride vessel bow waves. Aerial behavior is rare, and they generally do not lift the flukes out of the water before a dive. Botos swim into the flooded forest in the high-water season, and can often be heard searching for prey among the roots and trunks of partially-submerged trees. Mark/recapture studies have shown that some individuals are resident in specific areas year-round.

Reproduction is diffusely seasonal, apparently in each area peaking during the season of maximum flooding (which varies among areas). In Brazil, most births apparently occur in May to July. Females mature sexually at about 5 years of age and 1.6–1.75 m in length, and males do so much later (about 2.0 m in length). Gestation lasts about 11 months and lactation over one year.

A large boto in the Peruvian Amazon, upriver from Iquitos. The "lumpy" body, low dorsal ridge, and dorsal scarring are visible. PHOTO: T. A. JEFFERSON

An Amazon River dolphin spy-hops, showing the small eyes, very long narrow beak, bulbous forehead, and pinkish color pattern that easily distinguish this species from the only other cetacean that is broadly sympatric with it (the tucuxi). PHOTO: D. WALKER

Two botos moving towards the flooded forest in the Peruvian Amazon. These animals left the river channel, and disappeared into the trees, probably to feed among the roots. PHOTO: T. A. JEFFERSON



Like all river dolphins, botos have long beaks, which are useful for rooting around among the bases of trees and other vegetation for fish attempting to hide in the flooded forest. Brazil. PHOTO: T. PUSSER

Feeding and prey These animals feed on a large variety of fishes (over 43 species!), generally near the bottom. Some of their prey have hard outer shells, and dolphins have been observed breaking up their larger prey before swallowing them. They sometimes feed in a coordinated manner, occasionally with other species (such as *Sotalia*).

The boto is the only species of cetacean with heterodont teeth (the rear teeth have flanges that allow them to crush prey).

Threats and status The boto is unquestionably the species of river dolphin in least danger of extinction. It is still widespread and relatively numerous in many portions of its range, with some of the highest densities known for any species of cetacean. Threats include incidental catches in fishing gear, prey depletion, damming of rivers (although this is, at present, much less of a problem than for the susu and bhulan), and environmental pollution from organochlorines and heavy metals. Botos have received much protection from persecution by local people due to their prominent involvement in the folklore and culture of the Amazon; they are often seen as reincarnated humans and are attributed supernatural mischeivous powers. Unfortunately, these beliefs seem to be disappearing. There are thought to be about 13,000 botos in the central Amazon of Brazil (Mamiraua floodplain system), and about 350 each in two small areas of the upper Amazon of Brazil, Peru, and Colombia. Although, abundance has only been estimated in a few areas and accuracy of many of these estimates is questionable, it is likely that there are well over 20,000 botos throughout their range. Thus, while certain populations may be threatened, the species is in no immediate danger of extinction.

IUCN status Vulnerable.

Baiji—*Lipotes vexillifer*

(Miller, 1918)

Recently-used synonyms None.

Common names En.—baiji or Yangtze River dolphin; Sp.—*platanista del Yangtze*; Fr.—*dauphin fluviatile de Chine*.

Taxonomic information Order Cetacea, Suborder Odontoceti, Family Lipotidae. Recent molecular studies suggest the baiji may have a common ancestor with the boto and fanciscana, but not with the South Asian river dolphin. It is a relict species.

Species characteristics Outside of China, very little was known of the baiji's biology until the last few decades. Baiji have a fairly typical river dolphin appearance. These animals are moderately robust, with long, slightly-upturned beaks, rounded melons, and broad rounded flippers. The dorsal fin is fairly prominent, but low and triangular, with a wide base—it is set about 2/3 of the way back from the beak tip. The eyes are small and set higher on the face, compared to those of oceanic dolphins. Although their vision is apparently poor, the eyes are functional. The blowhole is a longitudinal oval.

Baiji have very simple, countershaded color patterns. They are predominantly gray to bluish-gray above and white to ashy-white on the ventral surface. There are light patches and brushings on the side of the face and the side of the tail stock.

Each tooth row of the baiji's mouth contains 31–36 conical teeth.

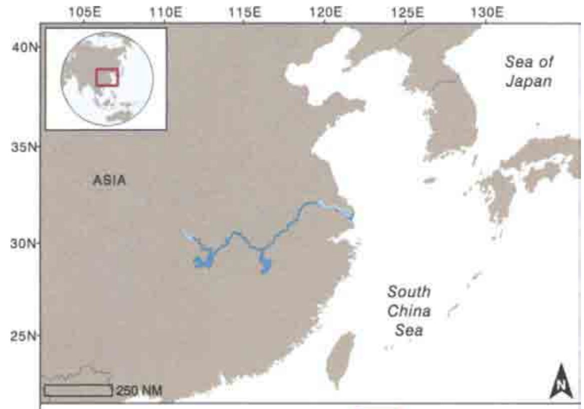
Male baiji reach sizes of 2.30 m and 157 kg, and females reach 2.59 m and over 167 kg. In addition to females being somewhat larger than males, there are some other, minor differences in external morphology. Apparently, newborn Yangtze River dolphins are about 92 cm in length.

A captive baiji swims in the clear waters of its tank in China. The waters of its natural habitat are in fact, very murky. PHOTO: WANG DING

Recognizable geographic forms None.

Can be confused with The only other small cetacean in the baiji's range is the Yangtze finless porpoise, which can be readily distinguished by its much darker coloration and absence of a beak and dorsal fin.

Distribution The baiji is found only in the middle and lower reaches of the mainstream Yangtze River in China (a length of about 1,400 km). The historical range was much broader, including waters of the Yangtze estuary, and several large lakes that dolphins entered during the flood season. Baiji may still enter some of these lakes,



Baiji or Yangtze River Dolphin
(Lipotes vexillifer)
Global Distribution

but apparently only during periods of intense flooding. They tend to congregate near confluences and sand bars with large eddies.

Ecology and behavior Groups of two to six baijis are most commonly seen, but aggregations of up to 16 animals sometimes form. Mixed groups with finless porpoises are now quite common (in recent surveys, about 63% of sightings). The porpoises appear to behave aggressively towards baiji on some occasions, although this may be unusual. Baiji groups in recent surveys have consisted of about 57% adults, 26% juveniles, and 17% calves.

These dolphins are generally shy of boats, and their surfacings are shallow, often exposing only the top of the head, dorsal fin, and a small part of the back. They generally breathe with little surface disturbance, and most submersions are 10–30 sec. long, with occasional longer dives (the longest ones recorded were slightly under 3.5 minutes). Baiji movements include both short- and long-distance (200+ km) meanderings.

Breeding occurs mainly in the first half of the year; the peak calving season appears to be February to April. Males reach sexual maturity at ages of about 4 years, and females do so at about 6 years. The oldest known individual was 30 years old. It is assumed that there is only a single population.

Feeding and prey Baiji are apparently opportunistic feeders. A large variety of freshwater fish species make up the diet of the baiji, the only limitation probably being size.

Threats and status For the past several decades, the baiji has been widely acknowledged to be the most critically-endangered cetacean in the world. In fact, sightings in the new millennium have become exceedingly rare. Although protected by Chinese law (it is a "Protected Species of the First Order"), and direct killing is considered virtually non-existent, other threats are rampant. The main threat is mortality from non-selective fishing gear, such as rollings hooks (a type of snagging "longline"), dynamite, and electric fishing (the latter is now considered the main threat, accounting for about 40% of baiji mortalities). Habitat deterioration/destruction is another major factor, as the Yangtze River has been dramatically modified to meet the needs of the huge surrounding human population (by some assessments, nearly 10% of the world's total). Other conservation issues include pollution, vessel collisions, and prey depletion. The genetic and demographic consequences of extremely low population size, although often overlooked, are another class of problems. The threats are only becoming more serious, and it now appears likely that the baiji has become the first species of cetacean to

A dead baiji, which was killed by rolling hook fishing gear, lies along the banks of the Yangtze River. The low, extremely wide-based dorsal ridge and "cheeks" are distinctive to this species. This animal appears to be emaciated. PHOTO: ZHOU KAIYA, COURTESY S. LEATHERWOOD

Qi Qi, for many years the only baiji in captivity, swimming in his tank at the Institute of Hydrobiology in Wuhan, China. Note the "cheeks" and small eyes. PHOTO: T. A. JEFFERSON

be exterminated by human activities. For the past several years, Chinese officials have been attempting to remove animals from the river, and place them into a "semi-natural reserve." However, a 3,500-km survey by an international team of experts, which covered nearly all of the species' known range over a 6-week period in late 2006, failed to observe a single dolphin. It is therefore likely that the species may already be extinct.

IUCN status Critically Endangered.

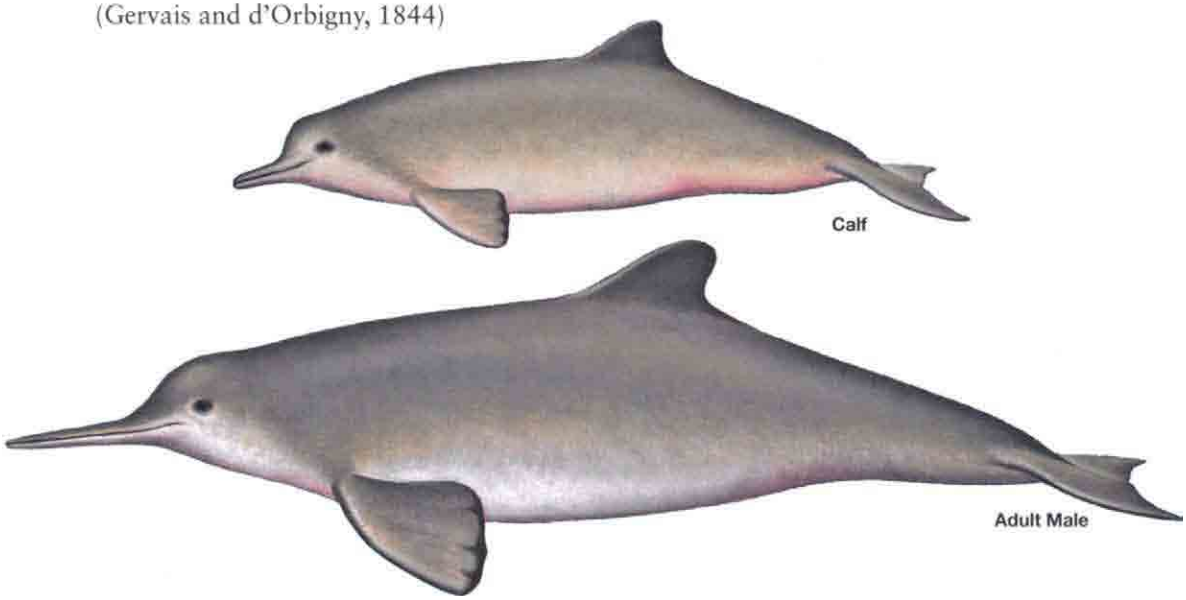
Franciscana—*Pontoporia blainvillei*

(Gervais and d'Orbigny, 1844)



Recently-used synonyms *Stenodelphis blainvillei.*

Common names En.—franciscana or La Plata river dolphin; Sp.—*franciscana*; Fr.—*dauphin de La Plata*.

Taxonomic information Order Cetacea, Suborder Odontoceti, Family Pontoporiidae.

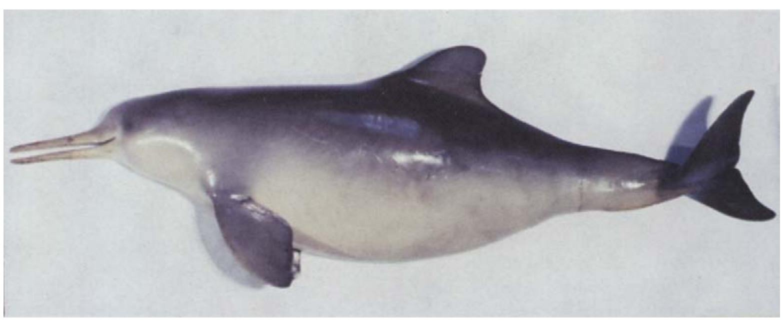
Species characteristics Although not a true freshwater dolphin, this primarily marine species nonetheless shares many features in common with the true "river dolphins." The franciscana's beak is extremely long and narrow, relatively the longest of any living species of cetacean (about 12–15% of total length in adults). The beak grows to be longer in adult females (17–22 cm) than in males (15–19 cm). Although in calves, the beak is much shorter and stouter than it is in older individuals. The forehead is steep and rounded. The dorsal fin is low to moderately tall, with a rounded tip. It is triangular, or sometimes slightly falcate. The flippers are broad spatulate, sometimes with an undulating trailing edge. In many animals (especially younger ones), there are visible ridges along the surface, corresponding to the finger bones. Newborns have proportionately larger flippers, dorsal fins, and flukes.

Franciscanas have a relatively simple, countershaded color pattern. They are brownish to dark gray above, and lighter brown (or even yellowish) to light gray below and on the lower flanks. The back is darker than the belly and sides, and a faint dorsal cape may sometimes be visible.

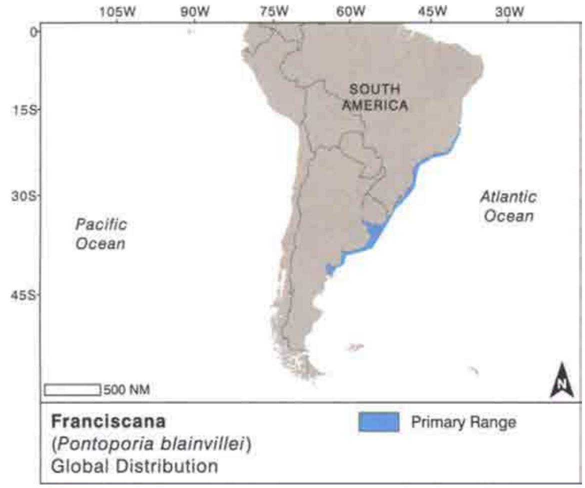
The long beak is lined with 50–62 fine pointed teeth per row, more than in nearly any other species of cetacean.

Franciscana females grow larger than males, with males reaching up to 1.63 m, and females 1.77 m in length. Asymptotic length ranges from 1.30–1.62 m for females and 1.13–1.36 m for males from different populations. Maximum recorded weight is about 53 kg. At birth, franciscanas measure about 71–80 cm, with an average of about 73 cm in length and 6.1 kg in weight.

Recognizable geographic forms Morphological studies have suggested the existence of at least two "forms" of franciscana, a smaller northern and a larger southern one (those in the far north may be intermediate in size). Other than length, there are no known obvious external morphological differences between them (although this may be due to lack of sufficient data). So,



A dead franciscana, showing the species' distinctive body shape and exceedingly long beak. PHOTO: R. BASTIDA



Four franciscanas killed by fishing gear. The animal in front is probably an adult female, and the one on the right is a young calf. PHOTO: COURTESY OF THE LATE S. LEATHERWOOD

although the franciscana is clearly divided into three genetically-distinct populations (currently managed as four separate stocks or "Franciscana Management Areas"), it is not currently possible to reliably distinguish distinct geographic forms. There is also evidence of geographic variation in coloration, but this remains unconfirmed.

Can be confused with If not seen well, franciscanas may be confused with marine dolphins of the genus *Sotalia*, but can be identified by their very long beaks and more rounded dorsal fins, broad flippers, and small eyes. Young franciscanas, with relatively short beaks, will cause the most confusion. Burmeister's porpoises overlap in distribution as well, but will be distinguishable by their lack of a prominent beak and oddly-shaped dorsal fin. Bottlenose dolphins should be easy to distinguish, based on their much larger size and tall, falcate dorsal fins.

A mother and calf franciscana swim in nearshore waters of southern Brazil. This photo shows the low-surfacing profile characteristic of the species. PHOTO: M. J. CREMER

Distribution Franciscanas are found only along the east coast of South America (Brazil, Uruguay, and Argentina), from Golfo San Matias, central Argentina (42°35'S), to Espirito Santo, southeastern Brazil (18°25'S). They are primarily shallow-water, coastal animals, generally ranging no farther offshore than the 30 m isobath. Some sightings in water beyond 50 m deep and 55 km offshore have been recorded, but the density is very low in such areas. They may also be found in some estuaries, and they sporadically enter the estuary of the La Plata River. Much of the franciscana's habitat is characterized by turbid waters.

Ecology and behavior Although there has been increased research interest in recent years, there is still little known about franciscana behavior. This is due to two factors: the difficulty of observing them in nature (they are somewhat cryptic), and the paucity of research effort. They are found singly or in small groups of up to 15 indi-

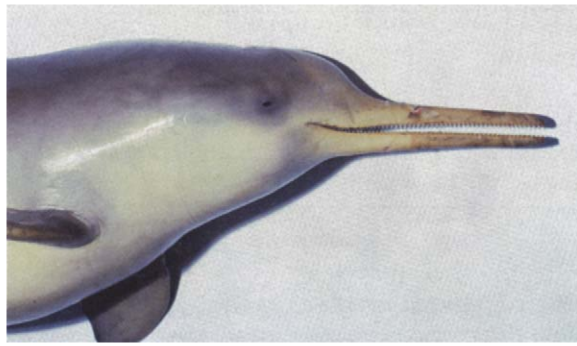
viduals. In general, they appear to avoid vessels, and do not ride bow waves. They are not considered to be aerially active, and the average swimming speed is about 4.7 km/h. Mean dive duration is about 22 sec. Cooperative feeding behavior has been observed in Argentina.

Although sometimes described as a "river dolphin," the franciscana is not truly a freshwater species. Franciscanas do not migrate, although seasonal inshore/offshore movements have been documented in some areas. Predation by both large sharks and killer whales has been documented.

Peak calving for this species occurs from October to December for most stocks, but in the Rio de Janiero area (northernmost stock) breeding occurs throughout the year. Until recently, there has not been much research on the life history of this species. Reproductive parameters have only been estimated for some of the stocks. For these, sexual maturity in females occurs at ages between 2 and 5 years, and for males between 3 and 4 years. Gestation lasts about 11 months. The relatively small testes of this species suggest that sperm competition is not a factor in their mating system. Although most individuals appear to live to less than 10 years, longevity is up to at least 15 years for males, and 21 years for females.

Feeding and prey Franciscanas feed on several species of shallow-water fish (e.g., sciaenids, engraulids, gadids, and carangids), cephalopods, and crustaceans. They feed mostly near the bottom, and appear to be opportunistic, with at least 58 fish species, 6 cephalopod species, and 6 crustacean species known from the diet. Shrimps are commonly eaten by juveniles, which then switch to a more piscivorous diet after one year.

Threats and status The main problem facing the species is incidental mortality in gillnet fisheries, which



The long, delicate-looking beak of a franciscana is among the longest of all the marine mammals. Argentina. PHOTO: R. BASTIDA

numbers at least 2,500 animals per year, and affects all 4 management stocks. Other threats include various forms of habitat degradation and pollution. Total abundance of the species is not known, but has been estimated for the two southern stocks. In 1996, there were an estimated 42,000 animals in southern Brazil and Uruguay, and 40,200 in Argentina. While the overall abundance of the species would seem to be high, in most areas the gillnet mortality alone is thought to be unsustainable. Therefore, the franciscana is potentially vulnerable to extinction.

IUCN status Vulnerable (southern Brazil/Uruguay stock), Data Deficient (all others).

True Seals *Phocidae*

Steller Sea Lion—*Eumetopias jubatus*

(Schreber, 1776)

Recently-used synonyms None.

Common names En.–Steller, Steller's, or northern sea lion; Sp.–*lobo marino de Steller*; Fr.–*lion de mer de Steller*.

Taxonomic information Order Carnivora, Family Otariidae.

Species characteristics Steller sea lions are the largest otariid and the fourth largest pinniped. Both sexes are robust and powerfully built at all ages. They are sexually dimorphic, with adult males weighing three times as much as females, and grow 20–25% longer. In addition to being larger, males have a mane of longer guard hairs extending from the back of the head to the shoulders and all around the neck. Breeding bulls are also very thick and wide in the neck and shoulder area. There is a sagittal crest on the skull that imparts a small to moderate forehead to adult and subadult males. Adult females and juveniles have no crest and have only a minor forehead dip in front of the eyes and appear to be almost flat from the crown to the tip of the nose. Males also have larger canines that are both longer and thicker than those of females.

Steller sea lions have a massive, wide head. The muzzle is thick, wide, long, and blunt on the end. The eyes are widely-spaced apart, and set well back from the end of the muzzle and, like the ear pinnae, appear small when compared with the size of the head. The vibrissae are pale, conspicuous, and long.

Both the fore- and hindflippers are long and broad. The foreflippers have sparse, short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface, and the palms of both foreflippers are covered with a hairless

black leathery skin. The first digit is the longest, widest and thickest, and curves posteriorly, giving the flipper a swept back look. Digits 2–4 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers. The hindflippers also have cartilaginous rods that extend the length of each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The first and fifth toes are longer than the three middle toes, and the first toe, or hallux, is longer and wider than the fifth toe. The hindflippers have short hair covering part of the proximal end of the flipper, and the rest of the dorsal surface, and the entire sole is covered in black leathery hairless skin.

Coloration in adults is pale yellow to light tan above, darkening around the insertion of the flippers to brown and shading to rust below. Unlike most pinnipeds, when wet, adult Stellers are paler, appearing light grayish-tan. Juveniles are darker than adults and are dark tan to light brown. Pups are born with a thick blackish-brown lanugo that is molted by about 6 months of age. Scars from bites and healed wounds are darker than the background color.

The maximum length of adult males is about 3.3 m and average weight is 1000 kg. The maximum length for adult females is about 2.5 m and average weight is 273 kg. Pups are born at an average of about 1 m and 18–22 kg.

The dental formula is I $^{3}/_{2}$, C $^{1}/_{1}$, PC $^{5}/_{5}$. There is a wide diastema (gap) between the 4th and 5th post-canines.

Recognizable geographic forms None.

Can be confused with Steller sea lions are readily separated from northern and Guadalupe fur seals that occur within their range by their massive size, large blocky head and muzzle, and pale color. California sea lions are the most likely species to be confused with Steller sea lions. Careful attention to head and muzzle size and shape, overall coloration, and length and width of fore- and hindflippers permits separation. Smaller Steller sea lions in the size range of large California sea lions, look like they are more muscular and powerfully built than the Californias, which look more rounded and streamlined. Also, smaller Stellers have little or no sagittal crest development and a nearly flat-topped head whereas comparably-sized adult and subadult California sea lion males have a moderate to large sagittal crest and more pronounced forehead. Steller sea lion eyes also seem smaller and set farther apart, due to the proportionately larger head and wider muzzle.

Distribution Steller sea lions are found from central California (formerly southern California), north to the Aleutian Islands, and west along the Aleutian chain to Kamchatka, and from there south along the Kuril Islands to northern Japan, the Sea of Japan, and Korea. Stellers also occur in the Sea of Okhotsk. From the Aleutians they range north across the Bering Sea to the Bering Strait. Throughout their range they are usually found from the coast to the outer continental shelf and slope.

Ecology and behavior Steller sea lions are polygynous, and breed in the late spring and summer. Adult males arrive at the rookeries before females and those that are nine years or older, claim territories, which they aggressively and vociferously defend. Stellers have deep voices and produce powerful low-frequency rolling roars and can be heard for long distances over the noise of wind and waves. Roaring males often bob their head up and down while vocalizing. This is in contrast to the side to side head wave of California sea lion males when they produce their characteristic repetitive bark.

Pups are born from May through July, and females stay continuously ashore with their newborns for the first week to ten days after giving birth. Following this period of attendance, females make foraging excursions, primarily at night for periods of 18–25 hours, followed by time ashore to nurse their pup. Females come into estrus and mate about two weeks after giving birth. Weaning often takes place before the next breeding season, but it is not unusual to see females nursing yearlings, older juveniles, or multiple offspring.

Steller sea lions can leave haulouts in large groups. Sightings at sea are most often of groups of 1–12 animals. They aggregate in areas of prey abundance, including near fishing vessels, where they will feed on netted fish and discarded by-catch. They are not considered migratory, and juveniles and subadults make most long distance trips. Adults usually forage and live near their natal colonies and return to these sites to breed. The area used by adult females for foraging in winter is considerably larger than the area used in the summer. Diving is generally to depths of 200 m or less and dive duration is usually two minutes or less, with both parameters varying by season and age of the animal. Adult females tend to dive deeper in winter than summer. Diving ability of pups and juveniles increases with age, and they routinely dive to depths of around 140 m for periods of two minutes as yearlings. The diving of adult males has not been studied. Predators include killer whales and sharks.

Feeding and prey Steller sea lions feed on many varieties of fish and invertebrates. Much of the information on diet comes from animals living in Alaska, where they feed on walleye pollock, Pacific cod, Atka mackerel, herring, sand lance, several varieties of flatfish, salmon and rockfish, and invertebrates such as squid, octopus, bivalves and gastropods. Adult females with young pups feed extensively at night, switching to foraging at any time after the breeding season. Adult males are known to occasionally kill and consume young northern fur seals.

Threats and status Steller sea lions have been important to the native people living near them for millenia. Native Alaskans currently take between 150–300 a year for food and other uses. The worldwide population of Steller sea lions declined by 64% during the period from 1960 to 1989, and is currently estimated to be approximately 100,000 animals. The decline has been most dramatic in the large populations from the Gulf of Alaska (-54%), west throughout the Aleutian Island chain (-81%), to the moderately-sized Russian population (-74%). During the same period, the moderately-sized southeastern Alaska population increased (+70%). The reasons for these changes and the overall decline are unclear, but are the subject of intensive ongoing investigations. Factors hypothesized include: the direct and indirect effects of large-scale commercial fisheries on key prey species, long-term ecosystem shifts, and changes in behavior by a primary predator, the killer whale, or a combination of these factors.

IUCN status Endangered.

References Loughlin 2002; Loughlin et al. 1987; Raum-Suryan et al. 2002; Schusterman 1981; Sease and York 2003; Trites and Donnelly 2003.

California Sea Lion—*Zalophus californianus*

(Lesson, 1828)

Recently-used synonyms *Zalophus californianus californianus.*

Common names En.–California sea lion; Sp.–*lobo marino de California*; Fr.–*lion de mer de Califonie.*

Taxonomic information Order Carnivora, Family Otariidae. Currently the California, Galapagos and Japanese sea lions are considered to be three separate species. Until recently most authors classified them as subspecies of *Z. californianus*.

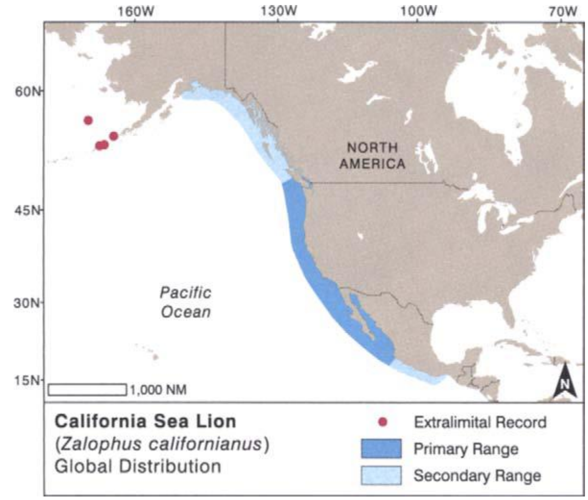
Species characteristics The California sea lion is the well-known performing "seal" of zoos, circuses, and oceanaria. It is a sexually dimorphic species, with males reaching three to four times the weight of adult females and 1.2 times their length. Males become very robust in the neck, chest, and shoulders. As males become sexually mature the sagittal crest enlarges. The crest first appears as a bump on the crown, then grows to become a large prominent ridge, often steep in the front, that creates a tall forehead. The canine teeth of adult males are larger and thicker than those of females.

The distinctive pale topped sagittal crest of the adult male California sea lion is unmistakable. Also note the pale muzzle and face around the eyes, and dark body. PHOTO: P. COLLA/OCEANLIGHT

Adult and subadult male California sea lions bark in often long, repeated sequences. The bark is loud, moderate in pitch, and often delivered while the head is waved from side to side. Females and juveniles do not produce the repetitive bark. Juveniles and subadults of both sexes growl, and when alarmed produce a loud shriek-like bark that is high pitched. The growl of adults is low-frequency and roar-like, and can be explosive, when the animal is angered or startled.

Both sexes have a long and somewhat narrow muzzle that tapers to a blunt nose. In profile, the face of younger animals is dog-like. Adult females and juveniles do not have a sagittal crest, and in profile have a flat head that smoothly transitions into the muzzle with a slight drop. In contrast to adult males, adult females have a long, relatively thin neck and a wide body behind the foreflippers.

The foreflippers have a sparse short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface, and the



palms of both foreflippers are covered with a hairless black leathery skin. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers. The hindflippers also have cartilaginous rods that extend the length of each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The first and fifth toes are longer than the three middle toes, and the first toe, or hallux, is longer and wider than the fifth toe. The hindflippers have short hair covering part of the proximal end of the flipper; the rest of the dorsal surface and the entire sole is covered in black, leathery, hairless skin.

The coloration of California sea lions is variable. When dry, the coat of most adult males is dark brown, and when wet they appear blackish. Males begin to darken as subadults, and complete this change when they reach physical maturity. However, some males do not darken completely or even extensively, and remain various shades of tan to light brown on the sides, belly, and rear quarters. Adult females are tan above, and various shades of tan to light brown below. They are usually the same color on the underside of the neck as on the back, and somewhat darker, on the rest of the ventrum and around the base of the flippers. Adult and large subadult males are light-colored on the muzzle, around and above the eyes, on the ear pinnae, and on the sagittal crest. Coloration of juveniles and young subadult males is similar to adult females. Pups are born with a thick brownish-black lanugo that is generally molted by the end of the first month. The succeeding light brown juvenile coat is shed 4–5 months later, and is replaced by adult coloration. California sea lions appear duller and grayer as they get close to the time of the annual molt.

Male California sea lions reach lengths of 2.4 m, and weights of more than 390 kg. Females only reach 2 m, and weigh an average of 110 kg. Newborn pups are about 80 cm long and 6–9 kg.

The dental formula is I $^{3}/2$, C $^{1}/1$, PC $^{5}/5$ (~79%), PC $^{6}/5$ (~21%).

Recognizable geographic forms None.

Can be confused with California sea lions share their range with three other otariids: Steller sea lions, and northern and Guadalupe fur seals. Juvenile, subadult, and smaller adult female Steller sea lions fall within the size range of California sea lions. Careful attention to head and muzzle size and shape, overall coloration, and length and width of fore- and hindflippers permits differentiation. Smaller Steller sea lions in the size range of large California sea lions will look like they are more muscular and powerfully built than similar-sized California sea lions, which look more rounded and streamlined. Also, smaller Steller sea lions have no sagittal crest development and a nearly flat-topped head, whereas comparably-sized adult and subadult California sea lion males have a moderate to large sagittal crest and more pronounced forehead. Steller sea lion eyes appear smaller and set farther apart, due to the proportionately larger head and wider muzzle.

Both northern and Guadalupe fur seals have thick

California sea lions are sexually dimorphic. The adult male is an uncommonly pale variation. San Miguel Island, California. PHOTO: M. WEBBER

pelage and look shaggier than the more sleek California sea lions. Males of both fur seals are dark in color, often with light tips to the long hairs that impart a grayish cast to the dark color. Adult females, juveniles and subadults are multicolored with dark gray or brown dorsal, tan to buff ventral coloration, and a pale band across the chest. Both fur seals have a more pointed face and proportionately longer ears that stand out farther from the head when they are in the water or otherwise wet. Adults of both fur seals have conspicuous, long, pale vibrissae.

Northern fur seals have a very short pointed muzzle, very long hindflippers with long cartilaginous extensions all of equal length and width. The fur on the dorsal surface of the foreflippers stops abruptly at the wrist line, or bend point, and the top of the flippers has a smooth "clean shaven look." This is in contrast to the California sea lion, which has fur on the top of the flipper extending in a "V" beyond the wrist.

Guadalupe fur seals have a long, pointed muzzle. The somewhat bulbous nose contributes to an upturned silhouette of the muzzle. The hindflippers are longer than those on California sea lions, but lack the extreme length of northern fur seal hindflippers. The foreflippers have short hair extending in a "V" beyond the wrist line on the dorsal surface.

Distribution The California sea lion occurs in the eastern North Pacific from the Tres Marias Islands north of Puerto Vallarta, Mexico, north throughout the Gulf of California, and around the end of the Baja California Peninsula north to the Gulf of Alaska. Vagrants have been reported from the Bering Sea in the north to Acapulco in the south. Most rookeries are south of Point Conception, Southern California. Many islands free of predators and sources of human disturbance throughout their range are used as haulouts. The California sea lion population is currently expanding, and is extending its breeding range northward. Females, which were only very rarely found north of Point Conception in the early 1980s, are now routinely found in northern California, where former breeding sites have been reoccupied. They are now occasionally found in Alaska, in the northern part of the species' range.

California sea lions are usually found in waters over the continental shelf and slope, however, they occupy several landfalls far offshore in deep oceanic areas, such as Guadalupe Island and Alijos Rocks off Baja California. Large numbers of adult and subadult males and juveniles undertake a post-breeding season migration north from the major rookeries in Southern and Baja California and winter from central California to Washington State. Smaller numbers of animals migrate to British Columbia and Southeast Alaska, making it to the northern Gulf of Alaska coast. California sea lions occupy the Gulf of California year round. Those residing there do not appear to make long migrations. Throughout their range, California sea lions frequent coastal areas including bays, harbors, and river mouths, and regularly haul-out on buoys, jetties, boat docks, and even on anchored boats. They traditionally haul-out on certain coastal headlands and under cliffs that limit access and approach by terrestrial predators.

Ecology and behavior Pupping and breeding take place from May through July. Males are highly polygynous and hold territories both on land and in shallow water near shore for periods up to 45 days. Females stay ashore with their newborn pups for about 7 days before they depart for the first of many foraging trips that usually last 2–3 days and are followed by attendance of the pup at the rookery for 1–2 days. Most pups are weaned at 10 months, but long before this, they start making foraging trips to sea with their mothers. Some pups continue to receive care as yearlings, and even as 2-year-olds. Estrus occurs around 27 days after giving birth. California sea lion females often gather in "milling groups," where they roll in the surf and sand, mounting each other and even nearby bulls. Often the females from the milling group disperse after one or more of them copulates with a bull.

The diving pattern of lactating adult females is consistent with a number of other otariid species. The deepest dive recorded to date was to approximately 274 m and the longest dive lasted just under 10 minutes. Typical feeding dives are shallower than 80 m, and last less than three minutes. Lactating adult females are active for most of the time they are at sea and feeding bouts occur during the day and at night, with peaks of activity at dawn and dusk. Feeding dives occur in bouts suggesting sea lions are frequently exploiting patches of prey. They are not known for deep or long dives.

California sea lions will "porpoise," or leap clear of the water when traveling rapidly at sea. Large, "porpoising" groups of sea lions can resemble a heard of dolphins. Juveniles and subadults may perform acrobatic and high vertical leaps, and individuals of all ages surf breaking waves and sometimes ride in the stern wakes of vessels. They are often seen at sea, rafting at the surface, alone or in groups. Animals in rafts frequently raise one or more of their flippers high out of the water, sometimes suggesting a tall slender shark fin at the surface. California sea lions will also float and sleep at the surface, far offshore in rafts of kelp. They are known to travel with several dolphin species and are thought to use dolphins to help them locate food. They will also swim alongside large cetaceans, such as blue and humpback whales and ride their bow waves.

California sea lions haul-out and travel at sea with Steller sea lions, where the two species co-occur. They will also haul-out near Guadalupe and northern fur seals

and elephant seals, and in a few locations, harbor seals. Predators of California sea lions include killer whales, sharks, coyotes and feral dogs, and, until they were extirpated from the California Channel Islands, bald eagles were known to take young pups.

Feeding and prey California sea lions are opportunistic and feed on a wide variety of prey, often taking what is abundant locally or seasonally in the areas they occupy. Principal prey taken in the Pacific includes: Pacific whiting, market squid, red octopus, jack and Pacific mackerel, blacksmith, juveniles of various species of rockfish, herring, northern anchovy, and salmon. Sea lions in the Gulf of California have northern anchovy, Pacific whiting, and rockfish as prey in common with animals in the Pacific, and also take various species of midshipmen, myctophids, and bass, as well as sardines, cutlassfish, alopus, and cusk eels. Because of their boldness and taste for commercially-important fish species, such as salmon and rockfish that are easily taken from fishing lines, they are considered a nuisance by many sport and commercial fishermen. California sea lions will also ascend rivers following spawning runs of anadromous fish, and take advantage of man-made structures, such as canal locks and fish ladders that concentrate prey.

Threats and status California sea lions are abundant and the population is growing. They were historically important to native people living in coastal areas and on islands. Numerous kitchen middens in Southern California and on the Channel Islands that contain large numbers of California sea lion and other pinniped bones, attesting to the importance of marine mammals in subsistence cultures prior to the arrival of Europeans. In the 19th and early 20th centuries, California sea lions were periodically harvested intensively for a variety of products, and hunted for bounties to such an extent that the population may have been reduced to as few as 1,500 by the end of this period. Protection that began in the mid-20th century and solidified with the Marine Mammal Protection Act of 1972 in the United States (and under similar measures in Mexico) provided the impetus for recovery of the population, which now numbers an estimated 211,000 to 241,000 animals in the US and Mexico.

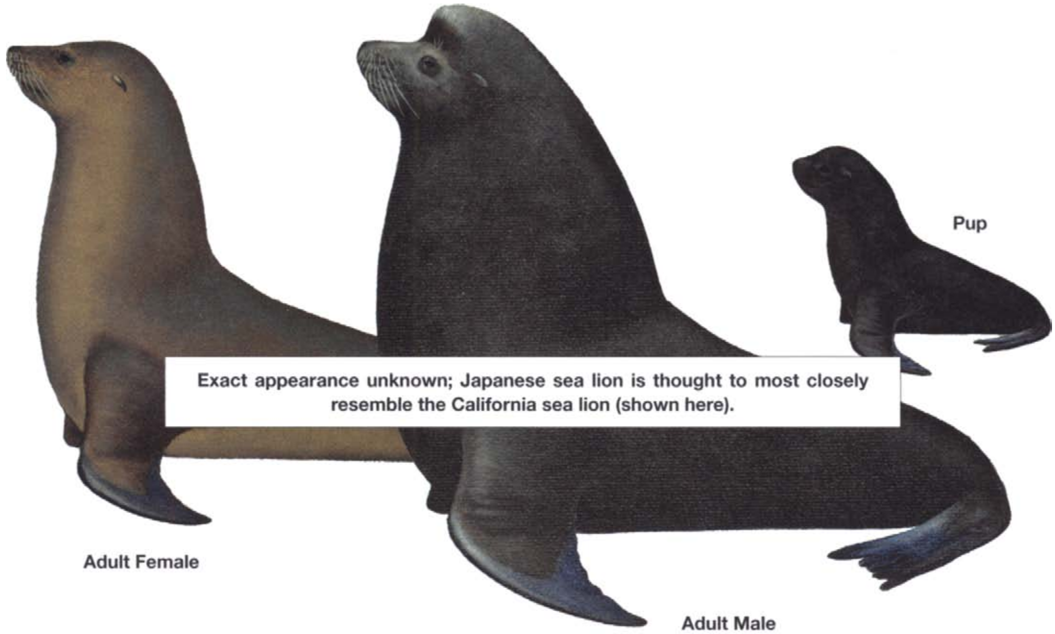
California sea lion mortality occurs in conflicts with fisheries, by poaching, and through entanglement in marine debris. Sea lions also accumulate pollutants through the food chain, and large amounts of DDT and PCBs discharged in the past continue to accumulate in coastal marine food chains, as evidenced in part by the burdens many marine mammals carry in their tissues and organs. Large amounts of agricultural and urban runoff and waste continue to be discharged into coastal marine habitats annually from numerous sources, and this pollution is having as-yet poorly-known effects on sea lion immune systems and overall health. California sea lions also die from periodic outbreaks of planktonic organisms that cause paralytic shellfish poisoning. Prey availability is greatly reduced during El Niño events, and large numbers of pups born during these periods die of starvation, as do weaker animals from all age classes.

IUCN status Least Concern.

References Aurioles and Zavala 1994; Bearzi 2006; Heath 2002; Le Boeuf et al. 1983; Lowry 1991; Odell 1981; Peterson and Bartholomew 1967.

Japanese Sea Lion—*Zalophus japonicus*

(Peters, 1866)



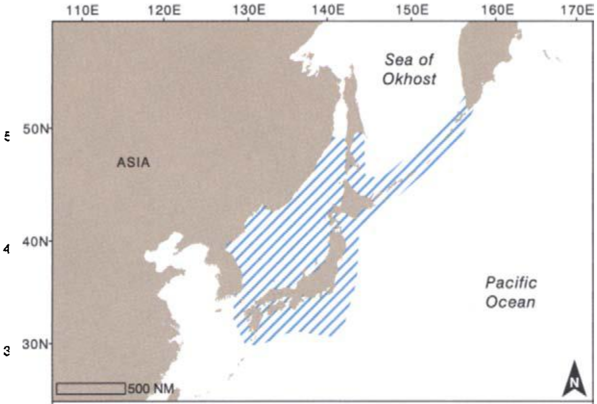
Recently-used synonyms *Zalophus californianus japonicus.*

Common names En.–Japanese sea lion; Sp.–*lobo marino de Japan*; Fr.–*lion de mer de Japan*.

Taxonomic information Order Carnivora, Family Otariidae. Currently the Japanese, California, and Galapagos sea lions are considered to be three separate species. Until recently most authors classified them as subspecies of *Z. californianus*.

Species characteristics The Japanese sea lion is considered by many authors to be extinct. It was long considered a subspecies of the California sea lion. Very little information exists on the appearance of this animal. In an account from otter and seal hunters working in the western Pacific in the early 20th century, the "black sea

There are very few photos of Japanese sea lions, such as this group at an unknown location on a rocky reef. The group includes several large, dark adult males with thick necks and pale faces and muzzles. At least one animal appears to have a sagittal crest, as seen on adult male California sea lions. There are also a number of smaller animals, several of which are partly or wholly pale. PHOTO: SHIMANE PREFECTURAL GOVERNMENT (NAKAWATSE ALBUM), WITH THE ASSISTANCE AND COURTESY OF T. SUYAMA AND T. YAMADA



Japanese Sea Lion (*Zalophus japonicus*) Global Distribution — Probable Former Primary Range

lion" was said to have been present in addition to Steller sea lions. This common name may usefully point-out that some animals, presumably adult males, as is the case for many adult male California sea lions, were black. An account from the text of a mid-19th century work, gave a description of the animal as "straw colored with a darker throat and chest in the female."

A Japanese zoologist interviewed in the 1950s gave the lengths of adult males as 2.5 m and adult females as 1.4 m, and reported a four-month-old pup as being 65 cm long and 9 kg. A review in the late 1950s listed eight specimens as existing in museums, with none of these in Japan. A study in 2004 examined 12 skulls and found them to be significantly longer than the skulls of adult male California sea lions. The difference was large enough, that only the largest California sea lion skull reached the length of the shortest Japanese sea lion skull. Japanese sea lion skulls were also larger in a number of other measurements, including having a significantly taller sagittal crest. This strongly suggests that adult male Japanese sea lions were larger than California sea lions. Only one adult female Japanese sea lion skull was examined in this study, so it was not possible to draw conclusions about females. Only a single photograph was found for use in the preparation of this account.

People traveling in the former range of this species should be vigilant, and record detailed notes of any otariid sightings that cannot be readily identified as Steller sea lions or northern fur seals. For field identification purposes, Japanese sea lion features should be presumed to be similar to those of California sea lion.

Recognizable geographic forms None.

Can be confused with Japanese sea lions shared their range with Steller sea lions and northern fur seals. Assuming that Japanese sea lions were similar to California sea lions, refer to the "Can be confused with" section for California sea lions.

Distribution Japanese sea lions were found from the southern end of Japan, along both coasts, and throughout the Sea of Japan to southern Sakhalin Island. They were also found throughout the Kuril Island Archipelago to southernmost Kamchatka.

Ecology and behavior Very little information is available on these animals, although they were assumed to be similar to the California sea lion. They were said to be good divers, although studies on diving were never conducted.

Feeding and prey It is said that Japanese sea lions fed on fishes, but no other information is available.

Threats and status The Japanese sea lion is probably extinct. A comprehensive survey has not yet been undertaken to determine if the species might still exist, or to search for specimens, accounts, data, and photographs in Japan, South and North Korea, and Russia. The last population estimates available were of 100 animals on Takeshima Island and a total population of 300 in the late 1950s. Estimates are that 30,000 to 50,000 animals may have been present in the mid-19th century and that the population was decimated by hunting. The species probably became extinct in the late 1950s, although the remote possibility of a remnant colony surviving in poorly-studied Korean waters still exists.

IUCN status Extinct.

Galapagos Sea Lion—*Zalophus wollebaeki*

Sivertsen, 1953

Recently-used synonyms *Zalophus californianus wollebaeki.*

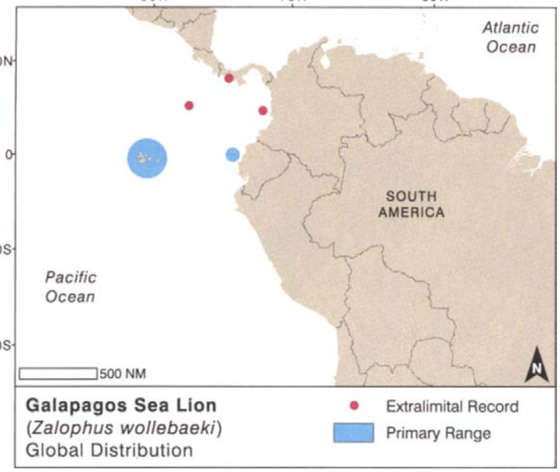
Common names En.–Galapagos sea lion; Sp.–*lobo marino de Galapagos* ; Fr.–*lion de mer de Galapagos*.

Taxonomic information Order Carnivora, Family Otariidae. Currently the Galapagos, California, and Japanese sea lions are considered to be three separate species. Until recently most authors classified them as subspecies of *Z. californianus*.

Species characteristics Galapagos sea lions are similar in appearance to California sea lions, but differ in size, behavior, and skull morphology. Galapagos sea lions are sexually dimorphic, with males growing larger than females and having several significant secondary sexual characteristics. The degree of sexual dimorphism appears to be less than in California sea lions, although few weights and measurements are available for adults.

Adult males are robust in the neck, chest, and shoulders and are proportionately much smaller in the abdomen. As males mature sexually the enlarging sagittal crest becomes evident as a bump on the crown. The crest grows until the male reaches physical maturity, at which time it forms a prominent ridge above and behind the eyes, and creates a steep forehead. Galapagos sea lion males are said to lack the pale pelage coloration on top of the sagittal crest common in California sea lions, although this feature appears to be present in at least one published photograph. Also, the skull of adult male Galapagos sea lions has a 20–25% smaller sagittal crest, a shorter muzzle, is about 10% shorter overall and

Adult female Galapagos sea lions with an unmolted pup in the foreground. Notice the pale tan color, thin necks and low, rounded heads without evidence of a sagittal crest. PHOTO: G. MEYER



is narrower than the skull of male California sea lions. As in all otariids, the canine teeth of adult males are larger and thicker than those of females.

Adult and subadult male Galapagos sea lions bark in often long repeated sequences. The bark is loud, rapidly repeated, and distinctive. Females and juveniles do not produce the repetitive bark. Juveniles, subadults and adults of both sexes will also growl.

Adult females and juveniles do not have a sagittal crest. When viewed in profile, juveniles have a nearly flat head with little or no forehead. Adult females have a slight forehead formed by a gentle slope from the crown to the muzzle. In contrast to adult males, adult females have a long relatively thin neck and a wide torso.

Both sexes have a long and somewhat narrow muzzle that tapers to a slightly pointed nose. In profile, the face of younger animals is dog-like. The foreflippers have a sparse short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern and does not reach the rounded tip. The rest of the dorsal surface, and the palms of both foreflippers are covered with a hairless black leathery skin. The first digit is the longest, widest and thickest, and curves posterioraly, giving the flipper a swept back look. Digits 2–4 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers. The hindflippers also have cartilaginous rods that extend the length of each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The first and fifth toes are longer than the three middle toes, and the first toe, or hallux, is longer and wider than the fifth toe. The hindflippers have short hair covering part of the proximal end of the flipper, and the rest of the dorsal surface, and the entire sole is covered in black leathery hairless skin.

The color of Galapagos sea lions is highly variable. When dry, the coat of adult males ranges from grayish and golden brown to the common dark brown, and most bulls appear blackish or very dark when wet. Darkening begins when males are subadults and is generally complete when a bull reaches physical maturity. Adult males can have light gray coloration on their backs. Adult females, juveniles and young subadult males are pale colored above, and can be many shades of tan to light brown. There are often light colored areas on the muzzle, and around and above the eyes in both sexes. The sparse short fur covering a portion of the tops of the flippers can be the same color or darker than the color of the body. Pups are born with a longer brownish-black lanugo coat that fades to pale brown by three to five months. Pups go through their first molt at around five months and emerge with the pelage of adult females and juveniles.

A dry adult male Galapagos sea lion with a moderate sagittal crest, pale muzzle, and paler-colored body. PHOTO: G. MEYER

A wet adult male Galapagos sea lion with a moderate sagittal crest. PHOTO: G. MEYER

There is little information on the lengths and weights attained by Galapagos sea lions, but they are said to be somewhat smaller than California sea lions. Adult males are estimated to weigh up to 250 kg. Four adult females caring for pups weighed from 50 to 100 kg. Pups of both sexes are born at approximately six kilograms and weaned at approximately 25 kg.

The dental formula is I $^{3}/_{2}$, C $^{1}/_{1}$, PC $^{6}/_{5}$, but PC $^{5}/_{5}$ occurs in approximately 25% of animals.

Adult female and dependant juvenile Galapagos sea lion. Note the pale tan color of both animals. Isla Española (Hood). PHOTO: M. ELLIS/FOOTLOOSE FORAYS

Recognizable geographic forms None.

Can be confused with Galapagos sea lions share the Archipelago with Galapagos fur seals. As vagrants, they may show up in the range of South American sea lions and South American fur seals, and there is a record of the former from the Galapagos.

Galapagos and South American fur seals have thick pelage and look shaggier, especially when wet, than Galapagos sea lions. Both fur seals are dark gray to brown and darker than similar-sized sea lions, with the exception of a fully-grown male Galapagos sea lion. Both fur seals have a more pointed muzzle and proportionately larger eyes and longer ears that stand out farther from the head when they are wet. Adults of both fur seals have long pale conspicuous vibrissae. Galapagos fur seals are the smallest otariids, reaching only 1.5 and 1.2 meters for males and females, respectively, and are stockier with a shorter neck and body than Galapagos sea lions.

South American sea lions have large blocky heads with a short, thick, blunt-ended muzzle. Adult male South American sea lions have huge fore quarters with a thick mane and a very large lower jaw.

Adult female, dependant juvenile, and newborn pup in lanugo coat Galapagos sea lions. PHOTO: M. ELLIS/FOOTLOOSE FORAYS

Distribution Galapagos sea lions are found throughout the Archipelago on all the major islands and on many smaller islands and rocks. A colony was established in 1986 at Isla de la Plata, just offshore of mainland Ecuador, and vagrants can be seen from the Ecuadorian coast north to Isla Gorgona in Colombia. There is also a record from Isla del Coco approximately 500 km southwest of Costa Rica although it might have been a misidentification of California sea lion. Additionally, fishermen in Costa Rica occasionally report seeing sea lions which could be either California, Galapagos, or both species.

Ecology and behavior Galapagos sea lions are non-migratory. They are unafraid of humans when ashore and will investigate and climb on backpacks and other things people leave lying around. Haulout sites can be on steep rocky shorelines, ledges and offshore stacks, but rookeries are mostly on gently sloping, sandy and rocky beaches. To avoid overheating, sea lions will use shade from vegetation, rocks, and cliffs, and wade into tidal and drainage pools or move into the ocean, as needed during the heat of the day.

Pupping and breeding take place across an extended period from May through January. Because of the protracted breeding season, non-migratory nature of this species, and the extended care females provide to the pups, there are dependent pups on the rookeries year-round. Females usually wean pups in 11–12 months, but some continue to suckle yearlings along with newborn pups. Pups are attended continuously for 6–7 days, after which the female goes to sea to feed and begins a cycle of daily, diurnal foraging trips that last an average of

A juvenile Galapagos sea lion. PHOTO: G. MEYER

12 hours. Pups will enter the water and begin to develop swimming skills 1–2 weeks after birth. Females return at night to nurse their pup, departing again the next morning. Females and pups recognize each other and reunite based on calls and scent. Galapagos sea lion females feed during the day, in contrast to Galapagos fur seals, which primarily feed at night. In addition to foraging niche separation, female sea lions reduce their thermoregulatory challenges by being at sea during the heat of the day.

Galapagos sea lions are polygynous; males hold territories both on land and in shallow water near shore that they vociferously and aggressively defend. Male tenure on territories usually lasts from 10 days to 3 months, and most copulations occur in the water. Adult males have been observed to mob Galapagos sharks that approach rookeries.

Diving has been studied in four females. The maximum depth of dive recorded was 186 m and duration of 6 minutes. Average depth of dive was approximately 37–38 m and duration of less than 2 minutes. At sea they will raft at the surface and rest on their sides with one or more flippers held vertically in the air.

Feeding and prey Very little information exists on Galapagos sea lion prey. The remains of small sardines have been observed in vomit found on beaches. Galapagos sea lions have been seen smashing octopus on the surface of the water, presumably to stun or break them up to facilitate swallowing. Foraging dives by lactating females occur predominantly during the day, and are only to relatively shallow depths. This usually precludes Galapagos sea lions from foraging on vertically-migrating species, such as myctophids, midshipmen, and other deeper living prey routinely taken by California sea lions. However, during El Niño events prey includes green-eyes and myctophids, suggesting a change in foraging strategy during periods of environmental flux.

Threats and status The majority of the Galapagos sea lion population lives in the Archipelago, which is an Ecuadorian National Park surrounded by a marine resources reserve. Tourism occurs on a large scale but is strictly controlled to protect wildlife.

The population fluctuates between 20,000 and 50,000 animals. Die-offs and cessation of reproduction during El Niño events, when marine productivity collapses, have caused episodes of population decline. Irruptions of a sea lion poxvirus have occurred during El Niño events, adding to the stress on individuals from starvation. Feral and uncontrolled dogs have been reported to kill sea lion pups, and could transmit diseases to the population. Shark predation is evident from animals seen with injuries and scars from attacks, and killer whales are presumed to be another predator.

IUCN status Vulnerable.

South American Sea Lion—*Otaria flavescens*

(Shaw, 1800)

Recently-used synonyms *Otaria byronia.*

Common names En.–South American sea lion, or southern sea lion; Sp.–*lobo común*; Fr.–*lion de mer d'Amerique du sud*.

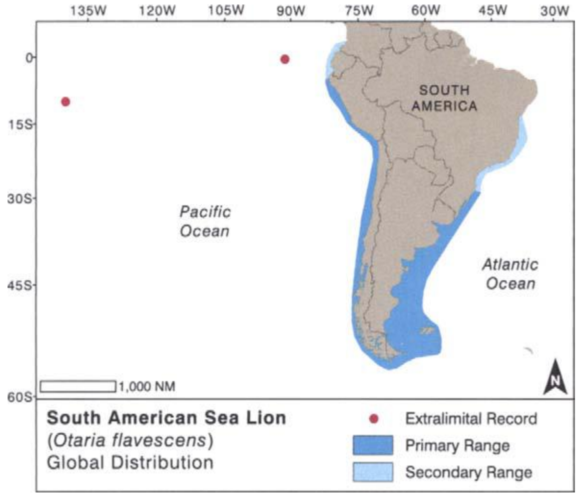
Taxonomic information Order Carnivora, Family Otariidae.

Species characteristics South American sea lions are stocky, heavy-bodied otariids that are strongly sexually dimorphic. In both sexes the muzzle is wide, short, and blunt. The nose is large and slightly upturned in females, and even more so in adult males. The lower jaw is wide and deep in both sexes. In adult males it juts forward, and is also accentuated by the longer hair of the mane on the chin. The ear pinnae are small and lie close to the side of the head; they are inconspicuous, particularly in adult males.

Adult males are unmistakable. They have a mane of long, coarse, erectile guard hairs, extending from forehead and chin to shoulders and mid-chest. The neck, head, jaws, and canine teeth are much larger than those of females. The large head and lower jaw, great bulk of the neck and shoulders, and thick mane make the front of the body appear disproportionately large and wide, despite the fact that the hindquarters are also large.

Adult females and subadults of both sexes do not have a mane. Their pelage is predominantly yellowish-gold to tan. They are not all uniformly colored, but can be patterned with areas of slightly different hues. Most males darken with age, becoming brownish-orange, although the mane and under parts frequently remain lighter. Males can have a darker face, giving them a slightly masked appearance. Some males remain the pale color of females and subadults throughout their lives.

Adult male, female, and pup South American sea lions. The enlargement of the male's chest and neck is striking. Peninsula Valdez, Argentina. PHOTO: G. MUELLER



Pups are born black above and paler below. Pups undergo their first molt approximately one month after birth, becoming dark brown. This color fades during the rest of the first year to a pale tan to light brown, with paler areas in the face.

The foreflippers have a sparse short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface and the palms of both foreflippers are covered with a hairless black leathery skin. The first digit is the longest, widest and thickest, and curves posteriorly, giving the flipper a swept back look. Digits 2–4 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers. The hindflippers also have cartilaginous rods that extend the length of each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The first and fifth toes are longer than the three middle toes, and the first toe, or hallux, is longer and wider than the fifth toe. The hindflippers have short hair covering part of the proximal end of the flipper, and the rest of the dorsal surface, and the entire sole is covered in black leathery hairless skin.

Adult males reach 2.6 m in length and weights of 300 to 350 kg; females reach 2 m and 144 kg. At birth, pups are 11–15 kg and 75–85 cm long.

The dental formula is I $^{3}/2$, C $^{1}/1$, PC $^{6}/5$.

Recognizable geographic forms None.

Can be confused with South American sea lions share most of their range with South American fur seals. Wandering South American sea lions have been recorded at the Galapagos and could occur within the range of Juan Fernandez fur seals, or vice versa. Also, Antarctic and Subantarctic fur seals occur as vagrants on the coast of South America.

South American sea lions are heavy-bodied animals with proportionately large heads and flippers, and are stockier and more muscular looking than similar size fur seals of any species. All fur seals have longer fur over the entire body and look shaggy when wet. The muzzle of fur seals is thinner and tapers to a pointed end, and the proportionately large eyes and long ear pinnae are more conspicuous. Fur seals are browns and grays, and darker than most South American sea lions of similar size, and have proportionately smaller flippers.

Galapagos sea lions are smaller overall and slimmer in build, with a much smaller head, proportionately longer and narrower muzzle, smaller lower jaw, and a smaller nose that is not turned up at the end. Coloration in smaller animals is similar, but bulls of each species are unmistakable in color and secondary sexual characteristics.

Distribution South American sea lions are widely-distributed, occurring more or less continuously from north-

ern Peru south to Cape Horn, and north up the east coast of the continent to southern Brazil, including the Falkland Islands. They are primarily a coastal species, found in waters over the continental shelf and slope, occurring less frequently in deeper waters. South American sea lions venture into fresh water, around tidewater glaciers, and up rivers. Vagrants have been found as far north as 13°S, near Bahia, Brazil, and in the Galapagos Archipelago.

Ecology and behavior South American sea lions are considered non-migratory, although some may wander long distances away from rookeries during the non-breeding season, and southerly locations such as the Falkland Islands are largely abandoned during the winter. However, most rookeries are continuously occupied by at least some animals, and the species has been described as sedentary.

South American sea lions are a highly polygynous species, with various strategies employed by males during the breeding season that are driven by substrate and terrain at the rookery, and thermoregulatory requirements imposed by weather conditions at the site. Adult males tend to establish territories through vocalizing, posturing, and fighting, when rookeries provide shade, have tidal pools that can be used for cooling, or funnel interior areas through narrow beaches between rocks or ledges to the sea. At more homogeneous locations with long shorelines, male strategy changes to focus on identifying, defending, and controlling individual cows in estrus, wherever they are found. Bulls actively and aggressively work to keep these cows close by grabbing, dragging, and throwing them back inland, away from the shoreline.

The start of the breeding season varies somewhat by location and latitude, with pups being born slightly earlier at more southern rookeries. At most sites, both sexes arrive in mid-December with peak numbers of males ashore just after mid-January and peak numbers of females ashore from mid- to late January. Females give birth 2–3 days after arrival, and pups are born from mid-December to early February with a peak in mid-January, coinciding with the timing of peak numbers of females ashore. Estrus occurs 6 days after parturition, and females make their first foraging trip 2–3 days later. From this point on, a cycle of foraging and pup attendance starts and lasts until pups are weaned at 8–10 months old. As is the case for many sea lions, it is not unusual for females to continue to care for yearlings. Pups gather in large pods on the rookeries while waiting for their mothers to return from 1–4 day long foraging trips. Females usually stay ashore for 2 days between trips.

An adult male South American sea lion. Notice the large head and thick muzzle with very large lower jaw, and the thick mane. Beagle Channel, Argentina. PHOTO: M. STOKKOM

At sea, South American sea lions are commonly seen rafting alone or in groups. They have been reported in association with feeding cetaceans and seabirds. The mean depth of lactating female foraging dives is about 61 m and the mean duration is just over 3 minutes. The maximum depth recorded for a dive is 175 m and duration 7.7 minutes. Two tagged adult males foraged on the con-

Young pup South American sea lion in the lanugo or birth coat. Peninsula Valdez, Argentina. PHOTO: G. MUELLER

Juvenile South American sea lions. Note the thick and wide muzzle, and tan color. PHOTO: M. JØRGENSEN

tinental shelf prior to the onset of breeding, making 5–6 day trips that covered an average of 600 km before they returned to land to haul-out. Lactating females routinely dive between 19–62 m, on dives lasting 2–7 minutes. The maximum depth of dive for the species is 250 m.

Predators include killer whales, sharks and leopard seals, and possibly the puma. At Peninsula Valdez, Argentina, killer whales are known to surf in on waves, partially beaching themselves while grabbing young sea lions off the shoreline. Vampire bats are known to drink blood from the skin of the flippers of sleeping animals.

Feeding and prey South American sea lions are opportunistic feeders, taking a wide variety of prey that varies by location. Their diet includes many species of benthic and pelagic fishes. Important prey species include South Pacific hake, herring, elephantfish, Peruvian anchovy, grenadier, South American pilchard, cusk-eels, and butterfish. Invertebrates taken include lobster krill, squid, octopus, jellyfish, and marine snails.

A small percentage of adult male South American sea lions regularly prey on South American fur seals. When adult male sea lions hunt for fur seals, they hunt alone and focus their attacks on pups and juveniles. About 17% of attacks are successful, but success varies widely between individual males. Subadult males also attack fur seals, but tend to abduct fur seals to serve as female sea lion substitutes, herding them and attempting to mate with them, usually killing them in the process. Female and juvenile sea lions have not been recorded to hunt fur seals. Sea lions have been observed killing young southern elephant seals in the Falkland Islands. They are also known to take several species of penguins, but the importance of penguins in the diet is unknown.

Threats and status The total population is estimated to be 200,000 to 300,000. South American sea lions were hunted by native people for thousands of years, and were taken by Europeans as early as the 16th century for food, oil and hides. Large commercial harvests, in several countries, drastically reduced sea lion numbers in the last several hundred years. Most populations are currently recovering from past harvests. Sea lions are taken incidentally or killed intentionally in a number of fisheries and fish farming operations throughout their range. Intensive trawl fishing in the coastal waters of southern South America has been implicated in the severe decline of sea lions in the Falkland Islands, where the population has fallen from 30,000 in the 1960s to approximately 15,000 in the 1980s, and possibly to as low as 3,000 in the 1990s.

Australian Sea Lion—*Neophoca cinerea*

(Peron, 1816)

Recently-used synonyms None.

Common names En.–Australian sea lion; Sp.–*l'otarie d'Australie*; Fr.–*lion de mer d'Australie*.

Taxonomic information Order Carnivora, Family Otariidae.

Species characteristics Australian sea lions are sexually dimorphic, with adult males reaching 1.25 times the length and 2.5–3.5 times the weight of adult females. The head is proportionately wide and long in both sexes, and is very large in adult males. The muzzle tapers to a blunt, somewhat rounded end. The eyes are widely set apart. There is a slight forehead that is more prominent in adult males due to an enlarged, but posteriorly-positioned, sagittal crest that elevates the crown. The ear pinnae are short and lie close to the head. Mystacial vibrissae are moderate in length, the longest ones reaching 18 cm. Two vibrissae are located above and behind each eye. In adult males, the neck and shoulders are greatly enlarged, and the canine teeth are thicker at the base and up to 2.5 times longer than those of adult females.

The foreflippers have a sparse short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface and the palms of both foreflippers are covered with a hairless black leathery skin. The first digit is the longest, widest and thickest, and curves posteriorly, giving the flipper a swept-back look. Digits 2–4 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers. The hindflippers also have cartilaginous rods that extend the length of each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the

A young adult male Australian sea lion with face beginning to darken and crown and neck beginning to lighten. PHOTO: T. HASSE

dorsal surface, set back from the end of the flipper. The first and fifth toes are longer than the three middle toes, and the first toe, or hallux, is longer and wider than the fifth toe. The hindflippers have short hair covering part of the proximal end of the flipper, and the rest of the dorsal surface, and the entire sole is covered in black leathery hairless skin.

Pups are dark chocolate brown to charcoal in color at birth and lighten to smoky gray. The crown is paler and there is a dark mask across the face. The postnatal molt starts when pups are 8–10 weeks old and is completed in several weeks. Pups molt to the juvenile pelage, which is like that of the adult females. Adult females and juveniles are fawn to silvery gray above and tan to pale yellow on the underside of the neck, chest, and abdomen. The underside of the abdomen can be darker in some animals. The demarcation between light and dark zones is high on the neck and dips down at the insertion of the foreflippers, remaining low on the sides between the fore- and hindflippers. The coloration of the face is variable, with the light coloration of the underside of the neck rising up to include the mystacial area and side of the face, frequently encircling the eyes, and reaching the ears. The foreflippers are often darker above. Some animals are darker overall and have little discernible contrast between coloration above and below.

Subadult males are colored like females, but darken as they mature, showing dark spots on the chest as the transition begins. The first evidence of this appears as dark spotting on the chest and darkening of the muzzle. Adult males have a mane of somewhat longer and coarser guard hairs from the crown to the shoulders. Their pelage is dark brown, with a whitish-creamy crown and nape of variable extent that gradually transitions to the darker body pelage on the back and sides of the upper neck. A scattering of light colored hairs sometimes reaching the underside of the neck. This area of pale coloration accentuates the darker "mask" across the face, which extends from ear to ear and covers the sides of the face, muzzle, lower jaw, and throat. Younger bulls are incompletely marked and can have a whitish ring around the eyes.

Very little information on sizes of adult males is available, and some values in the literature may be overestimates. Adult males reach lengths of at least 2.5 m and weights of 200 to at least 300 kg. Females are 1.3 to just over 1.8 m and weigh from 61–105 kg. At birth, pups are approximately 60–70 cm long and weigh 6.4–7.9 kg.

The dental formula is I $^3/2$, C $^1/1$, PC $^5/5$, and occasionally PC $^6/5$.

Recognizable geographic forms None.

Can be confused with New Zealand fur seals live within the range of Australian sea lions. The range of

Australian fur seals is adjacent to the range of this species. Wandering Subantarctic fur seals periodically show up as vagrants in mainland Australia and Tasmania. All of the fur seal species have a tapering pointed muzzle and more conspicuous ear pinnae. There are also differences in the size and shape of the toes on the hind flippers between Australian sea lions and all fur seals. In addition to these features, Australian sea lions can be differentiated from all southern fur seals based on differences in pelage color patterns, especially the paler coloration of juveniles and adult females. Australian sea lions lack the dense underfur and long guard hairs of fur seals making them appear more sleek. The Australian sea lion's shorter pelage (exclusive of the mane on adult males) looks shorter and less dense than the more luxuriant pelage of dry fur seals, or the shaggy look of fur seals when they are wet.

Distribution Australian sea lions occur in southern and southwestern Australia from just east of Kangaroo Island west to Houtman Albrolhos in Western Australia. Vagrants have come ashore in eastern Australia as far north as central New South Wales. Australian sea lions breed on at least 51 islands and at several mainland sites. Five sites account for about 50% of the annual pup production. At sea, Australian sea lions spend nearly all of their time in waters over the continental shelf.

Ecology and behavior Australian sea lions are unusual among pinnipeds in having a supra-annual pupping interval, with females producing pups every 17–18 months. Pups can be born at all times of the year, with females at a given site being loosely synchronous, and pupping over an approximately 5-month period. Neighboring sites are frequently on entirely different breeding schedules. Males are sequentially polygynous, establishing territories around individual females, herding them in an effort to keep them from departing until the onset of estrus, 7–10 days after they give birth, when they mate. This pattern is repeated until the male is compelled to go to sea and forage, after which he returns and repeats the strategy. Males defend their territories with guttural clicking, growling and barking vocalizations, posturing, and by fighting with rivals.

Pups are continuously attended for the first 9–10 days after birth. Over the next 5 months females make foraging trips that average 2 days, followed by pup attendance periods that average 1 1/4 days. Females suckle their pups for 15–18 months, usually weaning them a month before giving birth again. Some females care for their offspring for up to two years, and can be seen with a juvenile and a new pup. Adult female Australian sea lions behave aggressively toward pups that are not their own, as do adult males to all pups. Adult males will bite pups and throw them high in the air. Pups can be trampled when males are fighting or moving rapidly to confront

rivals and control females, and this can be a significant source of pup mortality. Pups will play at the shoreline and in tide pools while their mothers are away, and following their postnatal molt, they will actively swim on their own.

Adult female Australian sea lions are benthic, diurnal foragers. They routinely transit to foraging locations by swimming along the bottom. Mean depth of dives for a series of lactating females ranged from 41.5–83.1 m and maximum depth of dives ranged from 60–105 m. Mean duration of dives ranged from 2.2–4.1 minutes, and the longest dive recorded lasted 8.3 minutes. Australian sea lions are fast, powerful swimmers and will porpoise when moving rapidly at the surface.

These sea lions are considered non-migratory, and probably spend most of their lives near their natal colony. The greatest distance traveled by a tagged animal is approximately 250 km. Predators include great white sharks and presumably killer whales.

Feeding and prey Relatively little information exists on the diet of Australian sea lions. They are thought to concentrate their efforts on shallow-water benthic prey, but take a wide variety of fishes, such as rays, small sharks, Australian salmon, and whiting. Other prey includes squid, cuttlefish, small crabs, and occasionally penguins, flying seabirds, and small sea turtles. Fishermen complain of sea lions robbing lobster traps and fishing nets. Large prey items may be taken to the surface and shaken apart into portions that are easier to swallow.

Threats and status The total population of Australian sea lions was estimated at 9,900–12,500 in 1999 and was considered to be stable. This species is protected. A substantial sea lion viewing industry has developed, and is regulated at sea lion colonies in parks to minimize disturbance during the breeding season. Extensive disturbance can cause Australian sea lions to abandon colony sites.

Traditionally, Australian aborigines and early colonists took sea lions for food and other products. Harvests by sealers in the 17th and 18th centuries reduced the population and extirpated them from areas around Bass Strait and Tasmania. Although now protected, the population has not rebounded fully or reoccupied all of its former range. Conflicts and interactions with fisheries exist and some sea lions are shot as a result, while others are entangled in fishing gear, although the extent of the problem is not fully understood.

IUCN status Least Concern.

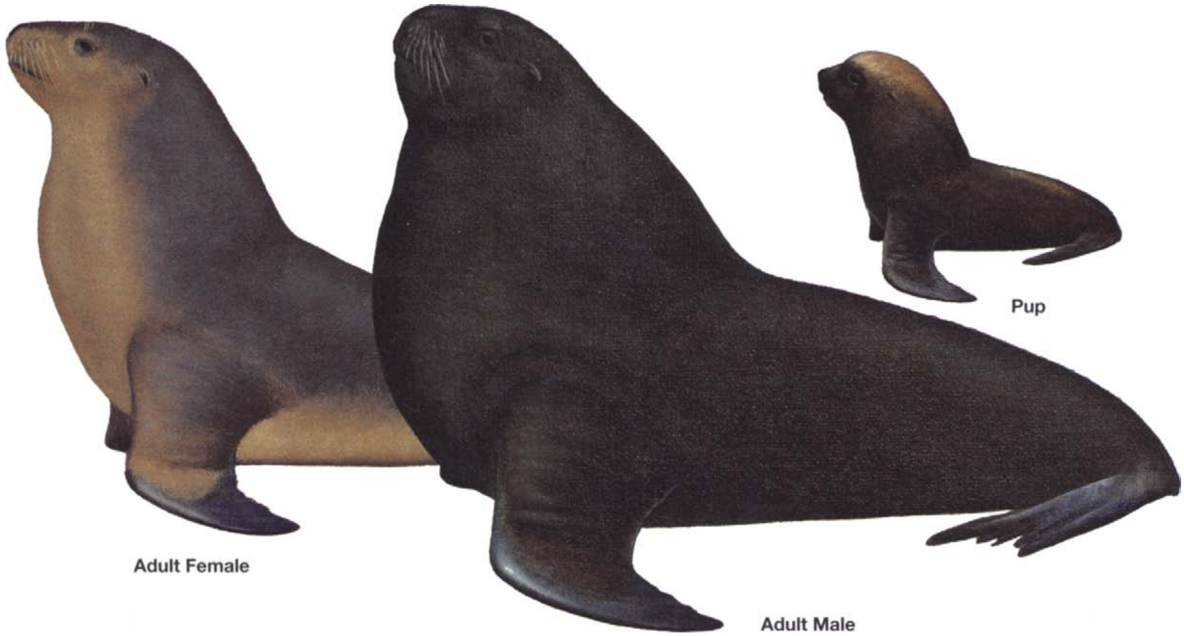
New Zealand Sea Lion—*Phocarctos hookeri* (Gray, 1844)



Recently-used synonyms *Neophoca hookeri.*

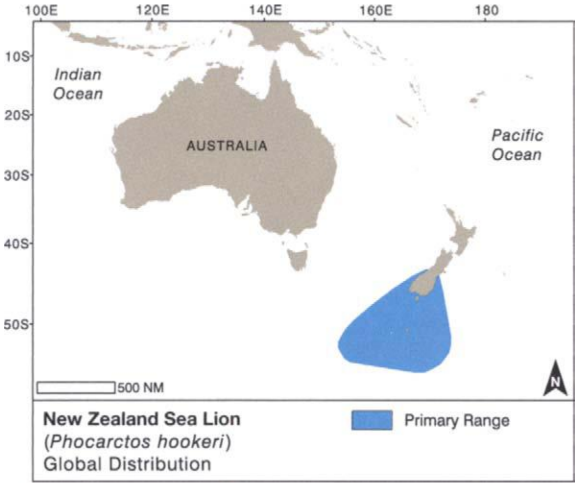
Common names En.– New Zealand or Hooker's sea lion; Sp.– *l'otarie de Nouvelle-Zélande*; Fr.–*lion de mer de Nouvelle-Zélande.*

Taxonomic information Order Carnivora, Family Otariidae.

Species characteristics New Zealand sea lions are large, heavy-bodied and sexually dimorphic. Adult males are 1.2–1.5 times longer and 3–4 times heavier than adult females. The head is large and blocky with a short, wide muzzle that is blunt to rounded on the end in both sexes. The ear pinnae are small and inconspicuous. The vibrissae are short to moderate in length, reaching as far back as the pinnae on some animals.

The head of adult males looks foreshortened as the neck widens rapidly behind the position of the ears, obscuring much of its length. Bulls have a strong sagittal crest well behind the eyes, creating a domed appearance to the crown and a downward slope to the end of the short muzzle with little or no discernable forehead. Depending on posture and viewing angle, the silhouette of the head in many males appears slightly convex from the crown to the end of the muzzle. Bulls have greatly enlarged, wide, thick, rounded necks, increasing in size from the nape and throat to the shoulders. The large neck is covered in a mane of longer coarser guard hairs. The hindquarters are not as enlarged as the neck, but are heavy and powerfully-built. Females and subadults have a flat-topped head with a slight downward slope to the end of the short muzzle. Their stocky body lacks the enlarged neck and longer guard hairs of the mane.

Adult male, female, and pup New Zealand sea lions showing the extent of sexual dimorphism. PHOTO: A. AUGE



Pups are born in a thick, long, lanugo and are dark brown with a lighter crown, nape, and mystacial area, and have a pale stripe on the top of the muzzle, originating on the crown. Female pups are lighter than male pups. Pups begin to molt their birth coat at 2 months and at the end of the molt look like females. Adult females and juveniles of both sexes are buff to creamy or silvery gray above and light tan to pale yellow below. The diffuse demarcation between light and dark is high on the neck usually rising over the insertion of the foreflippers, and is lower on the sides of the abdomen. There is considerable but subtle variation in the coloration of the head and muzzle. The light coloration often extends above the ears, above the eyes, and down the sides of the muzzle. The crown and top of the muzzle are usually darker. The area around the insertion of the foreflippers and the tops of the flippers is often darker grayish to light brown. In some adult females there may be little discernible contrast between coloration above and below, especially when they are faded just before they molt.

Males darken as they mature, and pass through a sequence of color phases before becoming fully dark blackish-brown as adults. From age 1–3 years they look like females, although some are light rusty brown. At 4 years they become darker brown above, but remain pale yellow to light brown, below. They also begin to show increased bulk in the neck and shoulders and signs of a mane at this age. At 5–6 years their coloration and body shape is that of the adult male and they are blackish-brown over the entire body. Physical maturity is reached in the 7^{th} year. Some older males have white hairs in the mane, giving them a subtle grizzled appearance. From age 2, New Zealand sea lions go through an annual molt that lasts approximately 2 months and can occur anytime between December and June. One-year-olds experience only a partial molt.

The foreflippers have a sparse short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface and the palms of both foreflippers are covered with a hairless black leathery skin. The first digit is the longest, widest and thickest, and curves posteriorly, giving the flipper a swept back look. Digits 2–4 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers. The hindflippers also have cartilaginous rods that extend the length of each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The first and fifth toes are longer than the three middle toes, and the first toe, or hallux, is longer and wider than the fifth toe. The hindflippers have short hair covering part of the proximal end of the flipper, and the rest of the dorsal surface, and the entire sole is covered in black leathery hairless skin.

Adult males are 2.3–2.7 m long and may weigh from 320–450 kg, although these values might be high in

A brown adult male New Zealand sea lion showing the enlarged neck, chest, and shoulders of bulls. PHOTO: A. AUGE

A black adult male New Zealand sea lion. Notice the thick, wide, and blunt-ended muzzle. PHOTO: L. MEYNIER

Pale-colored New Zealand sea lion bull. The huge neck and mane make the head look small. PHOTO: A. AUGE the light of recent information that males are probably shorter than previously reported. Adult females are 1.8–2 m long and weigh 90–165 kg. Newborns are approximately 70–100 cm long and weigh 7–8 kg.

The dental formula is I $^{3}/_{2}$, C $^{1}/_{1}$, PC $^{6}/_{5}$.

Recognizable geographic forms None.

Can be confused with Three fur seals: New Zealand, Antarctic, and subantarctic are known to occur in or near the present range of the New Zealand sea lion. New Zealand sea lions can be differentiated from all fur seals, based on a combination of features including coloration, fur characteristics, head and muzzle shape, short ear pinnae, and size and shape of the outer toes on the hindflippers.

Distribution The primary habitat of New Zealand sea lions is several subantarctic islands south of New Zealand, and their surrounding waters. The principal breeding colonies accounting for 95% of annual births are in the Auckland Islands, with smaller numbers breeding at Campbell Island and the Snares Islands. New Zealand sea lions regularly occur in small numbers at Stewart Island and on the southeast coast of the South Island of New Zealand, and there are occasional births. However, most of these animals are males ranging from 2–11 years old. Wandering New Zealand sea lions also reach Macquarie Island. Historically, New Zealand sea lions had a more extensive range that appears to have included most of New Zealand.

Ecology and behavior The breeding season for New Zealand sea lions begins in November when adult males return and establish themselves on territories through displays, vocalizing, and fighting. Adult females arrive in early December and give birth shortly after returning to the rookery. Males may have as many as 25 females within their territories. The bulls are frequently challenged by newly arriving males and neighbors, and turnover of males is a regular occurrence. Many territorial bulls depart in mid-January with the end of the pupping period.

The onset of estrus occurs 7–10 days after a female gives birth. Prior to this she continuously attends her newborn pup. Following mating, females begin a phase of short foraging trips, each trip followed by a period of attending their pups, typical of many otariids. Foraging trips average 1.7 days and are followed by 1.2 days of pup attendance and feeding ashore. Also typical of many otariids, pups gather into groups known as créches while their mothers are feeding. Females and pups recognize each other through vocalizations and scent, and a small percentage of females will allow additional pups to nurse along with their own pup, which is unusual behavior for a pinniped. Pups are weaned at approximately 10 months.

Two adult female New Zealand sea lions. Females of this species are only lightly countershaded. PHOTO: L. MEYNIER

New Zealand sea lion females with older molted pups (two with plastic tags on their foreflippers), and one unmolted pup still in its lanugo coat. PHOTO: F RIET

Adult males are a significant source of mortality to pups, occasionally killing them outright, including incidents of cannibalism. Pups are also trampled and killed by adult males challenging other males during territorial disputes.

New Zealand sea lions do not appear to be migratory, although they disperse widely over their range during the non-breeding season. Some animals can be found at major rookeries and haulouts year-round. At sea they are active divers that forage on benthic prey. Mean dives are to 123 m and mean duration is 3.9 minutes. Maximum dive depths are over 500 m and dives have been recorded

New Zealand sea lions will sometimes move into shoreline forests as these yearlings have done. PHOTO: A. AUGE

to last as long as 11.3 minutes. Predators include sharks, leopard seals and presumably killer whales.

Feeding and prey New Zealand sea lions take a wide variety of vertebrate and invertebrate prey. Frequently-taken species include: opalfish, octopus, munida, hoki, oblique-banded rattail fish, salps, squid and crustaceans. Prey is taken in both benthic and pelagic habitats. Antarctic, Subantarctic, and New Zealand fur seals are taken as prey by adult male sea lions. Penguins and sea lion pups are also occasionally taken.

Threats and status New Zealand sea lions once were more abundant, with a more extensive range that included the North and South islands of New Zealand. The Maori people of New Zealand traditionally hunted sea lions, as did Europeans upon their arrival. Commercial sealing in the early 19th century decimated the population in the Auckland Islands, but sealing continued until the mid-20th century, when it was halted. The population has yet to fully recover from this period of overexploitation.

At the present time, New Zealand sea lions have a highly restricted distribution, a small population that numbers approximately 12,500 animals, and most of their breeding is concentrated in one island group. This combination makes them vulnerable to disease outbreaks, environmental change, and human activities.

Commercial fisheries around the main sea lion population in the Auckland Islands have resulted in sea lion mortalities through drowning. The New Zealand government has responded with a variety of management actions that are aimed at documenting, reducing, and limiting the annual incidental take of sea lions. Tourism at mainland sites and remote subantarctic islands can cause disruption to haul-out patterns and breeding activities, and is regulated.

An epizootic outbreak in the Auckland Islands in 1998 led to more than 50% pup mortality, and also claimed the lives of many animals from other age classes. The source of the suspected bacterial agent and cause of the outbreak and subsequent mortality are unknown, but may have been triggered by El Niño-related food shortages stressing the population.

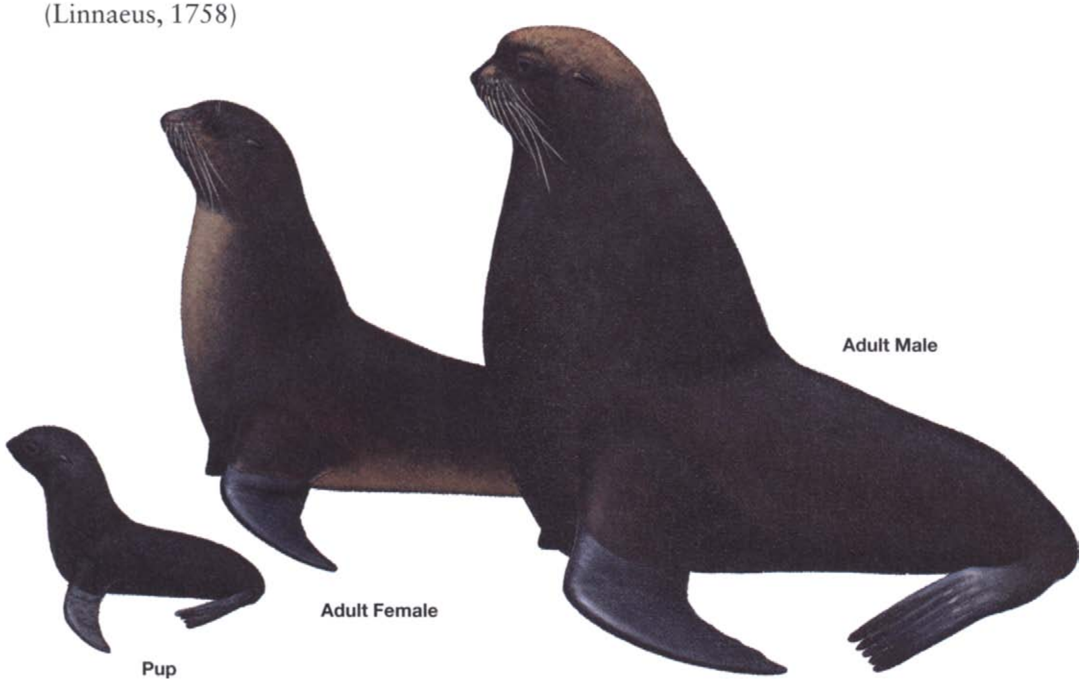
A group of New Zealand sea lion pups. The pale bridge of the nose, top of the head, and nape, are markings unique to pups of this species. PHOTO: K. WESTERSKOV/NATURAL IMAGES

IUCN status Vulnerable.

References Cawthorn 1985; Costa and Gales 2000; Gales and Fletcher 1999; Gales 2002; Walker and Ling 1981.

Northern Fur Seal—*Callorhinus ursinus*

(Linnaeus, 1758)



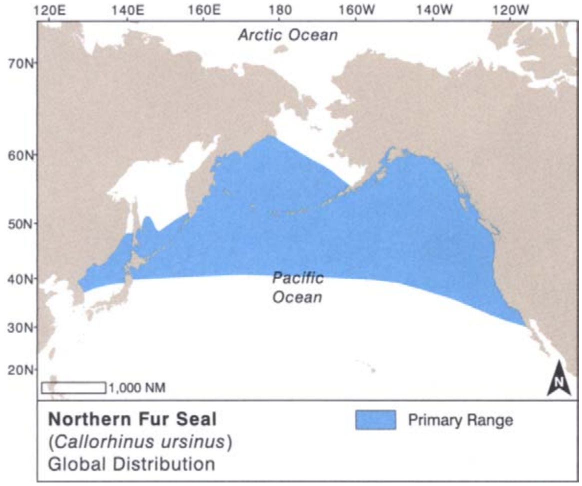
Recently-used synonyms None.

Common names En.–northern fur seal; Sp.–*lobo fino del norte*; Fr.–*otarie des Pribilofs*.

Taxonomic information Order Carnivora, Family Otariidae.

Species characteristics Northern fur seals show extreme sexual dimorphism. Adult males are 30–40% longer and more than 4.5 times heavier than adult females. The head appears foreshortened in both sexes because of the very short down-curved muzzle and small nose, which extends slightly beyond the mouth in females and more so in males. The pelage is thick and luxuriant, with a dense, cream-colored underfur. The underfur is obscured by the longer guard hairs, although it is partially-visible when the animals are wet. Features of both fore- and hindflippers are unique and diagnostic of the species. Fur is absent on the top of the foreflippers and there is an abrupt "clean shaven line" across the wrist where the fur ends. The hindflippers are proportionately the longest of any otariid because of extremely long, cartilaginous extensions on all of the toes. There are small claws on digits 2–4, well back from the flap-like end of each digit. The ear pinnae are long and conspicuous (naked of dark fur at the tips) in older animals. The mystacial vibrissae can be very long, and regularly extend beyond the ears. Adults older than 6–7 years have all pale vibrissae, juveniles and subadults have a

A bull with a large group of females and pups. Adult female color variation in this photograph is primarily due to staining from time spent on the rookery. Pribilof Islands, Alaska. PHOTO: C. FOWLER/NMFS



An unmolted northern fur seal pup. The hindflippers will enlarge and increase in relative size as the animals ages. San Miguel Island, California. PHOTO: M. WEBBER

mixture of pale and black vibrissae, including some that have dark bases and pale ends, and pups and yearlings have all-black vibrissae. The eyes are proportionately large and conspicuous, especially on females, subadults, and juveniles.

Adult males are stocky in build, and have an enlarged neck that is thick and wide. A mane of coarse longer guard hairs extends from the top of the head to the shoulders and covers the nape, neck, chest, and upper back. While the skull of adult males is large and robust for their overall size, the head appears short because of the combination of a short muzzle, and the back of the head behind the ear pinnae being obscured by the enlarged neck. Adult males have an abrupt forehead formed by the elevation of the crown from development of the sagittal crest, and thicker fur of the mane on the top of the head. The canine teeth are much longer and have a diameter greater in adult males than in adult females, and this relationship holds to a lesser extent for all age classes.

Adult females, subadults and juveniles, are moderate in build. It is difficult to distinguish the sexes until about 4 or 5 years old. The body is modest in size and the neck, chest, and shoulders are sized in proportion with the torso. Adult females and subadults have more complex and variable coloration than adult males. They are dark silver-gray to charcoal above. The flanks, chest, sides, and underside of the neck (often forming a chevron pattern in this area) are cream to tan with rusty tones. There are variable cream to rust-colored areas on the sides and top of the muzzle, chin, and as a "brush stroke" running backwards under the eye. In contrast, adult males are medium gray to black, or reddish to dark brown all over. The mane can have variable amounts of silver-gray or yellowish tinting on the guard hairs. Pups are blackish-brown at birth, with variable oval areas of buff on the sides, in the axillary area, and on the chin and sides of the muzzle. After 3–4 months, pups molt to the color of adult females and subadults.

Males can be as large as 2.1 m and 270 kg. Females can be up to 1.5 m and around 50 kg. Newborns weigh 5.4–6 kg, and are 60–65 cm long.

The dental formula is I $^{3}/_{2}$, C $^{1}/_{1}$, PC $^{6}/_{5}$.

Adult male, female, and pup northern fur seals. The fur stops abruptly at the wrist line of the foreflipper in this species. Also notice the very short, pointed muzzle and the enlarged neck, chest, and shoulders, of the male. PHOTO: C. FOWLER/NMFS

Recognizable geographic forms

None.

Can be confused with Northern fur seals can be confused with two other otariid species in their range: the Guadalupe fur seal, and California sea lion. Coloration of Guadalupe and northern fur seals is similar. Guadalupe fur seals have fur on the dorsum of the foreflipper beyond the wrist, proportionately shorter hindflippers, and a long tapering muzzle with a bulbous nose that makes the muzzle seem slightly-upturned on the end.

At sea, Guadalupe fur seals will rest in a posture characteristic of fur seals of the genus *Arctocephalus* with the head down and both hindflippers held in the air and apart forming a Y-shape. Northern fur seals will use this position infrequently. Both North Pacific fur seal species routinely rest in a "jug handle" position with the palm of one foreflipper draped over the soles of the hindflippers, which are rotated forward to meet the foreflipper.

Northern fur seals can be readily separated from California sea lions based on differences in thickness, length, and coloration of pelage, the lack of fur on the top of the foreflippers beyond the wrist, much longer hindflippers with longer digits, very short pointed muzzle, and longer prominent ear pinnae.

Dark adult male California sea lions have a conspicuous sagittal crest and lack a mane. California sea lion bulls lack the light tipped hairs on their neck. The loud repetitive bark of male California sea lions is distinctive and different from all northern fur seal vocalizations.

Distribution Northern fur seals are a widely-distributed pelagic species in the waters of the North Pacific Ocean and the adjacent Bering Sea, Sea of Okhotsk, and Sea of Japan. They range from Northern Baja California, Mexico, north and offshore across the North Pacific to northern Honshu, Japan. The southern limit of their pelagic distribution across the North Pacific is approximately 35° N. Vagrants reach the Yellow Sea in the west and eastern Beaufort Sea in the Arctic. The vast majority of the population breeds on the Pribilof Islands, with substantial numbers on the Commander Islands as well. Still other sites are used, including San Miguel Island in California, Bogoslof Island in the Bering Sea, and Robben Island off Sakhalin Island in Russia. Numerous other sites were formerly occupied and may still be visited.

Ecology and behavior This is a highly polygynous species. Males arrive at the rookeries up to one month before females and vocalize, display, and fight to establish and maintain territories. Breeding on the Pribilof Islands occurs from mid-June through August, with a peak in early July (the median date in southern California is approximately 2 weeks earlier than at the Pribilofs). Northern fur seals become sexually mature at 3–5 years old, at which time females usually produce one pup a year for most of the rest of their lives. Males do not become physically

mature, and large enough to compete for a territory that will be used by females, until they are 8–9.

Northern fur seals usually give birth a day after arrival at the rookery. Mean time from birth to estrus is 5.3 days, and 8.3 days for departure on the first feeding trip. Females breeding at the Pribilof Islands are relatively far from the foraging areas at the edge of the continental shelf. As a result, they consistently make longer foraging trips than most other female otariids, with a mean trip length of 6.9 days. Once foraging begins the mean depth of dives is 68 m and duration is 2.2 minutes with maximum depth recorded of 207 m, and duration of 7.6 minutes. Pups are visited 8–12 times and attended for a mean of 2.1 days before being abruptly weaned at 4 months old.

Northern fur seals are one of the most pelagic pinnipeds. Adults are at sea most of the year, only coming ashore for the breeding season for 35 and 45 days (on average) for adult females and males, respectively. They do not haul-out between breeding seasons, and once weaned, juveniles go to sea and do not haul-out until they return, usually to the island of their birth, 2–3 years later. Many animals, especially juveniles, migrate from the Bering Sea south into the North Pacific to spend the winter feeding.

At sea, northern fur seals are most likely to be encountered alone or in pairs, with groups of 3 or more being uncommon. They forage relatively far from shore, over the edge of the continental shelf and slope. Diving is very active at dawn and dusk, otherwise northern fur seals spend quite a bit of time rafting at the surface, either asleep or grooming. They employ a wide variety of resting postures, including raising one or more flippers into the air, and draping one of their foreflippers over both of the hindflippers to form a posture known as the "jug handle" position. Predators include killer whales, sharks, and Steller sea lions.

Feeding and prey The diet varies by location and season, and includes many varieties of epipelagic and vertically-migrating mesopelagic schooling and non-schooling fish and squid. Prey species of importance in

An unusually proportioned male with a collar of marine debris embedded in the skin. All white whiskers indicate an older animal, yet the lack of neck development suggest he may be a cryptorchid. Lovushki Island, Russia. PHOTO: J. WAITE

Adult male Northern ful seal with mange that has caused the loss of guard hairs on the crown and neck, revealing the cream-colored underfur. Patches of fur lost from mange can occur anywhere on the body. PHOTO: J. WAITE the waters off California and Washington include anchovy, hake, saury, several species of squid and rockfish, and salmon. In Alaskan waters, walleye pollock, capelin, sand lance, herring, Atka mackerel, and several species of squid are important prey.

Threats and status Northern fur seals have a long and complex history of commercial harvesting, which began when the main breeding colonies were discovered in the late 18th century, and that lasted until 1984. Numerous international treaties and agreements have been enacted to manage this species. There were many intervals of decline and recovery over this long period. It is estimated that the population numbered up to 2.5 million animals in the 1950s. They may even have been more numerous farther in the past when there were more rookeries before the onset of exploitation by Europeans and Americans. The current population is estimated at 1.1 million and is declining.

Entanglements in commercial fisheries gear, including derelict and discarded gear and marine debris, have caused significant annual mortality in the past. This mortality was highest during the period of active high seas driftnet fishing in the North Pacific in the 1980s. Entanglement in debris is ongoing and affects juveniles and subadults more than adults. Northern fur seals compete for walleye pollock with one of the largest commercial fisheries in the world. Mortality from interactions with numerous fisheries and entanglement in debris, large annual harvests of prey species in commercial fisheries, long-term ecosystem change in the North Pacific, and possible changes in the foraging patterns of a key predator (the killer whale), may all be working synergistically to cause the current population decline.

IUCN status Vulnerable.

The same hybrid Northern fur seal X California sea lion. It has long ear pinnae as found on a northern fur seal. The muzzle is long and somewhat blunt on the end as on a California sea lion. The eyes are proportionately large and bulging for either species. PHOTO: R. J. WILSON/THE MARINE MAMMAL CENTER

A different view of the same hybrid showing the relatively long hindflippers as found on northern fur seals and fur on the dorsum of the foreflipper past the wrist as found on California sea lions. Like northern fur seals, this animal has a pelt of long guard hairs with a cream-colored underfur. PHOTO: R. J. WILSON/THE MARINE MAMMAL CENTER

Note on Hybrid Southern Hemisphere Fur Seals Genus Arctocephalus

Hybrids of a number of species of otariids are known, and genetic, behavioral, and morphological characteristics have been published in the scientific literature. Only one wild hybrid phocid has been reported. It resulted from a harp seal and hooded seal mating. In general, most otariid hybrids have features that are a blend of the basic characteristics of the parent species.

Several otariid species hybridize, including: northern fur seal X California sea lion (see northern fur seal account), South American X California sea lions, and Guadalupe X northern fur seals. However, the most frequently encountered hybrids are from crosses of Southern Hemisphere fur seals, genus *Arctocephalus*, especially where several species occur at the same breeding islands, such as at Macquarie and Marion Islands, and the Juan Fernandez Islands. Examples of the known hybrid crosses are shown. The mating patterns, reproductive success, and behavior of hybrids are poorly known. Recent studies have shown that hybrid males may have reduced fertility and that females may depart their territories to bread with other males.

However, vocalizations of southern fur seals are well known, and hybrids are often first recognized or identified based on their unusual vocalizations. Vocalizations of pinnipeds, and particularly hybrid fur seals, are not covered in depth in this guide, and the reader can consult a number of the references provided for more information.

Special thanks are due to the researchers who made these previously-unpublished photographs, notes, and observations available for this brief overview.

Photograph notes and credits

A) Hybrid subantarctic X Antarctic fur seal bull with a mixture of features. The crest of longer guard hairs on the forehead and pale colored muzzle and lower jaw, and dark ear pinnae, are characteristic of subantarctic fur seal bulls. The dark neck and chest are characteristics of an Antarctic fur seal bull. The pale-color of the muzzle reaches to the eyes and partially around them, which is an intermediate pattern between subantarctic and Antarctic fur seals. The overall color is also intermediate between the two species, being paler than the subantarctic fur seal, and darker than the Antarctic fur seal. Marion Island, Prince Edward Islands. PHOTO: P. J. N. DE BRUYN

B) A hybrid subadult male subantarctic X Antarctic fur seal bull. The pelage is not as dark as on a subantarctic fur seal, and lacks the light-colored fur in the chest and face. The ears are pale, as is the case for Antarctic fur seals. The muzzle is short and sharply pointed as in the subantarctic fur seal. The identification of this animal as a hybrid was supported by his vocalizations. Marion Island, Prince Edward Islands. PHOTO: P. J. N. DE BRUYN

C) A hybrid subantarctic X Antarctic fur seal adult female and pup, with a subantarctic fur seal female in the background. This hybrid is presumed to be a first generation cross because of the small numbers of Antarctic fur seals breeding at Marion Island. She has a fairly even mix of features from both species. Her lighter chest suggests subantarctic fur seal, while her darker upper neck and face, paler back, and large muzzle and head, suggest Antarctic fur seal. Her darker pup looks more like a subantarctic than Antarctic fur seal (the unlikely possibility that this pup was adopted cannot be ruled out). Marion Island, Prince Edward Islands. PHOTO: P. J. N. DE BRUYN.

D) Subantarctic fur seal pup (right) and hybrid subantarctic-Antarctic fur seal pup (left). Subantarctic and Antarctic fur seal pups are difficult to separate in the field without experience. Additionally, pups of each species change slightly as they age and approach their first molt. During this time, their features can change to be like those of known hybrids. The identification of this hybrid pup was confirmed based on vocalizations. It has features similar to those found on Antarctic fur seal pups including an extensive area of pale color on the muzzle, and gray in the face. The muzzle is too large and wide, and the overall pelage color is not black enough for this to be a subantarctic fur seal pup. Marion Island, Prince Edward Islands. PHOTO: P. J. N. DE BRUYN

E) Adult male Antarctic X New Zealand fur seal hybrid confirmed by mtDNA analysis, as well as by vocalizations. His overall dark gray color is darker than that found in either Antarctic or New Zealand fur seals. His pale muzzle and face are similar to New Zealand fur seals. The muzzle is of medium length, without an upturned end, which is more like an Antarctic fur seal. The ear pinnae are pale and lighter than the surrounding fur, like on Antarctic fur seals. This bull has a slight crest of fur on his forehead, which is a feature occasionally seen on New Zealand fur seals and not found on Antarctic fur seals. Note the yellow tag on the foreflipper. Macquarie Island. PHOTO: B. PAGE.

F) Another Antarctic X New Zealand fur seal hybrid bull confirmed by mtDNA analysis and vocalizations. This animal has the same muzzle shape and facial color and a slight crest of fur on his forehead as on the animal in photo E, but his ear pinnae are dark. Macquarie Island. PHOTO: B. PAGE.

G) An adult female Antarctic X New Zealand fur seal hybrid. The identity of this female was confirmed by mtDNA analysis and vocalizations. The gray palage and pale ear pinnae are like that in Antarctic fur seals. The slightly up-turned muzzle is typical of New Zealand fur seals. Macquarie Island. PHOTO: B. PAGE.

H) A probable adult male subantarctic X Juan Fernandez fur seal hybrid. This animal has a crest of fur on his forehead and large tear-drop shaped eyes like a subantarctic fur seal. The body color is not as dark as a subantarctic fur seal, and not at all like the dark brown to blackish-brown of a Juan Fernandez bull. The lighter reddish-brown fur on the tops of the flippers is like the color found on Juan Fernandez fur seal flippers. The pale muzzle and face color is similar to the coloration found on other hybrid males. The hind- and possibly foreflippers appear small, and are proportionately more like the flippers found on subantarctic fur seals. Juan Fernandez Islands. PHOTO: J. FRANCIS.

Guadalupe Fur Seal—*Arctocephalus townsendi*

Merriam, 1897

Recently-used synonyms *Arctocephalus philippii townsendi*, *Arctophoca townsendi*.

Common names En.–Guadalupe fur seal; Sp.–*lobo fino de Guadalupe*; Fr.–*otarie de Guadalupe*.

Taxonomic information Order Carnivora, Family Otariidae.

Species characteristics Guadalupe fur seals are sexually dimorphic, with males 1.5–2 times longer and approximately 3–4 times heavier than adult females.

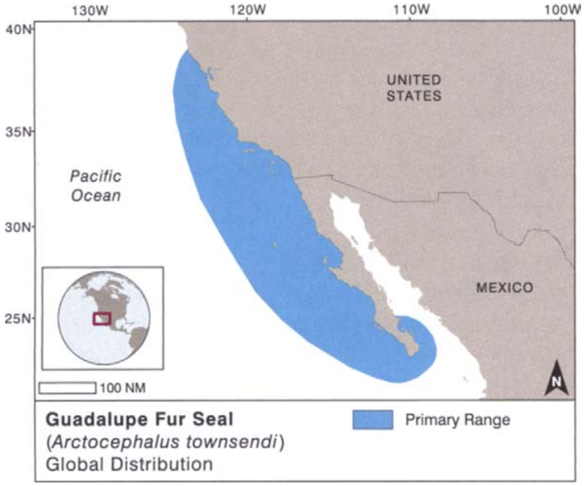
An adult female Guadalupe fur seal in prime condition on Guadalupe Island. PHOTO: C. ALLAN MORGAN

They have thick pelage, with dense, cream-colored underfur. Adults have moderate length pale vibrissae and long prominent ear pinnae.

Adult males have a slightly rounded crown with the apex above the ear pinnae. Longer, more erect, mane guard hairs on the head accentuate the minor elevation of the crown, and contribute to a slight sloping forehead, where the longer fur ends at the shorter, more swept-back, fur of the muzzle. The muzzle is long, narrow, straight, and tapers in width and thickness to a pointed end. The naked black skin area of the nose, the rhinarium, is bulbous and the nares are angled downward. A mane of longer and coarser guard hairs extends from the crown and nape to the shoulders on the back, and includes the sides and front of the neck. The neck, chest, and shoulders are greatly enlarged. The abdomen is thin in comparison, and tapers to the insertion of the hindflippers. The canine teeth of adult males are larger and thicker than those of females.

Adult females, subadults, and juveniles also have a long muzzle with downward-pointing nares, but the nose is not enlarged. The crown is flatter and the mane absent, and as a result they have a flat-topped head. The ear pinnae are long and stand-out from the head enough to make them conspicuous.

The foreflippers have a dark, sparse, short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface and the palms of both foreflippers are covered with a hairless



black leathery skin. The first digit is the longest, widest and thickest, and curves posteriorly, giving the flipper a swept-back look. Digits 2–5 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers.

The hindflippers have dark, short, sparse hair covering part of the proximal end of the flipper, and the rest of the dorsal surface, and the entire sole is covered in black leathery hairless skin. The hindflippers are long and each digit has a cartilaginous rod that adds a flap-like extension to each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The claws of digits 1 and 5 are vestigial like the claws on the foreflippers, and may or may not emerge from small openings set back from the end of the flaps. All of the flaps at the end of the flipper are of relatively equal length. The first toe or hallux and the fifth toe are somewhat wider than toes 2–4.

Coloration of adult males is dark grayish-brown to grayish-black. The longer guard hairs of the mane are often light tipped with off-white to buff tones on the crown, nape, and upper neck, creating a grizzled or gingered appearance. Adult females, subadults, and juveniles are dark brown to grayish-black above and paler in variable patterns below, especially on the chest and underside of the neck, which can be tan to creamy-gray. Both sexes have a variable amount of buff to reddish-brown color on the muzzle that often extends into the face and above the eyes. Pups are born in a black coat that lightens to a dark brown, and they probably molt to a juvenile coat several months after birth, but this has not been documented.

Adult male vocalizations include a single sharp, almost explosive, "puff" used in conflicts with other males; a bark that is repetitive, high-pitched with nasal qualities that are sometimes referred to as "whickery;" and a guttural growl. Females growl with their mouths open when angered or threatening another animal, and use a low-pitched, prolonged "bawl" for a pup attraction call. Young animals have a high-pitched roar; a cough which is less sharp and explosive than the puff of adult males, used when they threaten each other; and a bark used during play.

Adult males may reach 2 m in length. Two adult males measured approximately 1.8 and 1.9 m. The 1.9 m male was estimated to weigh 160–170 kg. Adult females average 1.2 m and reach approximately 1.4 m, and weigh 40–50 kg. Pups are estimated to be 50–60 cm long.

The dental formula is I $^{3}/2$, C $^{1}/1$, PC $^{6}/5$.

Recognizable geographic forms None.

Can be confused with Two other otariids, the California sea lion and northern fur seal can be confused with the Guadalupe fur seal.

Coloration of Guadalupe and northern fur seals is similar. Guadalupe fur seals have fur on the dorsum of the foreflipper beyond the wrist, proportionately shorter hindflippers, and a longer tapering muzzle that appears slightly upturned on the end in males and flat in females.

At sea, both species actively groom while at the surface. Guadalupe fur seals will rest in a posture characteristic of fur seals of the genus *Arctocephalus* with the head down and both hindflippers held in the air and apart forming a Y-shape. Both species sleep in a "jug handle" position with the palm of one foreflipper draped over the soles of the hindflippers which are rotated forward to meet the foreflipper.

Guadalupe fur seals can be readily separated from California sea lions based on differences in coloration, pelage length and thickness, length and pointedness of the muzzle, relative size and prominence of the ear pinnae, overall size, hindflipper length, and shape of toes. In California sea lions, the muzzle tapers to a blunt end, and the first toe or hallux is larger and longer than all of the other toes. Adult female, subadult, and juvenile California sea lions are tan to pale brown and much lighter in coloration than Guadalupe fur seals. Adult and subadult male California sea lions become dark brown and are similar in color to Guadalupe fur seal bulls. However, dark male sea lions have a sagittal crest in contrast to the head of Guadalupe fur seal bulls that is slightly domed and lacks a conspicuous sagittal crest. California sea lion bulls lack the light hairs in their much shorter mane. The loud repetitive bark of male California sea lions is distinctive and different from all Guadalupe fur seal vocalizations.

Distribution The distribution of Guadalupe fur seals has been expanding in recent years. The majority of the population is centered on Guadalupe Island, off the west coast of central Baja California, where nearly all pups are born. However, In 1997 a small colony with 9 pups was discovered at the San Benitos Islands, near the Baja California coast, at the site of a former rookery. This colony continues to grow. Also in 1997, a pup was born on San Miguel Island in the Channel Islands. Guadalupe fur seals have been reported on other Southern California islands, and the Farallon Islands off Northern California with increasing regularity since the 1980s. They have been sighted in the Sea of Cortez, and as far south as Zihuatanejo, Mexico. Their distribution at sea is poorly known.

Ecology and behavior Guadalupe fur seals are polygynous, with males establishing territories that are occupied by an average of six females. Pups are born from mid-June to August with a median birth date of 21 June. Male tenure on territories lasts at least 31 days. Males defend territories with vocalizations, displays and fighting with neighboring bulls. Once territories are established, fighting between males is rare. Females select male territories that provide cover and shade from the sun for pupping, and territories with females are fronted by water including tidal pools. Many animals breed in small caves, grottos, and cliff and boulder areas on the rugged east coast of volcanic Guadalupe Island. Adult

females enter the water daily, presumably for cooling, while otherwise ashore attending their pups.

Females returning to the rookery for the first time usually arrive at night or early in the morning. Estrus occurs 5–10 days after a female gives birth, and females can leave for their first foraging trip right after mating, or stay on the colony for another few days before departing. Foraging and attendance patterns are not well-known. Pups are weaned at 9–11 months, and females with pups can be seen on or around the island throughout the winter and into the spring.

Behavior at sea is not well known, but they appear to be mostly solitary. Observations of animals in captivity suggest that they spend considerable time grooming while floating at the surface. They will groom and rest at the surface in the characteristic "southern fur seal," head-down posture. They also raft with one or more flippers extended out of the water, and will use the "jug-handle" posture. When traveling rapidly, they have been observed to porpoise. Killer whales and sharks are undoubtedly predators, although there is no evidence in the literature to support this assumption. A wound on a male from a cookie-cutter shark bite has been reported.

A Guadalupe fur seal rafting in a "jug-handle" position. Notice the long narrow tapering muzzle and prominent ear pinnae. PHOTO: R. L. PITMAN

Feeding and prey Prey preference and foraging activity are poorly known. Stomach contents retrieved from stranded animals included a variety of squid, bony fishes, and crustaceans, including vertically-migrating species.

Threats and status Guadalupe fur seals have a long and mostly unfortunate history of association with humans. Hunted to the brink of extinction by the late 19th century, they were not reported again until 1926. Following this "rediscovery" all animals that could be found were taken and once again the species was thought to be extinct. Guadalupe fur seals were suspected to have survived based on scattered, unconfirmed reports in the 1930s, and were dramatically rediscovered again with the sighting of a bull on San Nicholas Island in Southern California in 1949. An expedition to Guadalupe Island in 1954 confirmed the survival of the species. Since the 1950s, the species has recovered from an estimated population of 200–500 animals to approximately 7,400 in 1993 and is increasing by 13.7% annually.

Although Guadalupe fur seal numbers are increasing, the species is still at risk because the total population is small and nearly all pups are born on one island. Guadalupe Island is relatively close to, and down current from, large human population centers with extensive oil tanker traffic. The species also shares all of its range with California sea lions, which have suffered from viral disease outbreaks in the past, and because of their coastal nature, they could be a vector for diseases from terrestrial sources. No conflicts with commercial fisheries are known to exist at the present time, although gillnet and set-net fisheries may take small numbers, as could entanglement in marine debris.

IUCN status Vulnerable.

Juan Fernandez Fur Seal—*Arctocephalus philippii*

(Peters, 1866)

Recently-used synonyms *Arctocephalus philippii philippii, Arctophoca philippii.*

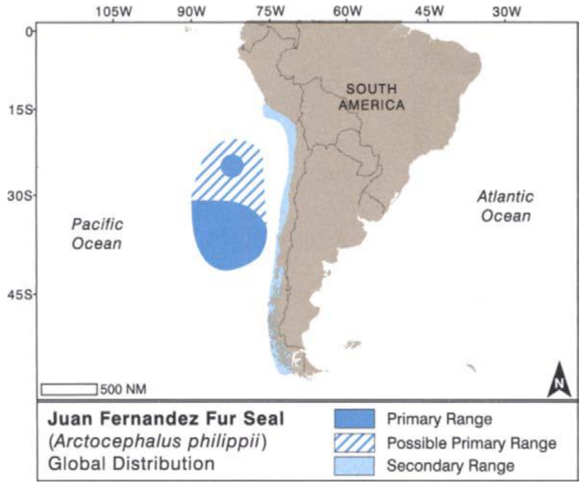
Common names En.–Juan Fernandez fur seal; Sp.–*lobo fino de Juan Fernandez*; Fr.–*otarie de Juan Fernandez*.

Taxonomic information Order Carnivora, Family Otariidae.

An aggressive interaction between two Juan Fernandez fur seal bulls in a rookery.
PHOTO: L. OSMAN

Species characteristics Juan Fernandez fur seals are sexually dimorphic, with males about 1.4 times longer and approximately 3 times heavier than adult females. Juan Fernandez fur seals have thick pelage with dense underfur. Adults have moderate length pale vibrissae and long prominent ear pinnae.

Adult males have a rounded crown with the apex above the ear pinnae. There is a slight rounded forehead. The muzzle is long, straight, somewhat flattened on top, and tapers in width and thickness to the fleshy nose on the end. The black, naked skin of the nose, or rhinarium, is large and somewhat bulbous and the nares orient downward. The mane extends from the shoulders to the crown, and the long erect guard hairs on the head accentuate the crown and forehead. This is especially noticeable where the longer fur of the crown meets the shorter, more swept-back, fur of the muzzle between the eyes. From the crown, the long coarse guard hairs of the mane cover the nape and neck to the shoulders, and on the sides and undersides of the neck from throat to chest. The neck, chest, and shoulders to the foreflippers are enlarged with muscle and fat. The abdomen is smaller, and



tapers to the narrow pelvis. The canine teeth of adult males are larger and thicker than those of females.

Adult females, subadults, and juveniles also have a long tapering muzzle, with nares angled slightly downward. However, because the rhinarium is not enlarged, the muzzle is more pointed. The crown is slightly domed, giving the head a rounded look in profile. The ear pinnae are long and stand out from the head enough to make them conspicuous.

The foreflippers have a dark, sparse, short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface and the palms of both foreflippers are covered with a hairless black leathery skin. The first digit is the longest, widest and thickest, and curves posteriorly, giving the flipper a swept-back look. Digits 2–5 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers.

The hindflippers have dark, short, sparse hair covering part of the proximal end of the flipper, and the rest of the dorsal surface, and the entire sole is covered in black leathery hairless skin. The hindflippers are long and each digit has a cartilaginous rod that adds a flap-like extension to each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The claws of digits 1 and 5 are vestigial, like the claws on the foreflippers, and may or may not emerge from small openings set back from the end of the flaps. All of the flaps at the end of the flipper are of similar length. The first toe or hallux and the fifth toe are somewhat wider than toes 2–4.

Adult female Juan Fernandez fur seal showing long slightly down-turned nose. PHOTO: M. GOEBEL/SWFSC

Pale streaks of underfur show through the wet guard hairs on this wet Juan Fernandez fur seal. PHOTO: M. GOEBEL/SWFSC

Adult males are dark grayish-brown to grayish-black. The longer guard hairs of the mane are tipped off-white to ginger on the crown, nape and, to a variable extent, on the sides and back of the neck, creating a grizzled cape. Adult females, subadults, and juveniles are dark brown to grayish-black above and paler in variable patterns below, especially on the chest and underside of the neck, which can be tan to creamy gray. Both sexes have a variable amount of lighter buff to reddish-brown color on the muzzle, which often extends into the face above the eyes. Pups are born with a black wooly coat.

Adult males are estimated to be 2 m long and weigh 140 kg. A series of lactating females, combined from several years, were an average of 1.42 m long and weighed an average of 48.1 kg. Newborn pups are approximately 65–68 cm and 6.2–6.9 kg

The dental formula is I $^3/_2$, C $^1/_1$, PC $^6/_5$.

Recognizable geographic forms None.

Can be confused with South American, Antarctic, and subantarctic fur seals, and South American sea lions have distributions that bring them near to the range of Juan Fernandez fur seals.

Adult male Juan Fernandez fur seals have a longer muzzle, distinctive bulbous rhinarium, and unique coloration of the crown, nape and upper neck that separate them from other southern hemisphere fur seals. Separating adult female, subadult, and juvenile southern fur seal species at a distance is usually difficult and often impossible without extensive experience with the species in question. In general, adult female Juan Fernandez fur seals are longer and heavier than female Antarctic, subantarctic, and South American fur seals, and have a proportionately longer muzzle with downward oriented nares, and a more rounded crown.

Adult subantarctic fur seals are uniquely cream-colored in the face and neck. They have a shorter muzzle and proportionately smaller flippers. Adult males have a crest of fur on the forehead.

Hybrid Juan Fernandez X subantarctic fur seals are known. The few photographs available show that they share characteristics of both species (see Note on Hybrid Southern Fur Seals Genus *Arctocephalus*, pages 340–341).

South American sea lions have large, blocky heads with a short muzzle that is blunt on the end, and smallish inconspicuous ear pinnae. They are also pale tan to light golden brown, with sleek fur that is not dense or shaggy, except in the case of the mane on the otherwise unmistakable adult males, and are heavy bodied.

Distribution The Juan Fernandez fur seal is only found ashore regularly in the Juan Fernandez Archipelago in the eastern South Pacific, west of Chile. The Archipelago includes the Juan Fernandez Island group, and the San Felix Islands, approximately 600 km to the north. Vagrant Juan Fernandez fur seals have been found on the west coast of South America from southern Peru to southern Chile. When ashore, these fur seals prefer rocky and volcanic shorelines with boulders, grottos, overhangs and caves.

Ecology and behavior The Juan Fernandez fur seal is a polygynous species. The breeding season lasts from mid-November to the end of January, and the colonies are essentially vacated by early September (based on the observations of sealers from the late 18th century), and no later than mid-October.

Males defend territories that are typically around 36 m^2 in size and that have an average of 4 females. Most adult females give birth within a few days of arriving at the rookery. Mean time from birth to departure on the first foraging trip is 11.3 days. Juan Fernandez fur seal females travel long distances to find adequate quantities of prey and, on average, have the longest foraging trips of any otariid. Although females can be gone for as little as 1 day, the mean is 12.3 days per foraging trip and the longest trip recorded lasted 25 days. Mean length of pup attendance is 5.3 days with a range of 0.3–15.8 days. Based on the onset of pupping and the observations of vacant colonies in early September, it has been calculated that pups are weaned in 7–10 months.

Juan Fernandez fur seals travel long distances to their foraging areas. The mean distance traveled away from the breeding colony is 653 km, and all tagged females traveled at least 550 km to forage. Most trips were southwest and west of the Juan Fernandez Islands, far offshore to deep oceanic areas. Despite this, the mean depth of dive of 12.3 m, and the mean duration of 51 seconds is shallow and short even for an otariid, and indicates surface feeding. The deepest dives are made to 90–100 m and the longest dives are just over 6 minutes. Nearly all foraging dives occur at night.

At sea, these fur seals can be quite animated as they groom at the surface. They also rest in, and assume a number of postures including: head down with hind-flippers elevated and swaying in the air, as is typical of many southern fur seals; asleep at the surface with both hindflippers tucked under a foreflipper in a "jug-handle" position, and with both foreflippers or all 4 flippers held in the air. Little is known about predators, but blue and great white sharks are suspected, as are killer whales, and possibly leopard seals that infrequently visit the islands.

Feeding and prey Juan Fernandez fur seals feed on vertically-migrating prey at night. Their diet is one of the least diverse of any otariid, and along with the long foraging trips made by lactating females, reflects the low productivity of their oceanic feeding areas. Diet varies between years and probably reflects abundance and availability of prey. Myctophids are the most important fishes in the diet and onychoteuthid squid are the most important cephalopods.

Threats and status Juan Fernandez fur seals were hunted to the brink of extinction by sealers trading pelts in China. Intensive sealing began in the late 18th century and ended in the late 19th century. It is likely that several million seals were killed during this period. Small numbers were seen in the early 20th century, but the species was thought to have gone extinct shortly thereafter. They were rediscovered in the middle of the 20th century and have since been making a slow comeback. Following the 1990–91 breeding season the total population was estimated to number 12,000 animals.

The limited size of the population and the fact that the species passed through a genetic bottleneck, make this species vulnerable to catastrophic events and stress from disease outbreaks, oil spills, environmental regime shift, disturbance, and fisheries conflicts. No fisheries conflicts have been identified to date. Individual seals have been seen with plastic bands around their necks since 1982, but the level of mortality from these entanglements is unknown.

IUCN status Vulnerable.

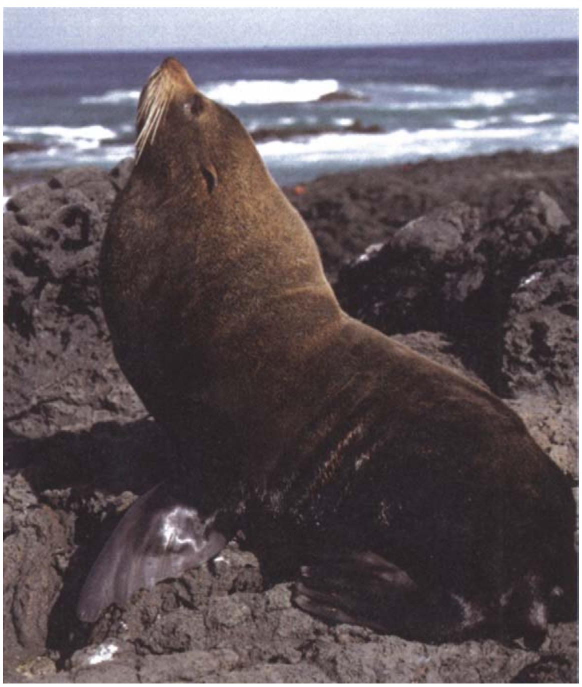
Galapagos Fur Seal—*Arctocephalus galapagoensis*

Heller, 1904

Recently-used synonyms *Arctocephalus australis galapagoensis*.

Common names En.–Galapagos fur seal; Sp.–*lobo fino de Galapagos*; Fr.–*otarie des Galapagos*.



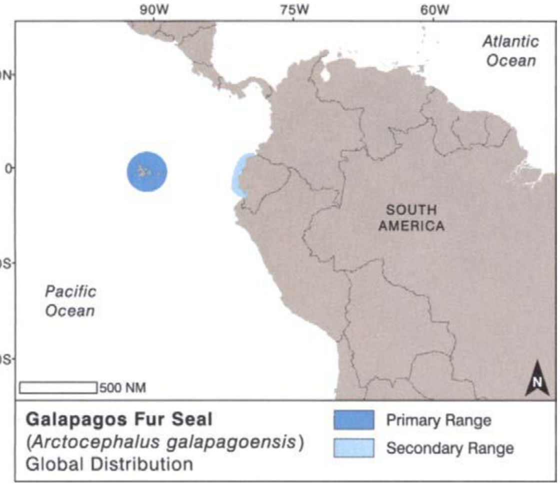
Adult male Galapagos fur seal. Note the enlarged chest and neck and pale-colored muzzle. PHOTO: G. MEYER

Taxonomic information Order Carnivora, Family Otariidae.

Species characteristics Galapagos fur seals are the smallest and the least sexually dimorphic otariid species. Adult males are 1.1–1.3 times longer and 2–2.3 times heavier than adult females. Galapagos fur seals are small and compact, and adult males are stocky in build. The muzzle is small: short, straight, and rapidly tapers in width and thickness to the small nose. Mystacial vibrissae are pale in adults. The eyes are proportionately large and the ear pinnae long and prominent.

Adult males are much thicker in the neck and shoulders than females, despite the fact that they lack a mane of longer guard hairs. Adult males do not have a conspicuous sagittal crest, but do have a slightly rounded crown and a short sloping forehead. The canine teeth of adult males are larger and thicker than those of females. Adult females and juveniles lack the thicker neck and shoulders of adult males, and have a flatter crown and barely noticeable forehead. Many adults have scars from shark attacks.

The foreflippers are short and wide and have a dark, sparse, short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface and the palms of both foreflippers are covered with a hairless black leathery skin. The first digit is the longest, widest and thickest, and curves posteriorly, giving the flipper a swept-back look. Digits 2–5 are



successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers.

The hindflippers have dark, short, sparse hair covering part of the proximal end of the flipper, and the rest of the dorsal surface, and the entire sole is covered in black leathery hairless skin. The hindflippers are long and each digit has a cartilaginous rod that adds a flap-like extension to each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The claws of digits 1 and 5 are vestigial, like the claws on the foreflippers, and may or may not emerge from small openings set back from the end of the flaps. All of the flaps at the end of the flipper are of relatively equal length. The first toe or hallux and the fifth toe are somewhat wider than toes 2–4.

Galapagos fur seals are medium to dark brown above and can have silvery gray to ginger grizzling. In both sexes, most of the muzzle is pale tan and in adult males, this color extends onto the face and forehead over the eyes, giving them a small pale mask. In adult females and subadults, the chest is pale grayish-tan, sometimes continuing to the back of the neck, and the belly is tan to reddish-brown. Bulls are dark above with lighter tones below. Pups are blackish-brown, sometimes with grayish to whitish margins around the mouth and nose. Pups molt this natal coat for one that resembles that of the adult female.

The few adult males measured to date have been 1.5–1.6 m and weighed 60–68 kg. Adult females have shown a range of curvilinear lengths of 1.1–1.3 m and an average weight of about 27.3 kg, with a maximum of 33 kg. Pups are 3–4 kg at birth, and an average of 11.3 kg when they are 12 months old.

The dental formula is I $^{3}/_{2}$, C $^{1}/_{1}$, PC $^{6}/_{5}$.

Recognizable geographic forms None.

Can be confused with Galapagos fur seals share their restricted range in the Galapagos Archipelago with the Galapagos sea lion. The fur seal can be readily distinguished from the sea lion by its small and compact stocky body, short pointed muzzle, long pale vibrissae (on adults), thick long fur and shaggy look when wet, long prominent ear pinnae, proportionately large eyes, and equal length toes on the hindflippers. The South American sea lion has also been recorded in the Galapagos from a single stranding. All of the features that separate Galapagos fur seals from Galapagos sea lions can be used to separate them from this even larger sea lion species. Galapagos fur seals are considerably smaller than South American fur seals, and can be separated from them based on overall size, and muzzle length and color.

Distribution Galapagos fur seals are found throughout the Archipelago. Lactating females make trips of relatively short duration, suggesting they do not get far from their colonies. Foraging by males and all animals outside the breeding season is unknown. They are present on nearly

Notice the short, sharply-pointed, pale-colored muzzle of this Galapagos fur seal. The all pale vibrissae suggest an adult, and the lack of an enlarged neck, chest and shoulders suggest a female. PHOTO: P. COLLA/OCEANLIGHT

all of the islands in the Archipelago, and prefer to haul-out near the shoreline on rocky coasts with large boulders and ledges that provide shade and the opportunity to rest in crevices and spaces between the rocks. Most of the colonies are also located in the western and northern parts of the Archipelago, close to productive upwelling areas offshore. Galapagos fur seals are also known to occasionally haul-out on the coast of mainland Ecuador.

Ecology and behavior The behavior of the Galapagos fur seal has been extensively studied. It has a fairly long pupping and breeding season, lasting from mid-August to mid-November. The peak of pupping shifts from year to year, but usually occurs sometime from the last week of September through the first week of October.

Galapagos fur seals mature at 3–5 years old. Males do not become physically mature, and large enough to compete for a territory that will be used by females until they are much older. Males hold territories that average 200 m^2, which is large compared to the average size of territories held by other otariid males, and especially so when considering Galapagos fur seal's small size.

Colonies are located close to foraging areas and the average length of female trips is the shortest for a fur seal with a mean trip length of 1.5 days. Most foraging occurs at night and the mean depth of foraging dives is 26 m and duration is less than 2 minutes with maximum depths recorded of 115 m, and duration of 5 minutes. Pups are visited around 300 times before weaning, with attendance periods of 0.5–1.3 days. Weaning occurs at 18–36 months, with most pups being weaned in their third year. Pups born prior to the weaning of an older sibling rarely survive, with most starving to death and a small percentage being killed by the older pup. Females will allow multiple pups to nurse, but this rarely lasts long enough for the youngest pup to get strong enough to survive. In exceptional cases offspring were allowed to nurse when they were 4–5 years old.

In the water near haulouts, Galapagos fur seals raft in postures typical of many of the southern fur seal species. There is no evidence for migration, and they do not seem to spend prolonged periods of time at sea. Predators at sea include sharks and killer whales. On land, feral dogs on Isabella Island decimated colonies on the southern end of the island killing both pups and adults.

Feeding and prey Food habits are poorly known. Galapagos fur seals consume a variety of small squids including *Onychoteuthis banksi*, and a number of species of ommastrephids. A variety of fish species are also taken including myctophids and bathylagids. They seem

to feed mostly at night, possibly exploiting vertically migrating species when they are at the surface.

Threats and status As with all the southern fur seals, there was a severe population decline as a result of 19th Century exploitation by sealers and whalers. The species was near extinction early in the 20th century, and has since recovered. A census conducted in 1988–89 estimated 40,000 animals. El Niño events dramatically raise pup mortality, may have an impact on the survival of other age classes, and cause population declines when upwelling and marine productivity dramatically decline around the Archipelago.

Tourism in the Galapagos, an Ecuadorian National Park, is heavy but regulated, and fur seals are protected. Episodes of entanglement in local net fisheries have been reported, but are thought to have been largely mitigated by no-fishing zones. Feral dogs on Isabela Island destroyed colonies on the south end of the island by killing seals of all ages. Subsequently, a feral dog control program was put in place, but this problem could erupt again if any remaining animals find their way to colony sites again. Both feral and pet dogs could transmit diseases to pinnipeds. Despite their population size, the Galapagos fur seal will always be vulnerable to a variety of threats because the species is restricted to a relatively small island group.

IUCN status Vulnerable.

South American Fur Seal—*Arctocephalus australis*

(Zimmerman, 1783)

Recently-used synonyms None.

Common names En.–South American fur seal; Sp.–*lobo fino austral lobo de dos pelos*; Fr.–*otarie d'Amerique du sud.*

Taxonomic information Order Carnivora, Family Otariidae. Recognized subspecies are *A. a. gracilis* from Peru to Brazil in South America, and *A. a. australis* from the Falkland Islands.

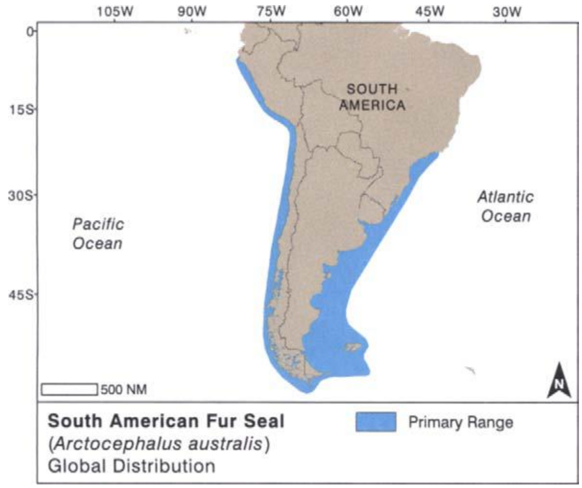
Species characteristics South American fur seals are sexually dimorphic. Adult males are approximately 1.3 times longer and 3.3 times heavier than adult females. Both adult males and females have a stocky robust build, large prominent eyes, long conspicuous ear pinnae, and moderate length pale vibrissae. The muzzle is moderately long, straight, and tapers in width and thickness to the nose. The rhinarium is slightly enlarged on the top, contributing to the somewhat upturned look to the end of the muzzle in profile. The crown is rounded and there is a conspicuous forehead that is steeper in adult males.

A South American fur seal bull with grizzled mane. New Island, Falkland Islands. PHOTO: M. WEBBER

Adult males have a very thick neck and large shoulders. They have a mane of longer guard hairs from the crown to the shoulders, including the neck and upper chest. The canine teeth of adult males are larger and thicker than those of females.

The foreflippers have a dark, sparse, short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface and the palms of both foreflippers are covered with a hairless black leathery skin. The first digit is the longest, widest and thickest, and curves posteriorly, giving the flipper a swept-back look. Digits 2–5 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers.

The hindflippers have dark, short, sparse hair covering part of the proximal end of the flipper, and the rest



A vocalizing adult male South American fur seal with an adult female behind. Peru. PHOTO: A. PHILLIPS

Two adult male South American fur seals engaged in a boundary dispute. Peru. PHOTO: S. CÁRDENAS ALAYZA

of the dorsal surface, and the entire sole is covered in black leathery hairless skin. The hindflippers are long and each digit has a cartilaginous rod that adds a flap-like extension to each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The claws of digits 1 and 5 are vestigial, like the claws on the foreflippers, and may or may not emerge from small openings set back from the end of the flaps. All of the flaps at the end of the flipper are of relatively equal length. The first toe or hallux and the fifth toe are somewhat wider than toes 2–4.

Adult females and subadults are brown to grayish-black above and paler, often with mixed shades of tan, gray, and rusty brown below. The chest, ventral part of the neck, and sides of the neck are light colored to a variable extent. The head and face are dark, but the sides of the muzzle in the mystacial area are paler. The ear pinnae are pale colored, and in females and juveniles the fur at the base of the pinnae can also be lighter colored. The fur on the top of the flippers is generally quite dark. As they age, males darken and become more uniformly-colored, generally dark brown, with grizzled frosting. Some bulls are paler. At birth, pups have a longer blackish fur, but there may be some paler markings on the face and muzzle, and some animals are paler below.

Adult males reach 1.9 m and 120–160 kg (possibly 200 kg) females are about 1.4 m and 40–50 kg. Newborns are 60–65 cm and 3.5–5.5 kg.

The dental formula is I $^{3}/2$, C $^{1}/1$, PC $^{6}/5$.

Recognizable geographic forms Although two subspecies are recognized by most authors, there is no known way to tell them apart in the field.

Can be confused with South American fur seals share most of their range with South American sea lions. Five other otariids: Juan Fernandez, Antarctic, subantarctic, and Galapagos fur seals, and Galapagos sea lion can be found as vagrants within the range of the South American fur seal.

South American sea lions have large, blocky heads with a short, blunt muzzle, and smallish inconspicuous ear pinnae. Similar-sized South American sea lions are tan to light brown, heavy bodied, with short, sleek fur that is not dense or shaggy except for the mane on bulls.

Female, juvenile, and subadult Galapagos sea lions are also pale tan to light golden brown, with sleek fur that is not dense or shaggy. Adult male Galapagos sea lions are dark brown to black, and thus similar in color to South American fur seals, but have a conspicuous sagittal crest on the crown behind the eyes and lack a conspicuous mane. All Galapagos sea lions have a proportionately wider muzzle that is blunt on the end, with less conspicuous vibrissae, and proportionately smaller eyes and shorter ear pinnae.

Adult male, female, and pup South American fur seals. Note the degree of sexual dimorphism. Peru. PHOTO: S. CÁRDENAS ALAYZA

A partially wet adult female and young pup South American fur seal. Peru. PHOTO: S. CÁRDENAS ALAYZA

Adult male Juan Fernandez fur seals have a longer muzzle with a bulbous, enlarged rhinarium and significantly downward-angled nares. The mane of adult males is grizzled principally on the crown, nape and upper neck whereas adult male South American fur seals are grizzled more evenly throughout the entire mane.

Galapagos fur seals are very small and stocky. The muzzle is quite short and tapers rapidly to a sharp point. Adult males have a paler "mask" of short lighter colored pelage on the muzzle and face to the eyes. Because of their small size the head of adult females seems proportionately wide.

Distinguishing adult male Antarctic fur seals from adult male South American fur seals is difficult due to similar size. Adult male Antarctic fur seals are darker brown or gray, have a shorter muzzle without any enlargement to the rhinarium and no upward angle at the end. Also, Antarctic fur seals have proportionately longer fore- and hindflippers. Subantarctic fur seals are uniquely colored with a pale face and neck. Both sexes have short, dark ear pinnae and adult males have a crest of longer pale fur on the dark crown. The flippers are proportionately small in both sexes.

With the exception of adult, female subantarctic fur seals, identifying lone adult female, subadult, or juvenile southern fur seals is usually difficult and often impossible without extensive experience. This is expecially true in an area like the southern South America where vagrants of a number of species are possible.

Distribution South American fur seals are widely-distributed from central Peru, around the southern tip of the continent, and north to southern Brazil. They also occur in the Falkland Islands. Distribution at sea is poorly-known. These seals are thought to forage primarily in continental shelf and slope waters. However, there are records from more than 600 km offshore.

Ecology and behavior Pupping and breeding takes place from mid-October through mid-December. Colonies are generally on rocky coasts on ledges above the shoreline or boulder strewn areas. Most areas provide some source of shade such as at the base of cliffs, and easy access to the water or tidal pools. Males are polygynous and territorial, and fighting can result in dramatic wounds and scars. Individual bulls can occupy territories for up to 60 days and have up to 13 females on their territories at Uruguayan colonies. Male vocalizations include a bark or whimper, a guttural threat, and a submissive call. Females growl and have a pup-attraction call that is a high-pitched wail.

Most females give birth for the first time when they are 4 years old. Pups are born shortly after females return to the colonies. Estrus is 7–10 days later, and following mating, a female begins to make foraging trips punctuated by time attending the pup ashore. Time spent on trips and attending the pup likely varies with location and changes in marine productivity such as during El Niño years for animals in Peru. Female attendance in Uruguay is effected by weather with females spending less time ashore during the day when ground temperature exceeds 36°C, and conversely, staying ashore longer during storms. Survival rates of pups can be quite low when marine productivity is low, and storm surges can sweep large numbers of pups off colonies. Locally, predation by adult male South American sea lions can be significant at some colonies. Data collected on adult females during an El Niño, resulted in mean dives to 29 m, with a maximum of 170 m, and mean duration of 2.5 minutes and maximum dive length of 7 minutes. Pups are weaned at 8 months to 2 years. Females will nurse a yearling and newborn pup.

No migration is known. Colonies on islands off Uruguay are occupied by portions of the population year-round. At sea, these fur seals may be seen traveling or rafting at the surface in groups. They will "porpoise," or leap clear of the water when moving rapidly at sea, sometimes traveling like this in large groups. While resting at the surface they spend considerable time grooming and assume many poses typical of southern fur seals, including waving both hindflippers in the air while the head is submerged. Groups often form in the water at the base of a colony. Predators include killer whales, sharks, South American sea lions, and leopard seals. Vampire bats are known to drink blood from the naked skin of the flippers of sleeping animals.

Feeding and prey Demersal and pelagic fishes make up the majority of the diet in Uruguay and include anchoveta, weakfish, cutlassfish, and anchovy. Cephalopods, lamellibranchs, and gastropods are also taken. Additional prey taken in other areas includes sardines, mackerel, and crustaceans such as lobster krill in southern Chile and the Falkland Islands where squid is also a common prey item.

Threats and status Humans have hunted South American fur seals for thousands of years. Exploitation began after discovery by Europeans and the onset of commercial sealing in the 18th century. Harvest levels declined in the 20th century, and hunting ended in many locations. A managed harvest of small numbers of adult males continues in Uruguay.

The effect of overfishing by large-scale commercial fisheries, and the ongoing take of numerous small-scale coastal fisheries has an unknown effect on the amount of food available to fur seals. Small numbers of fur seals are taken for food in Chile and Peru. The total population along the coast and offshore islands of South America is estimated at 215,000–265,000, with the majority of these in Uruguay. The Falklands population is estimated to be 15,000–20,000.

IUCN status Least Concern.

References Arnould 2002; Bonner 1981; Majluf 1987; Vaz-Ferreira 1979; Vaz-Ferreira and Ponce de Leon 1987.

New Zealand Fur Seal—*Arctocephalus forsteri*

(Lesson, 1828)

Recently-used synonyms *Arctocephalus doriferus* (population in Australia only).

Common names En.–New Zealand fur seal; Sp.–*l'otarie á fourrure de Nouvelle-Zélande*; Fr.–*otarie de Nouvelle-Zélande*.

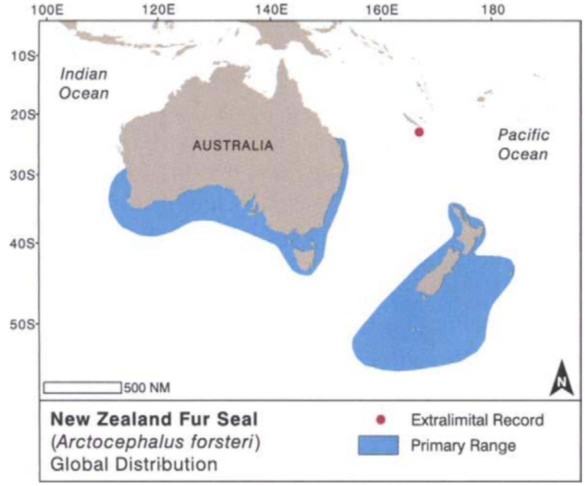
Taxonomic information Order Carnivora, Family Otariidae.

Species characteristics New Zealand fur seals are sexually dimorphic, with adult males reaching 1.3 times the length and 3 times the weight of adult females. The muzzle is moderately long, flat, and tapers in width and depth to a slightly upturned and pointed nose. In adults, the vibrissae are pale and medium to long. The ear pinnae are long and prominent, and the eyes are almond shaped.

Adult males have a mane of elongated, coarse guard hairs covering the greatly enlarged neck, chest, and shoulders, which extends to the nape and the top of the head. The crown is somewhat rounded, due to the modest sagittal crest, and there is a slight forehead. The canine teeth of adult males are larger and thicker than those of females. Adult females, subadults and juveniles have a flatter head with a minimal forehead.

New Zealand fur seal bull showing the slightly upturned muzzle, pale vibrissae, and slight crest. PHOTO: M. JØRGENSEN

New Zealand fur seal bull with a pale muzzle and enlarged forequarters. Kaikoura, New Zealand. PHOTO: M. WEBBER



The foreflippers have a dark, sparse, short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface and the palms of the foreflippers are covered with a hairless black leathery skin. The first digit is the longest and widest, and unlike most otariids has a relatively straight leading edge, giving the flipper a triangular look. Digits 2–5 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit.

The hindflippers are relatively long, and have dark, short, sparse hair covering part of the proximal end of the flipper. The rest of the dorsal surface, and the entire sole is covered in black leathery hairless skin. The hindflippers are long and each digit has a cartilaginous rod that adds a flap-like extension to each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The claws of digits 1 and 5 are vestigial like the claws on the foreflippers, and may or may not emerge from small openings set back from the end of the flaps. All of the flaps at the end of the flipper are of relatively equal length. The first toe or hallux and the fifth toe are somewhat wider than toes 2–4.

Adults are dark olive brown or gray brown above and paler below. The muzzle is variably paler, gray to rusty tan on the end, in the mystacial area, and around the line of the mouth. The ear pinnae are brown. Adult females are paler on the undersides than males, and are also pale from the lower sides of the abdomen to the chest and neck. Pups are blackish, except for a pale muzzle and undersides. They molt to adult pelage at 2–3 months.

There is some variation in weights of adult males in the literature. Some ranges are up to a maximum of 250 kg, others to 200 kg. The largest male weighed at the Open Bay Islands of New Zealand was 154 kg. Adult males 8–12 years old had a maximum weight of 124 kg. Adult males are up to 2 m long. Adult females are 1.5 m and 30–50 kg. Pups average 3.3–3.9 kg and 40–55 cm at birth, males average 14.1 kg and females 12.6 kg around weaning at 290 days old.

The dental formula is I $^{3}/_{2}$, C $^{1}/_{1}$, PC $^{6}/_{5}$.

Recognizable geographic forms None. Recent studies have determined that the New Zealand and Australian populations are more genetically distinct than some other fur seal species are from each other.

Can be confused with New Zealand fur seals share their range with five other otariids: Antarctic, subantarctic, and Australian fur seals, and New Zealand and Australian sea lions. Shape of the head and muzzle, presence of a dense underfur, coloration, size and prominence of ear pinnae, and length of the toes on the hindflipper readily distinguish New Zealand fur seals from both sea lions.

Adult female and young pup New Zealand fur seal showing typical adult female pelage. PHOTO: B. PAGE

A New Zealand fur seal female with a young pup in lanugo. PHOTO: K. ABERNATHY

Australian fur seal bulls are larger and heavier but less stocky, with a long head, and wider and blunter muzzle. The guard hairs of the mane are longer, and the neck and shoulders much more massive and muscular than on New Zealand fur seal males. Generally, both male and female Australian fur seals are paler above than New Zealand fur seals.

Distinguishing New Zealand fur seals from Antarctic fur seals is difficult due to similar size, shape and coloration. Adult male Antarctic fur seals are darker than adult male New Zealand fur seals. They are darker brown or dark gray and have extensive light grizzling on the mane. They also have long, pale-colored ear pinnae, a wider and shorter straight muzzle, smaller nose, and steeper forehead. Separating females, subadults and juveniles out of range or when isolated is problematic.

Subantarctic fur seals are uniquely colored with a pale face and chest, have ear pinnae that are short and black and have a short, sharply-pointed muzzle. There is also a crest of longer, pale fur in the dark crown. Adult females have similar coloration to the males, but have less well-defined pale facial markings that can be shaded with dull yellow orange to light brown. In both sexes the top of the foreflippers is darker as is the area where the flippers attach to the sides. The fore- and hindflippers are proportionately small.

Hybrid New Zealand X Antarctic fur seals are known. The few photographs available show that they share characteristics of both species (see Note on Hybrid Southern Hemisphere Fur Seals Genus *Arctocephalus*, pages 340–341).

Distribution New Zealand fur seals are distributed in two geographically-isolated and genetically-distinct populations. In New Zealand, they occur around both the North and South Islands, with small breeding colonies on the north, and larger colonies on the west and southern coast and islands of the South Island, and on all of New Zealand's subantarctic islands. They are less common off the North Island, with no colonies, but occur as far north as the Three Kings Islands. They are present, but do not breed, on Macquarie Island in April and May.

A separate population occurs in the coastal waters of southern and western Australia, from just east of Kangaroo Island west to the southwest corner of the continent in Western Australia. Vagrants have been recorded in New Caledonia, and from a bone in a 14th century archaeological site in the Cook Islands.

New Zealand fur seals prefer rocky habitat in windy locations with shelter from the sun. They will also readily enter vegetation. They prefer waters of the continental shelf and slope, and are found widely in waters over the Campbell Plateau, south of New Zealand.

Ecology and behavior New Zealand fur seals are polygynous. Males arrive at colonies in late October before females and acquire and defend territories with vocalizations, ritualized displays, and fighting. Male territories include an average of 5–8 females with numbers varying between colonies. Pupping and breeding occurs from mid-November to January. The number of animals ashore declines rapidly in January. Male vocalizations include a bark or whimper, a guttural threat, a low-intensity threat, a full threat, and a submissive call. Females growl and call their pups with a high-pitched wail.

Most pups are born from late November to mid-December. Estrus occurs 7–8 days after a female gives birth, and they usually spend another 1–2 days ashore

Compare the coloration and muzzle shape between the Australian sea lion (left) and New Zealand fur seal. PHOTO: B. PAGE

Juvenile New Zealand fur seals and a paler Australian fur seal (back, left). Note the straight leading edge of the foreflipper. PHOTO: T. HASSE

with their pup before departing and beginning a cycle of foraging trips and periods of pup attendance ashore. The female uses a high-pitched trilling call to attract her pup when she returns to the rookery. Pups are weaned when they are about 10 months old. Foraging trips are shorter when the pup is young and become longer as the pup gets older. The overall mean time ashore attending the pup is a little over 3 days, and is roughly equal to the mean time of all foraging trips combined: of approximately 3.3 days.

Foraging dives by lactating females are almost entirely at night to an average depth of 15 m with a maximum depth of 163 m. Mean dive duration is 50 seconds with a maximum of 6.2 minutes. Maximum depth of dive is 275 m and length of dive is approximately 11 minutes.

New Zealand fur seals are considered non-migratory. At sea they actively groom and raft in a variety of postures typical of southern fur seals including the "jug-handle" position while sleeping at the surface. They will also porpoise when traveling rapidly. Predators include killer whales, sharks, male New Zealand sea lions, and possibly leopard seals at subantarctic islands.

Feeding and prey The diet varies by location and time of year. Nearly all foraging by lactating females occurs at night. Important prey species include both vertically migrating species, and other species that occur throughout the water column and on the bottom. In New Zealand, arrow and other squid species, barracouta, anchovy, various lanternfish species, jack mackerel, red cod, hoki, octopus, and penguins are important prey species. They also feed on shearwaters and possibly other flying marine birds.

Threats and status Humans have likely harvested New Zealand fur seals since first contacts occurred. There is evidence that Polynesian colonization of New Zealand and harvest of seals led to declines and loss of colonies on the coast of North Island. European sealers nearly exterminated the species in the 19th century, but beginning with governmental protection starting in New Zealand and Australia in the late 19th century, the species has rebounded to occupy most of its former range.

Trawl and other fisheries are a source of entanglement and drowning. Tourism and disturbance at colonies can lead to disruption of breeding behavior and site abandonment, although most colonies are on offshore islands and are relatively inaccessible. The total population is estimated at approximately 135,000 with 35,000 of these in Australia.

IUCN status Least Concern.

Subantarctic Fur Seal—*Arctocephalus tropicalis*

(Gray, 1872)

Recently-used synonyms *Arctocephalus tropicalis tropicalis.*

Common names En.–Subantarctic, or Amsterdam fur seal; Sp.-*lobo fino de subantarctico*; Fr.–*otarie subantarctique.*

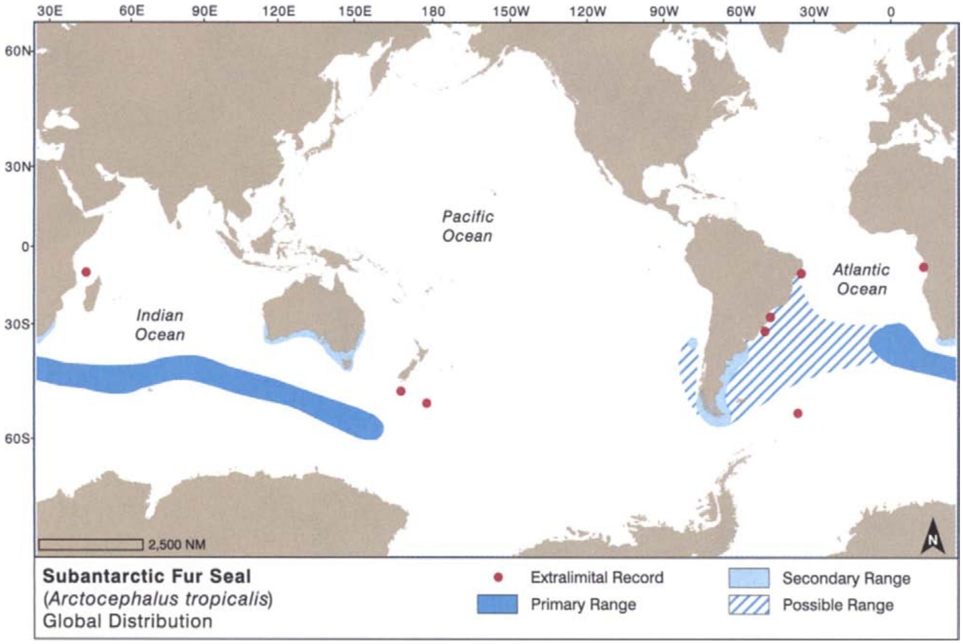
Taxonomic information Order Carnivora, Family Otariidae.

Species characteristics Subantarctic fur seals are sexually dimorphic, with adult males being 3 times heavier and 1.2–1.3 times longer than females. In both sexes, the muzzle is straight, short, and narrow, and tapers rapidly in width and thickness to a pointed end. The rhinarium is small. A forehead, more abrupt in males, separates the muzzle from the elevated, but somewhat flattened, crown. The vibrissae are very long and pale, and often reach well past the ears and down the neck. The short, dark, ear pinnae with naked tips, lie close to the head and are not particularly prominent. The eyes are rounded and teardrop shaped.

An adult male subantarctic fur seal. PHOTO: M. JØRGENSEN

Adult males are heavily-built; their enlarged chest and shoulders make the neck appear short. They develop a prominent tuft, or crest of long guard hairs on top of the head above and behind the eyes and forehead. The guard hairs on the neck and chest are somewhat longer than those on the rest of the body, but there is no conspicuous mane and grizzling is absent. Adult females, young subadult males, and juveniles do not have the crest of hair on the crown.

Overall, both the fore- and hindflippers are proportionately short and broad in all age classes and both sexes. A series of vagrant animals found in South Africa had foreflippers that measured from 19–26% of body length and hindflippers that were 12–16% of body length. The foreflippers have a dark, sparse, short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface and the palms of both foreflippers are covered with a hairless black leathery skin. The first digit is the longest, widest



and thickest, and curves posteriorly, giving the flipper a swept-back look. Digits 2–5 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers.

The hindflippers have dark, short, sparse hair covering part of the proximal end of the flipper, and the rest of the dorsal surface, and the entire sole is covered in black leathery hairless skin. Each digit has a cartilaginous rod that adds a flap-like extension to each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The claws of digits 1 and 5 are vestigial like the claws on the foreflippers, and may or may not emerge from small openings set back from the end of the flaps. All of the flaps at the end of the flipper are of relatively equal length. The first toe or hallux and the fifth toe are somewhat wider than toes 2–4.

Subantarctic fur seals are uniquely and strikingly colored. The back and rump of adult males are dark gray to brownish-black, subadults darkening as they age. From the chest through the muzzle, face, and area around the eyes, the pelage is continuously cream colored, with yellow to orange shading possible. The ear pinnae are dark, and attach in the dark pelage of the upperparts. The crest of longer fur above the eyes and behind the forehead is pale and is situated in the dark fur of the crown.

Adult females have similar coloration to males, but have less well-defined pale facial markings, which can be shaded with dull yellow orange to light reddish-brown. In both sexes, the top of the foreflippers is darker, as is the area where the flippers attach to the sides. The underside of the abdomen is dark ginger to reddish-brown.

Adult males are up to 1.8 m long and weigh 70–165 kg, and adult females are 1.19–1.52 m long and weigh 25–67 kg, with a mean of around 50 kg. Newborns are about 60 cm long and weigh 4–4.4 kg.

The dental formula is I $^{3}/_{2}$, C $^{1}/_{1}$, PC $^{6}/_{5}$.

Recognizable geographic forms None.

Can be confused with Subantarctic fur seals can be differentiated from all sea lions by their distinctive coloration, short and sharply pointed muzzle, large eyes, long white vibrissae, proportionately short and wide flippers, and thick pelage. They can be differentiated from all southern fur seals by their distinctive coloration and proportionately small flippers.

Hybrid subantarctic X Antarctic fur seals are known. The few photographs available show that they share characteristics of both species (see Note on Hybrid Southern Hemisphere Fur Seals Genus *Arctocephalus*, pages 340–341).

Distribution Subantarctic fur seals are widely-distributed in the Southern Hemisphere. They breed on subantarctic islands north of the Antarctic Polar Front, including Prince Edward, Marion, Crozet, and Macquarie islands, and north of the Subtropical Front at Tristan da Cunha, Gough, and Saint Paul and Amsterdam Islands. The northern limit of their range is not well-known, but vagrants have appeared in Brazil, the Juan Fernandez Islands, southern South America, southern Africa, Madagascar, Australia and Tasmania, and South Island, New Zealand. Subantarctic fur seals have also been recorded south of the convergence at South Georgia, and on the Antarctic continent at Davis and Mawson bases.

Ecology and behavior Subantarctic fur seals are polygynous, with males defending territories with vocal and postural displays and fighting. Typical territories include 1–5 females and are located on boulder-strewn beaches, at the foot of cliffs, shoreline ledges and terraces, and in shallow shoreline caves and grottos. Most areas have sources of shade or are exposed to prevailing winds. Male vocalizations include a bark or whimper, a guttural threat, a low-intensity threat, possibly a full threat, and a submissive call. Females growl and have a pup-attraction call that is a mournful wail without trilling.

Pups are born from late October to early January, with a peak in mid-December. Females give birth within 6 days of arriving at the colony and estrus and mating occur 8–12 days later. Females spend the time between the birth of their pups and estrus with their newborn before departing for their first foraging trip. Females wean their pups in approximately 10 months. Trip length by lactating females increases over the course of the summer from 5.7 to 10.8 days. Also during the summer, dives become deeper and slightly longer, starting at a mean of 16.6 m and increasing to a mean of 19 m. Dive duration at this time is generally just over 1 minute. In the winter, fur seals spend longer periods at sea, with a mean of almost 23 days, diving to a mean depth of 29 m for 1.5 minutes, with a maximum depth of 208 m and maximum duration of 6.5 minutes. Subantarctic fur seals are ashore for the annual molt between February and April.

Subantarctic fur seals share several breeding islands with Antarctic fur seals. Hybrids are known, and

Adult female subantarctic fur seals have similar coloration to adult males. Pups are dark, glossy black. PHOTO: I. CHARRIER

The short flippers and short pointed muzzle are visible on these plump juvenile subantarctic fur seals. PHOTO: I. CHARRIER

have grown to maturity and bred. With the exception of some information on appearance and vocalizations little is known of the foraging and behavior of these hybrids.

Little is known of their behavior at sea. Except for cows with pups, most of the population spends much of the winter and spring (June–September) at sea. Predators include killer whales, sharks, and at Macquarie Island, New Zealand sea lions.

Feeding and prey Generally, they are known to feed on varieties of nototheniid fishes, cephalopods, krill, and penguins. It has been estimated that their diet is 50% cephalopods, 45% fish, and 5% krill at the Prince Edward Islands. At Amsterdam Island they feed on cephalopods, fish, and rockhopper penguins.

Threats and status As with all other southern fur seals, subantarctic fur seals were over-exploited by sealers in the 19^{th} century and were hovering on the brink of extinction at the beginning of the 20^{th} century. Since then they have rebounded to refill much of their former range.

The total population is believed to be greater than the 310,000 animals estimated in 1987, as all indications are that it has been steadily growing since that time. Subantarctic fur seals live in some of the most remote oceanic areas, and breed on many of the most isolated islands on Earth. All of the breeding islands are managed as protected areas or parks by the governments that claim them. Human visitation and disruption from scientific research activities is minimal. Fisheries takes and entanglement in marine debris are not well understood, but are not listed as a major threat in status reviews.

IUCN status Least Concern.

References Arnould 2002; Bester 1987; Bonner 1981; Georges and Guinet 2000; Guinet et al. 1994; Shaughnessy 1982.

Antarctic Fur Seal—*Arctocephalus gazella*

(Peters, 1875)

Recently-used synonyms *Arctocephalus tropicalis gazella.*

Taxonomic information Order Carnivora, Family Otariidae.

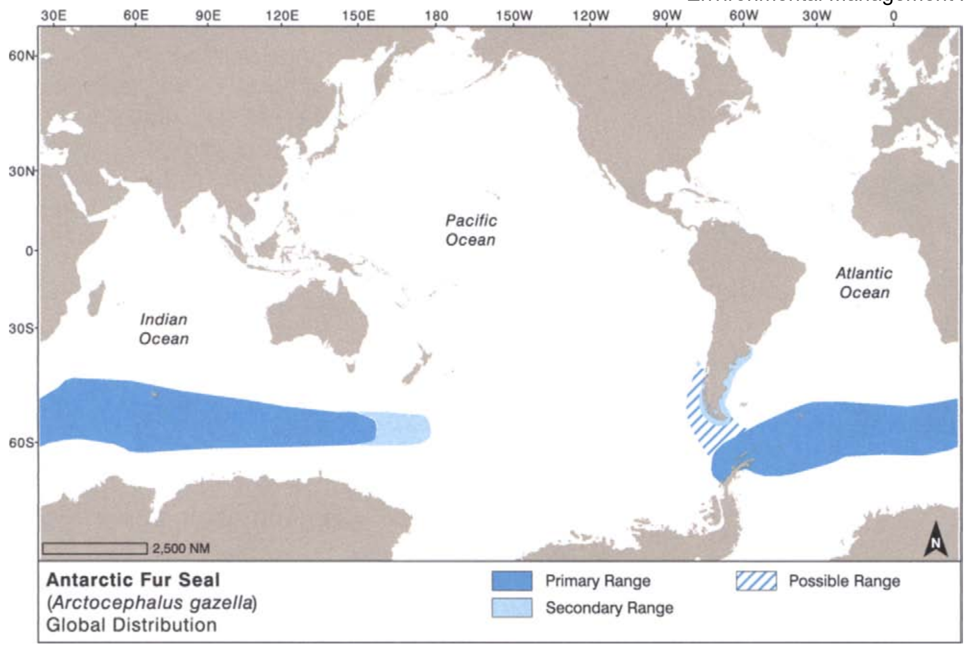
Common names En.–Antarctic fur seal; Sp.–*lobo fino antartico*; Fr.–*otarie antarctique.*

Species characteristics Antarctic fur seals are strongly sexually dimorphic with adult males 4–5 times the mass and 1.4–1.5 times the length of adult females. The muzzle is a medium length and width, straight, and tapers to a moderately pointed end. The rhinarium is modest in size and does not extend much past the mouth. The ear pinnae are long, prominent, and pale in color usually with lighter tips. The eyes are almond-shaped. The pale vibrissae are long and conspicuous. On adult males they are some of the longest found on any pinniped, reaching 35–50 cm.

Adult males develop a mane of thicker, coarser guard hairs on the chest, neck, and top of the head. The neck and shoulders are also greatly enlarged with fat and the development of muscles in older adult males. Adult females, subadults and juveniles are difficult to tell apart from males until the latter begin to grow larger when they are 4–6 years old. Juveniles and subadults have dark, to mixed light and dark vibrissae, becoming lighter as they age, and become pale when they are adults.

The fore- and hindflippers are proportionately long, at 28–33%, respectively, and 22–28% respectively of the total body length of all age classes. The foreflippers have a dark, sparse, short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a

Adult male and adult female Antarctic fur seals showing the extent of sexual dimorphism in this species. Males have a thick, grizzled mane which adds bulk to their larger size. South Georgia. PHOTO: M. WEBBER



"V" pattern that does not reach the rounded tip. The rest of the dorsal surface and the palms of both foreflippers are covered with a hairless black leathery skin. The first digit is the longest, widest and thickest, and curves posteriorly, giving the flipper a swept-back look. Digits 2–5 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers.

The hindflippers are long and dark, with short, sparse hair covering part of the proximal end of the flipper and the entire sole is covered in black, leathery skin. Each digit has a cartilaginous rod that adds a flap-like extension to each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The claws of digits 1 and 5 are vestigial, like the claws on the foreflippers, and may or may not emerge from small openings set back from the end of the flaps. All of the flaps at the end of the flipper are of relatively equal length. The first toe or hallux and the fifth toe are somewhat wider than toes 2–4.

Adult females and subadults are gray to brownish-gray above and cream to light gray below with shades of ginger and reddish-brown. There is usually an area of pale color of variable extent on the sides between the flippers. Pale color extends from the chest variably up the neck and on the sides of the neck to as high as the throat, eyes, and muzzle. The dark fur on the top of the foreflippers extends into the area where the foreflipper attaches at the

shoulder. Additional lighter areas often surround where the ear pinnae attach and are also on the scrolled pinnae. There is a variable amount of cream to reddish-brown color on the muzzle in the mystacial area. Newly molted juveniles have the same color pattern as adult females, but are silvery-gray in all lighter areas. At birth, pups are blackish, though they may be pale on the face and muzzle, and some animals are paler below.

Adult males are dark grayish-brown to charcoal, with off-white to silver grizzling on the guard hairs of the back, mane, and flanks. The long guard hairs of the mane often bunch up and reveal the fawn color underfur.

A cream- to honey-colored, leucistic morph of the Antarctic fur seal is seen at a rate of 1–2 per thousand at South Georgia. These golden animals are not albinos. They have normally pigmented eyes and paler, but not unpigmented, skin. The guard hairs on these pale animals lacks pigment, and the underfur and skin are paler than in normally-pigmented animals.

Adult males on breeding territories can be up to 2 m long, but are usually around 1.8 m long. Mean weight is 188 kg, but they can weigh 133–204 kg. Adult females are 1.2–1.4 m and 22–51 kg, with a mean weight of 26 kg. Newborns are 63–67 cm long, and weigh 6–7 kg.

The dental formula is $I\ ^{3}/_{2}$, $C\ ^{1}/_{1}$, $PC\ ^{6}/_{5}$.

Recognizable geographic forms None.

Can be confused with Antarctic fur seals can be confused with southern otariids that share their range or where Antarctic fur seal vagrants have been found. Subantarctic, New Zealand, South American, and Juan Fernandez fur seals, and South American and New Zealand sea lions are the most likely species to consider.

Subantarctic fur seals are uniquely colored with a very pale chest and face, and have short, dark ear pinnae. Males also have a crest of longer pale fur in the dark crown. The flippers are proportionately small on all comparable sizes of subantarctic fur seals.

Separating New Zealand and South American fur seals from Antarctic fur seals can be problematic especially with females and immature animals. Adult male New Zealand and South American fur seals are stockier in build with a longer, more pointed muzzle that appears slightly upturned at the nose. Adult male Antarctic fur seals are generally darker with paler grizzling than on either the grayer brown New Zealand or light to dark brown South American fur seals. New Zealand fur seals have brown ear pinnae while South American fur seals have pale pinnae. Separating adult female, subadult and juvenile New Zealand and South American fur seals from Antarctic fur seals of similar size and age is more problematic due to overlap of coloration. Note the muzzle size and rhinarium size and shape.

Adult male Juan Fernandez fur seals have a longer muzzle, distinctive bulbous rhinarium, and unique coloration of the crown, nape and upper neck. Separation of adult female, and subadult, and juvenile Juan Fernandez fur seals from Antarctic fur seals is problematic. In general, adult female Juan Fernandez fur seals are somewhat larger than female Antarctic fur seals, and have a longer muzzle, larger rhinarium and downward oriented nares, and a more rounded crown.

Hybrid Antarctic X subantarctic, and Antarctic X New Zealand fur seals are known. The few photographs

available show that they share characteristics of both species (see Note on Hybrid Southern Hemisphere Fur Seals Genus *Arctocephalus*, pages 340–341).

Antarctic fur seals can be differentiated from all Southern Hemisphere sea lions by their coloration, narrower, pointed muzzle, proportionately large eyes, long, pale vibrissae, and thick pelage. Sea lions have large, blocky heads with blunt-ended and wide muzzles, and are paler in color than comparably-sized animals. Adult males of all sea lions are much larger and distinctive.

Distribution Antarctic fur seals are widely distributed in waters south, and in some areas slightly north, of the Antarctic Convergence. Most of the population breeds on South Georgia and Bird islands, but colonies are widely spread-out and can be found in the South Shetland, South Orkney, South Sandwich, Prince Edward, Marion, Crozet, Kerguelan, Heard, McDonald, Macquarie, and Bouvetoya islands. Vagrants have been found in southern South America, the Juan Fernandez Islands, and at Australia's Mawson Station on the Antarctic Continent.

Males haul-out extensively in the mid- and late summer on islands along the Antarctic Peninsula. Ashore, they prefer rocky habitats, but will readily haul-out on sandy beaches and move into vegetation zones such as tussock grass. They disperse widely at sea. Distribution and movements in winter are not well-known. Males and subadults occur south to the edge of the consolidated pack ice, and can be found hauled-out on sea ice.

Ecology and behavior Antarctic fur seals are highly polygynous. Many males arrive at the colonies in late October 2–3 weeks before the first females arrive and establish themselves on territories. Males continue to arrive and challenge for territories through much of the season. Territories are acquired and held with vocalizations, threat postures and fighting. In prime areas territories can be as small as 20 m^2 and have up to 19 females. The mean length of tenure for bulls at South Georgia is approximately 34 days. Male vocalizations include a bark or whimper, a guttural threat, a low-intensity threat, and a submissive call. Females growl and have a pup-

attraction call that is a high-pitched wail that usually includes trilling.

Females begin to arrive in mid-November and most pupping and breeding occurs from late November to late December. They give birth 1–2 days after arrival at the colony, attend their pup for 6–7 days, come into estrus and mate, and then depart minutes to hours after mating for their first foraging trip. The length of foraging trips and attendance periods varies by year depending on the availability of the lactating female's chief prey, adult krill. Generally, 4–5 days at sea are followed by 2–3 days attendance on land. Lactating females routinely dive to 8–30 m and are submerged for less than 2 minutes, but have been recorded to depths of 181 m, and to undertake dives that have lasted 10 minutes. Mean dive depth and duration increase during the lactation period.

Pups are weaned in about 4 months. After they wean their pups, females disperse widely, possibly migrating north and are not seen at the colonies much until the next breeding season. Bulls also depart breeding areas, but subadults and adult males can be seen around the rookeries at South Georgia all year.

Like other southern fur seals, Antarctic fur seals porpoise when swimming rapidly. When rafting they often assume many of the typical fur seal resting postures. At other times, they can be found busily engaged in grooming. Predators include killer whales, leopard seals, and at Macquarie Island, New Zealand sea lions. Leopard seals have had a dramatic effect on several re-colonized areas in the South Shetland Islands and have caused a decline at one site due to their extensive predation on pups.

Feeding and prey The diet varies by season and location. Adult females at South Georgia feed heavily and selectively on adult krill. At Heard Island krill is not available and lactating females prey primarily on fish such as myctophids and mackerel icefish. In the winter, males and subadult males at South Georgia take krill and a variety of fish that eat krill, while squid and myctophids are only a small percentage of the diet. At Heard Island in the winter squid and myctophid fish dominate the diet. Foraging patterns of females in summer indicate nocturnal feeding.

Antarctic fur seals will eat penguins. Adult males have been documented chasing, killing and eating King penguins on land on Marion Island. They are also known to take Macaroni and Gentoo penguins in the water at Heard, Macquarie, and South Georgia islands.

Threats and status As was the case for all other southern fur seals, sealers drove the species to the brink of extinction by the late 19th century. The colony at South Georgia was thought to be as small as 100 animals in the 1930s. Today the population is estimated to exceed 3 million animals and is believed to be growing and expanding at a rapid rate with 95% of these using the colony at South Georgia.

The Antarctic Treaty and the Convention for the Conservation of Antarctic Seals protect this fur seal below 60° S. Various efforts to launch commercial fisheries for krill near South Georgia have been unsuccessful. Trawling activities developing around Macquarie Island may effect the prey base of the primarily fish-eating Antarctic fur seals that breed on those islands. No direct fisheries conflicts involving regular entanglements are known to exist.

Antarctic fur seals become entangled in marine debris such as discarded fishing line, nets, packing bands and anything that can form a collar. It was estimated from a 1988–89 study, that the numbers entangled might be as high as 1% of the total population, with the majority of the impact on juveniles and subadults, particularly males.

IUCN status Least Concern.

South African and Australian Fur Seals—*Arctocephalus pusillus*

(Schreber, 1775)

Recently-used synonyms *Arctocephalus doriferus*, *Arctocephalus tasmanicus* (both for the Australian subspecies).

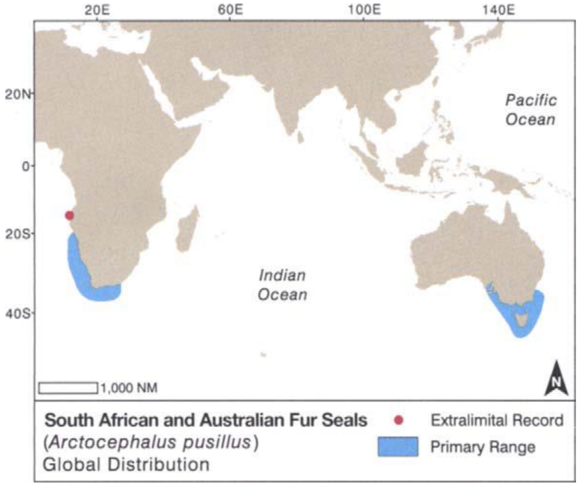
Common names *A. p. pusillus*: En.–South African or Cape fur seal; Sp.–*lobo marino de dos pelos de Sudafrica*; Fr.–*otarie du Cap. A. p. doriferus*: En.–Australian or Tasmanian fur seal; Sp.–*l'otarie á fourrure australe*; Fr.–*otarie d'Australie*

Taxonomic information Order Carnivora, Family Otariidae. There are two widely-separated subspecies: *A. p. pusillus* in southern Africa, and *A. p. doriferus* in southern Australia.

Species characteristics These two subspecies are the largest fur seals and have a high degree of sexual dimorphism. Adult males are 3.5 to almost 4.5 times heavier, and approximately 1.3–1.9 times longer, than females. Both sexes of Australian fur seals average heavier than their South African counterparts. Adult female Australian fur seals average slightly longer, and males slightly shorter than females and males of the South African subspecies, and the relationship between female and male Australian animals is closer, with males being about 1.1–1.8 times longer than females.

Both subspecies have been described as the most sea lion-like fur seals. In both, the head is large and wide, and the crown rounded in adult males and flatter in females. There is a sloping forehead that is more prominent in adult males, and less steep, but still present, on females. The muzzle is robust and long, flat and wide on top, tapering only somewhat in width and thickness to

There is less sexual dimorphism in overall size in South African and Australian fur seals than in most other otariids. Notice the enlarged forequarters of the adult males and the long straight muzzle on these South African fur seals. PHOTO: C. STEWARDSON



the large conspicuous nose. The rhinarium is large, wide and rounded in adult males, less so in adult females, and extends beyond the end of the mouth. The ear pinnae are long and prominent. The vibrissae are moderately long, pale, and regularly extend to the ear pinnae. Adult males are greatly enlarged in the neck and shoulders, with a mane of longer guard hairs from the nape and neck to shoulders and chest. Adult females, subadults, and juveniles are robust, but normally proportioned in the neck and shoulders.

The foreflippers have a dark, sparse, short fur that extends beyond the wrist onto the middle of the dorsal surface of the flipper in a "V" pattern that does not reach the rounded tip. The rest of the dorsal surface and the palms of both foreflippers are covered with a hairless black leathery skin. The first digit is the longest, widest and thickest, and curves posteriorly, giving the flipper a swept-back look. Digits 2–5 are successively shorter. There is a small opening in the skin at the end of each digit for a claw that is usually reduced to a vestigial nodule, and rarely emerges above the skin. The claw openings are set back from the free edge of the flippers by cartilaginous rods that extend the length of each digit, and expand the size of the flippers.

The hindflippers have dark, short, sparse hair covering part of the proximal end of the flipper, and the rest of the dorsal surface, and the entire sole is covered in black leathery hairless skin. The hindflippers are long and each digit has a cartilaginous rod that adds a flap-like extension to each toe. The bones of the three central toes terminate at the position of the small nails that emerge through the skin on the dorsal surface, set back from the end of the flipper. The claws of digits 1 and 5 are vestigial, like the claws on the foreflippers, and may or may not emerge from small openings set back from the end of the flaps. All of the flaps at the end of the flipper are of relatively equal length. The first toe or hallux and the fifth toe are somewhat wider than toes 2–4.

Adults are tan to grayish-brown with yellowish to orange highlights above and on the neck, and variably paler with reddish-brown shades on the abdomen. Males are usually darker than females and darken as they age. South African fur seals are generally darker than animals from Australia. The guard hairs have a slight grizzled appearance, especially on bulls. Females, subadults and juveniles can be lighter on the chest. The mystacial area can be paler. The tops of the flippers are very dark. Part of the ear pinnae and the area around the insertions of the pinnae are paler, however the tips of the pinnae are naked and dark in older animals. Pups are blackish, with variable hints of silver overall, and can be paler below. They first molt at 4–5 months to an olive-gray coat. As juveniles, they molt a year later into a silvery-gray coat.

Adult male Australian fur seals average just less than 2 m, and can reach 2.3 m in length. They attain an average weight of 279 kg, and can weigh up to 360 kg. Adult females are 1.2–1.8 m in length, and attain an average weight of 76 kg, and can weigh up to 110 kg. Newborns average 73 cm in length. Female newborns average

7.1 kg, and males 8.1 kg in weight. Adult male South African fur seals are 2–2.3 m long, average 247 kg in weight, and may reach 353 kg. Adult females are 120–160 cm long and weigh an average of 57 kg, with a maximum of 107 kg. Pups are born at around 6 kg and are 60–70 cm long.

The dental formula is I $^{3}/_{2}$, C $^{1}/_{1}$, PC $^{6}/_{5}$.

Recognizable geographic forms Although there are two widely-recognized subspecies that are slightly different in average size and weight of adults, there is otherwise no published information available on external differences between the two forms.

Can be confused with South African and Australian fur seals both share their ranges with vagrant subantarctic fur seals.

For the Australian fur seal, New Zealand fur seals and Australian sea lions pose a regular chance for confusion. New Zealand fur seals are grayer and darker, have a thinner and proportionately longer, more pointed, and slightly upturned muzzle, a more flattened crown, and darker brown ear pinnae. They are stocky, but smaller overall. The mane of Australian fur seal males is more conspicuous. On land, Australian fur seals move one foreflipper forward at a time, and the head sways from side to side with an alternating gait used by many sea lions. New Zealand fur seals extend both foreflippers ahead at the same time in a bounding gait.

Australian sea lions have large, blocky heads with a wide, blunt muzzle, distinctive coloration, lack the longer, thicker pelage of the Australian fur sea, and have shorter ear pinnae.

Subantarctic fur seals are uniquely colored with a pale head and chest. The ear pinnae are dark and short. Adult males have a crest of longer pale fur in the dark crown. Subantarctic fur seals also have proportionately small flippers.

Distribution South African fur seals are found along the south and southwest coasts of southern Africa, from South Africa to Angola. Australian fur seals are found along the coast and continental shelf and slope waters from western Victoria, east along the coast to the southeast corner of Australia, then north through most of New South Wales. The range also includes Tasmania, and the islands of Bass Strait. Australian fur seals will travel up to 160 km offshore. On land, they prefer preference for rocky habitat.

Ecology and behavior Both subspecies are highly polygynous. Adult males arrive at the colonies first. Breeding is from late October to the beginning of January. Males establish and defend territories with vocalizations, ritualized postures and fighting. The territories of bulls are a

mean of 62 m^2 and hold about 9 females on average. Male vocalizations include a bark or whimper, and a guttural threat. Females have a threat and a bawling pup attraction call.

Female Australian fur seals come ashore and give birth 1.5–2 days after arrival. The peak is in the first week of December, although there is some variation between colonies. Females attend the pup for 8–9 days before coming into estrus, mating, and departing on their first foraging trip. Foraging trips get longer as the season progresses from summer to winter, changing from a mean of 3.71 to 6.77 days. Periods of attendance stayed the same from birth to weaning, and had a mean length of 1.7 days. Pups are usually weaned at 10–12 months even though some pups begin to forage at 7 months, and others are nursed for 2–3 years. The data are similar for South African fur seals, except that foraging intervals are much shorter, probably reflecting greater availability of food near the colonies in the productive, upwelling waters off southwest South Africa.

Foraging dives by lactating Australian fur seal females are usually to 65–85 m with a maximum of 164 m, and last 2–3.7 minutes with a maximum recorded duration of 8.9 minutes. Unlike many other fur seals, considerable foraging occurs during the day. Two lactating female South African fur seals dove shallower averaging 41 and 49 m respectively, but had much deeper maximum dive depths of 191 and 204 m.

At sea, this species is found alone or in small groups, often gathering in huge rafts adjacent to rookeries. They adopt a variety of poses while resting in the water, including the "jug-handle." They also purposely entangle themselves in rafts of kelp, possibly using the kelp as an anchor and for camouflage. When traveling rapidly, they sometimes "porpoise." Neither of the subspecies is migratory; they move more locally within their restricted ranges. Predators include killer whales and great white sharks at sea, and black-backed jackals and brown hyenas for South African fur seals at their mainland colonies.

Feeding and prey Both subspecies are opportunistic feeders that take a wide variety of prey, including pelagic, mid-water, and benthic animals. Australian fur seals take squid, octopus, barracouta, whiting, flathead, red mullet, parrotfish, leather jackets, pilchards, and rock lobsters. For South African fur seals, the diet consists of fish (75%), cephalopods (17%), and crustaceans (8%). Important species are cape hake, horse mackerel, pelagic goby, pilchards, anchovy, squid of the genus *Loligo*, rock lobster, shrimp, prawns, and amphipods. South African fur seals have also been reported to occasionally take jackass penguins and several species of flying seabirds.

Threats and status South African and Australian fur seals were hunted heavily in the 19th century and both

populations were driven to very low levels. With protection, both have recovered, although the South African subspecies to a much greater extent than the Australian. South African fur seals numbered approximately 1.7–2 million animals in 1990, and the population was estimated to be increasing at a rate of 3% per year. Australian fur seals were estimated to number 35,000–60,000 in the early 2000s.

Fur seal harvests in South Africa were suspended in 1990, but are ongoing in Namibia. The South African fur seal is considered to be detrimental to commercial fisheries, costing large sums in damaged gear and stolen and damaged catch annually. Some are taken incidentally in fishing operations every year. Also, significant numbers of South African fur seals are known to become entangled in marine debris such as packing bands, discarded lines and nets, and other material that can become a collar around an animal's neck. Rates of entanglement vary by colony, but have been estimated to be between 0.12–0.66%. There is a potential for human disturbance from tourism at several large colonies. The population of South African fur seals is located beside one of the busiest shipping lanes for oil tankers, and is at risk from the potential for a catastrophic oil spill. Conflicts exist with commercial fisheries off South Africa, where this fur seal forages around trawlers bringing in their nets.

Australian fur seals are protected from harvest. There are conflicts with local commercial fisheries from fur seals stealing catch, damaging gear, and becoming entangled in nets and traps. They are considered a pest species by some, and are shot under permit to protect fishing gear and catch. Mortality is highest and more significant for younger age classes. They also live close to human population centers and agricultural areas and are exposed to a wide variety of pollutants through the food chain.

IUCN status Least Concern (for both subspecies).

References Arnould 2002; Arnould and Hindell 2001; Bonner 1981; David 1987; Shaughnessy 1985; Shaughnessy 1999; Shaughnessy and Warneke 1987.

Walrus—*Odobenus rosmarus*

(Linnaeus, 1758)

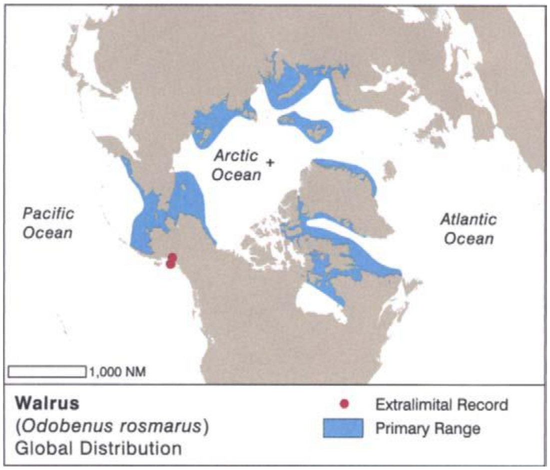
Recently-used synonyms None.

Common names En.–walrus, Pacific walrus, Atlantic walrus, Laptev walrus; Sp.–*morsa*; Fr.–*morse*.

Taxonomic information Order Carnivora, Family Odobenidae. Three subspecies are recognized: Atlantic, *O. r. rosmarus*, from the eastern Canadian Arctic, and Greenland east to Novaya Zemlya; Pacific, *O. r. divergens*, in the Bering Sea and adjacent Arctic Ocean, and *O. r. laptevi*, in the Laptev Sea, north of Siberia.

Species characteristics Walruses are very large, heavy-bodied pinnipeds. Males are longer and heavier than females. Adults have a short coarse pelage that becomes sparse as they age, more so for males than females. The skin is thick, rough and heavily marked with creases and folds. Older males have many lumps called tubercles on the neck and chest, giving them a warty appearance, and most become virtually hairless. The neck, chest, and shoulders are massive, and the body tapers towards the hindflippers. The head, and the muzzle, are short, but very wide. The "bloodshot" eyes are small, somewhat protruding, and set far apart. The end of the muzzle is flattened and has large, fleshy, forward-facing mystacial pads sprouting several hundred short, stiff, pale vibrissae. The nostrils are located on top of the muzzle. Walruses have no ear pinnae.

The foreflippers are short and squarish, resembling otariid foreflippers, but unlike otariids, each digit has a weakly developed claw. The hindflippers are phocid-like, with longer first and fifth digits, and strong expandable webbing between the digits, each with a small claw. The tail is attached to the body by a web of skin.



A large adult male Atlantic walrus with thick rolls of fat on the neck and shoulders. Svalbard. PHOTO: M. JØRGENSEN

Walrus coloration varies with age and activity. Most walruses are yellowish- to reddish-brown. When walruses remain in cold water for long periods of time, their coloration fades to a pale grayish-hue, due to reduced blood flow to the skin, known as peripheral vaso-constriction. Conversely, when they come out of the water, vaso-dilation causes blood and color to return to the skin, and under warm conditions, causes the animals to appear pink to reddish, giving them the appearance of having a sunburn. Calves are darker with slate-gray fur.

Males reach about 3.6 m and 880–1560 kg, females about 3 m and 580–1039 kg. Newborns are 1–1.4 m and weigh 33–85 kg.

The dental formula is: I $^{1}/_{0}$, C $^{1}/_{1}$, PC $^{3}/_{3}$. Walruses are unique among pinnipeds, as the upper canine teeth develop into tusks that grow throughout life. The tusks are longer (up to 1 m) and thicker, with more grooves and fracture lines in males than in females, and one or both tusks can be partially, or entirely, broken off in adults of both sexes. Tusks also tend to be less curved and more divergent at the tips in males. In general, adult male and female Pacific walruses have longer tusks than Atlantic walruses. Tusks about a meter long can be found on male Pacific walruses. Walrus calves are born without tusks, but they generally become visible below the lips at age 3–4 in the Pacific population.

Recognizable geographic forms There may rarely be transits of the Canadian Arctic Archipelago, resulting in either Pacific or Atlantic walruses showing up in the other's range. This would present an interesting identification problem. Some useful features to look for are: adult Pacific walruses of both sexes generally have longer, thicker, and more curving tusks than similar size and age Atlantic walruses, although there is overlap in tusk length. Pacific walruses have wider skulls than Atlantic walruses, and as a result, have somewhat wider heads and muzzles. There is overlap in the overall size of adults, and size is not a useful feature for separating Pacific and Atlantic walruses. Adult male Pacific walruses regularly have more

pronounced tubercles on the neck, chest, and shoulders than Atlantic walruses.

The status of the Laptev walrus as a subspecies is unclear. It is thought that they are most closely related to Pacific walruses, but this is uncertain. The appearance, distribution, and movements of Laptev walruses are poorly known, and as a result, identifying Laptev walruses outside their range should be considered problematic.

Can be confused with Walruses are unmistakable on land or ice and in most sightings at sea. At sea they should not be confused with any other species if more than the back is seen during a surface period.

Distribution Walruses have a discontinuous circumpolar distribution in the Arctic and subarctic. The Pacific subspecies is found in the Bering and Chukchi seas to the East Siberian Sea in the west and the Western Beaufort Sea in the east. The Atlantic subspecies occurs in numerous subpopulations from the Eastern Canadian Arctic and Hudson Bay, to the Kara Sea. The Laptev walrus is isolated in the Laptev Sea north of central Russia. All three subspecies of walrus are found in relatively shallow continental shelf areas, and rarely occur in deeper waters. They regularly haul-out on sea ice, sandy beaches, and rocky shores, to rest, molt, give birth and nurse their young.

Ecology and behavior Calves are born from mid-April to mid-June on sea ice. Courtship and mating has been little studied, because walruses mate in the harsh winter environment of the Arctic. It is believed that walruses are polygynous and that males may form a type of lek with small aquatic territories adjacent to females on ice floes, where they vocalize and display. There is also intense male-male fighting at this time.

Males produce an unusual bell-like sound when they are in the water. A pair of elastic pharyngeal pouches can be inflated with air and provide flotation when a walrus is resting in the water. Walruses can walk and climb on land by using all four flippers to move the body in the manner of an otariid, although they are far less agile and move much more slowly. In the water they primarily rely on side-to-side sculling strokes of the hindflippers for swimming in the manner of a phocid.

In the Pacific, walrus migration follows the seasonal advance and retreat of the sea ice. However, some walruses, particularly males, summer far from the sea ice, using land-based haulouts in Bristol Bay, Alaska, some islands in the Bering Sea, and in Russia from the Chukotka to the Kamchatka peninsulas. Walruses also haul-out on shore, away from ice in years of reduced pack ice. Walruses are among the most gregarious of pinnipeds. When hauled-out, they are regularly found in tightly hud-

dled masses, often lying on top of each other; at sea they are often seen in large herds. Tusks are used for aggressive displays, fighting, and pulling themselves onto ice floes, not for digging up food.

Feeding and prey Walruses feed on a variety of prey, chiefly benthic invertebrates including: clams, worms, snails, shrimp, and slow-moving fish. Some "rogue" walruses are known to prey on seals and small whales.

Threats and status The current population level of Pacific walruses is uncertain, but roughly estimated to be 200,000. This is also the case for the Laptev population, estimated to be 4,000–5,000. The better-known Atlantic population is about 10,000–19,000. All three populations were severely depleted by episodic commercial hunting that was heaviest from the 18th through the mid-20th centuries. Native peoples of the Arctic have depended on walruses for food, hides, ivory, bones and more since first contact, and subsistence harvests continue today in many parts of the species' range. Conflicts with fisheries are low. However, industrial development, dispersal of pollutants, and human disturbance along with global warming and associated reduction in sea ice extent and duration all have the potential to cause significant impacts on walrus populations.

IUCN status Data Deficient (*laptevi* subspecies); Least Concern (other subspecies).

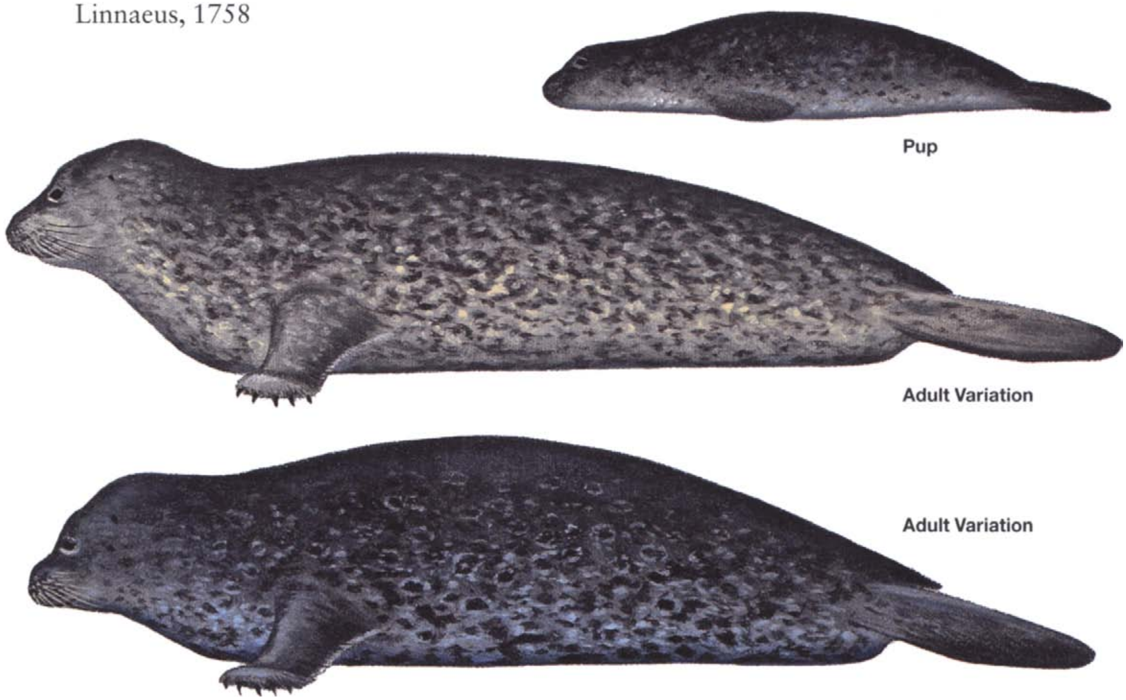
Harbor Seal—*Phoca vitulina*

Linnaeus, 1758



Recently-used synonyms None.

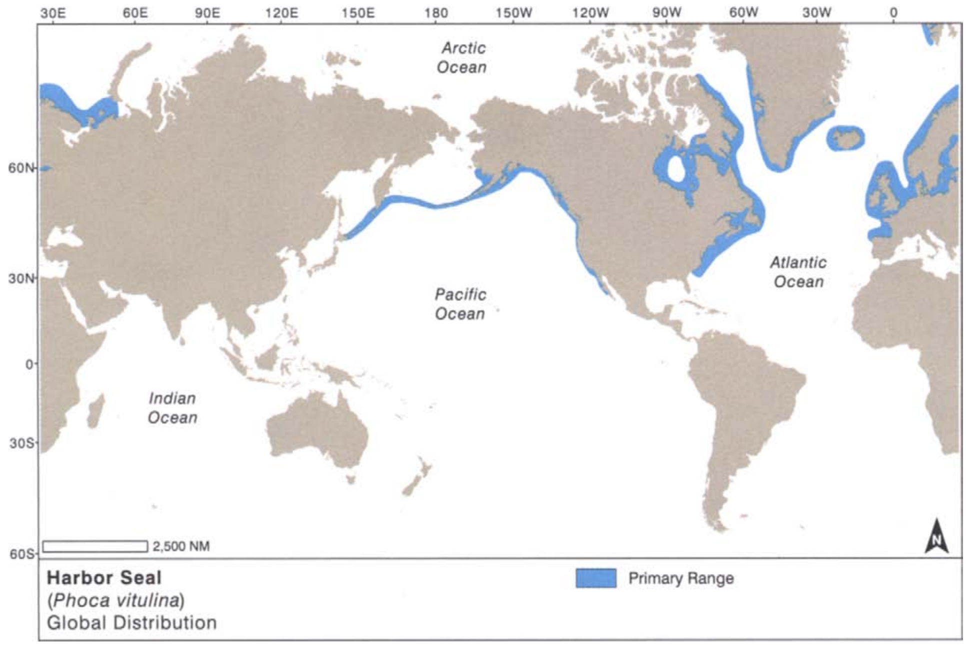
Common names En.–harbor seal, common seal; Sp.–*foca común*; Fr.–*phoque veau marin*.

Taxonomic information Order Carnivora, Family Phocidae. Five subspecies are currently recognized: *P. v. vitulina* in the eastern Atlantic; *P. v. concolor* in the western Atlantic; *P. v. mellonae*, in fresh water lakes in the Ungava Peninsula, Canada; *P. v. richardii* in the eastern Pacific; and *P. v. stejnegeri* in the western Pacific.

Species characteristics Harbor seals are small phocids. They have a torpedo-like body shape with little differentiation of neck or hips, with a thick, solid appearance. The head is medium-sized, and the eyes are relatively close-set, the inner corners being about as far apart as the outer edges of the nostrils. There are prominent light-colored, beaded vibrissae above the eyes and on the tapering, somewhat short muzzle. The nostrils are small and terminal, forming a "V" that converges at the bottom. The external ear openings are conspicuous, and positioned slightly behind and below the eyes. Harbor seals are not obviously sexually dimorphic, and observation of the pattern of genital openings and the presence or absence of mammary openings on the ventrum, or the close association of a pup with its mother are required to separate the sexes. The flippers are relatively short, only about $^1/5$ to $^1/6$ of standard length, with long, thin, dark hooked claws on all digits. The ends of the foreflippers are somewhat pointed, with a longer first digit and successively shorter digits two through five.

A lighter phase (and wet) *P. v. vitulina* harbor seal with her dark phase pup. Scotland. PHOTO: L. CUNNINGHAM

The most conspicuous feature of the variably-colored coat is the presence of many fine to medium-sized spots, usually with smaller numbers of ring-like markings and blotches. The markings are usually scattered liberally over the body, with higher densities occurring dorsally than ventrally. Fusion of markings, and the appearance of markings superimposed on other markings impart a confused speckled appearance to the backs of many animals. The most common base color pattern is a light to dark gray, or brown-gray, dorsally, forming a mantle or saddle, lightening to a paler belly in a countershaded pattern. Many dark-pelage animals are uniformly dark brown-black above and below, and appear to have only pale rings and ovals. In some localities,



a small percentage of animals have a rust-colored tinge to the head, which in extreme cases can form a complete hood that reaches the flippers and back. Most pups shed their silvery-gray lanugo coat in the uterus before birth. Exceptions to this include pups born early in the breeding season or those born prematurely.

The dental formula is I $^3/2$, C $^1/1$, PC $^5/5$.

Adult males are up to 1.9 m long and weigh 70–150 kg, females 1.7 m and 60–110 kg. At birth, pups are 65–100 cm and 8–12 kg.

Recognizable geographic forms Five subspecies of harbor seal are recognized. Unfortunately, there are no external characteristics known that could be used to identify individuals to any of the named populations, and identifications in the field are generally made based on location.

Can be confused with Eight other phocids share the range with one or more subspecies of harbor seal. Features for distinguishing harbor seals from northern elephant, gray, hooded, ringed, spotted, harp and ribbon seals are given in those respective species accounts. In the North Pacific, spotted seals pose the greatest identification challenge, and cannot reliably be separated from harbor seals where they share the same habitats, even by most experienced observers.

Distribution Harbor seals are one of the most widespread of the pinnipeds. They are confined to coastal areas of the Northern Hemisphere, from temperate to Polar regions. Five subspecies are recognized: *P. v. vitulina* occurs in the eastern Atlantic from northern Portugal to the Barents Sea in northwestern Russia, and north to Svalbard; *P. v. concolor* occurs in the western Atlantic from the mid-Atlantic United States to the Canadian Arctic and east to Greenland and Iceland; *P. v. richardii* is found in the eastern Pacific from central Baja California, Mexico, to the end of the Alaskan Peninsula, and possibly to the eastern Aleutian Islands; *P. v. stejnegeri* ranges

from either the end of the Alaskan Peninsula or the eastern Aleutians to the Commander Islands, Kamchatka, and through the Kuril Islands to Hokkaido in the western Pacific; and *P. v. mellonae*, occurring in rivers and landlocked lakes of the Ungava Penninsula, Canada.

Ecology and behavior Harbor seals are mainly found in the coastal waters of the continental shelf and slope, and can be found commonly in bays, rivers, estuaries, and intertidal areas, and are essentially non-migratory. On land, harbor seals are extremely wary and shy, and it is almost impossible to approach them when they are ashore without stampeding them into the water. In contrast, when in the water, they can be curious, often craning their necks to peer at people on shore or in boats. Most harbor seal haulout sites are used daily, based on tidal cycles, although foraging trips can last for several days.

Harbor seals are gregarious at haulout sites; however they usually do not lie in contact with each other. A hissing rolling growl is one of the few vocalizations made by this seal, and it frequently accompanies foreflipper slapping, batting and scratching of neighbors when a seal is agitated. This is a common occurrence at crowded haulouts where animals moving and shifting positions bump into or move too close to one another. At sea, they are most often seen alone, but occasionally occur in small groups. Localized aggregations can form in response to feeding opportunities.

The mating system is promiscuous or weakly polygynous. Mating usually takes place in the water, during the February to October breeding season. Pupping peaks sometime between April and July. In some regions, pupping occurs earlier in more southerly areas of a given population's range.

Feeding and prey Harbor seals are generalist feeders taking a wide variety of fish, cephalopods, and crustaceans obtained from surface, mid-water, and benthic habitats. Although primarily coastal, dives to over 500 m have been recorded.

Threats and status Many harbor seals live in close proximity to large populations of humans and are exposed to high levels of industrial, urban, and agricultural pollutants. Both chronic oil spills and discharges, and episodic large scale spills cause direct mortality, and have long term impacts on harbor seal health and their environment.

Harbor seals live in coastal areas in the middle of some of the most heavily fished waters on Earth, and as a result there are entanglement issues as well as effects on the food chains they depend on for their prey. There are also conflicts with smaller, localized fisheries, and historically there have been organized population reduction programs and bounties for taking seals.

Mass die-offs from viral outbreaks have claimed thousands of harbor seals. In the late 1980s more than 18,000 harbor seals are estimated to have been killed by a phocine distemper virus (morbillivirus). Exposure to diseases from terrestrial carnivores, including human pets, creates an increased risk of exposure to communicable diseases. Immunosuppression from chronic exposure to pollutant contaminants probably contributes to harbor seal susceptibility to diseases.

Despite the fact than most harbor seals live in relatively close proximity to humans, their population levels are generally not well-known. Combining recent estimates yields a world-wide population of 300,000 to 500,000 animals. The subspecies *P. v. stejnegeri* of the western Pacific (approximately 7,000), and *P. v. mellonae* (120–600) of the rivers and seal lakes of the lower Ungava Peninsula, Canada, may be the subspecies most at risk due to low population numbers. Isolated populations in Svalbard and the Baltic Sea, both in the hundreds, are also dangerously low.

IUCN status Data Deficient (*mellonae* subspecies), Least Concern (other subspecies).

References Bigg 1981; Burns 2002; Dietz et al. 1989; Harkonen and Heide-Jorgensen 1990; Heide-Jorgenssen and Harkonen 1988; Hoover 1988; Payne and Selzer 1989.

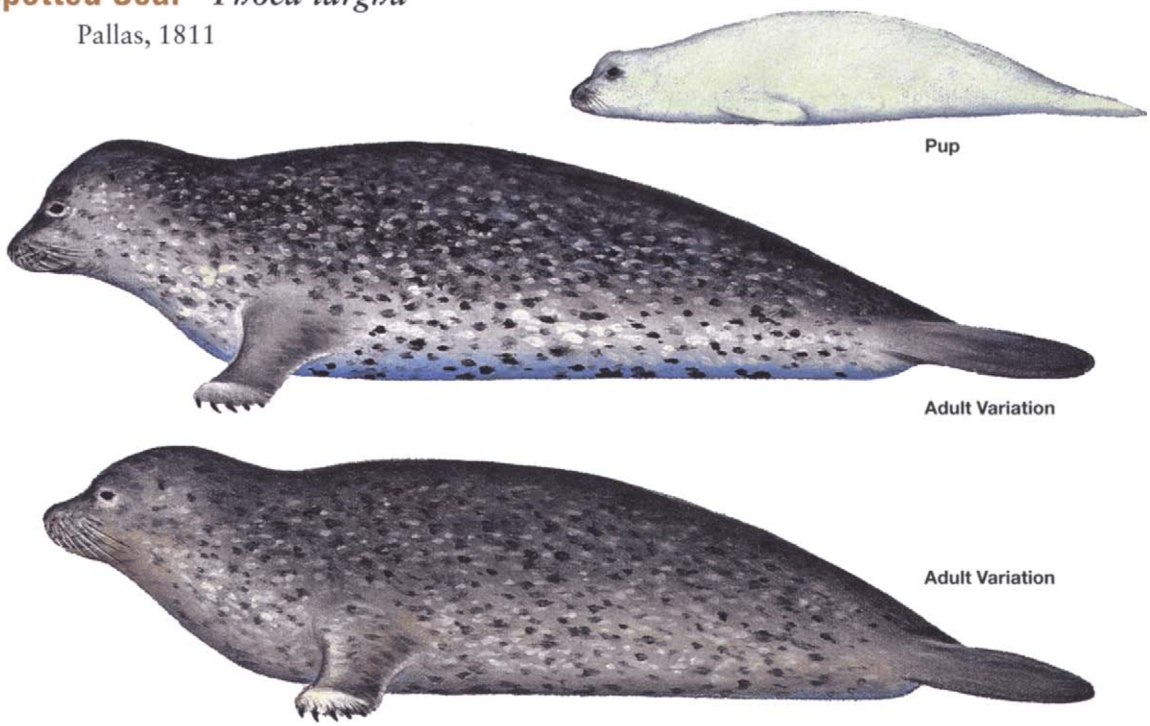
Phocidae

Harbor Seal

Spotted Seal—*Phoca largha*

Pallas, 1811



Recently-used synonyms None.

Common names En.–spotted seal or largha seal; Sp.–*foca largha*; Fr.–*veau marin du Pacifique*.

Taxonomic information Order Carnivora, Family Phocidae.

Species characteristics The spotted seal is a sibling species with the harbor seal. The coloration is generally pale, silver gray above and below. However, darker and brownish morphs also occur. The usually darker mantle is dominated by even darker oval spots of fairly uniform size (1–2 cm) and generally oriented parallel to the long axis of the body. There can be light rings around the spots, or large irregular spots or blotches. Spotting tends to be of fairly even distribution and darkness overall. Pups are born with a long, woolly, whitish lanugo, which is shed 2–4 weeks.

The dental formula of adults is I $^{3}/2$, C $^{1}/1$, PC $^{5}/5$.

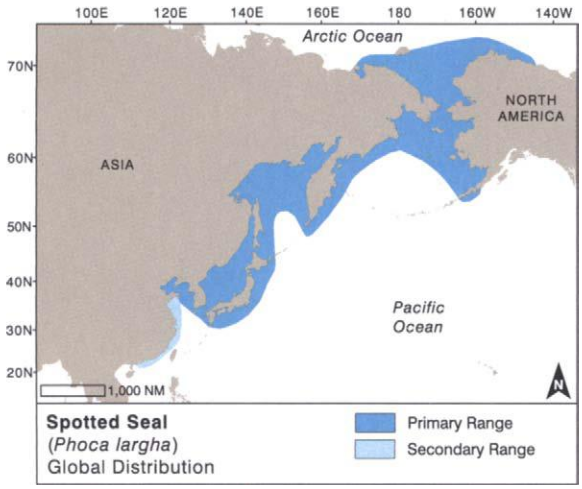
Adult males are up to 1.7 m and females to 1.6 m long. Adults weigh 82–123 kg. At birth, spotted seals are 77–92 cm long and weigh 7–12 kg.

A probable mating triad of spotted seals in spring. Southern Bering Sea. PHOTO: G. BRADY/NMFS

Recognizable geographic forms None.

Can be confused with Spotted seals share their range with ringed, ribbon, bearded, and harbor seals. Ribbon seals lack spots and have broad, pale to white bands on a black or brown body, or as juveniles are gray above and lighter below, but in all age classes, ribbon seals lack the abundant spots of the spotted seal.

The range of the eastern Pacific and western Pacific subspecies of the harbor seal overlaps with the range of the spotted seal. Unfortunately, the consistent differences between the



species are features of the skull and genetic characteristics. Coloration, body size, and shape overlap in the two species. The only known features for separating the species in the field, are behavioral. Spotted seals give birth on sea ice and usually are alone or accompanied by a male. Harbor seals give birth on land or glacial ice in haulout groups typical of the sites where they are found year-round. In addition to being born in a long gray lanugo coat, spotted seals spend their first weeks on the ice, while harbor seals are generally born in a short hair coat similar to the adult, and are able to swim within hours of birth. Where they occur together, spotted seals give birth up to 2 months earlier than harbor seals.

Spotted seals haul-out on land in Bristol Bay, Alaska where they can be found in mixed groups with harbor seals. Very experienced observers can separate them from harbor seals based on behavior, response to disturbance, and subtle differences in facial features.

Spotted seals and ringed seals can be confused. Spotted seals are longer and proportionately leaner, with a longer neck, head, and muzzle. Spotted seals rarely have many rings, whereas ringed seals have an abundance of rings and a low density of less conspicuous spots. Pups of both species are born in a long, grayish lanugo coat and would be difficult to tell apart if away from adults. However, spotted seal pups are born on top of ice floes, whereas ringed seal pups are born in lairs under snow and ice.

Distribution Spotted seals are widespread in the Sea of Okhotsk and the Sea of Japan, and reach China in the northern Yellow Sea. They are widespread in the Bering and Chukchi seas and range north into the Arctic Ocean north to about the edge of the continental shelf, west to about 170° E and east to the Mackenzie River Delta in Canada. They inhabit the southern edges of the pack ice from winter to early summer. In late summer and fall, spotted seals move into coastal areas, including river mouths. They breed exclusively, and haul-out regularly, on sea ice, but do come ashore on beaches, sandbars, mudflats, and rocky reefs.

Ecology and behavior Spotted seals are annually monogamous and territorial. Breeding takes place on pack ice from January to mid-April. Peak numbers of pups are born mid- to late March. Males associate with females and their pups, on sea ice, forming triads.

Feeding and prey Adults can dive to at least 300 m, and feed on a wide variety of organisms; composition of diet varies with the age of the seal, and on seasonal variation in abundance of preferred prey species. Newly weaned pups feed on small crustaceans, advance to schooling fishes, larger crustaceans, and octopuses, and finally "graduate" to higher percentages of bottom dwelling fish species.

Spotted seals are variable in coloration like harbor seals, with pale to dark phase animals. Korea. PHOTO: H. W. KIM

Threats and status Subsistence hunting of spotted seals has no doubt occurred since humans made first contact with the species. Intensive harvesting of commercial fish species in the North Pacific and southern Bering Sea poses an as-yet unquantified risk. Entanglement in commercial fishing gear occurs in Japan and the Sea of Okhotsk, and population culls regularly occur in Japan. The latest estimate for the populations of the spotted seal is by area: 100,000–135,000 in the Bering Sea; 100,000–130,000 in the Sea of Okhotsk; and 4,500 in the Bohai Sea off China.

These light phase spotted seals have few or no rings. Korea. PHOTO: H. W. KIM

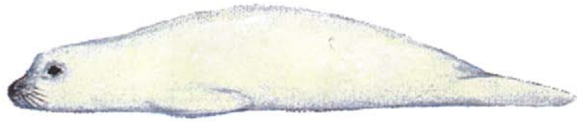
Global climatic change, including global warming, and decreases in annual sea ice development and extent of coverage pose an unknown, but potentially serious, threat to this pagophilic species.

IUCN status Least Concern.

References Angliss and Lodge 2004; Bigg 1981; Bradford and Weller 2005; Burns 2002; Lowry et al. 2000; Mizuno et al. 2002; Quakenbush 1988; Rugh et al. 1997.

Ringed Seal—*Pusa hispida*

(Schreber, 1775)



Pup

Adult Variation

Adult Variation

Recently-used synonyms *Phoca hispida.*

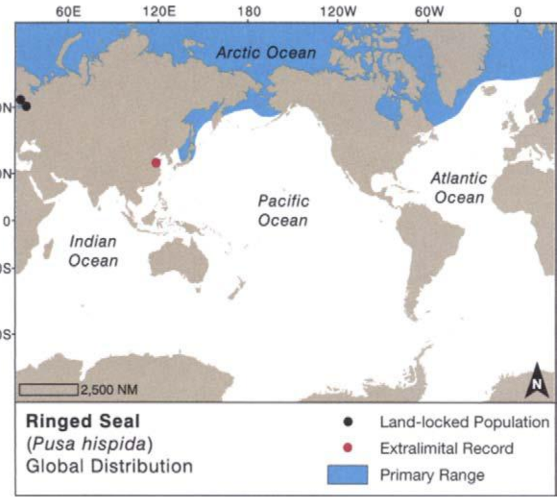
Common names En.–ringed seal; Sp.–*foca marbreada*; Fr.–*phoque annelé ou marbré*.

Taxonomic information Order Carnivora, Family Phocidae. There are five recognized subspecies: *P. h. hispida*, in the Arctic basin; *P. h. ochotensis*, in the Seas of Okhotsk and Japan; *P. h. saimensis*, in Lake Saimaa; *P. h. ladogensis*, in Lake Ladoga, and *P. h. botnica*, in the Baltic Sea.

Species characteristics Ringed seals resemble harbor and spotted seals, but are decidedly plumper (axillary girth may reach 80% of length). They also have a smaller, somewhat rounded head and muzzle, and a conspicuously short and thick neck. The muzzle is short, slightly broader than thick, and blunt. The vibrissae are light-colored and beaded. The eyes are relatively large and conspicuous. More than in other northern phocids, the size of the head and muzzle, and the close-set forward-facing eyes, impart a cat-like appearance. The foreflippers are relatively small and slightly pointed, as in the harbor seal.

The background coloration is variable, but normally is medium to dark gray above and light gray to silver below. Ringed seals are conspicuously marked with light gray to off-white rings that encircle "spots" of the darker dorsal and lateral background pelage coloration. Some ringed seals can be so heavily marked, that many rings and spots fuse, creating a confused paint-splattered appearance. The lighter colored sides have a variable number of dark spots that do not appear to be encircled by rings because of the paler lateral and ventral pelage. Pups are born with a wooly, thick, whitish lanugo. Fur of the succeeding coat is

This adult ringed seal was released after capture and tagging, and shows the complex pattern of interconnected rings and numerous spots typical of this species. Hudson Bay, Canada. PHOTO: B. DUNN



finer and slightly longer than that of adults, and is dark gray above, merging to silver below. There may be a few scattered dark spots on the undersides of these juveniles, and few, if any, rings on the back. At this stage, they are known as "silver jars".

The dental formula is: I $^3/_2$, C $^1/_1$, PC $^5/_5$.

Adults are up to about 1.65 m in length. Weight is 50–70 kg, with a maximum of 110 kg. Pups average about 60–65 cm and 4–5 kg at birth.

Recognizable geographic forms There are five recognized geographic forms of ringed seal. Of these, the primary subspecies that occupies most of the Arctic, *P. h. hispida* and the the Sea of Okhotsk subspecies *P. h. ochotensis* are very similar, and can only be can be separated in the field based on location of sighting. *P. h. botnica* is cut-off from the main ringed seal population through isolation in the Baltic Sea. This subspecies is dark overall with a scattering of light rings and may be the largest subspecies. Both the Saimaa *P. h. saimensis* and Ladoga *P. h. ladogensis* populations live in fresh-water lakes isolated from the Baltic Sea. Seals from both of these subspecies are dark compared to *P. h. hispida* that is found across most of the Arctic.

Can be confused with Ringed seals share their extensive range with seven other phocids. They are not likely to be confused with bearded, harp, hooded, gray, or ribbon seals because of differences in size, coloration, and body shape. However, care is required to distinguish them from other seals with rings, spots or spot-like markings, such as harbor and spotted seals. Separating these species requires paying attention to coloration and markings, noting the relative size and shape of the head, and to the overall body size and shape.

Spotted and harbor seals are very similar in build and length. Adults of both are longer than ringed seals, and the neck, head and muzzle are also proportionately longer. Also, most spotted seals have few or no rings. Spotted seals have their pups on the surface of the ice, whereas ringed seals have their pups in lairs under snow layers on sea ice, and inside pressure ridges.

Harbor seals do not regularly use ice except where glaciers discharge ice into bays and fjords and it is a semi-permanent feature. Except in rare cases, or when pups are born prematurely, the coloration of harbor seal pups is essentially the same as in adults and subadults. Harbor seals generally have some rings, but when present, always have a mixture of rings and spots and are far less uniformly marked with rings than most ringed seals.

Distribution Ringed seals have a circumpolar distribution throughout the Arctic basin, Hudson Bay and Straits, and the Bering, Okhotsk, and Baltic seas. The distribution of ringed seals is strongly correlated with pack and land-fast ice, and areas covered at least seasonally by ice. Adults use land-fast ice for breeding, molting, and over-wintering habitat.

Ecology and behavior Nearly all ringed seals breed on fast ice. Females excavate lairs in snow, in pressure ridges, and other snow-covered features. These lairs have access to the water, and provide camouflage and some protection from polar bears, which are the chief predator. Pupping generally occurs from March through April, and earlier in the Baltic Sea. Males are thought to be territorial, and possibly annually monogamous.

This ringed seal shows small tight rings, a small rounded head, and short and narrow muzzle. PHOTO: M. JØRGENSEN

A very young ringed seal pup in lanugo outside its lair. Barrow, Alaska. PHOTO: L. LOWRY

Many adults remain in the same localized areas year-round. Out of water, ringed seals are generally wary, regularly scanning for predators, such as polar bears and humans.

Feeding and prey Ringed seals consume a wide variety of small prey, including many species of fishes, and planktonic and benthic crustaceans. These opportunistic feeders are known to have over 72 different species in their diet. In deep water they forage in the water

A juvenile ringed seal. Ringed seals are some of the smallest seals and have a feline-like face, small features and long claws on the foreflippers. Disko Bay, Greenland. PHOTO: F. UGARTE

column and along the undersides of ice floes, while in shallow water they often forage along the bottom with polar cod being a preferred prey species. Ringed seals forage either singly or in small groups.

Threats and status The vast geographic range occupied by ringed seals, coupled with their solitary nature, and the challenges of conducting population assessments in remote polar areas, make it difficult to estimate ringed seal population levels. Estimates of the world-wide population range from 2.5 to 7 million, with most authors expressing caution over the accuracy of both local area and range-wide figures. *P. h. saimensis*, of Lake Saimaa, Finland, and *P. h. ladogensis*, found in Lake Ladoga, Russia, are both restricted to only these land-locked bodies of water, and occur in very low population numbers (approximately 200 and 5,000 respectively). The Baltic Sea population of *P. h. botnica* is estimated to be 5,000–8,000.

Native peoples of the Arctic hunt ringed seals for food and skins, and have done so for thousands of years. Direct human interaction and conflicts are otherwise minimal. Existing subsistence harvests, and the commercial use of skins from some of these harvests, such as occurs

in Greenland, do not appear to be negatively affecting any ringed seal populations. Most ringed seals take few commercially important prey species, with notable exceptions in Greenland and in the White and Barents seas. The Baltic Sea population, *P. h. botnica*, is surrounded by large human population centers and may suffer from exposure to pollutants that compromise the seal's immune system and lead to higher rates of disease that negatively affect reproduction.

The effects of global warming and the projected decreased extent and duration of sea ice cover associated with warming of the Arctic could have dire consequences for ringed seal survival. Several studies have already demonstrated decreased reproductive success in response to poor sea ice conditions.

IUCN status Endangered (*saimensis* subspecies), Vulnerable (*botnica* and *ladogensis* subspecies), Least Concern (other subspecies).

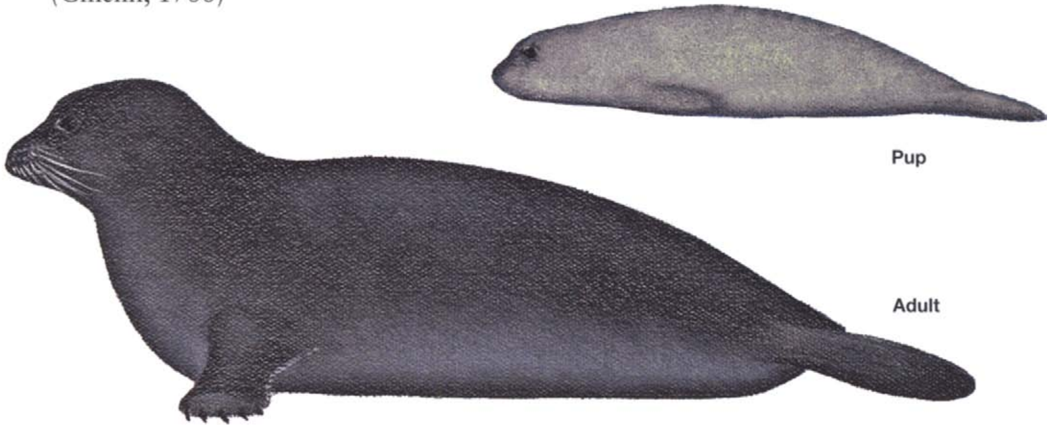
Baikal Seal—*Pusa sibirica*

(Gmelin, 1788)



Recently-used synonyms *Phoca sibirica*.

Common names En.–Baikal seal; Sp.–*foca de Baikal*; Fr.–*phoque du lac Baikal*; Ru.–*nerpa*

Taxonomic information Order Carnivora, Family Phocidae.

Species characteristics Baikal seals are dark silver gray above and lighter gray on their undersides. They appear charcoal to black above when wet. Pups are born in a whitish lanugo that is shed at 4–6 weeks, when they transition to a juvenile pelage that is lighter gray with a dark face. Baikal seals are unmarked, having no rings or spots.

These seals are plump, with a proportionately wide body and a small delicate-looking head. The eyes are proportionately large, forward set, and have a slight bulging appearance. The muzzle is small, wide, and delicate looking in juveniles. The vibrissae are beaded, long and prominent, including those over the eyes. The foreflippers are short, broad, and have large strong claws.

The dental formula is I $^{3}/_{2}$, C $^{1}/_{1}$, PC $^{5}/_{5}$.

Measurements of Baikal seals have been taken as curvilinear lengths, which yield longer measurements than the standard lengths used for other species. Adult Baikal seals have been reported to reach approximately 1.4 m and 80–90 kg. Newborn pups are 64–66 cm in length and 4–4.2 kg in weight.

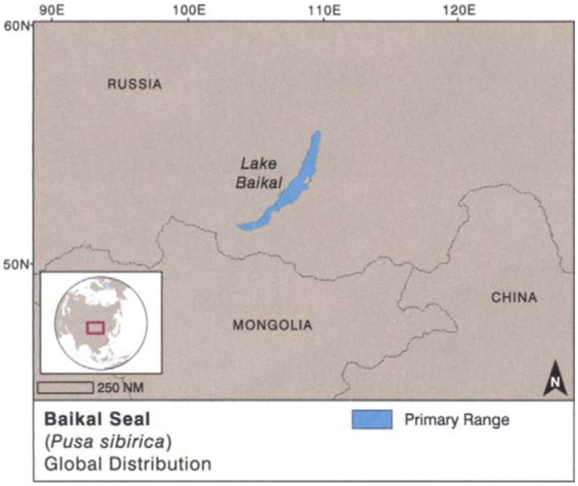
Recognizable geographic forms None.

Can be confused with There should be no confusion; the Baikal seal does not share its range with any other pinniped species.

Distribution Baikal seals are entirely confined to Lake Baikal and short distances up its rivers and streams. Most seals are found in the northern and central regions of the lake, and a portion of the population moves south in front of advancing ice that forms in the late fall and winter.

A group of wet and dry, adult and subadult, Baikal seals. Notice the short and very wide, rounded body of this species. PHOTO: Y. WATANABE

Ecology and behavior The origin of the Baikal seal is poorly known. They are believed to have made it to Lake Baikal sometime during Pleistocene glaciation events from northern Arctic Seas, and are derived from the ringed seal, or a ringed seal ancestor. Baikal seals use islands and the rugged lake shoreline for hauling-out in the summer, and during other ice-free periods, and are ice-living when the lake is frozen. They maintain breathing and access holes in ice, and give birth in snow-covered lairs excavated on lake ice. Twins are born at a rate of



The eyes on the Baikal seal are set particularly close together. PHOTO: Y. WATANABE

Dry Baikal seals have a soft looking gray pelage that is darker above, with no rings or spots. PHOTO: Y. WATANABE

approximately 4%, which is probably the highest for all pinnipeds. Pupping occurs from mid-February to the end of March, and pups are weaned in 2–3 months. Newly-weaned juveniles emerge from the lairs in April. Instrumented Baikal seals dove for 2–6 minutes, to depths of 10–50 m; the deepest dives were to 300 m.

Feeding and prey Baikal seals forage extensively through the winter. Their diet consists primarily of several species of sculpins and golomyanka (genus *Comephorus*), but includes many varieties of freshwater fishes, including commercially important species.

Threats and status The population of Baikal seals was estimated at 60,000–70,000 in 1978. Subsistence and commercial hunting, and poaching continue. Several mass mortality events have been recorded. One event, attributed to a distemper virus in 1987–88, resulted in a large number of deaths. Baikal seals have high organochorline contaminant burdens due to industrial wastes discharged into rivers feeding the lake and bioconcentrating up the Lake's food chain, and these pose an as-yet undetermined level of risk to the health of the population. Entanglement in commercial fishing nets accounts for an unknown level of mortality.

IUCN status Near Threatened.

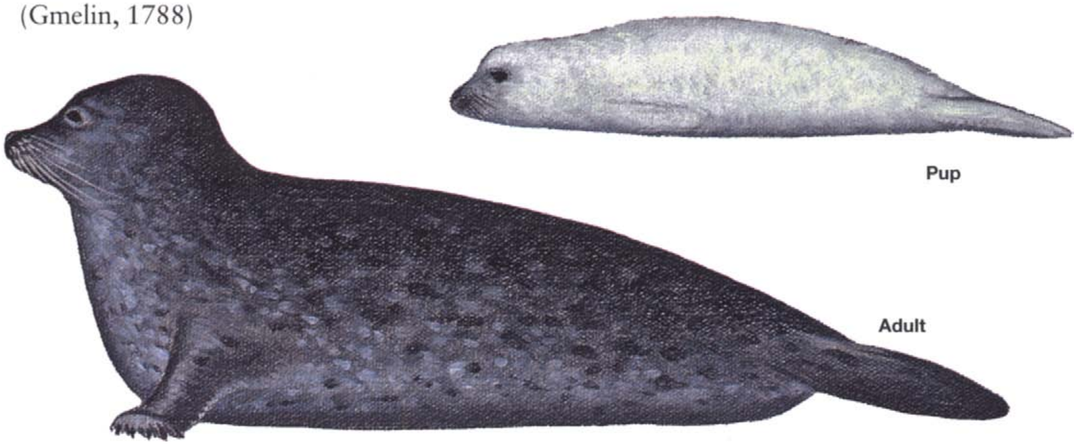
Caspian Seal—*Pusa caspica*

(Gmelin, 1788)



Recently-used synonyms *Phoca caspica*.

Common names En.–Caspian seal; Sp.–*foca del Caspio*; Fr.–*phoque de la Caspienne*.

Taxonomic information Order Carnivora, Family Phocidae. The origin of the Caspian seal is uncertain. Formerly they were thought to be closely related to ringed and Baikal seals, but recent genetic evidence suggests a closer connection to gray seals.

Species characteristics Caspian seals are medium gray to grayish-brown above and paler below in a typical countershaded pattern. There are often yellowish or tan undertones to the coat color. Caspian seals have a highly variable covering of light and dark spots and mottling all over their body. Males are typically more heavily spotted than females. Pups are born in a long white lanugo coat that is molted around weaning, at about 3–4 weeks. The juvenile coat is lightly spotted and more silvery and paler on the ventral surface than the adult pelage.

Caspian seals are relatively short and plump. The head is small in proportion to the body with large conspicuous eyes. The muzzle is relatively long for a small phocid, and has a wide and somewhat flattened appearance, with whitish vibrissae.

The dental formula is I $^{3}/2$, C $^{1}/1$, PC $^{6}/5$.

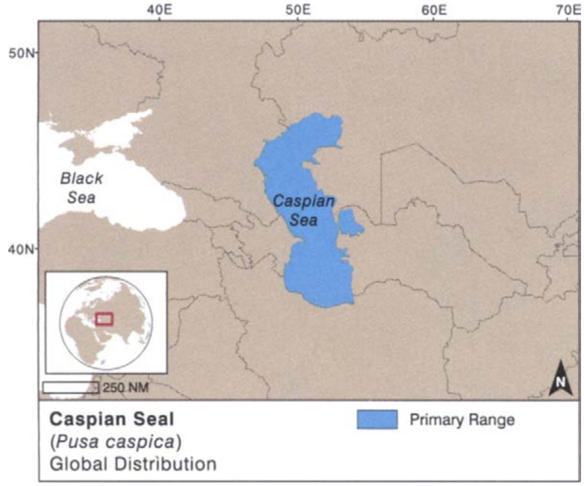
Adult males and females reach maximum lengths of 1.5 and 1.4 m, respectively, and weigh around 86 kg. Pups are 64–79 cm and about 5 kg at birth.

Recognizable geographic forms None.

Can be confused with No other pinniped occurs in the Caspian Sea, and this species occurs nowhere else in the world.

Distribution Caspian seals are entirely confined to the saline waters of the Caspian Sea and its feeder rivers. Seasonal movements of the Caspian seal are prompted by ice formation and foraging opportunities. In the late winter, breeding adults migrate to the northern part of the

The Caspian seal pup (left) is nearly completely molted from lanugo to juvenile pelage. The adult female provides a good view of the long and somewhat flattened muzzle characteristic of this species. PHOTO: S. WILSON



sea, where they haul-out on islands awaiting the formation of the ice. In late January, after the ice has formed, they assemble on the ice for pupping. Following pupping and the ice melt, the breeding seals again haul-out on the islands of the north Caspian, where they undergo their annual molt. After the molt, from late spring, they again disperse to all parts of the Caspian, particularly the deep central and southern basins. Non-breeding adults and juveniles may spend the winter in the central and southern Caspian. A small number of females may pup on Ogurchinsky Island in the southern Caspian.

Ecology and behavior Pups are born on the winter ice-field in the northern Caspian. Most pups are not concealed in snow lairs, but are born and nursed on the ice surface. Females may select the edges of cracks in the ice for pupping, or otherwise give birth amongst the rough mounded ice formations where they create and maintain a network of holes for access to the sea. Pups are weaned in 4–5 weeks, and females mate around this time. Molting follows breeding. Predators include wolves and several species of eagles that prey primarily on pups.

Dive data from two adult males revealed that most dives lasted less than 50 seconds, with some dives extending to over 3 minutes. Depths were typically less than 50 m with a few dives reaching over 200 m.

Feeding and prey Caspian seals take a wide variety of fishes and small crustaceans; the diet varies seasonally. Caspian kilka (sprat), silverside and gobies historically making up much of the diet.

Threats and Status Commercial and subsistence hunting continue to this day. The population probably exceeded one million animals early in the 20th century, and was estimated at 360,000–400,000 in the late 1980s. There have been several large mortality events beginning in the late 1990s and extending to 2001. The mortality in 2000 was attributed to canine distemper virus (morbillivirus), and this, at least initially, affected mainly young animals. A further threat to seal survival is by-catch in fishing nets and deliberate killing by fishermen. There has been considerable industrial development around the shores of the Caspian Sea, and discharge of high levels of many kinds of pollutants from the 20th century to the present time. Accumulation of organochlorine contaminants, including particularly high levels of DDT and derivatives in Caspian seals has been recently reported and it has been suggested that the levels may be high enough to play a role in weakening the immune systems

of these animals and contributing to these disease outbreaks and a reduced reproductive rate in females. Overfishing in this large, but essentially closed, ecosystem is an ongoing concern. An invasive comb jellyfish that is a predator on zooplankton, arrived in the Caspian Sea in 1999. It is believed to be causing a reduction in fish stocks including stocks of kilka, and poses an undetermined threat to the Caspian seal.

IUCN status Near Threatened.

Harp Seal—*Pagophilus groenlandicus*

(Erxleben, 1777)

Pup

"Spotted Harp" Adult

"Old Harp" Adult

Recently-used synonyms *Phoca groenlandica.*

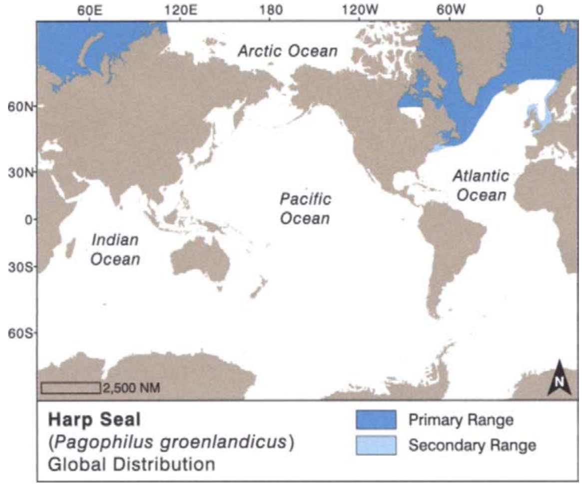
Common names En.–harp seal; Sp.–*foca de Groenlandia*; Fr.–*phoque du Groenland.*

Taxonomic information Order Carnivora, Family Phocidae. Two subspecies are recognized: *P. g. groenlandicus* of the eastern Canadian Arctic and subarctic, east to Jan Mayen, and including waters around Greenland and Iceland, and *P. g. oceanicus* of the White and Barents seas, south to Norway and east to about 110° E in north central Russia.

Species characteristics The harp seal's head appears somewhat long, wide, and flattened. The long muzzle tapers slightly, and in adults, can appear upturned. The eyes are close-set and there is a slight dip to the forehead. The flippers are relatively small. The foreflippers are slightly pointed and angular, with a short row of digit endings; the claws are strong and dark.

The change of pelage patterns over the lifespan of an animal is the most complicated of any pinniped, and in most stages is the species' most distinctive feature. The newborn's pure white coat, which can be stained yellowish for the first few days by amniotic fluid, persists for about 12 days, during which time they are known as "whitecoats". At this stage they are difficult to distinguish from other northern phocids born in a similar lanugo pelage. The "greycoat" and "ragged jacket" stages follow when the underlying juvenile pelage and spotted pattern

A group of mixed-age harp seals, several of which are in an alert posture probably in response to the passing ship. Harp seals will travel and haul-out together outside the breeding season. PHOTO: M. JØRGENSEN



shows through the lanugo, and then appears as the lanugo is molted. From approximately 3 to 4 weeks-old when they have completely molted out of their lanugo coat, through about age 13 to 14 months, harp seals are known as "beaters," at which time they can be countershaded slightly darker gray above and silver-gray below with numerous spots and irregular dark blotches all over the body. At their next molt they initially look about the same, but are then known as "bedlamers". They remain at this stage until a dark harp pattern begins to form on the back and sides and the spots start to disappear. Harp seals with both spots and a harp are known as "spotted harps". Finally, when all spots disappear and the harp and face become black, they are known as "old harps".

The adult pattern is complex and varied. The base color is silvery-white to light gray. Initially the harp pattern of the adult appears as a faint shadow of what it will become, as the seals transition to the "old harp" pattern. It consists of wide and irregular shaped bands with ragged edges starting at the pelvis, that dip down on each side before rising up and connecting over the shoulders. Seen from above, the pattern resembles a large irregular "V" with curving arms. The head of the adult is hooded: the face, chin, upper neck and top of the head are black. This hood also has ragged margins. Black marks may also occur at the insertions of the hindflippers.

The dental formula is I $^{3}/2$, C $^{1}/1$, PC $^{5}/5$.

Adult males are up to 1.9 m in length and average 135 kg in weight, females up to 1.8 m and 120 kg. Pups are born at about 85 cm and almost 10 kg.

Recognizable geographic forms There are 2 recognized subspecies of harp seal: those associated with the western Atlantic and Jan Mayen breeding aggregations, and those that breed in the White Sea. The subspecies were primarily established on the basis of differences in skull morphology. The mean length of both adult males and females from the White Sea subspecies is slightly longer than their counterparts from the Atlantic subspecies (about 8–9 cm), but there is overlap between the populations. Although, there may also be minor differences in the pelage between the two subspecies. Currently, there is no known reliable way to separate the two populations in the field, except by going to whelping grounds for each during the breeding season.

Can be confused with Harp seals in adult pelage are unlikely to be confused with any other animal. The silvery-white body, emblazoned with a conspicuous black harp pattern and hood, is unique. However, the "bedlamer" and "spotted harp" patterns are more generic and pose some possibility for confusion with the harbor, ringed, gray, and hooded seals that share their range. The irregular spots of the "bedlamer" and "spotted harp" phases are generally lower density, and randomly scattered over the entire body. Harbor seals tend to have more spots and markings dorsally than ventrally, and are usually countershaded. Harp seals lack the rings that characterize ringed seals. Hooded and gray

Molted pups and juveniles are called "beaters" because of the way they beat the water when they swim. PHOTO: IFAW/S. COOK

seals are much larger as adults and have distinctive heads with larger or unique features. Hooded seals have a larger head with a wider muzzle at all ages. Young hooded seals are strikingly countershaded dark, bluish-gray above and lighter gray below, and have no spots. Adult hooded seals are large with medium to large irregular spots over the entire body, and dark, sooty faces and foreflippers. Gray seals are also large, heavy-looking animals at all ages with proportionately large heads and a large muzzle that is long and wide, often with a convex bridge. Bearded seals lack spots, have very dense mystacial vibrissae, and have rounded-off ends of their foreflippers.

Distribution Harp seals are widespread in the Arctic and North Atlantic oceans and adjacent areas from Hudson Bay and Baffin Island east to Cape Chelyuskin, Russia. Vagrants reach New York and northern Europe. There are regular appearances of large numbers of animals in the coastal waters of central and northern Norway for feeding. The most famous of the four main breeding aggregations is the "Front," near the Magdalen Islands in the Gulf of St. Lawrence and waters off northeastern Newfoundland and southern Labrador. Harp seals live chiefly in pack ice, but can be found away from it in summer.

Ecology and behavior Harp seals congregate to whelp (pup) on pack ice, where they form huge groups.

A large, adult harp seal in the "old harp" pelage. Note the irregular edge to the black harp-shaped bands. White Sea, Russia. PHOTO: S. V. ZYRIANOV/PINRO

The black-masked faces of "old harps". Gulf of Saint Lawrence, Canada. PHOTO: IFAW/D. WHITE

Harp seals travel in groups at sea and churn the water up like a large school of dolphins, and are often followed by seabirds. Notice that many animals are swimming upside-down. Gulf of Saint Lawrence, Canada. PHOTO: IFAW/S. COOK

Pups are born from late February to mid-March. Mating occurs in the water from mid- to late March. Adult animals follow the ice north and haul-out for periods of time to undergo an annual molt after the breeding season.

Harp seals are migratory and following the breeding season and molt, they follow the ice north in summer to feed in the Arctic. They are very active in the water and sometimes travel in groups that are quite large and can churn the water like fast moving dolphin schools.

Feeding and prey Harp seals feed on a wide variety of crustaceans and fishes, with more than 130 species reported in their diet. Capelin, arctic cod, and polar cod are preferred fishes. Atlantic cod, a mainstay of North Atlantic fisheries and now severely reduced in numbers, makes up a small percentage of the diet. Dive durations averaged 16 minutes, and an maximum dive depth of 370 m was recorded during a study of seals carrying dive recording instruments.

Threats and status Harp seals have been at the center of controversies between environmentalists, sealers and governments for decades. Commercial hunting has been ongoing since the 1600s, with harp seals being particularly sought after when easily reached populations of walrus, gray and harbor seals had been dramatically reduced. Harp seals were harvested for oil, pelts and meat. As recently as 1999, over 460,000 animals were taken in Canada. The population of harp seals in the northwestern North Atlantic was recently estimated at approximately 5.2 million, in the White Sea at 1.5–2 million (1998), and 296,000 in the "West Ice" near Jan Mayen.

Attempts have been made to link harp seals with the demise of the once vast stocks of Atlantic cod, but this species is not an important component of the seal's diet. Despite this fact, efforts are continuously being made to justify reducing numbers of harp seals in response to pressures stemming from this complex fisheries management issue. Overfishing and alteration of marine ecosystems pose an ongoing threat to the health of harp seal populations, as does global warming and changes in sea ice patterns, and accumulation of toxic contaminants in the marine environment.

IUCN status Least Concern.

Ribbon Seal—*Histriophoca fasciata*
(Zimmerman, 1783)

Recently-used synonyms *Phoca fasciata.*

Common names En.–ribbon seal; Sp.–*foca fajada*; Fr.–*phoque a rubans*.

Taxonomic information Order Carnivora, Family Phocidae.

Species characteristics Adult male ribbon seals have the most striking color pattern found on any seal. Adults of both sexes have pale bands of variable width that encircle each foreflipper, the neck and nape, and the pelvic area. The bands have defined edges and vary greatly in width. On some animals, the bands are so wide that they merge. Band color ranges from a shade just paler than the surrounding dark pelage to white. Adult males are black to brownish-black, while females are light to dark brown. The bands are less distinct on females and subadults. Juveniles are plain looking until they are about two years old and lack the dramatic markings that will characterize them as adults. They are gray to brownish after molting the woolly whitish lanugo or birth coat at an age of about five weeks.

Ribbon seals are more slender than other Bering Sea ice seals. The head is small, relatively wide, and flat topped. The forehead is small in profile. The close-set eyes appear large. The muzzle is short, blunt, and slightly tapering. The vibrissae are light-colored, beaded, and fairly prominent. There are long, hooked claws on all digits of the foreflippers. The ends of the foreflippers are weakly pointed with a somewhat longer first or outer digit and successively shorter digits 2–5.

The dental formula is I $^{3}/2$, C $^{1}/1$, PC $^{5}/5$.

The same adult male, partially wet, and in an alert posture. PHOTO: D. WITHROW/NMFS

Adult ribbon seals reach a maximum length of about 1.8 m and weights of 90–148 kg. Pups are approximately 86 cm long and 10.5 kg at birth.

Recognizable geographic forms None.

Can be confused with Four other phocids: ringed, harbor, spotted, and bearded seals share the range of the ribbon seal. Adult ribbon seals have distinctive bands, and have no spots or rings. Juvenile ribbon seals lack bands, are countershaded, and also have no rings or spots. The bearded seal has a much greater density of downward-curving vibrissae than the ribbon seal, and has foreflippers that are rounded on the end.

Distribution Ribbon seal distribution most closely matches that of the spotted seal. They occur in the Seas of Okhotsk and Japan, the western North Pacific, and from the Bering Sea northward through the Chukchi Sea, east to the western Beaufort and west to about 180° longitude.

Three separate populations of ribbon seals have been proposed and include the southern and northern Sea of Okhotsk, and the Bering Sea breeding groups. Ribbon seals inhabit the southern edge of the pack ice from winter to early summer. Most are thought to be pelagic in the Bering Sea during the summer. Records from the North Pacific south of the Aleutians suggest a possibly wider range during the summer when ribbon seals are not associated with sea ice. A stranding from central California is evidence of occasional distant wanderings.

Ecology and behavior Ribbon seals are solitary for much of their lives. Pups are born on ice floes from early April to early May. Broken pack ice is preferred over solid ice sheets and highly concentrated pack ice, as ribbon seals can only open and maintain access holes in ice up to approximately 15 cm thick. Males are generally no-

Front view of the markings on a ribbon seal female with a pup in lanugo. Note the light areas around the eyes. PHOTO: K. FROST

Adult female ribbon seals are tans, grays, and browns with less distinct bands than adult males. PHOTO: L. LOWRY

where to be seen during the nursing period. Ribbon seals are able to move rapidly on ice using slashing side-to-side motions. They also extend their necks to peer at sources of disturbance but are fairly approachable by boat. They are rarely encountered because of the remote and inhospitable nature of their polar habitat.

Feeding and prey Diet varies by area and age of the seal. Ribbon seals in the Okhotsk and Bering seas are known to take 35 different species of fish and invertebrates. Young ribbon seals feed on euphausiids after weaning and until about age one when they switch to feed predominantly on shrimp for a year. As 2-year-olds they take up the adult diet, which includes a variety of fishes, squids, and octopuses. Ribbon seals in the Sea of Okhotsk have a diet that is 65% pollock, while those in the Bering Sea consume about the same percentage of squid and octopuses.

Threats and status The population of ribbon seals is estimated to be 90,000–140,000 in the Bering Sea. Commercial hunting was carried out in the Sea of Okhotsk and Bering Sea from the middle to the late 20th century. Subsistence hunting by Alaskan Natives occurs at low levels in the United States. Global warming, accumulation of contaminants, entanglements in commercial fishing gear and depletion of prey species (such as pollock) in commercial fisheries are all on–going threats and concerns.

IUCN status Least Concern.

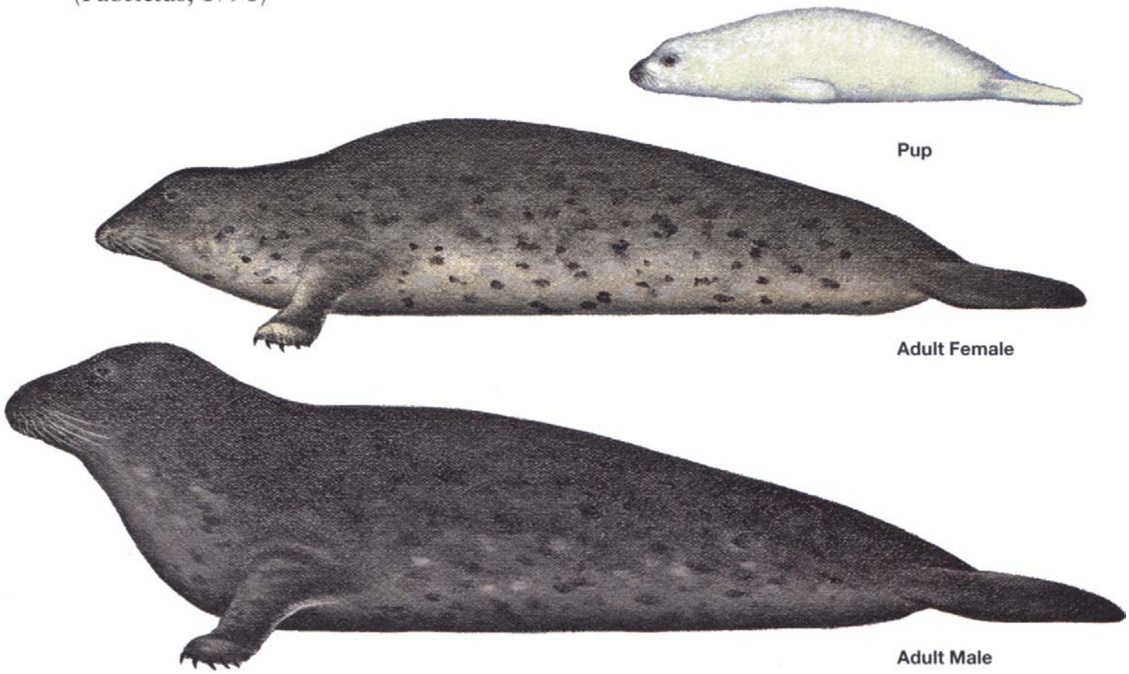
Gray Seal—*Halichoerus grypus*
(Fabricius, 1791)



Recently-used synonyms None.

Common names En.–gray seal, grey seal; Sp. *foca de gris*; Fr.–*phoque gris*.

Taxonomic information Order Carnivora, Family Phocidae. Two subspecies are recognized: *H. g. grypus* from the western North Atlantic east, including Greenland and Iceland, to western Russian, south to the British Isles and France; and *H. g. macrorhynchus* from the Baltic Sea.

Species characteristics Gray seals are robust and sexually dimorphic; males grow substantially larger, with a proportionately larger and broader head and larger muzzle. The most distinctive features are the muzzle and head. The muzzle is particularly long, and wide at the end, with a fleshy mystacial area. In adult males, the top of the muzzle is convex. In adult females and subadults, the top of the muzzle is variable and can be flat, slightly convex (as in adult males), or slightly concave; the last case produces a barely noticeable forehead. The shape of the head has led to the locally-used common name "horsehead". The nostrils are widely-separated and almost parallel to each other, forming a "W" pattern as opposed to the "V" of seals of the genus *Phoca*. The eyes are small in proportion to the size of the head, widely-separated, and due to the length of the muzzle, proportionately farther back from the nose than on other phocids that share the gray seal's range. The foreflippers are short and on adult males, wide and relatively thick. Adult males have a thicker neck than females.

Gray seal bulls generally darken with age. Notice the wide and long muzzle. Sable Island, Canada. PHOTO: R. W. BAIRD

Adult male and female gray seals. The difference in overall size and shape of the muzzle between the sexes is dramatic. PHOTO: G. CRESSWELL

Pelage color and pattern are variable within the sexes and age classes. Most gray seals are shades of gray, tan, or brown, and slightly darker above than below. There are usually numerous irregular dark blotches and spots on the back and sometimes a few below, although some females with very few spots appear to be solid grayish-cream color. Males darken with age, becoming dark brown to blackish, with a variable number of lighter blotches and spots. Orange to reddish coloration can be seen on the neck, undersides, and flippers of some animals. Gray seals appear paler and duller in coloration just prior to the annual molt. Newborns have a silky, creamy-white lanugo, occasionally with a grayish tinge. The lanugo is molted in 2–4 weeks, and is replaced by a pelage like that of the female, but with more subtle markings.

Adult males are up to 2.3 m long and weigh 170–310 kg; females average 2 m and 105–186 kg. Pups are 90–105 cm and 11–20 kg at birth.

The dental formula of adults is I $^3/_2$, C $^1/_1$, PC $^{5-6}/_5$.

Recognizable geographic forms The two subspecies of gray seal cannot be separated in the field, the distinctiveness being in features of the skull. Within the Atlantic subspecies, gray seals in Canada have been shown to be slightly larger than European animals. Other differences also exist between and within subspecies such as timing of birthing, and breeding on shorefast ice versus land. However, none of these differences have been used to separate or establish the two subspecies.

Can be confused with Harbor, ringed, bearded, hooded, and harp seals share the gray seal's range. The gray seal is larger, with a relatively larger head and longer muzzle; it has widely-separated eyes that are set far back from the end of the muzzle. It also has distinctly different pelage markings from the harbor, ringed, bearded, and harp seals. The shape of the head, nose, and muzzle,

placement of the eyes, impart and equine-like appearance. Overall coloration and markings, and head and muzzle size and shape, also facilitate separation of gray seals from similar-sized bearded and hooded seals. Gray seal nostrils are widely separated at the bottom of the nose and do not converge to a "V" shape.

Distribution Gray seals have a cold temperate to subarctic distribution in the North Atlantic. The North Atlantic subspecies has two somewhat isolated stocks: a western Atlantic stock, centered off northeastern North America, with Sable Island off Nova Scotia as an important breeding site, and an eastern Atlantic stock, at Iceland, the Faroe Islands, Norway, the United Kingdom and Ireland. The Baltic subspecies is isolated in the Baltic Sea.

Ecology and behavior Gray seals are polygynous, but males do not defend territories or herd females. They actively compete for access to females using vocalizations, threat gestures, and occasional fighting. Pupping and breeding occur between late September and early March, depending on location. Gray seals breed earliest in the British Isles, followed by those in Norway and Iceland, and finally by those off Canada, and in the Baltic Sea. The single pup is usually attended continuously by its mother and weaned in 15–20 days, at which time many have quadrupled their birth weight of 11–20 kg. After weaning, the pups remain ashore fasting for 2–4 weeks before dispersing to sea and wandering widely.

Many, but not all gray seals disperse from their rookeries during the non-breeding season, but gather again at traditional sites to haul-out for the annual molt. They are usually quite gregarious at haulouts with groups of 100 or more being common, and they will share haul-outs with harbor seals. When ashore, gray seals do not generally lie in contact with each other.

Gray seals spend most of their time in coastal waters. When not in the water they haul-out on isolated beaches and rocky ledges of islands, and will also haul-out and give birth on shore-fast and pack ice. At sea, gray seals are usually solitary, or can be seen in small dispersed groups. They will rest at the surface in a vertical "bottle" position, treading water with only the head and upper neck exposed. The maximum depth and duration of dives is about 300 meters and up to 30 minutes. Most dives are from 1 to 10 minutes, and to 60 meters or less.

Feeding and prey Gray seals feed on a wide variety of benthic and demersal prey in coastal areas. They also feed on schooling fish in the water column; and occasionally take seabirds. Prey species taken include: sand lance, whiting, saury, smelt, various kinds of skates, capelin, lumpfish, pollock, cod, haddock, saithe, plaice, flounder, salmon, and a variety of cephalods and mollusks. Cannibalism by adult males on pups has been reported.

Threats and status At present, the Atlantic gray seal population is healthy and growing, and the worldwide population is estimated at about 380,000. The Baltic Sea population, which once numbered 100,000 is now comprised of approximately 17,600 animals, having never fully recovered from sealing and poaching in the early 20th century. Atlantic gray seals experienced similar hunting pressures during this period, largely because of government-sponsored bounties to hunters. Bounties were established to control gray seal populations that were deemed to damage important commercial fisheries either directly (through feeding) or indirectly (as a vector for seal, or cod worm, a destructive parasite). Prior to bounty and commercial hunting, gray seals were locally important in subsistence harvests throughout the history of their contact with humans.

Some gray seal mortality has also been attributed to distemper virus outbreaks that caused extensive mortality in harbor seals. As a coastal species, gray seals are exposed to, and ingest, industrial and agricultural pollutants through the food chain. This may have an effect on their immune system, other aspects of health, and has been linked to reproductive declines in Baltic animals. Entanglement in fishing nets is another source of mortality. Interestingly, human over-exploitation of North Atlantic sharks may have had the effect of helping gray seal populations grow and recover by increasing survival, particularly of newly weaned pups and juveniles.

IUCN status Endangered (*macrorhynchus* subspecies), Least Concern (*grypus* subspecies).

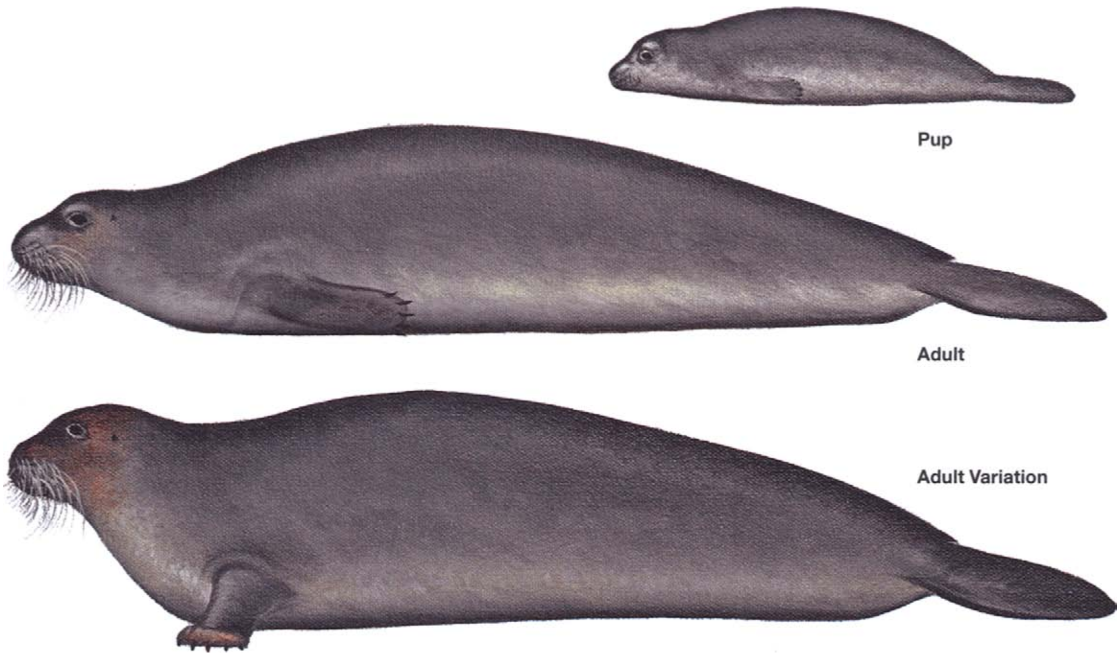
Bearded Seal—*Erignathus barbatus*
(Erxleben, 1777)



Recently-used synonyms None.

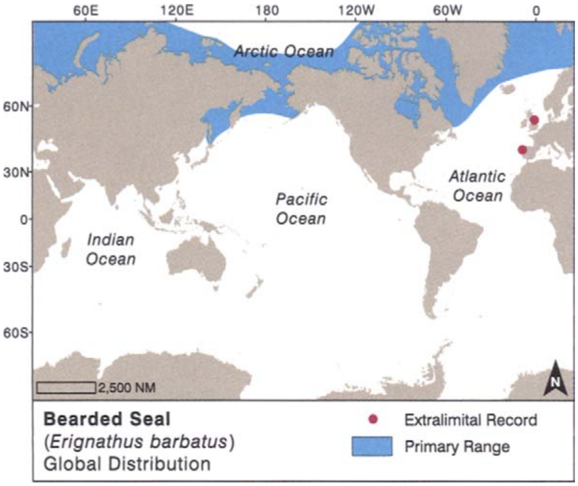
Common names En.–bearded seal; Sp.–*foca barbuda*; Fr.–*phoque barbu*.

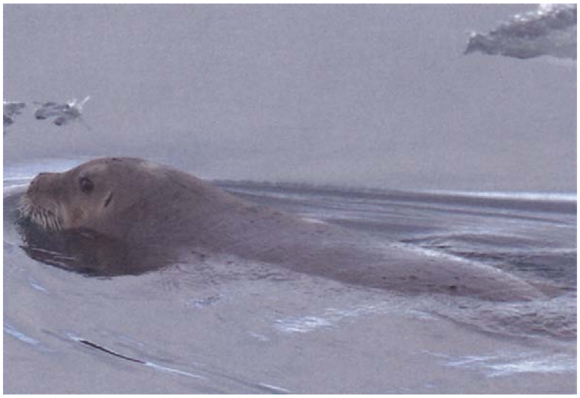
Taxonomic information Order Carnivora, Family Phocidae. Two subspecies are recognized: *E. b. barbatus* from the central Canadian Arctic, east to the central Russian Arctic, including Greenland, Iceland, Jan Mayen, and Svalbard, and south to Norway and Newfoundland, and *E. b. nauticus* from the central Canadian Arctic west, to central Arctic Russia, south to the Karaginsky Gulf, Russia, and Bristol Bay, Alaska, also including the Sea of Okhotsk, south to northern Japan.

Foreflippers with rounded ends are unique to this species. Notice also the rust color on the muzzle of this animal. The rust color can be more conspicuous and cover the head and neck. Svalbard. PHOTO: T. JACOBSEN/POLAR IMAGES

Species characteristics Bearded seals are large phocids with relatively small heads and short, rounded foreflippers. The head is small and somewhat narrow, for the size of the animal, and the eyes are relatively small and close-set. The muzzle is wide and fleshy, with rounded mystacial pads. The vibrissae are sufficiently conspicuous to have given rise to the common name, "bearded" seal. The abundant pale vibrissae are long, curved downwards, densely packed, and smooth, not beaded as in other Arctic phocids. When dry, the vibrissae curl inwards at the tips. The foreflippers are short, relatively broad, and strong, with robust claws. Unlike any other phocid, the bearded seal's foreflippers end in digits of about the same length, or with slightly longer middle digits. The result is a square, or slightly rounded end to the foreflippers. Also, unlike all other Arctic phocids, bearded seals have four retractable mammae instead of two.

Adults are slightly darker above than below. Body coloration varies considerably from light to dark gray, or tawny brown to dark brown. There can be rust coloration on the head, back of the neck and top of the foreflippers. The lanugo is shed in the uterus before birth and pups are born with a somewhat longer, dark brown to dark bluish-gray, wavy coat. There are pale areas on the muzzle, around





Bearded seals have a long, mostly plain body with no contrasting spots or color, a small head, and a relatively short muzzle. Svalbard. PHOTO: M. JØRGENSEN

the eyes, and sometimes on the crown and top of the back. A line of dark color runs from the top of the head between the eyes and along the bridge of the nose.

Adults range up to 2.5 m in length. Adult females are slightly longer than males. In the Bering Sea, males reach 262 kg and females 361 kg. Pups are, on average, about 1.3 m and 33.6 kg at birth.

The dental formula is I $^{3}/2$, C $^{1}/1$, PC $^{5}/5$.

Recognizable geographic forms There are two recognized subspecies of bearded seal whose ranges are given as meeting in central Arctic Canada, and central Arctic Russia. The Pacific subspecies may be slightly longer and heavier than the Atlantic, but the two subspecies are very similar, and no features have been identified that would permit separation in the field.

Can be confused with Bearded seals regularly share their range with seven other Arctic and subarctic phocids, including harbor, spotted, ringed, ribbon, harp, hooded, and gray seals. All of these have either spots, rings, bands, or a combination of these features. In the North Atlantic, the bearded seal is most likely to be mistaken for the similar-sized hooded seal when hauled-out, except when the distinctive coloration of the hooded seal can be seen.

Distribution Bearded seals have a circumpolar distribution in the Arctic, generally south of 80° N. They are subarctic in some areas, such as the lower Bering Sea, Sea of Okhotsk to northern Japan, and western North Atlantic, where they reach the Gulf of St. Lawrence.

Ecology and behavior Pups are born in the open on the surface of the pack ice, from mid-March to early May. After the breeding season, many seals migrate northward with the retreating ice, returning south again as the ice advances in fall and winter.

Bearded seals are solitary and rarely haul-out on the same ice floe together, and even then, maintain healthy distances from neighbors. Mother and pup pairs are an exception to this rule. At times, bearded seals seem to concentrate in an area, but this may be due to shifting winds and currents driving ice floes together or because of favorable feeding opportunities. Bearded seals are exceptionally wary and always haul-out and position themselves with their head very close to the water at the edge of an ice floe, along a crack, or by a hole.

In the water, bearded seals can be found “bottling,” or floating vertically, head-up, asleep. When startled, they bolt into the water and swim with strong strokes of the foreflippers with the head held up in a manner that looks like they are rising and surging through the surface of the

Adult bearded seals are often found alone, and when hauled-out with others, are usually spaced well apart. PHOTO: Y. WATANABE

water. When in the water and disturbed by a passing ship, bearded seals will roll steeply forward to dive, raise the lower back and hindflippers in the air and slap the flippers on the surface. This is often done repeatedly as the seal swims away from the direction the ship is traveling.

They usually restrict themselves to areas of sea ice and stay in relatively shallow continental shelf areas of continuously moving ice, where open leads and polynyas regularly form. In some areas, they are known to haul-out on shore, ascend streams, or live a pelagic existence away from ice and land for long periods of time.

Bearded seals primarily feed on or near the bottom, and live in shallow areas overlying the continental shelf. They generally dive to depths of 200 m or less and frequently are found in much shallower areas. The longest dives recorded have been 20–25 minutes, with most dives lasting less than 10 minutes. They are quite vocal in the water and are known for their oscillating frequency-modulated songs that can last more than a minute and be heard in air, and for long distances underwater. Singing has largely been attributed to males, but it is likely that females sing as well. Besides humans, predators include polar bears, killer whales and Greenland sharks.

Feeding and prey Bearded seals feed on a large diversity of demersal fish species and invertebrates that live on and in the bottom. Different combinations of prey dominate feeding at different times of year and in different locations, and juveniles and adults have different prey preferences. In the Bering and Chukchi seas fishes taken include capelin, Arctic and saffron cod, long-snouted pricklebacks, sculpins, flatfishes, several snailfish species, and eelpouts. Invertebrates were dominated by several species each of crabs, clams, snails, amphipods, shrimps, marine worms, and octopuses.

Threats and status Native peoples of the Arctic have hunted bearded seals for subsistence for thousands of years. This practice continues to the present, with several thousand being taken annually throughout their circumpolar Arctic range. Bearded seals provide numerous products, including food for humans and sled dogs, oil for lamps, skins for clothing, boats and tent coverings, and leather for sinews, to name a few, and they are valuable in many other culturally important ways. The worldwide population is estimated at 450,000–500,000 with more than half of these thought to live in the Bering and

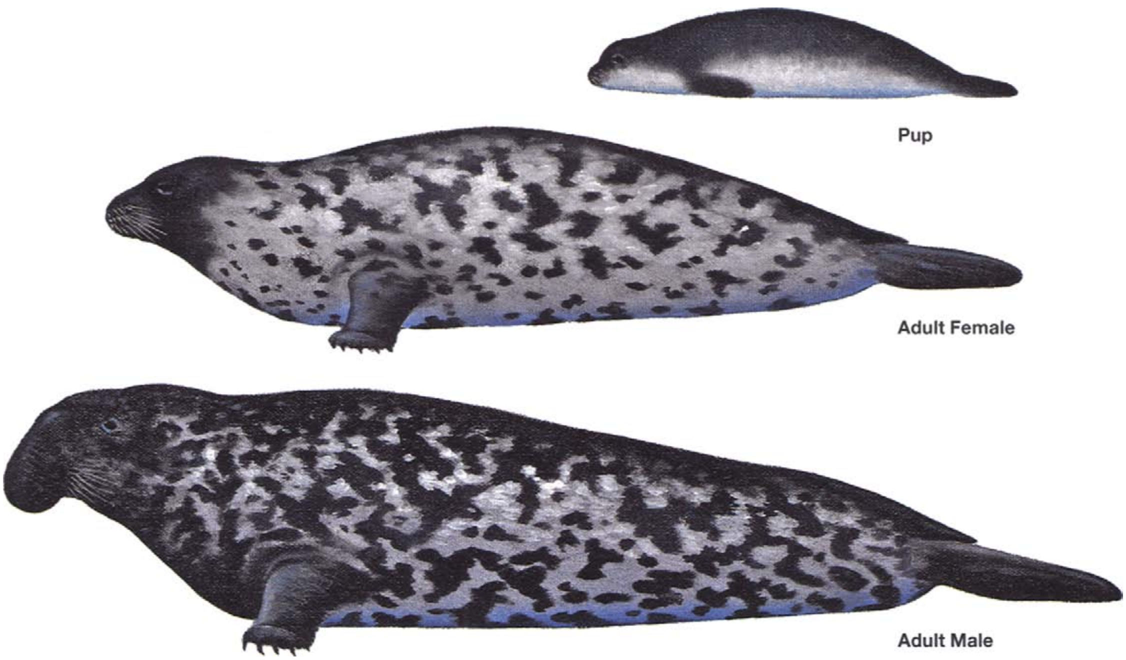
Hooded Seal—*Cystophora cristata*
(Erxleben, 1777)



Recently-used synonyms None.

Common names En.–hooded seal; Sp.–*foca capuchina*; Fr.–*phoque a crete*.

Taxonomic information Order Carnivora, Family Phocidae.

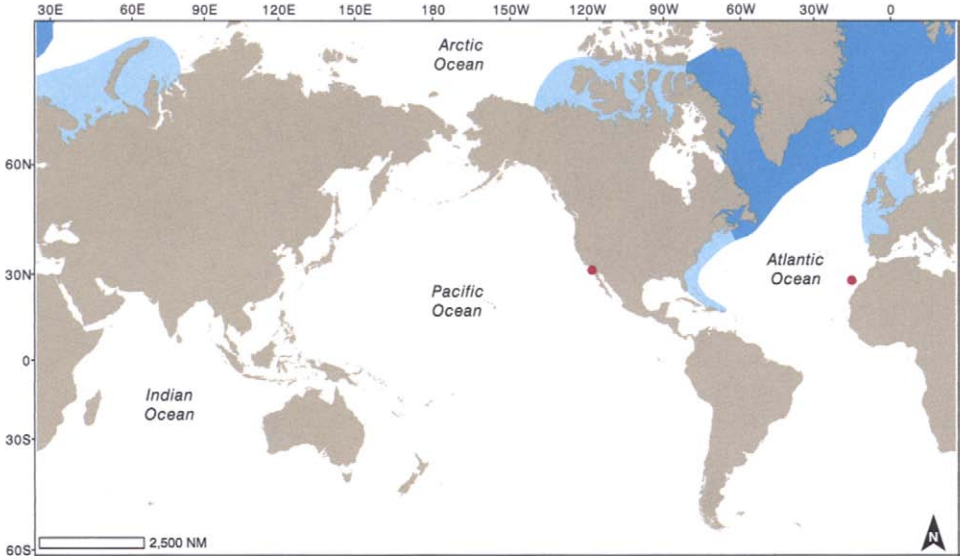
Species characteristics Hooded seals are large, sexually-dimorphic phocids. The muzzle is wide and droops slightly, overhanging the mouth in adult females and subadults. In adult males, there is an inflatable nasal cavity in the form of a black bladder. When flaccid, it hangs down in front of the mouth; when inflated, it forms a taught, bi-lobed, crescent-shaped hood that almost doubles the size of the head and substantially elevates the profile. Another secondary sexual characteristic of male hooded seals is that after partially inflating the hood they can close a nostril and extrude the elastic bright red nasal septum from the other nostril and inflate it like a balloon.

The flippers are relatively short, slightly pointed and angular, with a longer first digit. The vibrissae are beaded, relatively short, and inconspicuous; they are dark in pups and light in adults. Hooded seals have two mammae, typical of most northern phocids

Adults are silvery white, with numerous, small to large, irregularly shaped, dark blotches and clusters of blotches. The head to behind the eyes and jaws, and the tops of the flippers are blackish.

Pups, called "blue-backs", are born in a handsome coat of dark blue-gray above and creamy white below. The dark color continues onto the hindflippers and also extends downward to include the foreflippers. The face and muzzle are very dark, with almost black coloration extending behind the eyes. The pale color rises high on the flanks and neck, and encompasses the lower jaw. Blue-backs retain their coat until the following summer, when they molt at 14 months and start to develop adult markings as juveniles.

A hooded seal female and her blue-back pup in the foreground. In the backround notice the adult male with black hood inflated for display. PHOTO: IFAW/D. WHITE



Hooded Seal
(*Cystophora cristata*)
Global Distribution

Adult males reach lengths of 2.6 m and weights of 192–352 kg; females average about 2 m in length and weigh 145–300 kg. Pups are born at 87–115 cm and weigh 20–30 kg.

The dental formula is I $^{2}/1$, C $^{1}/1$, PC $^{5}/5$.

Recognizable geographic forms None.

Can be confused with Hooded seals share their range with five other phocids. Harp, harbor, ringed, bearded, and gray seals can be distinguished by pelage color, and head shape and size. Harp seals are smaller and uniquely marked. Bearded seals have no dark blotches, are larger, have a small head, densely-packed, downward-pointing, smooth vibrissae, and four mammae. Gray seals can have similar blotches but have a very different size and shape to their head and muzzle.

Distribution Hooded seals are found in the Arctic Ocean, and in high latitudes of the North Atlantic. They breed on pack ice and are associated with it for most of their lives, shifting their distribution with seasonal fluctuations. There are four major whelping or pupping areas: the Gulf of St. Lawrence, north of Newfoundland and east of Labrador, in the Davis Strait, and near Jan Mayen. Hooded seals can wander widely, and animals have beached as far south as Portugal in Europe, and from New England to Florida in North America. An exceptional journey was made by an animal found in Southern California. Presumably, it crossed the Canadian Arctic and Beaufort Sea, and then traveled down the Bering Sea and North Pacific to San Diego where it beached.

Ecology and behavior Hooded seals pup away from floe edges, on pack ice in March and early April. Females

A "blue-back" hooded seal weaned pup. Note the short, wide, dark face. Cape Cod. PHOTO: CAPE COD STRANDING NETWORK

are usually widely-separated and aggressively defend their pups. Remarkably, pups are weaned in an average of only four days, the shortest time for any mammal. Males are territorial and patrol the ice edge, often hauling-out near females and forming trios. Bulls actively fight among themselves, and can inflict bloody wounds; they routinely display by inflating their black nasal bladders and extruding their nasal septum, shaking this bright red "balloon" violently in efforts to ward off competing males. They also vocalize at the same time, producing a loud "pinging" noise. Mating follows weaning of the pup.

The pack ice edge is home to hooded seals throughout the year and they migrate with it as it retreats north in summer and advances south in the fall. Aggregations form in the Denmark Strait east of Greenland and near Jan Mayen during the late spring molt, which begins after the pupping season. Following the molt, they disperse widely for the summer and winter, primarily living along the ice edge.

Hooded seals are deep divers and are capable of long dives. The maximum-recorded depth reached is over 1,000 m and the longest dive has been nearly one hour. Typical dives while foraging are to depths of 100–600 m and last around 15 minutes. Polar bears and killer whales are known hooded seal predators.

Feeding and prey Hooded seals typically fast during breeding and molting, but actively feed during much of the rest of the year. Their diet consists primarily of squids and fishes such as Greenland halibut, Atlantic and Arctic cod, several redfish species, herring, and capelin. Newly weaned pups feed on pelagic crustaceans prior to taking on the adult diet.

Threats and status The current worldwide population of hooded seals is estimated at 450,000–550,000. They were subjected to episodes of intense commercial hunting from the late 1800s to the late 1900s. Harvests were often conducted in association with harp seal harvests and commercial fisheries for Greenland sharks. Norway, the Soviet Union, Canada, and Greenland have been principally involved in the commercial harvests, which were primarily focused on newborns, because of their highly prized "blue-back" pelt. A permanent import ban on hooded seal pelts by the European Economic Community ended most of the commercial harvesting of this species, although Canada took approximately 26,000 as recently as 1996. The number of "takes" is presumed to have been higher than the reported number harvested due to the killing of females that aggressively defend their pups, and the loss of animals that are injured and escape to the water, only to die later.

There is a large annual by-catch of hooded seals in coastal net fisheries in Norway. Hooded seals are important in subsistence harvests on both coasts of central and southern Greenland, where they are used for food for humans and sled dogs.

IUCN status Least Concern.

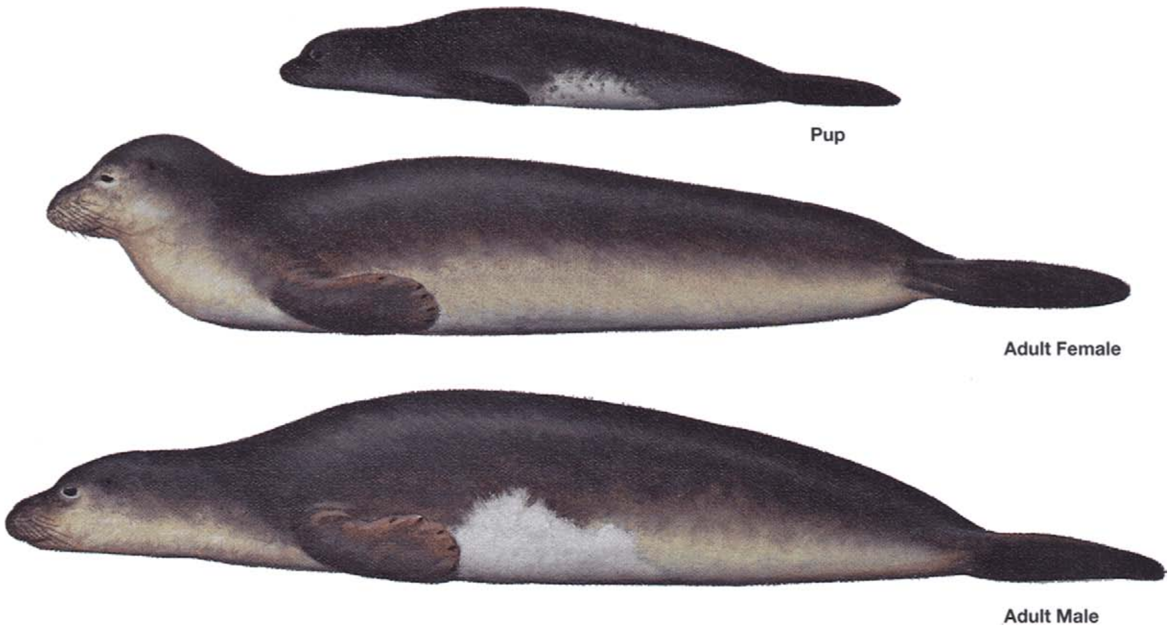
Mediterranean Monk Seal—*Monachus monachus*
(Hermann, 1779)



Recently-used synonyms None.

Common names En.–Mediterranean monk seal; Sp.–*foca monje del Mediterráneo*; Fr.–*phoque moine de Méditerranée*.

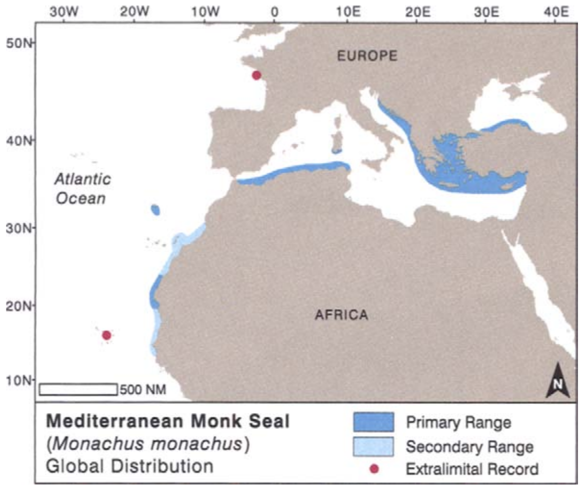
Taxonomic information Order Carnivora, Family Phocidae.

Species characteristics Adults are robust, with short flippers, a long fusiform body, and a moderately-sized head. The head and muzzle are somewhat flat and wide, with the eyes spaced widely apart. The mystacial pads are large, fleshy, and extend beyond the nostrils. The nostrils are in a sub-terminal position, pointed up, rather than in a terminal position facing forward, as is typical of most northern hemisphere phocids. The vibrissae of Mediterranean monk seals are smooth and not beaded.

Coloration is variable, with differences existing between adult males and females and between age classes. Variation also occurs within each age class, and has been proposed to be present between the now-isolated sub-populations. Adult males are dark brown to black over most of the body. they retain a pale area on the throat and upper neck. The back and hindflippers are frequently patterned with pale scratches and speckles which are scars from healed bite wounds from other seals. They can also have a concentrated, scratched area on the nape. The pale belly patch on the abdomen rises up as a wedge on both sides about half way to the top of the back.

Most adult females are brownish-gray to dark gray above and paler below, the colors separated by either a gradual blending or a sharp demarcation. The dark coloration is made paler by light tips to the hairs. Female

An adult female with a pup less than two months old. This female has a "hood" of dark coloration and a light "mask" around the eyes. The pup is in its lanugo coat. Cabo Blanco, Morocco/Mauritania. PHOTO: M. CEDENILLA/CBD-HABITAT



coloration is highly variable. They have a hood of darker color on the head. This "frontal hood" stops above the eyes but can have an extension down the muzzle to the nose creating a "pale mask" around the eyes. If the hood extends down the side of the head beyond the ear openings, it is called a "lateral hood". The lumbar area can have a pale, irregular "sash" from a concentration of scratches and scars, and localized depigmentation. They frequently have pale scratches on the back which are scars from bite wounds from other seals.

Juveniles and subadults can be a range of gray and brown tones above, and off-white to light gray below.

Pups are born in a brownish-black, woolly lanugo coat that is molted at 6–7 weeks to a juvenile color pattern. This pattern is comprised of a mixture of weakly developed countershaded coloration features and pup markings. Most pups have a large, irregular, light gray, ventral patch on the abdomen that can rise up on the sides at mid-abdomen, well behind the foreflippers. The pale ventral patch disappears at the second molt from youngster to juvenile pelage at about 7–9 months, when the animals essentially become fully countershaded. Interestingly, this belly patch reappears, later in life, on adult males.

Animals from the eastern Mediterranean are generally darker than those found in the Atlantic Ocean. Little is known about the adult and subadult molts; however, the related Hawaiian monk seal is known for its dramatic epidermal molt, in which hair is shed attached to layers of skin.

Adults are up to 2.8 m in length, and weigh 250–400 kg. In contrast to the Hawaiian monk seal, Mediterranean monk seal males may grow to be slightly heavier and longer than females. Newborns are 80–120 cm and 15–26 kg.

The dental formula is I $^{2}/_{2}$, C $^{1}/_{1}$, PC $^{5}/_{5}$.

Recognizable geographic forms
None.

Can be confused with Mediterranean monk seals do not regularly share their range with any other pinniped. The nearest occurring species are eastern Atlantic Ocean populations of the more northerly distributed harbor and gray seals. As vagrants, these species, along with wandering hooded and bearded seals from the Arctic, have occurred in the Mediterranean monk seal's range. Mediterranean monk seals can be

readily distinguished from harbor, gray, and adult hooded seals by the lack of spots or blotches covering most or all of their body, distinctively wide and somewhat flattened head and muzzle, sub-terminal, upward-facing nostrils, smooth vibrissae, and four mammae.

Like Mediterranean monk seals, bearded seals have few to no spots, and share smooth vibrissae and four abdominal mammae as features in common with Mediterranean monk seals. However, bearded seals have a proportionately smaller head with much more densely packed, longer, and predominantly downward pointing vibrissae. The short, rounded foreflipper with a short first digit is also unique to the bearded seal and gives the end of the flipper a rounded edge. Mediterranean monk seals have typically proportioned foreflippers, with the first digit longer than all other digits.

Distribution Mediterranean monk seals are widely-distributed in the Mediterranean Sea, as well as the Aegean, Ionian, and Black seas, and the Sea of Marmara. Historically, they occurred nearly continuously throughout the region, but now are only found in small remnant aggregations. They occur in the eastern North Atlantic from the Strait of Gibraltar south and west to Mauritania at 19° N, with wanderers reaching Dakar, Senegal, at 15° N. They are offshore at Desertas Island in the Madeira Island group.

Although Mediterranean monk seals can still be seen on occasion throughout much of their former range, this is becoming increasingly rare. On land, they choose rocky coastlines, with a preference for sea caves and grottos that are generally inaccessible from land approaches, and sometimes have only submarine entrances. In West Africa, they will come ashore on open beaches.

Ecology and behavior This seal is considered non-migratory, with individuals spending most of their time within a very limited home range. They make extensive use of grottos and sea caves for hauling-out and breeding. The single pups are born across an extended pupping season that can last from May through at least November, and possibly January, with an October peak, but some authors speculate that pupping could occur year-round. Females are on an 11-month cycle of copulation to birth, and then wean their pups at 4 months, but can allow offspring to stay with them up to 4 years.

Mediterranean monk seals are among the least social of pinnipeds when ashore; they are presumed to be

Mother with a pup older than two months that has molted into the juvenile pelage. Note the scars on the back of the female and the "frontal hood" and pale face "mask" on both animals. Cabo Blanco. Morocco/Mauritania. PHOTO: M. CEDENILLA/ CBD-HABITAT

Two juveniles and a subadult Mediterranean monk seal. All have a pale "mask" and a "frontal hood" with dark color extending down the bridge of the nose and onto the muzzle. The subadult has extensive scarring on the back. Cabo Blanco. Morocco/Mauritania. PHOTO: M. CEDENILLA/CBD-HABITAT

most socially active in the water, where the only copulation ever witnessed was seen. Little information is available on diving, but most dives are thought to be shallow, less than 70 m, and short, less than 10 minutes in duration.

Feeding and prey The diet consists of a large variety of coastal fishes, octopus, and at least one type of ray. Large fish that cannot be swallowed whole are brought to the surface and shaken apart.

Threats and Status The Mediterranean monk seal is the most endangered pinniped species, with an estimated population of 350–450 animals. This small population is widely-scattered in isolated subpopulations from the North Atlantic to the eastern Mediterranean and Black seas, most of which are reproductively isolated from one another. There is a high risk of inbreeding depression and low genetic variability in these sub-populations, resulting from the species being so widely-distributed in small breeding groups.

The Mediterranean and Black seas, and adjacent North Atlantic are heavily fished. In many areas, monk seals are viewed as a pest species, and competitors for fish, and in some instances have been shot. They are also susceptible to entanglement in fishing nets, marine debris and discarded and lost nets and line. Human disturbance of animals at haulout sites and in foraging areas could also contribute to lower reproductive success. An outbreak of a phytoplankton-based paralytic toxin was the probable cause of a large-scale die-off in a colony along the Western Sahara coast. A morbillivirus may also have been a factor in this mortality event.

IUCN status Critically Endangered.

Hawaiian Monk Seal—*Monachus schauinslandi*

Matschie, 1905

Pup

Adult Female

Adult Male

Recently-used synonyms None.

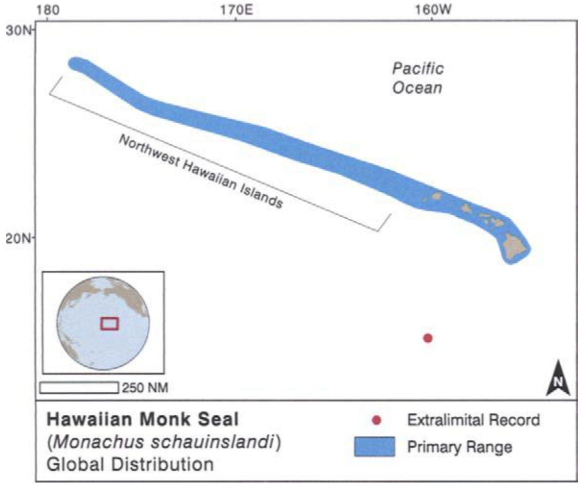
Common names En.–Hawaiian monk seal; Sp.–*foca monje del Hawaii*; Fr.–*phoque moine d'Hawai*.

Taxonomic information Order Carnivora, Family Phocidae.

Species characteristics In Hawaiian monk seals, females grow slightly longer, and are heavier than males. The long, fusiform body is robust, with relatively short fore- and hindflippers. The relatively small head is wide and somewhat flat, and the eyes are spaced fairly widely apart. The muzzle is also wide, "U" shaped, and somewhat flattened. The mystacial pads are large and fleshy, extending beyond the nostrils. The nostrils are in a sub-terminal position, pointed up, rather than in a terminal position facing forward, as is typical of most northern hemisphere phocids. The vibrissae of Hawaiian monk seals are smooth and not beaded. Hawaiian monk seal vibrissae vary from short to moderately long, and are black at the base, often having lighter yellowish-white tips. There can be a scattering of all-light vibrissae throughout. There are four functional mammae.

Just following the annual molt, most females and subadults are silvery to slate gray above, fading to cream or light silver gray below. During the course of the 11–12 months between molts the coat fades to dull brownish above and yellowish-tan below. Males and some females become completely dark brown to blackish as they age. There can be a variable amount of highlighting on the mystacial area and on both the upper and lower lips. Adults and juveniles can have a greenish cast from algal growth. Pups are born in a black woolly coat, which is molted completely by about 6 weeks. The first molt from the lanugo coat is a shedding of individual hairs, but each successive annual molt is a more dramatic epidermal

An adult male Hawaiian monk seal approaching a female from the water. Note the wide U-shaped muzzle of both animals. PHOTO: B. BECKER/NMFS



A healthy Hawaiian monk seal juvenile. Juveniles are grayish and somewhat countershaded. Monk seals have smooth black vibrissae. PHOTO: B. BECKER/NMFS

molt of hair and skin, which detaches in patches. Many animals have pale birthmarks that take the form of smallish irregular patches, which look like pale bleached areas on the darker pelage, and can occur anywhere on the body. If the pale bleached areas occur on the ends of flippers, the nails in those areas can be whitish.

Adults and some subadults have varying amounts of scars, particularly on the back and neck. Males can be heavily scarred on the lower jaw and neck, and some adult females become severely injured when mobbed by males attempting to mate with them. These injuries can include massive gashes and skin on the back torn away, that when healed develop into long, jagged, irregular scars. Injuries and scars from shark attacks are also regularly seen and include oval and semi-circular scars from tearing wounds and wounds formed by the penetration of individual teeth in rows.

Adult male Hawaiian monk seals reach lengths of about 2.1 m, and females reach lengths of about 2.4 m. Males weigh an average of 172 kg, and females weigh up to 272 kg. Pups are about 1 m and weigh about 16–18 kg at birth.

The dental formula is I $^{2}/2$, C $^{1}/1$, PC $^{5}/5$.

Recognizable geographic forms None.

Can be confused with No other pinnipeds regularly occur within the tropical and subtropical central North Pacific habitat of this seal. However, a northern elephant seal has been recorded at Midway Island. Adult northern elephant seals are much larger than Hawaiian monk seals, and only juveniles and small subadults could be confused with monk seals. The large body size and more rounded shape of the larger head and muzzle of northern elephant seals are diagnostic. Additionally, elephant seal nostrils are terminal and forward facing, and female northern elephant seals have only two abdominal mammae.

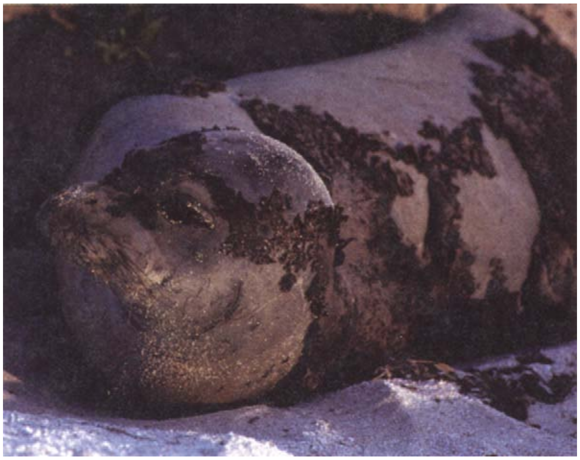
Many young monk seals are emaciated and juvenile mortality rates are up at some sites. PHOTO: B. BECKER/NMFS

Distribution Hawaiian monk seals are distributed throughout the northwestern chain of Hawaiian Islands from Nihoa Island to Kure Atoll. They are also now regularly seen on all of the main Hawaiian Islands, but particularly on Kauai. Some adult males involved in mobbing incidents with females have been translocated to the main Hawaiian Islands and Johnston Atoll, about 1,000 km south of the Hawaiian Archipelago. Hawaiian monk seals are considered non-migratory, and most are typically faithful to their atoll or island of birth. However, small numbers do relocate temporarily or permanently to nearby sites in the island chain. Long distance wanderers have been recorded at Palmyra Atoll and Wake Island.

Ecology and behavior On land, Hawaiian monk seals haul-out and breed on beaches of sand and coral rubble, and on rocky terraces. They sometimes leave the beach if vegetation is available for shade. The long breeding season lasts from late December to mid-August, although most pups are born between March and June. Males in this polygynous species patrol the water adjacent to rookeries, or haul-out beside females with pups. There are up to three times more breeding-age males than females at some colonies; this contributes to mobbing of estrous females, which are often severely injured and killed in these incidents.

When approached by another seal or human on land, Hawaiian monk seals often roll to present their underside to the intruder, arch their back, raise a flipper in the air, and open their mouth. They are generally solitary, both on land and at sea. Even when seals gather together on land, they are not generally gregarious and only mothers and pups regularly make physical contact.

Evidence suggests that foraging activities and prey preferences can vary considerably by location, age and sex of the seal, and season. They are known to forage diurnally and nocturnally in the shallow waters surrounding islands and sea mounts, and within atolls. Their movements and habitat at sea are not well known, but recent work with satellite tags, dive recorders, and video camera tags, or "critter cams", on adult and subadult males has shown that at French Frigate Shoals they frequently venture far offshore to deep, outer slopes of islands and reefs, and to neighboring seamounts and banks, where they appear to feed on the bottom. They also travel to deep ocean areas, also presumably to forage. In contrast, seals at Pearl and Hermes Reef forage almost entirely within or around this atoll. Most dives that have been



Hawaiian monk seals go through a dramatic epidermal molt once a year. Molting seals are frequently seen resting on beaches until the molt is mostly finished. PHOTO: B. BECKER/NMFS

recorded have been relatively shallow ones of 100 meters or less, with a record of one subadult male diving to at least 500 meters, which was the maximum the device could record.

Feeding and prey Hawaiian monk seals consume over 40 species of prey. Species from many families of reef fish, octopus, squid and crustaceans have been identified from analysis of scats and spews collected from beaches. Some of the most common varieties were various representatives of the fish families Labridae, Holocentridae, Balistidae, and Scaridae, and many varieties of eels. Some of the octopus and squid species taken are found over reef environments, while others are from offshore and pelagic midwater habitats.

Threats and status Unlike the situation for the Mediterranean monk seal, the vast majority of Hawaiian monk seals live in protected areas, isolated from most direct human contact. Despite this, and as a direct result of 19th and early 20th century exploitation, the species is critically endangered, numbering about 1,400 animals. Recovery of the species has been affected to an unknown degree by military activities such as development and occupation of bases on several islands, and dumping of waste that started before World War II. Also, development of several fisheries in Northwestern Hawaiian Island waters has led to conflicts from entanglements and animals returning to haulouts with long-line hooks in their mouths. The effect of these fisheries on the ecosystem and prey of monk seals is poorly known and hotly debated.

Marine debris, particularly lost and discarded fishing gear, has been shown to be a significant source of mortality for monk seals. Efforts have been underway to remove this debris from breeding beaches for many years, and more recently from waters surrounding these sites. Large predatory shark species regularly occur at, and seasonally congregate in large numbers in the Northwestern Hawaiian Islands, to prey upon fledgling albatrosses, as well as seals. While the role of shark predation is not completely understood, actions have been taken to reduce shark numbers around certain monk seal breeding beaches in order to reduce mortality on newborn and juvenile seals.

IUCN status Endangered.

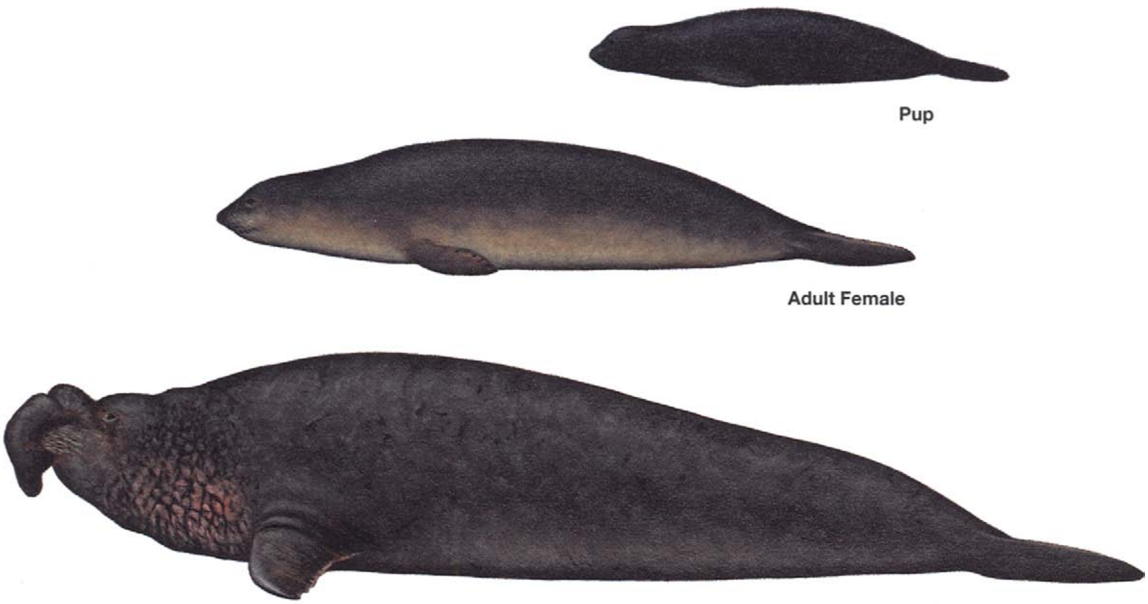
Northern Elephant Seal —*Mirounga angustirostris*
(Gill, 1866)



Recently-used synonyms None.

Common names En.–northern elephant seal; Sp.–*foca elephante del norte*; Fr.–*elephant de mer boréal*.

Taxonomic information Order Carnivora, Family Phocidae.

Species characteristics Northern elephant seals are huge and imposing. Significant sexual dimorphism exists in size and secondary sexual characteristics. In both sexes, the body is long and robust, and the neck very thick. The eyes are large, widely-spaced, and have a forward orientation that is especially noticeable in females and younger animals. The vibrissae are beaded, short to medium length, and black. In addition to the mystacial clusters, there are one to two rhinal vibrissae on the bridge of the nose, and several in prominent supra-orbital patches above and slightly behind each eye. Each foreflipper digit bears a large blackish-brown nail. The nails on the hindflippers rarely emerge, but there is a vestigial nail beneath a small opening located above the end of each hindflipper digit.

In females, young subadult males, and juveniles the head, muzzle, and lower jaw are all proportionately large and conspicuously broad. The mystacial area and nose are thick, full, and rounded across the top and on the sides. In profile, the bridge of the nose forms an arc ending in the terminally placed nostrils, and there is a downward droop to the end of the nose.

Adult males are unmistakable because of their great size, heavily scarred and cornified chest and neck, and large inflatable fleshy nose, called a proboscis. When

Northern elephant seal bulls are unmistakable. This is a large fully grown animal with a well-developed cornified chest "shield" and a long proboscis that droops into his mouth as he vocalizes. PHOTO: P. COLLA/OCEANLIGHT

(Mirounga angustirostris)
Global Distribution

Extralimital Record
Primary Range
Secondary Range

relaxed, the proboscis hangs down in front of the mouth and resembles a shortened elephant trunk, thus the species' common name. The chest shield is made up of thickened, creased, hardened, nearly hairless skin, and accumulated scars. The chest shield and neck become increasingly pink over a large area as the male ages. In old bulls the chest shield can completely ring the neck. Fighting, which occurs when bulls are ashore during the breeding season, adds more red coloration from raw open wounds and patches of dry crusted blood caked on the shield. Wounds and scars accumulate all over the back, sides, and head of males during their lives, and as these heal, the scars become tan to lighter gray on the darker pelage. The proboscis can be bloody and ragged from fighting, and is also often pink and scarred. As subadult males grow, their proboscis lengthens so that it may extend 15–25 cm below the lower lip. A male ashore, asleep on his chest and chin, is readily identified as an older bull when his proboscis is long enough to touch the ground and be bent under or off to the side. In addition to their much longer and larger body size, males also have larger canines that are both considerably longer and thicker than those of adult females.

Northern elephant seal coloration varies from uniformly dark charcoal gray or dark brown to light gray or tan, with coloration fading as time progresses from the end of the last annual molt. With the exception of adult males, most northern elephant seals are lightly to moderately countershaded, being darker above and paler below. Adult males are typically dark brown to charcoal overall, with the already-noted coloration of chest shield, neck, proboscis and body scarring. Northern elephant seals are multicolored and ragged looking during their annual molt, when they shed their fur and epidermis together in patches, starting in the axillary region and progressing around the body. During this time they have varying amounts of darker more richly-colored new fur appearing as the faded duller fur is lost.

An adult male northern elephant seal with a long proboscis. San Benitos Islands, Mexico. PHOTO: M. WEBBER

Pups are born in a long woolly black lanugo coat that is shed without the epidermis starting at about 3 weeks and usually lasting several weeks until after the pup is weaned. After molting, the newly-weaned juvenile's coat is made up of short hairs like those found on adults, and it is countershaded dark gray above and silver gray below.

Sexual dimorphism is significant in this species, with males being three to four times heavier, and nearly 1.5 times the length of adult females. Adult males reach 4.2 m in length and a maximum weight of 2,500 kg. Mean length is 3.8 m and mean weight is 1,844 kg. Maximum weight is seen when the bulls are newly arrived for the breeding season after a summer and fall largely spent feeding. The mean length of adult females is 2.7 m, and they can reach a length of 2.8 m.

Mean mass is 488 kg, with a maximum recorded of 710 kg, both values are from shortly after females give birth. Newborn pups are about 1.2 m long and weigh 30–40 kg.

Body weight declines dramatically due to the demands of fasting during the breeding season. Adult females can lose almost half their mass during lactation, when they take their single pup from birth to weaning in approximately 28 days during which time it can more than quadruple its birth weight. The situation is similar for breeding males, which also lose about half their mass while ashore for periods that may exceed 90 days.

The dental formula is: I $^{2}/_{1}$, C $^{1}/_{1}$, PC $^{5}/_{5}$.

Adult male and female northern elephant seals. The male has a heavily-cornified chest shield that wraps around the back of the neck, a heavily-scarred proboscis, and pale coloration on the head and around the eyes. PHOTO: T. A. JEFFERSON

Recognizable geographic forms None.

Can be confused with The great size of northern elephant seal bulls makes them unmistakable. The massive head and the large fleshy proboscis are unique features. Only one other phocid, the harbor seal, regularly shares the range of the northern elephant seal, and it is much smaller, being only as large as a juvenile northern elephant seal and has a spotted coat. Even female and subadult male elephant seals can be distinguished from other vagrant seals within their range by a combination of features including: large body size, large size and shape of the head and muzzle, pelage coloration and the lack of spots, blotches or bands. The prominent, all-black, vibrissae, and the large eyes are also distinctive.

Molting subadult male northern elephant seals. San Miguel Island, California. PHOTO: M. WEBBER

Distribution Northern elephant seals are found in the eastern and central North Pacific. Breeding takes place on offshore islands and at mainland localities from central Baja California to northern California. Northern elephant seals migrate to and from their rookeries twice a year, returning to breed from December to March, and again to molt for several weeks, at different times, depending on sex and age. They also molt at additional coastal sites, as far north as southern Oregon. Their post-breeding and post-molt migrations take most seals north and west to oceanic areas of the North Pacific and Gulf of Alaska twice a year. Adult males tend to travel further north and west than adult females. Wanderers have been found as far away as Japan and Midway Island.

Ecology and behavior Northern elephant seals are highly polygynous, but not territorial. Male competition for access to females establishes a hierarchy on the rookery. There is much male-male fighting, vocalizing, and displaying during the breeding season, when bulls may be ashore for months at a time. One of the most impressive displays occurs when a male rears up on his hindquarters, thrusts $^{1}/_{2}$–$^{2}/_{3}$ of his body upward, and produces a distinctive clap-threat vocalization as a challenge to other bulls. The vocalization is a loud rolling, resonant, metallic series of backfire-like sounds.

Females give birth within a few days of coming ashore, from late December to March, and wean their pups in 28 days on average. Females have a throaty sputtering growl, made with the mouth wide open as a threat gesture. Females and pups have a warbling scream that they use to call to each other, and in the case of the pup, when disturbed. Mother and pup form a strong bond immediately after birth, and females aggressively bite other pups that approach them, occasionally killing them with bites to the head. Bulls also cause pup mortality by crushing them as they charge through mothers and pups to chase off or fight approaching males. Occasionally, they suffocate pups by stopping on top of them and not moving off soon enough.

Great white sharks and killer whales are predators of northern elephant seals. Recent work at the Farallon Islands off central California has revealed that large great white sharks aggregate around the islands in the fall when juvenile elephant seals return for their annual molt. Seals that swim at or near the surface as they are approaching or departing the islands are particularly vulnerable to ambush attacks by fast-rising sharks that patrol near the bottom in 7–10 meter deep waters.

Northern elephant seals hold the record as the deepest-diving pinniped. Time-depth recording devices have documented dives to an astounding 1580 m by an adult male. They also have extreme breath-holding ability and have been recorded to dive for as long as 77 minutes. Rest intervals at the surface are usually short, lasting only several minutes between routine dives that last 20–30 minutes and reach 300 to 800 m in depth. After leaving the rookeries, these seals routinely spend over 90% of their time underwater, helping explain why they are infrequently seen at sea.

Feeding and prey The diet of northern elephant seals includes fifty-three species of prey. More than half of these species are squid. Other prey includes fishes, such as Pacific whiting, several species of rockfish, and a variety of small sharks and rays. They have also been reported to feed on pelagic red crabs. The habitat of 70% of their prey is open ocean and includes species from surface, mid- and deep water zones.

Threats and status The northern elephant seal was hunted to the brink of extinction in a surge of commercial exploitation in the late 1800s. Much speculation exists on the numbers of animals that survived this population bottleneck. Some estimates are as low as 50 animals or fewer. Fortunately, for the species, their pelagic nature and the fact that most seals spend 80% or more of their lives at sea, and that they do not all return to their rookeries at the same time, ensured that enough seals were at sea to support continuation of the species when sealers undertook wholesale slaughters at rookery sites. Following a slow recovery in the early 1900s, northern elephant seals began to re-colonize former sites, a process that continued throughout the 1980s; by 1991 the population was estimated to have reached more than 120,000. The current estimate of 150,000 suggests that the population is continuing to increase, although there has not been a recent range-wide survey to confirm this figure.

Northern elephant seals are fully protected in Mexico and the US. Incidental take in fisheries is low. Most of the prey of the northern elephant seal is either of low commercial value or minimally harvested in fisheries. If the population continues to expand there will likely be new rookeries on mainland beaches, and there will be additional challenges to keep conflicts with humans and domestic animals to a minimum. The risk of transfer of diseases, such as morbillibivirus from other species to northern elephant seals is unknown.

IUCN status Least Concern.

Southern Elephant Seal —*Mirounga leonina*

(Linnaeus, 1758)

Recently-used synonyms None.

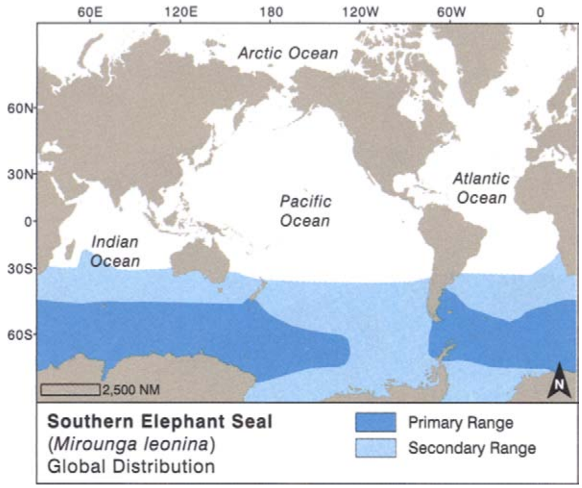
Common names En.–southern elephant seal; Sp.–*foca elephante del sur*; Fr.–*éléphant de mer austral*.

Taxonomic information Order Carnivora, Family Phocidae.

Species characteristics The southern elephant seal is the largest pinniped species. In both sexes, the body is robust and the neck is very thick. The head, muzzle, and lower jaw are broad. The mystacial area and nose are fleshy and blunt, and the bridge of the nose angles down slightly to the nostrils on females and young subadult males. The eyes are large, widely-spaced, and have a forward orientation that is especially noticeable in females and young animals. The vibrissae are beaded, short to medium length, and black. In addition to the mystacial clusters, there are one to two rhinal vibrissae on the bridge of the nose, and several in prominent supra-orbital patches above and slightly behind each eye. Each foreflipper digit bears a large blackish-brown nail. The nails on the hindflippers rarely emerge, but there is a vestigial nail beneath a small opening located above the end of each hindflipper digit.

Adult males are unmistakable. The long and enlarged nose, the proboscis, is inflatable. When relaxed, it hangs down in front of the mouth. Curiously, the proboscis is shorter in the southern than in the northern elephant seal, even though the former has a larger body. The proboscis is said to enlarge somewhat during the breeding season. Bulls also develop a chest shield of thickened, creased and heavily scarred skin. The chest shield on southern elephant seals is also not as developed as those on northern elephant seals. There is a varying amount of scarring on the rest of the body, and the proboscis is often heavily torn and scarred. Many bulls become pale in the face, proboscis, and head with increasing age. Bulls are longer and heavier than adult females and also have longer and thicker canines.

Two southern elephant seal bulls about to fight. Saint Andrew's Bay, South Georgia.
PHOTO: M. JØRGENSEN



Adult southern elephant seals have an unspotted pelage of light to dark gray, or tan to dark brown. There is a slight difference between dorsal and ventral coloration, except in newly molted pups which are somewhat more countershaded. Adult females can be tan, gray, or light brown, and are lightly countershaded. Their coloration fades as time progresses from last annual molt. Southern elephant seals also become stained rusty orange and brown, from lying in their own excrement on beaches, in muddy wallows, and tussock grass areas.

A mud-stained southern elephant seal bull. PHOTO: L. CUNNINGHAM

During the annual epidermal molt, they look ragged and multicolored, as they slough patches of faded and soiled fur with skin attached to reveal the new, clean, dark silver gray fur coming in underneath. The molt begins in the axillary region, between the hindflippers, around the tail, and progresses around the body. Pups are born in a long woolly black lanugo coat that is shed at about 3 weeks of age, to reveal a silver gray countershaded coat that is yellowish-gray ventrally.

Adult males typically reach 4.5 m and a maximum of 5.8 m in length weigh 1,500–3,000 kg with a maximum weight of about 3,700 kg. The literature contains numerous accounts of much larger males, with maximum lengths of 6–7 m, but these dimensions usually include hindflippers, whereas the standard length measurements in use today are from tip of nose to tip of tail. Adult females are similar in size and weight to northern elephant seal females, weighing 350–600 kg, with exceptionally large females reaching 800 kg. Newborn pups are about 1.3 m and 40–50 kg.

The dental formula is I $^{2}/_{1}$, C $^{1}/_{1}$, PC $^{5}/_{5}$.

Recognizable geographic forms None.

Can be confused with The massive head and the large fleshy proboscis make southern elephant seal bulls virtually unmistakable. Three of the four other phocids that occur within the southern elephant seal's range: Weddell, Ross, and leopard seals, can be separated from any age southern elephant seal by coloration and the presence of spots, blotches of color, or streaks. With the exception of crabeater seals, all three other species are noticeably countershaded as adults, whereas southern elephant seals have subtle countershading as subadults and adults. Crabeater seals are relatively thin with a narrow head, smaller eyes, a relatively long muzzle, subterminal nostrils, and proportionately longer and pointed foreflippers.

The head of female and subadult elephant seals is proportionately large and broad and the muzzle is broad, massive and somewhat blunt, with more forward facing

An adult male southern elephant seal bull with an inflated proboscis. Grytvikken, South Georgia. PHOTO: M. JØRGENSEN

Two subadult male southern elephant seals spar while ashore molting. South Shetland Islands. PHOTO: M. JØRGENSEN nostrils. The vibrissae of elephant seals are black, relatively long, whereas they are inconspicuous and pale all other Antarctic phocids.

Distribution Southern elephant seals have a nearly circumpolar distribution in the Southern Hemisphere. Although they reach the Antarctic continent, and even very high latitude locations such as Ross Island, they are most common north of the seasonally shifting pack ice, especially in subantarctic waters where most rookeries and haulouts are located. Notable exceptions include the northern breeding colonies at Peninsula Valdez in Argentina, and on the Falkland Islands. Also, some pups are born on the Antarctic continent. Southern elephant seals prefer sandy and cobble beaches, but will haul-out on ice, snow, and rocky terraces, and regularly rest above the beach in tussock grass and other vegetation, and in mud wallows. At sea, females and males disperse to different feeding grounds. Wandering and vagrant southern elephant seals reach southern Africa, southern Australia, New Zealand and Brazil. An Indian Ocean record at Oman on the Arabian Peninsula represents the northernmost record.

Ecology and behavior Southern elephant seals spend a large percentage of their lives at sea far from land, and only return to land to give birth, breed, and molt. At sea, they travel great distances from their rookeries and predominantly feed between the Subantarctic Convergence and the northern edge of the pack ice, south of the Antarctic Convergence. Adult males venture further south than females, and are known to forage at the outer edge of the Antarctic continental shelf.

They are prodigious divers and routinely reach the same depths as their northern counterparts. Dive depth and duration vary during the year and between the sexes, but normally range from 300 to 500 m deep and from 20 to just over 30 minutes in duration. A maximum depth of 1430 m was recorded for a female, following her return to sea after the molt. Another post-molt female dove for an astonishing 120 minutes, which is by far the longest dive ever recorded for a pinniped.

Southern elephant seals are highly polygynous with males establishing dominance hierarchies on beaches to monopolize access to groups or harems of females. Adult males return first in August, and most of them are ashore by mid-September to establish their status in the breeding hierarchy through displays, vocalizing and violent fighting. One of the male's most impressive displays is achieved by rearing up on his hindquarters and lifting almost two-thirds of his bulk straight up to fight with a peer or issue vocal challenges to nearby bulls.

Pregnant females arrive from September to October, and usually give birth within five days of their return. Pups are nursed for an average of 23 days, and abruptly weaned when the female departs to sea. Females come into estrus about four days before they wean their pup and mate, starting a new reproductive cycle before completing their current effort. Females first return to mate somewhere between 3–6 years of age. Pups remain on the breeding beaches for 8–10 weeks, during which time they complete the molt of their lanugo coat before departing to sea.

Vocalizations include a loud booming call made by adult males during the breeding season, variously called a bubbling roar, a harsh rattling sound, and a low-pitched

A very large southern elephant seal bull, pushing into an adult female in an attempt to mate gives perspective to the degree of sexual dimorphism. Saint Andrew's Bay, South Georgia. PHOTO: M. JØRGENSEN

series of pulses with little variation in frequency. Adult females have a high-pitched, yodeling call, which they use when distressed, and to call their pups. They will also utter a low pitch, sputtering growl. Pups call to their mothers with a sharp bark or yap, which is also used when interacting with other seals.

Feeding and prey Prey consists of approximately 75% squid and 25% fish. Antarctic *Notothenia* fishes are thought to be important prey when these seals are near the Antarctic continental shelf. Most feeding by females occurs in deep ocean areas at midwater depths. Adult males pass through female feeding areas on their way south to the outer edge of the Antarctic continental shelf where their diving activity suggests they pursue more benthic prey.

Threats and status The worldwide population of southern elephant seals is currently estimated at 650,000. Colonies in the South Atlantic, which include the largest breeding aggregation at South Georgia, are stable or growing, while those in the Southern Indian and Pacific Oceans have decreased by up to 50%. The reasons for these declines, which began in the 1950s and 1960s and are ongoing, are not understood.

Southern elephant seals were hunted by aboriginal and native peoples in Australia and South America. More recently, they were subjected to intensive commercial harvests starting in the early 19th Century and not ending until 1964 at South Georgia. They were prized for their large quantity of blubber that could be rendered to fine, valuable oil.

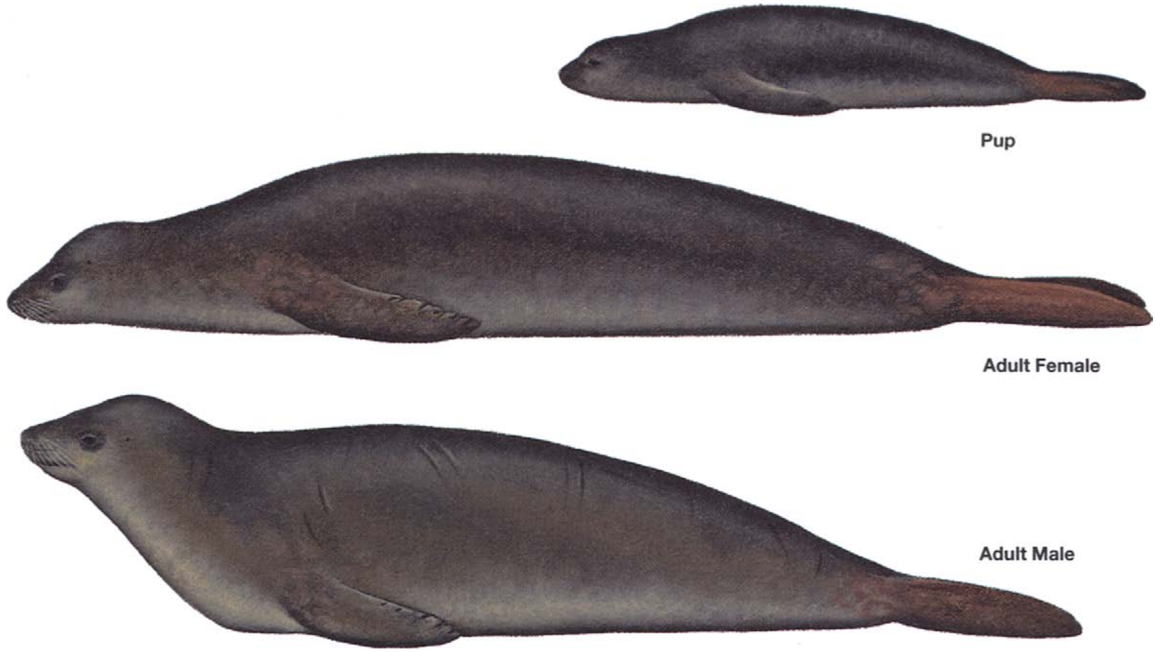
There are few threats and conflicts today, as southern elephant seals live far from human population centers and have minimal interactions with commercial fisheries.

IUCN status Least Concern.

References Hindell 1991; Hindell 2002; Laws 1994; Ling and Bryden 1981.

Crabeater Seal—*Lobodon carcinophaga*

(Hombron and Jacquinot, 1842)



Recently-used synonyms *Lobodon carcinophagus.*

Common names En.–crabeater seal; Sp.–*foca cangrejera*; Fr.–*phoque crabier*.

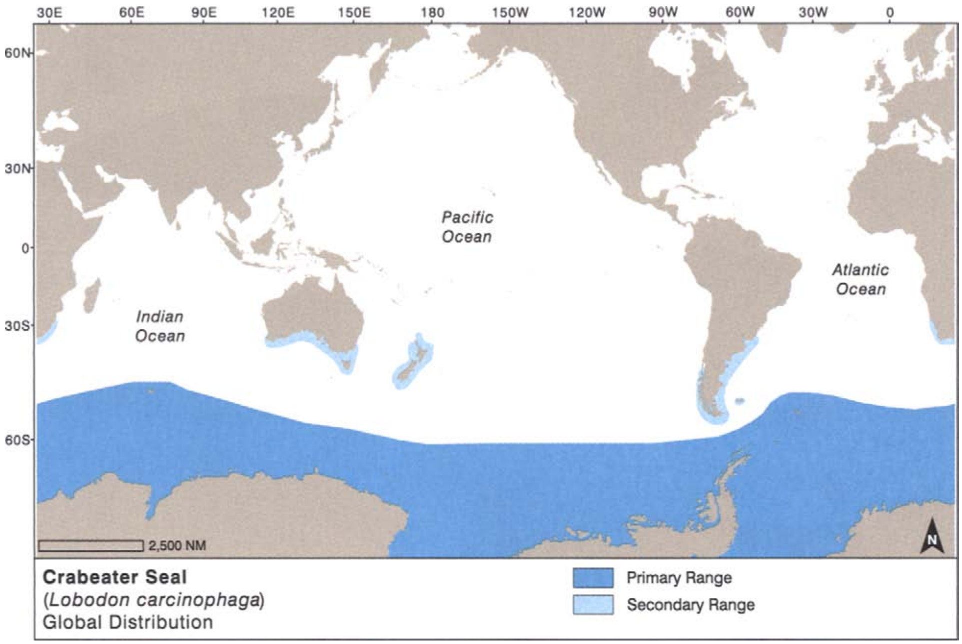
Taxonomic information Order Carnivora, Family Phocidae.

Species characteristics The head and muzzle are moderately long and slender relative to the animal's length. The eyes are set well apart and the head tapers to the base of the straight muzzle, forming a slight forehead in profile. The nostrils are on top of the muzzle, just back from the end, and in profile look slightly enlarged. This gives the end of the muzzle a slight tipped-up appearance. The tipped-up appearance is enhanced by the crabeater's tendency to raise the end of the muzzle to the level of the eye or higher when disturbed. The line of the mouth is virtually straight from the gape to the end of the muzzle. The vibrissae are short, pale to clear, and inconspicuous.

The foreflippers are long, wide, and somewhat sickle-shaped. The first digit tapers to a pointed end, and is similar to those of otariids, but the foreflipper is fully furred. Crabeater seals can spread the digits of the foreflippers while swimming and stretching, greatly enlarging the surface area. Many crabeaters bear long dark scars, either singly or as a parallel pair, that have been attributed to attacks by leopard seals. Many older males have numerous smaller scars and injuries to the face and sides of the mouth and head, presumably from intraspecific fighting.

The coat of a freshly molted crabeater has a rich sheen, and can be light to dark shades of colors ranging from silvery gray to tawny brown. Irregular patch-

Crabeater seals often haul-out in groups. Three animals are in an alert position. Note the animal with dark irregular blotches. PHOTO: P. A. OLSON



es of spots and rings can be found on the shoulders, sides, tops of the flippers, and around the insertion of the flippers. These markings produce a reticulated or web-like pattern on the sides of many crabeaters between their fore- and hindflippers. The flippers can be so heavily marked with spots and rings that they appear darker than the rest of the body. As time progresses from the molt, crabeaters fade dramatically, becoming light tan, pale gray, or whitish. As these seals become older they become paler overall, and some look faded all year long. Pups are born with a soft woolly coat that is grayish-brown in color and has been described as light, coffee-with-cream brown, with darker coloring on the flippers. Molt begins in about 2–3 weeks and the pup sheds into a subadult pelage similar to that of the adult.

Adults reach 2.6 m in length and weigh an estimated 200–300 kg, although little data are available on this species. Neonates are thought to be at least 1.1 m and 20–40 kg.

The dental formula is I $^{2}/2$, C $^{1}/1$, PC $^{5}/5$. All of the post-canine teeth are ornate, with multiple accessory cusps. Upper and lower teeth interlock to form a network for straining krill from the seawater. A ridge of bone on each mandible fills the gap in the mouth behind the last upper postcanine teeth and helps prevent the loss of krill from the back of the mouth when feeding.

Recognizable geographic forms None.

Can be confused with Crabeater seals are most likely to be confused with leopard, Weddell, Ross, or young elephant seals. Leopard seals have a much larger, almost reptilian-looking head, with a very broad muzzle, and proportionately longer foreflippers. Weddell seals have a small round head, close-set eyes, a short, narrow muzzle and a proportionately long and heavy-set body with short foreflippers and distinctive spots. Ross seals have a wide head with a short muzzle, giving the snout a

blunt appearance. The foreflippers are proportionately about the same length as in crabeater seals. They also have irregular dark streaks originating from the head, lower jaw, and thick neck that extend down the sides of the body.

The presence of long scars and sets of parallel scars are much more common and readily visible on the pale, relatively unmarked pelage of crabeaters than on the other Antarctic phocids. Of all the Antarctic phocids, only crabeaters occur routinely in closely associated groups in the water or on ice floes. Young southern elephant seals of similar size are gray to brownish, lack any markings, and have large wide heads with large eyes and prominent dark vibrissae.

Distribution Crabeater seals are circumpolar in the Antarctic and tied to seasonal fluctuations of the pack ice. They can be found up to the coast of Antarctica, as far south as McMurdo Sound, during late summer ice break-up, and as vagrants as far north as New Zealand and the southern coasts of Africa, Australia, and South America. Crabeaters have been known to wander far inland and die in the dry valleys adjacent to McMurdo Sound.

Ecology and behavior Pups are born from September to December, and weaned in approximately 3 weeks. There are no specific rookeries; females haul-out on ice singly to give birth. Adult males attach themselves to female/pup pairs and stay with the female until her estrus 1–2 weeks after the pup is weaned. Mating has not been witnessed and presumably occurs in the water. Females are reported to bite males around the mouth and flippers and this may account for the abundant small scars on the faces of older males. Mortality is high in the first year and may reach 80%. Much of this mortality is attributed to leopard seal predation, and up to 78% of crabeaters that survive through their first year have injuries and scars from leopard seal attacks. Leopard seal attacks appear to fall off dramatically after crabeaters reach one year of age.

Crabeaters are frequently encountered alone or in small groups on the ice or in the water. However, much larger groups of up to 1,000 have been observed hauled-out together. They will swim together in herds estimated to be up to 500 animals, breathing and diving almost synchronously. The molt is in January and February. They have a pattern of feeding from dusk until dawn, and hauling-out in the middle of the day. A large proportion of the animals in an area routinely haul-out during the annual molt. Crabeaters frequently use their foreflippers for propulsion, and surface and roll forward to begin a dive. They are known for their ability to move rapidly on ice, with sinuous serpentine motions of the back, aided by the flippers. When agitated, their response is to arch their back and raise their neck and head in an alert posture.

Recent research has revealed that crabeater seals can dive to 430 m and stay submerged for 11 minutes, although most feeding dives were to 20–30 m; and

Crabeater seals have moderately long pointed foreflippers with a long first digit, and a moderately long head and muzzle. Andvord Island, Antarctic Peninsula. PHOTO: M. JØRGENSEN

shorter. Foraging occurs primarily from dusk to dawn, and instrumented seals have been recorded to regularly dive continuously for periods up to 16 hours. Dives at dusk and dawn are deeper than at night, and indicate that crabeater feeding reflects the daily vertical migrations of krill.

Feeding and prey Crabeater seals feed primarily on Antarctic krill, *Euphausia superba*, and 95% of their diet may be made up of this species. Small amounts of fish and squid are also part of the diet.

Threats and status Crabeater seals are probably the most abundant seal species, and the most numerous large mammal on earth. Population estimates range from 2–75 million animals. There is no recent population estimate available, but the most widely-used estimates are of 10–15 million animals.

A mass die-off was reported from an area near a base on the Antarctic Peninsula in 1955. About 3,000 animals were trapped in areas 5–25 km from the nearest open water and most died over a 2–3 month period. None of the animals examined appeared to be starving, and numerous abortions of fetuses were noted. A disease outbreak was suspected, but never identified. In the 1980s, a study of archived samples revealed antibodies to a distemper-like virus in crabeater seals from this die-off.

Several brief episodes of commercial harvesting ended when they were determined to be economically unsuccessful. Commercial harvest of krill may pose a threat to crabeater seals if conducted on a large scale. There are currently no direct threats from human activity throughout most of the species' normal range. The effect of global climate change on the formation and extent of antarctic pack ice, and crabeater seal prey, poses an unknown threat to this ice-dependent species. Crabeater seals are protected by the Antarctic Treaty and the Convention for the Conservation of Antarctic Seals.

IUCN status Least Concern.

Ross Seal—*Ommatophoca rossii*

Gray, 1844

Pup

Adult

Recently-used synonyms *Ommatophoca rossi.*

Common names En.–Ross seal Sp.–*foca de Ross*; Fr.–*phoque de Ross*.

Taxonomic information Order Carnivora, Family Phocidae.

Species characteristics Ross seals are typically countershaded, blending along the sides. The coloration is described as ranging from dark brown to dark gray and black. Most striking are a series of dark streaks, unique to this pinniped, originating from the masked face and dark lower jaw that extend down the neck and sides parallel to each other. There may also be spots, particularly on the sides, where the dark coloration of the back merges with the light color of the undersides.

Coloration becomes duller with more brown and tan tones in late summer before the molt. The epidermal molt occurs in January and possibly February, and involves shedding small pieces of skin with the fur. Scars are often seen on the neck, possibly from intraspecific fighting, and a small percentage of animals have scars from wounds believed to be from leopard seal or killer whale attacks. Pups are born in a two-toned lanugo that is dark brown to blackish above and lighter gray, yellowish to silver below.

The head and neck are thick and wide, while the rest of the body appears proportionately short and slender. The muzzle and mouth are short and wide, giving the end of the head a blunt appearance. The vibrissae are sparse, short, and inconspicuous. The eyes are proportionately larger than in any other seal and set widely apart.

The foreflippers are proportionately long, with short claws as is typical of all four Antarctic phocid species. The first digit is very long and robust and the rest of the digits are successively shorter, the length tapering rapidly to create a pointed flipper that is similar in profile to the foreflipper of a sea lion. The hindflippers are long, to $^1/5$ or more of the standard length and are proportionately the longest of any phocid seal. The first and fifth digits of the hindflippers are very long, and much thicker than the other digits.

When disturbed, Ross seals lift their head and neck to the position of the foreflippers, and point the muzzle skyward in a characteristic and unique "singing" position. This position is also used for in-air vocalizations.

At maturity, Ross seals are the smallest of the four Antarctic phocids. Based on a small sample of measured

A Ross seal in the "singing" position. Notice how the back is slightly arched and the hindflippers pushed down and forward. This animal has inconspicuous stripes on the neck. PHOTO: M. CAMERON/MNFS

A singing Ross seal is recorded by researchers. Note the strongly developed countershading, the streaked and spotted sides, and the curving neck stripes. PHOTO: J. THOMAS

animals, Ross seals reach at least 2.4 m and 204 kg. Females are slightly larger than males. It is estimated that pups are about 1 m and 16 kg at birth.

The dental formula is I $^{2}/2$, C $^{1}/1$, PC $^{5}/5$.

Recognizable geographic forms None.

Can be confused with Of the four other phocids that share the Ross seal's range: Weddell, crabeater, leopard, and southern elephant seals, the Weddell is most similar in appearance. When compared to Weddell seals, Ross seals are shorter, and much smaller in the torso, but have a proportionately much wider neck and head, and have irregular dark streaks on the sides of the neck and body, and proportionately longer foreflippers.

Distribution Ross seals have a circumpolar distribution in the Antarctic. They are usually found in dense consolidated pack ice, but can also be found on smooth ice floes in more open areas. Results of recent tagging efforts have revealed that Ross seals migrate north out of the pack ice zone into open water to forage. Vagrants have been reported from Kerguelen, Heard Island, and South Australia.

Ecology and behavior Pups are born in November and December, with a peak from early to mid-November. Weaning takes place at about one month, although little is known of the relationship between mother and pup. Nursing-age pups have been seen swimming between ice floes. Mating is thought to occur in the water, but has not been observed. When hauled-out, Ross seals are generally encountered alone. Occasionally, a small number of individuals may be found in the same area, but they are usually widely-spaced apart. Ross seals may haul-out more often from morning to late afternoon. During the period of the molt, they may be out of the water for longer periods of time.

Few behaviors have been noted, except for the interesting habit of raising up the head and neck and opening the mouth when approached by a human. This has been described as the "singing posture," but seems to more often serve as an aggressive or defensive posture, from which chugging and trill vocalizations are produced when an animal is approached. Vocalizations are also made from other positions and while they are in the water, and the species' repertoire includes many calls that have been variously described to include pulsed chugs, clucks, loud cries, trills, and tonal siren calls.

Little is known of the activities of Ross seals in the water, although recent work has revealed that dives average 100 m in depth and 6 minutes in duration.

Feeding and prey The diet of Ross seals consists primarily of cephalopods, but also includes fish and krill.

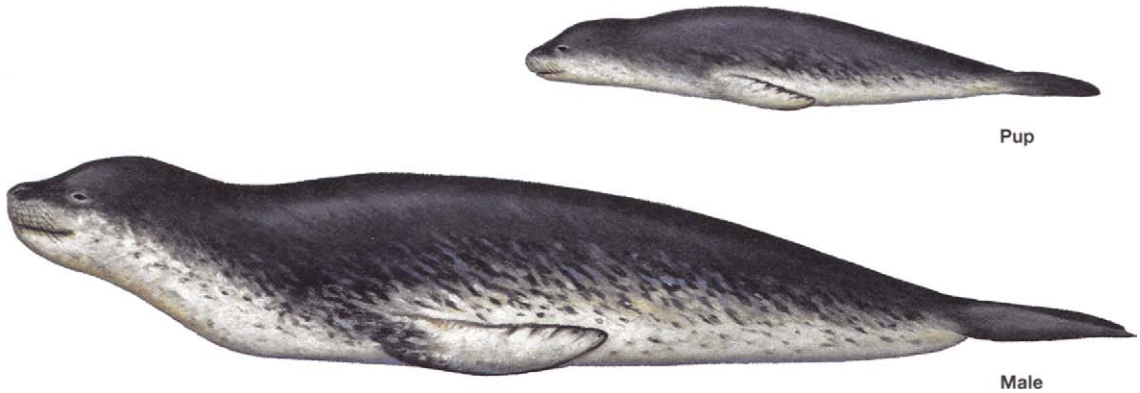
Four views of a molting Ross seal, sex unknown. The old fur is being replaced by richly colored, new pelage. This animal has a dark face with broad streaks that are different on each side. Note the large, unusually-shaped head, bulging eyes, short muzzle, thick neck, and medium length foreflippers. PHOTOS: P. A. OLSON

Threats and status Ross seals typically haul-out in dense consolidated pack ice that can usually only be reached by icebreakers. Small numbers have been collected for commercial purposes, scientific studies and museums, but otherwise interactions with humans have been few. Ross seals are protected by the Antarctic Treaty and the Convention for the Conservation of Antarctic Seals. When wandering outside the pack ice zone, they could come in contact with commercial fishing operations, but there are no reports of interactions to date. The Ross seal is the rarest phocid in Antarctica. No detailed surveys have been conducted recently, but the population is thought to be around 130,000.

IUCN status Least Concern.

References Erickson and Hanson 1990; Ray 1981; Skinner and Klages 1994; Thomas 2002.

Leopard Seal—*Hydrurga leptonyx*
(Blainville, 1820)



Recently-used synonyms None.

Common names En.–leopard seal; Sp.–*foca leopardo*; Fr.–*léopard de mer*.

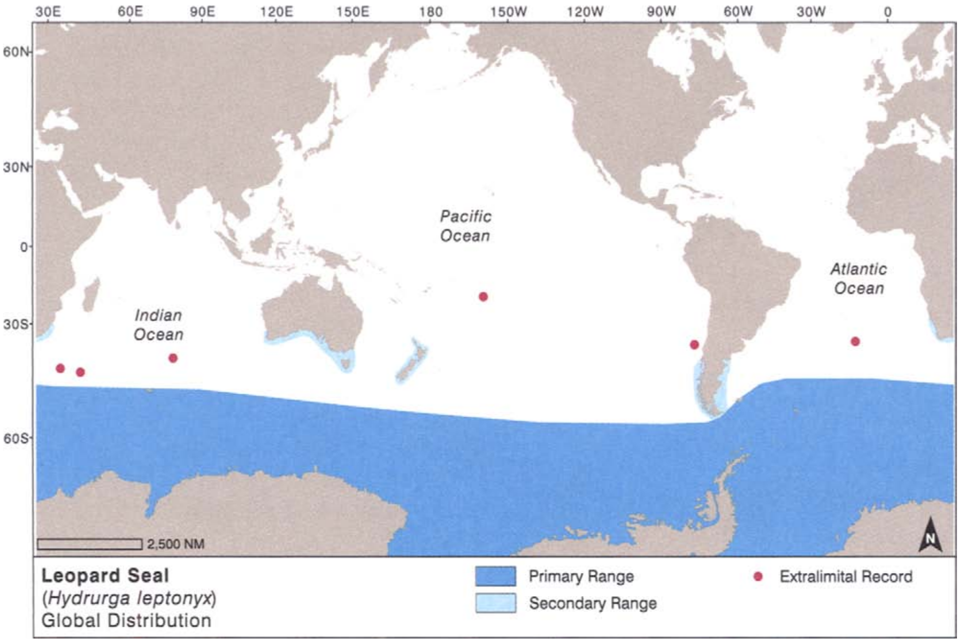
Taxonomic information Order Carnivora, Family Phocidae.

Species characteristics Leopard seals have a sinuous body and massive head and jaws. Because of the shape of the head, they appear almost reptilian. Females grow slightly longer and heavier, but not so much larger that the sexes can be distinguished in the field based on size. The long body usually appears slender, and is thickest through the shoulders and upper chest. There is no trace of a forehead. The head is widest at the eyes, which appear small and set both far apart and well back from the end of the broad U-shaped muzzle. The nostrils are situated on top and just back from the end of the muzzle. The lower jaw is massive, both long and wide, and the throat and neck are thick. Leopard seals have an enormous gape, and the teeth, especially the canines, are conspicuously large. The vibrissae are clear to pale, generally quite short and inconspicuous. The foreflippers are long, wide and somewhat sickle-shaped, tapering to a rounded end, and similar to those of otariids, but fully furred. The first digit is long and wide, creating a thick strong leading edge to the flipper. Leopard seals can spread the digits of the foreflippers while swimming and stretching, greatly enlarging the surface area. The foreflippers are situated farther back on the body from the muzzle than on other antarctic phocids, creating the proportionately long neck of the leopard seal.

Leopard seals have a countershaded color pattern. They are dark gray above and light silvery gray below, the shades meeting and blending high on the sides of the torso and neck, where the light ventral coloration rises to just below the level of the eye. A swath of lighter color from the neck extends forward on the upper jaw above the mouth to the end of the muzzle, which highlights the line of the mouth. Leopard seals are spotted to varying degrees, most noticeably on the sides, neck, and belly. Pups have essentially the same markings in the same proportions as adults, although their coat is softer, longer and thicker. Dense constellations of spots may occur without any pattern or symmetry. One area where dense clusters of spots normally occur is around the insertions of the foreflippers.

Adult males are 2.8 to 3.3 m long and weigh up to 300 kg. Adult

Adult leopard seals have a very large head with a long, wide muzzle and powerful jaws. Neko Harbour, Antarctic Peninsula. PHOTO: M. JØRGENSEN



females are 2.9 to 3.6 m, with very large animals possibly reaching 3.8 m, and can weigh 260 to upwards of 500 kg. Pups are 1 to1.6 m in length and weigh 30 to 35 kg at birth.

The dental formula is I $^2/_2$, C $^1/_1$, PC $^5/_5$. The canine teeth are very long and sharply pointed. The post-canine teeth are ornate with several large lobes, and resemble those of crabeater seals.

Recognizable geographic forms None.

Can be confused with Seen well, the distinguishing features of the leopard seal: large head and muzzle, long neck and very long foreflippers, long thin body, irregular spotting pattern, and usually strong countershaded coloration, are unmistakable. At a distance, however, they most likely would be confused with crabeater seals. Both Weddell and Ross seals have much smaller heads, and very short and blunt muzzles, with proportionately shorter foreflippers that are situated farther forward on the body than on the leopard seal.

Crabeater seals are shorter, with a proportionately smaller head and shorter muzzle that is demarcated by a small angular forehead, and are generally lighter in color, with minimal or no countershading. Also, they often have long scars, and usually have small numbers of spots concentrated on the shoulders, flanks, tops of the foreflippers, and around the insertions of the flippers.

Distribution Leopard seals are widely-distributed in Antarctic and subantarctic waters of the Southern Hemisphere, from the coast of the continent north throughout the pack ice and at most subantarctic islands. Vagrants regularly reach warm temperate latitudes. They haul-out on ice and land, often preferring ice floes near shore, when available.

The very long foreflippers of a leopard seal. The first digit provides a strong cutting edge. PHOTO: M. WEBBER

Ecology and behavior Pups are born on the ice from early November to late December and the period may be as long as early October to early January. Births at South Georgia occur from late August to the middle of September. Pups are probably weaned at 4 weeks, and female estrus occurs at or shortly after weaning. Unlike crabeater seals, male leopard seals do not haul-out with female/pup pairs. Mating is believed to occur in the water.

At sea and on the ice, leopard seals tend to be solitary. They float at the surface, and crane their neck high to view objects of interest in the air, and will hide around ice floes while underwater, stalking prey. Leopard seals can submerge by sinking, which is typical of most phocids (which use their hindflippers for propulsion), or by rolling forward, the more typical method of otariids (which use their foreflippers for propulsion). Leopard seals are fast, powerful, agile swimmers. Swimming is most often accomplished with long, powerful, coordinated sweeps of the foreflippers, rather than the side-to-side strokes of the hindflippers typical of most phocids. Leopard seals mostly sleep or are otherwise inactive when out of the water, but will move in a serpentine slithering manner across ice, and toboggan like penguins. They are curious and unafraid of humans and small boats and will approach, occasionally brush against, and even mouth small boats.

Explorers and scientists from the heroic age of exploration to the present occasionally report being stalked by leopard seals swimming along the ice edge or leads, where people are working and walking. Leopard seals have lunged at ankles and, rarely, briefly grabbed people. They will closely approach human divers and appear to be very curious during these encounters. On one occasion, a leopard seal dragged and held a snorkeler underwater long enough to drown the person. Despite being a top predator, leopard seals themselves are prey for killer whales.

Feeding and prey Leopard seals are probably best known for their habits of preying upon penguins. Their diet is actually quite varied and changes with seasonal and local abundance of prey. Leopard seals will consume krill, fish, squid, penguins, a variety of other types of seabirds, and young seals, including phocids, such as young crabeater and southern elephant seals and otariids, such as young fur seals. They will also occasionally scavenge from carcasses of whales.

Most prey is caught in the water, but they will also sometimes take penguins while hauled-out. Penguins are regularly held in the teeth by one end and slung in an arc with a rapid snap of the head and neck to be smashed, and torn open at the surface. Smaller pieces are then swallowed. The loud crack produced when a leopard seal slaps a penguin on the surface has been reported to

The very long foreflippers of leopard seals are often pale to different degrees. PHOTO: M. JØRGENSEN

The band of light color above the jaw line on the large head and thick muzzle is unique to the leopard seal. Cooper Bay, Antarctic Peninsula. PHOTO: M. JØRGENSEN

Leopard seals usually attack penguins in the water and smash them on the surface to break them into smaller pieces. Port Lockroy, Antarctic Peninsula. PHOTO: M. JØRGENSEN

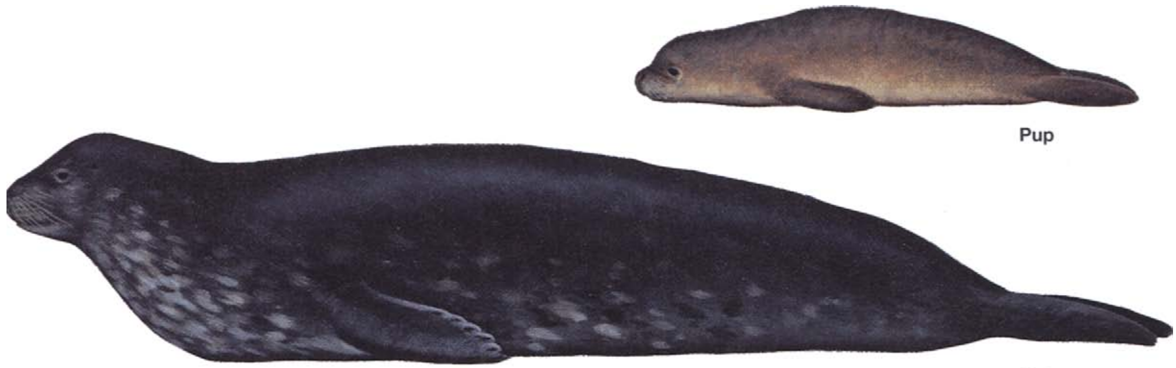
be audible in air for more than a kilometer. Young, newly fledged naïve penguins are most vulnerable, but adult birds are taken as well. Leopard seals patrol and regularly station themselves just off penguin rookeries and wait to ambush and chase penguins transiting to and from these colonies.

Threats and status The leopard seal is not listed as endangered or threatened. The population is estimated to be 220,000 to 400,000, with highest densities occurring in pack ice with large brash ice blocks and cake ice floes that are 2 to 20 meters in diameter. Leopard seals are protected by the Antarctic Treaty and the Convention for the Conservation of Antarctic Seals. There are currently no threats from human activity throughout most of the species' normal range. The effect of global climate change on the formation and extent of Antarctic pack ice, and leopard seal prey, poses an unknown threat to this ice-dependent species.

IUCN status Least Concern.

References Erickson and Hanson 1990; Hiruki et al. 1999; Hofman 1979; Kooyman 1981; Rogers and Bryden 1997; Rogers 2002.

Weddell Seal—*Leptonychotes weddellii*
(Lesson, 1826)



Recently-used synonyms *Leptonychotes weddelli.*

Common names En.–Weddell seal; Sp.–*foca de Weddell*; Fr.–*phoque de Weddell.*

Taxonomic information Order Carnivora, Family Phocidae.

Species characteristics Weddell seals are long, heavy-bodied phocids. The chest and abdomen of the fusiform body are long and thick. The neck is short and the head is small and rounded. The eyes are forward facing and large. The muzzle is short and somewhat narrow with a sparse number of inconspicuous, short vibrissae. Taken together, the head and muzzle shape, large eyes, and upturned mouth line impart a feline appearance to the face. Weddell seal foreflippers are proportionately short, relatively narrow, and owing to the short neck, originate in the forward third of the body.

In freshly molted pelage, adult Weddell seals are generally dark gray above with silver to light gray highlights, and pale gray to off-white below. There is a variable amount of light and dark spotting, streaking, and blotching. These markings are fewer or absent on the top of the back, and become heavier on the sides and ventral surface, where the markings can fuse into irregular shapes. Dorsal color fades from a rich, very dark gray just after the molt, to a dull brownish-gray over the 11 to 12 months prior to the start of the next molt. The pelage on the end and sides of the muzzle has light gray to whitish highlights, and sometimes there are similar crescent-shaped highlights above and behind the eyes. Pups are born in a woolly silver-gray coat, with a darker swath along the mid-line of the back. This lanugo coat is molted for the adult pelage starting 1–4 weeks after birth, and the molt is usually completed in 2–3 weeks.

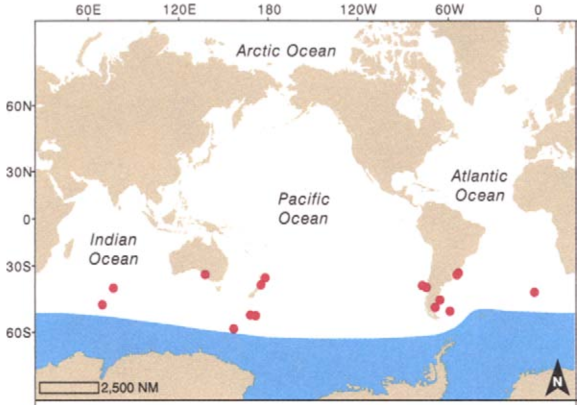
Adult males reach 2.9 m in length, females 3.3 m. Adults in their prime weigh 400 to 450 kg, with females somewhat heavier than males, but not enough to permit separation of the sexes in the field based on weight or length. Adult female weight fluctuates dramatically during the year with most weight loss occurring after birth and during lactation. Newborns are about 1.5 m long and average 29 kg.

Adult female with her molting pup, and a third seal at a hole in the fast ice. The markings on the female are typical for Weddell seals, and the pup is molting its lanugo. PHOTO: K. WESTERSKOV/NATURAL IMAGES

The dental formula is I $^{2}/_{2}$, C $^{1}/_{1}$, PC $^{5}/_{5}$. The second upper incisors and the upper canines are procumbent, or forward facing, a special adaptation used for rasping ice to keep breathing holes open.

Recognizable geographic forms None.

Can be confused with Four phocids share the Weddell seal's range. Of these, Ross and crabeater seals are the most similar, and leopard and southern elephant seals are more



Weddell Seal
(*Leptonychotes weddellii*)
Global Distribution

readily separated from Weddell seals. Ross seals differ in having a proportionately larger and wider head and neck, very small muzzle, and that taken together, impart a blunt profile to the face. They also have dark streaks on the neck, throat and sides, and proportionately longer foreflippers.

Crabeater seals have a longer head and muzzle, with an upturned appearance to the end of the muzzle. They are also paler dorsally and on their sides, with few or no spots. Also, Weddell seal foreflippers are shorter and set more forward on the body than those on crabeater and Ross seals.

Distribution Circumpolar and widespread in the Southern Hemisphere, Weddell seals occur in large numbers on fast ice, right up to the Antarctic continent. They also occur offshore in the pack ice zone north to the seasonally shifting limits of the Antarctic Convergence. Weddell seals are present at many subantarctic islands and islands along the Antarctic Peninsula that are seasonally ice-free. Vagrants have been recorded in many northern areas including South America, New Zealand and southern Australia.

Ecology and behavior Weddell seal pups are born from September through November and nursed for 7–8 weeks. Animals in lower latitudes pup earlier than animals living at higher latitudes. Males set up territories in the water around access holes in the ice used by females to enter and leave the water. The only copulation that has been observed occurred underwater. The behavior of animals breeding in the pack ice is not well-known.

Weddell seals are not very social when out of the water, avoiding physical contact most of the time. When in the fast ice habitat, they tend to congregate in groups along recurrent cracks, leads, and near access holes to the water. There is debate over whether or not this species is migratory. Some individuals remain in residence year-round in the fast ice at latitudes as high as 78° S in McMurdo Sound. Others, particularly newly weaned and subadult animals, move north from the continent and spend the winter in the pack ice.

Weddell seals are prodigious divers reaching over 600 m, and have the capability of undertaking 82 minute dives. Deep dives are regularly used for foraging and long

The Weddell seal has a small head and short muzzle as seen on this juvenile. Paulett Island, Weddell Sea. PHOTO: M. WEBBER

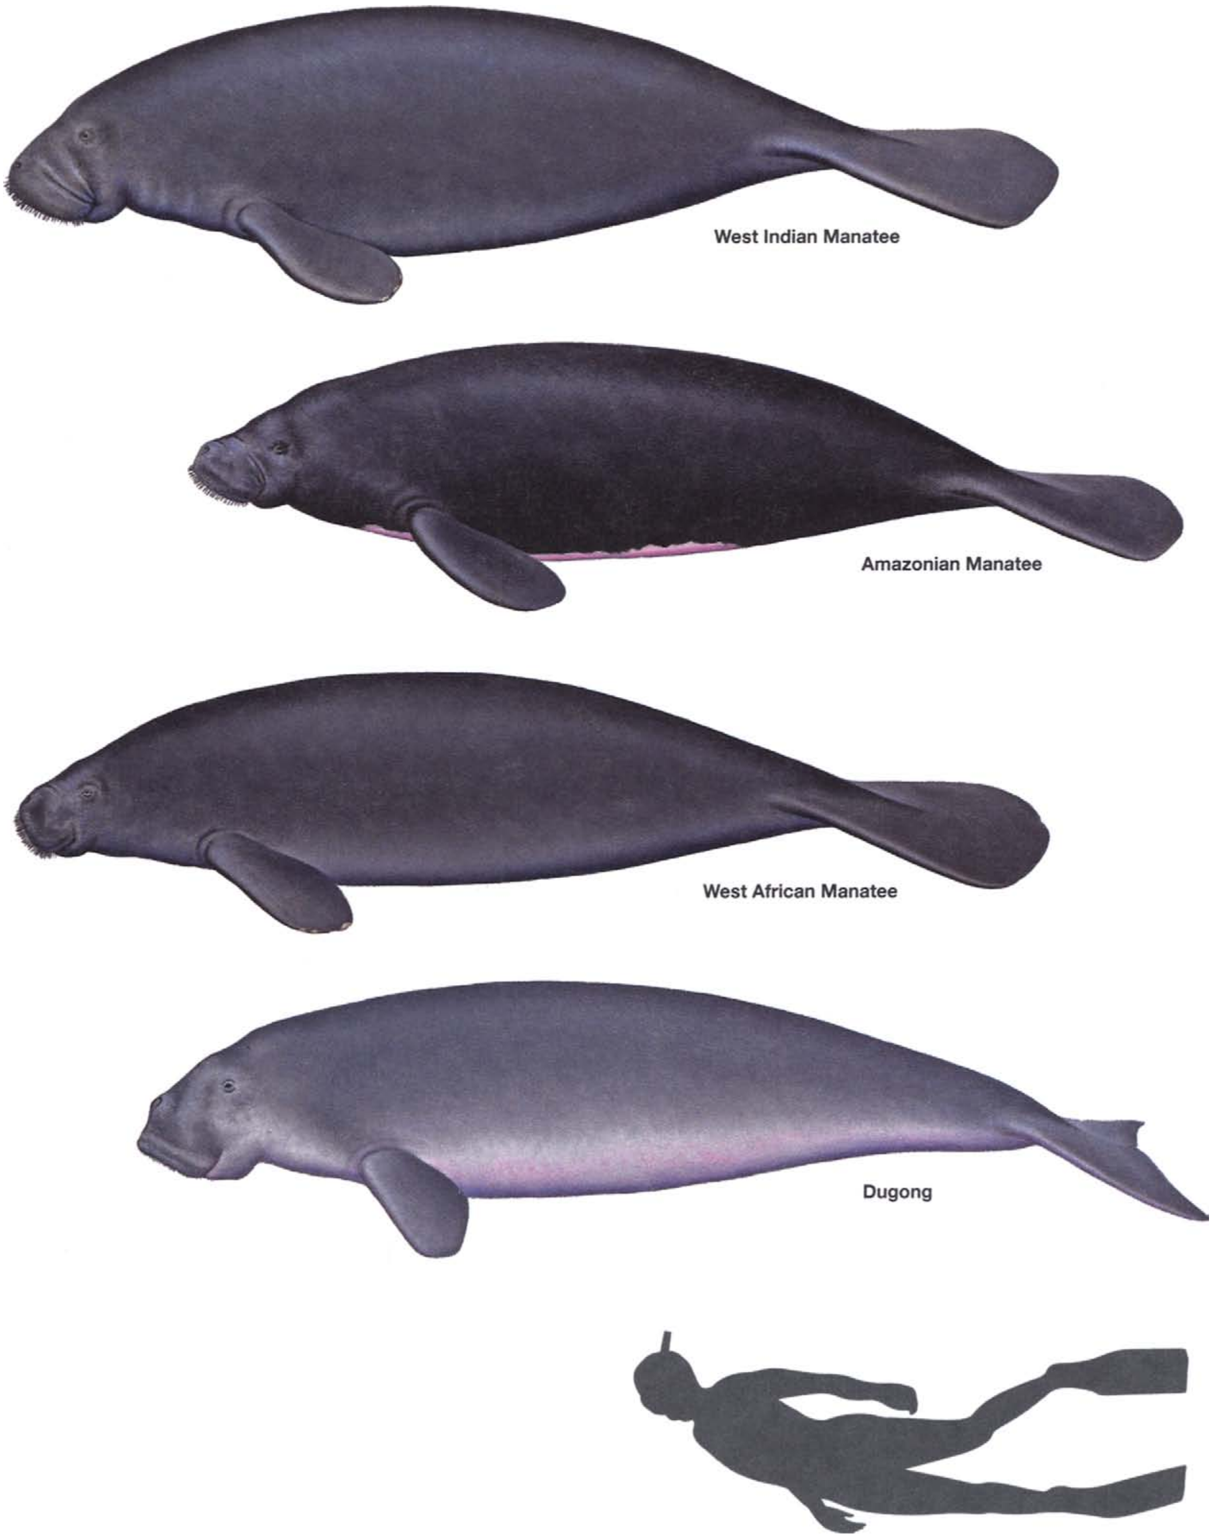
dives for searching for new breathing holes, cracks and leads. Seals living in fast ice, or facing freezing over of access holes and leads, abrade and grind the ice to maintain access to and from the water. They bite at the ice and then rapidly swing the head from side to side to rasp and grind away the ice with their teeth. Predators include killer whales and leopard seals.

Feeding and prey The diving abilities of this species are helpful in finding new breathing holes and obtaining important prey, such as the huge Antarctic toothfish. In addition to Antarctic toothfish, Weddell seals also take a variety of other *Nototheniid* fishes. Squid and other invertebrates are also taken as small percentages of the diet.

Threats and status Weddell seals served as an important source of food for men and dogs throughout the heroic period of Antarctic exploration. They continued to be taken to feed sled dogs into the 1980s. Local populations of seals no doubt suffered declines from these harvests, but in the case of the population in McMurdo Sound the population has recovered in the 20 years since the harvest ended. The population of Weddell seals has been variously estimated at 500,000 to one million or more. This is a widespread species and, as with other Antarctic seals inhabiting the pack ice, population assessments are very difficult and expensive to conduct and therefore infrequently undertaken. At present there are no immediate threats to the Weddell seal, and they are protected by the Antarctic Treaty and the Convention for the Conservation of Antarctic Seals.

IUCN status Least Concern.

References Burns and Kooyman 2001; Erickson and Hanson 1990; Kooyman 1981; Kooyman 1981; Testa and Siniff 1987; Testa et al. 1990, Thomas 2002.



West Indian Manatee
Amazonian Manatee
West African Manatee
Dugong

6. Sirenian and Other Species

Sea Otter

Marine Otter

Polar Bear

West Indian Manatee—*Trichechus manatus*

Linnaeus, 1758

Recently-used synonyms None.

Common names En.–West Indian manatee; Sp.–*manati* or *vaca marina*; Fr.–*lamantin des Caraibes*.

Taxonomic information Order Sirenia, Family Trichechidae. There are two subspecies recognized: the Florida manatee (*T. m. latirostris*) in the southeastern US and the Antillean manatee (*T. m. manatus*) from northern Mexico to northern South America, including islands of the Caribbean. Hybrids between West Indian and Amazonian manatees have been documented near the mouth of the Amazon River (and possibly also near the mouth of the Orinoco River).

Species characteristics West Indian manatees are rotund, with broad backs, and have long flexible forelimbs and rounded, paddle-like tails. The head is small, with no discernible neck, and the body exhibits numerous folds and fine wrinkles. The squarish, thickened snout has fleshy, mobile lips (with stout bristles on the upper lip) and two semi-circular nostrils at the front. The rostrum is strongly deflected downwards (29–52°—more so than in the other manatee species), which reflects the species' preference for feeding on submerged vegetation. The skin is very rough and thick, and has fine hairs sparsely distributed over its surface. Each flipper has 3–4 fingernails at the tip. The tail stock is not laterally compressed into a peduncle. The mammary glands of manatee females are located in the axillary region.

The color of the skin is generally gray to brown, sometimes with a green, red, white, or black tinge caused by algal and/or barnacle growth. The short hairs are colorless. Calves appear to be a darker shade of gray, almost black.

There are 5–7 pairs of bicuspid post-canines/molars in each jaw. When forward teeth are worn or lost, they are replaced from behind. At birth, each jaw also has 2 vestigial incisors, which are lost as the animal ages.

West Indian manatee adults are up to 3.5 m (4.0 m maximum) long and weigh up to 1,590 kg. Females tend to be a bit larger than males. Newborns measure about 120 cm and weigh about 30 kg.

West Indian manatees (in this case a mother and calf) are found in very clear water in some areas of Florida. PHOTO: L. KEITH

Recognizable geographic forms The two subspecies are separated largely by their distribution and differences in skeletal morphology. Reliable methods of distinguishing them from external appearance are not known.

Can be confused with The West Indian manatee is the only sirenian throughout most of its range,

A West Indian manatee calf suckles from its mother in Florida waters. The teats are near the axillae in sirenians. PHOTO: T. PUSSER

with the exception of the area around the mouth of the Amazon River (and maybe the Orinoco as well). In this region, special care must be taken to distinguish it from the Amazonian manatee. Pay special attention to head shape (shorter and wider rostrum in the West Indian), body color (lighter, generally without white belly patches in the West Indian), skin texture (rougher in the West Indian), and presence/absence of nails on the flippers (present in the West Indian).

Distribution West Indian manatees are found in coastal marine, brackish, and freshwater areas of the southeastern US coast, tropical/subtropical Gulf of Mexico, Caribbean Sea, and Atlantic coast of northeastern South America. There are 2 subspecies: the Florida manatee (*T. m. latirostris*) from Texas to Virginia (occasionally to Rhode Island) in the northern Gulf of Mexico and southeast United States, and the Antillean manatee (*T. m. manatus*) from northern Mexico to central Brazil and the islands of the Caribbean. Increasing numbers of records of manatees in the US Gulf of Mexico, west of Florida, have been documented in recent years, probably due to both increases in public awareness and manatee dispersal. Extralimital records have been recorded from the Bahamas, the western Florida keys, and at Turneffe Atoll, Belize. Recently, a few West Indian manatees transplanted into the Panama Canal may have passed through the locks and made it to the Pacific side, but this is not part of their normal range.

Ecology and Behavior West Indian manatees are slow-moving and lethargic, and can be very difficult to observe, since they generally only expose the tip of the muzzle and possibly the upper back when they surface. They are seen mostly alone or in groups of up to six. However, some feeding groups may number up to about 20. For instance, during cold weather, large aggregations assemble near sources of warm water (such as power plant outfalls) in Florida, and these aggregations occasionally contain hundreds of animals. Mating groups of manatees clasp and touch each other, with much rolling and cavorting. Individual manatees are identified by scars and marks on the body (many of these inflicted as a result of boat collisions).

Most individuals in the southeastern US migrate between a summer range and a winter range further south in warmer waters. These movements, which are determined by water temperature changes, may span hundreds or even thousands of kilometers. However, the presence of warmwater sources (such as power plant outfalls) has encouraged some animals to delay their migration or even not to migrate. They tend to show strong fidelity among years to specific ranges. Within the species, there is strong population structure, with the Lesser Antilles apparently representing a barrier to gene flow. In the Florida manatee, four populations or management stocks are recognized (Atlantic Coast, Southwest, Upper St. John's River, and Northwest).

West Indian manatee females reach sexual maturity at about 3–4 years. They breed throughout the year, with a peak, at least in Florida, in the spring and sum-

mer months (May–September). Generally, a single calf is born (twins occur sometimes—about 1–2% of births) after a gestation period of about 11–13 months. The calf is weaned typically at the age of about 1–2 years, but some females nurse their calves for up to 4 years. The lifespan is about 60–70 years.

Feeding and prey These animals are herbivores, feeding on a wide variety of aquatic plants, such as water hyacinths and marine seagrasses. At times in some areas, they also eat algae, parts of mangrove trees, floating and shoreline vegetation, and even fish that they remove from fishing nets.

Threats and status Although hunting was prevalent in the past, it only occasionally occurs (illegally) today in US waters. Human-caused threats include vessel collisions, incidental kills in fishing nets and lines, disturbance from boat traffic and other human activities, entrapment in flood control structures, pollution (especially from pesticides and herbicides in central America), ingestion of plastic debris, loss and degradation of habitat, and harassment by ecotourists. In addition, several natural mortality factors are important, and these include biological toxins (red tides), cold-related mortality, and apparently-high levels of perinatal mortality. The dependence of some manatees in Florida on warm water from power plant outfalls concerns many scientists, as the loss of these warm-water sources, even temporarily, could cause mass die-offs. Boat collisions are the number-one human-related cause of death (causing about 25% of manatee deaths) in Florida waters, where high-speed watercraft are extremely common and widespread. Abundance of the Florida manatee was estimated to be about 3,300 individuals. The Antillean manatee's numbers are unknown, but at least 400 have been counted on recent surveys in Belize and southern Mexico and about 500 are thought to exist in Brazilian waters. Some populations are growing, while many others are declining. Despite the species still facing significant threats, it is being actively managed in at least portions of its range. It is therefore probably facing much less danger of extinction than the other two manatee species.

IUCN status Vulnerable.

Amazonian Manatee—*Trichechus inunguis*

(Natterer, 1883)

Recently-used synonyms None.

Common names En.–Amazonian manatee; Sp.–*vaca marina*; Fr.–*lamantin de l'Amazone*. In Brazil, they are called *peixe-boi*.

Taxonomic information Order Sirenia, Family Trichechidae. Hybrids between West Indian and Amazonian manatees have been documented near the mouth of the Amazon River (and possibly also near the mouth of the Orinoco River).

Species characteristics Amazonian manatees are the smallest, most slender of the 3 species of manatees. They have the rounded, paddle-like tails characteristic of all manatees. The skin of adults and juveniles is smooth, rather than wrinkled as in their relatives (it has been described as 'rubbery'). The flippers are longer than in the other species and they lack nails, which is in contrast to the other two manatee species. There are thick bristles on the lip pads of both jaws, and the rostrum is longer, narrower, and less deflected downwards than in the West Indian manatee. The body has a sparse covering of fine hairs.

Amazonian manatees are black or dark gray; most have white or pink belly and chest patches with irregular shapes and very distinct borders (these only rarely occur in Florida manatees). However, not all individuals have the belly patches, and they may just have a slightly lighter ventrum.

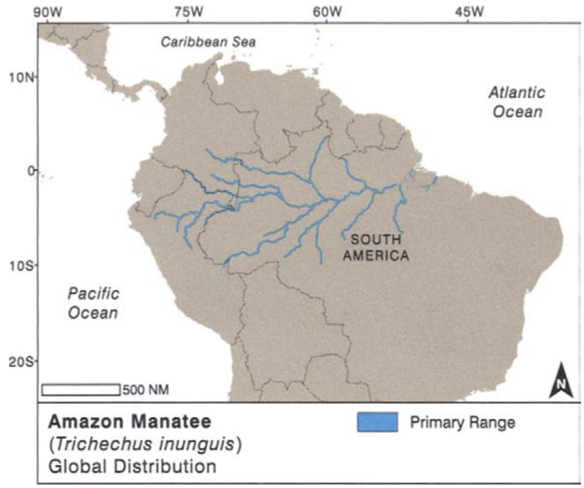
Five to seven functional post-canines/molars, and 2 vestigial incisors (the latter are resorbed after birth) are found in each jaw. Typical of manatees, teeth are replaced from the rear throughout life. The teeth are smaller than those of other manatee species.

Amazonian manatees reach lengths of about 2.8–3.0 m, and weights of up to 480 kg. There is no known sexual dimorphism in body size. Length at birth is not well-known, but is probably around 80–110 cm.

Recognizable geographic forms None.

Can be confused with Amazonian and West Indian manatees may co-occur in or near the mouth of the Amazon River (and possibly also near the mouth of the Orinoco River). Although they may be very difficult to distinguish when seen from a distance, in closer views, the size, shape, and coloration differences listed

Amazonian manatees are the most distinctive of the three manatee species. They are darker in color, with more distinct white belly patches, and they are generally more slender and smoother than the others. Brazil. PHOTO: D. PERRINE@/SEAPICS.COM



above should help in identification. Pay special attention to head shape (longer and narrower rostrum in the Amazonian), body color (darker, with frequent white belly patches in the Amazonian), skin texture (smoother in the Amazonian), and presence/absence of nails on the flippers (absent in the Amazonian).

Distribution The Amazonian manatee is an exclusively freshwater species. It is found in calm waters of the Amazon River and its tributaries and appended lakes in Brazil, Guyana, Colombia, Peru, and Ecuador. Apparently it does not occur in the Orinoco drainage. It occurs from near the headwaters of the rivers (although not in the fast-flowing and turbulent waters) to the Amazon estuary. It can be found in all three water types in the Amazon (i.e, black, white, and clear waters).

Ecology and behavior The Amazonian manatee remained poorly-known until more intensive studies of its biology began in the mid-1970s. It occurs singly or in feeding groups of up to 8 individuals, although animals in feeding aggregations generally show little social interaction. The large herds often seen in the past are a rarity today, although aggregations do form for mating. They are active both day and night (however, hunting disturbance may have caused some animals to become more nocturnal in their habits), and their activities are strongly influenced by the seasonal floods. As water levels rise, they move into the flooded forest and "varzea" areas to feed, and they return to the main river channels and perennial lakes during the dry season. Amazonian manatees may survive for long periods in pools separated from the main river during the dry season, and have developed impressive fasting abilities (documented up to 200 days) to survive these events. They are able to hold their breath for up to 20 minutes. Individuals may emit low-frequency sounds in and out of water.

Breeding may occur throughout the year, but there is a calving peak in February to May, when the water level in the river rises and food is plentiful and nutritious. A single calf is born after a gestation of about 12 months. Lactation lasts up to two years. The age at sexual maturity is not well known, but is thought to be between 6 and 10 years. Potential predators are sharks, caimans (crocodiles), and jaguars. The lifespan is thought to be around 60–70 years.

In nature, Amazonian manatees are generally very difficult to detect. They may hide away in weeds along the river banks, and remain quiescent during much of the day. These may be, at least partially, adaptations to avoid detection by hunters. Brazil. PHOTO: D. PERRINE@/SEAPICS.COM

Feeding and prey Amazonian manatees feed on at least 24 species of vascular aquatic plants, but they have also been observed to eat floating palm fruits. Emergent species are preferred, followed by floating, and finally submerged types. Some manatees may fast or eat dead plant material during the dry season. They consume about 8% of their body weight per day.

Threats and status Amazonian manatees have been hunted heavily throughout the Amazon basin since at least 1542. Between 1935 and 1954, a commercial fishery killed 80,000 to 140,000 Amazonian

This mother and calf Amazonian manatee show the white belly patches that characterize many adults in this species. Brazil. PHOTO: D. PERRINE@/SEAPICS.COM

manatees for their meat and hides (which were used to make leather). Manatees are still hunted (often illegally) in at least Peru, Colombia, Brazil, and Ecuador. Additional potential threats to their survival include incidental catch, pollution associated with mining and other industrial and agricultural practices, damming of rivers, and large-scale deforestation. Amazonian manatees apparently do not often get hit by boats (this is a major problem for the West Indian species). About 500–1,000 manatees were thought to occupy Amana Lake in Brazil in the early 1980s. There are no statistically-defensible estimates of overall abundance or population size. However, the population was undoubtedly seriously reduced by the commercial exploitation of the past, and is being further reduced by the current smaller-scale subsistence hunts. Legal protection occurs in most range countries, but enforcement is generally lax to non-existent. The Amazonian manatee is therefore in real danger of extinction in the next couple of decades.

IUCN status Vulnerable.

References Husar 1977; Reeves et al. 1996; Reynolds and Powell 2002; Rosas 1994.

West African Manatee—*Trichechus senegalensis*

Link, 1795

Recently-used synonyms None.

Common names En.–West African manatee; Sp.–*vaca marina*; Fr.–*lamantin d'Afrique*.

Taxonomic information Order Sirenia, Family Trichechidae.

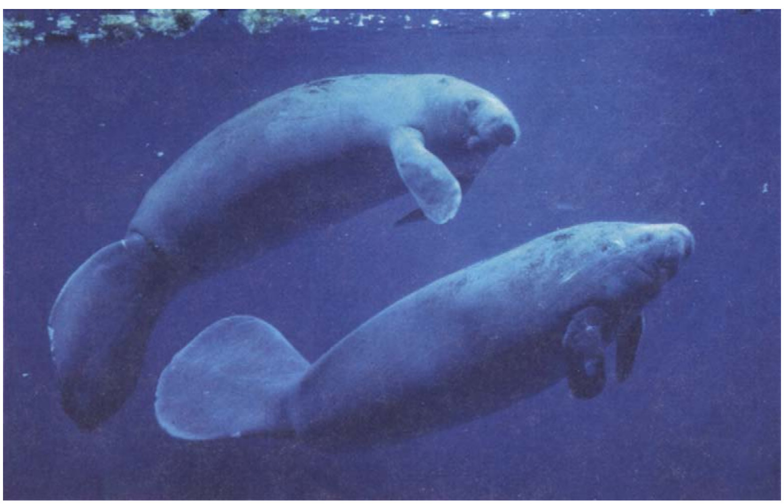
Species characteristics West African manatees are very similar in appearance to West Indian manatees, although they tend to be a bit more slender. They have rounded, paddle-like tails. The head shape is similar to that of the West Indian manatee, but the snout is blunter, and the small eyes protrude from their sockets more. Additionally, the rostrum is less deflected downwards than in the West Indian manatee. There are stiff bristles on the lips. As in other manatees, the flippers are paddle-like; there are 3–4 nails on the upper surface (although there are reports of animals with no nails). The skin is wrinkled, with a sparse covering of short hairs.

The bodies of West African manatees are dark grayish-brown; the sparse hairs found on the body are white. Individuals in coastal marine waters may have some barnacles growing on the surface.

There are 5–7 functional teeth (all molars) in each tooth row. These are replaced from the rear by newly-erupting teeth. Newborn animals have 2 vestigial incisors, which are later lost.

Adult West African manatees reach about 3.5 m in length (although there is a questionable report of an animal that was 4 m long) and to over 1,000 kg in weight. Newborns are presumably about 1.0–1.2 m long.

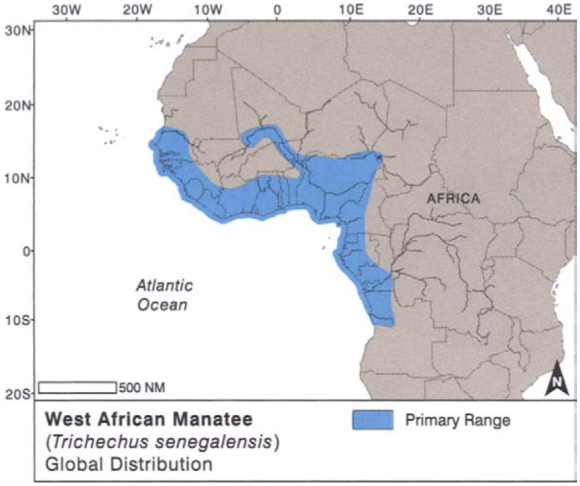
Recognizable geographic forms None.



West African manatees are very similar in appearance to their West Indian cousins. Although they have a tendency to be slightly more streamlined, captivity has fattened these ones. PHOTO: TOBA AQUARIUM

Can be confused with West African manatees should be easy to identify, as they are the only sirenians in their range, and the only marine mammals in most of the riverine waters that they occur in.

Distribution West African manatees are found in coastal marine waters, enclosed lagoons, the lower parts of rivers, and estuaries from the Senegal/Mauritania border to southern Angola. The species may also occur in the upper reaches of some rivers (e.g., the Niger, Benue, Congo, Ubangi, and Chari rivers in Mali and Chad) up to 2,000 km from the sea. Additionally, there are some reports of manatees in several lakes in the land-



locked country of Chad. They appear to prefer areas with abundant growth of mangroves and aquatic grasses.

Ecology and behavior Manatees are mostly solitary, but individuals are found together in mother/calf pairs and aggregations of up to 15 for feeding and reproductive purposes. The mating herds may exhibit much rolling and splashing, and tend to have several (male?) animals apparently pursuing a single female. Manatees sometimes rest in the middle of lagoons, along river banks, and underneath overhanging vegetation or roots, generally during the day. They tend to feed at night. The average breathing interval is slightly over 6 minutes, but they can hold their breath for at least 18 minutes. They migrate seasonally in rivers with large seasonal fluctuations in freshwater flow. Radiotagging studies show that West African manatees tend to be rather sedentary, but they do make some larger-scale movements (to at least 42 km). These animals may occasionally be eaten by crocodiles. There is little else known of their behavior.

There is some breeding year-round, but there also appear to be seasonal peaks between June and September in some areas, related to the rainfall and water levels. A single calf is born, generally in shallow lagoons. The limited evidence suggests the existence of strong population structure, with several different stocks in different parts of the species' range. The lifespan is not well known, but based on its close relatives, may be greater than 60 years.

Feeding and prey Aquatic vascular plants comprise much of the diet of West African manatees. They may also feed on mangrove leaves or plants on the banks of rivers or channels. Fish are sometimes taken from gillnets. Clams have been found in the stomachs of some animals.

Threats and status The folklore of the West African peoples contains many stories of manatees. Although never subjected to large-scale commercial hunting, like their congeners, West African manatees have been killed on a smaller scale for many decades throughout most, if not all, of their range. This is done mainly to obtain meat for food and also in some cases to reduce perceived interference with fisheries and agriculture. They are harpooned, captured in drop traps, and tangled in specialized nets. Manatees damage fishing gear and apparently invade flooded rice fields and eat rice, damaging the crops. Other potential threats include incidental mortality in fisheries, contaminants, boat collisions, ingestion of plastics, and damming of rivers. Manatee reserves exist in several West African countries, including the Ivory Coast, Cameroon, and Nigeria, although their effectiveness is often questionable. There are no estimates of abundance for any portion of the range, however it is quite clear that the West African manatee is the most highly-threatened of all the sirenians. Despite national protection in virtually all countries of origin, the species appears to be declining, and there is a very real chance that it will disappear in the next few decades.

IUCN status Vulnerable.

References Husar 1978; Marsh and Lefebvre 1994; Powell 1996; Reynolds and Powell 2002.

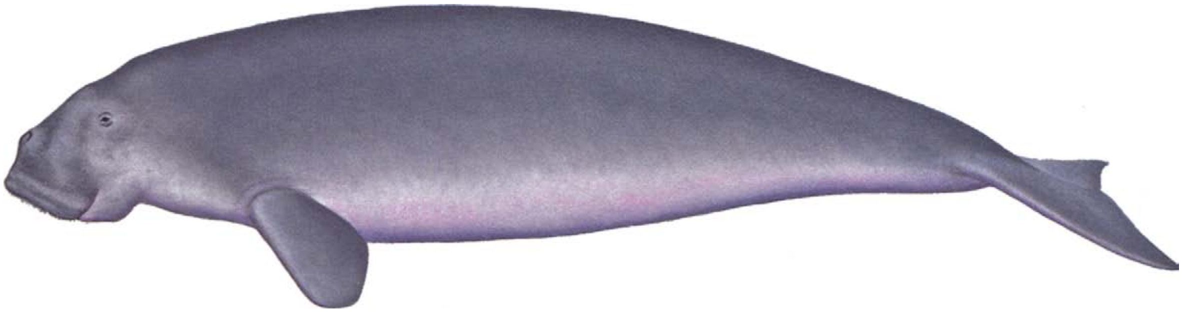
Trichechidae

West African Manatee

Dugong—*Dugong dugon*

(Müller, 1776)



Common names En.–dugong; Sp.–*dugón*; Fr.–*dugong*.

Taxonomic information Order Sirenia, Family Dugongidae. Some biologists recognize two subspecies: *D. d. dugon* in the Indian and western Pacific oceans, and *D. d. hemrichii* in the Red Sea. These subspecies designations are not well-accepted, however, and most marine mammal researchers don't use them.

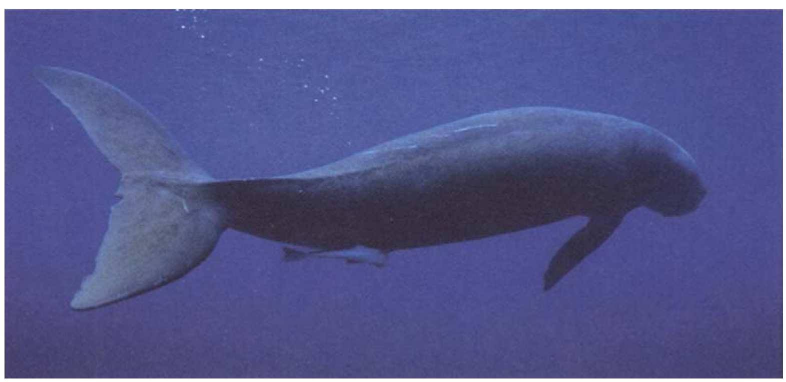
Species characteristics The dugong is unique among living sirenians in having whale-like flukes with a median notch, instead of the rounded tails possessed by manatees. They have been described as looking something like a cross between a dolphin and a walrus. In general, dugongs are more streamlined and cetacean-like than manatees, with a smooth, fusiform body. The tail stock in front of the flukes is laterally compressed into a peduncle. The paddle-shaped flippers have no nails. There is a downward deflection to the muzzle, which ends in a "rostral disk" with short, dense bristles. The nostrils are valve-like and are situated on the top and front of the animal's snout. The eyes are very small, and there are no external earflaps. The skin is generally smooth (not wrinkled, although there are folds) and is sprinkled with short hairs. The mammary glands of females are located in the axillae (armpits), unlike those of cetaceans.

Adult dugongs are brownish to slate gray on the back (generally appearing more brown when seen from above the surface), slightly lighter on the belly (which sometimes can have a pinkish hue). Older individuals may have a large unpigmented area on the back (these are called "scarbacks"). Calves are a slightly paler gray color than adults.

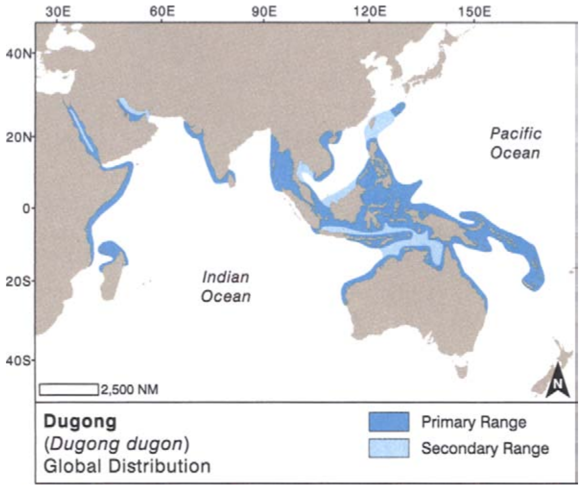
The dental formula is I $^{2}/_{3}$, C $^{0}/_{1}$, PM $^{3}/_{3}$, M $^{3}/_{3}$. The lower incisors and canines, and the inner pair of upper incisors, are vestigial. The outer pair of upper incisors of males and some females erupt from the gums, and are referred to as "tusks." However, they do not extend outside the closed mouth.

Maximum known size for dugongs is about 3.3 m and at least 400 kg (a specimen reported to be 4.06 m

Dugongs are truly creatures of the tropical oceans, and it is not uncommon to see them swimming in areas of coral reefs. Indonesia. PHOTO: B. KAHN



Of the four living species of sirenians, dugongs have the most cetacean-like appearance, with bilobed flukes, rather than the rounded paddles of manatees. Vanuatu. PHOTO: I. VISSER



A dugong swims near the bottom in very clear waters of Palau, showing its cetacean-like tail flukes. PHOTO: I. VISSER

This dugong is swimming off the Cocos-Keeling Islands of the southern Indian Ocean. Many of the species' distinctive characters can be seen here. PHOTO: K. WILLSHAW

and 1,016 kg is considered to be an error). There is not much difference in size between males and females. At birth, dugongs are between 1 and 1.5 m long and weigh about 20 kg.

Recognizable geographic forms None.

Can be confused with This is the only sirenian in the Indo–Pacific. There is some possibility of confusion with the finless porpoise or Irrawaddy/snubfin dolphins, but the single blowhole of the cetaceans and the double nostrils of the dugong will generally allow them to be easily distinguished. Also, pay attention to head and flipper shape (and dolphins of the genus *Orcaella* have a small dorsal fin). Dugongs also tend to move more slowly than most dolphins.

Distribution Dugongs are widely distributed in the Indo–Pacific region in coastal tropical and subtropical waters, covering some 37 countries. They are still present at the limits of their original range; however, there have been many reductions in their historical range. Dugongs appear to prefer shallow protected bays and channels, and the lee sides of large inshore islands, often in muddy waters. Although primarily coastal, dugongs do occur farther offshore in areas where the continental shelf is wide and protected, in water up to about 33 m deep. The range is discontinuous: it extends from southeast Africa north to the Red Sea; in the Persian Gulf; along western India to Sri Lanka; and throughout the Indo–Malay archipelago and the Pacific islands, to the Ryukyu Islands in the north and the central coasts of Australia in the south.

Ecology and behavior Dugongs occur mostly in small groups of up to 6 individuals. Herds as large as several hundred animals periodically form, although apparently not as often as in the past. Dives up to 8 minutes have been recorded, although most dives are much shorter.

The specific function of the tusks is not known. Although they are not known to migrate *per se*, and most movements are small-scale, dugongs do undertake large-scale movements of thousands of kilometers. They can move up to several hundred kilometers in just a few days. The social behavior of this species appears to be more complex than for the related manatees. Average swimming speed is about 10 km/hr. They may roll like a cetacean when traveling or deep diving. These animals are preyed upon by large sharks, killer whales, and crocodiles. The seagrass beds that dugongs rely on are vulnerable to human destruction and disturbance. The dugong has gained cultural significance to many of the peoples of the tropical Indo–Pacific, such as those of northern Australia and Papua New Guinea.

Although reproductive activity can occur throughout the year in most areas, there are calving peaks in June to September in at least some parts of the range. Not much is known about reproductive behavior in the dugong, but it is thought to be polygamous. Groups of males seem to compete to mate with a single estrus female. Females do not produce their first calf until at

When seen from above the surface, dugongs have a very low surfacing profile, and can be easily missed in anything but very calm seas. PHOTO: C. GARRIGUE

A dugong feeds at the bottom of the sea off Vanuatu. These animals feed on seagrasses and other vegetation generally found along the bottom in shallow, tropical seas. PHOTO: I. VISSER

least 10 years of age (sometimes as late as 17). The gestation period is about 13–14 months, and a single calf is born, with high investment in the calf. Calves are weaned at about 18 months, but may remain with the mother for several more months. Dugongs are very long-lived, to at least 73 years.

Feeding and prey Dugongs have a very specialized diet. Their food consists of various types of bottom vegetation, primarily seagrasses. Feeding trails in seagrass beds can be seen in dugong feeding areas exposed by the tides.

Threats and status Historically, dugongs were probably hunted nearly everywhere in their range for meat and oil, but now in most countries this practice is illegal (although it still commonly occurs). The hunting dates back about 4,000 years. Body parts are also used in traditional medicine and for amulets in some parts of southeast Asia. Legal hunting still occurs in Papua New Guinea and northern Australia, where it is managed to be sustainable. Dugongs are highly vulnerable to human impacts, due to their life history and dependence on easily-damaged coastal seagrass beds. Additional threats include loss of and damage to seagrass beds, incidental catches in fishing nets, and captures in shark nets set to protect bathing beaches. There are several natural threats as well: cyclones, storm surges, parasites, and predation. Dugongs are afforded legal protection in much of their range, although these laws are seldom enforced. In Australia, there is a rigorous system of management, which incorporates not only extensive research and the establishment of reserves, but also community involvement by indigenous peoples in the overall management scheme. There have been documented or presumed population declines in many areas of the range, and the species is considered to be at risk of extinction in East Africa, India/Sri Lanka, Japan, and Palau. Except in Australia, dugongs are probably mostly represented by relict populations, separated by areas of complete or near-total local extinction. Thus, Australia is seen as almost the only hope for the long-term survival of this species (although the Red Sea also appears to contain a reasonably healthy population). There were estimated to be about 100,000 dugongs worldwide in the 1980s; 85,000 are considered to occur in Australia alone. Along the Andaman Sea coast of Thailand, there are estimated to be at least 120 dugongs. About 7,300 are estimated to occur in the Persian (Arabian) Gulf. Few other regional abundance estimates are available.

IUCN Status Vulnerable.

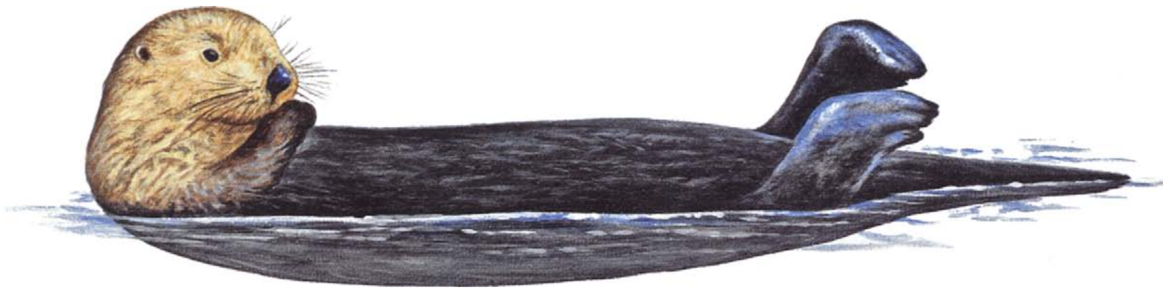
Sea Otter—*Enhydra lutris*

(Linneaus, 1758)



Recently-used synonyms None.

Common names En.–sea otter; Sp.–*nutria marina*; Fr.–*loutre de mer d'Amerique du nord.*

Taxonomic information Order Carnivora, Family Mustelidae. Three subspecies are currently recognized: *E. l. lutris* in the western North Pacific, *E. l. kenyoni* from the Aleutian Islands to Washington State, and *E. l. nereis* from central California to northern Mexico.

Species characteristics The sea otter is the most derived of the otters. The muzzle has a set of thick vibrissae. The large head has a blunt snout, and is connected to the body by a short, stocky neck. The forelimbs are short and similar to those of other otters, with a loose flap of skin under each that serves as a pocket to store food. The forepaws are very dexterous and sensitive. The hindlimbs are large and flattened like flippers; they are oriented backwards. Although the tail is relatively short (among otters), it is not noticeably tapered. It is flattened top to bottom into a paddle-like structure.

The pelage of sea otters is the densest of any mammal (more than 100,000 hairs/cm^2). A layer of sparse guard hairs overlays the dense underfur. Sea otters are completely covered with fur, except for the nose pad, inside the ear flaps, and the pads on the bottom of the feet. The color of the fur is dark reddish brown to black. Some individuals, especially older ones, may become grizzled, with the fur around the head, neck, and shoulders becoming almost white.

The dental formula is I $^3/_2$, C $^1/_1$, PM $^3/_3$, M $^1/_2$. Male sea otters reach lengths of 148 cm and weights of 45 kg. Females can be up to 140 cm and 32.5 kg. Newborns are about 0.6 m long and weigh about 1.8–1.9 kg.

***Pup*—**Size 0.6–1.1 m; fur is light buff in color and very fluffy; younger animals closely associated with mother.

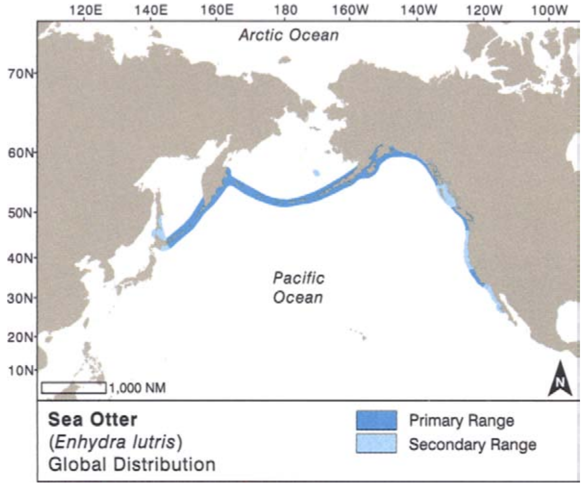
***Juvenile*—**Size 1.1–1.3 m; pelage more sleek, and dark brown to black in color; independent of mother at about 0.5 years.

***Adult*—**Adult size (> 1.3 m); pelage dark brown to black. Older individuals become grizzled around the head and shoulders (males more so than females). Females may have pinkish nose scars.

Recognizable geographic forms The different subspecies are generally not recognizable in the field from external differences.

Can be confused with The sea otter is the only truly marine otter in its range, although North American river otters (*Lontra canadensis*) and Eurasian otters (*Lutra lutra*) are often found in marine waters along the northwest

Two sea otters lie wrapped in kelp off the Monterey Peninsula. Otters rest in the kelp beds to avoid large waves and rough water. PHOTO: T. A. JEFFERSON



coast of North America and in the western North Pacific, respectively. River otters are smaller and more slender than sea otters, with longer tails. Also, river otters generally swim belly down even at the surface, while sea otters usually (but not always) swim along the surface on their backs.

Distribution Sea otters are found in shallow, nearshore waters of the North Pacific Rim, from the southern Kurile Islands, north along the Kamchatka Peninsula, then east along the Aleutian Islands to the Alaska Peninsula and Prince William Sound, and thence south to southern California (and occasionally as a vagrant to central Baja California, Mexico). Originally, their distribution was nearly continuous from Hokkaido, Japan, to central Baja California, Mexico. However, there are now 4 disjunct remnants: Kurile Islands to southeast Kamchatka Peninsula (classified as *E. l. lutris*); Commander Islands; Aleutian Islands to Prince William Sound, Alaska (these

A close-up of the head of a sea otter lifting its head high out of the water to look around in Monterey Bay, showing the small eyes and ears, and heavy whiskers characteristic of the species. PHOTO: D. FRANK

two groups are classified as *E. l. kenyoni*); and central/southern California (classified as *E. l. nereis*). In addition, there have been several reintroduction attempts (some successful, others not) along the west coast of North America. Southeast Alaska, British Columbia, and Washington State are three areas where reintroductions have been successful.

Ecology and behavior Sea otters can be seen singly or in groups (most often resting groups called rafts). Rafts in California tend to be small, between 2 and 12 animals, and rarely exceed 50 individuals. Those in Alaska are also generally small, but can contain up to 2,000 otters. They are thought to be capable of having a major influence on their prey populations, with cascading effects on coastal marine communities, especially where sea otter densities are high. Foraging generally occurs singly, although animals may aggregate in good feeding areas. Females with small pups may leave their pups on the surface while diving, and spend more time feeding at night to avoid eagle predation.

Sea otters are most often seen floating on their backs in and around kelp beds or in protected areas while resting. They bring their prey to the surface to feed on it. Rocks and other hard objects are used as tools to crack open shells of their prey, which they eat using their bellies as "dinner tables". They sometimes store tools in the skin flaps under the front limbs. They use their sense of smell in many aspects of their life, and can be difficult to approach from upwind (presumably because they can smell the intruder). When they enter a group, otters use a ritualized greeting that apparently involves scent recognition. Sea otters spend up to 10% of their time grooming their fur, which maintains its insulation properties. They are not deep divers, as marine mammals go, and most dives are to less than 60 m. However, they are capable of dives of over 100 m and up to about 7 minutes. Sea otters can haul-out onshore, and retain limited ability to walk around on shore and over rocks.

Sea otters are polygynous; males tend to defend large (average about 0.4 km^2) territories that encompass the home ranges of several females. Females aged 3 and above give birth to a single pup annually. Pupping occurs throughout the year, but peaks in April to June in Alaska, and December to February in California. During mating, the male bites the nose of the female to position himself; thus, females often have nose scars (these are useful to researchers in identification of individuals).

Feeding and prey Sea otters consume up to 25% of their body weight per day to maintain their high metabolic rate. They feed on or near the bottom in shallow waters (often in kelp beds). They have a diverse diet of over 150 prey items. Major prey are benthic invertebrates, such as abalones, sea urchins, and rock crabs. However, sea

otters also eat other shellfishes, cephalopods, and some near-bottom fishes in Asia and the Aleutian Islands. Diet is often highly variable among individuals.

Threats and status Historically, sea otters have been hunted by aboriginal peoples of the North Pacific for many centuries. Although the primitive methods sometimes were sustainable, there is evidence that some maritime peoples hunted otters to local extinction. Sea otters were commercially hunted heavily between 1750 and 1900 throughout their range for the North Pacific fur trade, and most likely less than 1,000 sea otters survived this carnage. In the 20th century the survivors thrived and increased under protection and intensive management efforts. However, recently there have been several disturbing declines in abundance. Populations in the Aleutian Islands of Alaska declined by about 80–90% in the 1990s, and this may have been at least partially related to killer whale predation. The decline is continuing, and it appears possible that otters may disappear from most or all of the Aleutians in the next 10 years or so. The California population declined by about 12% to just under 2,000 individuals in the mid- to late 1990s, and since then the numbers have increased to about 2,700. The reasons for the decline are unknown (although pollution, disease, fisheries, and food limitations have all been suggested). In Asia, sea otters have been much less intensively studied than in the rest of their range. There, they occupy most of their historic range, but abundance is thought to be reduced, and there is apparently frequent poaching in Russian waters. Globally, there were estimated to be about 100,000 sea otters in the 1990s, mostly in Alaskan waters. Current worldwide estimates of abundance are between 82,000 and 95,000. Overall, sea otters are not in danger of global extinction, as they were in the past, but problems persist. The main threats today include pollution, disease, by-catch, hunting by native peoples, poaching, habitat loss, and predation by killer whales and sharks.

IUCN status Endangered.

Marine Otter—*Lontra felina*

(Molina, 1782)

Recently-used synonyms *Lutra felina*.

Common names En.–marine otter or chungungo; Sp.–*nutria de mar* or *chungungo*; Fr.–*loutre de mer* or *loutre marine d'Amérique du Sud*.

Taxonomic information Order Carnivora, Family Mustelidae. As a result of recent molecular studies, most mammalogists now use the genus name *Lontra*, instead of *Lutra*, for the New World otters. Two subspecies have been designated, but their validity is doubtful.

Species characteristics Marine otters are very similar in general appearance to freshwater otters. The snout is blunt at the tip and the rhinarium (nose pad) is naked and relatively flat. The head slopes smoothly back from the nose. The ears are small and set far back on the head. The tail tapers to a point, typical of fresh-water otters, and is relatively short—about 30–36 cm long (about $^{1}/_{3}$ of the total length). The feet are of moderate size, with well-webbed digits, and strong claws. The ventral surface of the webs are partially furred. The coarse pelage is rough in appearance, and has a dense underfur and a set of long guard hairs (up to 20 mm long). The vibrissae of the upper lip and corner of the mouth are large.

Marine otters are dark brown above and on the sides, with a lighter fawn color below, especially on the throat. The muzzle, throat, and lips are not spotted, as in some other otter species. The nose pad is black, and its structure may be geographically variable (nose pad variations are used to distinguish different species within the otter subfamily). Juveniles are slightly lighter than adults.

The dental formula is I $^{3}/3$, C $^{1}/1$, PM $^{3\text{–}4}/3$, M $^{1}/2$, for a total of 36 teeth.

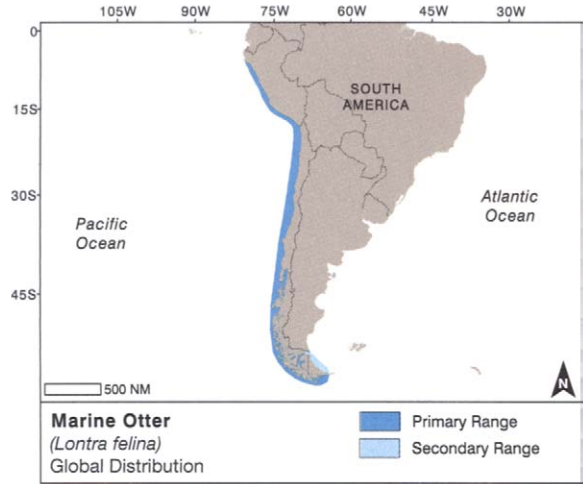
Marine otters are the smallest species of the genus *Lontra*. They attain total lengths (including the tail) of 0.87–1.15 m.

A chungungo eating a prey item on a rocky Chilean shoreline.
PHOTO: C. OLAVARRIA

Recognizable geographic forms None.

Can be confused with This is the only truly marine otter along the west and southwest coasts of South America, although there are southern river otters (*Lontra provocax*) along some parts of the coast and marine otters do enter rivers on occasion. However, marine otters tend to occur in exposed outer coast habitats, while river otters are often found in more protected inner waters (most live entirely in freshwater habitats). Also, river otters can be distinguished from marine otters by their larger size, darker color, finer fur, and more peaked nose pads.

Distribution These coastal otters are found in a narrow strip on open, wave-exposed rocky shores (to about 30 m inland) and adjacent waters (to about 150 m offshore) from the southern tip of Chile (Cape Horn, 56°S)



A marine otter hauled-out on rocks. Note the similarity in appearance to terrestrial otter species. PHOTO: J. MANGEL

to Chimbote, southern Peru (6°S). They were thought to have been extirpated from Argentina, but there still may be groups extant at Isla de los Estrados and in the Strait of Magellan. They are largely restricted to marine waters, but sometimes enter rivers.

Ecology and behavior Very little is known of the biology of the marine otter. They are found mostly singly or in pairs, but groups of 3 or more are sometimes seen. Marine otters are not known to be territorial, and they have overlapping home ranges. They are diurnally active, but their activities at night are not known. There is some evidence that marine otters at Chiloe Island, Chile, may have a narrower diet based on larger prey than at other nearby sites. Marine otters are more agile in the water than on land, although they are capable of climbing rocks. They sometimes float on their back, like sea otters. Hunting dives last an average of about 30 sec, although dives of over one minute have been recorded. They often occur around large rock outcroppings with caves, which are used for pupping, resting, feeding, and defecation. Predators of the marine otter are probably killer whales and sharks.

Marine otters are thought to be monogamous, sometimes tending toward polygamy. The reproductive season is not well-known, but much of the pupping may occur from January to March. The usual litter of 2 pups (ranging from 2–4) is born after a gestation period of 60–65 days. Pups remain with the mother for about 10 months.

A marine otter hauled-out near the entrance to a sea cave. Notice the coarse guard hairs around the neck. PHOTO: J. MANGEL

Feeding and prey Marine otters are opportunistic feeders, taking crabs, shrimps, mollusks, and fish. The diet in southern Chile is made-up of 52% crustaceans, 40% fish, and 8% mollusks. Prey size averages 95–185 g. They sometimes enter rivers to feed on freshwater prawns.

Marine otters are among the least adapted of the marine mammals to an oceanic existence. They spend much time ashore, and when in the water generally don't range far from land. PHOTO: J. MANGEL

Although most marine mammals are quite large, the marine otter manages to get by at about the same size as terrestrial otters. PHOTO: C. OLAVARRIA

Threats and status The marine otter is rare and is considered to be threatened with extinction. Historically they were heavily involved in fur trading, but this does not happen much anymore. The main threats to their survival are remaining illegal hunting for fur, habitat destruction by urban and industrial development, mining, pollution, competition with fisheries, bycatch, and explosive use by fisheries. Invasive species and tourism may also be factors in some areas. There are no reliable estimates of global abundance for the species. About 750 are thought to occur in Peruvian waters, and the largest populations apparently occur in Chilean waters. But by some estimates the total population may be < 1,000 individuals. The species may already be extinct in Argentina.

IUCN status Endangered.

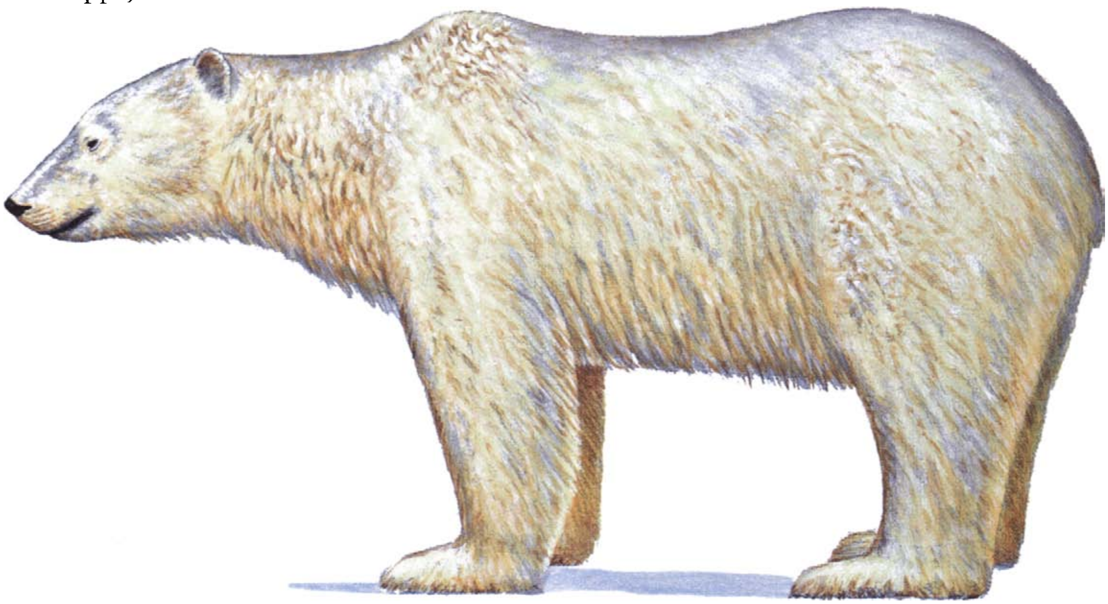
Polar Bear—*Ursus maritimus*

Phipps, 1774



Recently-used synonyms None.

Common names En.–polar bear; Sp.–*oso polar* or *oso blanco*; Fr.–*ours blanc*.

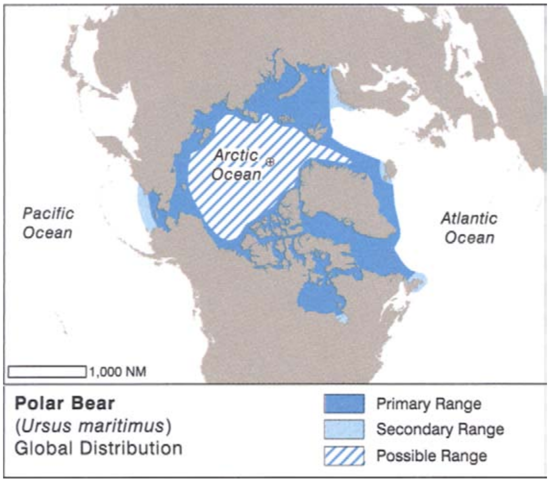
Taxonomic information Order Carnivora, Family Ursidae. Two subspecies are recognized: *U. m. maritimus* in the Atlantic Arctic and *U. m. marinus* in the Pacific Arctic, although there is some doubt about their validity.

Species characteristics The polar bear is not radically different from other bears in body form. It is similar in size to brown and grizzly bears (*Ursus arctos*), but is more slender, and has a longer neck and more elongated head. It also lacks an enlarged shoulder hump. The ears are small, an adaptation to the bitterly cold environment it lives in. Large, partially-webbed paws on the front limbs are used for swimming (hindlimbs are not used). There are five digits on each foot, each with a heavy, non-retractable claw. Polar bears are covered with fur on all but the nose and the pads on the bottoms of the feet. The guard hairs overlaying the underfur are up to 15 cm long, and they reach greater lengths on the forelegs in males. Females typically have four functional mammae.

Generally, the pelage of polar bears is white, but (depending on lighting and condition) it can appear yellow, light brown, or even light gray. The area around the mouth may be stained with blood after a recent meal. The nose, lips, eyes, and footpads are all black, as is the skin underneath the fur.

The dental formula is I $^{3}/3$, C $^{1}/1$, PM $^{2–4}/2–4$, M $^{2}/3$. The back cheek teeth are much smaller than those of other bears. Males may be up to 250 cm long and may weigh up to 800 kg, which is somewhat larger than females. Females reach lengths and weights of 200 cm and 350 kg, respectively. Pregnant females sometimes attain weights of up to 500 kg. Adult males are generally about twice as heavy as females. At birth, the tiny cubs weigh only about 0.6 kg.

A polar bear walking on land, showing the characteristic coloration and body shape of the species. As the only truly white bear, and the only one found regularly in Arctic coastal areas, the polar bear is usually easy to identify, even for novices. Svalbard. PHOTO: M. JØRGENSEN



There will generally be no identification problems with polar bears—the great white bear of the north is unmistakable. Spitsbergen. PHOTO: I. VISSER

Three polar bears provide a variety of views of the species. With the exception of their eyes, inner ears, noses, and lips, these animals are virtually all-white, providing them with excellent camouflage among the Arctic ice. PHOTO: M. JØRGENSEN

Recognizable geographic forms There is some slight geographic variation, but the subspecies are generally not recognizable in the field.

Can be confused with There should be no problem recognizing polar bears in most cases. In the few areas where grizzly/brown (*Ursus arctos*) and American black (*Ursus americanus*) bears are found within the polar bear's range, the much lighter color of the polar bear's fur will make it virtually unmistakable.

Distribution Polar bears have a circumpolar distribution in the Northern Hemisphere. Their southern limits fluctuate with the ice cover (they have been recorded as far south as the Pribilof Islands in the Pacific and Newfoundland in the Atlantic). The northernmost record is from around 88°N. Polar bears are generally associated with sea ice, but they have been seen swimming at sea many kilometers away from the nearest land of ice.

Ecology and behavior Polar bears tend to be solitary, but breeding pairs and females with up to 3 cubs may be seen together. They also aggregate in areas of high ringed seal density (their primary prey), and around refuse dumps. These bears can swim well, using their large webbed paws. They spend most of their time on ice, but sometimes spend significant periods of time on land. Polar bears in Hudson Bay and southeastern Baffin Island (where snow melts completely in summer), spend several months fasting on land before ice forms in the autumn. They have impressive fasting abilities, due to their fat storage capabilities. Those that have access to sea ice throughout the year tend not to fast. Polar bears typically hunt by waiting near a hole in the ice used by seals for breathing. They then pull the seal out onto to the ice when it surfaces and devour it. These bears have an excellent sense of smell, and do much of their hunting with the assistance of olfaction. They are the top marine predator in the Arctic ecosystem, and they get virtually all of their sustenance from the sea, although they rarely hunt in the water directly.

Polar bears make long migrations of 2,000–4,000 km across the ice, and may move over 100 km in the water. They are capable of moving quite fast on ice, up to 40–50 km/hr for short sprints. This large predator is potentially quite dangerous to people in the Arctic and does occasionally kill and eat humans.

Mating in polar bears occurs from April to June. Each male may mate with one or several females. Females breed for the first time at 4–5 years of age. In November to December, the pregnant female excavates a den, where typically 2 cubs (sometimes 3 and occasionally just 1) are born in December and January. Females show some fidelity to denning areas, but not necessarily to individual dens. The cubs are generally nursed for about 2.5 years. Polar bears can live to be in their early 30s. About 20 different populations are recognized.

A mother teaches her three cubs how to move among the ice floes, an essential life skill for polar bears, which obtain most of their food from the Arctic ice. Global warming and consequent melting of the ice is therefore a big concern for this species. Svalbard. PHOTO: M. JØRGENSEN

Feeding and prey The primary prey of polar bears consists of ringed seals, but they also take bearded, harp, and hooded seals, and rarely walruses and white whales. These bears sometimes also eat Arctic cod and other forms of animal and vegetable matter. They even scavenge on refuse at dumps in some areas.

A polar bear mother with three small cubs sniffs the air for approaching signs of danger. The only real threat to this species comes from humans and the changes in climate that we have caused. Svalbard. PHOTO: M. JØRGENSEN

Threats and status Polar bears have been hunted by aboriginal peoples of the north for a long time, and are still killed by natives in at least Alaska, Canada, Greenland, and Siberia. About 800–900 per year are taken, and many of these hunts are carefully regulated to make sure they are sustainable. Thus, hunting is not the major threat to these animals. Other potential threats to the animals include pollution, global warming and ice breakup, and disturbance from oil and other mineral extraction operations. Issues related to environmental contamination have become increasingly worrisome in recent years, although exactly how contaminants affect the bears is still not well known (although some bears with high PCB levels have had both male and female reproductive organs). In addition, disturbance from ecotourism could be problematic in some areas, although such tourism has increased the public appreciation for these animals to be kept alive. For instance, in Churchill, Manitoba, Canada, there is a thriving bear-watching industry. Recently, a new threat has been identified—the changes in sea ice and associated impacts caused by global warming. In fact, there is some speculation that the global warming issue could threaten the future survival of the species. Total global abundance of the species was estimated to be about 22,000–27,000 bears in 1997.

Polar bears are most often seen and photographed on land. However, these bears are indeed marine mammals. Despite their seemingly incomplete adaptation to the marine environment, they are excellent swimmers, sometimes moving many kilometers from the nearest land or ice. Svalbard. PHOTO: M. JØRGENSEN

IUCN status Vulnerable.

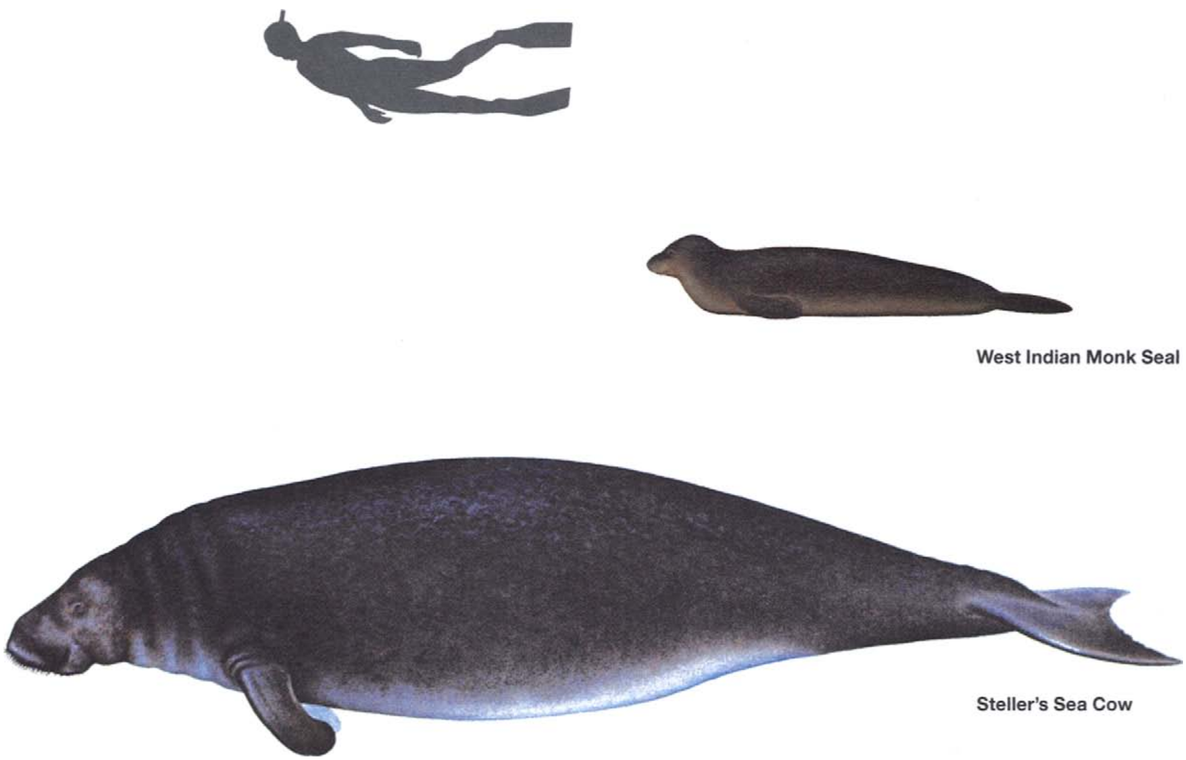
7. Extinct Species



West Indian Monk Seal—*Monachus tropicalis*

(Gray, 1850)

Recently-used synonyms None.

Common names En.–West Indian monk seal or Caribbean monk seal; Sp.–*foca monja del Caribe*; Fr.–*le phoque moine de la Caribe*.

Taxonomic Information Order Carnivora, Suborder Pinnipedia, Family Phocidae.

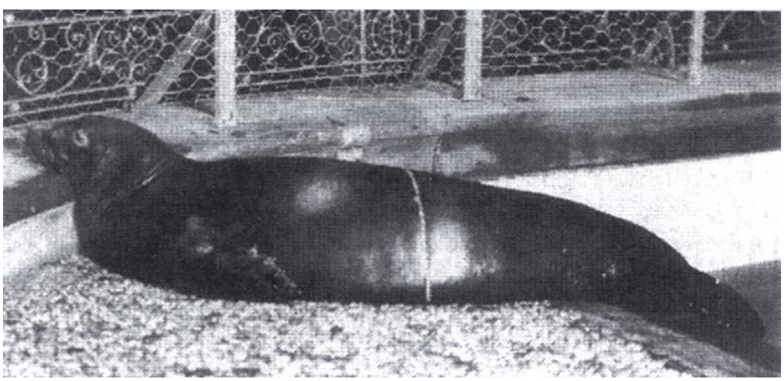
Species characteristics Coloration of adult West Indian monk seals was brown with a grayish tinge above, due to the tips of the hairs being lighter. The color became lighter on the sides, and transitioned to yellowish-white below. The end of the muzzle and lower lip, and the sides of the muzzle were yellowish white. Adult vibrissae were predominantly whitish and smooth with a few having darker bases, and still other short vibrissae were entirely dark. No difference was noted between the external coloration of males and females. Younger animals tended to be paler than adults, being more yellowish dorsally, with ochre tones ventrally, and a dusky central area at the end of the muzzle. Like Hawaiian monk seals, West Indian monk seals were said to occasionally have green algae growing on the pelage. Females had four abdominal mammae.

Newborn West Indian monk seals had a long, soft, glossy black lanugo coat that persisted for an unknown period of time. Generally, these seals were described as having very few scars from fighting, although one large adult male was observed with gashes and scars that resembled seams. The vibrissae of pups were uniformly dark.

Adult West Indian monk seals reached at least 2.4 m in length, (females may have been slightly larger than males). Hawaiian monk seals of comparable length to the largest reported for West Indian monk seals weigh 170–270 kg. Newborns were probably about 1 m and 16–18 kg.

The dental formula was: I $^{2}/_{2}$, C $^{1}/_{1}$, PC $^{5}/_{5}$.

Can be confused with No other pinniped species regularly inhabits the former range of the West Indian monk seal. Hooded, harbor, and less frequently, harp seals are known to stray occasionally as far south as the central east coast of Florida, near the edges of the West Indian monk seal's former range. A monk seal could easily be distinguished from all of the above by the following collection of features: their long unspotted and unbanded body, brownish dorsal and pale ventral coloration, broad flat head and muzzle, and smooth unbeaded vibrissae. California sea lions that have escaped from captivity have also been reported from the Gulf of Mexico, but otariid seals differ from monk seals by the presence of external ear pinnae, long oar-like fore flippers, and a long narrow head and dog-like muzzle.



A rare photograph, from around 1910, of a West Indian monk seal. This was one of three animals captured in 1909 and exhibited at the New York Aquarium. Its age and sex are unknown. Captured at Arrecifés Triángulos or Arrecife Alacrán, Mexico.
PHOTO: COURTESY OF THE DEPARTMENT OF MAMMALOGY ARCHIVES, AMERICAN MUSEUM OF NATURAL HISTORY.

Distribution This monk seal once inhabited most of the Caribbean Sea and Gulf of Mexico. One exception was the western and northern Gulf of Mexico, where historic records from Texas have been refuted, and prehistoric midden material was re-evaluated to have come from trading. In prehistoric times, the range of the West Indian monk seal may have reached north to South Carolina. The last stronghold of the species was Serranilla Bank, about half way between Jamaica and Honduras, where the final reported sighting occurred in 1952.

Ecology and behavior Observations made in the field and from animals collected in the 19th century provide evidence that pups were born from at least late fall to early winter. A long pupping season is known for both the Hawaiian and Mediterranean monk seals, which also live in sub-tropical habitats, and it is reasonable to assume this was also the case for the West Indian monk seal. The animals collected in December 1886 included newborn pups, and several females with term fetuses. Also, an animal described as recently weaned was encountered in the spring and a female with a large fetus was taken in July.

It can be inferred that the West Indian monk seal was a social species, possibly in the manner of the Hawaiian monk seal in that the large number collected in 1886 were all taken from three small cays in three days. Furthermore, the collectors describe finding females with term fetuses hauled out near one another, and in another case a pregnant female was hauled-out in the vicinity of a female suckling a pup. Hauled-out groups of 20–40 were observed and reference was made to groups of 100 or more in earlier times. An otherwise undescribed group of five animals hauled-out together included a large, scarred adult male. On another occasion, the collectors encountered a group whose composition and numbers were not given, but the seals were "huddled together." Young West Indian monk seals were also said to rest in pools of water, presumably for thermoregulation.

Several descriptions exist of the vocalizations of the West Indian monk seal. A young animal briefly held in captivity was said to grunt like a pig, and bark, growl and snarl like a dog. In another account, seals that were approached by hunters were said to "bark in a hoarse, gurgling, death-rattle tone."

Feeding and prey There is no information on food and feeding habits. The specimens collected in 1886 all had stomachs that had fluid only, or were empty. The assumption at the time was that the diet consisted of fish.

Threats and status The West Indian monk seal is now extinct. Extensive searches for West Indian monk seals have been conducted with no success. The last sightings were from Serranilla Bank in 1952. The seals were hunted heavily for oil after western discovery of the New World, and later, as the species become rare, large sums were paid for zoo and museum specimens. Forty-nine specimens were collected in December of 1886. J. A. Allen examined the skins of 17 of these animals, including adult males and females, immatures, and suckling pups in January of 1897, and this study represents the best description of the physical appearance of the species available. Additionally, the original field notes taken during another 19th-century collection were recently found and provide first-hand accounts of the behavior of this species in the wild.

IUCN Status Extinct.

Steller's Sea Cow—*Hydrodamalis gigas*

(Zimmerman, 1780)

Recently-used synonyms None.

Common names En.–Steller's sea cow; Sp.–*vaca marina de Steller*; Fr.–*rhytine de Steller*.

Taxonomic information Order Sirenia, Family Dugongidae. Although classified with the dugong in the family Dugongidae, the Steller's sea cow was very distinctive and is generally placed in a separate subfamily.

Species characteristics The external morphology of the Steller's sea cow is not well-known, since the species was exterminated in 1768, before it could be studied in any detail. One thing is clear –this was a very large sirenian. It was rotund, especially in the summer, when feeding was good. It had a small head (only about 10% of body length) and horizontal flukes with a notch. The short, stubby forelimbs were about 67 cm long, with no nails or claws (and in fact, they lacked finger bones as well). The skin was rough on most of the body (so much so that people referred to it as like "bark"), although somewhat smoother on the back. It was very thick, up to at least 3 cm thick in places. There was a sparse covering of white hairs on the body, as well as stiff white bristles on the lips and foreflippers. The nostrils were round, and the eyes small and black. There were no external ear pinnae, only minute auditory openings. Steller's sea cow was brownish-black on the body, with a few white patches and streaks, especially on the undersides.

Functional teeth were completely absent, and grinding of food was done by keratinized masticatory plates inside the mouth. These were apparently white in color and "boat-shaped."

These massive animals grew to lengths of at least 7.52 m. The weights attained by these animals are not known, but have been estimated to be somewhere between 4 and 10 metric tons. They were, by far, the largest of the sirenians.

Can be confused with As the only sirenians in the northern North Pacific Ocean, and the only non-tropical sirenian, the Steller's sea cow would be difficult to confuse with any other marine mammal. It would have been more likely to confuse for a cetacean, but a good look would have been enough to resolve any such issues.

Distribution These animals lived only in the shallow, nearshore waters of the subarctic Bering Sea. They were found along the Bering and Commander Islands, and probably also occurred in the western Aleutian Islands. They were said to come very close to shore during high tide. A skull fragment from Monterey suggests that historically the species may have ranged farther south.

Ecology and behavior Steller's sea cows often congregated in small herds in shallow waters. Young were said to have been kept at the front of the group, surrounded by adults on the sides and from behind. While largely defenseless, the Steller's sea cow's huge size may have kept it safe from most enemies, except killer whales (and of course, humans). Seabirds often picked parasites from the animals' backs.

Not much is known of the behavior of this species. They spent most of their time feeding in kelp beds, near the islands. However, they apparently had difficulty submerging, due to their great buoyancy. They floated with their backs exposed and lifted their heads to breath every 4 to 5 minutes. They pulled themselves through the shallows with their short forelimbs, and used their flukes both vertically and horizontally to move through the water. Apparently, they sometimes slept on their backs. Animals were observed to stand-by injured conspecifics. They were thought to have been largely mute, with few sounds heard from them (although of course, no underwater recordings were made).

Virtually nothing is known about reproduction in this species, except that a single young was born, apparently mostly in the autumn. Copulation is said to have taken place in the early spring months, and gestation lasted more than 1 year.

Feeding and prey Steller's sea cows fed mostly on algae, especially kelp. They apparently only ate the leafy parts of the plants.

Threats and status Steller's sea cow was discovered in 1741, and after 27 years of relentless exploitation, it became extinct in 1768. It was hunted with harpoons from boats, and with spears and hooks from shore. It was highly prized for its meat, skin and blubber by fur traders in the North Pacific. The meat was used for food, the skin for shoes and boats, and the fat for food and lamp oil. It was thought by those who observed them that the population was larger than it actually was (pre-exploitation numbers were estimated at about 1,500 to 2,000 animals), and there was no restraint on the wasteful hunting. Later reports of sightings of this species have been convincingly refuted, and there is no doubt that it is long extinct, the first marine mammal species to be wiped out by human greed.

IUCN Status Extinct.

8. Dichotomous Identification Keys

General Notes on the Use of the Keys

The following general rules on the use of the keys should be kept in mind:

1. Use multiple features to make an identification and don't rely on a single feature.

2. Use the information in the key with more latitude when dealing with young or damaged specimens, or those from a very poorly-studied geographic region.

3. Feel free to jump to any place in the key to begin. For instance, if you are sure that the specimen you are working with is a toothed whale, jump to that part of the key (don't feel the need to go through each step of the key related to baleen whales).

4. If possible, try to have calipers, a ruler, or tape measure available to take measurements.

5. Always confirm your final identification by examining photos/illustrations, and comparing to appropriate descriptions in the species accounts.

6. Use geographical information as little as possible. Be aware that these are wide-ranging animals that sometimes wander far outside their normal ranges.

7. The keys (skull keys in particular) will be most useful to those with some previous experience with these animals.

A. Key to Identification of Cetaceans of the World, Based on External Appearance

1a. Double blowhole; no teeth present; baleen plates suspended from upper jaw

Mysticete, **Go to 2**

b. Single blowhole; teeth present (though sometimes not protruding from gums); no baleen plates

Odontocete, **Go to 14**

2a. Long ventral pleats absent (though 2–7 short creases or furrows may be found on throat)

Other baleen whale, **Go to 3**

b. Long ventral pleats present; dorsal fin present; upper jaw relatively flat viewed from the side and broad viewed from the top

Balaenopteridae, **Go to 5**

3a. 2–7 short creases or furrows on throat; upper jaw and mouthline flat to slightly arched; dorsal fin or hump present

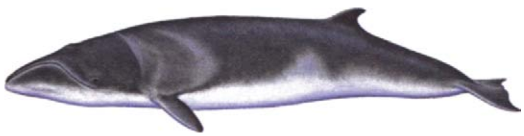
Caperea or *Eschrichtius,* **Go to 4**

b. No creases on chin or throat; no dorsal fin or hump; upper jaw and mouthline strongly arched viewed from the side and very narrow viewed from the top; long, narrow black baleen plates with fine black fringes

Balaena or *Eubalaena,* **Go to 11**

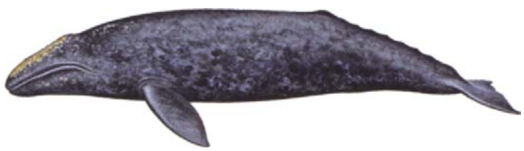
4a. 2 indistinct creases on throat; prominent falcate dorsal fin set about $^{2}/_{3}$ of the way back from tip of jaw; upper jaw arched when viewed from side; 213–230 yellowish white baleen plates in each side; maximum body length 7 m; Southern Hemisphere distribution only

Pygmy right whale *(Caperea marginata)*



b. 2–7 short furrows on throat; mouthline slightly arched; no dorsal fin, but small dorsal hump followed by 8–14 crenulations present; 130–180 white to yellowish baleen plates with coarse bristles per side; body mottled gray and usually covered with patches of reddish to yellowish whale lice and gray to white barnacles; maximum body length 15 m; North Pacific distribution only

Gray whale *(Eschrichtius robustus)*



5a. Ventral pleats end before navel

Minke or sei whale, **Go to 6**

b. Ventral pleats extend to or beyond navel

Humpback, Bryde's, blue, or fin whale, **Go to 8**

6a. 22–70 ventral pleats, longest ending before navel (often ending between flippers); 200–300 baleen plates with coarse bristles per side, less than 21 cm long, mostly white or yellowish white (sometimes with dark margin along outer edge); often conspicuous white bands on upper surface of flippers; from above, head sharply pointed; maximum body length 11 m

Minke whale, **Go to 7**

b. 32–65 ventral pleats, longest ending past flippers, but well short of navel; 219–402 pairs of black baleen plates with many fine whitish bristles, less than 80 cm long; flippers all dark; from side, snout slightly downturned at tip; maximum body length 18 m

Sei whale (*Balaenoptera borealis*)

7a. Usually, there is a brilliant white band running across each flipper (although occasionally the band may be very indistinct)

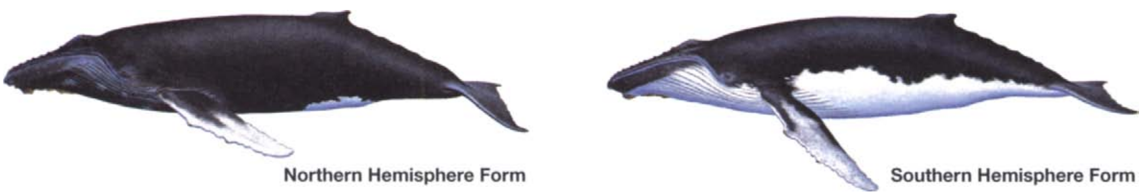
Common minke whale (*Balaenoptera acutorostrata*)

b. Usually, there is no white band across the flippers; distribution limited to the Southern Hemisphere

Antarctic minke whale (*Balaenoptera bonaerensis*)

8a. Flippers 1/4 to 1/3 of body length, with knobs on leading edge; flukes with irregular trailing edge; 14–35 broad conspicuous ventral pleats, longest extending at least to navel; top of head covered with knobs, one prominent cluster of knobs at tip of lower jaw; 270–400 black to olive brown baleen plates with gray bristles per side, less than 80 cm long; dorsal fin usually atop a hump; maximum body length 17 m

Humpback whale (Megaptera novaeangliae)



b. Flippers less than 1/5 of body length, lacking knobs; 40–100 fine ventral pleats; head lacking knobs

Bryde's, blue, Omura's, or fin whale, **Go to 9**[2]

9a. Three conspicuous ridges on rostrum; 40–70 ventral pleats extending to umbilicus; 250–370 slate gray baleen plates per side, with white to light gray fringes; head coloration symmetrical; maximum body length 16.5 m; tropical/subtropical distribution only

Bryde's whale *(Balaenoptera edeni/brydei)*

b. Only one prominent ridge on rostrum; 55–100 ventral pleats

Blue or fin whale, **Go to 10**

10a. Head broad and almost U-shaped from above; dorsal fin very small (about 1% of body length) and set far back on body; 260–400 black baleen plates with black bristles per side

[2] Due to uncertainties in the external appearance of Omura's whale, it is not possible to use this key for that species.

(all three sides of each plate roughly equal in length); head coloration symmetrical; body mottled gray, with white under flippers; maximum body length 33 m

Blue whale *(Balaenoptera musculus)*

b. From above, head V-shaped and pointed at tip; dorsal fin about 2.5% of body length; 260–480 gray baleen plates with white streaks per side (front 1/3 of baleen on right side all white); head coloration asymmetrical (left side gray, much of right side white); back dark, with light streaks; belly white; maximum body length 27 m

Fin whale *(Balaenoptera physalus)*

11a. Callosities (roughened areas of skin to which whale lice attach) present on head; 200–270 long (up to 2.8 m) baleen plates per side; body black, often with white ventral blotches; maximum body length over 18 m; temperate to subpolar distribution

Right whale (*Eubalaena spp.*), **Go to 12**

b. No callosities; white chin patch and often white band just before flukes; 230–360 long (some longer than 4 m) baleen plates per side; maximum body length 20 m; Arctic distribution only

Bowhead whale *(Balaena mysticetus)*

12a. Northern Hemisphere distribution

Northern right whale (*Eubalaena spp.*), **Go to 13**

b. Southern Hemisphere distribution

Southern right whale *(Eubalaena australis)*

13a. North Pacific distribution

North Pacific right whale *(Eubalaena japonica)*

b. North Atlantic distribution

North Atlantic right whale *(Eubalaena glacialis)*

14a. Upper jaw extending well past lower jaw; lower jaw very narrow

Sperm whale *sensu lato*, **Go to 15**

b. Upper jaw not extending much or at all past lower jaw; lower and upper jaws about same width

Other odontocete, **Go to 17**

15a. Body black to charcoal gray, with white lips and inside of mouth; head squarish and large, 1/4 to 1/3 of body length; short creases on throat; S-shaped blowhole at left side of front of head; low, rounded dorsal "hump" followed by a series of crenulations along the midline; 18–26 heavy, peg-like teeth in each side of lower jaw, fitting into sockets in upper jaw; body 4–18+ m

Sperm whale *(Physeter macrocephalus)*

b. Body less than 4 m; head not more than 15% of body length; blowhole set back from front of head; prominent dorsal fin; 8–16 long, thin, sharply-pointed teeth in each side of lower jaw, fitting into upper jaw sockets

Kogia sp., **Go to 16**

16a. Throat creases generally absent; dorsal fin shorter (< 5% of body length); distance from tip of snout to blowhole greater than 10.3% of total length; 12–16 (rarely 10–11) sharp teeth in each half of lower jaw

Pygmy sperm whale *(Kogia breviceps)*

b. Inconspicuous throat creases; dorsal fin taller (> 5% of body length); distance from tip of snout to blowhole less than 10.2% of total length; 7–12 (rarely up to 13) teeth in each side of lower jaw, sometimes 1–3 in each half of upper jaw

Dwarf sperm whale *(Kogia sima)*

17a. Two conspicuous creases on throat, forming a forward-pointing V; notch between flukes usually absent or indistinct; dorsal fin relatively short and set far back

Ziphiidae, **Go to 18**

b. No conspicuous creases on throat; prominent median notch in flukes

Delphinoidea or Platanistoidea, **Go to 27**

18a. Teeth in both upper and lower jaws (may be inconspicuous)

Tasmacetus or *Mesoplodon grayi,* **Go to 19**

b. Not more than 1–2 pairs of teeth in lower jaw only (even these not erupted in many individuals)

Other species, **Go to 20**

19a. Many teeth in both jaws (17–28 per tooth row); pair of tusks at tip of lower jaw that erupt only in males; maximum body length about 7 m; white ventral field extending onto sides in three areas of body; Southern Hemisphere distribution only

Shepherd's beaked whale *(Tasmacetus shepherdi)*

b. Small head; extremely long, narrow beak; white lower jaw and dark gray upper jaw; 2 small triangular teeth well behind tip of lower jaw in males; 17–22 pairs of vestigial teeth in upper jaw of both sexes

Gray's beaked whale *(Mesoplodon grayi)*

20a. One or two pairs of teeth at or near tip of lower jaw, erupted only in some adults; head either with indistinct beak, or with distinct beak and steep forehead

Other species, **Go to 21**

b. Usually one pair of teeth well behind tip of lower jaw, erupted only in adult males; small head; prominent beak with forehead rising at shallow angle; sometimes flippers fit into depressions on the body; scratches and scars often common on body; maximum body length 6.2 m

Mesoplodon sp.[3], **Go to 26**

21a. Two pairs of teeth in lower jaw, one pair at tip exposed outside closed mouth, second smaller pair behind first; long tube-like snout; rounded forehead rises from snout at a shallow angle

Berardius sp., **Go to 22**

[3] The species of the genus *Mesoplodon* are generally poorly-known. External morphology and pigmentation patterns have not been properly described for some of them, and it is generally not possible for non-experts to identify whales of this genus to species. Even for experts, examination of skulls or genetic evidence may be required to identify anything but mature males.

b. One pair of teeth at tip of lower jaw (exposed only in adult males)
Other species, **Go to 23**

22a. Maximum body length 12 m; Northern Hemisphere distribution only
Baird's beaked whale *(Berardius bairdii)*

b. Maximum body length 10 m; Southern Hemisphere distribution only
Arnoux's beaked whale *(Berardius arnuxii)*

23a. Beak indistinct; head small relative to body size; forehead slightly concave in front of blowhole; single pair of teeth directed forward and upward at tip of lower jaw (exposed only in adult males); mouthline upturned at gape; head light colored; maximum body length 7.0 m
Cuvier's beaked whale *(Ziphius cavirostris)*

b. Tube-like beak distinct; pronounced bulge to steep forehead; tall, pointed dorsal fin; maximum length about 10 m
Hyperoodon or *Indopacetus*, **Go to 24**

24a. Northern Hemisphere or tropical distribution
H. ampullatus or *Indopacetus*, **Go to 25**

b. Southern Hemisphere temperate/subpolar distribution only
Southern bottlenose whale *(Hyperoodon planifrons)*

25a. North Atlantic distribution only
Northern bottlenose whale *(Hyperoodon ampullatus)*

b. Warm temperate and tropical Pacific and Indian Ocean distribution

Longman's beaked whale *(Indopacetus pacificus)*

26a. Moderate beak, not sharply demarcated from forehead; white jaws; males with white "cap" or "beanie" in front of blowhole; adult males with large flattened tusk in the middle of each side of lower jaw, protruding above upper jaw when mouth is closed; known from North Pacific only (females and subadults require museum preparation for identification)

Hubbs' beaked whale *(Mesoplodon carlhubbsi)*

b. Mostly dark beak, possibly with white jaws; in adult males, tusks near middle of lower jaw barely breaking gumline; known from the Pacific and Indian oceans only (females and subadults require museum preparation for identification)

Ginkgo-toothed beaked whale *(Mesoplodon ginkgodens)*

c. White markings on beak and forehead absent; lower jaw usually light in color; tusks of males very large, located on bony prominences near corners of mouth, and oriented slightly forward; lower jaw massive (particularly in adult males), with high arching contour; forehead has concavity in front of blowhole (females and subadults require museum preparation for identification)

Blainville's beaked whale *(Mesoplodon densirostris)*

d. Flattened tusks of adult males near tip of lower jaw; jaws white in adults (females and subadults require museum preparation for identification)

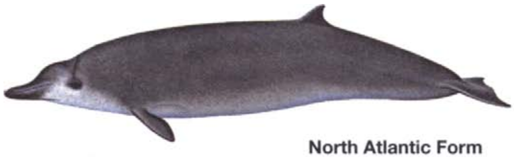
Hector's beaked whale *(Mesoplodon hectori)*

e. Small (maximum length about 4 m); dorsal fin small, triangular, and rounded at tip; color dark gray above fading to lighter below; small egg-shaped teeth located on prominences near the middle of the lower jaw in adult males; known only from eastern Pacific (females and subadults require museum preparation for identification)

Pygmy beaked whale *(Mesoplodon peruvianus)*

f. Pair of small oval teeth at tip of lower jaw of adult males; body gray with dark areas around eyes (females and subadults require museum preparation for identification)

True's beaked whale *(Mesoplodon mirus)*



North Atlantic Form

Southern Hemisphere Form

g. Two small flattened teeth near front of lower jaw of males; body dark gray above, light gray below; known only from Atlantic Ocean (females and subadults require museum preparation for identification)

Gervais' beaked whale *(Mesoplodon europaeus)*

h. White areas in head and neck area; large flattened tusk at top of each arch in lower jaw of adult males (protruding above upper jaw when mouth closed); known only from North Pacific Ocean, found in subarctic waters of North Pacific (females and subadults require museum preparation for identification)

Stejneger's beaked whale *(Mesoplodon stejnegeri)*

i. Adult males with white jaws and tusks on slightly raised prominences in middle of jaw; known mostly from South Pacific and Indian oceans (females and subadults require museum preparation for identification)

Andrews' beaked whale *(Mesoplodon bowdoini)*

j. Complex pattern of black, white, and gray; adult males with pair of tusks that grow outside of mouth from lower jaw, and wrap around upper jaw, preventing it from opening more than a few centimeters; known only from Southern Hemisphere (females and subadults require museum preparation for identification)

Strap-toothed beaked whale *(Mesoplodon layardii)*

k. Gray with lighter sides and belly; teeth of adult males protrude outside mouth in middle of lower jaw; vestigial teeth sometimes present in both jaws; known only from the temperate and subarctic North Atlantic (females and subadults require museum preparation for identification)

Sowerby's beaked whale *(Mesoplodon bidens)*

l. Color pattern apparently non-descript; tusks of males flattened and triangular, located just behind tip of lower jaw; known only from the eastern North Pacific (females and subadults require museum preparation for identification)

Perrin's beaked whale *(Mesoplodon perrini)*

m. Nothing is known of the external appearance of this species; tusks of males are massive and lean backwards at a 45° angle, they are spade-shaped with a prominent denticle at the tip (any specimens require museum preparation for identification)

Spade-toothed beaked whale *(Mesoplodon traversii)*

27a. Teeth blunt with expanded crowns, laterally compressed, and relatively small; beak extremely short or nonexistent

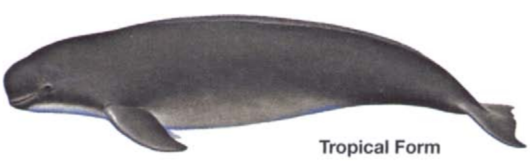
Phocoenidae, **Go to 28**

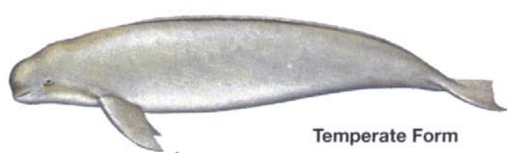
b. Teeth conical and sharply pointed, unless heavily worn (in cross section, circular or oval)

Platanistoidea, Mondontidae, or Delphinidae, **Go to 33**

28a. Body dark gray or black, with lighter belly; no dorsal fin; dorsal ridge present; 15–22 teeth in each tooth row; maximum size to 2.3 m; distribution limited to the Indo–Pacific area

Finless porpoise *(Neophocaena phocaenoides)*





b. Dorsal fin present

Other species, **Go to 29**

29a. Body dark charcoal gray to black; dorsal fin set far back on body, rising at a shallow angle from back, with long leading edge and convex trailing edge; 10–23 pairs of teeth in upper jaw, 14–23 in lower; maximum size to 2 m; distribution limited to coastal South America

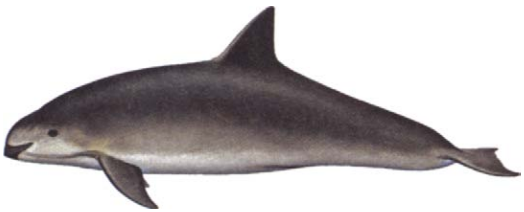
Burmeister's porpoise *(Phocoena spinipinnis)*

b. Dorsal fin upright and set near middle of back

Other species, **Go to 30**

30a. Body gray to brownish gray, with light belly, and dark lip patches and eye rings; flippers large; dorsal fin tall and slightly falcate; 16–22 teeth per side of each jaw; maximum size about 1.6 m; distribution limited to the Gulf of California, Mexico

Vaquita *(Phocoena sinus)*



b. Triangular dorsal fin; found outside the Gulf of California

Other species, **Go to 31**

31a. Body dark gray on back to white below; dark gape to flipper stripe; short, triangular, wide-based dorsal fin; 19–28 pairs of teeth in each jaw; maximum size to about 2 m; Northern Hemisphere distribution only

Harbor porpoise *(Phocoena phocoena)*

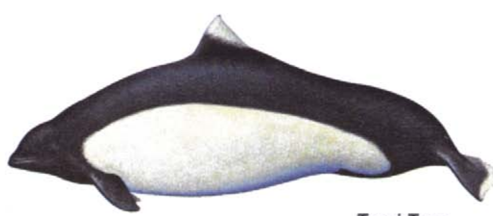
b. Color pattern sharply demarcated black and white

Other species, **Go to 32**

32a. Black body with striking large white patch on sides and belly; extremely robust, with small head and appendages; deepened caudal peduncle; dorsal fin triangular, with recurved tip; white or light gray trim on dorsal fin and flukes; 23–28 pairs of extremely small teeth per jaw; maximum size to 2.4 m; North Pacific distribution only

Dall's porpoise *(Phocoenoides dalli)*

Dalli-Type



Truei-Type

b. Body bicolored, black on dorsal half and white on ventral half; black lips; white "spectacle" surrounding eye; dorsal fin triangular to rounded; 17–23 pairs of teeth in upper jaw, 17–20 in lower; maximum size to about 2.3 m; distributed only in cold temperate waters of the Southern Hemisphere

Spectacled porpoise *(Phocoena dioptrica)*

33a. No dorsal fin or prominent dorsal ridge (there may be a slight dorsal ridge)

Monodontidae or *Lissodelphis*, **Go to 34**

b. Dorsal fin or prominent dorsal ridge present

Other species, **Go to 37**

34a. Slight dorsal ridge present, sometimes marked with nicks or cuts; jaws short and wide; forehead high and globose; flippers short, broad, and rounded; distribution limited to Arctic and subarctic areas

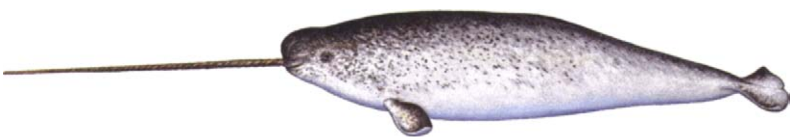
Monodontidae, **Go to 35**

b. No dorsal ridge present; body extremely slender; small flippers and flukes; beak short but distinct

Lissodelphis, **Go to 36**

35a. Body gray to brownish-gray, mottled; short flippers often upturned at tips; flukes with more or less convex trailing edge; only two teeth in upper jaw, unerupted except in adult males, in which the left tooth develops into a left-spiraled tusk up to 2.7 m long; maximum size up to 5 m (excluding tusk); distribution limited to high Arctic

Narwhal *(Monodon monoceros)*



b. Body white to dark gray; extremely stocky; melon bulbous; beak short; head and appendages small; "neck" often visible; 9 pairs of teeth in upper jaw, 8 in lower; maximum size 5.5 m

Beluga whale *(Delphinapterus leucas)*

36a. Body black with white lanceolate pattern on belly; 37–54 fine pointed teeth per side of each jaw; maximum body length 3.1 m; North Pacific distribution only

Northern right whale dolphin *(Lissodelphis borealis)*

b. Body black above and white below; flippers, beak, and forehead mostly white; 44–49 teeth in each tooth row; maximum size to at least 3 m; Southern Hemisphere distribution only

Southern right whale dolphin *(Lissodelphis peronii)*

37a. Jaws extremely long; flippers broad and more or less triangular; eyes small; low, broad-based dorsal fin or dorsal ridge; distributed in rivers and lakes, only rarely in estuaries

Platanistoidea, **Go to 38**

b. Prominent dorsal fin; distribution estuarine or marine

Delphinidae or *Pontoporia*, **Go to 41**

38a. Blowhole transverse and crescentic; body gray, often with pinkish cast; dorsal hump low and set two-thirds of the way from the snout tip; forehead steep; 23–35 teeth per tooth row; maximum size to 2.8 m; distribution limited to Amazon and Orinoco drainage basins of Brazil, Bolivia, Peru, Colombia, Ecuador, Guyana, and Venezuela

Boto *(Inia geoffrensis)*

b. Blowhole longitudinal

Other species, **Go to 39**

39a. Body bluish-gray above and white below; blowhole oval; beak upturned at tip; dorsal fin triangular with blunt tip; 31–36 teeth per tooth row; maximum size to 2.6 m; distribution limited to the Yangtze River of China

Baiji *(Lipotes vexillifer)*

b. Body gray with lighter or pinkish belly; blowhole slit-like; eyes extremely small; beak long, narrow when viewed from above, with interlocking teeth protruding outside closed mouth at front half; low dorsal ridge; 26–39 teeth in each row; maximum size to 2.5 m

South Asian River Dolphin, **Go to 40**

40a. Distribution limited to the Ganges and Brahmaputra River systems of India, Nepal, Bangladesh, and (possibly) Bhutan

Ganges River dolphin *(Platanista gangetica gangetica)*

b. Distribution limited to the Indus River system of Pakistan

Indus River dolphin *(Platanista gangetica minor)*

41a. Body dark gray with lighter belly; prominent triangular dorsal fin with rounded tip; flippers broad with curved leading edge and serrated trailing edge; eyes small; 50–62 teeth per tooth row; maximum size to 1.8 m; distribution limited to coastal and estuarine waters of Argentina, Uruguay, and Brazil

Franciscana *(Pontoporia blainvillei)*

b. Flippers without serrated trailing edges; eyes not particularly small

Delphinidae, **Go to 42**

42a. Head blunt with no prominent beak

Blackfish or other species, **Go to 43**

b. Head with prominent beak

Long-beaked delphinids, **Go to 54**

43a. 2–7 pairs of teeth at front of lower jaw only (rarely 1–2 pairs in upper jaw), but teeth may be absent or extensively worn; forehead blunt with vertical crease; dorsal fin tall and dark; body gray to white, covered with scratches and splotches in adults; flippers long and sickle-shaped; maximum body length 4 m

Risso's dolphin *(Grampus griseus)*

b. Teeth (7 or more pairs) in both upper and lower jaws; forehead without vertical median crease

Other species, **Go to 44**

44a. Flippers broad and paddle-shaped with rounded tips

Blackfish and other species, **Go to 45**

b. Flippers long and slender with pointed or blunt tips

Other species, **Go to 50**

45a. Flippers large and paddle-shaped; dorsal fin tall and erect (up to 0.9 m in females and 1.8 m in males); striking black and white coloration, with white post-ocular patches, white lower jaw, white ventrolateral field, and light gray saddle patch behind dorsal fin; 10–14 large (to 2.5 cm in diameter) oval teeth in each tooth row; maximum body length 10 m

Killer whale *(Orcinus orca)*

Type A

Type C

b. Dorsal fin low and rounded or triangular; adults less than 3 m; greater than 12 teeth per tooth row

Other species, **Go to 46**

46a. Body gray with lighter belly; dorsal fin small and slightly falcate; forehead bluff; neck crease often present; 8–22 teeth per row; maximum size 2.8 m; distribution limited to coastal areas and rivers of southeast Asia and northern Australia

Orcaella sp., **Go to 75**

b. Color pattern with distinct lobes of light and dark; dorsal fin relatively large; no neck crease; 27–35 teeth per row; distribution limited to southern South America, southern Africa, New Zealand and the Kerguelen Islands

Cephalorhynchus sp., **Go to 47**

47a. Sides light gray; dark gray cape (very narrow just behind blowhole area); belly white, with "arms" that surround the urogenital area and extend up both sides; white throat patch; white axillary patches; dorsal fin moderately tall and triangular; 22–28 teeth in each row; maximum size 1.8 m; distribution limited to southwest coast of Africa

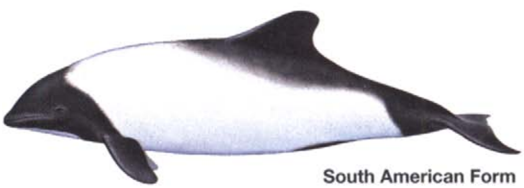
Heaviside's dolphin *(Cehalorhynchus heavisidii)*

b. Dorsal fin rounded

Other species, **Go to 48**

48a. Distinct black and white (or dark and light gray) color pattern, with black head and flippers, and black from the dorsal fin to the flukes; white chin patch; black genital patch; 28–35 teeth per row; maximum size 1.8 m; distribution limited to coastal and inshore waters of southeast South America and the Kerguelen Islands

Commerson's dolphin *(Cephalorhynchus commersonii)*



South American Form

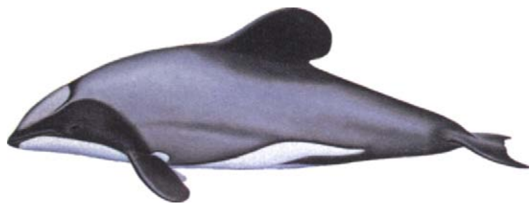
Kerguelen Form

b. Coloration largely various shades of gray

Other species, **Go to 49**

49a. Body mostly gray, with white belly and "arms" that extend up the sides on the tail stock (clearly demarcated by a dark gray line), and black dorsal fin, flippers, flukes, face, beak tip, and blowhole area; 24–31 teeth per row; maximum size to 1.7 m; distribution limited to coast of New Zealand

Hector's dolphin *(Cephalorhynchus hectori)*



b. Body gray with clearly demarcated white belly and chin; dark band between the flippers; white spots in axillae; 29–34 teeth in each row; maximum size to at least 1.7 m; distribution limited to west coast of South America, especially protected inshore waters of southern Chile

Chilean dolphin *(Cephalorhynchus eutropia)*

50a. Dorsal fin low and broad-based, located on forward third of back; head bulbous; body black to dark gray with light anchor-shaped patch on belly and often light gray saddle behind dorsal fin; often a light streak above and behind each eye; deepened tail stock; long sickle-shaped flippers; 7–13 pairs of teeth in front half only of each jaw

Globicephala sp., **Go to 51**

b. Dorsal fin near middle of back

Other species, **Go to 52**

51a. Flipper length 18–27% of body length, with prominent "elbow;" 8–13 teeth in each tooth row; maximum size to 6.7 m; distribution limited mostly to cold temperate regions of North Atlantic and Southern Hemisphere

Long-finned pilot whale *(Globicephala melas)*

b. Flipper length 14–19% of body length; 7–9 pairs of teeth in each tooth row; maximum body length 7.2 m; distribution limited to tropical and warm temperate waters

Short-finned pilot whale *(Globicephala macrorhynchus)*

52a. Flipper with distinct hump on leading edge; body predominantly black; no beak; 7–12 large teeth in each half of both jaws, circular in cross-section; maximum body length 6 m

False killer whale *(Pseudorca crassidens)*

b. Body black or dark gray with white lips; white to light gray patch on belly; flipper lacks hump on leading edge; 8–25 teeth in each tooth row

Other species, **Go to 53**

53a. Less than 15 (8–13) teeth in each half of both jaws; flippers slightly rounded at tip; indistinct dorsal cape; head rounded from above and side; maximum body length 2.6 m

Pygmy killer whale *(Feresa attenuata)*

b. More than 15 (20–25) teeth per side of each jaw; flippers sharply pointed at tip; face often has triangular dark mask; indistinct cape that dips low below dorsal fin; head triangular from above; extremely short, indistinct beak may be present in younger animals; maximum body length 2.8 m

Melon-headed whale *(Peponocephala electra)*

54a. Head long and conical; beak runs smoothly into forehead, with no crease; body dark gray to black above and white below, with many scratches and splotches; narrow dorsal cape; flippers large; 19–28 slightly wrinkled teeth in each half of both jaws; maximum body length 2.8 m

Rough-toothed dolphin *(Steno bredanensis)*

b. Beak distinct from forehead (however, there may not be a prominent crease between beak and melon)

Other species, **Go to 55**

55a. Beak very short and well-defined (less than 2.5% of body length); body stocky

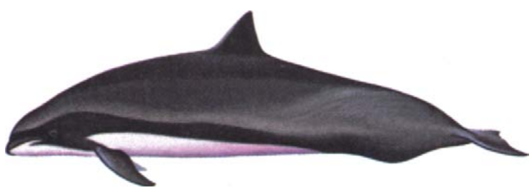
Lagenodelphis or *Lagenorhynchus,* **Go to 56**

b. Beak moderate to long (greater than 3% of body length)

Other species, **Go to 62**

56a. Flippers, flukes, and dorsal fin small; broad dark stripe from eye to anus area (muted in some animals); dorsal fin slightly recurved and uniformly dark; extremely short, but well-defined beak; grooves on palate; 38–44 teeth in each side of each jaw; maximum length at least 2.7 m

Fraser's dolphin *(Lagenodelphis hosei)*

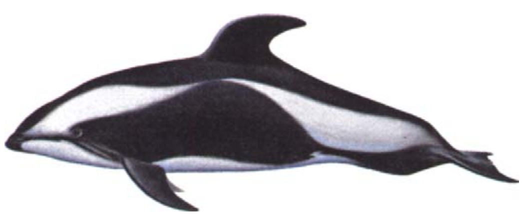


b. Dorsal fin large; no palatal grooves

Lagenorhynchus sp., **Go to 57**

57a. Body sharply demarcated black and white, with distinct white hourglass pattern on side, and white belly; dorsal fin strongly falcate; 26–35 teeth in each row; maximum size to about 2 m; distribution limited to colder waters of circumpolar Antarctic currents

Hourglass dolphin *(Lagenorhynchus cruciger)*



b. Color pattern complex with light gray patches on sides

Other species, **Go to 58**

58a. Body mostly black to dark gray, with white to light gray patches on the sides, and white belly and beak; dorsal fin large and falcate; 22–28 teeth in each row; maximum size to 3.1 m; distribution limited to cold waters of North Atlantic

White-beaked dolphin *(Lagenorhynchus albirostris)*

b. Prominent light gray flank

Other species, **Go to 59**

59a. Back dark gray, belly white, and sides light gray with white (below the dorsal fin) and yellowish-brown (on the tail stock) patches; black eye ring; extremely deepened tail stock; 30–40 teeth in each row; maximum length 2.8 m; distribution limited to cold waters of the North Atlantic

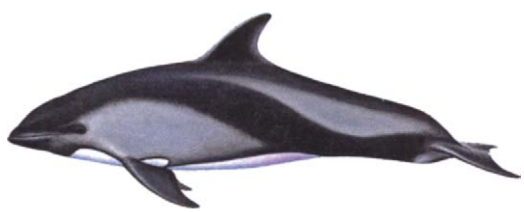
Atlantic white-sided dolphin *(Lagenorhynchus acutus)*

b. Large light gray lateral patch and gray stripes on tail stock with extensions running forward to thoracic area

Other species, **Go to 60**

60a. Black to dark gray above, white below, with light gray patches on sides; face, beak, melon, and most of the chin grayish-black; body relatively robust; up to at least 37 teeth in each row; maximum size to about 2.5 m; known distribution limited to southern South America and around Palmerston Atoll (although the latter is probably extralimital)

Peale's dolphin *(Lagenorhynchus australis)*

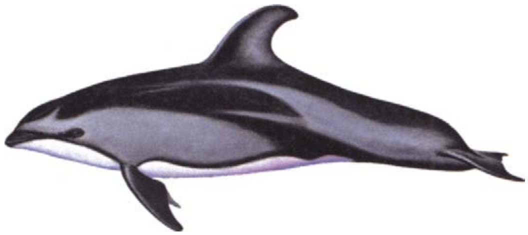


b. Much of face and lower jaw white to light gray; dorsal fin bicolored

Other species, **Go to 61**

61a. Appendages relatively large; dorsal fin bicolored and falcate (sometimes extremely hooked); back dark gray with light "suspender stripes" from forehead to tail stock, white belly, light gray flank patches (black lines separate belly from sides); 23–36 pairs of teeth in each jaw; maximum body length 2.5 m; distribution limited to North Pacific

Pacific white-sided dolphin *(Lagenorhynchus obliquidens)*



b. Belly white, back dark, flank patch light gray (no black line separates flank patch and belly); dorsal fin and flippers bicolored; 27–36 teeth in each tooth row; maximum length to at least 2.1 m; distribution limited to Southern Hemisphere (known mostly from South America, southern Africa, and New Zealand)

Dusky dolphin *(Lagenorhynchus obscurus)*

62a. Less than 39 teeth per tooth row

Tursiops, Sotalia, or *Sousa,* **Go to 63**

b. Greater than 39 teeth per row

Delphinus or *Stenella*, **Go to 67**

63a. Moderately robust; 18–29 teeth in each half of the jaws (teeth may be extensively worn or missing); body to 3.8 m; moderately long robust snout set off by distinct crease; color dark to light gray dorsally, fading to white or even pink on belly

Bottlenose dolphin (*Tursiops* sp.), **Go to 64**

b. 26 or more teeth in each tooth row; indistinct crease between melon and beak

Sotalia or *Sousa*, **Go to 65**

64a. Beak relatively short and stubby; generally no spotting on belly; spinal blaze often indistinct; 18–27 pairs of teeth; maximum size up to 3.8 m; distributed worldwide

Common bottlenose dolphin *(Tursiops truncatus)*

Offshore Ecotype

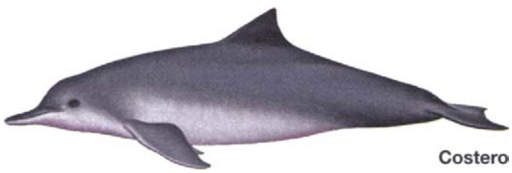
Atlantic Coastal Ecotype

b. Beak relatively long and slender; generally with black spotting on the belly; often a spinal blaze below the dorsal fin; 21–29 paris of teeth; maximum size 2.7 m; distributed only in the Indo–Pacific

Indo–Pacific bottlenose dolphin *(Tursiops aduncus)*

65a. Back dark gray and belly light; beak long without distinct crease; low triangular to slightly falcate dorsal fin; 26–36 teeth in each tooth row; maximum size to 2.2 m; distribution limited to coasts, rivers, and lakes of the east coast of South America from Panama to southern Brazil, including the Amazon and Orinoco drainage basins

South American dolphins *(Sotalia fluviatilis or S. guianensis)*



Costero

Tucuxi

b. Body gray with bluish, cream, or pink tinge, and light belly; base of dorsal fin of adults often expanded to form longitudinal ridge, especially west of Bay of Bengal; beak long, crease indistinct; 26–39 teeth in each tooth row; maximum size to 2.8 m

Humpback dolphin (*Sousa* sp.), **Go to 66**

66a. Distribution limited to Indo–Pacific, from the southern tip of Africa to Australia and eastern China

Indo–Pacific humpback dolphin *(Sousa chinensis)*

Chinensis-type

Plumbea-type

b. Distribution limited to Atlantic Ocean off West Africa

Atlantic humpback dolphin *(Sousa teuszii)*

67a. Dorsal fin erect to slightly falcate; back dark and belly white; tan to buff thoracic patch and light gray streaked tail stock form an hourglass pattern that crosses below dorsal fin; cape forms a distinctive "V" below dorsal fin; chin to flipper stripe; maximum size 2.7 m; 40–67 teeth in each row; palate with two deep longitudinal grooves

Common dolphin (*Delphinus* sp.), **Go to 68**

b. No hourglass pattern on side; palatal grooves, if present, shallow

Stenella sp., **Go to 69**

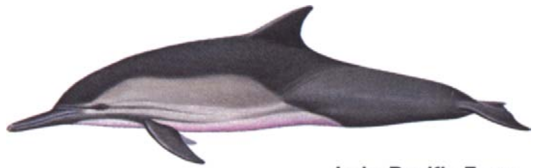
68a. Body relatively stocky; beak shorter; slope of forehead relatively steep; flipper stripe narrow and not approaching gape; often light patches on flippers and dorsal fin; anus stripe faint or absent

Short-beaked common dolphin *(Delphinus delphis)*

b. Body relatively slender; beak longer; slope of forehead relatively shallow; flipper stripe wide and often contacting gape; light patches on flippers and dorsal fin generally absent; anus stripe may be distinct

Long-beaked common dolphin *(Delphinus capensis)*

Standard Form



Indo-Pacific Form

69a. Color pattern black to dark gray on back, white on belly, prominent black stripes from eye to anus and eye to flipper; light gray spinal blaze extending to below dorsal fin (not always present); shallow palatal grooves often present; 40–55 teeth in each row; maximum size 2.6 m

Striped dolphin *(Stenella coeruleoalba)*

b. Generally, no eye to anus stripe; distribution limited to tropical and warm temperate waters

Other species, **Go to 70**

70a. Light to heavy spotting present on dorsum of adults (on some individuals, spots may appear absent); no palatal grooves

Spotted dolphin, **Go to 71**

b. No spotting on dorsum of adults; cape dips to lowest point at level of dorsal fin; eye-to-flipper stripe; shallow palatal grooves often present

S. clymene or *S. longirostris*, **Go to 73**

71a. Body moderately robust, dark gray above, with white belly; light spinal blaze; slight to heavy spotting on adults (occasionally spotting nearly absent); maximum size 2.3 m; 30–42 teeth per row; distribution limited to warm waters of the Atlantic Ocean

Atlantic spotted dolphin *(Stenella frontalis)*

b. Dorsal fin narrow and falcate; dark cape that sweeps to lowest point on side in front of dorsal fin; dark gape to flipper stripe; beak tip and lips white; adults with light to extensive spotting and gray bellies (spotting sometimes absent); 34–48 teeth in each half of each jaw; maximum size 2.6 m

Pantropical spotted dolphin (*Stenella attenuata*), **Go to 72**

72a. Body and beak relatively robust; heavy spotting that nearly obliterates cape; known distribution limited to within 185 km of the coast in the eastern tropical Pacific

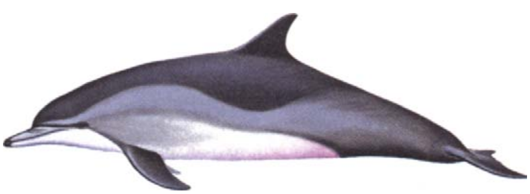
Coastal pantropical spotted dolphin (*S. a. graffmani*)

b. Body and beak slender; spotting slight to moderate; maximum body length 2.4 m; distributed more than 30 km from shore in eastern tropical Pacific and found in oceanic waters worldwide

Offshore pantropical spotted dolphin (*S. a. attenuata*)

73a. Body color three-part (dark gray cape, light gray flanks, white belly); cape dips in two places (above eye, and below dorsal fin); snout light gray with dark tip, dark lips, and dark line from tip to apex of melon; often, dark "moustache" on top of beak; more robust than spinner dolphins; 39–52 teeth in each tooth row; maximum size about 2.0 m; distribution limited to tropical Atlantic Ocean

Clymene dolphin *(Stenella clymene)*

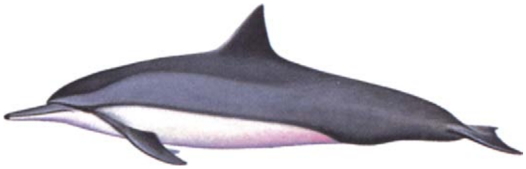


b. Dorsal fin slightly falcate to canted forward; beak exceedingly long and slender; 40–62 very fine sharply pointed teeth per tooth row; maximum size 2.4 m

Spinner dolphin (*Stenella longirostris*), **Go to 74**

74a. Color pattern three-part (white belly, light gray sides, dark gray cape); dorsal fin falcate to erect; body more robust than in other forms; post-anal hump of adult males nearly absent; distribution pantropical, except eastern tropical Pacific

Gray's spinner dolphin *(S. l. longirostris)*



b. Pigmentation monotone gray, with light patches around genital area and axillae; dorsal fin triangular to canted forward (extremely canted in adult males); adult males with deepened tail stock and enlarged post-anal hump; maximum size 2 m; known distribution limited to the eastern tropical Pacific east of 145°W

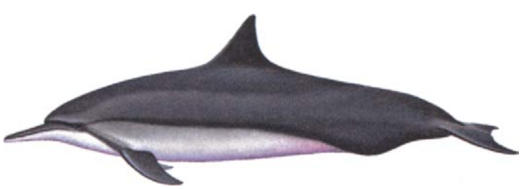
Eastern spinner dolphin *(S. l. orientalis)*

c. Pigmentation monotone gray; apparently, no light patches around genital area and axillae; dorsal fin triangular to canted forward (extremely canted in adult males); adult males with deepened tail stock and enlarged post-anal hump; to 2.2 m long; known distribution limited to 80 km offshore from southern Mexico to Panama in the eastern tropical Pacific

Central American spinner dolphin *(S. l. centroamericana)*

d. Body slightly more robust than above two forms; color pattern largely bipartite, with dark dorsal cape, and white belly and lower sides; dorsal fin slightly falcate to slightly canted (tending towards canted in adult males); post-anal hump of adult males small to moderate; distribution limited to offshore eastern tropical Pacific

Whitebelly spinner dolphin (hybrid *S. l. longirostris* X *S. l. orientalis*)



e. Body very small (<1.6 m), with a relatively large head and flippers; dorsal fin not canted; post-anal hump small or absent; tripartite color pattern; distribution limited to the Indo–Pacific, from northern Australia to southeast Asia

Dwarf spinner dolphin *(S. l. roseiventris)*

75a. Dorsal groove present; color pattern bipartite; white ventral field extends onto underside of flippers; distribution limited to East Asia (eastern India to southern Vietnam and central Indonesia)

Irrawaddy dolphin *(Orcaella brevirostris)*

b. No dorsal groove; color pattern subtly tripartite; no extension of white ventral field onto underside of flippers; distribution limited to Australia and Papua New Guinea

Australian snubfin dolphin *(Orcaella heinsohni)*

B. Key to Identification of Cetaceans of the World, Based on Skull Morphology

Notes on the use of this key *This key is intended to allow the user to identify a skull of any cetacean, even if the area of origin is not known (therefore we do not use geographic information as primary features in the key). Although it is intended primarily for adult skulls, it may be useful for identifying skulls of subadults in some cases as well.*

For some parts, this key is based on incomplete information, and thus may not always be reliable. It is presented here because of the lack of other suitable materials for identifying cetacean skulls. Skulls from subadult mammals often do not show the species' diagnostic characters, and geographic variation may yield it unreliable when examining skulls from certain areas. Clearly, a damaged skull may not be possible to identify to species, no matter what aids are used. So, while it will not be possible to identify every cetacean skull with this key, we hope that it will aid readers in identifying a large majority of them. We urge users to contact us to let us know how it can be improved.

1a. Teeth and alveoli absent; skull bilaterally symmetrical; lower jaw lacking bony symphysis; posterior portion of mandible not hollowed; maxillae extend posteriorly underneath frontal; size always large (adult skull >1.5 m)

Mysticeti, **Go to 2**

b. Teeth or alveoli present (although they may not emerge from jaw bones in some beaked whales); skull generally asymmetrical; lower jaw possessing bony symphysis; posterior non-tooth-bearing portion of mandible hollowed-out to form thin-walled "pan bone"; maxillae and premaxillae extend posteriorly over the frontal; skull generally much smaller (<1.5 m, except in *Physeter*)

Odontoceti, **Go to 11**

2a. Rostrum strongly arched from lateral view (>20° between basicranium and base of rostrum); base of rostrum narrow (< 1/3 cranial width); mandibles strongly bowed out

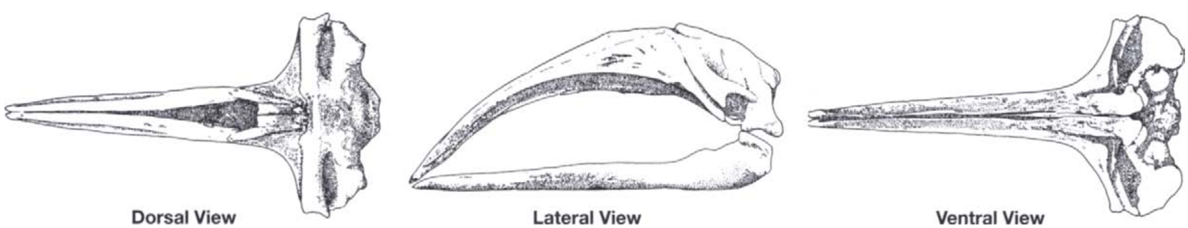
Balaenidae, **Go to 3**

b. Rostrum slightly arched or flat from laterial view (<18° between basicranium and base of rostrum); base of rostrum wide (>1/2 cranial width); mandibles only slightly bowed

Neobalaenidae, Eschrichtiidae, or Balaenopteridae, **Go to 4**

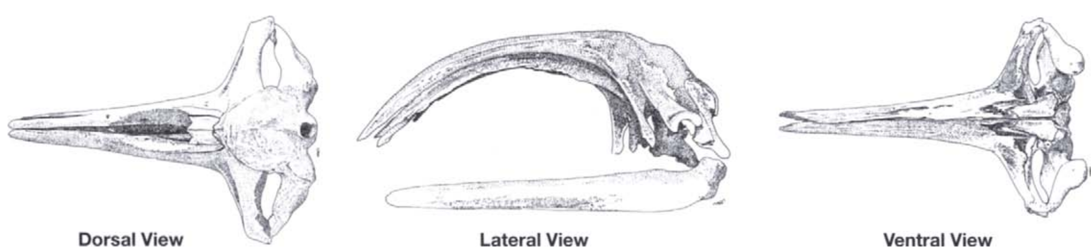
3a. In lateral view, skull has a continuous curve from occipital condyles to tip of rostrum; occipital shield does not overhang temporal fossae; nasals long (about 3 times their width); high latitude Northern Hemisphere distribution only

Bowhead whale (*Balaena mysticetus*)



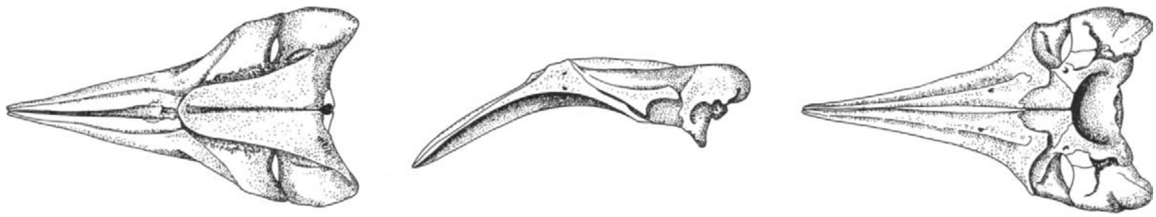
b. In lateral view, skull has a distinct angled apex between rostral and cranial bones; occipital shield overhangs temporal fossae; nasals relatively short (about twice their width)

Right whale (*Eubalaena* sp.)



4a. Rostrum moderately arched in lateral view (>14° between basicranium and base of rostrum); large anteriorly-thrust occipital shield (extending forward to base of rostrum); overall posterior margin of cranium strongly concave when viewed from above; high latitude Southern Hemisphere distribution only

Pygmy right whale (*Caperea marginata*)



Dorsal View | Lateral View | Ventral View

b. Rostrum only slightly arched in lateral view (<13° between basicranium and base of rostrum); no prominent occipital shield (occipital only extends forward up to 75% of length of brain case); overall posterior margin of cranium convex or relatively straight

Eschrichtiidae or Balaenopteridae, **Go to 5**

5a. Nasals large (nearly 1/2 length of post-rostral cranium); paired occipital tuberosities on posterior portion of cranium; rostrum relatively arched (>8° between basicranium and base of rostrum); North Pacific distribution only

Gray whale (*Eschrichtius robustus*)

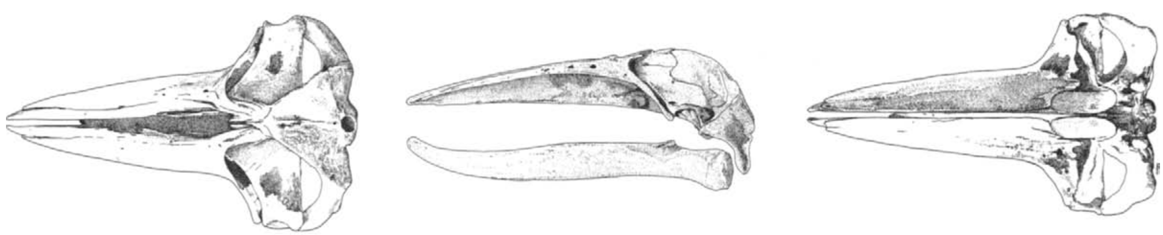
Dorsal View | Lateral View | Ventral View

b. Nasals smaller (< 1/4 length of post-rostral cranium); occipital tuberosities absent; rostrum relatively flat (<7° between basicranium and base of rostrum)

Balaenopteridae, **Go to 6**

6a. Base of rostrum about 1/2 cranial width; anterior margin of squamosal rounded or U-shaped

Humpback whale (*Megaptera novaeangliae*)



Dorsal View | Lateral View | Ventral View

b. Base of rostrum at least 2/3 cranial width; anterior margin of squamosal pointed or V-shaped

Balaenoptera sp, **Go to 7**

7a. Rostrum U-shaped and somewhat rounded at tip; rostral borders parallel along proximal half; from above, occipital length <1/5 CBL

Blue whale (*Balaenoptera musculus*)

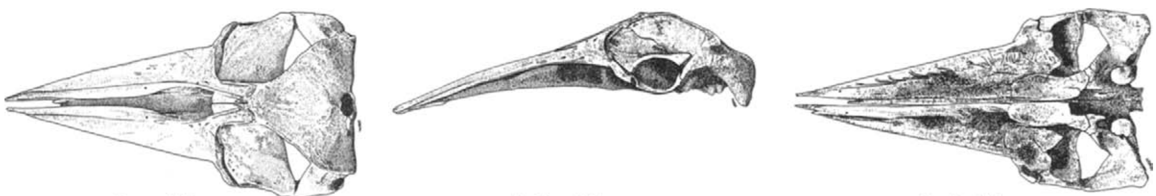
Dorsal View | Lateral View | Ventral View

b. Rostrum V-shaped and pointed; rostral borders convergent throughout their length; from above, occipital length >1/5 CBL

Minke, Omura's, Bryde's, sei, or fin whale, **Go to 8**

8a. CBL of adults <2.0 m

Minke or Omura's whales (*Balaenoptera acutorostrata/bonaerensis/omurai*)



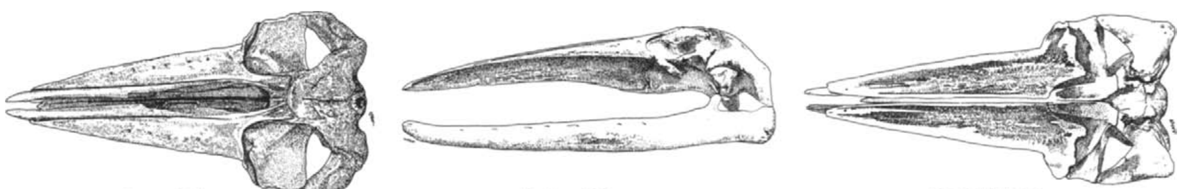
Dorsal View | Lateral View | Ventral View

b. CBL of adults >2.0 m

Fin whale, sei whale or Bryde's whale, **Go to 9**

9a. Nasals small—length (measured along their suture) less than 1/2 length of nasofrontal process; vomer widely expanded at its posterior end

Fin whale (*Balaenoptera physalus*)



Dorsal View | Lateral View | Ventral View

b. Nasals relatively large—length more than 1/2 length of nasofrontal process; vomer not expanded at its posterior end

Sei or Bryde's whale, **Go to 10**

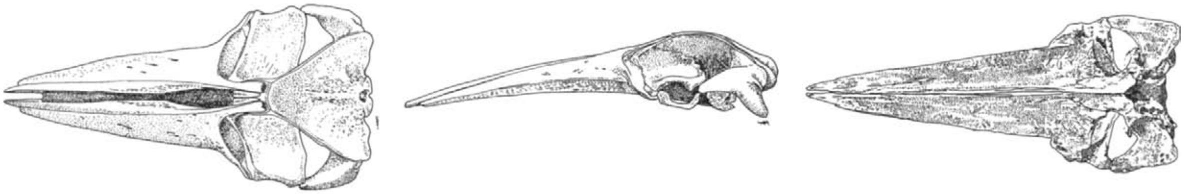
10a. Anterior edge of nasals concave or straight; rostrum relatively flat in lateral view; from below, palatines do not extend far back and basicranial part of skull exposed behind palatines much longer than broad

Bryde's whale (*Balaenoptera edeni/brydei*)

Dorsal View | Lateral View | Ventral View

b. Anterior edge of nasals convex; rostrum tip may be downturned in lateral view; from below, basicranial part of skull exposed behind palatines squarish to broader than long

Sei whale (*Balaenoptera borealis*)



Dorsal View Lateral View Ventral View

11a. Anterior cranial region basin-like, or with elevated maxillary ridges on vertex; functional teeth generally restricted to lower jaw; lack of distinct ventral cranial hiatus (opening for cranial nerves VII to XI) around the periotics

Physeteroidea or Ziphioidea, **Go to 12**

b. Anterior cranial region not basin-like, nor with elevated maxillary ridges (except in some river dolphins); teeth in both upper and lower jaws (except *Monodon* and *Grampus*); cranial hiatus present

Delphinoidea or Platanistoidea, **Go to 20**

12a. Nares extremely assymmetrical (left naris at least twice as large as the right); rostrum much wider than deep; one or both nasal bones lacking; no strongly elevated vertex; lateral furrow of tympanic bullae absent

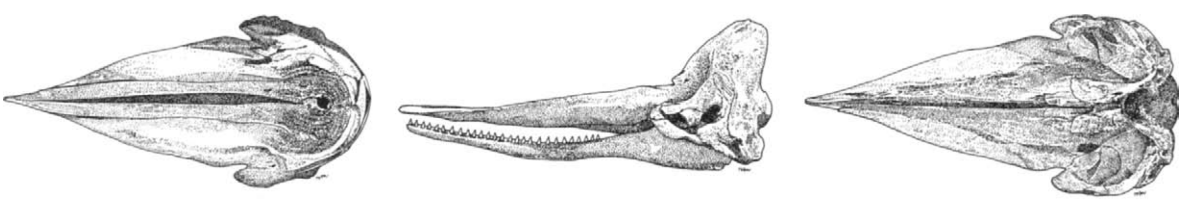
Physeteroidea, **Go to 13**

b. Nares similar in size; rostrum nearly as deep as wide; two nasal bones present; vertex (including nasals, as well as portions of maxillae and premaxillae) strongly elevated; lateral furrow of tympanic bullae present

Ziphiidae, **Go to 15**

13a. Rostrum long (>60% of CBL); apex of rostrum composed of only premaxillae; zygomatic arches complete; >17 pairs of teeth; mandibular symphysis long (>30% of mandibular length); jugal present; one nasal bone present

Sperm whale (*Physeter macrocephalus*)



Dorsal View Lateral View Ventral View

b. Rostrum short (<60% of CBL); apex of rostrum composed of maxillae, premaxillae, and vomer; zygomatic arches incomplete; <17 pairs of teeth; mandibular symphysis short (< 30% of mandibular length); jugal absent; nasal bones absent

Kogiidae, **Go to 14**

14a. Adult skull relatively large (CBL >35 cm); rostrum relatively long (generally >35% of CBL); typically 12–16 pairs of teeth (sometimes 10 or 11) only in lower jaw; teeth curved (but not strongly hooked)

Pygmy sperm whale (*Kogia breviceps*)

Dorsal View Lateral View Ventral View

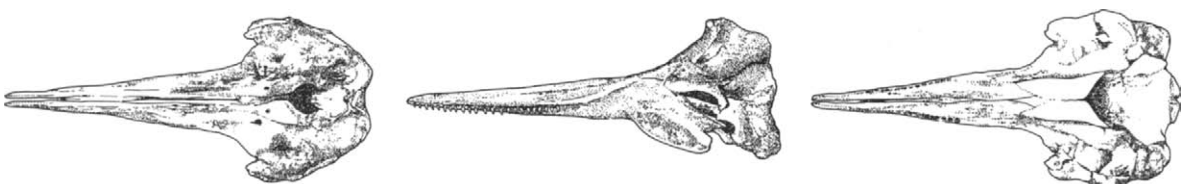
b. Adult skull relatively small (CBL <35 cm); rostrum relatively short (generally <35% of CBL); typically 8–11 pairs of teeth (sometimes 12 or 13) in lower jaw, and occasionally up to 3 vestigial pairs in upper jaw; teeth strongly hooked

Dwarf sperm whale (*Kogia sima*)

Dorsal View Lateral View Ventral View

15a. Numerous teeth (17–29 pairs) in both upper and lower jaws; Southern Hemisphere distribution only

Shepherd's beaked whale (*Tasmacetus shepherdi*)



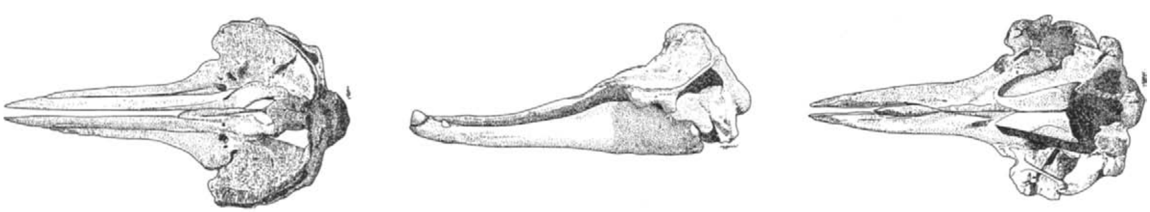
Dorsal View Lateral View Ventral View

b. No teeth in upper jaw

Berardius, Hyperoodon, Ziphius, Mesoplodon or *Indopacetus*, **Go to 16**

16a. Two pairs of mandibular teeth

Baird's/Arnoux's beaked whale (*Berardius* sp.)



Dorsal View Lateral View Ventral View

b. No more than one pair of mandibular teeth (occasionally extra rudimentary teeth present)

Mesoplodon, Indopacetus, Ziphius or *Hyperoodon*, **Go to 17**

17a. Enlarged maxillary crests present (may be relatively small in females)

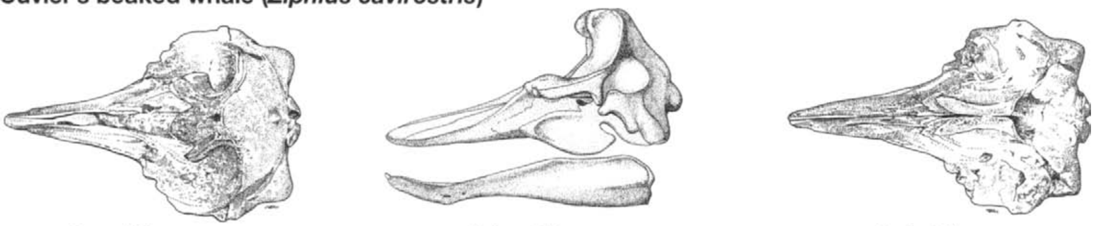
Dorsal View | Lateral View | Ventral View

b. No enlarged maxillary crests

Mesoplodon, Indopacetus or *Ziphius*, **Go to 18**

18a. On vertex, enlarged nasals extend forward past premaxillaries and overhang external bony nares; teeth conical and located at tips of mandibles

Cuvier's beaked whale (*Ziphius cavirostris*)



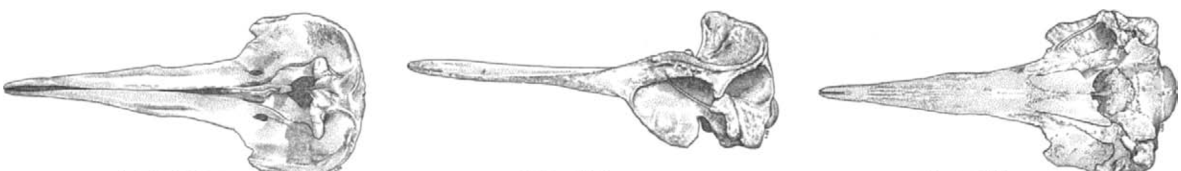
Dorsal View | Lateral View | Ventral View

b. On vertex, premaxillaries extend forward past nasals; teeth (if present) flattened (except in *Indopacetus*, *M. peruvianus*, and *M. mirus*) and often (but not always) located well back from tip of mandibles

Indopacetus/Mesoplodon spp., **Go to 19**

19a. In the lateral extension of the maxillary over the orbit, there is a deep groove, about half as long as the orbit; at midlength of the rostrum, there is a lateral swelling caused by the maxillae not coverging for a short distance; apical teeth in lower jaw are nearly conical

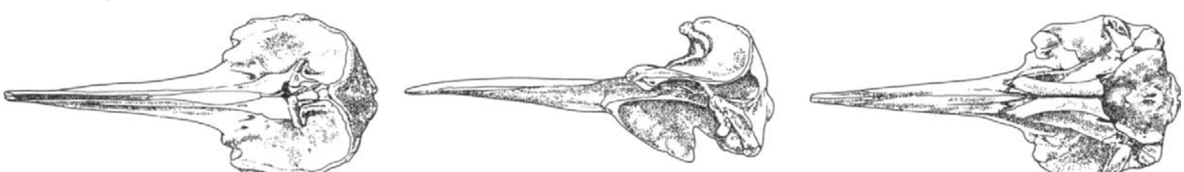
Longman's beaked whale (*Indopacetus pacificus*)



Dorsal View | Lateral View | Ventral View

b. No groove in the maxillary over the orbit; no lateral swelling of the rostrum; teeth generally highly flattened

Mesoplodont beaked whale (*Mesoplodon* sp.[4])



Dorsal View | Lateral View | Ventral View

---

[4] The species of the genus *Mesoplodon* are generally poorly-known. Intraspecific variation in skull morphology has not been adequately described for all of them, and it is generally not possible for non-experts to identify whales of this genus to species reliably. Even for experts, detailed measurements of skulls or genetic evidence may be required. However, see the following website: http://www.nmnh.si.edu/vert/mammals/beaked_whales/pages/main_menu.htm

20a. Mandibular symphysis very long (>40% mandibular length); tympanic bullae convex in outer lateral view; distributed only in rivers and coastal waters of Asia and South America

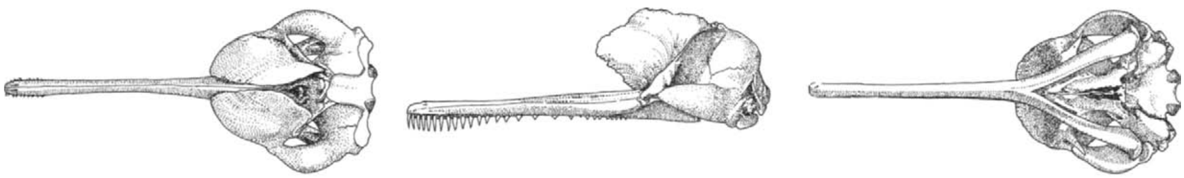
Platanistoidea, **Go to 21**

b. Mandibular symphysis relatively short (<40% mandibular length); tympanic bullae concave in outer lateral view

Delphinoidea, **Go to 24**

21a. Large, pneumatized maxillary crests present and overhanging anterior face of cranium; distributed only in the Indian subcontinent

South Asian River dolphin (*Platanista gangetica*)



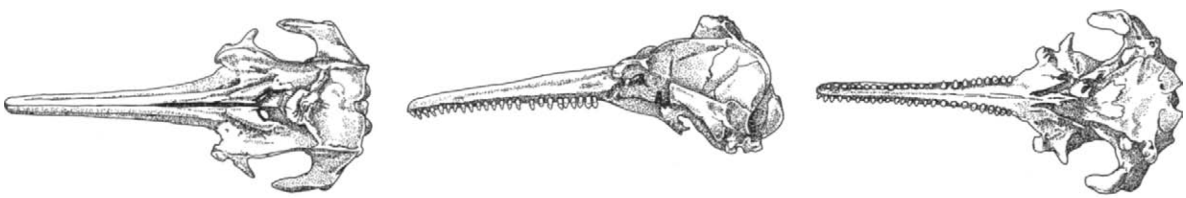
Dorsal View **Lateral View** **Ventral View**

b. Maxillary crests absent or relatively small; distributed only in China or South America

Inia, Lipotes, or *Pontoporia*, **Go to 22**

22a. Heterodont dentition; posterior teeth with lateral flanges; zygomatic arches incomplete; distributed only in the Amazon/Orinoco River systems

Amazon River dolphin (*Inia geoffrensis*)



Dorsal View **Lateral View** **Ventral View**

b. Homodont dentition; zygomatic arches complete or with only small gap (<5 mm); distributed only in China or coastal waters of eastern South America

Lipotes or *Pontoporia*, **Go to 23**

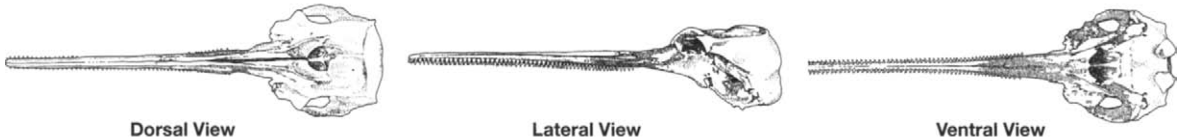
23a. Mandibular symphysis 50% or less of length of mandible; area of bony nares moderately assymetrical; tooth counts <45 in each tooth row; distinct "pinch" at base of rostrum; distributed only in China

Baiji (*Lipotes vexillifer*)

Dorsal View **Lateral View** **Ventral View**

b. Mandibular symphysis >50% length of mandible; area of bony nares relatively symmetrical; tooth counts >45 in each tooth row; no "pinch" at base of rostrum; distributed only in eastern South America

Franciscana (*Pontoporia blainvillei*)



24a. Teeth spade-shaped or peg-like; rounded bony bosses on premaxillae anterior to nares; premaxillae do not contact nasals

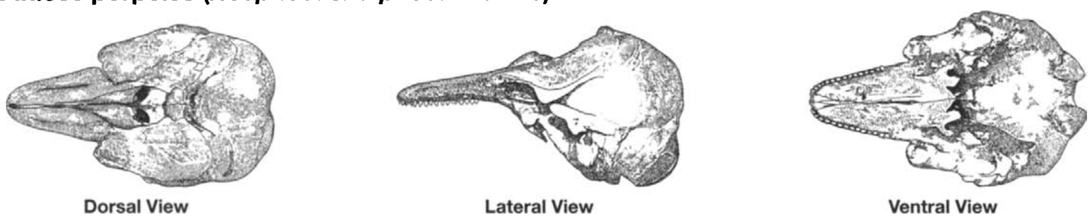
Phocoenidae, **Go to 25**

b. Teeth generally conical (except in *Orcaella*); no bosses anterior to nares (except in *Cephalorhynchus*, in which they have sharpened ridges); right premaxilla in contact with right nasal

Other Delphinoidea, **Go to 30**

25a. Rostrum short and wide (length/width ratio <1.28) and rounded at the tip; antorbital notches present and relatively deep (>2 mm); premaxillae level with maxillae in distal quarter of rostrum; distributed only in the Indo–Pacific

Finless porpoise (*Neophocaena phocaenoides*)



b. Rostrum relatively long and narrow (length/width ratio >1.25) and relatively pointed at the tip; antorbital notches absent or very shallow (<2 mm); premaxillae elevated above maxillae (visible in lateral view)

Phocoenoides or *Phocoena*, **Go to 26**

26a. Face of cranium high and nearly vertical, with strong development of supraoccipital crest; frontal not visible where it meets supraoccipital (in dorsal view)

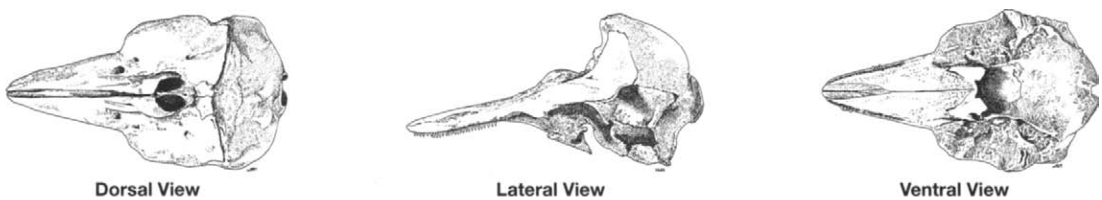
Phocoenoides dalli or *Phocoena dioptrica*, **Go to 27**

b. Face of cranium low and strongly diagonal, with weak development of supraoccipital crest; frontal on at least one side visible where it meets supraoccipital (in dorsal view)

Phocoena spp., **Go to 28**

27a. Teeth very small and peg-like; tooth counts >23 per row; premaxillary bosses with vertical or near-vertical lateral margins; distributed only in the North Pacific

Dall's porpoise (*Phocoenoides dalli*)



b. Teeth relatively large; tooth counts generally <23 per row (sometimes up to 26); premaxillary bosses with strong vertical overhang; distributed only in the Southern Hemisphere

Spectacled porpoise (*Phocoena dioptrica*)

Dorsal View Lateral View Ventral View

28a. Adult skull small (CBL <245 mm); rostrum short (length/width ratio <1.4); posterior margin of palate usually U-shaped; distributed only in the northern Gulf of California

Vaquita (*Phocoena sinus*)

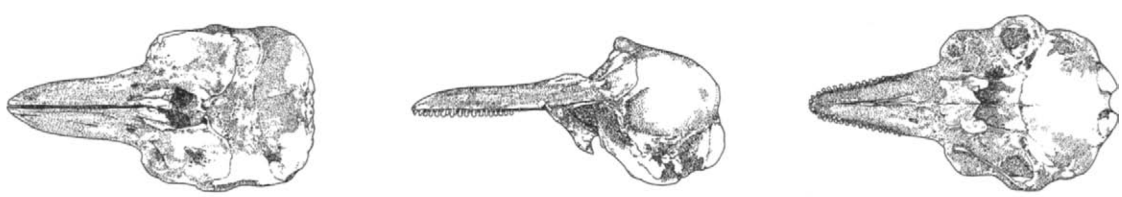
Dorsal View Lateral View Ventral View

b. Adult skull relatively large (CBL >245 mm); rostrum long (length/width ratio >1.4); posterior margin of palate usually W-shaped

Other species, **Go to 29**

29a. Rostrum relatively short (length/width ratio <1.8); distributed only in the coastal waters of South America

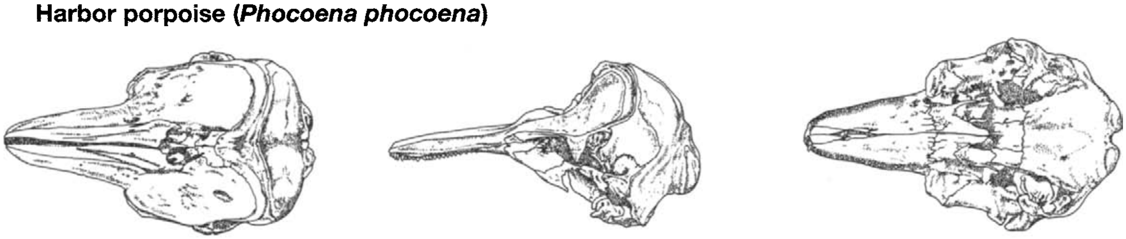
Burmeister's porpoise (*Phocoena spinipinnis*)



Dorsal View Lateral View Ventral View

b. Rostrum relatively long (length/width ratio >1.8); distributed only in the Northern Hemisphere

Harbor porpoise (*Phocoena phocoena*)



Dorsal View Lateral View Ventral View

30a. In profile, facial plane very flat or convex, with little or no rise in area of nares; spiracular plate slightly rugose; distributed only in high latitudes of the Northern Hemisphere

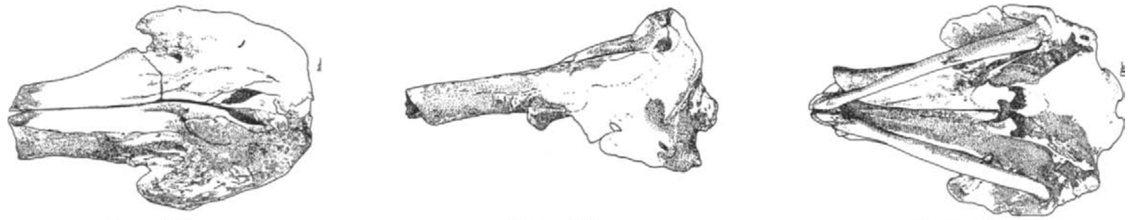
Monodontidae, **Go to 31**

b. In profile, facial plane concave and cranium rising dramatically in area of nares (except in *Grampus*); spiracular plate relatively smooth

Delphinidae, **Go to 32**

31a. Facial profile flat; no teeth in lower jaw; upper jaw teeth number no more than 2, including a long forward-directed and spiraled tusk in some animals

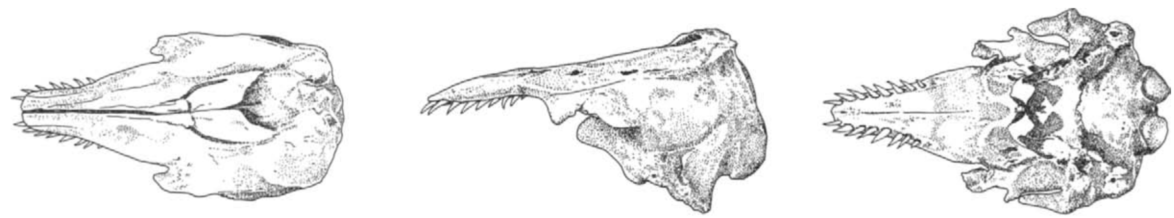
Narwhal (*Monodon monoceros*)



Dorsal View | Lateral View | Ventral View

b. Facial profile slightly convex, with downturned tip of rostum; 8–9 teeth present in each row of both upper and lower jaws

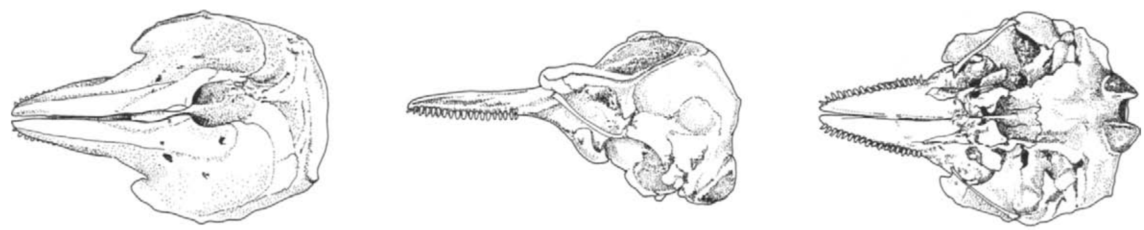
Beluga whale (*Delphinapterus leucas*)



Dorsal View | Lateral View | Ventral View

32a. Rostrum very short (<45% of CBL); teeth peg-like, with slightly expanded crowns; tympanoperiotic bones attached to cranium by a triangular ventral pad on zygomatic arch; distributed only in the coastal waters of the Indo–Pacific

Irrawaddy/Australian snubfin dolphin (*Orcaella* sp.)



Dorsal View | Lateral View | Ventral View

b. Rostrum may be relatively long (>45% of CBL); teeth conical (generally pointed), without expanded crowns; tympanoperiotic bones attached to cranium by a cavity formed by squamosal, exoccipital and basioccipital bones

Other Delphinidae, **Go to 33**

33a. Mandibular symphysis long (generally >25% mandibular length); margins of rostrum somewhat concave throughout most of their length, when viewed from above

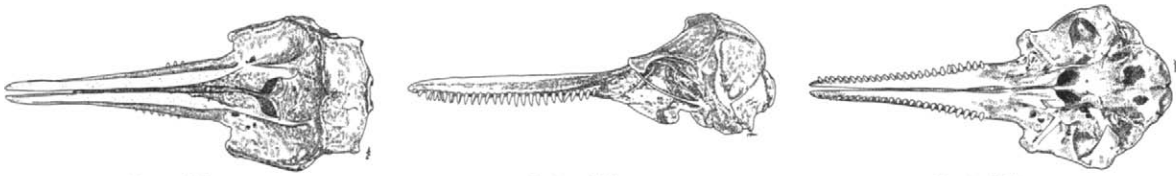
Other species, **Go to 34**

b. Mandibular symphysis short (<25% mandibular length); margins of rostrum convex, or concave only along middle of their length

Globicephalinae or Delphininae, **Go to 37**

34a. Teeth with shallow vertical wrinkles; 19–28 teeth in each row; constriction at base of rostrum; orbits very large; prominent cylindrical ridge at 45° angle on ventral aspect of frontal; pterygoids only slightly separated

Rough-toothed dolphin (*Steno bredanensis*)



Dorsal View Lateral View Ventral View

b. Teeth smooth (no wrinkles); 26–39 teeth in each row; orbits relatively small; no prominent ridge on ventral aspect of frontal; pterygoids widely separated; distributed only in Indo–Pacific, West African, and South American waters

Sousa/Sotalia, **Go to 35**

35a. Skull relatively small (adult CBL <400 mm); rostral margins relatively straight; distributed only in Central and South America

Tucuxi/costero (*Sotalia* sp.)

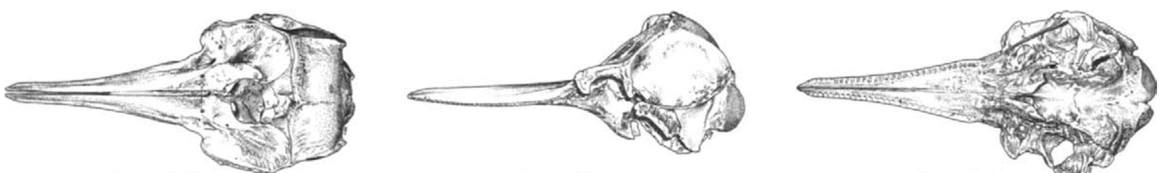
Dorsal View Lateral View Ventral View

b. Skull relatively large (adult CBL >405 mm); rostral margins strongly concave distributed only in the Indo–Pacific and West Africa

Sousa, **Go to 36**

36a. Relatively high tooth counts (>31 teeth per row); rostrum relatively long (generally >60% of CBL); distributed only in the Indo–Pacific

Indo–Pacific humpback dolphin (*Sousa chinensis*)



Dorsal View Lateral View Ventral View

b. Relatively low tooth counts (<32 teeth per row); rostrum relatively short (generally <60% of CBL); distributed only in West Africa

Atlantic humpback dolphin (*Sousa teuszii*)

Dorsal View Lateral View Ventral View

37a. Less than 27 teeth per toothrow

Globicephalinae, *Tursiops*, or *Grampus,* **Go to 38**

b. Greater than 27 teeth per toothrow

Lagenodelphis, *Delphinus*, *Lagenorhynchus*, or *Stenella,* **Go to 46**

38a. 2–7 pairs of teeth present near tip of lower jaw only (uncommonly 1–2 pairs in upper jaw); lateral margins of rostrum concave along middle part of their length

Risso's dolphin (*Grampus griseus*)

b. At least 7 teeth present in each toothrow of both upper and lower jaws; lateral margins of rostrum generally convex

Globicephalinae or *Tursiops*, **Go to 39**

39a. Greater than 15 teeth per toothrow

Tursiops or *Peponocephala,* **Go to 40**

b. Less than 15 teeth per toothrow

Globicephala, *Feresa*, *Pseudorca*, or *Orcinus,* **Go to 42**

40a. Rostrum relatively wide (length/breadth ratio <2); antorbital notches very deep; teeth absent in posterior 25% of upper jaw; 20–26 teeth per row

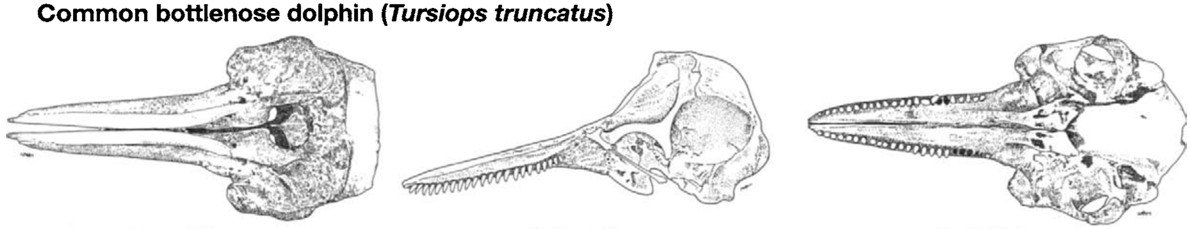
Melon-headed whale (*Peponocephala electra*)

b. Rostrum relatively narrow (length/breadth ratio >2); antorbital notches relatively shallow; teeth present in posterior 25% of upper jaw; 18–26 teeth per row

Bottlenose dolphin *Tursiops sp.*, **Go to 41**

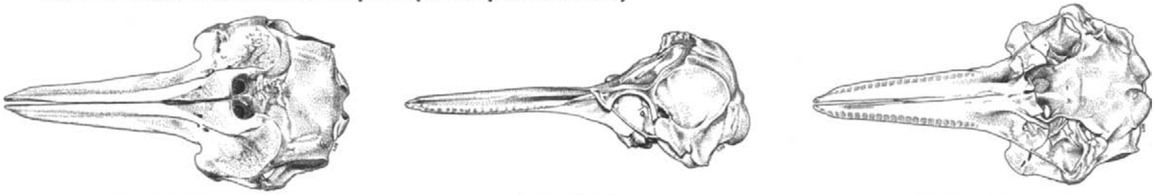
41a. From lateral view or dorsal view, no obvious premaxillary convexity; premaxillary "pinch"; tip of rostrum to apex of premaxilla convexity divided by length of rostrum <0.6; tooth counts 18–27

Common bottlenose dolphin (*Tursiops truncatus*)



b. From lateral view, premaxillary convexity and from dorsal view, premaxillary "pinch" obvious; tip of rostrum to apex of premaxilla convexity divided by length of rostrum > 0.6; tooth counts 21–29 distributed only in the Indo–Pacific

Indo–Pacific bottlenose dolphin (*Tursiops aduncus*)



Dorsal View | Lateral View | Ventral View

42a. 7–9 teeth present only in anterior half of rostrum; rostrum wide (length/breadth ratio generally < 1.3)

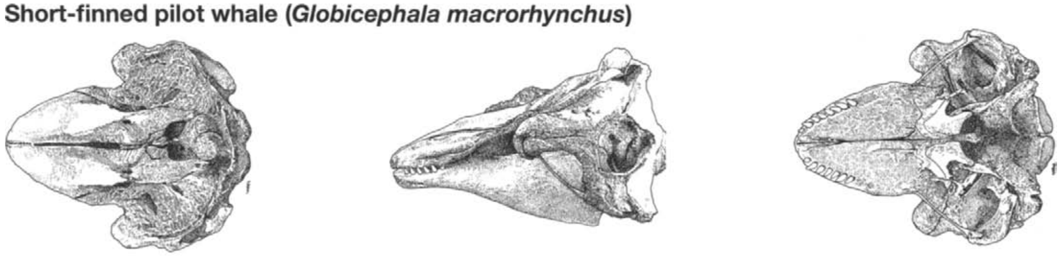
Globicephala, **Go to 43**

b. Teeth present in both anterior and posterior halves of rostrum; rostrum relatively narrow (length/breadth ratio generally > 1.3)

Feresa, *Pseudorca*, or *Orcinus*, **Go to 44**

43a. Rostrum very wide; premaxilla expanded and completely covering maxilla along anterior half of rostrum (or leaving only a very small portion visible in dorsal view)

Short-finned pilot whale (*Globicephala macrorhynchus*)



Dorsal View | Lateral View | Ventral View

b. Rostrum relatively narrow; premaxilla not completely covering maxilla along anterior half of rostrum (at least a 1 cm portion of maxilla visible in dorsal view)

Long-finned pilot whale (*Globicephala melas*)

Dorsal View | Lateral View | Ventral View

44a. Teeth relatively slender (generally < 10 mm in diameter); adult CBL < 50 cm; 8–13 teeth in anterior 2/3 of rostral tooth row only

Pygmy killer whale (*Feresa attenuata*)

Dorsal View | Lateral View | Ventral View

b. Teeth relatively robust (generally >10 mm in diameter); adult CBL >50 cm; teeth present in posterior 1/3 of rostral tooth rows

Pseudorca or *Orcinus*, **Go to 45**

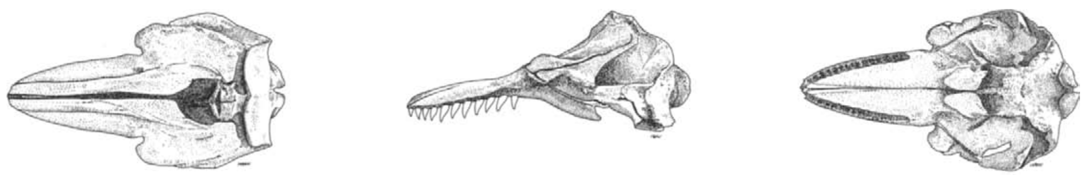
45a. Teeth round in cross-section (greatest diameter of largest teeth generally <23 mm); adult CBL<78 cm; 7–12 teeth in each row; width across premaxillae >50% of rostral basal width

False killer whale (*Pseudorca crassidens*)

Dorsal View | Lateral View | Ventral View

b. Teeth oval in cross-section (greatest diameter of largest teeth generally >23 mm); adult CBL >78 cm; 10–14 teeth in each row; width across premaxillae <50% of rostral basal width

Killer whale (*Orcinus orca*)



Dorsal View | Lateral View | Ventral View

46a. Deep palatal grooves present (>3 mm at midlength of rostrum)

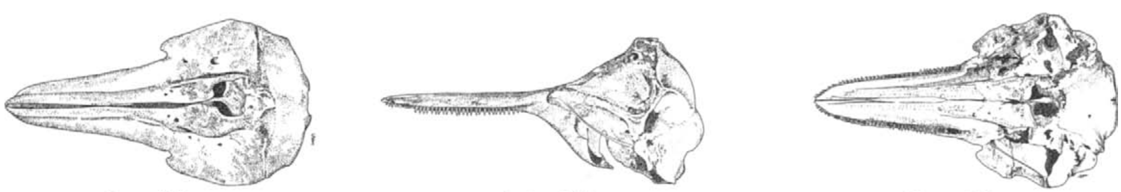
Lagenodelphis or *Delphinus*, **Go to 47**

b. Palatal grooves shallow (<3 mm at midlength of rostrum) or non-existent

Cephalorhynchus, *Lissodelphis*, *Lagenorhynchus* or *Stenella*, **Go to 49**

47a. Rostrum relatively wide (length/breadth ratio <2.4); <45 teeth per row

Fraser's dolphin (*Lagenodelphis hosei*)



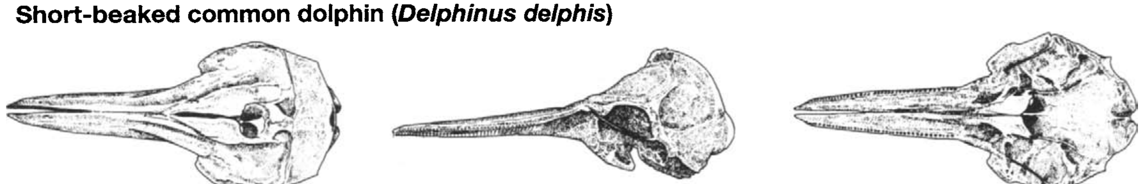
Dorsal View | Lateral View | Ventral View

b. Rostrum relatively narrow (length/breadth ratio >2.5); >40 teeth/row

Delphinus, **Go to 48**

48a. Rostrum relatively short and wide (<275 mm long; length/breadth ratio <3.2; rostrum lenth/zygomatic width ratio 1.25–1.62); 41–54 teeth in each row; trapezoid-shaped palatal ridge with no "pinch"

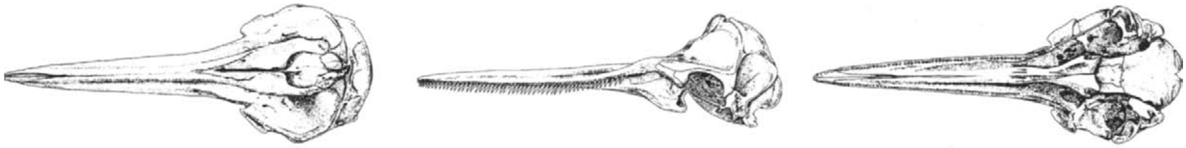
Short-beaked common dolphin (*Delphinus delphis*)



Dorsal View | Lateral View | Ventral View

b. Rostrum relatively long and slender (>275 mm; length/breadth ratio >3.2; rostrum length/zygomatic width ratio 1.46–2.06); 47–67 teeth in each row; lanceolate-shaped palatal ridge with distinct “pinch”

Long-beaked common dolphin (*Delphinus capensis*)



Dorsal View | Lateral View | Ventral View

49a. Rostrum relatively narrow (width at base generally <25% CBL, length/breadth ratio > 2.1); >30 teeth per tooth row

Stenella or *Lissodelphis*, **Go to 50**

b. Rostrum relatively wide (width at base generally >25% CBL, length/breadth ratio <2.2); <40 teeth per tooth row

Cephalorhynchus or *Lagenorhynchus*, **Go to 55**

50a. Premaxillaries converge and meet or nearly meet along dorsal aspect of rostrum; orbits relatively deep; distal portions of mandibles more robust; rostrum relatively long and narrow (length generally >2.3 times its width at base)

Stenella, **Go to 51**

b. Premaxillaries remain widely separated along dorsal aspect of rostrum (starting at base and moving toward tip); orbits relatively shallow; distal portions of mandibles very narrow; rostrum relatively short and wide (length about 2.2 times its width at base); distributed only in the North Pacific and Southern Hemisphere

Right whale dolphins (*Lissodelphis* spp.)

Dorsal View | Lateral View | Ventral View

51a. Mandibular symphysis relatively long (usually >17% of mandible length); mandible arcuate; <49 teeth/row; temporal fossa relatively large (length >14% CBL); distal half of rostrum rounded on dorsal surface; no palatal grooves; tooth rows converge throughout their length

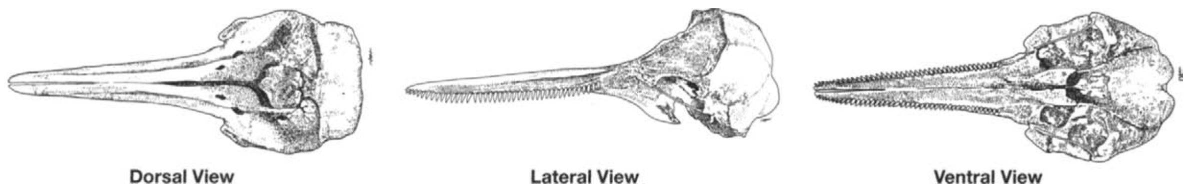
S. attenuata or *S. frontalis*, **Go to 52**

b. Mandibular symphysis relatively short (usually <17% of mandible length); mandible sigmoid; >38 teeth/row (usually >40); temporal fossa relatively small (length <17% CBL); distal half of rostrum flattened on dorsal surface; shallow palatal grooves sometimes present; central portions of tooth rows parallel or nearly so

S. longirostris, *S. coeruleoalba*, or *S. clymene*, **Go to 53**

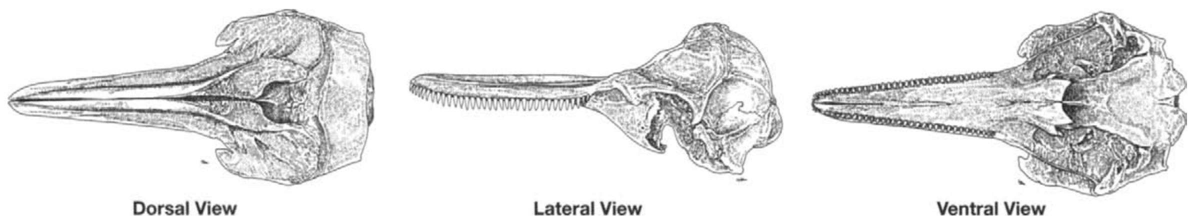
52a. >42 teeth/row; teeth relatively small (<3.2 mm in diameter); rostrum narrow distally (width at 3/4 length <13% length)

Pantropical spotted dolphin (*Stenella attenuata*)



b. <34 teeth/row; teeth relatively large (>4.1 mm in diameter); rostrum broad distally (width at 3/4 length >16% length); distributed only in the Atlantic Ocean

Atlantic spotted dolphin (*Stenella frontalis*)

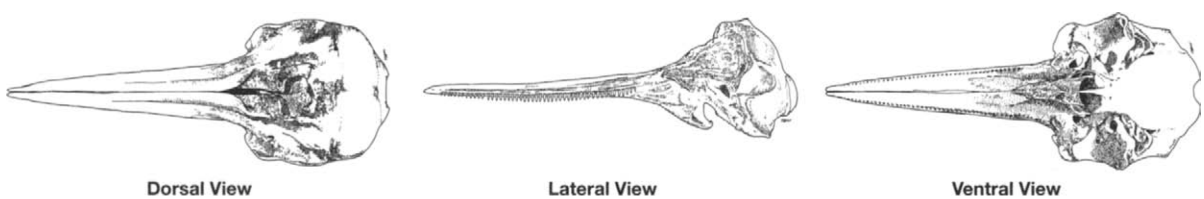


c. 34–42 teeth/row; teeth 3.2–4.1 mm in diameter; rostrum width at 3/4 length 13–16% length

Use discriminant function in Perrin et al. (1987)

53a. Rostrum relatively long and slender (>61% CBL; length/breadth ratio >3); 40–62 teeth/row; preorbital width <158 mm

Spinner dolphin (*Stenella longirostris*)

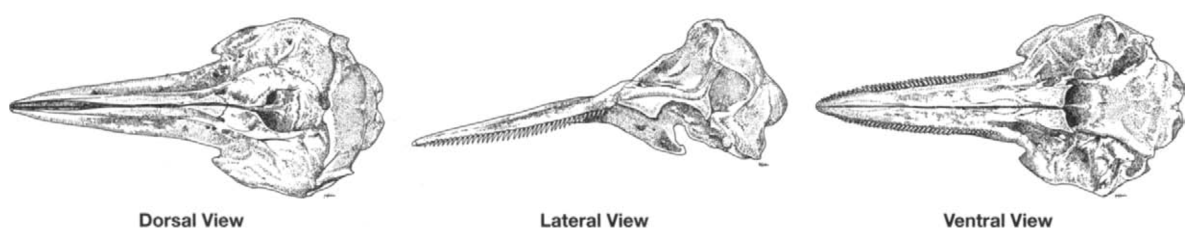


b. Rostrum relatively short and wide (<62% CBL; length/breadth ratio <3); <56 teeth/row; preorbital width >149 mm

S. coeruleoalba or *S. clymene*, **Go to 54**

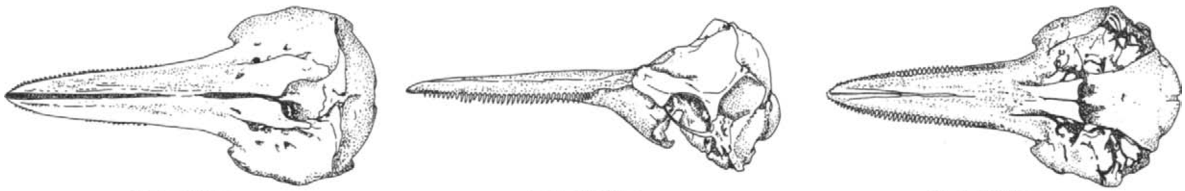
54a. Adult skull relatively large (CBL >420 mm); 40–55 teeth/row; palatal grooves usually shallow (0.5 mm or less at 1/2 length of rostrum); upper toothrow >212 mm; preorbital width >177 mm; often a raised area on premaxillae near base of rostrum (visible in lateral view)

Striped dolphin (*Stenella coeruleoalba*)



b. Adult skull relatively small (CBL <415 mm); 39–52 teeth/row; palatal grooves usually distinct and relatively deep (0.5 mm or more at 1/2 length of rostrum); upper toothrow <212 mm; preorbital width <175 mm; rostrum relatively flat when viewed from lateral aspect; distributed only in the Atlantic Ocean

Clymene dolphin (*Stenella clymene*)



Dorsal View Lateral View Ventral View

55a. Skull relatively large (adult CBL generally >350 mm); pterygoids in contact along at least a portion of posterior half; zygomatic processes robust

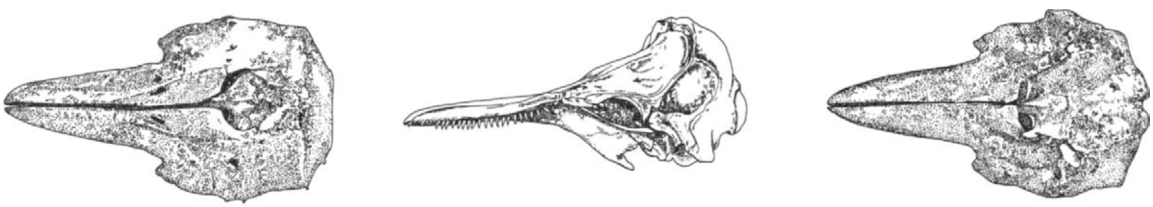
Lagenorhynchus, **Go to 56**

b. Skull relatively small (adult CBL generally <350 mm); pterygoids separated along entire posterior half; zygomatic processes slender (longer than high); distributed only in coastal waters of the Southern Hemisphere

Cephalorhynchus, **Go to 61**

56a. Rostrum very wide at base (>30% of CBL); upper tooth counts <29; distributed only in the North Atlantic Ocean

White-beaked dolphin (*Lagenorhynchus albirostris*)



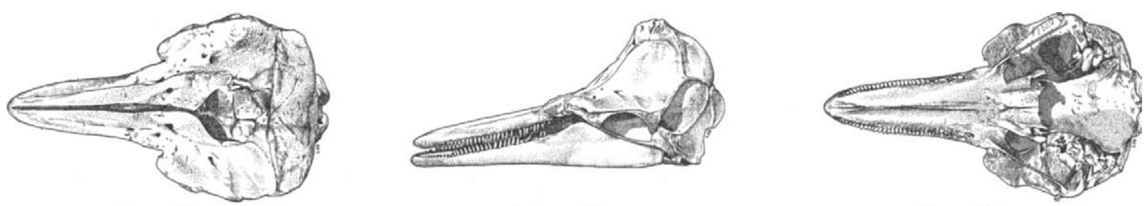
Dorsal View Lateral View Ventral View

b. Rostrum relatively narrow at base (<31% of CBL); upper tooth counts generally >28

Other species of *Lagenorhynchus*, **Go to 57**

57a. Length of lacrimal >12% of CBL; upper tooth counts generally >35; distributed only in the North Atlantic Ocean

Atlantic white-sided dolphin (*Lagenorhynchus acutus*)



Dorsal View Lateral View Ventral View

b. Length of lacrimal <12% of CBL; upper tooth counts <37 per row

Other species of *Lagenorhynchus*, **Go to 58**

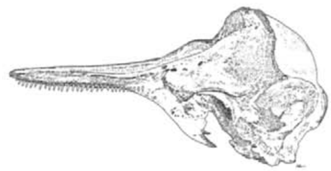
58a. Height of mandible >18% CBL; distributed only in the high latitudes of the Southern Hemisphere

L. cruciger or *L. australis*, **Go to 59**

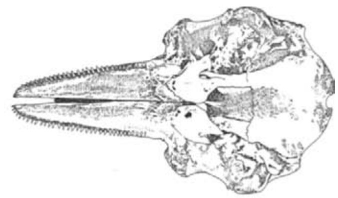
b. Height of mandible <18% CBL
L. obscurus or *L. obliquidens*, **Go to 60**

59a. Width of external nares <15% CBL; width of rostrum at base generally <26% CBL
Peale's dolphin (*Lagenorhynchus australis*)

Dorsal View



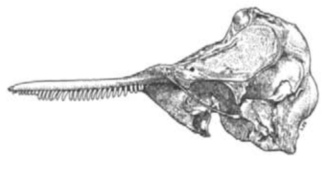
Lateral View



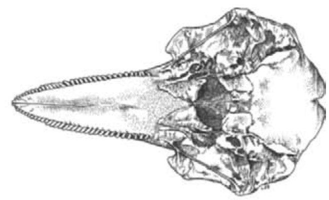
Ventral View

b. Width of external nares >15% CBL; width of rostrum at base >26% CBL
Hourglass dolphin (*Lagenorhynchus cruciger*)

Dorsal View

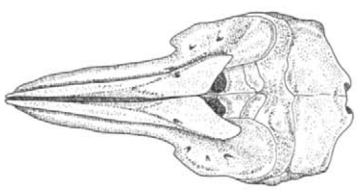


Lateral View

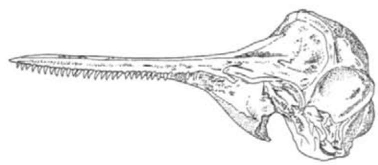


Ventral View

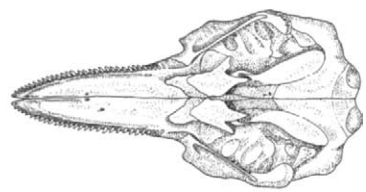
60a. Preorbital width >165 mm; distributed only in the North Pacific Ocean
Pacific white-sided dolphin (*Lagenorhynchus obliquidens*)



Dorsal View

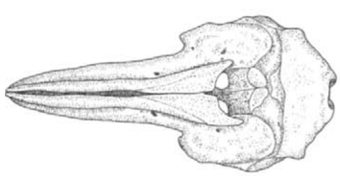


Lateral View

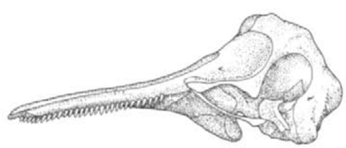


Ventral View

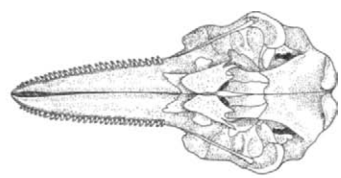
b. Preorbital width <165 mm; distributed only in the Southern Hemisphere
Dusky dolphin (*Lagenorhynchus obscurus*)



Dorsal View

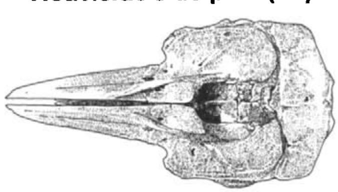


Lateral View

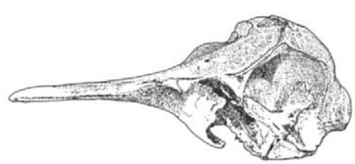


Ventral View

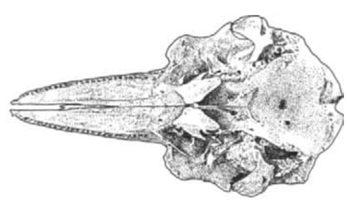
61a. Pterygoids separated by a finger-like projection of the palatines; <116 total teeth; distribution limited to southwestern Africa
Heaviside's dolphin (*Cephalorhynchus heavisidii*)



Dorsal View



Lateral View



Ventral View

b. No finger-like projection of the palatines; >116 total teeth; distributed only in New Zealand, South America and the Kerguelen Islands

Other species of *Cephalorhynchus*, **Go to 62**

62a. CBL generally >300 mm; length of rostrum >50% CBL; left premaxilla extends posterior to the midpoint of the nares; distributed only on the west coast of South America

Chilean dolphin (*Cephalorhynchus eutropia*)

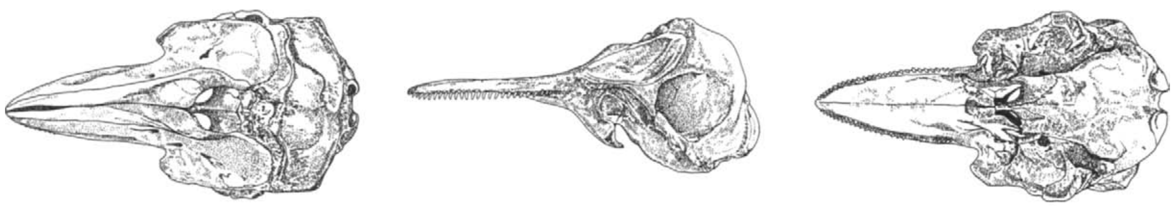
Dorsal View Lateral View Ventral View

b. CBL generally <300 mm; length of rostrum <50% CBL; left premaxilla does not extend posterior to the midpoint of the nares

Cephalorhynchus hectori or *C. commersonii*, **Go to 63**

63a. Area of nasals combined <650 mm^2; distributed only in New Zealand

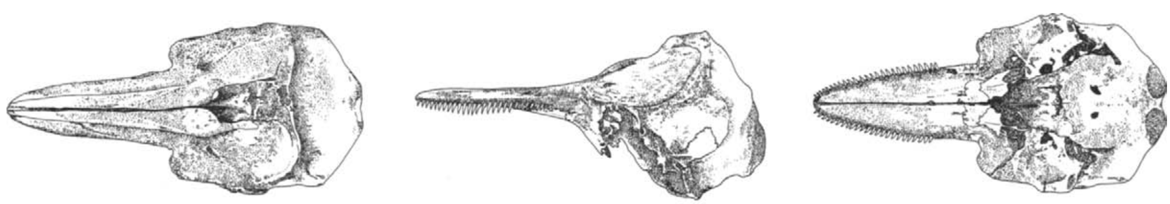
Hector's dolphin (*Cephalorhynchus hectori*)



Dorsal View Lateral View Ventral View

b. Area of nasals combined >650 mm^2; distributed only in southern South America and the Kerguelen Islands

Commerson's dolphin (*Cephalorhynchus commersonii*)



Dorsal View Lateral View Ventral View

C. Key to Identification of Pinnipeds of the World, Based on External Appearance

1a. Tail attached to body by web of skin; muzzle very short with broad and flat end; nearly all vibrissae on the end (as opposed to the sides) of the muzzle; 2 massive upper canine teeth enlarged to form tusks that project up to 1 m out of the mouth (except in infants, or when broken off or worn in adults); only 3 post-canine teeth in each tooth row; distribution limited to high latitudes of the Northern Hemisphere

Walrus (*Odobenus rosmarus*)

b. Short free tail; muzzle generally tapering and somewhat pointed; nearly all vibrissae on the sides of the muzzle; upper canines never enlarged to form tusks that project out of the mouth; 5–6 post-canines in each row

Phocidae or Otariidae, **Go to 2**

2a. External ear pinnae present; all flippers incompletely furred, with only a sparse growth of short hair on top; claws on foreflippers vestigial or absent; 3 claws on each hindflipper on the 3 central digits; long terminal flaps beyond the claws on the digits of the hindflippers; hindflippers can rotate under the body (permitting walking); skin light in color; first 2 upper incisors with transverse grooves

Otariidae, **Go to 3**

b. No external ear pinnae; all flippers completely furred on top and bottom; 5 usually-prominent claws (except in *Hydrurga*, in which they are small), 1 on each digit of both foreflippers; hindflippers cannot be rotated under the body (thus cannot walk on land); 5 or no claws visible near the end of each digit on the hindflippers; no long flaps of skin beyond claws on hindflipper digits; skin dark in color; upper incisors not grooved transversely

Phocidae, **Go to 16**

3a. Dense underfur present; guard hairs (outer visible fur) long, giving a thick woolly appearance; terminal flaps on hindflipper digits all approximately equal in length and shape; relatively long prominent ear pinnae

Fur seal, **Go to 4**

b. Fur short and stiff; hindflipper digits unequal in length, with the hallux and the 5th digit longer (the hallux is longer and wider) than digits 2–4; ear pinnae relatively short and lying close alongside head

Sea lion, **Go to 12**

4a. Fur on the foreflippers stops abruptly at the wrist, with the top of the foreflippers entirely naked; hindflippers long, about $^1/_4$ standard length; very long terminal flaps beyond the claws on the hindflippers; muzzle very short; distribution limited to North Pacific and adjacent seas

Northern fur seal (*Callorhinus ursinus*)

b. Fur on top of foreflippers beyond the wrist (bend point when the animal is sitting upright); hindflippers about $^{1}/_{5}$ of standard length; terminal flaps beyond the claws on the hindflippers moderate in length; muzzle relatively long; distribution limited to Southern Hemisphere and warm temperate North Pacific

Arctocephalus sp.[5], **Go to 5**

5a. Muzzle short, with somewhat flattened end creating a pug appearance

Subantarctic, Antarctic, or Galapagos fur seal, **Go to 6**

b. Muzzle moderate to long (may not be possible to distinguish from 5a for females and subadults)

Other fur seal, **Go to 8**

6a. Adults with yellowish to orangish upper chest, neck, and face (to above the eyes); prominent crest of longer guard hairs on crown just behind the eyes

Subantarctic fur seal (*Arctocephalus tropicalis*)

[5] The "southern fur seals" (genus *Arctocephalus*) are all very similar in appearance and have overlapping distributions, and it may be very difficult for non-experts to identify them accurately. Also, some species (i.e., *A. gazella* and *A. tropicalis*) are known to hybridize, providing further challenges to identification. Skulls or genetic material may be required to positively identify some species and separate them from related forms.

b. Adults with moderate to no contrast in coloration on upper chest, neck, and face
Antarctic or Galapagos fur seal, **Go to 7**

7a. Adults medium-sized; silver gray with frosted guard hair tips; distribution Antarctica and subantarctic only
Antarctic fur seal (*Arctocephalus gazella*)

Adult Female/Adult Male

b. Adults small; generally minimal frosting on tips of guard hairs (if present usually not silver gray); distribution confined to Galapagos Archipelago
Galapagos fur seal (*Arctocephalus galapagoensis*)

Adult Female/Adult Male

8a. Small to moderate nose; nostrils facing ahead
Juan Fernandez or Guadalupe fur seal, **Go to 9**

b. Large bulbous nose; downward-facing nostrils (adult males)
Other fur seal, **Go to 10**

9a. Distribution confined to area around Juan Fernandez Archipelago, off the coast of Chile
Juan Fernandez fur seal (*Arctocephalus philippii*)

Adult Female/Adult Male

b. Distribution confined to eastern North Pacific, from about Guadalupe Island north to central California

Guadalupe fur seal (*Arctocephalus townsendi*)

10a. Distribution confined to coastal South America, from Peru, south to Cape Horn, and north to Brazil and the Falkland Islands

South American fur seal (*Arctocephalus australis*)

b. Distribution limited to New Zealand, southern Australia and adjacent subantarctic islands and waters, or South Africa

Cape, Australian or New Zealand fur seal, **Go to 11**

11a. Very large, robust build; head massive; distribution limited to southwestern and southern Africa and southeastern Australia, including Tasmania

Cape or Australian fur seal (*Arctocephalus pusillus*)

b. Medium size; moderate build and head size; distribution limited to New Zealand and adjacent subantarctic islands, and southwestern Australia

New Zealand fur seal (*Arctocephalus forsteri*)

12a. No distinct mane on adult males; head of moderate-size, with relatively long dog-like muzzle; bulging sagittal crest on adult male; distribution limited to the temperate eastern North Pacific or area around the Galapagos Islands and adjacent waters

California or Galapagos sea lion (*Zalophus* spp.)

b. Heavy mane on adult males; head massive with blunt broad muzzle that is usually relatively short (the latter not so for adult male Australian sea lion)

Other sea lions, **Go to 13**

13a. Both sexes massive in size; wide diastema (gap) between 4th and 5th post-canine teeth; distribution limited to temperate and subpolar rim of North Pacific

Steller sea lion (*Eumetopias jubatus*)

b. Both sexes moderate in size; no wide diastema between 4th and 5th post-canines; distribution limited to Southern Hemisphere

Other sea lions, **Go to 14**

14a. Extremely heavy (thick) mane of very long guard hairs; very short broad muzzle; massive (deep and wide) lower jaw; distribution along coastal South America, from Peru on the west coast, south to Cape Horn, and north to Brazil on the east coast, including the Falkland Islands

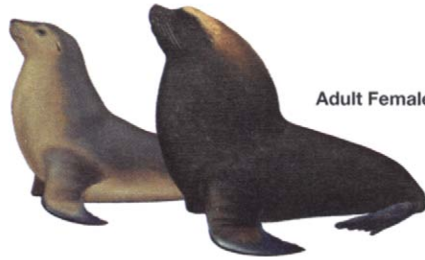
South American sea lion (*Otaria flavescens*)

b. Moderate mane of medium-length guard hairs; muzzle blunt, but moderate in length; distribution limited to New Zealand and adjacent subantarctic islands, or southern to southwestern Australia

Australian or New Zealand sea lion, **Go to 15**

15a. Adult males with mane extending up onto the top of the head and relatively flat-topped muzzle; generally brownish, with yellowish back of neck and crown; females often strikingly bicolored, dark above, pale below, with pale color on the face and over the eyes; distribution limited to southern and southwestern Australia in coastal waters

Australian sea lion (*Neophoca cinerea*)



Adult Female/Adult Male

b. Adult males with mane that stops at nape (head seems disproportionately small because of this); muzzle usually slightly convex in silhouette; color blackish-brown; distribution limited to southern New Zealand and adjacent subantarctic islands

New Zealand sea lion (*Phocarctos hookeri*)

Adult Female/Adult Male

16a. Vibrissae smooth in outline

Bearded, monk, or elephant seal, **Go to 17**

b. Vibrissae beaded (sometimes only weakly) in outline

Other seal, **Go to 22**

17a. Foreflippers square to rounded, with equal length digits, or digits 2–4 slightly longer; vibrissae very densely packed, so as to obscure mouthline

Bearded seal (*Erignathus barbatus*)

Adult Male

Adult Female

b. Foreflippers pointed, with first digit longer and digits 2–5 becoming shorter; vibrissae with sparse to moderate density

Monk or elephant seal, **Go to 18**

18a. Adults medium-sized; muzzle and head moderate in size and somewhat flattened; nostrils pointing slightly upwards; males without enlarged nose; females with 4 mammary teats

Monk seal (*Monachus* sp.), **Go to 19**

b. Adults very large; muzzle and head very broad and deep; nostrils point ahead or down; adult males with large inflatable proboscis; females with 2 mammary teats

Elephant seal (*Mirounga* spp.), **Go to 21**

19a. Distribution limited to the Pacific Ocean (generally the northwestern Hawaiian Islands)

Hawaiian monk seal (*Monachus schauinslandi*)

b. Distribution limited to the North Atlantic Ocean and surrounding seas (Mediterranean, Black, and Caribbean seas, and Gulf of Mexico)

Mediterranean or Caribbean monk seal, **Go to 20**

20a. Distribution limited to portions of the Mediterranean Sea, Black Sea, and West African coast)

Mediterranean monk seal (*Monachus monachus*)

b. Formerly found in the Caribbean Sea and Gulf of Mexico (now considered extinct)

West Indian monk seal (*Monachus tropicalis*)

21a. Proboscis of adult males relatively large; distribution limited to temperate eastern and central North Pacific

Northern elephant seal (*Mirounga angustirostris*)

b. Proboscis of males relatively small; distribution circumpolar in polar to temperate waters of the Southern Hemisphere

Southern elephant seal (*Mirounga leonina*)

22a. Distribution limited to Southern Hemisphere

"Antarctic seal", **Go to 23**

b. Distribution limited to Northern Hemisphere

Other seal, **Go to 26**

23a. Head and muzzle short and wide; foreflippers about 1/5 or less of standard length; post-canine teeth relatively simple

Weddell or Ross seal, **Go to 24**

b. Head and muzzle long and narrow; foreflippers long, at least 1/4 standard length; post-canines ornate and multi-cusped

Leopard or Crabeater seal, **Go to 25**

24a. Adults very long (2.5–3.3 m) and massive, with a relatively small head; numerous blotches of light and dark, particularly on sides and belly

Weddell seal (*Leptonychotes weddellii*)

b. Adults generally < 2.5 m; long streaks of color on face, neck, chest, and extending onto the sides; head more normal in size, neck appears thick and enlarged

Ross seal (*Ommatophoca rossii*)

25a. Head and jaws massive and reptilean in appearance; body long (to 3.3 m), and serpent-like, thickest at shoulders; foreflippers very long, almost 1/3 standard length; foreflipper claws very small

Leopard seal (*Hydrurga leptonyx*)

b. Head and jaws long, but tapering, with a somewhat flattened muzzle (dorso-ventrally); body moderately robust, more filled out; foreflippers long, but only to about 1/4 standard length; foreflipper claws more normal in size

Crabeater seal (*Lobodon carcinophagus*)

26a. Distribution limited to Lake Baikal or the Caspian Sea, far from oceanic areas

Baikal or Caspian seal (*Pusa* sp.), **Go to 27**

b. Distribution oceanic or in lakes or rivers near oceanic areas

Other seal, **Go to 28**

27a. Distribution limited to Lake Baikal and connecting rivers

Baikal seal (*Pusa sibirica*)

b. Distribution limited to the Caspian Sea and connecting rivers

Caspian seal (*Pusa caspica*)

28a. Pelage markings consist of bands or broad swaths of light or dark color

Ribbon or Harp seal, **Go to 29**

b. Pelage markings consist of spots, rings, or blotches

Other seal, **Go to 30**

29a. Body orange-brown to black; lighter color bands encircling each foreflipper, around neck, and around abdomen; distribution limited to Bering Sea, Sea of Okhotsk, and adjacent Arctic Ocean

Ribbon Seal (*Histriophoca fasciata*)

b. Body generally silvery-white, with some animals sooty gray and others with scattered blotches; body marked with a broad swath of black on each side, meeting (generally) over the shoulders to roughly form a "V" pattern[6]

Harp seal (*Pagophilus groenlandicus*)

30a. Pelage markings consist of irregular, small to large, dark brown to black or sometimes tan blotches; distribution limited to North Atlantic and adjacent Arctic areas

Hooded or gray seal, **Go to 31**

---

[6] Some harp seals never develop the harp pattern and remain blotched as adults. These blotched animals can be separated from gray seals, based on their smaller size, clearly demarcated and shorter muzzle, and closer-set nostrils; and from hooded seals, based on their longer, but thinner, head and muzzle and lack of a hood pattern on the head.

b. Pelage markings consist primarily of round to oval smaller spots or rings around spots, or a combination of the above

Other seal, **Go to 32**

31a. Head broad and short with short muzzle on females, and large fleshy nasal bladder (with overhanging nostrils) on males; head dark in both sexes from merged blotches, creating hooded appearance

Hooded seal (*Cystophora cristata*)

Adult Male

Adult Female

b. Head and muzzle very long and somewhat narrow; in silhouette, nose is rounded outwards (convex) in males and straight to slightly rounded in females; adult males dark brown to gray black with lighter (tan) blotches

Gray seal (*Halichoerus grypus*)

Adult Male

Adult Female

32a. Pelage pattern with few or no spots that are not encircled by a lighter outer ring

Ringed seal (*Pusa hispida*)

Adult Variation

Adult Variation

b. Pelage pattern consists mostly of small round to oval spots with few or no rings

Largha or harbor seal (*Phoca* sp.), **Go to 33**

33a. Often no, or occasionally a few, rings; spotting more even from top to bottom; face generally dark, like the back; distribution limited to North Pacific and adjacent Arctic areas

Spotted seal (*Phoca largha*)

Adult Variation

Adult Variation

b. Usually a moderate number of light rings around spots; more heavily spotted above than below; face generally light, unlike the back

Harbor seal (*Phoca vitulina*)

Adult Variation

Adult Variation

D. Key to Identification of Pinnipeds of the World, Based on Skull Morphology

1a. Tympanic bullae flat, small, and angular; supraorbital processes present on the frontal bones in most species (except Odobenidae); frontals penetrating anteriorly slightly to moderately between nasals on the midline; antorbital processes present

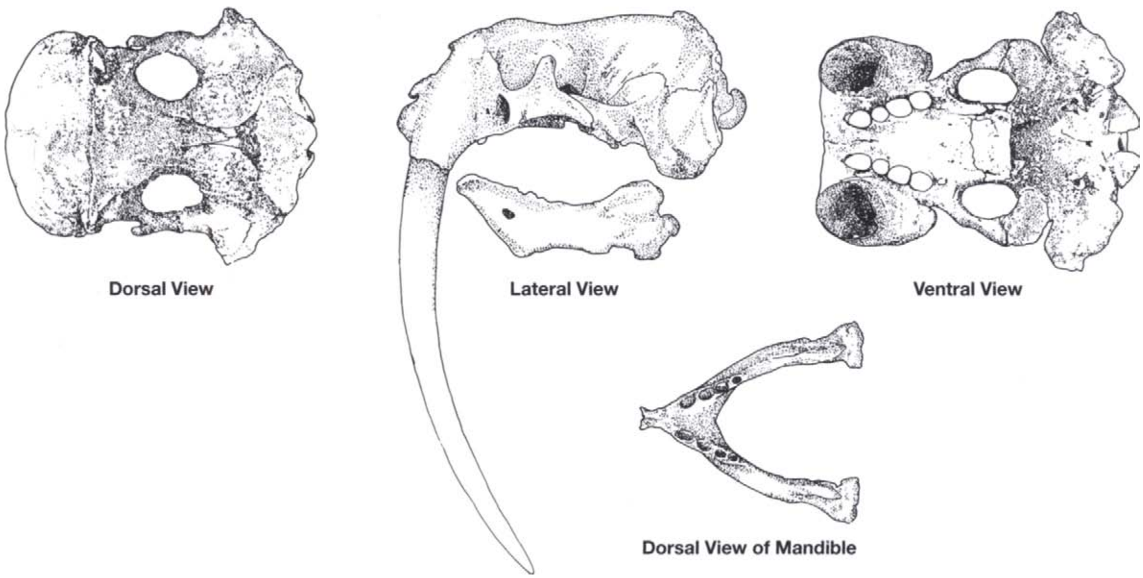
Otarioidea, **Go to 2**

b. Tympanic bullae inflated and rounded; supraorbital processes absent; nasals narrow and penetrating deeply back between frontals on midline; antorbital processes absent

Phocidae, **Go to 9**

2a. Upper canines massive, enlarged to form tusks; no supraorbital processes; frontals and nasals make a relatively straight point of contact; no grooves on upper incisors; only 3 post-canines on each side; mandibular symphysis exhibiting bony fusion; distributed only in the Northern Hemisphere

Walrus (*Odobenus rosmarus*)

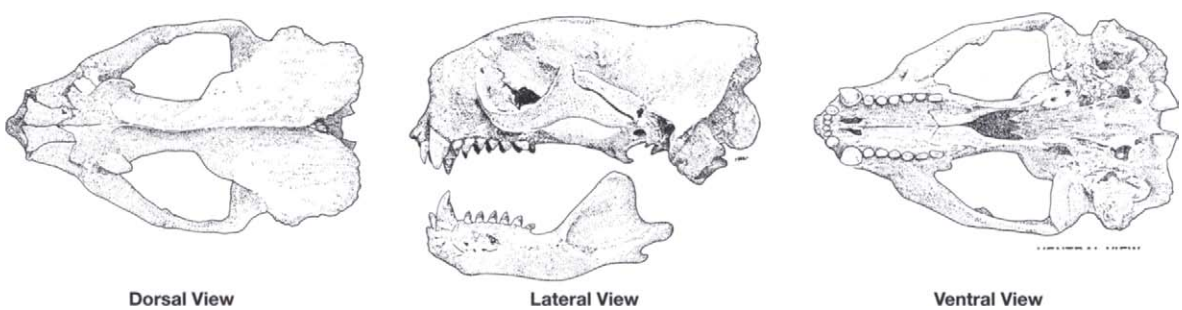


b. Upper canines not enlarged into tusks; supraorbital processes present; frontals and nasals make a W-shape at their point of contact; 2 lower incisors on each side; transverse groove on first 2 upper incisors; 5-6 post-canines on each side; mandibular symphysis not fused

Otariidae, **Go to 3**

3a. Facial angle < 125°; distributed only in the Northern Hemisphere

Northern fur seal (*Callorhinus ursinus*)



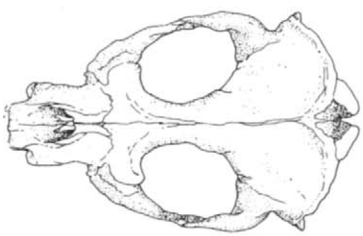
b. Facial angle > 125°
Other species, **Go to 4**

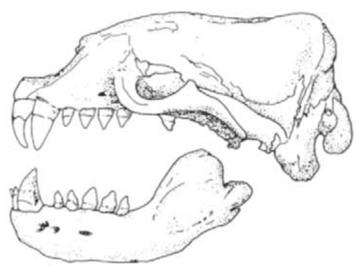
4a. Very long palate, extending posterior to orbitemporal; distributed only in South America
South American sea lion (*Otaria flavescens*)

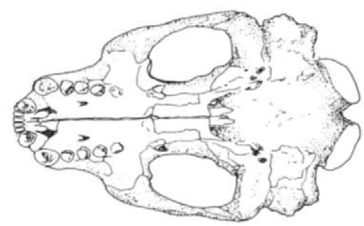
Dorsal View | Lateral View | Ventral View

b. Palate much shorter, not extending posterior to orbitemporal
Other species, **Go to 5**

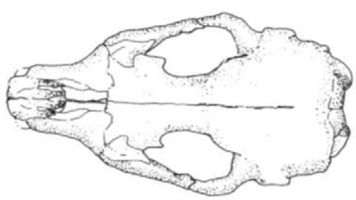
5a. Large diastema (gap) between 4th and 5th post-canines (width of about 2 teeth); distributed only in the North Pacific
Steller sea lion (*Eumetopias jubatus*)

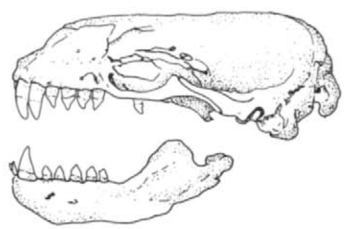


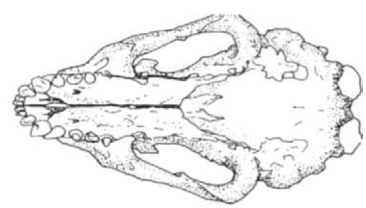




Male
Dorsal View | Lateral View | Ventral View







Female
Dorsal View | Lateral View | Ventral View

b. No diastema (or very reduced gap) between 4th and 5th post-canines
Other species, **Go to 6**

6a. Tympanic bullae with caudal extensions (approximately cylindrical in old individuals); distributed only in the region around New Zealand

New Zealand sea lion (*Phocarctos hookeri)*

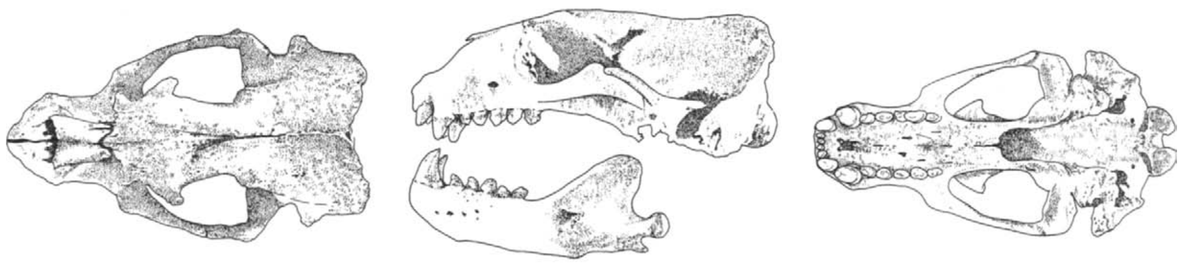
Dorsal View | Lateral View | Ventral View

b. Tympanic bullae of irregular form, without caudal extensions

Other species, **Go to 7**

7a. Anterior process of orbitotemporal very broad; distributed only in the area of southern Australia

Australian sea lion *(Neophoca cinerea)*



Dorsal View | Lateral View | Ventral View

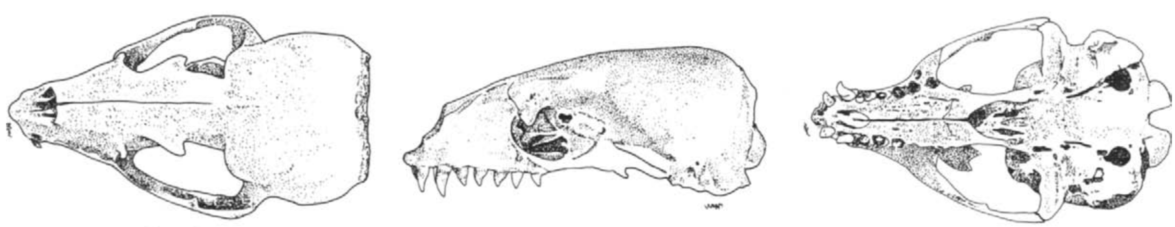
b. Anterior process of orbitotemporal relatively narrow

Other species, **Go to 8**

8a. Facial part of cranium lengthened; nasals relatively long and narrow; distributed only in North Pacific and equatorial waters of the Pacific

California, Japan, or Galapagos sea lion *(Zalophus* spp.)

Male
Dorsal View | Lateral View | Ventral View



Female
Dorsal View | Lateral View | Ventral View

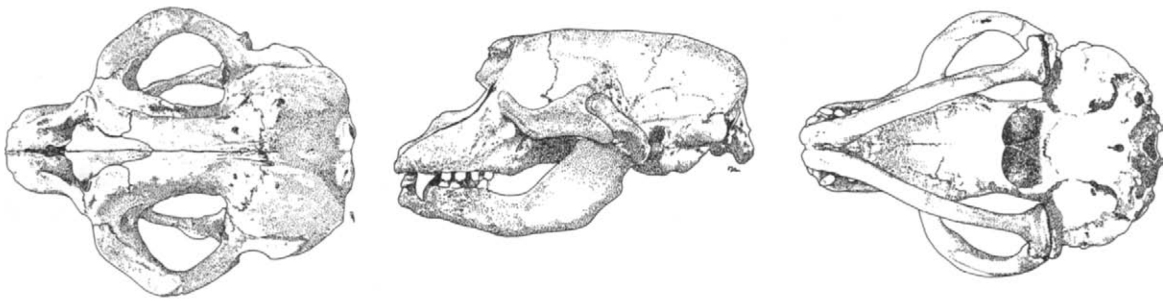
b. Short, broad cranium; short facial part; nasals widening distinctly anteriorly

Southern fur seal *(Arctocephalus* sp.)

Dorsal View Lateral View Ventral View

9a. Zygomatic arches heavy and extremely stout; nasals covered over $^{1}/_{3}$ of their length; distributed only in high latitudes of the North Atlantic

Hooded seal (*Cystophora cristata)*



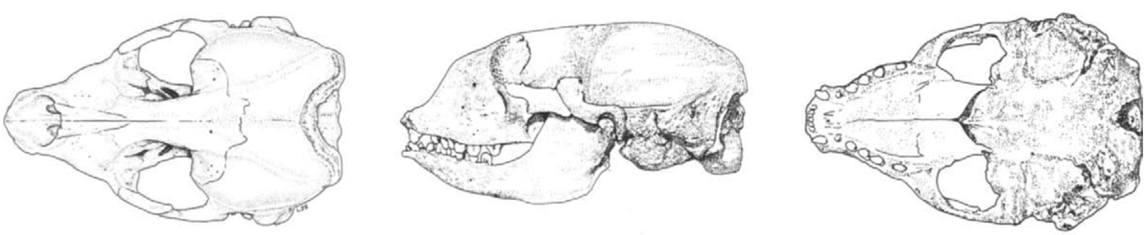
Dorsal View Lateral View Ventral View

b. Zygomatic arches relatively slender; nasals not or only slightly projecting

Other species, **Go to 10**

10a. Dorsal profile of cranium highly arched; jugals short and broad; distributed only in high latitudes of the Northern Hemisphere

Bearded seal (*Erignathus barbatus)*



Dorsal View Lateral View Ventral View

b. Dorsal profile of cranium not at all or only slightly arched; jugals relatively long and narrow

Other species, **Go to 11**

11a. Three upper incisors in each upper tooth row; distributed only in high latitudes of the Northern Hemisphere

Halichoerus/Phoca, **Go to 12**

b. Two upper incisors in each upper tooth row

Other species, **Go to 13**

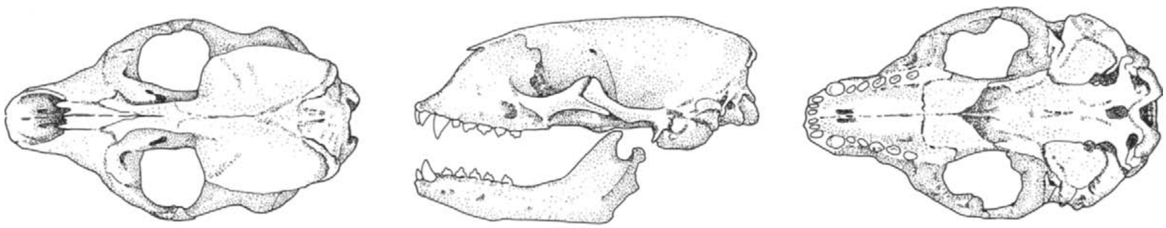
12a. Muzzle long, high, and wide; naso-frontal area elevated; premaxillae extend back to reach nasals; distributed only in high latitudes of the North Atlantic

Gray seal (*Halichoerus grypus)*

Dorsal View Lateral View Ventral View

b. Muzzle relatively short and low; naso-frontal area less elevated; premaxillae do not extend back as far

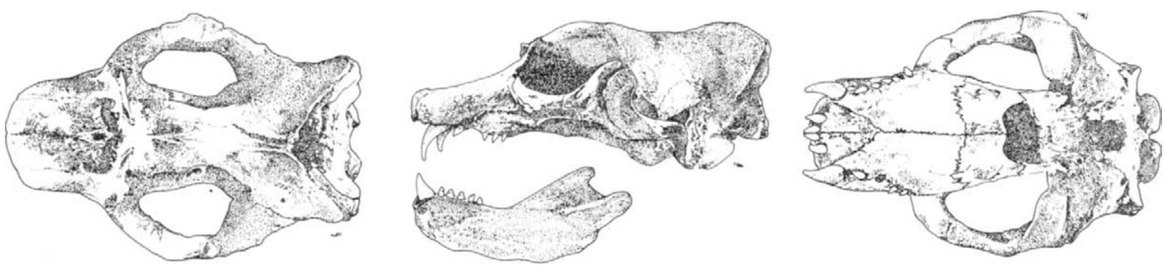
Harbor or spotted seals (*Phoca* sp.)



Dorsal View Lateral View Ventral View

13a. Muzzle low and long, generally with concave upper margin; distributed only in the mid- to high latitudes of the North Pacific and Southern Hemisphere

Elephant seal (*Mirounga* sp.)



Dorsal View Lateral View Ventral View

b. Muzzle relatively high and with straight or convex upper margin

Other species, **Go to 14**

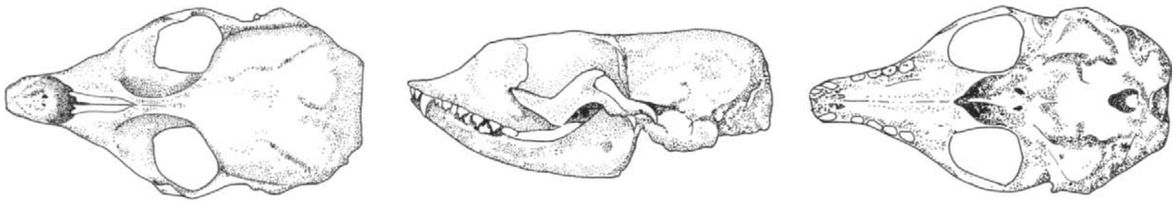
14a. Lateral swelling of mastoid process forms an oblique ridge at an angle of ca. 60° with the long axis of the mastoid bone

Pusa/Histriophoca/Pagophilus, **Go to 15**

b. Ridge of mastoid process absent

Other species, **Go to 17**

15a. Interorbital area extremely reduced and narrow (interorbital width < 7 mm)
Ringed, Caspian, and Baikal seal (*Pusa* sp.)



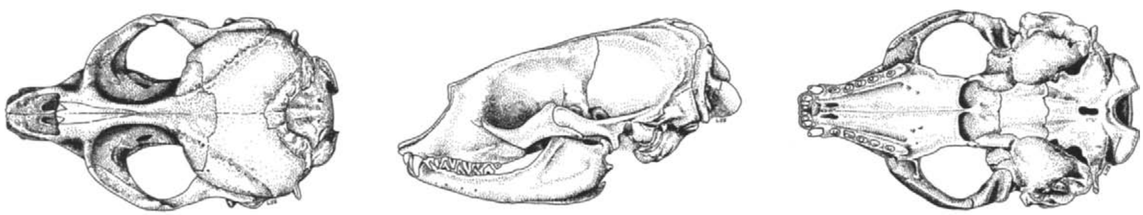
Dorsal View **Lateral View** **Ventral View**

b. Interorbital area relatively broad (interorbital width generally > 7 mm)
Histriophoca /Pagophilus, **Go to 16**

16a. Alveolar edge of premaxillae arched in horizontal and vertical planes; posterior palate short and very broad; distributed only in the North Pacific and adjacent Arctic waters
Ribbon seal (*Histriophoca fasciata)*

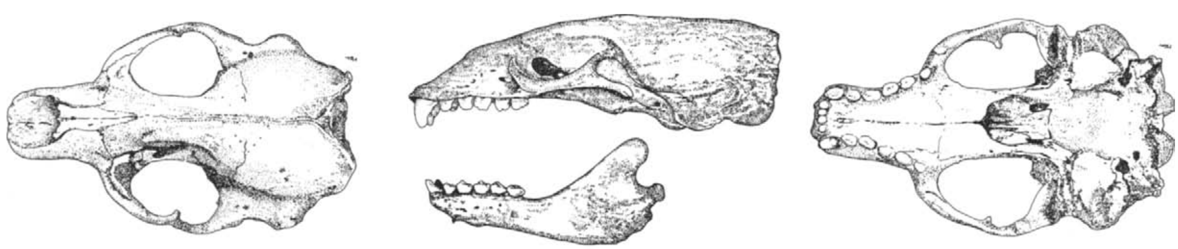
Dorsal View **Lateral View** **Ventral View**

b. Alveolar edge of premaxillae straight or only slightly arched; posterior palate relatively long and narrow; distributed only in the North Atlantic and adjacent Arctic waters
Harp seal (*Pagophilus groenlandicus)*



Dorsal View **Lateral View** **Ventral View**

17a. Nasal processes of premaxillae broadly in contact with nasals; post-canines wide and heavy (crushing type); distributed only tropical and warm temperate regions
Monk seal (*Monachus* sp.)



Dorsal View **Lateral View** **Ventral View**

b. Nasal processes of premaxillae barely touching or not touching nasals; post-canines not crushing type; distributed only in high latitude areas of the Southern Hemisphere

Lobodontini, **Go to 18**

18a. Highly specialized cheek teeth, with well-developed accessory cusps; muzzle long; occiput high

Lobodon/Hydrurga, **Go to 19**

b. Cheek teeth reduced, with small or absent accessory cusps; muzzle relatively short; occiput relatively low

Leptonychotes/Ommatophoca, **Go to 20**

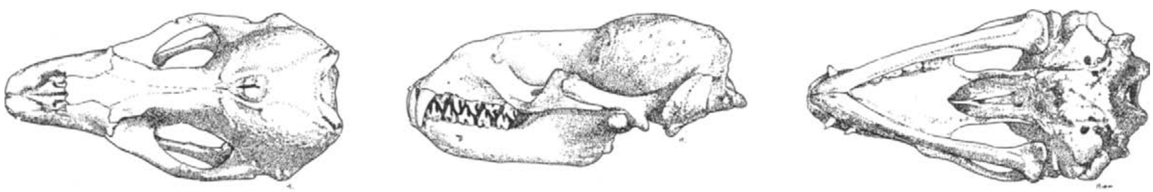
19a. Post-canines with 4–5 cusps

Crabeater seal (*Lobodon carcinophagus*)

Dorsal View **Lateral View** **Ventral View**

b. Post-canines tricuspid

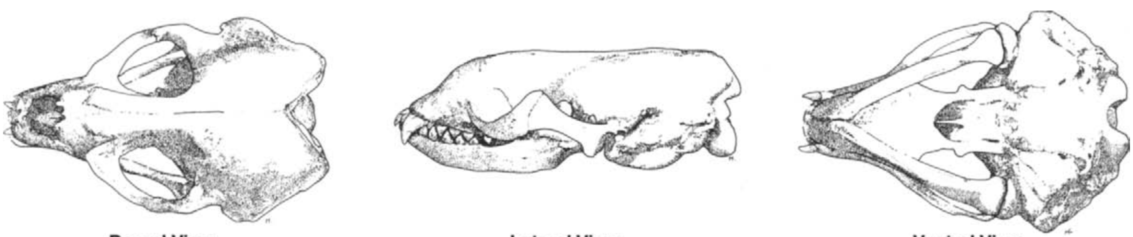
Leopard seal (*Hydrurga leptonyx*)



Dorsal View **Lateral View** **Ventral View**

20a. Upper incisors of unequal size (inner ones much smaller than outer ones); upper incisors and canines with oblique roots; orbits of normal size

Weddell seal (*Leptonychotes weddellii*)



Dorsal View **Lateral View** **Ventral View**

b. Upper incisors all of similar size, with vertical orientation; orbits extremely large

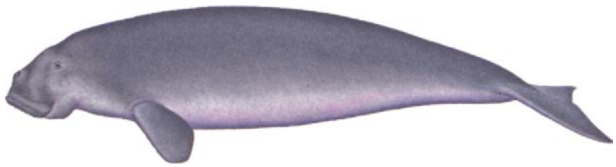
Ross seal (*Ommatophoca rossii*)

Dorsal View **Lateral View** **Ventral View**

E. Key to Identification of Sirenians of the World, Based on External Appearance and Distribution

1a. Tail split into flukes, with a median notch; tail stock laterally compressed; nostrils on top of snout; incisors (tusks) present; distribution limited to the Indo-Pacific region

Dugong (*Dugong dugon*)



b. Tail rounded and paddle-like; tail stock not laterally compressed; nostrils at front of snout; incisors not present in adults; distribution limited to Atlantic Ocean and surrounding seas and rivers

Manatee (*Trichechus* sp.), **Go to 2**

2a. No nails on flippers; skin of non-calves unwrinkled; light patches on belly and chest; maximum length 3 m; distribution limited to Amazon River and its tributaries

Amazonian manatee (*Trichechus inunguis*)

b. Nails present on flippers; skin wrinkled; generally, no light ventral patches; occurrence near the Amazon River limited to vicinity of river mouth

West Indian or West African manatee, **Go to 3**

3a. Distribution limited to coastal and inland waters of West Africa

West African manatee (*Trichechus senegalensis*)

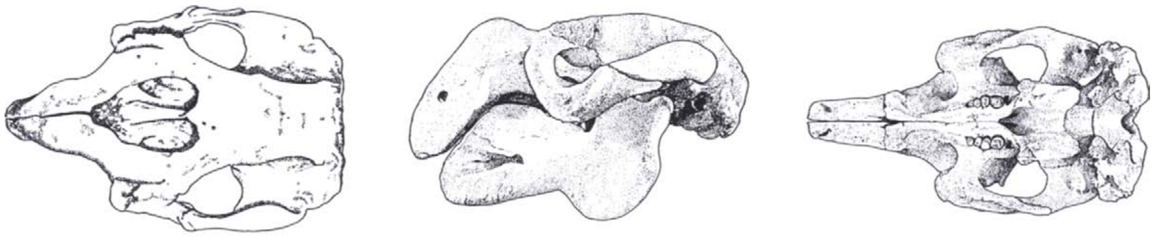
b. Distribution limited to waters of the southeastern United States, Gulf of Mexico, Caribbean Sea, and northeastern coast of South America

West Indian manatee (*Trichechus manatus*)

F. Key to Identification of Sirenians of the World, Based on Skull Morphology

1a. Rostrum relatively long and strongly deflected (generally > 60°); outer pair of upper incisors enlarged into tusks

Dugong (*Dugong dugon*)



Dorsal View Lateral View Ventral View

b. Rostrum relatively short and less strongly deflected (15–52°); incisors vestigial and generally lost in adults (no tusks)

Manatee (*Trichechus* sp.), **Go to 2**

2a. Skull relatively narrow and elongate; rostrum long and narrow; temporal crests laterally overhanging; zygomatic arches at angle of 25° laterally from long axis of skull

Amazonian manatee (*Trichechus inunguis*)

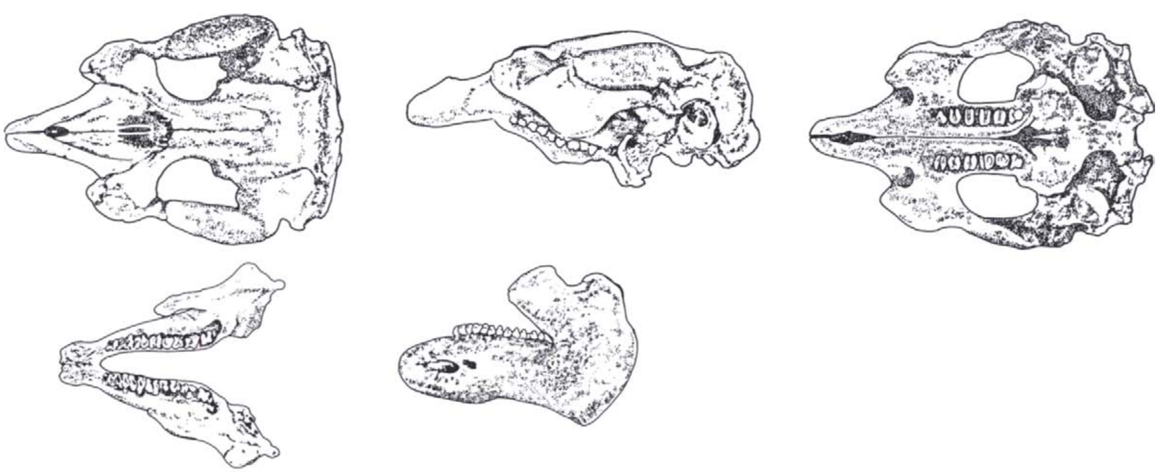
Dorsal View Lateral View Ventral View

b. Skull relatively broad; rostrum shorter and wider; temporal crests usually rise above level of skull roof; zygomatic arches at angle of 35-40° laterally from long axis of skull

West Indian or West African manatee, **Go to 3**

3a. Rostral deflection 15–40°; nasal bones usually absent; anterior border of frontals usually smooth; distribution limited to Western Africa

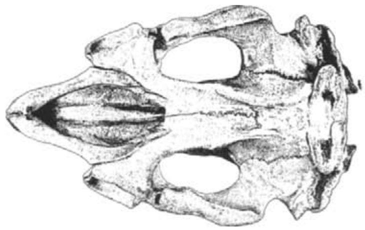
West African manatee (*Trichechus senegalensis*)



Dorsal View Lateral View Ventral View

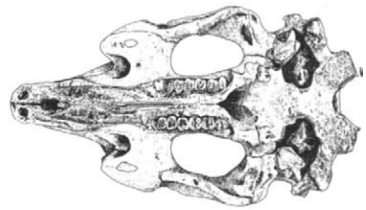
b. Rostral deflection 29–52°; nasal bones usually present; anterior border of frontals usually jagged; distribution limited to western Atlantic Ocean

West Indian manatee (*Trichechus manatus*)



Dorsal View

Lateral View



Ventral View

9. Summaries of Characters for Similar Species

A. Summary of Identifying Features for Large Beaked Whale Species

Species	Distribution	Max. Known Length (m)	Beak Length	Forehead	Mouthline	Erupted Tusks	Coloration
B. bairdii	Cool temp. N. Pacific	11.1	Long	Steep	Straight	Two pairs, tri-angular/peg-like	Non-descript
B. arnuxii	Circumglobal, S. Hemis.	9.3	Long	Steep	Straight	Two pairs, tri-angular/peg-like	Non-descript
H. ampullatus	Cool temp., North Atlantic	10.0	Moderately long	Steep	Straight	Single pair, conical	Grayish-brown, non-descript
H. planifrons	Circumglobal, cool S. Hemis.	7.5	Moderatelyy long	Steep	Straight	Single pair, conical	Grayish-brown, to yellowish
Z. cavirostris	Cosmopolitan	7.0	Short	Shallow	Curved at rear	Single pair, conical	Head and much of back whitish
T. shepherdi	Cool temp. S. Hemis.	7.0	Long	Moderately Steep	Straight	One pair of tusks, +17–28 pairs of teeth	Unique, with white belly ex-tending to sides
I. pacificus	Tropical Indo-Pacific	6.5	Moderate	Moderately steep	Straight	Single pair, oval	Brownish-gray, dark band behind head

B. Summary of Identifying Features for *Mesoplodon* Beaked Whale Species

Species	Distribution	Maximum Known Length (m)	Beak Length	Mouthline Male	Mouthline Female	Erupted Tusks	Tusk Position	Coloration
M. densirostris	Circumglobal, warm waters	4.7	Moderate arched	Strongly (massive)	Arched	Large and flat, rise above upper jaw	Middle of jaw	Non-descript; paired scratches common on male
M. grayi	Circumglobal, S. Hemis.	5.6	Long	Straight	Straight	Small, triangular	Middle of jaw	White beak and lower jaw in both sexes
M. ginkgodens	Indo-Pacific, tropical–temperate waters	5.3	Moderate	Slightly arched	Slightly arched	Small	Middle of jaw	Non-descript, scratches rare on male, beak often white
M. hectori	Circumglobal, S. Hemis.	4.3	Long	Straight	Straight	Flattened triangular	Just behind tip	White beak in males, non-descript in fems.
M. perrini	Eastern N. Pacific?	4.4	Short	Straight	Straight	Flattened, triangular	Just behind tip	Non-descript
M. carlhubbsi	Temperate N. Pacific	5.3	Short	Arched to strongly arched	Slightly arched	Large and flat, rise above upper jaw	Middle of jaw	Unique. White rostrum; white "beanie" on male
M. peruvianus	Eastern Pacific and New Zealand	3.9	Short	Straight	Straight	Small and egg-shaped	Middle of Jaw	Two morphs; male black with white chevron on back
M. bidens	Temperate N. Atlantic	5.5	Long	Slightly arched	Slightly arched	Small, flattened	2/3 back from tip	Non-descript
M. europaeus	Atlantic	4.8	Short	Straight	Straight	Triangular, flattened	1/3 back from tip	Non-descript
M. mirus	N. Atlantic/ S. Indian Ocean	5.4	Short	Straight	Straight	Small and oval	Tip of the jaw	White tail stock and dorsal surface in SH
M. layardii	Circumglobal, cool temper-ate S. Hemis	6.2	Long	Straight	Straight	Very long, curving over upper jaw	Middle of jaw, angled back	Unique. White beak, dark head, light thorax
M. bowdoini	Circumglobal S. Hemis.?	4.4	Short	Arched to strongly arched	Slightly arched?	Large and flat, rise above upper jaw	Middle of jaw	Front half of beak white
M. stejnegeri	Cool N. Pacific	5.7	Short	Arched	Arched	Large and flat, rise above upper jaw	Middle of jaw	Relatively non-descript; white striations on flukes; dark head
M. traversii	S. Hemis.	4.5-5.5?	Unknown	Unknown	Unknown	Long, curving up and back with denticle	Middle of jaw	Unknown

C. Summary of Identifying Features for Similar-Appearing Blackfish Genera

Genus	Maximum Length (m)	Head Size	Flippers Shape	Dorsal Fin	Teeth	Coloration	Group Size	Behavior
Peponocephala	2.8	Rounded, but triangular from above	Acutely pointed tips	Falcate, with wider base	20–25 small slender teeth	Indistinct cape dips low; white lips; face mask	Large (often 100-500)	Tends to be energetic
Feresa	2.6	Bulbous (rounded from above	Rounded tips	Falcate, with wider base	8–13 moderate size teeth	Cape more distinct, dips only slightly; white lips	Rel. small (usually) <50	Tends to be somewhat sluggish
Pseudorca	6.0	Bulbous (slender from above	Rounded tips, with hump on leading edge	Falcate and slender along entire height	7–12 large, stout teeth	Light gray patch on chest; lips generally dark	Variable, but most often 10–60	Variable, but most often quite lively

D. Summary of Identifying Features for Similar-Appearing Long-Beaked Marine Dolphins

Species	Distribution	Max. Length (m)	Teeth per Tooth Row	Body Shape	Beak	Dorsal Fin	Cape	Belly Color	Facial Stripes
D. delphis	Atlantic/ Pacific	2.4	41–54	Mod. robust	Moderately long and slender	Slightly falcate	Hourglass shape	White	Chin to flipper
D. capensis	Coastal all oceans	2.6	48–67	Mod. slender	Long and slender	Slightly falcate	Hourglass shape	White	Lower jaw/ gape to flipper
S. longirostris	Pantropical	2.4	45–62	Slender	Very long and slender	Triangular to canted	Variable	White to gray	Eye to flipper
S. clymene	Tropical Atlantic	2.0	39–52	Moderate	Moderately long and slender	Slightly falcate	Dips below dorsal fin	White	Eye to flipper and "moustache"
S. coeruleoalba	Panglobal	2.6	40–55	Mod. to robust .	Long and moderate	Slightly falcate	Distinct spinal blaze	White	Multiple
S. attenuta	Pantropical	2.6	34–48	Slender	Long and slender	Narrow and falcate	Dips below dorsal fin	White to gray	Gape to flipper
S. frontalis	Tropical Atlantic	2.3	30–42	Moderate	Moderately long and slender	Tall and slightly falcate	Present, with spinal blaze	White with dark spots	Faint face to flipper
T. truncatus	Cosmo-politan	3.8	18–27	Robust	Moderate to short and stocky	Wide-based and slightly falcate	Usually faint	White	Faint face to flipper
T. aduncus	Coastal Indo-Pacific	2.7	23–29	Moderate	Moderately long and slender	Tall and slightly falcate	Present, with spinal blaze	White with dark spots	Face to flipper

10. Glossary of Technical Terms

albino—An individual with a specific genetic condition that causes the eyes and skin to be unpigmented.

allopatric—Complete geographic separation of species or geographic forms.

ambergris—A substance that forms in the gut of sperm whales, which is used for some products (e.g., in candles, cosmetics, and medications).

amphipod—A type of invertebrate crustacean that is a food source for some whales.

ancestral—A pre-existing character or condition. Also known as primitive.

anterior—Forward, in the direction of the snout tip, referring to the front (head area) of an animal.

antitropical—A distribution pattern in the higher latitude waters of both hemispheres, but absent along the equator.

antorbital—The area in front of the orbits of the skull, as in antorbital notches.

archaeocete—Extinct group of ancient whales.

archipelago—An oceanic group of islands of common origin.

artisanal hunting—Hunting conducted from shore-based operations using low-technology methods, and resulting in limited local distribution of products.

axilla—Armpit, or in the case of marine mammals, "flipper-pit." Plural = axillae.

balaenopterid—A term used by marine mammal biologists to refer to the any or all of the species of rorqual whales in the family Balaenopteridae.

baleen—Plates of keratin hanging from the inside of the upper jaw of mysticetes, used instead of teeth to capture prey. Also called "whalebone."

barnacle—A type of sessile (mooring) crustacean that is found living on the surface of some marine mammals.

beak—The elongated rostrum of some cetaceans.

benthic—Organisms living on or in the sea floor; demersal.

bicuspid—Teeth with two cone shaped prominences on the surface (cusps).

blackfish—Non-taxonomic grouping of predominantly dark small cetaceans, possessing blunt heads. Includes the killer, pilot, false killer, and melon-headed whales. Some people may include the Risso's dolphin as well.

blaze—A streak-like marking on the body of an animal.

blow—The spout of water vapor that results from the exhalation of whales.

blowhole(s)—Nasal opening(s) on the top of the head of cetaceans. They are paired in mysticetes, and single in odontocetes. Sometimes called the spiracle in older literature.

blubber—The specialized layer of fat just under the skin of most marine mammals, which serves several functions (e.g., insulation, thermoregulation, and streamlining).

boss—A raised protruberance on the skull.

bowriding—The act of riding on the pressure wave in front of the bow of a ship, commonly performed by dolphins and some porpoises. Also called bow-wave riding.

breach—A complete or nearly-complete leap from the water, resulting in a splash.

bubble-net—A circle of bubbles blown around a prey patch by humpback whales, to corral and aid in capture of the prey.

bycatch—The part of the catch consisting of non-target organisms.

bull—An adult male cetacean, pinniped, or sirenian.

calf—A young cetacean or sirenian.

callosities—Areas of roughened skin on the heads of right whales, to which whale lice and barnacles attach.

calving—The process of giving birth by cetaceans or sirenians.

canines—The set of long, sharp teeth on either side of the front of the upper and lower jaws (abbreviated C in dental formulas).

canted—Oriented forward or curved toward the head; the opposite of falcate.

cape—A darker region on the back of many species of dolphins and small whales, generally with a distinct margin. Also called the dorsal cape.

cephalopod—A group of marine molluscs, including the squids, cuttlefishes, and octopuses which form the prey of many species of marine mammals.

chevron—Light-colored, V-shaped marking on the back or side of an animal.

circumglobal—Ranging completely around the globe.

circumpolar—Ranging completely around either polar area (i.e., the Antarctic or Arctic).

circumtropical—Occurring around the tropical regions of the world; pantropical.

click—A pulsed vocalization produced by toothed whales, and used for echolocation.

continental shelf—The oceanic margin of the continents, characterized by a relatively flat bottom. Generally defined as the area out to approximately 200 m depth.

continental slope—The oceanic region of steep drop-off just beyond the continental shelf. Generally defined as the area of depths of approximately 200-2000 m.

convergence—A similarity between or among organisms that is not a result of having a common ancestor.

cookie-cutter shark—A type of small shark that takes bites out of marine mammals, often leaving a round scar (generally non-fatal).

copepod—A type of small crustacean fed on by some whales.

cosmopolitan—Having a broad, wide-ranging distribution over much of the earth.

countershading—Cryptic coloring with the upper surface dark and the lower surface light.

cow—An adult female cetacean, pinniped, or sirenian.

cranial hiatus—opening in the base of skull near the tympanoperiotic bones, in which cranial nerves VII-XI emerge.

cranium—The main part of the skull, exclusive of the lower jaw bones (mandibles).

crustacean—Member of a subphylum of mostly aquatic arthropods, which are food for many marine mammal species.

cub—A young bear.

deep scattering layer (DSL)—A dense aggregation of largely light-sensitive aquatic organisms (mostly fish and various invertebrate species) that migrates vertically in the water column each day (towards the surface in darkness and deeper in brightness).

demersal—Found on or near the bottom of the sea; benthic.

dental formula—A convenient way of designating the kind and number of mammalian teeth. Note that this does not apply to cetaceans, which have undifferentiated teeth.

denticles—Small bumps along the edges of the flippers and dorsal fins/ridges of some small cetaceans.

dentition—Teeth.

derived—A character is that is changed from the more primitive ancestral condition.

diatoms—Algae with glass-like walls. They are the basis of oceanic food webs, and also are found on the surfaces of some marine mammals.

diphyletic—Having two separate ancestors. Same as biphyletic.

distal—Closer to the outer part of the body, as opposed to proximal.

dorsal—Relating to the upper surface of an animal.

dorsal fin—The structure on the back of most cetaceans (not supported by bone). Some species only have a dorsal hump or ridge, others have no hint of a dorsal structure.

dorsal ridge—A low ridge of connective tissue along the upper surface of the back in some cetaceans, which replaces the dorsal fin.

dorsum—The dorsal or upper surface of an animal.

echolocation—The process of sending out sounds and using the returning echoes to locate objects; biological sonar.

ectoparasite—Parasite that lives on the external surface of an animal, such as barnacles.

epizootic—A disease that appears as new cases in a given animal population, during a given period, at a rate that substantially exceeds what is "expected" based on recent experience (the equivalent term for humans would be epidemic).

El Niño Southern Oscillation (ENSO)—A sporadic oceanographic event in the eastern Pacific Ocean in which prevailing currents change, resulting in changes in water temperature, upwelling, and precipitation patterns.

endemic—A species or group of species that is found only in a given area.

epipelagic—Associated with the surface layer of the oceans (< 200 m depth).

estrus—The period of sexual receptivity of a female mammal.

estuary—An area partly enclosed by land, where saltwater and freshwater meet.

euphausiids—Group of small crustaceans taken as prey by many marine mammals species. Also called krill.

extant—A group with all or some living members; as opposed to extinct.

extinct—A group that has no living representatives; as opposed to extant.

extirpate—To exterminate a species only from a specific part of its range.

extralimital—Outside the normal limits of an animal's distribution.

falcate—Sickle-shaped and curved toward the tail; recurved.

fast ice—Sea ice attached to land.

flipper—Flattened fore- or hindlimb of a marine mammal (supported by bone). The foreflipper is also called the pectoral fin.

flipper pockets—Shallow depressions on the body of beaked whales, into which the flippers sit, making them relatively flush against the body.

flukes—The horizontally flattened and blade-shaped tail of cetaceans or dugongs (not supported by bone); often called the tail flukes.

fluke notch—The indentation along the midline between the two fluke blades of most cetaceans.

fluke-slap—The act of slapping the flukes against the water's surface, creating a loud sound. Also sometimes called lobtailing.

fluke-up—To raise the tail flukes into the air upon diving.

foreflipper—The front flipper of a pinniped.

frontal bone—The major bone comprising the forehead.

fusiform—Torpedo-shaped, elongated with tapering ends.

gape—The corner of the mouth. Also, the widest opening of the mouth.

gestation—The period between fertilization and birth in mammals.

gillnet—A passive type of fishing net that uses a wall of net to ensnare or entangle the target animals.

guard hairs—The long, sparse outer layer of hairs of a pinniped or otter.

hallux—Digit #1 on the hindflipper of a pinniped (counting from the outside in).

haul-out—The act of bringing the body on to land, ice, or other substrate by a pinniped, otter, or very rarely, a sirenian. It is also used as a noun to describe the places where hauling-out occurs.

herd—A coordinated group of marine mammals (often used synonymously with school for dolphins, and pod for whales).

hindflipper—The rear flipper of a pinniped.

homodont—All teeth having the same basic structure; undifferentiated dentition (i.e., not divided into canines, incisors, premolars, molars, etc.).

hybrid—The offspring resulting from a cross between two species.

incidental catch—The part of the catch consisting of non-target organisms.

incisors—The front, cutting teeth between the canines (abbreviated I in dental formulas).

Indo-Pacific—The area of the Indian and western Pacific oceans.

inshore—Shallow waters inshore of the surf zone; most often used to refer to bays, channels, and other enclosed waters.

jug-handling—The posture used by most fur seals of lying at the surface with fore- and hindflippers curled into a loop.

junk—The modified melon of sperm whales.

keel—A deepening of the body, especially in the tail area of some cetaceans.

krill—A small shrimp-like crustacean that forms the major food of many baleen whales. Also called euphausiids.

lair—A shelter under snow and/or ice, with an opening to the water, used by some seals.

lanugo—The birth coat of fur of a pinniped (sometimes shed in the uterus).

lateral—Referring to the side of an animal; toward the periphery of the body.

leading edge—The anterior (forward-facing) edge of the appendage (dorsal fin, flippers, or flukes) of a marine mammal.

lek—A mating strategy in which males display to females on a particular ground or area.

longline—A type of fishing gear that uses baited hooks to catch the target species.

lunge feeding—A batch feeding method employed by some baleen whales, in which the animal lunges through swarms of small prey, taking in great mouthfuls of prey and water.

mandible—The lower jaw bone.

mane—A region of long fur around the neck of some male pinnipeds.

mass stranding—The simultaneous stranding of two or more animals (excluding mother and calf/pup) of the same species in the same area.

maxilla—One of the two major bones of the upper jaw, occurring on the distal side.

median notch—The cleave between the two fluke blades of most cetaceans.

median ridge—One or more raised ridges on the upper surface of the rostrum of some cetaceans.

melon—The fatty organ in the forehead of toothed whales believed to be used in echolocation.

mesonychid—Group of extinct ungulates were previously thought to be the ancestors of modern whales and dolphins.

mesopelagic—Associated with the middle layer of the oceans (200–1,000 m depth).

mesoplodont—A term used by marine mammal biologists to refer to the any or all of the species of beaked whales in the genus *Mesoplodon*.

migration—The large-scale, systematic movement of individuals from one location to another, usually on a seasonal basis.

molars—The grinding teeth at the back of the jaw (abbreviated M in dental formulas)

mollusk—A type of invertebrate, including clams, squids, and octopuses.

molt—The process of shedding the skin and fur, to be replaced by a new set.

monogamy—A social system in which individuals have only one mate per breeding season.

monophyletic—Having a single common ancestor.

monopecific—A taxonomic group that has only one species.

monotypic—A taxonomic group that has only one member.

morbillivirus—A serious pathogen that is contagious, and affects animals by suppressing their immune responses.

mottling—Patterns of spotting on the body; often (but not always) they take the form of enlongated spots.

muzzle—The projecting part of the head, including the mouth, nose, and jaws.

mysid—A shrimp-like invertebrate that is the food of some marine mammals.

mystacial area—The area around the vibrissae, or whiskers, in pinnipeds and otters.

nares (singular: naris)—The paired bony nasal openings of the skull.

nasal bones—The small bones around the nasal openings of the skull.

neonate—A newborn animal.

neritic—Referring to the shallow waters adjacent to shore; coastal or nearshore.

occipital condyles—The rounded areas on the occipital bone of the skull where the vertebral column attaches.

oceanic—The ocean region past the edge of the continental shelf (generally deeper than 200 m); the open sea.

osteology—The study of bones.

pachyostotic—A condition in which the bone is particularly dense and heavy.

pack ice—Sea ice that is not attached to land.

pagophilic—"Ice-loving," referring to species that inhabit ice.

palate—The roof of the mouth.

panarctic—Occurring around the entire Arctic region.

pantropical—Occurring globally around the tropics; circumtropical.

parasite—An organism that obtains a benefit from another organism while causing it harm.

parturition—The act of giving birth.

pectoral fin—Flattened forelimb of a cetacean or sirenian (supported by bone). Also often called the flipper.

peduncle (caudal)—The laterally compressed region between the dorsal fin and tail flukes of cetaceans and dugongs; a narrow tail stock.

pelage—Fur.

pelagic—Inhabiting the water column of the oceans past the inter-tidal zone.

perinatal—The period immediately following birth.

pinnae (ear) (singular: pinna)—The external ear flaps. They are reduced or absent in many species of marine mammals.

photo-identification—The method of study of marine mammals using photographs to identify individuals.

plankton—Small, passive drifting or weak-swimming organisms that occur in swarms.

pod—A social unit of cetaceans; generally a coordinated group of whales.

polar—Relating to the regions near the poles.

polygyny—A social system in which males have more than one mate per breeding season. This is the most common mating system of marine mammals.

population—A biological population is a group of interbreeding individuals of the same species, isolated from other such groups.

porpoising—The act of leaping out of the water while moving forward at speed.

post-anal hump/keel—A protuberance of connective tissue just behind the anus of some cetaceans.

post-canines—The set of all undifferentiated teeth behind the canines in pinnipeds (abbreviated PC in dental formulas).

posterior—Referring to the rear (tail area) part of an animal.

premaxilla—One of the two major bones of the upper jaw, occurring on the medial side.

premolars—The set of bicuspid teeth in front of the molars (abbreviated PM in dental formulas).

proboscis—A dangling enlargement of the nose.

promiscuity—A mating system in which males randomly associate with females for variable periods of time, and no long-term pair bonds are formed.

proximal—Closer to the center of the body, as opposed to distal.

pterapods—A group of invertebrates taken as prey by some marine mammals.

pup—A young pinniped or otter.

pupping—The process of giving birth by pinnipeds or otters.

purse seine—A type of fishing gear that uses a net to encircle schools of the target species; then the bottom is closed by drawing a cable, thereby effectively capturing the targets without entangling them.

rafting—The act of several individuals lying together at the surface.

rhinarium—The wet, naked surface around the nostrils of the nose in terrestrial and some marine mammals (e.g., pinnipeds, otters, and bears).

rookery—A terrestrial breeding area for pinnipeds; breeding colony.

rorqual—Whale of the family Balaenopteridae, which includes the blue, fine, sei, Bryde's, minke, and humpback whales.

rostral ridges—One or more ridges along the upper surface of the upper jaw in some baleen whales. Most species have just a single median ridge, but Bryde's whales have three.

rostrum—Beak or snout. Also refers to the upper jaw of the skull.

saddle—A light patch behind the dorsal fin of some cetaceans; often called saddle patch.

sagittal crest—A bony crest on the top of the skull in some pinnipeds, often resulting in an external bump on the forehead.

school—A coordinated group of cetaceans (often used synonymously with herd for dolphins), generally with long-term associations.

sexual dimorphism—A difference in the appearance of the sexes, generally with males larger than females, often accompanied by differences in body shape.

snoutriding—The act of riding on the pressure wave in front of the head of a whale, commonly performed by dolphins and some porpoises. Apparently analogous to bowriding.

sonar—The system of echolocation used by toothed whales; also a man-made echo-ranging system generally used in military applications.

spatulate—Spade-shaped. Often used to describe the teeth of porpoises.

species—A unique type of plant or animal, which is on a separate evolutionary pathway from other such units, and with negligible amount of gene flow between them. The species is the primary unit of biological evolution.

spermaceti—The oil found in the spermaceti organ of sperm whales.

sperm competition—A component of some polygynous mating systems in which males do not compete overtly, but rather multiple males mate with a female and the competition to inseminate her is undertaken by sperm.

spinal blaze—A light streaking of color invading the cape below the dorsal fin of some dolphins.

splashguard—Elevated area immediately in front of the blowholes of baleen whales.

spy-hop—The act of bringing the head vertically out of the water, performed by whales and dolphins.

standard length—The length of the body between the tip of the snout and the ends of the hindflippers for pinnipeds.

sternum—The breastbone.

stock—A biological population, generally defined for management purposes.

stranding—The act of coming on to land, either alive or dead, intentional or accidental, of cetaceans or sirenians.

subspecies—Geographical forms of a species that appear to be on separate evolutionary pathways from other such units, but with still some significant amounts of gene flow between them. The subspecies is the smallest unit used in formal taxonomy.

subtropical—Inhabiting the intermediate zone between the tropics and the temperate zones.

supraorbital processes—Small bony protruberances above the orbits on the skull.

sympatric—Having at least partially overlapping ranges of species or geographic forms.

symphysis (mandibular)—The articulation (or contact) of the two lower jaw bones of cetaceans.

systematics—The science of the evolutionary relationships of organisms.

tail stock—The region just ahead of the tail, connecting it to the rest of the body. Also called the peduncle, or caudal peduncle.

taxonomy—The science of classification of organisms using different groupings. From highest to lowest level of organization the groupings of interest to this guide (with examples for the bottlenose dolphin) are: Class (Mammalia), Order (Cetacea), Suborder (Odontoceti), Family (Delphinidae), Genus (*Tursiops*), and Species (*Tursiops truncatus*).

telescoping—The sliding, over the course of evolutionary history, of the cetacean skull bones to form their current configuration (different in mysticetes vs. odontocetes).

temperate—Inhabiting the mid-latitudes characterized by a mild, seasonally changing climate. The temperate zones are between 23°27'N and the Arctic Circle, and between 23°27'S and the Antarctic Circle.

territory—An area occupied exclusively by a single animal (or sometime a small group), and defended aggressively against others.

thorax—The front or top region of the body, behind the head.

throat grooves/creases/furrows—Grooves on the throat, characteristic of some groups of whales. In beaked whales, they are short and there is generally a single pair. In rorquals, they are long (extending to or past the navel) and there may be several hundred.

total length—The length of the body between the tip of the jaw and the notch in the tail flukes (for cetaceans), or the end of tail (for carnivores and sirenians).

trailing edge—The posterior (rearward-facing) edge of the appendage (dorsal fin, flippers, or flukes) of a marine mammal. The trailing edges of the dorsal fin and flukes of cetaceans are usually very thin and easily tattered.

trawl—An active type of fishing gear that is pulled through the water, and the target species are scooped up by the forward open end of the net, and funneled back to a closed end (cod end), where they are effectively captured.

tributary—A river or stream that flows into a larger river or stream.

tricuspid—Teeth with three cone shaped prominences on the surface (cusps).

tropical—Inhabiting the low latitudes between 23°27'N (Tropic of Cancer) and 23°27'S (Tropic of Capricorn), which are characterized by a warm, seasonally stable climate.

tubercles—Knob-like bumps on the bodies of some species of cetaceans.

tusks—Enlarged teeth (usually incisors or canines in species with differentiated teeth) that typically protrude outside the closed mouth. In walruses, they are massively-enlarged canines that extend downward outside the closed mouth in adults of both sexes. In some beaked whales, they are a single pair of protruding teeth, found only in adult males. In narwhals, there is generally a single, forward-spiraling tusk in subadult and adult males (rarely also in females). In dugongs, they are enlarged incisors that erupt after puberty; they are not visible outside the closed mouth.

tympanic bullae—One of the two major inner ear bones of mammals.

typanoperiotic bones—The ear bones, consisting of the tympanic bullae and periotic bones.

ultrasonic—Sounds above the human hearing range.

underfur—The short, numerous hairs underlying the guard hairs of pinnipeds and otters.

underslung—The condition of being shorter than the corresponding upper part.

upwelling—The transport of nutrient-rich waters to the surface off continental margins, caused by circulation and wind patterns.

urogential area—The region around the anal and genital slits in cetaceans.

vagrant—A wandering animal, outside the normal range.

vasoconstriction—The constriction of the blood vessels, causing a shunting of blood preferentially to other vessels.

vasocodilation—The dilation (opening-up) of the blood vessels, causing a shunting of blood preferentially from other vessels.

ventral—Relating to the lower surface of an animal.

ventral pleats—The long pleats extending from the tip of the jaw to as far back as the navel in balaenopterid whales. Also sometimes called throat grooves.

ventrum—The ventral or lower surface of an animal.

vertebrae—The bones of the vertebral column, consisting of five sections (cervical, thoracic, lumbar, sacral, and caudal). Some marine mammals do not have true sacral vertebrae.

vertex—The dorsal portion of the skull immediately behind the bony nares, strongly elevated in some species of odontocetes.

vestigial—Existing as a trace of something that is in the process of being evolutionarily lost.

vibrissae—Whiskers.

vocalization—A sound produced by animal through its vocal apparatus.

whalebone—A term for baleen, which is not often used anymore.

whale lice—Amphipod crustaceans (cyamids) found on the external surface of some whales.

zooplankton—Animal forms of plankton.

zygomatic arch—The bony arch of the cheekbone in marine mammals, generally composed of the jugal bone.

SEA TURTLE HANDLING AND RESUSCITATION REQUIREMENTS

IF YOU ENCOUNTER AN ENTANGLED, INJURED OR UNRESPONSIVE SEA TURTLE,
please immediately call the National Marine Fisheries Service Northeast Region Hotline:

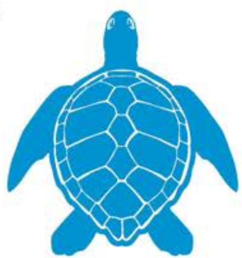
866-755-NOAA (6622)

Any sea turtle taken incidentally during fishing must be handled with care to prevent injury, observed for activity, and returned to the water according to the following procedures:

A A SEA TURTLE THAT IS ACTIVELY MOVING OR IS DEAD (THAT IS, IF MUSCLES ARE STIFF AND/OR THE FLESH HAS BEGUN TO ROT) MUST BE RELEASED OVER THE VESSEL'S STERN ONLY:

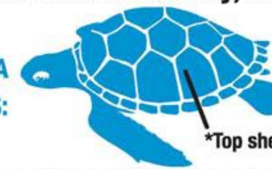
- When fishing gear is not in use,
- When the engine is in neutral, and
- In areas where the turtle is unlikely to be recaptured or injured by vessels.

OTHERWISE, YOU MUST CONSIDER THE TURTLE UNRESPONSIVE AND ATTEMPT RESUSCITATION AS DESCRIBED IN B.



You are strongly encouraged to read the full regulation, which can be found at 50 CFR 223.206(d)(1).

B YOU MUST ATTEMPT RESUSCITATION ON SEA TURTLES THAT ARE UNRESPONSIVE AS FOLLOWS:



1 Place the turtle top shell up* and elevate its hindquarters at least 6" (or 15-30°) for at least 4 hours and up to 24 hours.

- The amount of elevation depends on the turtle's size; larger turtles require greater elevation.
- In warm weather (over 60 °F), keep the turtle shaded and moist, preferably by placing a damp towel over the head, shell, and flippers. You must NOT place the turtle into a container of water.

2 Periodically rock the turtle gently side to side by holding the outer edge of the shell and lifting one side about 3", then alternate to the other side.

3 Periodically gently touch the eye and pinch the tail (reflex tests) to see if there is a response.

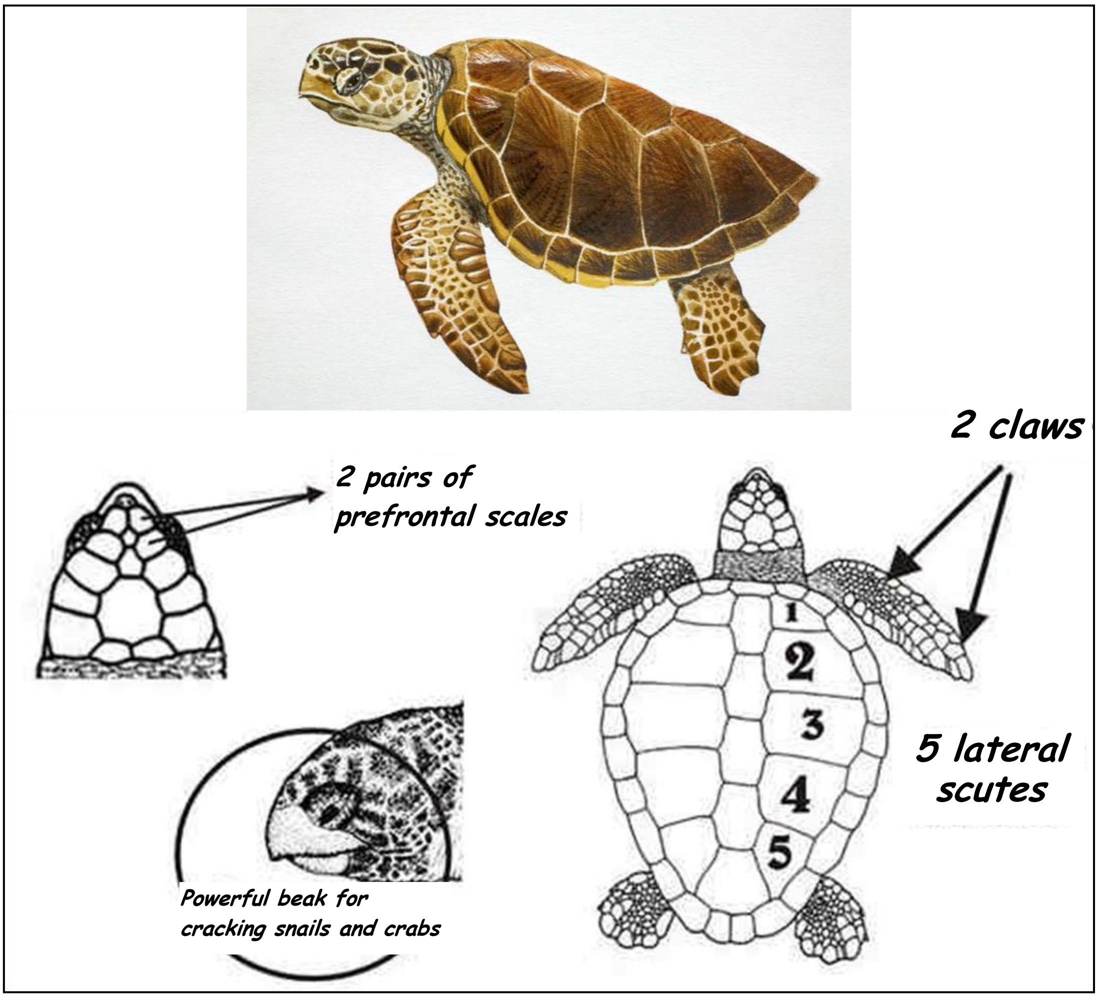
C IF THE TURTLE REVIVES AND BECOMES ACTIVE DURING RESUSCITATION EFFORTS, you must release it over the vessel's stern as described in A. If the turtle does not respond to the reflex test (as described in B 3) or move within 4 hours (up to 24 hours, if possible), you must return the turtle to the water in the same manner.

LOGGERHEAD (Caretta caretta)

Description

In adults, the carapace, viewed from above, is heart-shaped, lightly serrated on the posterior margin on juvenile individuals (Pritchard & Mortimer, 1999). It has a large head with two pairs of prefrontal scales and one interfrontal. The carapace is composed of five pairs of lateral scutes, five vertebral scutes and 25 to 27 marginal scutes. The relatively short front flippers have two claws on the leading edge. The carapace, head and members are brown in color; the plastron is yellowish in color. It weighs up to 180 kg; the head measures as much as 28 cm wide and the carapace as much as 105 cm long (Figure 10) (Pritchard & Mortimer, 1999).

Loggerhead (Caretta caretta)



Distribution and migration

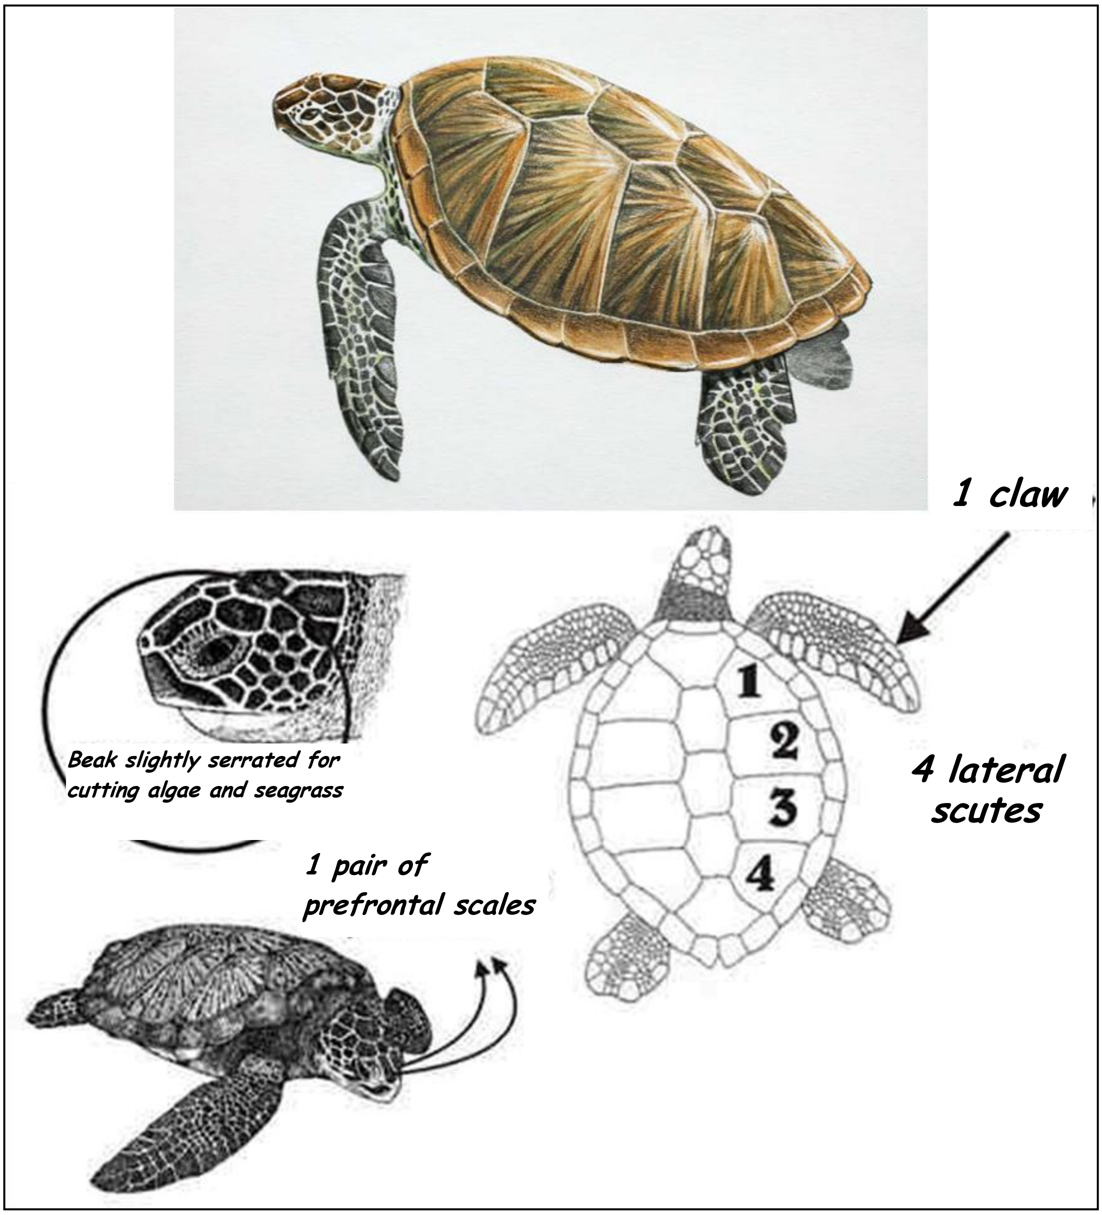
It is widely distributed in tropical and subtropical coastal waters between 15º and 20º C. It generally inhabits the coastal areas of warm and temperate seas, from the United States to Argentina, including the Gulf of Mexico and the Caribbean. The migratory routes are not clearly delineated, but they appear to follow the currents.

GREEN TURTLE (*Chelonia mydas*)

Description

Oval-shaped carapace, margin sometimes scalloped by not serrated (Pritchard & Mortimer, 1999). It has four pairs of lateral scutes, five vertebral scutes and 25 small marginal scutes. The head is relatively small, with a pair of prefrontal scales. The beak is slightly serrated. It has one claw visible on each flipper. The carapace on juveniles is a brilliant reddish-brown color; dark gray head and flippers, but centrally, like the plastron, they are light yellow. The may weigh up to 230 kg, the head measures 15 cm wide, and the carapace is up to 125 cm long (Figure 11) (Pritchard *et al.,* 1984; Pritchard & Mortimer, 1999).

Green turtle (Chelonia mydas)

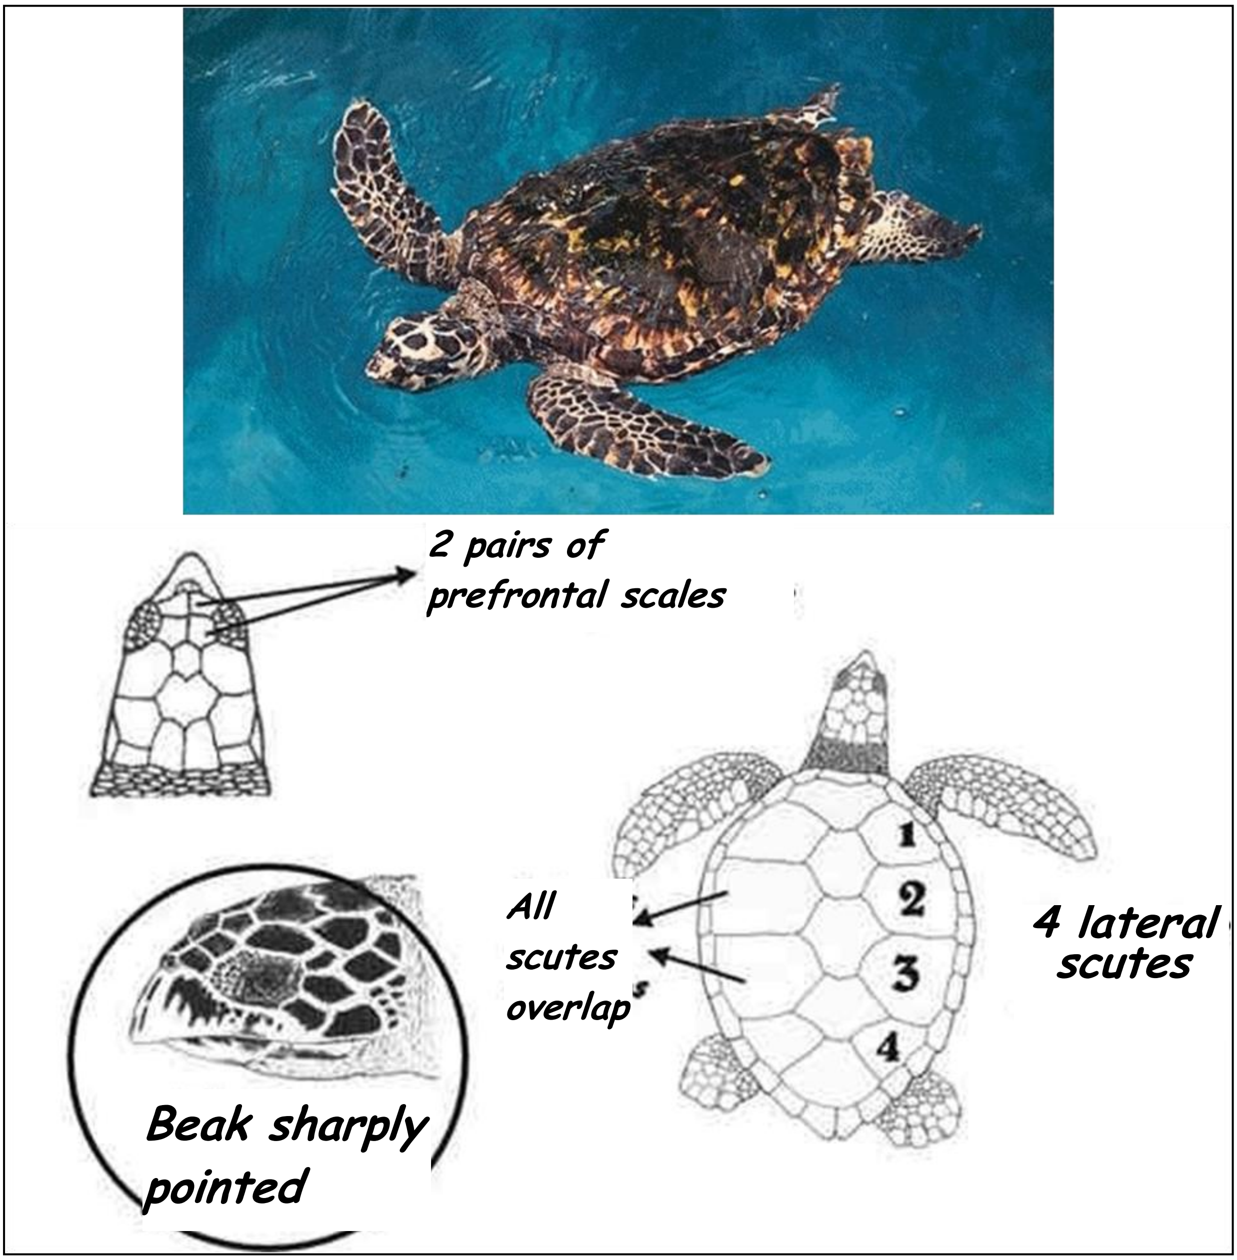


HAWKSBILL (Eretmochelys imbricata)

Description

Its carapace is oval, with a strongly serrated posterior margin; it is the only sea turtle that has overlapping (imbricate) scutes (Pritchard & Mortimer, 1999). It has four lateral scutes, five vertebral and 30 marginal. It has four prefrontal scales on its head and two claws on each flipper. It is dark brown in color with patches of reddish, orangish and yellowish coloring. The plastron is yellow. They weigh up to 80 kg, the head is up to 12 m wide and the carapace up to 90 cm long (Figure 12) (Pritchard *et al.,* 1984; Pritchard & Mortimer, 1999).

Hawksbill (Eretmochelys imbricata)

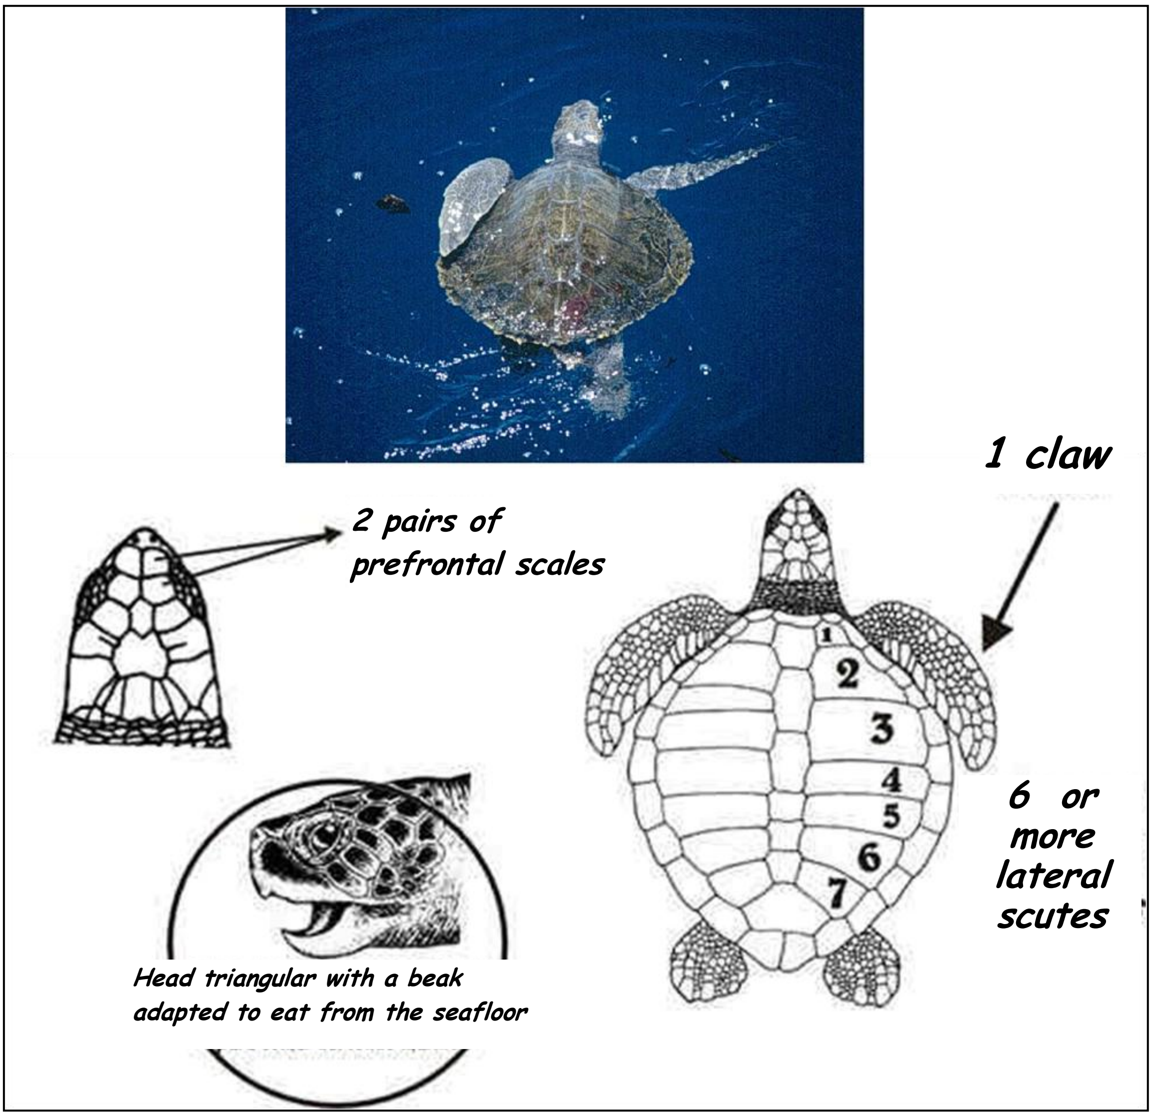


OLIVE RIDLEY (Lepidochelys olivacea)

Description

Its head is triangular. The carapace is wide, with 5 to 9 pairs of lateral scutes, 5 to 9 vertebral scutes and 12 to 14 pairs of marginal scutes. The dorsum is olive green to brown or gray-black, while the underside is light yellow (Pritchard & Mortimer, 1999). They weight up to 45 kg; the head measures up to 13 cm wide and the carapace up 70 cm long (Figure 14) (Pritchard *et al.,* 1984; Pritchard & Mortimer, 1999).

Olive ridley (Lepidochelys olivacea)

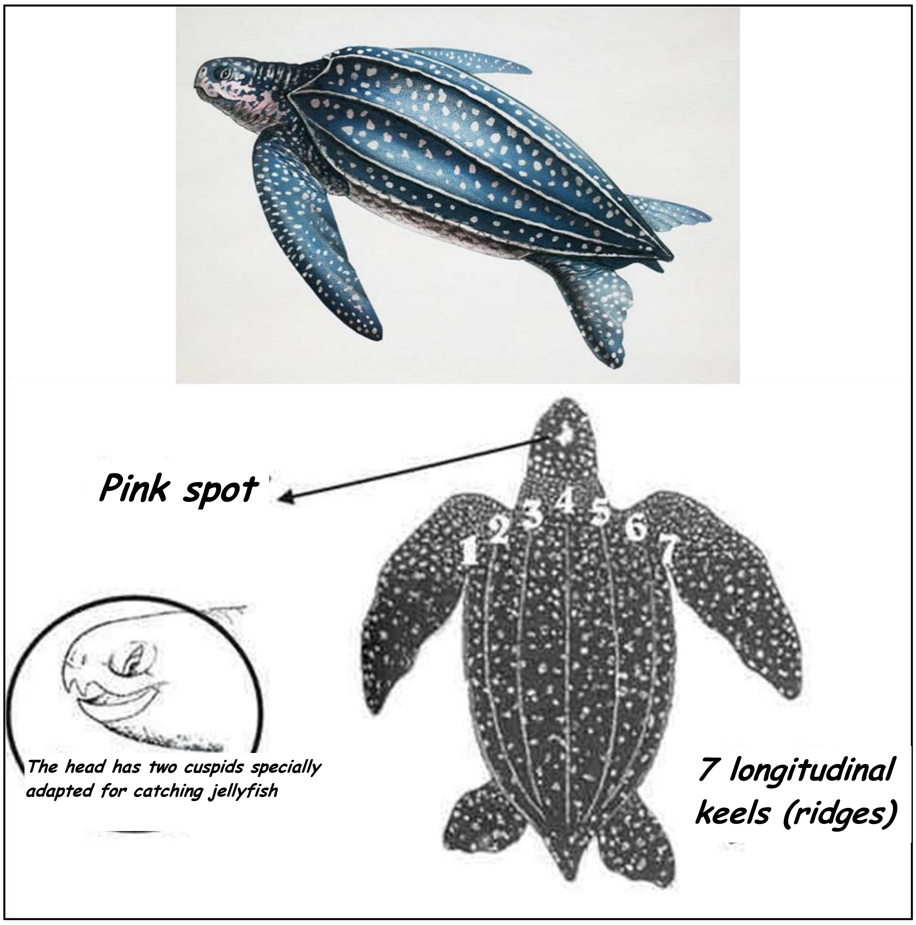


LEATHERBACK (Dermochelys coriacea)

Description

Scales, scutes and claws absent. The carapace is reduced in sized and formed by small bones. The surface of the carapace has the consistency of leather, several centimeters thick. It has seven prominent longitudinal keels (ridges) on the dorsum (Pritchard & Mortimer, 1999), which is black, with round white spots, while the plastron is predominately white. Front fins are paddle-shaped and well developed. They have a pinkish spot on the back of the head. They weigh up to 600 kg, the head measures up to 25 cm wide and the carapace up to 180 cm long (Figure 15) (Pritchard *et al.,* 1984; Pritchard & Mortimer, 1999).

Leatherback (Dermochelys coriácea)

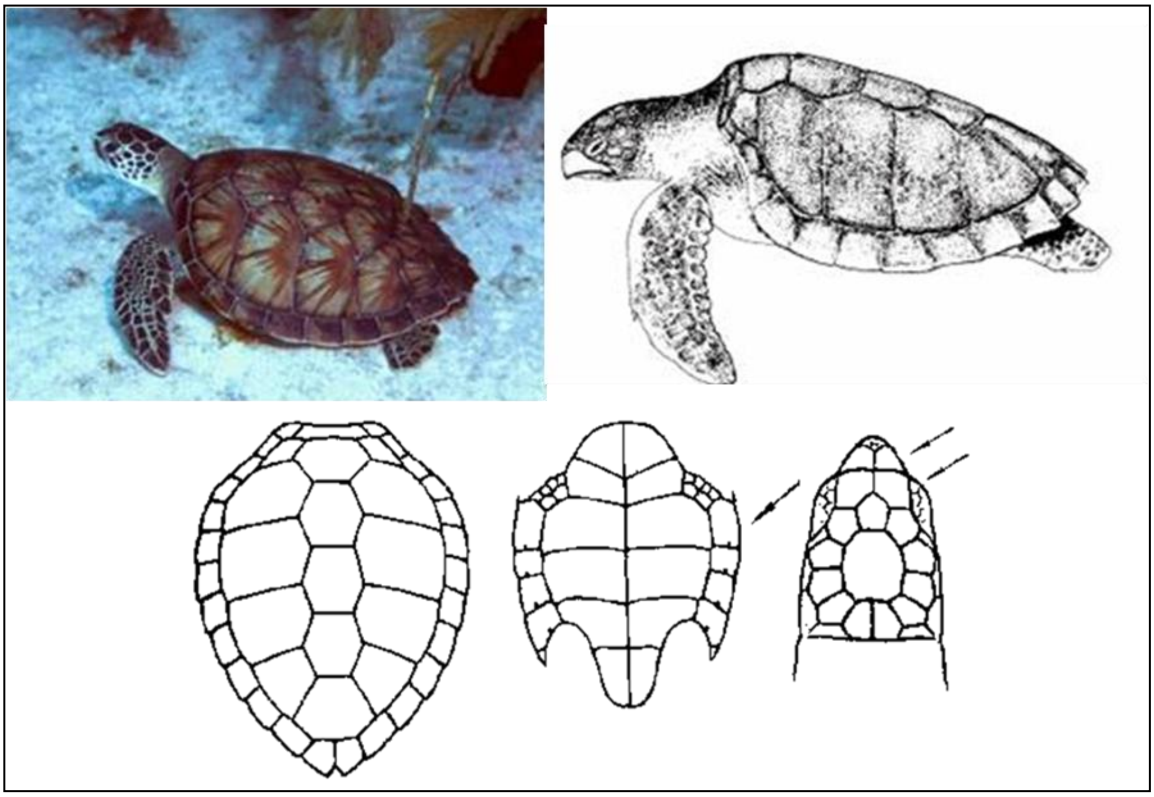


KEMP'S RIDLEY (Lepidochelys kempii)

Description

The carapace of this turtle measures up to 72 cm, a little wider than that of the olive ridley. The margin is slightly serrated. The head is relatively large and slightly triangular, measuring up to 13 cm wide. It has two claws on each flipper as a juvenile, while adults have only one. Juveniles are gray in color with a white plastron, adults light olive green with a yellow plastron. Typically weighs 35 to 50 kg (Figure 17) (Pritchard & Mortimer, 1999).

Kemp's ridley (Lepidochelys kempii)



Distribution and migration

It is found in the Gulf of Mexico, the eastern part of the United States, and sometimes in western Europe (Pritchard & Mortimer, 1999).

Species Descriptions

Common Name	Spanish Name	Scientific Name

Leatherback — **Baula, Tortuga Laúd, Tora** — ***Dermochelys coriacea***

Color	dark gray/black with white spots	**Carapace**	tapered; leathery with 5 ridges
Max Length	165 - 180 cm	**Plastron**	relatively small
Max Weight	400 - 500 kg	**Head**	tooth-like notch on either side of upper jaw; no scales

Range all oceans, subarctic to tropical; pelagic

Green Turtle — **Tortuga Verde, Tortuga Blanca** — ***Chelonia mydas***

Color	J: radiating streaks; A: brown, buff	**Carapace**	4 costal scutes
Max Length	120 cm	**Plastron**	yellowish; 4 inframarginal scutes
Max Weight	230 kg	**Head**	round face; serrated jaw; 1 pair elongate prefontal scales

Range all subtropical and tropical seas; bays and coastal waters

Black Turtle* — **Tortuga Negra, Prieta** — ***Chelonia* mydas**

Color	black or grayish with black markings	**Carapace**	4 costal scutes
Max Length	90 cm	**Plastron**	cream to gray; 4 inframarginal scutes
Max Weight	150 kg	**Head**	round face; serrated jaw; 1 pair elongate prefontal scales

Range East Pacific Ocean; bays and coastal waters

*The status of the Black turtle or east Pacific green turtle, sometime referred to as *Chelonia agassizii* or *C. mydas agassizii*, remains uncertain. Recent genetic evidence supports an Atlantic-Mediterranean vs. Indian-Pacific grouping, while morphological and behavioral data suggest an east Pacific species or subspecies.

Flatback Turtle — **Kikila, Tortuga Franca Oriental** — ***Natator depressus***

Color	olive grey	**Carapace**	4 costal scutes; broad and round; upturned margins
Max Length	100 cm	**Plastron**	yellowish; 4 inframarginal scutes
Max Weight	90 kg	**Head**	preoccular scale; wide; flat; triangular

Range tropical coastal Australia

Hawksbill Turtle — **Tortuga Carey** — ***Eretmochelys imbricata***

Color	amber and brown streaks	**Carapace**	4 costal scutes; (usually) overlapping scutes; oval
Max Length	90 cm	**Plastron**	cream with dark blotches front and rear; 4 inframarginal scutes
Max Weight	80 kg	**Head**	curved beak; distinct overbite; 2 pair prefrontal scales

Range all oceans; tropical waters; reef areas

Loggerhead — **Caguama, Amarilla, Cabezona, Tortuga Boba** — ***Caretta caretta***

Color	red brown to brown	**Carapace**	longer than wide; 5 or more costal scutes, first very small
Max Length	90 - 110 cm	**Plastron**	yellow to orange, 3 inframarginal scutes
Max Weight	100 - 180 kg	**Head**	large head; 4 or more prefontal scales

Range all oceans; primarily temperate waters; near shore, often associate with structures (i.e., wrecks, platforms)

Kemp's Ridley — **Tortuga Lora, Cotorra** — ***Lepidochelys kempii***

Color	gray to light olive green	**Carapace**	round; 5 (sometimes 6) costal scutes
Max Length	70 cm	**Plastron**	white to yellow; 4 inframarginal scutes with pores
Max Weight	40 - 50 kg	**Head**	triangular; relatively large; 2 pair prefrontal scales

Range Gulf of Mexico, eastern USA; coastal; < 16° N

Olive Ridley — **Tortuga Golfina, Tortuga Olivacea, Parlama** — ***Lepidochelys olivacea***

Color	gray to olive green	**Carapace**	nearly round; 6 - 9 costal scutes, number may be asymmetrical
Max Length	70 - 80 cm	**Plastron**	cream/white; 4 inframarginal scutes with pores
Max Weight	45 - 60 kg	**Head**	triangular; relatively large; 2 pair prefrontal scales

Range tropical waters of Pacific, Indian and South Atlantic Oceans; pelagic

Morovision Night Vision proudly offers the PVS-7 Delta Generation 3 PINNACLE® Delta Kit. The PVS-7 goggle is standard issue goggle type supplied to the U.S. Military and its allies. Equipped with a factory new, high-performance, ITT Generation 3 PINNACLE® image intensifier tube, the PVS-7 PINNACLE® night vision goggle is designed for the most demanding of night time applications. Battle-proven technology includes Automatic Brightness Control which automatically adjusts the brightness of the image tube to achieve the highest quality image resolution under varying light conditions as well as protect the user and the system against inadvertent exposure to excessive light. In addition, a built-in infra-red illuminator with momentary or continuous switching function allows the user to operate under zero light

DESCRIPTION

The Miniature Thermal Acquisition Clip-On System (TACS-M) provides the soldier with ultimate performance in technology. Low power consumption, optimal sensor technology, and high-performance optics all seamlessly integrate to provide state of the art long wave infrared (LWIR) technology.

When added to a standard image intensified system, TACS-M provides a second channel with LWIR capability, extending engagement capabilities through obscurants. The TACS-M unit along with Nivisys experience and expertise provides the best value solution for adding low light and no light performance to currently fielded night vision systems.

The unit's waterproof and rugged construction stands up to the harshest environments and features a red display for visual security. This multi-purpose surveillance tool uses the latest in miniature thermal sensor technology and a high resolution display to provide superior imagery in the smallest package available.

For more information on the TACS-M or other Nivisys products call (480) 970-3222 or visit us on the web at www.nivisys.com.
