

Ultramid® (PA)

Product Brochure

 **BASF**

We create chemistry

Ultramid® (PA)

BASF's Ultramid® grades are molding compounds on the basis of PA6, PA66 and various co-polyamides such as PA66/6. The range also includes PA610 and semi-aromatic polyamides such as PA6T/6. The molding compounds are available unreinforced, reinforced with glass fibers or minerals and also reinforced with long-glass fibers for special applications. Ultramid® is noted for its high mechanical strength, stiffness and thermal stability. In addition, Ultramid® offers good toughness at low temperatures, favorable sliding friction behavior and can be processed without any problems. Thanks to its excellent properties, this material has become indispensable in almost all sectors of engineering for a wide range of different components and machine elements, as a high-grade electrical insulation material and for many special applications.

Ultramid® in automotive applications

Automotive engineering demands very high quality and safety standards; this is also reflected in the continually increasing demands on the materials used. Ultramid® products possess very good thermal and chemical stability, static and dynamic strength, impact resistance and good long-term performance. These technical properties make them particularly suitable for use in a wide range of automobile components.

The development of Ultramid® products keeps pace with new drive concepts, advances in electrification and trends such as autonomous driving, making it possible to create new components.

Ultramid® products also help to satisfy other requirements for lightweight construction and recyclability.

The comprehensive Ultramid® product range allows customers to select the most appropriate products, enabling them to manufacture components and assemblies economically and competitively.

Typical applications of Ultramid® in motor vehicle construction are:

Engine and transmission: intake manifolds and charge air distributors, caps and pipes, cylinder head covers, engine covers, oil sumps, oil filter housings, oil sensors, oil modules, chain guide rails, drive belt covers, transmission controls, sensors, roller bearing cages, gear wheels, mounting clips

Cooling system: radiator caps, thermostat housings, cooling water pipes, fan wheels, fan shrouds

Fuel system: fuel filter housings, fuel lines, carbon canisters, quick connectors

Chassis and engine mounting: engine mounts, torque arms, coupling rods, transmission cross beams, strut bearings, spring washers

Interior: pedals and pedal brackets, levers and control elements, door handles, seat structures

Exterior: structural components, exterior door handles, mirror base plates, wheel trims, front ends, impact absorbers, door and tailgate locking systems

Electrical systems: plugs, sensors, control units, fuse boxes, switches, relays, generator/electric motor components, actuators, contact and brush holders, bulb sockets, cable ties, clips and conduits, fuel cell components

Gearbox control unit

High-voltage connector

Air and oil suction
module

Heat shield

Ultramid® in the electrical and electronics sector

The good electrical insulation properties, attractive sliding friction behavior, outstanding mechanical strength and a wide range of flame-retardant grades make Ultramid® a material that is used in virtually all areas of industrial power engineering, electronics and domestic appliance technology.

Power technology

High-insulation switch parts and housings, series- and connecting terminals, power distribution systems, cable ducts and fastenings, contactors and power switches, coils, circuit breakers, programmable logic controllers

Electronics

Plug-in connectors, electrical and mechanical components for IT equipment and telecommunications, capacitor cans, chip carriers

Domestic appliances

Components for domestic appliances such as switches, magnetic valves, plug-in devices, program control equipment, housings for electric power tools; electrical equipment and housing parts for large domestic appliances such as washing machines and dishwashers and smaller appliances such as coffee machines, electric kettles and hair dryers

Photovoltaics

Connection boxes and plug-in connectors

Circuit breaker

Photovoltaic connector

Terminal strip

Power electronics

Switch gear

Ultramid® for industrial products and consumer goods

High mechanical strength combined with good toughness and, in particular, the possibility for customization of products make Ultramid® suitable for a wide variety of applications in consumer goods and industrial products.

These are mainly applications demanding high mechanical properties in order to replace traditional materials such as metals by plastics with tailor-made properties. Ultramid® products also benefit from good chemical stability and easy colorability. Additionally, special Ultramid® products are used in applications in which regulatory requirements for drinking water and food contact are necessary.

The varied and in some cases tailor-made properties result in broad application fields such as:

Structural and installation engineering

Wall and facade dowels, fixing elements for facades and in solar technologies, thermal insulation profiles for windows

Sanitary services

Handles, brackets, fixtures, fans, flow water heaters, fittings, water meter housings

Household

Seating, chair castors and bases, furniture fittings, power tools, domestic appliances, sport and leisure equipment

General mechanical and apparatus engineering

Ball bearing cages, gears and gear wheels, seals, flanges, connectors, screws, sliding components

Materials handling

Rollers, pulleys, bearing bushes, transport containers, conveyor belts, conveyor chains

Design chairs

Multi-Wing

Frames for office chairs

Dowels

Ax handle

Cooking set

Ski binding

Ultramid® product range

Product range

Ultramid® is the trade name for the polyamides supplied by BASF for injection molding and extrusion. The product range includes PA66 grades (Ultramid® A), PA6 grades (Ultramid® B), semi-aromatic polyamides (Ultramid® T, Ultramid® Advanced N, T1000, T2000), specialty polyamides (Ultramid® D), PA610 (Ultramid® S Balance) and special grades based on special copolyamides. Ultramid® A is produced by condensation polymerization of hexamethylene diamine and adipic acid, Ultramid® B by hydrolytic polymerization of caprolactam. These materials are obtained from petrochemical feedstocks such as benzene, cyclohexane and p-xylene.

Many products are reinforced with glass fibers or other fillers and contain special additives to improve toughness, flame-retardant properties or resistance to environmental influences in order to allow a wide range of different properties.

Ultramid® Advanced and Ultramid® S Balance also have other advantages, such as higher dimensional stability or chemical stability.

The most important characteristics of Ultramid® are:

- High strength and rigidity
- Very good impact strength
- Good elastic properties
- Outstanding resistance to chemicals
- Dimensional stability
- Low tendency to creep
- Exceptional sliding friction properties
- Simple processing

The basis of the Ultramid® grades are polyamides which are supplied in a variety of molecular weights or viscosities, have a range of additives and are reinforced with glass fibers or minerals. More detailed information on the individual products can be found in the Ultramid® product range and the tables 1, 2 and 3.

The Ultramid® range comprises the following groups of products:

Ultramid® A

in its unreinforced state, is an extremely rigid, abrasion-resistant, heat resistant and hard material. It is one of the preferred materials for parts subject to mechanical and thermal stresses in electrical, mechanical and automotive engineering.

Ultramid® B

in its unreinforced state, is a tough, hard material affording parts with good damping characteristics and high shock resistance even in dry state and at low temperatures. It is particularly tough and easy to process. Translucent products are also available under the name Ultramid® Vision.

CEE connector

Ultramid® C

is the name given to copolyamides made from PA6 or PA66 elements that exhibit different melting points or a lower crystallinity according to their composition.

Ultramid® D

are blends of PA6 or PA66 and other polyamides with customized properties, available as unreinforced grades (e.g. Ultramid® Deep Gloss D3K) and reinforced grades (e.g. Ultramid® Endure D3G10 BK20560).

Ultramid® S Balance

is particularly resistant to chemicals and is also known for its low moisture absorption. Ultramid® S Balance is preferably used in components that come into contact with media.

Ultramid® Structure LFX

is a long glass fiber-reinforced polyamide providing a high degree of stiffness at high temperatures. It shows significantly lower creep, particularly at higher temperatures, very good fatigue strength and significantly improved notched impact strength, especially at low temperatures down to -30 °C. Further information can be found in the Ultramid® Structure LFX brochure.

Ultramid® T

has a semi-aromatic structure and is a highly rigid material with a high melting point, known for its dimensional stability, high chemical resistance and constant mechanical properties covering a wide range of different applications.

Ultramid® Advanced T1000

has a very high, constant stiffness and strength over a temperature range of -40 °C to over 80 °C. It is resistant to high temperatures and against aggressive media.

Ultramid® Advanced T2000

is a polyphthalamide providing good E&E performance with a high melting point, low water absorption, good mechanical properties at high temperatures and good chemical resistance.

Ultramid® Advanced N

is characterized by very low water absorption, excellent chemical resistance and good mechanical properties at high temperatures in conditioned state.

Glass-fiber reinforced Ultramid®

These materials are distinguished by high mechanical strength, hardness, rigidity, thermostability and resistance to hot lubricants and hot water. Parts made from them show dimensional stability and high creep strength. Glass fiber-reinforced Ultramid® T also has extraordinarily high heat distortion temperature (up to 280 °C).

Reinforced and unreinforced grades with flame retardants

The specially modified grades Ultramid® C3U, A3X2G5, A3X2G7, A3X2G10, B3U50G6, A3U42G6, B3UG4, B3U30G6 and T KR 4365 G5 are particularly suitable for electrotechnical components with higher fire protection requirements and high tracking resistance.

Mineral- and glass bead-filled Ultramid®

Materials filled with minerals and glass beads show increased rigidity, good dimensional stability, low tendency to warp, optically appealing surfaces, partly excellent ability for metallizing and good flow characteristics.

Ultramid®	Polyamide	Chemical structure	Melting point [°C]
Ultramid® A	66	basis hexamethylene diamine, adipic acid	260
Ultramid® B	6	polycaprolactam – NH(CH ₂) ₅ CO	220
Ultramid® C	66/6	basis hexamethylene diamine, adipic acid, caprolactam	242
Ultramid® S Balance	610	basis hexamethylene diamine, sebacic acid	222
Ultramid® T	6T/6	copolymer of caprolactam hexamethylene diamine and terephthalic acid	295
Ultramid® Advanced N	9T	basis nonane diamine, terephthalic acid	300
Ultramid® Advanced T1000	6T/6I	basis hexamethylene diamine, terephthalic acid, isophthalic acid	325
Ultramid® Advanced T2000	6T/66	basis hexamethylene diamine, terephthalic acid, adipic acid	310

	B3W...GM24/GM35/GM45			glass-fiber and mineral reinforced with medium to high rigidity and strength, low warpage
	B3WGM24 HP			glass-fiber and mineral reinforced with medium to high rigidity and strength, low warpage and optimized demolding for fast cycle times
	B3WM8			miner filler for optimized surface appearance and low warpage, especially for electroplating processes
	B3...M6/M8			mineral filled, with medium rigidity and strength, low warpage
	Special products			
	B3E...G4/G6/G8/G10 SI			surface improved for excellent visual appearance and smoothness
	B3EG6 EQ			meets the special demands on purity for sensitive applications in the electronics industry
	B3W...G6/G7/G8/G12 High Speed			excellent flow properties and fast cycle times
	B3WG6 GIT			suited for processing for gas injection technology (GIT)
	B3WG6 SF			suitable for physical foaming processes
	Structure B3W...G10 LFX			with long glass fiber reinforcement
Ultramid® D				
Injection molding grades (reinforced)	D3EG10 FC Aqua®			high stiffness and low water absorption, with material approvals for drinking water or food contact
	Endure D3...G7/G10			very high level of heat-aging resistance
	Structure D3E...G10/G12 LFX			with long glass fiber reinforcement
	Structure D3E...G8 SI LFX			with long glass fiber reinforcement and improved surface quality
Blow molding grades (reinforced)	Endure B5G3 BM			highest heat-aging resistance, e. g. for parts in the charge air duct
Ultramid® S				
Injection molding grades (unreinforced)	S3W Balance			easy flowing, fast processing
	S3Z4 Balance			impact-modified, especially suitable for applications within the sports and leisure industry
	S3Z5 Balance			impact-modified, especially suitable for applications within the sports and leisure industry
Injection molding grades (reinforced)	S3EG6 Balance			good dielectric properties
	S3WG6 Balance			excellent heat-aging and hydrolysis resistance
Ultramid® T				
Injection molding grades (unreinforced)	T KR 4350			easy flowing, fast processing
Injection molding grades (reinforced)	T KR 4355...G5/G7/G8/G10			fiber-reinforced products
	T KR 4357 G6			fiber-reinforced and impact-modified
	Special products			
	T KR 4355 G5 LS			especially suitable for laser markable parts
Ultramid® Advanced T1000				
Spritzgusstypen (verstärkt)	T1000H...G7/G10			high stiffness and strength up to over 80 °C and in conditioned state, resistant against aggressive media
Ultramid® Advanced N				
Spritzgusstypen (unverstärkt)	N4H			dimensionally stable and resistant, also against wear and abrasion
Spritzgusstypen (verstärkt)	N3HG6			high flowability, for E&E applications, JEDEC class 1
	N4WG7			high toughness, excellent resistance against heat and chemicals, for automotive applications

● Main field of application

○ Other fields of application

Semi-aromatic polyamides (PPA)

BASF offers a portfolio of polyphthalamides (PPA) based on four PPA polymers and comprising more than 50 compounds, which are described in more detail in separate brochures. The PPA portfolio includes Ultramid® Advanced N (PA9T), Ultramid® Advanced T1000 (PA6T/6I), Ultramid® Advanced T2000 (PA6T/66) and Ultramid® T (PA6T/6). The PPA portfolio is globally available and is complemented by the BASF simulation tool Ultrasim® and extensive experience in application development.

Ultramid® Advanced N

A high-performance polyphthalamide with constant mechanical properties up to 100 °C (glass transition temperature: 125 °C) combined with outstanding chemical resistance, low water absorption and good tribological properties. The material permits a wide processing window and short cycle times. Parts made of Ultramid® Advanced N are lighter, smaller and stronger. The material can solve a wide range of application problems: Ultramid® Advanced N is suitable for small connectors and functionally integrated housings in domestic appliances, consumer electronics and mobile devices. It can be used in automotive and structural parts near the engine and the transmission system, which are in contact with hot, aggressive media and different fuels. Ultramid® Advanced N can also be used in applications such as gear wheels and other wear parts.

Further information can be found in the Ultramid® Advanced N brochure.

Ultramid® Advanced T1000

Within the Ultramid® family, Ultramid® Advanced T1000 is the strongest and stiffest product group. It has consistent mechanical properties at temperatures of up to 120 °C (dry) and up to 80 °C (conditioned). Thanks to its semi-aromatic chemical structure, it shows low water absorption and is highly resistant to aggressive media. Ultramid® Advanced T1000 can be used in the automotive industry, particularly in areas where materials have to remain strong to whatever temperatures or climates they are exposed to; it can also be used in all other industries which require dimensional stability or resistance to chemicals, e.g. thermostat housings and water pumps, in vehicle fuel systems, exhaust gas recirculation, actuators and clutch components, in coffee machines, furniture fittings and in structural applications such as water distributors, heating systems and pumps.

Further information can be found in the Ultramid® Advanced T1000 brochure.

Gear wheels

Ultramid® Advanced T2000

A polyphthalamide combining excellent mechanical, insulation and dielectric properties at high temperatures. Due to its semi-aromatic chemical structure, Ultramid® Advanced T2000 is the ideal solution for components that require a high degree of consistent stiffness and strength over a wide temperature range, combined with heat resistance, low moisture uptake and optional flame retardance. The PPA has the same level of impact resistance as standard PA66 and lower water absorption than aliphatic standard polyamides, which gives it a high degree of dimensional stability. The high melting point (310 °C) and high heat resistance (>280 °C, HDT-A) make it a suitable material for lead-free soldering, while preventing component deformation. It can therefore be used to manufacture sensitive connectors, structural components in laptops and circuit breakers.

Further information can be found in the Ultramid® Advanced T2000 brochure.

Ultramid® T

The partially aromatic polyamide Ultramid® T has outstanding properties:

- Dimensional stability even at higher temperatures (melting point: 295 °C)
- Excellent stiffness and strength
- Mechanical properties uncompromised by external conditions
- Toughest of all partially aromatic polyamides
- Low shrinkage and warpage
- Slow water absorption
- Good chemical resistance
- Excellent electrical properties

The highly glass fiber-filled grades are particularly suitable as a substitute for metal because of their high mechanical strength.

Mechanical properties

In comparison to conventional polyamides (e. g. PA6 or PA66), Ultramid® T is noted for its much slower water absorption. Furthermore, moisture absorption does not result in any significant change to the mechanical properties at room temperature because of the basically higher glass transition temperature of Ultramid® T.

Fig. 1: Tensile strength of Ultramid® T compared to PA66 at 23 °C, different moisture contents

Semi-aromatic polyamides are generally not the toughest materials. Because of its molecular structure, Ultramid® T has significantly higher impact resistance values than other semi-aromatic polyamides (Fig. 2) and does not lose its impact resistance in cold environments or in the dry state. Due to its excellent toughness in cold environments and in dry state, Ultramid® T is ideally suited, e.g. as material for plugs and connectors.

Chemical resistance

Like all polyamides, Ultramid® T also shows excellent chemical resistance. The material also offers other advantages compared to polar substances such as alcohols and aqueous calcium and zinc chloride solutions. Moreover, the strength and rigidity reduction and the change in volume are much lower with Ultramid® T than with a PA6.

Shrinkage and warpage

Products based on Ultramid® T show lower shrinkage in the longitudinal and transverse direction in comparison to PA66. Depending on the component geometry, this leads to extremely low warpage. In addition, as a result of the slow water absorption compared with standard polyamides, components made from Ultramid® T have significantly higher dimensional stability under different external conditions.

Fig. 2: Impact strength (23 °C) of Ultramid® T compared to PPS (glass fiber content: 30-35%)

Fuel pressure sensor

Ultramid® S Balance

As a long-chain polyamide, Ultramid® S Balance has the following properties:

- Good hydrolysis resistance
- High stress cracking resistance
- Low water absorption, high dimensional stability
- Mechanical properties largely independent of the level of conditioning

Among long-chain polyamides, Ultramid® S Balance has one of the highest level of rigidity and strength. This makes it the material of choice in areas that require a combination of resistance to media and the mechanical properties of conventional materials like PA6 and PA66.

Mechanical properties

The lower water absorption of Ultramid® S Balance compared to PA6 or PA66 results in constant mechanical properties under changing climatic conditions. Furthermore, Ultramid® S Balance has a higher heat-aging resistance compared to PA12 and thus offers a balanced range of properties for a variety of applications.

Chemical and hydrolysis resistance

Like all polyamides, Ultramid® S Balance shows excellent chemical resistance. In addition, this material also offers a number of other advantages, e.g. increased hydrolysis resistance compared with PA6 or PA66. This makes Ultramid® S Balance the perfect material for plug-in connectors, pipes and vessels in cooling circuits. The material can also be used in fuel applications, such as quick connectors.

Stress cracking resistance due to the presence of zinc chloride is an important requirement for car exteriors. Due to their inherent molecular structure, long-chain polyamides have a clear advantage. For instance, glass-fiber reinforced Ultramid® S Balance meets the conditions of the standards SAE 2644 and FMVSS 106. This means that the material is particularly suited to the overmolding of metal and electronic components that come into contact with aggressive media, e.g. wheel speed sensors.

Fig. 3: Hydrolysis resistance of Ultramid® S Balance compared with PA66, in Glystantin®/water (1:1) at 130 °C

Quick connector

Ultramid® Vision

With Ultramid® Vision, BASF has succeeded for the first time in developing a semi-crystalline polyamide that allows light to pass through largely unhindered. Compared to opaque standard polyamides, Ultramid® Vision displays very high light transmission with low light scattering.

The new polyamide combines the best properties of two groups of materials:

- The chemical resistance, temperature resistance and easy processing of semi-crystalline, opaque materials and
- The translucence of amorphous polymers at a competitive price.

Ultramid® Vision thus represents a cost-efficient material solution for applications in chemically challenging environments that require a high level of light transmission or even translucency.

The free colorability with suitable dyes makes it possible to achieve luminous color effects that offer a wide range of design possibilities. In addition, the translucent Ultramid® Vision can be combined with other polyamide materials in a multi-component injection-molding process, allowing multi-functional parts with translucent or illuminated areas to be manufactured easily.

If components manufactured from Ultramid® Vision are exposed to higher temperatures and moisture, the haze and transmission values barely change compared to the initial state. The translucent polyamide also has a convincing combination of high UV resistance, scratch resistance and outstanding chemical stability.

Beyond the uncolored base-grade Ultramid® Vision B3K UN, specially equipped products with diffuse light transmission (DLT) at high transmission rate as well as products colored according to customer requests can also be manufactured. The Ultramid® Vision portfolio therefore offers designers and developers a broad range of possibilities for realizing design features and lighting elements in car interiors and various consumer and industrial applications.

Fig. 4: Haze values of Ultramid® B3S UN and Ultramid® Vision B3K UN as function of the wall thickness

Ultramid® Deep Gloss

Ultramid® Deep Gloss is the specialty polyamide for high-gloss components in automobile interiors. The balanced property profile of Ultramid® Deep Gloss makes it the ideal solution for visual appealing and yet durable parts without any additional painting steps.

- High gloss
- Excellent scratch resistance
- High chemical stability
- Low emissions
- Good UV resistance

Because of its balanced property profile, Ultramid® Deep Gloss is the ideal material for:

- Decorative parts, e.g. the edges of displays
- Decorative trim around lights
- Headliner pockets
- Functional components e.g. air vents
- Inserts in vehicle doors or center consoles

Special additives provide the properties required to ensure the durability of high-quality surfaces, such as scratch and abrasion resistance and sufficiently high UV resistance.

Ultramid® Deep Gloss accurately reproduces every detail of structures without the need for variothermal mold temperature control. This offers designers new possibilities for combining high gloss surfaces with unique textures.

In addition to the glossy deep black main product, it is also possible to realize other colors and the latest color trends. Ultramid® Deep Gloss has been developed primarily to satisfy the requirements of automobile interiors. But it is also possible to produce components with similar demands in the consumer goods sector.

DIN 75202	L	ΔE	Greyscale	Gloss 20°
0h	2.77	0	5	91.4GU
280h (4 Cycles)	2.98	0.31	4 - 5	94.3GU
420h (6 Cycles)	3.41	0.73	4	74.8GU

The properties of Ultramid®

Mechanical properties

The Ultramid® A (PA66) and Ultramid® B (PA6) grades, which are described here offer various combinations of mechanical properties and thus meet a variety of requirements, for example from the E&E and automotive industries as well as from numerous other sectors.

Special about polyamide as a material is its ideal combination of strength, rigidity and toughness together with excellent longevity across a wide temperature range. These advantages can be attributed to the partially crystalline structure of the polyamide: strong hydrogen bonds between molecules give strength to the crystalline areas and allow high operating temperatures, while more flexible molecule chains in the amorphous regions ensure exceptional toughness.

When choosing materials on the basis of key mechanical data, one special feature of the polyamide must be taken into account: freshly molded components are always dry and will absorb moisture depending on the ambient conditions. This leads to a considerable change in key mechanical properties, particularly in typical test conditions of 23°C. This is why in the data sheets a distinction is frequently made between the key material data “dry” and “conditioned”.

Fig. 5 shows unreinforced Ultramid® A3K to demonstrate the influence of conditioning on the tensile modulus of elasticity (shift in the glass transition temperature). Ultramid® A3EG10, a 50 % glass fiber-reinforced product, has a reduced moisture uptake (compared with an unreinforced grade) as moisture is only taken up by the amorphous part of the PA matrix.

In the following part, the mechanical properties of the Ultramid® range are described on the basis of dry test specimens.

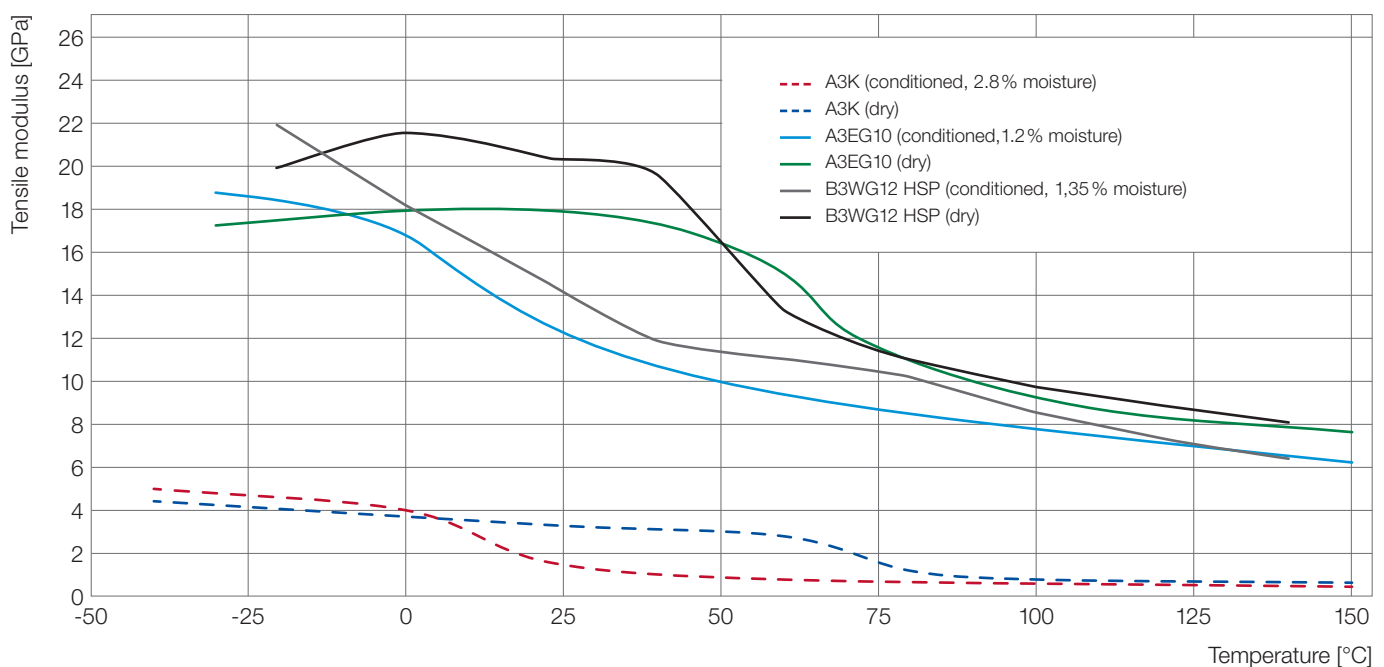

Fig. 5: Modulus of elasticity for selected Ultramid® grades as function of temperature and conditioning

Fig. 6: Yield stress (tensile stress in the case of reinforced grades) for selected Ultramid® grades at 23°C, dry (ISO 527)

Fig. 8: Tensile stress (yield stress in the case of unreinforced grades) for Ultramid® grades as a function of moisture content at 23°C (ISO 527)

Fig. 7: Modulus of elasticity for selected Ultramid® grades at 23°C, dry (ISO 527)

The product range can be divided into six groups according to the range of the modulus of elasticity (dry):

- Impact-modified unreinforced grades 1500 - 2000 MPa
- Unreinforced grades 2700 - 3500 MPa
- Mineral-filled, impact-modified grades (+GF) 3800 - 4600 MPa
- Mineral-filled grades (+GF) 3800 - 9300 MPa
- Impact-modified, glass-fiber reinforced grades 5200 - 11200 MPa
- Glass-fiber reinforced grades 5200 - 21100 MPa

The mechanical properties depend on various factors like testing temperature, moisture content, storage time (post-crystallization) and the molding conditions of the respective test specimens.

Fig. 9: Shear modulus of Ultramid® A grades as a function of temperature and glass fiber content according to ISO 6721-2, dry

Fig. 10: Shear modulus of Ultramid® B grades as a function of temperature and filler, according to ISO 6721-2, dry

Fig. 11: Flexural modulus of reinforced Ultramid® A grades as a function of temperature (ISO 178 flexural strength test, dry)

Fig. 12: Flexural modulus of reinforced Ultramid® B grades as a function of temperature (ISO 178 flexural strength test, dry)

In the case of the reinforced grades, the specific filler has a pronounced influence on the properties. The most important modification is the reinforcement with glass fibers. Influencing factors are: glass fiber content, average glass fiber length, glass fiber length distribution and the glass fiber orientation. The latter is caused by the flow process of the melt and results in anisotropic material properties. These effects can be calculated quantitatively with the BASF simulation tool Ultrasim® for the purpose of optimizing part design.

The behavior under short-term uniaxial tensile stress is shown as a stress strain diagram (Fig. 13 and 14), which illustrates the influence of temperature and reinforcement. The values shown originate from uncolored products and may be influenced by coloring. The yield stress of unreinforced Ultramid® ranges from 70 to 100 MPa while the stress at break for reinforced grades reaches up to 250 MPa.

Impact strength, low-temperature impact strength

Polyamides are very tough materials. They are suitable for parts required to exhibit high resistance to fracture. Standard test values generally determined under different conditions are used to characterize their impact behavior (see the Ultramid® product range).

Although the values are not directly comparable with one another due to the differing test setups, test specimen dimensions and notch shapes, they do allow comparison of molding materials within the individual product groups. Tests on finished parts are indispensable for the practical assessment of impact behavior. However, the behavior of Ultramid® grades when subjected to impact is affected by many factors, of which the most important are the shape of the part, the rigidity of the material and the moisture content.

The Ultramid® portfolio offers grades with different combinations of impact strength and rigidity. Depending on application, requirements, design and processing, products which are unreinforced, of relatively high molecular weight, glass-fiber reinforced, mineral-filled or impact modified can be selected, each having an optimum relationship between impact strength and rigidity.

Fig. 13: Stress-strain diagrams for Ultramid® B3S and B3WG5 (dry) in accordance with ISO 527

Fig. 14: Stress-strain diagrams for Ultramid® A3K and A3EG5 (dry) in accordance with ISO 527

The advice below should also be taken into account when choosing suitable materials. Moisture promotes the toughness of Ultramid®, even at low temperatures. In the case of glass-fiber reinforced grades the impact strength of finished parts decreases as the glass fiber content rises while strength and the values in the flexural impact test for standardized test specimens increase. This effect is caused by differences in glass fiber orientation within the test specimens.

Unreinforced products of high molecular weight have proved to be effective for thick-walled engineering parts required to exhibit high impact strength.

Even in the dry state the impact-modified, unreinforced Ultramid® grades like B3L exhibit high impact strength. They are employed when conditioning or intermediate storage for absorption of moisture are uneconomic or when extremely high notched or low-temperature impact strength are required.

Apart from the particular processing conditions, the geometry of the molded part – with the resultant moments of resistance – and especially the wall thicknesses and the notch radii also play a major role in determining the fracture energy. Even the speed and point of impact significantly affect the results.

Behavior under long-term static loading

The static loading of a material for relatively long periods is caused by a constant stress or strain. The tensile creep test in accordance with ISO 899 and the stress relaxation test in accordance with DIN 53441 provide information about extension, mechanical strength and stress relaxation behavior under sustained loading.

The results are presented as creep curves, creep modulus curves, creep stress curves and isochronous stress-strain curves (Figs. 15 and 16). The curves shown here are obtained at standard atmosphere according to ISO 291 and 120 °C and represent only a selection of the results from our comprehensive investigations.

Further values and diagrams for different temperatures and atmospheric conditions can be requested from the Ultra-Infopoint or in the program “Campus”. Data obtained from uniaxial tensile loads can also be used to assess the behavior of a material under multiaxial loads. Especially reinforced grades are noted for their high creep rupture strength and low tendency to creep.

Fig. 15: Isochronous stress-strain curves for Ultramid® A3K in accordance with ISO 899 under standard atmospheric conditions (23/50) and at 120 °C (in the dry state)

Fig. 16: Isochronous stress-strain curves for Ultramid® A3WG10 in accordance with ISO 899 under standard atmospheric conditions (23/50) and at 120 °C (in the dry state)

Behavior under cyclic loads, flexural fatigue strength

Engineering parts are also frequently subjected to stress by dynamic forces, especially alternating or cyclic loads, which act periodically in the same manner on the structural part. The behavior of a material under such loads is determined in long-term tests using tensile and compressive loading alternating up to very high load-cycle rates. The results are presented in Woehler diagrams, obtained by plotting the applied stress against the load-cycle rate achieved in each case (Fig. 13). When transferring the test results in practice, it has to be taken into account that at high cycle fatigue frequencies the test specimen may heat up considerably due to internal friction. In such cases it may make sense to apply a higher testing temperature. (Fig. 13).

Tribological behavior

The smooth, tough and hard surface, partially crystalline structure, high thermostability and resistance to lubricants, fuels and solvents make Ultramid® an ideal material for parts subjected to sliding friction.

Whereas metallic materials tend to jam under dry-running conditions, pairings with Ultramid® run satisfactorily in most cases without lubrication.

Wear and friction are system properties which depend on many parameters, e.g. on the paired materials, surface texture and geometry of the sliding parts in contact, the intermediate medium (lubricant) and the stresses due to external factors such as pressure, speed and temperature.

The most important factors determining the level of wear due friction and the magnitude of the coefficient of sliding friction of Ultramid® are the hardness and surface roughness of the paired materials, the contact pressure, the distance traversed, the temperature of the sliding surfaces and the lubrication. Further information can be found in the Technical Information "Friction and wear of polymer materials".

Fig. 17: Fatigue of Ultramid® A3WG7 at different temperatures (dry, R = -1, 10 Hz, lengthwise oriented, thickness = 3 mm)

Thermal properties

Ultramid® has the following melting temperatures:

Ultramid® A:	260 °C
Ultramid® B:	220 °C
Ultramid® C:	243 °C
Ultramid® S:	222 °C
Ultramid® T:	295 °C
Ultramid® Advanced T1000:	325 °C
Ultramid® Advanced T2000:	310 °C
Ultramid® Advanced N:	300 °C

Due to its semicrystalline structure and strong hydrogen bonding Ultramid® retains its shape even at elevated temperatures close to the melting range.

Ultramid® stands out among other partially crystalline thermoplastics due to its low coefficients of linear expansion.

The reinforced grades in particular exhibit high dimensional stability when exposed to temperature changes. In the case of the glass-fiber reinforced grades, however, linear expansion depends on the orientation of the fibers.

Behavior on heat

Apart from its product-specific thermal properties the behavior of components made from Ultramid® on exposure to heat depend on many factors: Exposure time, the specific source of thermal stress and mechanical load at elevated temperature. The design of the parts also has an effect. Accordingly, the thermostability of Ultramid® parts cannot be estimated simply on the basis of the temperature values from the various standardized tests no matter how valuable the latter might be for guidance and comparisons.

The shear modulus and damping values measured as a function of temperature in torsion pendulum tests in accordance with ISO 6721-2 afford valuable insight into the temperature behavior. Comparison of the shear modulus curves (Fig. 9 and 10) provides information about the different thermomechanical effects at low deformation stress and speed. Based on practical experience, the thermostability of parts produced in optimum manner is in good agreement with the temperature ranges determined in the torsion tests in which the start of softening becomes apparent.

The test for heat resistance in accordance with IEC 60695-10-2 (ball indentation test), is usually specified for applications in electrical equipment. All Ultramid® grades can pass this test at 125 °C, making Ultramid® the material of choice for voltage carrying parts. Higher temperature requirements can also be met with Ultramid®. We recommend reinforced grades for this purpose.

Circuit breaker

Heat-aging resistance

Stabilized Ultramid®, with K, E, H or W as the second letter of the nomenclature, is suitable for parts subject to long periods of temperature stress. Depending on the respective application requirements, the Ultramid® portfolio covers the entire range of continuous operating temperatures: W2 stabilization is suitable for temperatures up to 190 °C, and W3 stabilization for temperatures up to 210 °C. The spectrum is completed by Ultramid® Endure, which can be used up to 220 °C. Optimized products with E or H stabilization are suitable for sensitive applications, e.g. in electronics.

The adjacent figure 18 summarizes the features and effectiveness of each stabilization. The temperature ranges are given only for guidance and depend on the particular product. The tensile strength as a function of the storage time is shown in Figure 19 for a number of Ultramid® grades.

Fig. 18: Typical continuous operating temperatures (in relation to the retention of tensile strength after 3,000 h) for Ultramid® grades

Fig. 19: Heat-aging resistance of different Ultramid® grades (23 °C, dry)

Heat-aging resistance in hot lubricants, coolants and solvents

The widespread application of Ultramid® in engineering, especially in automotive applications, e.g. in engine oil circuits and gearboxes, is based on its outstanding long-term resistance to hot lubricants, fuels, coolants and to solvents and cleaning agents. Figures 20 and 21 show how the elongation at break of glass fiber-reinforced Ultramid® grades can be affected by storage in hot lubricants or coolants. A3HG6 HR and A3WG6 HRX are particularly suitable for parts of the vehicle cooling system, the latter one is especially effective at high operating temperatures.

Water absorption and dimensional stability

A special characteristic of polyamides in comparison with other thermoplastics is their water absorption. In water or in moist air depending on its relative humidity and dependant on time, temperature and wall thickness moldings absorb a certain quantity of water so that their dimensions increase slightly. The increase in weight on saturation depends on the respective Ultramid® grade and is listed in the tables in the range chart. Fig. 22 shows how the absorption of moisture on saturation depends on the relative humidity.

Fig. 20: Tensile strength of different Ultramid® A grades after storage in oils or lubricating greases

- A3HG7, gear oil – Pentosin FFL2, 150 °C
- A3WG7, engine oil – Aral Extra Turboral SAE 10W-40, 150 °C
- A4H, lubrication grease – Fuchs Renolit LT1, 120 °C
- A3WG7, gear oil – Dexron VI ATF2, 150 °C

Fig. 21: Tensile strength of different Ultramid® grades after storage in Glycantin®/water 1:1

- A3HG6 HR, 130 °C
- A3WG6 HRX, 130 °C
- S3WG6 Balance, 130 °C
- Advanced N4HG7, 135 °C

Fig. 22: Equilibrium moisture content of Ultramid® as a function of relative humidity in the temperature range 10°C - 70°C (scatter: ± 0.2 to 0.4% absolute)

Fig. 23: Water absorption of Ultramid® B as a function of storage time and the conditioning parameters (specimen thickness 2 mm)

Figs. 23 and 24 show the water absorption of Ultramid® as a function of storage time under various test conditions.

The impact resistance, elongation at break and creep increase with water absorption, while strength, stiffness and hardness decrease. Respective test results for different products are shown in the Ultramid® range chart or CAMPUS.

Provided that the water is uniformly distributed in the part, Ultramid® A and Ultramid® B undergo a maximum increase in volume of about 0.9% and a mean increase in length of 0.2 to 0.3% per weight percent of absorbed water. The dimensional change of the glass-fiber reinforced grades amounts to less than 0.1% in the direction of the fiber orientation (longitudinally). As a result these grades, in addition to mineral-filled grades, remain particularly constant dimensions when humidity varies.

Further information can be found in the brochure "Conditioning Ultramid® moldings".

Fig. 24: Water absorption of Ultramid® A as a function of storage time and the conditioning parameters (thickness of specimen 2 mm)

Electrical properties

The paramount importance of Ultramid® in electrical engineering, especially for electrical insulating parts and housings in power engineering, is attributable to its good insulating properties (volume and surface resistance) combined with its high impact strength and creep strength as well as its advantageous properties in relation to heat-aging. As a result, Ultramid® is numbered among the high-performance insulating materials. Flame-retardant grades are always preferred where fire behavior requirements are high.

Connector

Concerning electrical properties the following should be considered:

- The products are characterized by a high tracking current resistance which is only slightly impaired by the moisture-content of the material.
- The specific volume resistance and the surface impedance are very high; these values decline at elevated temperatures and also when the water content is relatively high.
- As for all electrical insulating materials, when used in harsh conditions, continual wetting due to condensation must be prevented by appropriate design measures.
- Unfavorable operating environments such as hot pockets combined with high air humidity, moist, warm conditions or poor ventilation can adversely affect the insulating properties.

For the above reasons, the performance of the components should be carefully checked for each application. The values of the electrical properties are listed in the range chart.

For reliable micro-electronics in sensitive automotive applications such as control units and sensors, BASF has developed a portfolio of various polyamide 6 and 66 grades that help prevent damage to circuits by electric corrosion. The different Ultramid® EQ grades (EQ=electronic quality) are extremely pure, which means they have hardly any electrically active or corrosion-generating contents, yet still offer good resistance to heat-aging. They are subject to special quality tests that cover raw material selection, the production process, and the analysis of the halogen content. The globally available portfolio consists of uncolored and black grades with a glass fiber content of 30 % and 35 %, which are also laser-markable.

Brush holder

Figs. 25 and 26 show the effect of temperature and moisture on the dielectric strength and specific volume resistivity of Ultramid®.

For an important grade within the flame-retardant product range, i. e. Ultramid® A3X on the basis of red phosphorous, the following applies: The Ultramid® A3X grades contain a special stabilizer to prevent the formation of red phosphorus decomposition products which can occur in polyamides with phosphorus-based flame retardants. When applied as an electrical insulating material, especially when heat and humidity are an issue, inspections and constructive measures must ensure the reliability of the final parts. Overviews, tables and examples illustrating the use of Ultramid® in electrical engineering can be found in the brochure “Engineering Plastics for the E&E Industry – Products, Applications, Typical Values”.

Gearbox control

Fig. 25: Dielectric strength of Ultramid® A3EG6 at different temperatures as a function of moisture content (IEC 60243; wall thickness 3 mm)

Fig. 26: Specific volume resistivity of glass-fiber reinforced Ultramid® A with different moisture contents as a function of temperature (IEC 60093)

Fire behavior

General notes

Ultramid® products slowly start to decompose above a certain temperature. This is dependent on the composition of the particular product. Flammable gases can form, which continue to burn after ignition. These processes are influenced by many factors, so it is impossible to give a definite flash point. Flame retardant additives are used to prevent fires (ignition) or to minimize the spread of fires (self-extinguishing).

Decomposition products and combustion gases in general can be toxic. The safety data sheets contain the corresponding product-specific physical and chemical properties.

Tests

Electrical engineering

The glow wire test according to IEC 60695-2-10ff is often required in Europe (Tables 3 and 5). IEC 60335-1 also requires the GWIT 775 (IEC 60695-2-13) to be met by live components in unattended household appliance.

Another method based on standardized test specimens is the flammability test according to "UL94 Standard, Tests for Flammability of Plastic Materials for Parts in Devices and Appliances" of Underwriters Laboratories Inc./USA.

The unreinforced grades Ultramid® A3K R01 and B3S R03 are classified in Class UL94 V-2 according to this test procedure. The unreinforced and flame retardant grades Ultramid® A3U32 and C3U achieve a UL94 V-0 classification.

Product	UL 94	Glow wire test ¹⁾ IEC 60695 2-12	FMVSS 302 (d > 1 mm)
A3K R01	V-2, 0.4	960 °C ²⁾	reached

Adv. N3U40G6	V-0, 0.25	960 °C	reached

Table 5: Fire performance

¹⁾ Material testing conducted on sheets (thickness of 1 mm)

²⁾ Undyed; dyeing can have an influence

The glass fiber-reinforced Ultramid® grades generally require a flame retardant additive to achieve a good classification. Examples are Ultramid® A3X2G, A3U42G6, B3U50G6, B3U30G6 and Ultramid® Advanced N3U40G6. The flame retarding properties are summarized in Tables 3 and 5.

Transportation

In traffic and transport engineering, plastics contribute substantially to the high performance of road vehicles and trains. Materials used inside motor vehicles are governed by the fire safety requirements according to DIN 75200 and FMVSS 302, which are met by most Ultramid® products with a wall thickness of 1 mm and above (Table 5). For rail vehicles, in addition to different national regulations, a European standard EN 45545 was established. Among other things it also contains requirements regarding side effects of fires such as the density and toxicity of smoke gases.

Construction industry

The testing of building materials for the construction industry is carried out in accordance with DIN 4102, Part 1, "Fire behavior of building materials and building parts". Sheets of unreinforced and glass-fiber reinforced Ultramid® (thickness ≥ 1 mm) are rated as normally flammable building materials in Building Materials Class B 2 (designation in accordance with the building regulations in the Federal Republic of Germany).

Further literature

The wide variety of existing applications and sets of rules can be difficult to keep track with. More detailed information and key material figures can be obtained from the following BASF brochures:

- Engineering Plastics for the E&E Industry – Products, Applications, Typical Values
- Engineering Plastics for Automotive Electrics – Products, Applications, Typical Values

Terminal carrier

Generator end cap

Resistance to chemicals

Polyamide shows good resistance to lubricants, fuels, hydraulic fluids and coolants, refrigerants, dyes, paints, cleaners, degreasing agents, aliphatic and aromatic hydrocarbons and many other solvents even at elevated temperatures.

Ultramid® is resistant to corrosion, to aqueous solutions of many inorganic chemicals (salts, alkalis). Special mention should be made of its outstanding resistance against stress-crack formation compared to many amorphous plastics. Many media such as, for instance, wetting agents, ethereal oils, alcohols and other organic solvents do not detrimentally affect the creep behavior of polyamide.

Good resistance to chemicals is an important prerequisite for the use of Ultramid® in automotive, aerospace and chemical engineering.

Ultramid® is not resistant to concentrated mineral acids. The same applies to certain oxidants and chlorinated hydrocarbons, especially at elevated temperatures. Attention should also be given to its sensitivity to certain heavy-metal salt solutions such as, for example, zinc chloride solution. The semi-aromatic chemical structure of Ultramid® Advanced (PPA) makes those products particularly resistant to moisture and aggressive media.

Table 6 summarizes Ultramid®'s resistance to the most important chemicals. Further information on the effect of solvents and chemicals can be found on the Internet at www.plastics.basf.com or in the brochure "Ultramid®, Ultradur® and Ultraform® – Resistance to chemicals". The brochure gives an overview over the long-term and short-term media resistance of Ultramid® based on a variety of test results. This should give an impression of the phenomena and influencing factors that can be met when thermoplastic components are exposed to chemicals. The statements made here are of a general nature and do not claim being complete or universally valid. Specific cases must be evaluated individually to assess all possible effects.

Thermostat housing

The consequences of exposing a polymeric material to various types of media can depend on many factors that sometimes interact in a complex way. Consequently, testing a component under realistic circumstances and under typical application conditions always gives the most meaningful results on whether a material is suited for a given application or not. In contrast, when it comes to laboratory tests, simple test specimens are often exposed to a medium under well-defined and constant conditions. Such experiments allow a relative comparison between different materials and thus lay the foundation for pre-selecting potential candidates as the right material for a given application. However, these experiments cannot substitute actual-practice testing.

Before selecting a material, especially for components subject to high stresses and possible exposure to corrosive chemicals, its chemical suitability should be verified. This may be done on the basis of experience with similar parts made of the same material in the same medium under comparable conditions or by testing parts under practical conditions.

Oil sensor

Behavior on exposure to weather

Ultramid® is suitable for outdoor applications. Different grades come into consideration depending on requirements.

The unreinforced, stabilized grades with K as identifier are highly resistant to weathering even when unpigmented. Suitable pigmentation increases outdoor performance further, best results are achieved with carbon black.

The reinforced grades also exhibit good weather resistance; stabilized grades, e.g. Ultramid® B3WG6 BK564, will retain their weather resistance for well over ten years.

However, owing to the glass fibers, the surface is attacked to a greater extent compared to unreinforced Ultramid®, which means that the quality of the surface and its color can change after a short period of outside weathering. As a result, such materials can slowly turn grey. In the case of colored grades, the level of resistance is essentially dependent on the pigments that are used. The natural and pigmented products from the E2 portfolio are suitable for applications requiring a particularly high degree of color and UV stability. Grades with special UV stabilization and products with a high carbon black content, e.g. Ultramid® B3GM35 SWQ642 23220, have proved effective in exterior applications, e.g. housings for automobile mirrors that must retain their surface quality even over many years of use.

After several years of weathering, the surface layer of standard grades is likely to show signs of wear down to several micrometers. This causes a slight discoloration as described before. In the case of dark shades the material turns greyish. However, experience shows that this does not have any obvious adverse effect on the mechanical properties. This is illustrated by results from ten-year outdoor weathering tests (Fig. 27). Only a slight reduction of mechanical values is observed once the conditioned state has been reached.

Fig. 27: Change in the mechanical values of Ultramid® B3WG6 BK564 after outdoor weathering

Fixing clip for photovoltaic modules

The processing of Ultramid®

Processing characteristics

Ultramid® can be processed by all processing techniques known for thermoplastics primarily injection molding and extrusion. Complex moldings are economically manufactured in large numbers by injection molding. The extrusion method is used to produce films, semi-finished products, pipes, profiles, sheets and monofilaments. Semi-finished products are usually further processed by machining to finished parts.

Some general aspects regarding injection molding of Ultramid® is shown in the following chapters. Detailed information can be found at www.plastics.basf.com or via Ultraplaste Infopoint (ultraplaste.infopoint@basf.com). The injection molding conditions of each individual product are given in the respective processing data sheet.

Melting and setting behavior

The softening behavior of Ultramid® on heating is shown by the shear modulus measured in accordance with ISO 6721-2 as a function of temperature (Figs. 9 and 10). Pronounced softening only occurs just below the melting point. Glass fibers increase the softening point. A measure commonly used to determine the softening temperature is the heat deflection temperature HDT in accordance with ISO 75.

The melt solidifies during cooling within a narrow temperature range around 20 °C to 40 °C below melting point depending on the cooling rate and the Ultramid® grade. At the same time there is a contraction in volume of roughly 3 % to 15 %. The total volume contraction can be deduced from the curves of the pvt diagram in fig. 28. The crystallization temperature and pvt behavior is also included in commonly available programs for the simulation of injection molding process.

Fig. 28: pvt diagram of Ultramid® A and B grades

Thermal properties

The relatively high specific enthalpy of Ultramid® requires efficient heating elements. As the freezing and cooling times increase with the square of the wall thickness, varying wall thicknesses should be avoided to ensure cost-efficient production.

Melt viscosity

The flow behavior of Ultramid® melts can be evaluated on the basis of viscosity diagrams, obtained from measurements using a capillary rheometer or on the basis of injection molding tests.

In the range of the processing temperatures the Ultramid® grades have a melt viscosity of 10 to 1,000 Pa·s (Figs. 29 and 30), highly depending on temperature and shear rate. The higher the relative molar mass or the relative solution viscosity (given by the first digit in the nomenclature), the higher is the melt viscosity and the lower the flowability (Fig. 29). In the case of Ultramid® grades with mineral filler or glass-fiber reinforcement, the viscosity increases depending on the amount of reinforcement. In addition to standard materials, the Ultramid® portfolio includes products with optimized flowability (Fig. 30).

The melt viscosity can change due to different reasons. For example if the melt is too moist, too hot or exposed to high mechanical shear forces the viscosity can decrease. Oxidation can lead to a lower viscosity. All these factors have an effect on mechanical properties and the heating aging resistance of the finished parts or the semi-finished products.

Thermostability of the melt

Appropriate processing assumed the thermostability of Ultramid® melts is outstanding. With normal processing conditions, the material is not affected. Degradation in the polymer chains only occurs when the residence time is too long or the temperature is too high. The recommended melt temperatures for processing can be found in Tables 7 and 8 and the Ultramid® range overview or the processing data sheet of the relevant product.

If the melt does not come into contact with oxygen, no significant color changes occur. Exposed to air, for example, when open injection nozzles are used or in case of interruptions in production, the surface can already become discolored after a brief time.

Fig. 29: Apparent viscosity of Ultramid® B (unreinforced) as a function of shear rate

Fig. 30: Apparent viscosity of Ultramid® A and B with different glass fiber contents, T = 280°C

General notes on processing

Preliminary treatment, drying

Ultramid® must be processed dry. If the moisture content is too high, it can result in losses of quality. This may affect the quality of the molded part surface. A loss in mechanical properties, e.g. resulting from polymer degradation, is also possible. During processing of flame-retardant grades which are not dry enough, mold deposit can occur.

The maximum acceptable moisture content for processing by injection molding is 0.15 %; for extrusion 0.1 %. The granules supplied in moisture-proof packaging can be processed without any special preliminary treatment. However drying is recommended, and may be necessary, if the containers were stored outside or were damaged. The moisture content of some moisture-sensitive products e.g. Ultramid® T or Ultramid® Advanced should be much lower.

In order to prevent the formation of condensation, containers which are stored in non-heated rooms should only be opened once they have reached the temperature in the processing room.

The drying time – usually from 4 to 8 hours – is dependent on the moisture content and product. Among the different dryer systems, dehumidifying dryers are the most efficient and reliable. The optimum drying temperatures for Ultramid® are approx. 80°C to 120°C. As a general rule, the specifications of the equipment manufacturer should be followed. The use of vented screws for releasing the moisture as part of the injection molding process is not advisable.

Pale granules and thermally sensitive colors should be dried under careful conditions at granule temperatures not exceeding 80°C in order to avoid a change in color. The mechanical properties of the finished parts are not influenced by drying temperatures of up to 120°C.

Detailed recommendation for drying each product can be found in the processing data sheets.

Self-coloring

Self-coloring of Ultramid® by the injection molder is generally possible. The colorants of Ultramid® T and Ultramid® Advanced, which are generally processed at temperatures above 310 °C, must be thermally stable.

The properties of self colored parts, especially homogeneity, impact strength, fire and shrinkage characteristics, have to be checked carefully because they can be dramatically influenced by the additives and the processing conditions.

Ultramid® grades that are UL94-rated must adhere to the stipulations of UL 746D if the UL rating is to be retained. Only PA-based color batches that are HB-rated or higher may be used for the self-coloring of UL 94 HB-rated Ultramid® grades. Ultramid® grades that are UL 94 V-2, V-1 or V-0 rated may only be colored with UL-approved color batches (special approval required).

Self-colored molded parts used in the food contact sector must comply with special requirements (see “Safety notes – food legislation”).

Reprocessing and recycling

Regrind material from sprues and rejected parts from the processing of Ultramid® can be reused to a limited extent, provided they are not contaminated. It should be noted that the regrind is particularly hygroscopic, so it should generally be dried before being processed. Repeated processing can cause damage.

In specific cases, it may be helpful to check the solution viscosity or the melt viscosity. Whether the addition of recycled material is permitted in the particular application must be clarified in advance. Restrictions on the amount of recycled material in flame-retardant products (e.g. under UL specifications) must also be considered..

As Ultramid® is not homogeneously mixable with most other thermoplastics, including PS, ABS, and PP, only pure mixtures of new and recycled product may be processed. Even small amounts of such “impurities” usually have a negative effect which becomes apparent, for example, as delaminated structures – especially close to the gate – or in a reduced impact strength.

Machine and mold technique for injection molding

Ultramid® can be processed on all commercial injection molding machines.

Plasticizing unit

The single-flighted three-section screws usual for other engineering thermoplastics are also suitable for the injection molding of Ultramid®. In modern machines, the effective screw length is $20\text{--}23 \cdot D$ and the pitch $1.0 \cdot D$. The geometry of the three-section screw, which has long proved effective, is shown in Fig. 31.

Fig. 31: Screw geometry – terms and dimensions for three-section screws for injection-molding machines

Recommended flight depths are shown in Fig. 32. These flight depths apply to standard and more shallow-flighted screws and afford a compression ratio of about 1 to 2. Shallow-flighted screws convey less material than deep-flighted ones. The residence time of the melt in the cylinder is therefore shorter. This means that more gentle plasticization of the granules and greater homogeneity of the melt can be an advantage for the quality of injection-molded parts.

Fig. 32: Screw flight depths for three-section screws in injection-molding machines

In order to ensure that moldings can be manufactured in a reproducible way, it is important to have a non-return valve, which is designed to enable a good flow and a tight closing. This allows a constant melt cushion and a sufficient holding pressure time to be achieved. The clearance between the cylinder and the valve ring should be no more than 0.02 mm.

Ultramid® can be processed both with needle valve nozzles and open nozzles. Open nozzles are advantageous for material and color changes and lead to lower shear stresses. As a vertical plasticizing unit is used and/or the melt viscosity is lower it is often impossible to stop the melt from running out of an open nozzle. In this case needle valve nozzles have to be preferred.

The machine nozzle should be easy to heat and has an additional heater band for this purpose if necessary. So it is possible to prevent undesired freezing of the melt. For the processing of mainly glass-fiber reinforced materials the use of hard-wearing plasticizing units is recommended. The processing of flame-retardant grades may require the use of corrosion-resistant steels.

Injection mold

The design rules for injection molds and gating systems which are specified in the relevant literature also apply to moldings made of Ultramid®.

Filling simulations at an early stage can make an important contribution to the design, especially if the molded parts have complex geometries.

Molded parts made of Ultramid® are easy to demold. The draft on injection molds for Ultramid® is generally 1 to 2 degrees. With drafts of a lower angle, the demolding forces increase greatly, which means that more attention has to be paid to the ejector system.

In principle, Ultramid® is suitable for all usual kind of gates. If hot runner nozzles are used, it should be possible to regulate them individually. Heated components must have a homogeneous temperature level.

Front end carrier

Gates must be sufficiently large in size. Gate cross sections that are too small can cause a wide range of problems. These include material damage resulting from excessively high shear stress or insufficiently filled molded parts as a result of pressure losses. Premature freezing of the melt before the end of the holding pressure time can cause voids and sink marks.

In the case of fiber-reinforced grades, increased wear occurs in the gate area at relatively high output rates; this can be countered by selecting suitable types of steel and using changeable mold inserts. Corrosion-resistant, high-alloy steels (for example DIN 1.2083, X42Cr13) have proven suitable for processing flame-retardant products.

When the melt is injected, the air in the mold cavity must be able to escape easily – especially at the end of the flow path or at places where flow fronts meet – so that burned marks from compressed air are not produced (diesel effect). This applies particularly to the processing of flame-retardant grades. Figure 33 illustrates how mold vents can be realized.

The quality of moldings is highly dependent on the temperature conditions in the mold. A precise and effective mold temperature control is possible only with a well-designed system of temperature control channels in the mold, together with temperature control devices of appropriate power. The mold temperatures required for Ultramid® can be achieved with temperature control devices using water, with system pressure being superimposed in a controlled way if necessary.

Fig. 33: Design diagram for mold venting (all size in mm)

Injection molding

The injection molding machine is started up in the usual way for thermoplastics: the cylinder and nozzle heating are adjusted to ensure that the required melt temperature is reached (guide values in Table 8). As a precaution, the melt exposed to thermal stresses during the heating-up phase is pumped off. After this, the optimum processing conditions have to be determined in trials.

If flame-retardant grades are processed, it is recommended that the melt should not be pumped off but rather injected into the mold. If pumping off cannot be avoided, an extraction device (hood) should be available and the melt cooled in the water bath. Further information can be found in the chapter "General information" under "Safety notes – safety precautions during processing".

The residence time of the plastic in the plasticizing cylinder is a major factor determining the quality of the molding. Residence times that are too short can result in thermal inhomogeneities in the melt whereas, if they are too long (> 10 min), they often result in heat damage.

Processing temperatures

The different Ultramid® product groups are processed over a wide melt and mold temperature range. An overview of the guide values for each of the product groups can be found in Fig. 34.

Detailed information on the melt and mold temperature range and the optimum processing parameters is provided in the processing data sheet for the particular product. The optimum melt temperature within the given range is dependent on the flow path distance and wall thickness of the molded part as well as the plasticizing unit and used injection molding process itself.

Low melt temperatures can be used for short flow paths and/or larger flow cross sections. Higher melt temperatures are to be avoided because of possible thermal damage or even decomposition of the melt. Slight increases are permitted only for short production or dwell times of the melt in the cylinder. Damage can appear as impaired optical and mechanical properties.

When dwell times are long, careful melting is achieved by adjusting the temperatures of the cylinder heater bands so that they increase gradually between the hopper and the nozzle (between 50 °C and 80 °C). An increase from 20 °C below the desired melt temperature to the melt temperature at the nozzle has proved effective (e.g. 260 °C rising to 280 °C for unreinforced Ultramid® B).

Fig. 34: Melt and mold temperature range of different Ultramid® product groups

When dwell times are short, horizontal cylinder temperature control makes sense.

When using an open nozzle, the melt can be prevented from leaking by reducing the nozzle temperature. Measurement of the actual melt temperature in front of the screw, either with an inserting thermometer or an integrated temperature sensor, is recommended.

Unreinforced Ultramid® is processed usually at mold temperatures of 40°C to 80°C. Reinforced Ultramid® grades require higher temperatures. In order to achieve good surface qualities and moldings meeting high requirements for hardness and strength, the surface temperatures of the mold cavities should be 80°C to 90°C, and in special cases 120°C to 140°C. An increase in the mold temperature may require a longer cooling time, which extends the cycle time.

Screw speed

If possible, the screw speed should be adjusted in order that the available time for plasticising within the molding cycle is fully utilised. For instance, a speed of 75 to 115 min⁻¹ (corresponding to a peripheral screw speed of 0.2 to 0.3 m/s) is often adequate for a 50 mm diameter screw. Too high screw speeds lead to temperature rises due to frictional heating. During the processing of glassfiber reinforced products a high screw speed may result in a shortening of the glass fibers.

Injection rate

The rate at which the mold is filled affects the quality of the moldings. Fast injection leads to equal solidification and a good quality of the surface, especially in the case of parts made of glass-fiber reinforced Ultramid®. However, a reduced injection speed can be used for very thick-walled molded parts to avoid an open jet.

Transmission cross beam

Exterior mirror base

Holding pressure

In order to prevent sink marks and voids, the holding pressure and the holding pressure time must be chosen to be sufficiently high so that the contraction in volume which occurs when the melt cools is largely compensated for. If the holding pressure is too high, it can cause internal stresses in the component or lead to demolding problems. In some cases, a stepwise reduced holding pressure can be an advantage.

Flow behavior

The flow behavior of plastic melts can be estimated through a spiral test using spiral molds on commercial injection molding machines. The flow path covered by the melt – the length of the spiral – is a measure of the flowability of the processed material.

The flow path distances of flow spirals of different thicknesses are shown in Table 7 for some Ultramid® grades. The relationship between the flow spiral length and the wall thickness produces the flow path-wall thickness ratio. This ratio allows a rough comparison of the flow properties of the different thermoplastics. However, it has to be considered that the flow properties depend on the mold design and the moisture content of the granulate as well as the processing conditions (particularly the temperatures). The Ultramid® range contains some grades with optimized flowability, which can cover longer flow paths at the same wall thickness e.g. Ultramid® High Speed.

Table 7: Flow behavior of different Ultramid® grades during injection molding

Shrinkage and aftershrinkage

ISO 294-4 defines the terms and test methods for shrinkage in processing. According to this, shrinkage is defined as the difference in the dimensions of the mold and those of the injection-molded part at room temperature. It results from the volumetric contraction of the melt in the injection mold due to cooling, change in the state of aggregation and crystallization.

Shrinkage is also affected by the geometry (free or impeded shrinkage) and the wall thickness of the molded part (Fig. 35). In addition, the position and size of the gate and the processing parameters (melt and mold temperature, holding pressure and holding pressure time together with the storage time and storage temperature) play an important role. The interaction of these various factors makes it difficult to predict the shrinkage of a part exactly.

Ultramid®	Melt temperature [°C]	Mold temperature [°C]	Molding shrinkage [%]		
			Testbox ¹⁾	Sheet ²⁾	
				crosswise	lengthwise

Table 8: Shrinkage behavior of different Ultramid® grades

¹⁾ Impeded shrinkage, see Fig. 36, x axis, line A, wall thickness 1.5 mm, holding pressure 800 bar

²⁾ Free shrinkage according to ISO 294-4, sheet 60 x 60 x 2 mm, internal mold pressure 500 bar

Fig. 35: Impeded shrinkage of Ultramid® as a function of wall thickness, test box, line A, holding pressure: 600 bar

Fig. 36: Shrinkage of Ultramid® A, B and T as a function of holding pressure, test box, line A, thickness: 1,5mm

The shrinkage values measured on plates 60 mm x 60 mm x 2 mm according to ISO 294 can be used to compare the shrinkage of different materials. The plaques injected with a film gate have the minimum and maximum shrinkage parallel and perpendicular to the flow direction because of the high orientation of the molecules and, particularly, the fibers. The value measured on the test box (Fig. 37) can be used as a guide for the average shrinkage in a real part since, here, the flow front tends to run radially from the injection point. Table 8 gives an overview of the shrinkage values of various Ultramid® grades.

Unreinforced polyamides generally shrink more than reinforced grades. Some processing conditions have a significant effect on dimensional stability, particularly in unreinforced products. These include the mold temperature, holding pressure and time. Nevertheless, the possible holding pressure range of a real part is usually limited, as a too low holding pressure can lead to sink marks and a too low holding pressure to demolding problems. However, the melt temperature generally has relatively little effect. The factors that may affect reinforced Ultramid® are limited by the processing parameters. Figures 36, 38 and 39 show shrinkage values of reinforced and unreinforced Ultramid® as a function of holding pressure, melt and mold temperature.

Fig. 37: Test box

Post-shrinkage means that the dimensions of the moldings may change slightly over time because internal stresses and orientations are dissipating and post-crystallization can take place depending on time and temperature. Whereas the post-crystallization is comparatively low at room temperature, at higher temperatures it can result in a possibly significant dimensional change. The process of post-shrinkage can be accelerated by annealing. High mold temperatures reduce the level of post-shrinkage and can therefore replace an additional annealing process (Fig. 39).

Moldings of glass-fiber reinforced products show a significant difference in the shrinkage perpendicular and parallel to the flow direction (shrinkage anisotropy). This is the result of the typical orientation of the glass fibers longitudinally to the flow direction (Fig. 40).

Fig. 38: Shrinkage of Ultramid® A and B as a function of melt temperature (test box, thickness: 1.5 mm)

Fig. 39: Shrinkage after storage in standard climate (23 °C, 50 % r.h.) and after heat-aging 20 h at 160 °C of Ultramid® A and B as a function of the mold temperature, test box, thickness: 1.5 mm

Warpage

Warpage in a molding is mainly caused by different shrinkages in flow direction and perpendicular. That is why parts made of glass-fiber reinforced materials tend more to warp than those made of unreinforced products. In addition, it depends on the shape of the moldings, the distribution of wall thicknesses and on the processing conditions.

In the case of unreinforced grades, different temperature control of individual parts of the mold (core and cavity) can allow the production of warp-free or low-warp molded parts. Thus, for example the warpage of housing parts to the inner side can be counteracted by low core and high cavity temperatures.

Mineral and glass bead-filled grades are characterized by largely isotropic shrinkage. They are therefore the preferred materials for molded parts with low warpage.

Fig. 40: Impeded shrinkage of different Ultramid® grades as a function of wall thickness, sheet measuring 110x110mm with a film gate and injection molded corners to impede deformation, holding pressure = 500 bar; perpendicular (⊥) and parallel (||) to the flow direction

Special processes

Multi-component technology

The combination of several materials in one molding has become firmly established in injection molding technology. Various Ultramid® grades are used here, depending on what component properties are required. The components must be matched to one another in respect of their processing and material properties. A lot of experience exists in relation to the way that different materials adhere to Ultramid®. Information can be obtained from the technical information "Rigid-flexible joints in injection molding technology".

Injection molding with fluid injection technology (FIT)

Fluid injection technology offers opportunities that are interesting from a technological and economic point of view for producing complex, (partially) thick-walled molded parts with hollows and functions that can be integrated. Typical FIT components made of Ultramid® are media lines in automobiles, handles, brackets and chairs.

After the melt has been injected, a fluid is used to eliminate any residual molten material. Depending on the application, the fluid used can be gas or water. With projectile injection technology, a fluid-driven projectile is used.

The fluid pressure applied internally can reduce the warpage of the component. Shorter cycle times can also be achieved because more heat is dissipated with water and the accumulation of melt is avoided. Other advantages are greater freedom of design and the opportunity to create components with high specific rigidity.

At present, the products used are primarily reinforced Ultramid® grades. Some Ultramid® grades are optimized for FIT; for example the hydrolysis-resistant Ultramid® A3HG6 WIT is particularly suitable for cooling water pipes, while other grades, e.g. Ultramid® B3WG6 GIT, allow particularly good surface qualities.

Coolant water pipe

Overmolding of inserts

Well known applications in which metal inserts are overmolded with Ultramid® include connecting elements such as shells or inserts and conductor paths or similar elements in control housings. These molded parts require a particularly good joint between the metal and plastic if they need to be resistant to media or are exposed to varying temperatures. The metal inserts should be pre-heated to 100°C to 150°C, but at least to mold temperature, before overmolding to prevent excessive internal stresses in the molded part. The metal parts must be grease-free and, where necessary, should have knurls, surrounding notches or similar elements for more fixing. Other metal pre-treatments such as structuring of the contact area, plasma nitriding or special coatings can also improve adhesion.

Chemical and physical foaming

The addition of chemical or physical blowing agents causes the melt to expand during the filling of the mold. Sink marks can be avoided even with large wall thicknesses. If necessary, it also allows the weight of the component to be reduced. In addition, the fill pressure is considerably reduced so that a machine with a lower clamping force can be used. Foamed components have lower warpage than compact injection molded components. However, it should be considered that the mechanical and the surface properties can be influenced in a negative way depending on the level of expansion. With selected Ultramid® grades from the range, good surfaces can be achieved, even with foam injection molding.

An experienced team of experts is available to answer questions about processing, processing methods and special processing methods. A well-equipped processing technology center can be used for research, development and project studies. The back injection molding of thermoplastic composites, multi-component injection molding, GID/WIT technology and processing of high-temperature thermoplastics are some of the special processes that are possible in our technical lab.

Rear axle transmission cross beam

Joining methods

Parts made of Ultramid® can be joined by a variety of different methods. These include the following in particular:

- Snapping together
- Screwing together with self-tapping metal screws
- Screwing together with threaded inserts
- Riveting
- Adhesive bonding
- Welding

Snap fittings can easily be integrated into Ultramid® plastic parts. Good flexibility over a large temperature range is particularly advantageous for this joining method.

Direct screw fixings and screw fixings with threaded inserts allow strong bonds to be formed between two Ultramid® parts and between Ultramid® parts and parts made of other materials.

Riveted joints are generally produced with integrated rivets. These can be softened by ultrasound, a hot riveting die, hot gas or a laser. A form closure is created by the subsequent molding of the rivet head.

All common adhesive systems are suitable for bonding Ultramid®. The complexity of the bonding process requires particular care to be taken when choosing the adhesive and pre-treating the parts.

Virtually all common methods can be used to weld Ultramid®:

- Friction welding (vibration and spin welding)
- Ultrasonic welding
- Laser beam welding
- Infrared welding
- Hot gas welding
- Heat impulse welding
- High frequency welding

These welding methods have their own specific advantages and disadvantages and require certain material properties. As the optimum weld geometry depends on the welding method used, the method should be chosen before the final design is drawn up.

With Ultrajoin™ and Ultratest™ BASF offers its customers extensive support: from the choice of the most suitable bonding technique to the design of the joint to the optimization of the joining process.

Machining

Semi-finished products made from Ultramid® can be processed with all commonly known tooling machines. As a general rule of guidance, one might use an adjusted feed rate and a high cutting speed. Additionally, tools should be checked for sufficient sharpness.

Marking and coating

Laser marking

Marking Ultramid® using lasers affords a series of advantages over conventional methods, particularly when there are tough requirements for permanence, flexibility and speed.

The following information is intended only to provide initial guidance. The Ultra-Infopoint will be happy to give more detailed advice on the choice of Ultramid® colors that are best suited to laser marking.

Nd-YAG lasers (wavelength 1064 nm)

Uncolored standard Ultramid® grades are practically impossible to mark with Nd-YAG lasers due to very low absorption of energy. This also applies to glass-fiber reinforced and mineral-filled grades. Better markability for Ultramid® grades can be achieved by using special additives. High-contrast lettering is obtained with certain black pigmentations.

Uncolored Ultramid® A3X grades can be marked with good contrast but not in customary black colors.

The Ultramid® LS range comprising unreinforced, reinforced and flameproofed grades was specially developed for marking using the Nd-YAG laser. The Ultra-Infopoint will be happy to send you an overview on request.

Nd-YAG lasers (wavelength 532 nm)

A frequency-doubled Nd-YAG laser can generally produce higher definition and higher contrast images on uncolored and brightly colored Ultramid® grades than a Nd-YAG laser with 1064 nm. There is no advantage in the case of black colors.

Excimer lasers (wavelength 175-483 nm)

Excimer lasers produce a higher definition and a better surface finish on Ultramid® than do Nd-YAG devices. Good results are achieved especially for bright colors.

CO₂ lasers (wavelength 10640 nm)

Uncolored and colored Ultramid® is practically impossible to mark with CO₂ lasers. At best there is only barely perceptible engraving of the surface without color change.

Laser marked test specimen

Printing

Printing on Ultramid® using conventional paper-printing methods requires no pretreatment. Injection-molded parts should be largely free of internal stresses and produced as far as possible without mold release agents, particularly those containing silicone. Special tried and tested inks are available for printing to Ultramid®.

Hot embossing

Ultramid® can be hot-embossed easily with suitable embossing foils.

Surface coating

Due to its outstanding resistance to most solvents, Ultramid® can be coated in one or more layers with various paints, which adhere well and have no adverse effects on mechanical properties. One- or two-component paints with binders matched to the substrate are suitable. Waterborne paints and primers can also be applied to Ultramid®. A mixture of isopropanol and water or other specific cleaning agents can be used for preliminary treatment. Industrial processes, such as preliminary treatment in automotive paint shops, are also suitable for cleaning. Coating based on electrostatics is only possible with what is known as a conductive primer as Ultramid® is not sufficiently conductive in its own right.

Metallizing

After proper pre-treatment, parts made of Ultramid® can be metallized galvanically or in a high vacuum. A flawless surface is achievable with both unreinforced as well as reinforced grades. Metallized parts made of Ultramid® are increasingly used in the sanitary, the electronics and automotive industries.

Conditioning

Ultramid® parts only achieve their optimum impact strength and largely constant dimensions after absorbing moisture. Conditioning, i.e. immersion in warm water or storage in warm, moist air, is used to increase the moisture content rapidly to 1.5 to 3 %, the equilibrium moisture content of normal moist air (see Fig. 22 and individual values in the Ultramid® range chart).

Practical conditioning method

Immersion in warm water at 40 °C to 90 °C is simple to carry out but it can result in water stains, deposits and, especially in the case of thin parts with internal stresses, in warpage. Additionally, in the case of the reinforced grades, the quality of the surface can be impaired. Furthermore, conditioning of A3X grades in a waterbath at higher temperatures is not recommended.

Accordingly, preference is generally given to the milder method of conditioning in humid air (e.g. at 40 °C and 90 % relative humidity or in 70/62 conditions for the accelerated conditioning of test specimens in accordance with ISO 1110). Here too, the temperature should not exceed about 40 °C for parts made from Ultramid® A3X.

The conditioning of molded parts affects their dimensional stability. Figure 41 shows the shrinkage values of test boxes made of Ultramid® A and B. The dimensions of the molded parts increase because of the absorption of moisture (less shrinkage). Processing unreinforced Ultramid® A3K at low mold temperatures causes two contrary processes to overlap: swelling due to the absorption of moisture and subsequent shrinkage caused by the tempering process.

Duration of conditioning

The time required for conditioning to the normal moisture content (SC23 °C/50 % r.h.) increases with the square of the wall thickness of the parts but decreases significantly with rising temperature. Table 9 contains the immersion times required for flat parts (sheets) of Ultramid® A and B as a function of the wall thickness and conditioning conditions, either in a moist climate or a water bath. Conditioning in a moist climate, e.g. at 40 °C/90 % r.h. is generally recommended as a thermally gentle conditioning climate.

The technical information "Conditioning Ultramid® moldings" provides further details.

Fig. 41: Influence of conditioning 40h at 70 °C 62 % r.h. on the shrinkage of Ultramid® A and B, test box, line A (fig 37), thickness: 1.5mm

Annealing

Annealing, e. g. by heat treatment for 12 to 24 hours (in air or in an annealing liquid at 140 °C to 170 °C) can largely remove the internal stresses that occur in thick-walled parts made from highly reinforced Ultramid® grades (e. g. Ultramid® A3EG7) or in extruded semi-finished parts.

Annealing also results in postcrystallization of incompletely crystallized injection-molded parts (produced with a cold mold). On the one hand this causes an increase in density, abrasion resistance, rigidity and hardness and on the other hand it gives rise to slight after-shrinkage and sometimes a small amount of warpage.

Ultramid®	Equilibrium moisture content atmosphere SC 23/50 [%] ¹⁾	Conditions		Thickness [mm]					
				1	2	4	6	8	10
A grades unreinforced glass-fiber reinforced mineral-filled	2.8	Water bath	40°C	6	31	110	240	480	670
			60°C	1,5	6	24	60	120	190

Table 9: Time in hours required for Ultramid® sheet to attain a moisture content corresponding to the equilibrium moisture content obtained in a standard atmosphere (23 °C/50 %)¹⁾ at storage of Ultramid® sheet in hot waterbath or in moist climate

¹⁾ Values for individual grades in SC 23/50 are given in the Ultramid® product range

²⁾ Used in ISO 1110- Polyamides- Accelerated conditioning of test specimens in SC 23/50

General information

Safety notes

Safety precautions during processing

As far as the processing is done under recommended conditions (see the product-specific processing data sheets), Ultramid® melts are thermally stable and do not give rise to hazards due to molecular degradation or the evolution of gases and vapors. Like all thermoplastic polymers, Ultramid® decomposes on exposure to excessive thermal load, e.g. when it is overheated or as a result of cleaning by burning off. In such cases gaseous decomposition products are formed. Further information can be found in the product-specific data sheets.

When Ultramid® is properly processed, no harmful vapors are produced in the area of the processing machinery.

In the event of incorrect processing, e.g. high thermal stresses and/or long residence times in the processing machine, there is the risk of elimination of pungent-smelling vapors which can be a hazard to health. Such a failure additionally becomes apparent due to brownish burn marks on the moldings. This is remedied by ejection of the machine contents into the open air and reducing the cylinder temperature at the same time. Rapid cooling of the damaged material, e.g. in a waterbath, reduces nuisances caused by odors.

In general, measures should be taken to ensure ventilation and venting of the work area, preferably by means of an extraction hood over the cylinder unit.

Dry sump oil pan

Food regulations

The grades in the Ultramid® range marked FC comply with the current legislation on plastics in contact with food in Europe and the USA. In addition, the conformity of these products is guaranteed by manufacturing in accordance with the GMP (Good Manufacturing Practice) Food Contact standard. If detailed information about the food approval status of a particular Ultramid® grade is required, please contact BASF directly (plastics.safety@basf.com). BASF will be happy to provide an up-to-date declaration of conformity based on the current legal regulations.

Available under the name FC Aqua® are Ultramid® grades which, in addition to being used in components in contact with food, also have different country-specific approvals for applications involving contact with drinking water. All plastics in the Aqua® range have the approvals in line with KTW¹⁾, DVGW²⁾, and WRAS³⁾ in cold-water applications, and a large proportion of them for warm and hot water, too. In order to make it easier for the finished components to be approved, BASF provides all the certificates required for Germany and Great Britain. If approvals from the ACS⁴⁾, the 5NSF⁵⁾ or other institutes are required, BASF assists by disclosing the formulation to the institutes. For questions regarding compliance with further regulations and certificates, please contact your local BASF representative or Plastics Safety (e-mail: plastics.safety@basf.com).

¹⁾ KTW: Kontakt mit Trinkwasser (Germany)

²⁾ DVGW: Deutscher Verein des Gas- und Wasserfachs (Germany)

³⁾ WRAS: Water Regulation Advisory Scheme (UK)

⁴⁾ ACS: Attestation de Conformité Sanitaire (France)

⁵⁾ NSF: National Sanitation Foundation (USA)

Sustainability

Responsible management of resources at BASF

BASF works with customers to provide sustainable products and solutions, which help it to achieve its sustainability targets and market differentiation. Technical plastics such as Ultramid® can be produced efficiently and save resources during the lifetime of the components. BASF has also set itself the objective of closing material cycles and making the best possible use of resources along the value chain. BASF is focusing on two approaches: biomass balance and ChemCycling.

In the biomass balance approach, some fossil raw materials are replaced by renewable raw materials in the first stage of the production process and then allocated to the corresponding product. These certified materials are obtained from various value chains, preferably from organic waste or byproducts. The method promotes the use of renewable raw materials, saves fossil resources and reduces greenhouse gas emissions. In the group as a whole, more than 20,000 customer products can be produced using the biomass balance approach.

In the ChemCycling project, BASF is following a new approach to recycling plastic waste. Partner companies use thermo-chemical processes to convert the waste into raw materials (e.g. pyrolysis oils) which are fed into the BASF group's production stream.

New chemical products are therefore created on the basis of recycled plastic waste, which are given the suffix 'Cycled'. Chemical recycling can help to reduce the amount of plastic waste sent to landfill sites or for thermal recycling. With chemical recycling we are helping our customers to produce products from recycled materials.

Both approaches have these advantages in common:

- Some fossil raw materials are replaced with renewable raw materials, obtained from biomass or raw materials produced from recycled plastic waste.
- The raw materials can be used in all BASF materials produced by the group. They can be used universally in end user products.
- The end product retains the same chemical composition and quality.
- The use of biomass and raw materials recovered from plastic waste saves CO₂.
- The mass balance process ensures that the renewable or recycled raw material is allocated correctly to the relevant BASF product.
- The ChemCycling or biomass balance products are certified by independent external institutions in accordance with the relevant standards.

BASF is working with customers to develop solutions for their sustainability requirements on the basis of these approaches.

Fig. 42: ChemCycling: from plastic waste to new products

Delivery and storage

Ultramid® is supplied as cylindrical or lenticular granules. The products are normally dried ready for processing and supplied in moisture-tight packaging.

Ultramid® is not classed as hazardous within the meaning of CLP Regulation (EC) no. 1272/2008 and is therefore not considered a dangerous good for transportation. Further information can be found in the product safety data sheets.

Ultramid® is classed as not hazardous to water. Standard packaging is 25 kg bags and 1,000 kg octabins; it can also be supplied in other types of packaging or in silo trucks by agreement. All containers are tightly sealed and should not be opened until immediately prior to use.

Storage and transport

Ultramid® can in principle be stored in dry, well-ventilated areas for some time without affecting the properties, but if it is stored for a prolonged period (>3 months for IBCs or >2 years in bags) or taken from opened containers, it is recommended to warm it first to eliminate any moisture. Containers stored in cold areas should be allowed to warm up before opening so in order for no condensation settling onto the granules. Please follow the instructions for storage given in the product safety data sheets.

Ultramid® is supplied in both colored and uncolored form. A number of products are available in shades of black. Individual grades can be supplied in a variety of shades upon request. With light colors, a color shift can occur (yellowing) after longer storage periods and depending on the storage conditions.

Exceptions: The H and W stabilized Ultramid® grades as well as Ultramid® A3X grades are exceptions which can only be supplied in black or natural because their natural color does not permit colored pigmentation to a specific shade. Other fillers, e.g. carbon fibers, can also affect the natural color.

Disposal

All Ultramid® grades can be incinerated in accordance with official regulations. The calorific value of unreinforced grades is 29,000 to 32,000 kJ/kg (Hu according to DIN 51900).

Flame-retardant grades of Ultramid® containing halogen must be disposed of as hazardous waste in line with the national waste disposal requirements and local regulations.

Recovery

Like other production wastes, sorted Ultramid® waste materials, e.g. ground up injection-molded parts and the like, can be fed back to a certain extent into processing depending on the grade and the demands placed on it. In order to produce defect-free injection-molded parts containing regenerated materials, the ground material must be clean and dry (drying is usually necessary). It is also essential that no thermal degradation has occurred in the preceding processing. The maximum permissible amount of regrind that can be added should be determined in trials. It depends on the grade of Ultramid®, the type of injection-molded part and on the requirements. The properties of the parts, e.g. impact and mechanical strength, and also processing behavior, such as flow properties, shrinkage and surface finish, can be markedly affected in some grades by even small amounts of reground material.

Front-end carrier

Integrated management system

QHSE management

Quality, health, safety and environmental management are key elements of BASF's corporate policy. Our primary aim is to become even better at identifying and fulfilling our customers' needs. The continuous improvement of our products and services in terms of quality, safety, environment and health is a fundamental element of this.

BASF's Performance Materials Europe business unit uses an integrated management system for the Ultramid® products certified according to the following standards

The business unit is recognized by an accredited certification company for its:

- ISO 9001 (Quality management system)
- IATF 16949 (Automobile industry quality management standard)
- ISO 14001 (Environment management system) and
- ISO 50001 (Energy management system) or EMAS.

Services

BASF is more than a manufacturer of raw materials, able to deliver innovative plastics on time and to the required quality. We support and advise our customers on sustainable developments in many different application areas with application-specific know-how, technical service and simulations. We also have well equipped technical departments which specialize in processing technologies, material and component testing.

Ultrasim®

Ultrasim® is BASF's comprehensive and flexible CAE expertise with innovative BASF plastics. The modern calculation of thermoplastic components is very demanding for the developer. When it comes to the interaction between manufacturing process, component geometry and material, only an integrated approach can lead to an ideal component. Plastics reinforced with short glass fibers in particular have anisotropic properties depending on how the fibers perform in injection molding. Modern optimization methods support the component design and can improve it in every phase of its development.

BASF's integrative simulation incorporates the manufacturing process of the plastic component into the calculation of its mechanical performance. This is provided by a completely new numerical description of the material which takes the properties typical of the plastic into account in the mechanical analysis. These properties include

- Anisotropy
- Non-linearity
- Dependence on strain rate
- Tension-compression asymmetry
- Failure performance
- Dependence on temperature.

The new Ultrasim® thermomechanics module can also be used to simulate temperature-dependent deformations under any temperature load and distribution. A separate module for simulating thermally conductive plastics completes the Ultrasim® modeling portfolio.

As seen, BASF is more than a raw material manufacturer supplying innovative plastics that meet delivery time and quality requirements. Ultrasim® adapts flexibly to meet individual customer requirements – for highly loadable efficient, lightweight parts and thus longterm market success.

Ultratest™ and Ultrajoin™

Ultratest™ represents the many different competences and activities which support our customers with component analysis and optimization through experimental methods.

Ultrajoin™ contains our comprehensive know-how and our unique infrastructure for bonding techniques.

Support, which is available worldwide, makes an important contribution in all phases of development – from the material, and application development through simulation to component analysis for series production.

If necessary, the extensive equipment can be adapted or new test set-ups can be developed to ensure that tests meet the customer-specific requirements. Live transmissions allow our customers to take part in the tests without having to be in the BASF laboratory.

The test options include e.g.:

- Temperature, temperature shock and climate tests, including in an inert atmosphere
- Chemical stability tests
- Quasi-static, dynamic and impact tests with external forces or internal pressures
- Vibration analyses, acoustic analyses
- Flow and leak tests
- Non-destructive testing with computer tomography
- Digital geometry, deformation and strain measurements
- Temperature field analyses with IR thermography
- Documentation of all transient processes with high-speed cameras
- Testing, evaluation and optimization of all relevant joining methods (see also Joining methods chapter)
- Laser transparency and laser markability analyses

Torque rod support

Nomenclature

Structure

The name of Ultramid® commercial products generally follows the scheme below:

Ultramid®	Subname	Technical ID	Suffixes	Color
-----------	---------	--------------	----------	-------

Subnames

Subnames are optionally used in order to particularly emphasize a product feature that is characteristic of part of a range.

Examples of subnames:

Endure	Particularly good long-term stabilization against hot air
Structure	Particularly good notched impact strength at low temperatures, and without any disadvantages for the stiffness and strength
Vision	Significantly increased translucence in the visible range
Advanced	Polyphthalamide
Deep Gloss	High-gloss with increased abrasion resistance and UV stability

Technical ID

The technical ID is made up of a series of letters and numbers which give hints about the polymer type, the melt viscosity, the stabilization, modification or special additives and the content of reinforcing agents, fillers or modifiers. The following classification scheme is found with most products:

B	3	E	2	G	6
Polymer type	Viscosity class	Type of stabilization or modification, special additives	Generation number (optional)	Type of reinforcing agent/filler	Content of reinforcing agent/filler or modifier

Ultramid® T generally has the following classification scheme:

T	KR	4	3	.	.	G	6
Polymer type						Type of reinforcing agent/filler	Content of reinforcing agent/filler or modifier

Letters for identifying polymer types

A	Polyamide 66
B	Polyamide 6
C	Copolyamide 66/6
D	Special polymer
N	Polyamide 9T
S	Polyamide 610
T	Copolyamide with 6T

Numbers for identifying viscosity classes

3	Free-flowing, low melt viscosity, mainly for injection molding
35	Low to medium viscosity
4	Medium viscosity

Letters for identifying stabilization

E, K	Stabilized, light natural color, increased heat-aging, weather and hot water resistance, electrical properties are not impaired
H	Stabilized, increased heat-aging, hot water and weather resistance only for engineering parts, electrical properties remain unaffected, depending on the grade light-beige to brown natural color
W	Stabilized, high resistance to heat-aging, can only be supplied uncolored and in black, less suitable if high demands are made on the electrical properties of the parts

Letters for identifying special additives

F	Functional additive
L	Impact-modified and stabilized, impact resistant when dry, easy flowing, for rapid processing
S	For rapid processing, very fine crystalline structure, for injection molding
U	With flame-retardant finish without red phosphorus
X	With red phosphorus as the flame-retardant finish
Z	Impact-modified and stabilized with very high low-temperature impact strength (unreinforced grades) or enhanced impact strength (reinforced grades)

Letters for identifying reinforcing agents/fillers

C	Carbon fibers
G	Glass fibers
K	Glass beads
M	Minerals
GM	Glass fibers in combination with minerals
GK	Glass fibers in combination with glass beads

Key numbers for describing the content of reinforcing agents/fillers or modifiers

2	approx. 10 % by mass
3	approx. 15 % by mass
4	approx. 20 % by mass
5	approx. 25 % by mass
6	approx. 30 % by mass
7	approx. 35 % by mass
8	approx. 40 % by mass
10	approx. 50 % by mass

In the case of combinations of glass fibers with minerals or glass beads, the respective contents are indicated by two numbers, e. g.

GM53	approx. 25 % by mass of glass fibers and approx. 15 % by mass of minerals
GK24	approx. 10 % by mass of glass fibers and approx. 20 % by mass of glass beads

M602 represents approx. 30% by mass of a special silicate (increased stiffness).

Suffixes

Suffixes are optionally used in order to indicate specific processing or application-related properties. They are frequently acronyms whose letters are derived from the English term.

Examples of suffixes:

Aqua®	Meets specific regulatory requirements for drinking water applications
Balance	Based at least partly on renewable raw materials
BM	Blow molding grade
CR	Crash Resistant
EQ	Electronic Quality
FC	Food Contact; meets specific regulatory requirements for applications in contact with food
GIT	Gas Injection Technology
GP	General Purpose
GPX	New Generation "General Purpose"
High Speed	High flowability of the melt
HP	High Productivity
HR	Hydrolysis Resistant, increased hydrolysis resistance
HRX	New generation of HR products
LDS	Laser Direct Structuring, for preparing the electroplating of electrical conductor tracks
LF	Long Fiber Reinforced
LS	Laser Sensitive, can be marked with Nd:YAG laser
LT	Laser Transparent, can be penetrated well with Nd:YAG lasers and lasers of a similar wavelength
SF	Structural Foaming
SI	Surface Improved, for parts with improved surface quality
ST	Super Tough
WIT	Water Injection Technology

Color

The color is generally made up of a color name and a color number.

Examples of color names:

Uncolored
Black 00464
Black 00564
Black 20560
