What I do not find in this essay is a clear conception of a "theoretical construct" or theoretical concept -- that is, a scientifically useful concept that does not have criteria of empirical application. Theoretical concepts in physics are thought to be "non-observational" -- that is, there are no direct criteria for applying the concept of a quark to a specific observable thing in a specific time-space location. Instead, theoretical terms are employed in theoretical hypotheses along with "bridge laws" that permit us to relate the theory to the range of observable evidence. The observation-theoretic distinction becomes a crucial one in later analytic philosophy of science; but it doesn't seem to be explicit here in Neurath's essay. (He does refer to the Newtonian concept of gravity; but he doesn't specifically describe the logic of this concept and how it relates to observation; 26.)

Neurath also advocates caution in the search for predictions about social behavior and social processes: "As social scientists, we have to expect gulfs and gaps everywhere, together with unpredictability, incompleteness, and one-sidedness of our arguing, wherever we may start" (27). He reinforces this point with a strikingly modern-sounding point about the non-linearity of social processes: a small deviation at one end can lead to a major deviation at the other end (28).

So the main elements of a logical empiricist philosophy of sociology are here, in the form of a number of prescriptions:

- logical specification of concepts
- specification of empirical criteria of application of concepts to observations
- description of social phenomena in terms of this conceptual system
- observational assessment of statements
- discovery of regularities among descriptive statements
- avoidance of claims of causation
- disregard of theoretical concepts

And these prescriptions, in turn, seem to lead to a particular model of sociology research -- one that appears to have guided the conduct of quantitative-statistical sociological research for several decades at mid-century. This is a variant of positivist philosophy of science that most strongly encourages general descriptive concepts, strong empirical procedures, and the discovery of statistical regularities among variables. It is what Andrew Abbott refers to as the "variables" paradigm.

Did the Vienna Circle view of the social sciences have any influence on working sociologists in the 1940s and 1950s? Or, more generally, did the writings of logical positivism influence the development of the methodologies and theories of sociology? One direct form of influence can be traced through the priority that behavioral scientists gave to "concept formation" and operationalizability -- for example, Carl Hempel's Fundamentals of Concept Formation in Empirical Science (International Encyclopedia of Unified Science, Vol 2 No 7) (1952) or P. W. Bridgman's The logic of modern physics (1927). The requirement of testability certainly recurs throughout much methodological writing by sociologists in the 1950s and 1960s. The insistence on discovering regularities among social facts plays directly into more sophisticated efforts to understand sociology as a statistical/quantitative science. The idea that the social sciences should avoid using "cause-effect" vocabulary seems to resonate with methodologists who insist that "we discover regularities but cannot assess causal relationships." So there does appear to be

a fairly high degree of fit between the views that Neurath advances concerning sociology, and the content of positivist sociological methodology a few decades later.

A final question is this: how should science and philosophy interrelate? Do philosophical findings about scientific method imply that the scientific enterprise needs to start over? In response to this question, the book closes with one of Neurath's most famous passages -- the description of what is now known as "Neurath's raft".

Imagine sailors who, far out at sea, transform the shape of their clumsy vessel from a more circular to a more fishlike one. They make use of some drifting timber, besides the timber of the old structure, to modify the skeleton and the hull of their vessel. But they cannot put the ship in dock in order to start from scratch. During their work they stay on the old structure and deal with heavy gales and thundering waves. In transforming their ship they take care that dangerous leakages do not occur. A new ship grows out of the old one, step by step -- and while they are still building, the sailors may already be thinking of a new structure, and they will not always agree with one another. The whole business will go on in a way we cannot even anticipate today. That is our fate. (47)

This is his metaphor for the reconstruction of the sciences along the lines of logical empiricism and terminological empiricism: gradual reconstruction of the enterprise while underway in the business of performing scientific research.

Neo-positivist philosophy of social science

Sunday, September 27, 2009

The 1960s witnessed the development of a second generation of analytic philosophy of science inspired broadly by logical positivism and the Vienna Circle (post, post). The "received view" of the 1950s and 1960s, as expressed by philosophers such as Carl Hempel, Ernest Nagel, and Israel Scheffler (and others pictured above), presented a view of scientific knowledge as consisting of theories, general laws, observational predictions, and a logic of confirmation according to which theories are evaluated by their observational consequences (Patrick Suppes, The Structure of Scientific Theories). There was a largely unquestioned assumption that all scientific theories have the same logical structure (the unity of science doctrine; post); so physics, economics, or evolutionary biology could equally be represented as a system of theoretical terms and statements, a set of general laws, and a set of observational or experimental consequences that can be empirically evaluated. Here is an illustration of the idea in the natural sciences; the black line is the theoretical calculation of ferromagnetic properties, and the colored lines are the observed behavior of metals under difference conditions.

This general view of the logic of scientific knowledge was applied to the social sciences by some philosophers of science, and the result was a neo-positivist philosophy of social

science. Richard Rudner was an important player in the formation of the received view in the 1960s, and he served as editor-in-chief of the core journal, Philosophy of Science, from 1959 to 1975. (His collected papers are held at Washington University, and the breadth of his correspondence gives some idea of his centrality in discussions of neo-positivist philosophy of science.) His 1966 textbook, Philosophy of social science, represents the high-water mark of neo-positivist philosophy of social science. So let's review the main features of Rudner's representation of social-scientific knowledge. (May Brodbeck's 1968 Readings in the Philosophy of the Social Sciences is a fairly direct complement to Rudner's book, in that it provides a fairly definitive representation of the philosophy of social science in the late 1960s.)

Several core assumptions about the social sciences are advanced in Rudner's book.

- unity of science and naturalism; all sciences should resemble physics
- emphasis on the distinction between the context of discovery and context of justification
- insistence on the symmetry of explanation and prediction
- insistence on the essential role of lawlike generalizations in explanation
- fundamental reliance on a strict distinction between observation and theory
- advancement of "formalizability" as a desirable characteristic of a theory

Here is Rudner's definition of a theory:

A theory is a systematically related set of statements, including some lawlike generalizations, that is empirically testable.... Accordingly, to the extent that a theory has been fully articulated in some formulation, it will achieve an explicit deductive development and interrelationship of the statements it encompasses. (10-11)

This formulation doesn't yet make explicit the notion that "theory" is non-observational, or that theoretical concepts lack direct criteria of application to observational experience. Rather, Rudner emphasizes the characteristic of formalizability and deductive consequences. And this takes him in the direction of non-observational concepts; they are the concepts that are introduced into a scientific system as formal "place-holders" without explicit definition. Instead, their meaning is determined by the deductive consequences that the sentences in which they appear give rise to. The intended analogy here is with the axioms of geometry; the concepts of "point," "line," and "plane" are introduced as primitives without further definition, and their meaning is defined simply by the role they play in the full deductive system of geometry. So, notably, Rudner treats the problem of theory formation in the sciences as entirely analogous to the problem of creating a formal mathematical system -- number theory or topology, for example. All concepts are either primitive -- introduced without definition; or defined -- introduced with strict logical definitions in terms of other concepts that already exist in the theoretical vocabulary. (It is interesting to note that Carl Hempel's contribution to the Vienna Circle International Encyclopedia of Unified Science is on this subject; Fundamentals of Concept Formation in Empirical Science (International Encyclopedia of Unified Science, Vol 2 No 7) .)

Notice how foreign this approach is to actual theoretical work by social scientists. Weber or Durkheim do not attempt to strip away "connotation" or ordinary associations from their theoretical concepts; rather, they make full use of the complexity and open-endedness of concepts like capitalism or solidarity as a way of allowing them to describe and theorize complex social realities. Rudner's approach seems to reflect the program of logical positivism, attempting to utilize the apparatus of formal logic to clarify scientific reasoning. But it misses the mark in application to the actual reasoning of path-breaking social thinkers such as Durkheim, Weber, Tocqueville, or Marx.

Rudner turns to the observation-theoretic distinction in short order. First, he describes observational concepts or predicates in these terms: "One set of primitives should be comprised of observational, or as we shall sometimes say, experimental terms (i.e., that such predicates should refer to observable features of the universe)" (21). And second, he introduces theoretical concepts: "The latter refer to nonobservable or nonmanifest characteristics of nonobservable entities. Thus, theoreticals include terms such as 'electron,' 'superego,' 'institutional inertia,' 'cultural lag,' which do not or are not (when the appropriate theories come to be formulated) likely to apply to observable entities at all" (23).

This is the standard view of the observation-theoretic distinction within the "received view" of neo-positivist philosophy of science. It was recognized that it is not possible to achieve the scientific goals of physics or chemistry if we are restricted to a purely observational vocabulary. We evidently need to refer to hypothetical entities and forces if we are to be able to explain observable phenomena. So hypothetical constructs must be permitted. But their "empirical content" is exhausted by their observational consequences.

Rudner attempts to provide a positivistic interpretation of Weber's concept of ideal types. He writes, "Our concern is with the logical character of idealizations and their methodological uses. In this latter respect, concepts that happen to be idealizations have, as we shall see, no special methodological role--regardless of the heuristic or suggestive value they may have in leading theorists to form hypotheses or frame theories about related phenomena" (56). This is a surprising exercise, since it involves the requirement that the social scientist provide a precise specification of the scope and implications of the term. I've always understood Weber's emphasis to be on the open-endedness of ideal-type concepts; and certainly Weber's use of ideal-type concepts did not remotely resemble the axiomatic, formalistic use that Rudner attributes to scientific concepts generally.

So what is the logic of scientific explanation in the social sciences, according to Rudner? His answer is straight from Hempel's covering law theory:

The formal structure of a scientific explanation of some particular event has three parts: first, a statement E describing the specific event to be explained; second, a set of statements C1 to Cn describing specific relevant circumstances that are antecedent to, or otherwise causally correlated with, the event described by E; third, a set of lawlike statements L1 to Ln, universal generalizations whose import is roughly 'Whenever events of the kind described by C1 through Cn take place, then an event of the kind described by E takes place.' (60)

Perhaps the key philosophical assumption that Rudner defends is the idea that the logic of science is everywhere the same. Concept formation, deduction, confirmation, and explanation all involve the same formalizable operations. A theory should be formalized

as a first-order deductive system with primitive terms and defined terms; some of its terms should have criteria of application to observable outcomes; explanation proceeds by deriving a description of the explanandum from the theory; and the theory should be tested by evaluating the truth or falsity of its observational consequences.

In addition to these extended discussions of the putative logic of social-science reasoning, Rudner also addresses the topics of "objectivity" in social-science research and the concepts of functionalism and teleology in the social sciences.

What are the strengths and weaknesses of this approach to the philosophy of the social sciences? The strength of the book is also its debilitating weakness: it is an exceptionally clear exposition and development of the central ideas of logical positivism in application to social-science theorizing. Unfortunately, this approach proves to be singularly unhelpful when it comes to actually understanding and criticizing the social sciences as they actually exist. It has the effect of attempting to force a style and form of reasoning onto social researchers that deforms the ways in which they attempt to theorize and explain the social world.

Key weaknesses include these points.

First, this formulation pays virtually no attention to the actual content and methods of existing social science disciplines. The foundational premise is that all sciences have the same fundamental logic. So it isn't necessary to examine sociology, political science, or economics in detail in order to trace out the particular characteristics of inquiry, explanation, and theory in these disciplines. Either the social-science disciplines conform to the received view, or they do not and for that reason show themselves to be defective as science. So the philosophy of a special science is simply the special case of the more general theory of scientific knowledge represented by the received view. This is a bad way of beginning the philosophical study of any science, whether the social sciences or the biological sciences.

Second, by highlighting the issues that are central to the exposition of the received view -- for example, the observation-theoretic distinction -- the neo-positivist philosopher of social science is drawn away from consideration of other, more substantive problems to which philosophers could make a useful contribution. For example, the assumptions of purposive rationality underlie many explanations in areas of political science and economics; and it turns out to be very productive to examine the intricacies that arise when we try to give a careful explanation of the concept of rationality and to link this assumption to particular areas of social explanation. The intellectual disposition created by the neo-positivist view is to reduce this question to a simple matter of "concept formation." "Rationality" becomes simply another theoretical construct to be introduced into scientific theories. But as Sen, Harsanyi, Margolis, and dozens of other philosophers and social scientists have demonstrated, we need to spend quite a bit of intellectual energy to the task of unpacking the theory of rationality if it is to be of use in the social sciences.

Third, this approach imposes an inappropriate simplification on the social sciences when it comes to empirical evaluation of social-science hypotheses. It presupposes the comprehensive generality of the hypothetico-deductive model of confirmation theory. Once again, the intellectual error derives from the assumption that the logic of scientific reasoning must be the same in every area of science. The social sciences sometimes involve the sorts of theoretical systems that are found in physics; but more commonly a

social science analysis is comprised of a number of relatively independent models and mechanisms -- theories of the middle range -- that are amenable to piecemeal evaluation. Social science analyses are not generally not unified theoretical systems along the lines of the theory of thermodynamics or genetics. And there are other ways of providing empirical evaluation and support for these sorts of analyses -- for example, process-tracing, piecemeal empirical evaluation, and applying the logic of comparative causal analysis.

In hindsight, the neo-positivist paradigm for analyzing the social sciences just didn't go very well. It pushed an esoteric theology of logical analysis onto the enterprise of understanding society that really didn't conform very well to the reasoning and explaining that talented sociologists, anthropologists, and political scientists were creating for themselves. And it did not succeed in focusing productive attention by philosophers on the difficult problems of theory construction and explanation that social scientists really confronted.

Alternative economists

Tuesday, September 29, 2009

Traditional neoclassical economics has missed the mark quite a bit in the past two years. There is the financial and banking crisis, of course; neoclassical economists haven't exactly succeeded in explaining or "post-dicting" the crisis and recession through which we've traveled over the past year and more. But perhaps more fundamentally, neoclassical economics has failed to provide a basis for understanding the nuance and range of our economic institutions -- nationally or globally. Contemporary academic economics selects a pretty narrow range of questions as being legitimate subjects for economists to study; so topics such as hunger, labor unions, alternative economic institutions, and the history of economic thought generally get fairly short shrift. Don't expect to see the perspectives of Steven Marglin or Samuel Bowles in Economics 101 in most U.S. universities! The profession has a pretty narrow conception of what "economics" is.

And yet, when intelligent citizens think about the key problems of economics in a broader sense -- the problems that we really care about, the problems that will really influence our quality of life -- we certainly think of something broader than the mathematics of supply and demand or the solution of a general equilibrium model. We're ultimately not as interested in the formalisms of market equilibrium as we are in an analysis of the institutions that define the context of economic activity. We want to know more about the ways in which features of economic organization and the basic institutions of our economy influence individual behavior; we are curious about how our institutions create distributive outcomes that fundamentally affect people's lives differently across social groups. We would like to have a clearer understanding of some of the ways that non-economic factors -- race, gender, age, city -- influence people's economic outcomes. We want to know how the institutions and incentives defined by our economic system bring about effects on the natural environment. And we are often curious about how it might be

possible to reform our basic economic institutions in ways that are more favorable to human development. In other words, we are often brought to think along the lines of some of the great dissenters in the economics tradition -- Polanyi, Dobb, Marx, Sen, McCloskey, and Dasgupta (An Inquiry into Well-Being and Destitution), for example. (In a very contemporary and topical way, Richard Florida takes on a lot of these issues; see his blog, the Creative Class.)

It is therefore pleasing to find that some publishers like Routledge are bringing out serious academic works in what they refer to as "social economics". The Routledge series, Advances in Social Economics, has a list of titles representing recent work that is rigorous and insightful but that explores other points of the compass within the field of political economy. I certainly hope that university libraries around the world are paying attention to this series; these are titles that can add a lot to the debate.

One book in the series in particular catches my eye. My colleague Bruce Pietrykowski raises an important set of "alternative" economic issues in his recent book, The Political Economy of Consumer Behavior: Contesting Consumption. (Here is a preview of the book from Routledge.) The book is a valuable contribution and very much worth reading.

Pietrykowski has two intertwined goals in the book. First, he wants to provide a broader basis for understanding ***consumer behavior and psychology*** than is presupposed by orthodox economists. And second, he wants to help contribute to a broader understanding of the scope, methods, and content of political economy than is provided by mainstream economics departments today.

Here is his preliminary statement of his goal:

I argue that in order to arrive at a more compelling account of consumer behavior we need to transform the discipline of economics by opening up the borders between economics and sociology, geography, feminist social theory, science studies and cultural studies. (2)

The fact of consumption is a crucial economic reality in any economy. How do individuals make choices about what and how to consume? Pietrykowski makes the point that consumption behavior shows enormous heterogeneity across groups defined in terms of ethnicity, gender, region, and time -- a point made here as well (post). So a single abstraction representing the universal consumer won't do the job. The standard economic assumption of the rationally self-interested consumer with consistent and complete preference rankings is seriously inadequate; instead, we need to develop a more nuanced set of views about the psychological and social factors that influence consumer preferences and choices.

So it is important to develop alternative theoretical tools in terms of which to analyze consumer psychology. Here Pietrykowski draws on ideas from Karl Marx (fetishism of commodities), Amartya Sen, and other political economists who have attempted to provide "thick" descriptions of economic behavior. The point here is not that we cannot usefully investigate and theorize about consumer behavior; rather, Pietrykowski is looking for an analytical approach that operates at the "middle range" between complete formal abstraction and the writing of many individual biographies.

Second, Pietrykowski is interested in contributing to a "re-mapping" of the knowledge system of economic thought, by exploring some of the alternative constructions that have

been bypassed by the profession since World War II. (These arguments are largely developed in Chapter Two.) Pietrykowski begins with the assumption that the discipline and profession of economics is itself socially constructed and contingent; it took shape in response to a fairly specific set of theoretical and methodological ideas, it was subject to a variety of social and political pressures, and there were viable alternatives at every turn. Here is how he formulates the social construction perspective:

> The claim that economic knowledge is socially constructed allows for an understanding of the field as the outcome of interpretation, negotiation and contestation over the constituents of economic knowledge and the legitimacy of particular practices, methods, and techniques of analysis. (19)

Like Marion Fourcade, Pietrykowski argues that there is a great deal of path dependence in the development of economics as a discipline and profession; and there are identifiable turning points where we can judge with confidence that themes that were eliminated at a certain time would have led to a substantially different intellectual system had they persisted. Pietrykowski's analysis of the fifty years of development of professional economics in the first half of the twentieth century is a very nice contribution to a contemporary history of science, and very compatible with Fourcade's important work in Economists and Societies: Discipline and Profession in the United States, Britain, and France, 1890s to 1990s.

The discipline of "home economics" in the 1920s and 1930s is the example that Pietrykowski examines in detail. "This task ... of defining economics as a distinct professional discipline involved both recruitment and exclusion" (28). Here is how Pietrykowski describes home economics:

> Departments of home economics were quite diverse in the early twentieth century. Commonly associated with maintaining and preserving the cult of domesticity, home economics programs emerged from multiple sources including progressive political reform of public health, labor conditions, and household management. (35)

And, of course, home economics did not long remain a part of the professional discipline of economics. Pietrykowski looks in detail at the way in which home economics developed as an academic discipline at Cornell University; and he documents some ways in which the discipline of economics was constructed in a gendered way to exclude this way of understanding scientific economics: "The decision was made that women involved in the emerging field of home economics were to be excluded from the AEA.... Economics was to be concerned neither with women's activities in the home nor with women's activities in the workplace" (28-29).

Pietrykowski develops his full analysis of consumption by focusing on three heterodox approaches to understanding consumption: home economics and feminist analysis, psychological and behavioral research on consumer behavior (George Katona), and Fordism and the theory of mass consumption. He also gives some attention to the emerging importance of experimental economics as a tool for better understanding real economic decision-making and behavior (20-25).

After discussing these heterodox theories, Pietrykowski illustrates the value of the broader framework by examining three fascinating cases of consumption: the complex motivations that bring consumers to purchase the Toyota Prius, the motivations behind the Slow Food movement, and the choice that people in some communities have to engage in a system of alternative currency. These are each substantial examples of arenas where consumers are choosing products in ways that make it plain that their

choices are influenced by culture, values, and commitments no less than calculations of utilities and preferences.

Between the theories and the cases, Pietrykowski offers a remarkably rich rethinking of how people choose to consume. He makes real sense of the idea that consumption is socially constructed (drawing sometimes on the social construction of technology (SCOT) literature). He demonstrates that models based on the theory of the universal consumer are not likely to fit well with actual economic outcomes. And he makes a strong and persuasive case for the need for academic economics to expand its horizons.

I find it interesting to notice that Pietrykowski's account of the ascendency of neoclassical economics since the 1950s converges closely with prior postings on positivist philosophy of science. One of the explicit appeals made by neoclassical economists was a methodological argument: they argued that their deductive, formal, and axiomatic treatments of economic fundamentals were more "scientific" than case studies and thick descriptions of economic behavior. So many of the failings of mainstream economic thought today can be traced to the shortcomings of the positivist program for the social sciences that was articulated in the middle of the twentieth century.

A Michigan job loss tsunami

Wednesday, September 30, 2009

The whole country knows that unemployment is very high in Michigan, and most people also know that the automotive manufacturing industry has taken a nose dive in the past five years. But the situation is even worse than most people imagine. Bureau of Labor statistics indicate several important facts. In 2000 the total private sector employment in the United States was 110,798,000; by August 2009 this number had dropped to 109,540,000 -- a net loss of 1,258,000 jobs nation-wide. This is a 1.1% drop. In 2000 the number of private sector jobs in Michigan was 3,996,000; this number dropped to 3,213,000 by August 2009 -- a drop of 783,000 jobs (19.6%). This is a shocking number -- one out of five jobs in Michigan has disappeared since 2000.

Other Midwestern manufacturing states also had significant job losses during the period. Ohio lost 9.8% of its 4,840,000 jobs since 2000, and Illinois lost 6.6% of its 5,205,000 jobs since 2000. But Michigan's losses dwarf every other state by a large margin. Among the fifty states and the District of Columbia there were winners and losers; 25 states gained private sector jobs during these years, with Texas the big winner (700,000 new jobs). Altogether 1,952,000 new jobs were created in 25 states and 3,207,000 jobs were lost in 25 states and DC. But consider this: fully 24% of all private sector job losses nation-wide occurred in Michigan during this time period. Think of that: one out of four of all private-sector job losses in the country during these years occurred in one state, Michigan. This could reasonably be called a one-state depression. It is as if a slow-moving Katrina had hit the state, and no one noticed.

So what is needed in order for Michigan to regain its economic wellbeing?

Plainly a 20-30% unemployment rate is unacceptable. So if the state maintains its current population, then the communities, businesses, and government of the state need to stimulate substantial job growth. And we can put some numbers on this obvious truth. If the population remains constant then it would take eight years for the state to recover to the 2000 level if jobs grow at 3% per year. And this would require the creation of about 100,000 new private sector jobs each year.

What would be needed in order to get to 100,000 new jobs per year in Michigan? Here is one pathway: succeed in attracting or creating --

- two large firms of 5,000 workers,
- 10 firms of 1000 workers,
- 50 firms of 500 workers,
- 400 firms of 100 workers,
- 1500 small businesses of 10 workers, and
- 2000 small businesses that expand by three workers.

That gets us to 106,000 new jobs. And it means creating or attracting two large firms, almost 2,000 small and medium businesses, and expanding another 2,000 small businesses. And this needs to happen every year for eight years.

Is this feasible? Is it possible for a state of about 10 million people to create new businesses and jobs on this scale? That is the crucial question for the state of Michigan. And there are many organizations and incubators devoted to this goal in the state of Michigan -- Ann Arbor SPARK, TechTown, Automation Alley, Detroit Renaissance, Michigan Economic Development Corporation, and the Detroit Regional Chamber, to name a few. Further, the universities are doing everything possible to help provide the talented graduates and the new innovations that will be needed for the creation of successful new businesses. But ultimately it is very hard to see how this kind of business creation and job growth can occur year after year.

So Michigan's problem is also a crucial challenge for the nation as a whole. The plain truth is that Michigan has born the largest burden of the decline of manufacturing jobs in the past decade, and the solutions may be beyond the grasp of the state itself. This situation may require intelligent and substantial Federal solutions.

Internal migration

Friday, October 02, 2009

People move around in most modern societies. Recent graduates of most universities often compete in national job markets, and large engineering, accounting, and consulting firms recruit at elite universities throughout the country. So there is a certain amount of location churning created by the need for talent that draws talented young people from one region to another. (In fact, it would be interesting to try to quantify this fact of

geographical mobility: for example, what percentage of college graduates from New York or Florida take their first job in another state or economic region?)

But this kind of career-based mobility isn't quite what we mean when we refer to internal migration. Intuitively, we mean significant numbers of people relocating from their home region to another region for economic reasons. Internal migration leads to enduring population shifts across regions of the country.

We've seen periods of this kind of population relocation several times in our own history: the westward movement from the east coast of poor and working people in the mid-nineteenth century, the mass migration of African-Americans from the rural south to northern cities in the 1920s, and the exodus of the Tom Joad family and their generation from Oklahoma to California in the 1930s. We might even put the flow of people from Michigan to the sunbelt in the 1980s into this category, and perhaps the displacement of poor people from New Orleans by Katrina and its aftermath reaches the threshold as well.

So here is my question for the moment: is the United States on the verge of another period of significant internal migration, as workers downsized in Detroit or Akron make the painful decision to relocate in Houston or Phoenix? Are we about to see a significant shift of population from the rustbelt to the sunbelt? And what consequences would this have for Illinois, Ohio, or Michigan?

Think about the situation that faces young people in these states today. What is the best strategy for 25-year-olds in Akron or Detroit? One is to maximize their twenty-first century source of wealth and well-being -- their education and talent levels. But the second is to relocate to a place where there are the largest number of economic opportunities available to them at their existing levels of skills. And today that means a certain number of cities and much of the sunbelt. Chicago looks good, Houston looks good, and maybe Salt Lake City looks good.

If these are the primary choices available to young people in the industrial midwest, what should we expect about their behavior? And what consequences do these incentives give rise to? First, this situation seems to imply a surge in university enrollments (a good thing); rationally, we would imagine that young people would invest their time, energy, and resources towards getting a good education. But second, these considerations also seem to imply a surge in out-migration to more dynamic regions once it becomes clear that current conditions are likely to persist (a bad thing). So current economic conditions in the midwest seem to increase the chances that significant internal migration will occur in the next few years.

One way of thinking about the likelihood of significant population movement from one economic region to another is to consider the economic capacity of a state or region to support a certain level of income for a given population size. Industrial states in the Midwest were strong economic engines in the 1950s through the 1980s. Steel, cars, and chemicals generated a great deal of revenue every year, and this supported a large and relatively prosperous population. But two things happened: these industries were forced

into lower costs and higher productivity -- so the demand for labor fell even when demand for cars remained high. And global competitors appeared on the scene to capture part of the market for these products -- reducing even further the demand for labor. Moreover, both processes led to a premium on skilled labor, thus further reducing the demand for one segment of the workforce.

There is an important implication here: it seems to imply that the basis for a high quality of life for 10 million people in Michigan or Ohio has basically disappeared. If technology and market conditions don't change, then Michigan and Ohio will either lose population or adjust to a permanently reduced standard of living.

We would prefer to believe that we'll find a way out of the box. But looking at things dispassionately, what seems equally likely is a restructuring of population around the new realities of America's economic macroregions. (Texas alone gained 700,000 jobs during the period of 2000-2009.) And this would mean large-scale internal migration, with a "right-sizing" of the population sizes of states and regions around their current economic capacities. (Basically, this is the central theorem of the theory of labor markets: we should expect migration from one region to another up to the point where employment prospects and wages are equal in the two regions.) For Michigan this might imply a loss of population of one or two million people, as workers and their families seek to improve their prospects. Moreover, there is a great risk that among the first to go will be the best educated and most innovative young people; these are the people who have the greatest options throughout the national labor market. And they are precisely the people who will be needed if Michigan or Ohio are to succeed in nurturing a "New Economy."

This scale of internal migration would have enormous consequences on both ends. Communities would be significantly disrupted, as families exit their locations in the social networks of their local communities. This magnitude of loss of population would mean a shift of political representation; for example, Michigan would lose roughly 10-20% of its Congressional seats (depending on the population results for the rest of the country). Michigan's public schools, community colleges, and universities would lose a significant number of students and would need to downsize. The state's fiscal equation would change on both expenditures and revenues. Tax revenues would fall as a result of fewer taxpayers, less business activity, and less aggregate demand and sales tax revenue. But the volume and cost of public services would also fall. So managing change and rationalizing the delivery of public services could actually improve the state's fiscal situation. The ultimate result would be a fundamental transformation of the cultural and social life of the state -- and not in a direction that most people would willingly choose.

Is this just a worst-case scenario? Maybe not. Here is a well researched Detroit News story by Ron French and Mike Wilkinson in April 2009. The story estimates that Michigan has lost 465,000 people since 2001 -- and the number continues to rise. Moreover, French and Wilkinson offer data that confirm that there is a disproportionate number of talented, skilled professionals in the mix -- with substantial costs to the Michigan economy with their departure. Ohio State University economist Mark Partridge is quoted in the article in these words (webpage):

Migration is good for the migrants but bad for the state they're leaving. It's a vicious downward cycle; the best and brightest leave; entrepreneurs don't come to the state because the best and brightest are elsewhere; as more people leave, that leaves fewer people to pay for services. Neither one will make Michigan a very appealing place.
There is a happier alternative, of course -- the creation of a New Economy for the

rustbelt. This is what governors like Jennifer Granholm in Michigan and Ted Strickland in Ohio are advocating. Elected officials, economic development experts, and business leaders call for the creation of new and diversified industries for the rustbelt economy. Some experts and politicians point to a new green economy based on alternative energy technologies; others point to the prosperity possible by producing and selling innovations in biological and medical products. And yet others pin their hopes on the encouragement of large numbers of innovative, nimble companies that generate wealth, jobs, and prosperity. Let's hope that some of these strategies will succeed on a large scale. But, as noted in an earlier posting, the challenge is a great one. New economic activities need to create a hundred thousand jobs a year if we are to recover the ground we've lost in Michigan. And that is a large number.

Kuhn's paradigm shift

Sunday, October 04, 2009

Thomas Kuhn's The Structure of Scientific Revolutions (1962) brought about a paradigm shift of its own, in the way that philosophers thought about science. The book was published in the Vienna Circle's International Encyclopedia of Unified Science in 1962. (See earlier posts on the Vienna Circle; post, post.) And almost immediately it stimulated a profound change in the fundamental questions that defined the philosophy of science. For one thing, it shifted the focus from the context of justification to the context of discovery. It legitimated the introduction of the study of the history of science into the philosophy of science -- and thereby also legitimated the perspective of sociological study of the actual practices of science. And it cast into doubt the most fundamental assumptions of positivism as a theory of how the science enterprise actually works.

And yet it also preserved an epistemological perspective. Kuhn forced us to ask questions about truth, justification, and conceptual discovery -- even as he provided a basis for being skeptical about the stronger claims for scientific rationality by positivists like Reichenbach and Carnap. And the framework threatened to lead to a kind of cognitive relativism: "truth" is relative to a set of extra-rational conventions of conceptual scheme and interpretation of data.

The main threads of Kuhn's approach to science are well known. Science really gets underway when a scientific tradition has succeeded on formulating a paradigm. A paradigm includes a diverse set of elements -- conceptual schemes, research techniques, bodies of accepted data and theory, and embedded criteria and processes for the validation of results. Paradigms are not subject to testing or justification; in fact, empirical procedures are embedded within paradigms. Paradigms are in some ways incommensurable -- Kuhn alluded to gestalt psychology to capture the idea that a paradigm structures our perceptions of the world. There are no crucial experiments -- instead, anomalies accumulate and eventually the advocates of an old paradigm die out and leave the field to practitioners of a new paradigm. Like Polanyi, Kuhn emphasizes the

concrete practical knowledge that is a fundamental component of scientific education (post). By learning to use the instruments and perform the experiments, the budding scientist learns to see the world in a paradigm-specific way. (Alexander Bird provides a good essay on Kuhn in the *Stanford Encyclopedia of Philosophy*.)

A couple of questions are particularly interesting today, approaching fifty years after the writing of the book. One is the question of origins: where did Kuhn's basic intuitions come from? Was the idea of a paradigm a bolt from the blue, or was there a comprehensible line of intellectual development that led to it? There certainly was a strong tradition of study of the history of science from the late nineteenth to the twentieth century; but Kuhn was the first to bring this tradition into explicit dialogue with the philosophy of science. Henri Poincaré (The Foundations of Science: Science and Hypothesis, The Value of Science, Science and Methods) and Pierre Duhem (The Aim and Structure of Physical Theory) are examples of thinkers who brought a knowledge of the history of science into their thinking about the logic of science. And Alexandre Koyré's studies of Galileo are relevant too (From the Closed World to the Infinite Universe); Koyré made plain the "revolutionary" character of Galileo's thought within the history of science. However, it appears that Kuhn's understanding of the history of science took shape through his own efforts to make sense of important episodes in the history of science while teaching in the General Education in Science curriculum at Harvard, rather than building on prior traditions.

Another question arises from the fact of its surprising publication in the Encyclopedia. The Encyclopedia project was a fundamental and deliberate expression of logical positivism. Structure of Scientific Revolutions, on the other hand, became one of the founding texts of anti-positivism. And this was apparent in the book from the start. So how did it come to be published here? (Michael Friedman takes up this subject in detail in "Kuhn and Logical Positivism" in Thomas Nickles, Thomas Kuhn (link).) George Reisch and Brazilian philosopher J. C. P. Oliveira address exactly this question. Oliveira offers an interesting discussion of the relationship between Kuhn and Carnap in an online article. He quotes crucial letters from Carnap to Kuhn in 1960 and 1962 about the publication of SSR in the Encyclopedia series. Carnap writes,

I believe that the planned monograph will be a valuable contri-bution to the Encyclopedia. I am myself very much interested in the problems which you intend to deal with, even though my knowledge of the history of science is rather fragmentary. Among many other items I liked your emphasis on the new conceptual frameworks which are proposed in revolutions in science, and, on their basis, the posing of new questions, not only answers to old problems. (REISCH 1991, p. 266)
I am convinced that your ideas will be very stimulating for all those who are interested in the nature of scientific theories and especially the causes and forms of their changes. I found very illuminating the parallel you draw with Darwinian evolution: just as Darwin gave up the earlier idea that the evolution was directed towards a predeter-mined goal, men as the perfect organism, and saw it as a process of improvement by natural selection, you emphasize that the develop-ment of theories is not directed toward the perfect true theory, but is a process of improvement of an instrument. In my own work on in-ductive logic in recent years I have come to a similar idea: that my work and that of a few friends in the step for step solution of prob-lems should not be regarded as leading to “the ideal system”, but rather as a step for step improvement of an instrument. Before I read your manuscript I would not have put it in just those words. But your formulations and clarifications by examples and also your analogy with Darwin’s theory helped me to see clearer what I had in mind. From September on I shall be for a year at the Stanford

Center. I hope that we shall have an opportunity to get together and talk about problems of common interest. (REISCH 1991, pp.266-267)

Against what Oliveira calls "revisionist" historians of the philosophy of science, Oliveira does not believe that SSR was accepted for publication by Carnap because Carnap or other late Vienna School philosophers believed there was a significant degree of agreement between Kuhn and Carnap. Instead, he argues that the Encyclopedia group believed that the history of science was an entirely separate subject from the philosophy of science. It was a valid subject of investigation, but had nothing to do with the logic of science. Oliveira writes,

Thus, the publication of Structure in Encyclopedia could be justified merely by the fact that the Encyclopedia project had already reserved space for it. Indeed, it is worth pointing out that the editors commissioned Kuhn's book as a work in history of science especially for publication in the Encyclopedia.

Also interesting is to consider where Kuhn's ideas went from here. How much influence did the theory have within philosophy? Certainly Kuhn had vast influence within the next generation of anti-positivist or post-positivist philosophy of science. And he had influence in fields very remote from philosophy as well. Paul Feyerabend was directly exposed to Kuhn at UCLA and picks up the anti-positivist thread in Against Method. Imre Lakatos introduces important alternatives to the concept of paradigm with his concept of a scientific research programme. Lakatos makes an effort to reintroduce rational standards into the task of paradigm choice through his idea of progressive problem shifts (The Methodology of Scientific Research Programmes: Volume 1: Philosophical Papers). An important volume involving Kuhn, Feyerabend, and Lakatos came directly out of a conference focused on Kuhn's work (Criticism and the Growth of Knowledge: Volume 4: Proceedings of the International Colloquium in the Philosophy of Science, London, 1965). Kuhn's ideas have had a very wide exposure within the philosophy of science; but as Alexander Bird notes in his essay in the *Stanford Encyclopedia of Philosophy*, there has not emerged a "school" of Kuhnian philosophy of science.

From the perspective of a half century, some of the most enduring questions raised by Kuhn are these:

- What does the detailed study of the history of science tell us about scientific rationality?
- To what extent is it true that scientific training inculcates adherence to a conceptual scheme and approach to the world that the scientist simply can't critically evaluate?
- Does the concept of a scientific paradigm apply to other fields of knowledge? Do sociologists or art historians have paradigms in Kuhn's strong sense?
- Is there a meta-theory of scientific rationality that permits scientists and philosophers to critically examine alternative paradigms?
- And for the social sciences -- are Marxism, verstehen theory, or Parsonian sociology paradigms in the strong Kuhnian sense?

Perhaps the strongest legacy is this: Kuhn's work provides a compelling basis for thinking that we can do the philosophy of science best when we consider the real epistemic practices of working scientists carefully and critically. The history and sociology of science is indeed relevant to the epistemic concerns of the philosophy of science. And this is especially true in the case of the social sciences.

Technology innovation in Chinese agriculture

Tuesday, October 06, 2009

醫藥鏡合序
竊聞澤物之謂仁辨物之謂智
二者相分若蓬與楹然欲行澤
物之事必先施辨物之材故日
月照臨品彙昭蘇水火澄灼古

It is a commonplace in world history to observe that China had achieved a high level of sophistication in science, medicine, and astronomy by the Middle Ages, but that some unknown feature of social organization or culture blocked the further development of this science into the expansion of technology in the early modern period. Chinese culture was "blocked" from making significant technological advances during the late Ming and early Qing periods -- in spite of its scientific advantage over the West in medieval times; or so it is believed in a standard version of Chinese economic history.

A variety of hypotheses have been offered to account for this supposed fact. For example, Mark Elvin argues that China's social and demographic system created conditions for a "high-level equilibrium trap" in the early modern period in The Pattern of the Chinese Past. According to Elvin, Chinese social arrangements favored population growth; innovative and resourceful farmers discovered all feasible refinements of traditional agricultural techniques to refine a highly labor-intensive system of agriculture; and population expanded to the point where the whole population was at roughly the subsistence level while consuming virtually the whole of the agricultural product. There was consequently no social surplus that might have been used to invest in discovery of major innovations in agricultural technology; so the civilization was trapped. (Here is a more developed discussion of Elvin's argument.)

Other historians have speculated about potential features of Confucian culture that might have blocked the transition from scientific knowledge to technology applications. The leading Western expert on Chinese science is Joseph Needham (1900-1995), whose multi-volume studies on Chinese science set the standard in this area (Science and Civilisation in China. Volume 1: Introductory Orientations; Clerks and Craftsmen in China and the West). And Needham attributes China's failure to continue to make scientific progress to features of its traditional culture.

But here is a more fundamental question: is the received wisdom in fact true? Was Chinese technology unusually stagnant during the early-modern period (late Ming, early Qing)? Agriculture is a particularly important aspect of traditional economic life; so we might reformulate our question a bit more specifically: what was the status of agricultural technology in the seventeenth and eighteenth centuries (late Ming, early Qing)? (See an earlier posting on Chinese agricultural history for more on this subject.)

Economic historian Bozhong Li considers this question with respect to the agriculture of the lower Yangzi Delta in Agricultural Development in Jiangnan, 1620-1850. And since this was the most important agricultural region in China for centuries, his findings are important. (It was also the major cultural center of China; see the concentration of literati in the map above.) Li makes an important point about technological innovation by distinguishing between invention and dissemination. An important innovation may be discovered in one time period but only adopted and disseminated over a wide territory much later. And the economic effects of the innovation only take hold when there is broad dissemination. This was true for Chinese agriculture during the Ming period, according to Li:

The revolutionary advance in Jiangnan rice agriculture technology appeared in the late Tang and led to the emergence and development of intensive agriculture composed of double-cropping rice and wheat. But this kind of intensive agriculture in pre-Ming times was largely limited to the high-fields of western Jiangnan. In the Ming this pattern developed into what Kitada has called the 'new double-cropping system' and spread throughout Jiangnan, but only in the late Ming did it become a leading crop regime. Similar were the development and spread of mulberry and cotton farming technologies, though they were limited to particular areas and cotton technology's advances came later because cotton was introduced later. Each had its major advances in the Ming. Therefore, technology advances in Ming Jiangnan agriculture were certainly not inferior to those of Song times which are looked at as a period of 'farming revolution'. (40)

Li also finds that there was a significant increase in the number of crop varieties in the early Qing -- another indication of technological development. He observes, "The later the date, the greater the number of varieties. For example, in the two prefectures of Suzhou and Changzhou, 46 varieties were found in the Song, but the number rose to 118 in the Ming and 259 in the Qing" (40). And this proliferation of varieties permitted farmers to adjust their crop to local soil, water, and climate conditions -- thus increasing the output of the crop per unit of land. Moreover, formal knowledge of the properties of the main varieties increased from Ming to Qing periods; "By the mid-Qing, the concept of 'early' rice had become clear and exact, and knowledge of 'intermediate' and 'late' strains had also deepened" (42). This knowledge is important, because it indicates an ability to codify the match between the variety to the local farming environment.

Another important process of technology change in agriculture had to do with fertilizer use. Here again Li finds that there was significant enhancement, discovery, and dissemination of new uses of fertilizer in the Ming-Qing period.

A great advance in fertilizer use took place in Jiangnan during the early and mid-Qing, an advance so significant that it can be called a 'fertilizer revolution'. The advance included three aspects: (a) an improvement in fertilizer application techniques, centring on the use of top dressing; (b) progress in the processing of traditional fertilizer; and (c) an introduction of a new kind of fertilizer, oilcake. Although all three advances began to appear in the Ming, they were not widespread until the Qing. (46)

And the discovery of oilcake was very important to the increases in land productivity that Qing agriculture witnessed -- thus permitting a constant or slightly rising standard of living during a period of some population increase.

There were also advances in the use of water resources. Raising fish in ponds, for example, became an important farming activity in the late Ming period, and pond fish

became a widely commercialized product in the Qing. Li describes large-scale fishing operations in Lake Tai in Jiangnan using large fishing boats with six masts to catch and transport the fish (62).

So Li's estimate of agricultural technology during the Ming period is that it was not stagnant; rather, there was significant diffusion of new crops, rotation systems, and fertilizers that led to significant increases in agricultural product during the period. "In sum, in the Jiangnan plain, land and water resources were used more rationally and fully in the early and mid-Qing than they had been in the late Ming" (64).

Two points emerge from this discussion. First, Li's account does in fact succeed in documenting a variety of knowledge-based changes in agricultural practices and techniques that led to rising productivity during the Ming-Qing period in Jiangnan. So the stereotype of "stagnant Chinese technology" does not serve us well. Second, though, what Li does not find is what we might call "science-based" technology change: for example, the discovery of chemical fertilizer, controlled experiments in rice breeding, or the use of machinery in irrigation. The innovations that he describes appear to be a combination of local adaptation and diffusion of discoveries across a broad territory.

So perhaps the question posed at the start still remains: what stood in the way of development of empirical sciences like chemistry or mechanics that would have supported science-based technological innovations in the early modern period in China?

Rebuilding employment

Friday, October 09, 2009

The Federal Reserve Bank of Chicago hosted a two-day conference in Detroit this week on the subject of work force adjustment (link). It was convened by the Federal Reserve Bank, the W. E. Upjohn Institute for Employment Research, and the Brookings Institution Metropolitan Policy Program. This is one of the many efforts underway to attempt to address the unemployment crisis we now face in the industrial Midwest. Participants included state and federal jobs officials, foundation leaders, and a few academic specialists.

Are there strategies that a region can pursue that will result in significant jobs creation? To grow employment in a region there are only a couple of possibilities: to expand employment in existing companies, to stimulate the creation of new businesses, and to recruit relocation of existing businesses from other regions. In each case the business owner or entrepreneur needs to be confident that he/she can add marginal revenue to the company by hiring the additional worker. This requires that the worker has knowledge and skills whose use will contribute to a saleable product. The product needs to have features of quality and utility that consumers want. Finding the workers who have the right kinds of talent, skill, and knowledge is a key challenge for the business owner. And availability of talented prospective workers is a key aspect of the company's decision to locate or grow in the region.

So what options do these pathways suggest for policy intervention to increase employment? It might be the case that there is latent labor demand out there in existing industries, where employers would hire more workers if they could find people with the right qualifications. In this case, remedial and transformative training could lead to new jobs, shifting workers from old industries to new industries. Second, there may be identified areas of potential expansion of employment where there are specific skills missing in the workforce. Maybe specialized bakeries could sell more products if they could only hire more qualified pastry chefs. Here too it is credible that we could devise specialized training programs that fill in the missing skills. There are specific community college programs that were developed for this reason, responding to the specialized needs of existing employers. But third, we can imagine a region preparing itself for a new surge of business creation and job growth in new industries and sectors. And this requires raising the number of college-educated adults in the region. This constitutes a talent pool that will encourage the expansion of businesses and overall employment.

And sure enough -- this conference focused on "talent" and "entrepreneurship." The industrial Midwest needs more of both; it is pretty well recognized that revitalization requires enhancement of the talent base of the region, and it is recognized that recovery requires the creation of vast numbers of new small businesses.

But what I find interesting and worrisome is the level of skill development that gets most of the attention in these discussions. There is a very clear focus on training rather than higher education. Much of the focus in this conferences was on targeted jobs training at a pretty low level -- training programs that provide new skills for unemployed and underemployed workers, with emphasis on laid-off auto workers in Ohio and Michigan. Several speakers emphasized that training programs need to tailor their educational programs closely to the specific needs of regional employers. The key words are skills and training --not creativity, innovation, and the bachelor's or master's degree.

But this seems wrong-headed to me; surely the most valuable asset a region can have is a significant population of well-educated, creative, and innovative people who have been challenged and stretched by a demanding university education. So shouldn't there be a lot of priority given to the complicated challenge of sustaining high-quality universities and making sure that a high percentage of high school graduates attend them?

In fact, people like Richard Florida at CreativeClass sound a very consistent drumbeat when they talk about the twenty-first century economy, emphasizing innovation and the college-educated workforce. Creativity and invention are the central components of future economic success. But the jobs-training orthodoxy points in a different direction. They emphasize vocational training and community college programs -- the message conveyed by President Obama in his July announcements at Macomb Community College relating to investments in the US community college system. (Perhaps the President's position was influenced by the findings of the 2009 Economic Report to the President, which is worth reading in detail; post.)

It seems to me that Richard Florida is surely right about the medium- and long-term story: our economy needs to constantly move towards greater innovation and greater concentration on knowledge-based sectors. So the goal of increasing the percentage of baccalaureate-level adults in a region is a crucial element of our future economic success. The ability to offer innovative ideas, to provide new kinds of problem-solving, and to work well in nimble teams -- these are crucial "skills" that emerge most frequently

from a college-educated workforce. And they are crucial for vibrant business and job growth.

This means that states really need to recognize the crucial role that their universities play in their economic potential for the future. And we need to work hard in seeking out ways of allowing talented young adults to complete their college degrees -- including those 25-34 year-olds who have done some college without completing a degree. Unfortunately, public universities are suffering from fiscal crisis almost everywhere in the country. This implies that we are likely to fall even further behind in creating the highly qualified talent pools that our regional and national economies need in order to thrive in conditions of global competition. And this in turn is likely to impede the growth of employment that we all want to see.

If Marx had been born in Shanghai

Saturday, October 10, 2009

Is Marx's vision still relevant in the twenty-first century world?

At bottom, Marx's biggest ideas were "critique," "exploitation," "alienation," "ideology," and "class." He also constructed a fairly specific theory of capitalism and capitalist development -- a theory that has historical pluses and minuses -- and a theory of socialism that can be understood along more democratic and more authoritarian lines. We might say that his theory of capitalism was too deeply grounded in the observed experience of mid-nineteenth-century Britain, and his theory of socialism paid too little attention to the crushing possibilities of power wielded by a future socialist state. Too much economics, too little politics in his worldview -- and too much of a Hegelian "necessitarianism" in his expectations about the future.

History has shown us a few things that Marx too would have recognized, with the benefit of another century of experience. History does not conform to a necessary logic of development. Capitalism is not one thing, but a set of institutions that have proven fairly malleable. There is no single "logic of capitalist development." Compromises and institutional accommodations are possible between contending economic classes. Social democracy, democratic socialism, Stalinist communism, fascist dictatorship, and liberal democracy are all feasible political institutions governing "modern" economic development.

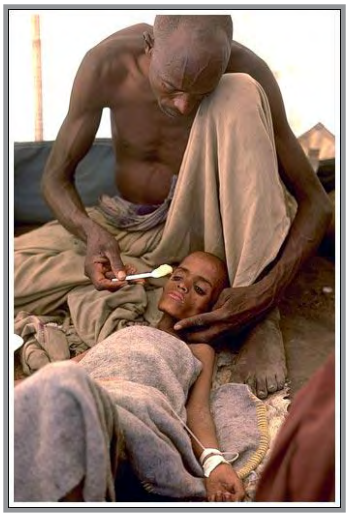
So we might take a deep breath, take a step back, and ask a big counterfactual: How might Marx, with his critical eye for inequality and power and his acute sensibilities as a sociologist -- how might this social critic and theorist have processed the social realities of China in Shanghai in the 1980s?

The question forces a lot of refocusing for historical particulars. China was a "proletarian and peasant" state under the governance of a Communist Party. The Great Leap Forward had taken place, massive famine had occurred during agricultural collectivization, the Cultural Revolution had recently ended with great violence throughout

-- and the beginnings of a new direction in economic life were starting. Private incentives and market forces were beginning to find a place in the economy. The "family responsibility system" in agriculture was beginning to demonstrate major improvements in productivity in farming. Similar reforms were beginning in industrial ownership and management.

Given these large differences between China and Birmingham -- what sorts of analysis might Marx have arrived at? What would Capital have looked like?

Here are a few possibilities. Given the pre-eminence of politics in China's affairs, the book would have been less exclusive in its focus on the "economic mode of production" and might have offered analysis of the instruments and institutions of coercion. It would have given less prominence to the labor theory of value, even as it would have retained some scheme for tracking value and wealth. Political institutions, and the forms of power associated with office and position, would have been a prominent part of the analysis. The role and dynamics of great cities would have come in. The book would have paid much more attention to international economic relations -- Marx would surely have had much to say about globalization. (Why? Because Marx was an astute and nuanced social observer; and these are crucial factors in metropolitan China in the 1980s-2000.)



But a distinctly Marxist analysis could nonetheless have emerged. The Chinese version of Capital would have emphasized some of the same human and social circumstances that are highlighted in Capital: coercion, inequality, exploitation, domination, and human suffering as a result of social institutions; the leverage provided for the personnel of the state; population movement; and the alienation of ordinary people from their species being. Marx surely would have examined very carefully the large social effects of official corruption, as a system of surplus extraction. The result would have been a different theory, emphasizing different social mechanisms; but giving primacy to many of the same large social characteristics of inequality, domination, and exploitation; perhaps more about the full social order and less of a microscopic view of the economic relations of "capitalism."

This small counterfactual experiment perhaps underlines something else too: that there are important threads of Marx's social theory and social critique that continue to be relevant as we try to analyze and diagnose the fundamental social realities of contemporary societies. And we might also draw this hypothetical impression as well: Marx would probably have been as unwelcome to the authorities of the CCP in China as he was to the rulers of the Prussian state.

Food security

Friday, October 16, 2009

Food security is a crucial aspect of life, both for a population and a household. By "food security" specialists often mean two different things: the capacity of a typical poor ***household*** to secure sufficient food over a twelve-month period (through farm work, day labor, government entitlements, etc.); and the capacity of a poor ***country*** to satisfy the food needs of its whole population (through direct production, foreign trade, and food stocks). This involves both food availability and the ability to gain access to food (through entitlements).

A representative description of food security is offered by Shlomo Reutlinger in Malnutrition and Poverty: Magnitude and Policy Options:

Food security ... is defined here as access by all people at all times to enough food for an active, healthy life. Its essential elements are the availability of food and the ability to acquire it. Conversely, food insecurity is the lack of access to sufficient food and can be either chronic or transitory. Chronic food insecurity is a continuously inadequate diet resulting from the lack of resources to produce or acquire food. Transitory food insecurity, however, is a temporary decline in a household's access to enough food. It results from instability in food production and prices or in household incomes. The worst form of transitory food insecurity is famine.

Here is how Sen formulates his "capabilities" understanding (developed, for example, in Hunger and Public Action):

The standard of adequacy is best understood functionally: a person, household, or population has food security if it has sufficient access to food to permit full, robust human development and realization of human capacities.

There is an obvious connection between the two definitions at the household and country levels; but from a human point of view it seems more useful to focus on household food security rather than national food security. A country may in principle have more than sufficient resources to satisfy the food needs of its population, but fail to do so because of internal inequalities. Thus achieving household food security in the less-developed world requires both equity and growth. Amartya Sen and Jean Dreze have made major contributions on hunger and famine in the developing world, and their work can almost always be linked back to the household level. Here is a good source on their writings: The Amartya Sen and Jean Dreze Omnibus: (comprising) Poverty and Famines; Hunger and Public Action; India: Economic Development and Social Opportunity.

Michael Lipton has also been an important voice on this set of topics. His central task in Poverty, Undernutrition, and Hunger is an attempt to provide criteria for distinguishing between the poor and the ultra-poor. The ultra-poor have incomes and entitlements that are absolutely below that required to gain access to 80% of 1973 FAO/WHO caloric requirements. Below this level is likely to lead to undernutrition (the failure of food security). Lipton constructs a "food adequacy standard" as a way of measuring the incidence in a given country of absolute poverty. Here is his statement of a food adequacy standard:

Income or outlay, just sufficient on this assumption to command the average caloric requirement for one's age, sex and activity group (ASAG) in a given climatic and work environment, will be taken as meeting the poverty FAS; this is income or outlay on the borderline of poverty, indicating a risk of hunger. Income or outlay, just sufficient to command 80% of this average requirement, will be taken as meeting the ultra-poverty FAS; this is income or outlay at the borderline between poverty and ultra-poverty, indicating a risk of undernutrition and a severe risk of important anthropometric shortfalls. (Lipton 1983): 7.)

Food security can be put at risk in a variety of ways. Natural conditions can lead to a shortfall of grain production -- flood, drought, or other natural disasters can reduce or destroy the crop across a wide region, leading to a shortfall of supply. Population increase can gradually reduce the grain-to-population ratio to the point where nutrition falls below the minimum required by the population or household. And, perhaps most importantly, prices can shift rapidly in the market for staple foods, leaving poor families without the ability to purchase a sufficient supply to assure the nutritional minimum. It is this aspect of the system that Amartya Sen highlights in his study of famine (Poverty and Famines: An Essay on Entitlement and Deprivation). And it is the circumstance that is most urgent in developing countries today in face of the steep and rapid rise in grain prices over the past year.

The results of a failure of food security are dire. Chronic malnutrition, sustained over months and years, has drastic effects on the health status of a population. Infant and child mortality increases sharply. Often the gender differences in health and mortality statistics widen. And economic productivity falls, as working families lack the strength and energy needed to labor productively. Famine is a more acute circumstance that arises when food shortfalls begin to result in widespread deaths in a region. The Great Bengal famine, the Ethiopian famine, the Great Leap Forward famine, and the famines in North Korea offer vivid and terrible examples of hunger in the twentieth century.

So what is needed to maintain food security in a poor nation? Some developing countries have aimed at food self-sufficiency -- to enact policies in agriculture that assure that the country will produce enough staples to feed its population. Other countries have relied on a strategy of purchasing large amounts of staple foods on international markets. Here the strategy is to generate enough national income through exported manufactured goods to be able to purchase the internationally traded grain. This is the strategy recommended by neoliberal trade theory. If agriculture is a low value-added industry and the manufacture of electronic components is high value-added, neoliberals reason, then surely it makes sense for the country to generate the larger volume of income through the latter and purchase food with the proceeds.

This logic has given rise to several important problems, however. First is the vulnerability it creates for the nation in face of sharp price shocks. This is what we have seen in many countries over the past year. And the second is the reality of extensive income inequalities in most developing countries -- with the result that the "gains of trade" may not be sufficiently shared in the incomes of the poorest 40% to permit them to maintain household food security.

These considerations suggest the wisdom for developing countries to expend more resources on agricultural development (which often has an income-inequality narrowing effect) and a greater emphasis on national and regional food self-sufficiency.

Demystifying social knowledge

Saturday, October 17, 2009

There seem to be a couple of fundamentally different approaches to the problem of "understanding society." I'm not entirely happy with these labels, but perhaps "empiricist" and "critical" will suffice to characterize them. We might think of these as ***styles*** of sociological thinking. One emphasizes the ordinariness of the phenomena, and looks at the chief challenges of sociology as embracing the tasks of description, classification, and explanation. The other highlights the inherent obscurity of the social world, and conceives of sociology as an exercise in philosophical theory, involving the work of presenting, clarifying and critiquing ***texts*** and abstract philosophical ideas as well as specific social circumstances.

The first approach looks at the task of social knowing as a fairly straightforward intellectual problem. It could be labeled "empiricist", or it could simply be called an application of ordinary common sense to the challenge of understanding the social world. **It is grounded in the idea that the social world is fundamentally accessible to observation and causal discovery.** The elements of the social world are ordinary and visible. There are puzzles, to be sure; but there are no mysteries. The social world is ***given*** as an object of study; it is partially orderly; and the challenge of sociology is to discover the causal processes that give rise to specific observed features of the social world.

This approach begins in the ordinariness of the objects of social knowledge. We are interested in other people and how and why they behave, we are interested in the relationships and interactions they create, and we are interested in institutions and populations that individuals constitute. We have formulated a range of social concepts in terms of which we analyze and describe the social world and social behavior -- for example, "motive," "interest," "emotion," "aggressive," "cooperative," "patriotic," "state," "group," "ethnicity," "mobilization," "profession," "city," "religion." We know pretty much what we mean by these concepts; we can define them and relate them to ordinary observable behaviors and social formations. And when our attention shifts to larger-scale social entities (states, uprisings, empires, occupational groups), we find that we can observe many characteristics of each of these kinds of social phenomena. We also observe various ***patterns and regularities*** in behavior, institution, and entity that we would like to understand -- the ways in which people from different groups behave towards each other, the patterns of diffusion of information that exist along a transportation system, the features of conflicts among groups in various social settings. There are myriad interesting and visible social patterns which we would like to understand, and sociologists develop a descriptive and theoretical vocabulary in terms of which to describe and explain various kinds of social phenomena.

In short, on this first approach, the social world is ***visible***, and the task of the social scientist is simply to discover some of the observable and causal relations that obtain among social actors, actions, and composites. To be sure, there are hypothetical or

theoretical beliefs we have about less observable features of the social world -- but we can relate these beliefs to expectations about more visible forms of social behavior and organization. If we refer to "social class" in an explanation, we can give a definition of what we mean ("position in the property system"), and we can give some open-ended statements about how "class" is expected to relate to observable social and political behavior. And concepts and theories for which we cannot give clear explication should be jettisoned; obscurity is a fatal defect in a theory. In short, the task of social science research on this approach is to discover some of the visible and observable characteristics of social behavior and entities, and to attempt to answer causal questions about these characteristics.

This is a rough-and-ready empiricism about the social world. But there is another family of approaches to social understanding that looks quite different from this "empiricist" or commonsensical approach: critical theory, Marxist theory, feminist theory, Deleuzian sociology, Foucault's approach to history, the theory of dialectics, and post-modern social theory. These are each highly distinctive programs of understanding, and they are certainly different from each other in multiple ways. But they share a feature in common: **they reject the idea that social facts are visible and unambiguous.** Instead, they lead the theorist to try to uncover the ***hidden*** forces, meanings, and structures that are at work in the social world and that need to be brought to light through critical inquiry. Paul Ricoeur's phrase "the hermeneutics of suspicion" captures the flavor of the approach. (See Alison Scott-Baumann's Ricoeur and the Hermeneutics of Suspicion for discussion.) Neither our concepts nor our ordinary social observations are unproblematic. There is a deep and sometimes impenetrable difference between appearance and reality in the social realm, and it is the task of the social theorist (and social critic) to lay bare the underlying social realities. The social realities of power and deception help to explain the divergence between appearance and reality: a given set of social relations -- patriarchy, racism, homophobism, class exploitation -- give rise to systematically misleading social concepts and theories in ordinary observers.

Marx's idea of the fetishism of commodities (link) illustrates the point of view taken by many of the theorists in this critical vein: what looks like a very ordinary social fact -- objects have use values and exchange values -- is revealed to mystify or conceal a more complex reality -- a set of relations of domination and control between bosses, workers, and consumers. With a very different background, a book like Gaston Bachelard's The Psychoanalysis of Fire makes a similar point: the appearance represented by behavior systematically conceals the underlying human reality or meaning. The word "critique" enters into most of Marx's titles -- for example, "Contribution to a Critique of Political Economy." And for Marx, the idea of critique is intended to bring forward a methodology of critical reading, unmasking the assumptions about the social world that are implicit in the theorizing of a particular author (Smith, Ricardo, Say, Quesnay). So Capital: Volume 1: A Critique of Political Economy is a book about the visible realities of capitalism, to be sure; but it is also a book intended to unmask both the deceptive appearances that capitalism presents ***and*** the erroneous assumptions that prior theorists have brought into their accounts.

The concepts of ideology and false consciousness have a key role to play in this discussion about the visibility of social reality. And it turns out to be an ambiguous role. Here is a paragraph from Slavoj Zizek on the concept of ideology from Mapping Ideology:

These same examples of the actuality of the notion of ideology, however, also render clear the reasons why today one hastens to renounce the notion of ideology: does not the

critique of ideology involve a privileged place, somehow exempted from the turmoils of social life, which enables some subject-agent to perceive the very hidden mechanism that regulates social visibility and non-visibility? Is not the claim that we can accede to this place the most obvious case of ideology? Consequently, with reference to today's state of epistemological reflection, is not the notion of ideology self-defeating? So why should we cling to a notion with such obviously outdated epistemological implications (the relationship of 'representation' between thought and reality, etc.)? Is not its utterly ambiguous and elusive character in itself a sufficient reason to abandon it? 'Ideology' can designate anything from a contemplative attitude that misrecognizes its dependence on social reality to an action-orientated set of beliefs, from the indispensable medium in which individuals live out their relations to a social structure to false ideas which legitimate a dominant political power. It seems to pop up precisely when we attempt to avoid it, while it fails to appear where one would clearly expect it to dwell.

Zizek is essentially going a step beyond either of the two positions mentioned above. The empiricist position says that we can perceive social reality. The critical position says that we have to discover reality through critical theorizing. And Zizek's position in this passage is essentially that there is no social reality; there are only a variety of texts.

So we have one style that begins in ordinary observation, hypothesis-formation, deductive explanation, and an insistence on clarity of exposition; and another style that begins in a critical stance, a hermeneutic sensibility, and a confidence in purely philosophical reasoning. Jurgen Habermas draws attention to something like this distinction in his important text, On the Logic of the Social Sciences (1967), where he contrasts approaches to the social sciences originating in analytical philosophy of science with those originating in philosophical hermeneutics: "The analytic school dismisses the hermeneutic disciplines as prescientific, while the hermeneutic school considers the nomological sciences as characterized by a limited preunderstanding." (This text as well as several others discussed here are available at AAARG.) Habermas wants to help to overcome the gap between the two perspectives, and his own work actually illustrates the value of doing so. His exposition of abstract theoretical ideas is generally rigorous and intelligible, and he makes strenuous efforts to bring his theorizing into relationship to actual social observation and experience.

A contemporary writer (philosopher? historian? sociologist of science?) is Bruno Latour, who falls generally in the critical zone of the distinction I've drawn here. An important recent work is Reassembling the Social: An Introduction to Actor-Network-Theory, in which he argues for a deep and critical re-reading of the ways we think the social -- the ways in which we attempt to create a social science. The book is deeply enmeshed in philosophical traditions, including especially Giles Deleuze's writings. The book describes "Actor-Network-Theory" and the theory of assemblages; and Latour argues that these theories provide a much better way of conceptualizing and knowing the social world. Here is an intriguing passage that invokes both themes of visibility and invisibility marking the way I've drawn the distinction between the two styles:

Like all sciences, sociology begins in wonder. The commotion might be registered in many different ways but it's always the paradoxical presence of something at once invisible yet tangible, taken for granted yet surprising, mundane but of baffling subtlety that triggers a passionate attempt to tame the wild beast of the social. 'We live in groups that seem firmly entrenched, and yet how is it that they transform so rapidly?' ... 'There is something invisible that weights on all of us that is more solid than steel and yet so incredibly labile.' ... It would be hard to find a social scientist not shaken by one or more

of these bewildering statements. Are not these conundrums the source of our *libido scindi*? What pushes us to devote so much energy into unraveling them? (21)

What intrigues many readers of Latour's works is that he too seems to be working towards a coming-together of critical theory with empirical and historical testing of beliefs. He seems to have a genuine interest in the concrete empirical details of the workings of the sciences or the organization of a city; so he brings both the philosophical-theoretic perspective of the critical style along with the empirical-analytical goal of observational rigor of the analytic style.

Also interesting, from a more "analytic-empiricist" perspective, are Andrew Abbott, Methods of Discovery: Heuristics for the Social Sciences, and Ian Shapiro, The Flight from Reality in the Human Sciences. Abbott directly addresses some of the contrasts mentioned here (chapter two); he puts the central assumption of my first style of thought in the formula, "social reality is measurable". And Shapiro argues for reconnecting the social sciences to practical, observable problems in the contemporary world; his book is a critique of the excessive formalism and model-building of some wings of contemporary political science.

My own sympathies are with the "analytic-empirical" approach. Positivism brings some additional assumptions that deserve fundamental criticism -- in particular, the idea that all phenomena are governed by nomothetic regularities, or the idea that the social sciences must strive for the same features of abstraction and generality that are characteristic of physics. But the central empiricist commitments -- fidelity to observation, rigorous reasoning, clear and logical exposition of concepts and theories, and subjection of hypotheses to the test of observation -- are fundamental requirements if we are to arrive at useful and justified social knowledge. What is intriguing is to pose the question: is there a productive way of bringing insights from both approaches together into a more adequate basis for understanding society?

Paying for health

Monday, October 19, 2009

A person's income determines his/her access to many things he wants and needs: food, clothing, transportation, housing, entertainment, and the internet, for example. And people who have higher income are able to consume more of all of these categories than people with lower income, if they choose to. More affluent people shop for food at Papa Joe's or Whole Food; live in larger and more luxurious homes; buy their clothing from boutiques rather than Penny's or the thrift shop; and drive multiple handsome cars. Poor people can't afford the luxury end of these forms of consumption. And in some way our culture has judged that these sorts of inequalities of consumption are a legitimate and fair part of a market economy; if you judge that inequalities of income are justifiable (perhaps with some limits on extremes), then you pretty much have to support the idea of inequalities of consumption as well.

But what about goods that have a price but that are essential to living a decent human life? Food certainly falls in this category; if 30% of society could literally not afford to purchase enough calories to provide 2200-2900 calories per day for adults and 1800 calories for children, then we would probably have a different idea about the fairness of a market for food -- the principle that says "to each according to his/her earning capacity" doesn't seem very convincing in circumstances where it leads to malnutrition or starvation. In other words, if the normal workings of a market economy left a significant segment of the population without the ability to purchase enough food for subsistence, we would surely judge that this isn't a fair or socially just way of distributing income and food. And there is an important point to be noted here: there is hunger in America, and the system of producing goods and income isn't fully satisfying the subsistence needs of the whole population. (This is exactly what makes it compelling that our government needs to provide food assistance for the very poor, through food stamps or targeted income supplements.) So there is an important issue about the justice of current actual distributions of such basic goods as food, clothing, or shelter across the U.S. population.

But push a little deeper and consider the "market for health care". Supporting one's current healthy status is a costly effort; repairing the body in times of traumatic injury or serious illness is even more costly; and our society leaves a lot of the allocation of health care services to private purchasing power. Health insurance is the primary vehicle through which many Americans provide financially for their health care needs. Some people have insurance provided or subsidized through their employers; some families purchase health insurance through the private market; and many families lack health insurance entirely. Upwards on 47 million Americans are uninsured, including 20% of adults and 9% of children (CDC link). And this includes a wide range of Americans, from the extremely poor to the working poor to the solidly middle class.

It is clear that access to doctors, hospitals, nurses, and prescription drugs is a critical need that everyone faces at various points in life. It is obvious as well that one's future ability to live and work productively and to enjoy a satisfying life is conditioned by one's ability to gain access to health care when it is needed. It is also clear that uncertainty about the availability of health care is a major source of anxiety for many, many people in U.S. society today. So it is self-evident that decent health care is one of our most basic and unavoidable needs.

So what do people do when they lack health insurance and serious illness or injury occurs? This isn't a mystery anymore; families go into debt to doctors and hospitals, they face bankruptcy, they find some limited sources of free care (free clinics, pro bono doctors' services), and they forego "optional" treatments that may well extend the length or quality of life. And it is evident that this pattern results in very serious harms and limitations for people in these groups. People who have the least access to health care through our basic institutions may be expected to live shorter lives and to suffer more.

And what about people at the high end of the income spectrum? How do they relate to the problems of health? Here too the answers are fairly well known: they are able to seek out the best (and most expensive) specialists, travel to national centers for specialized treatment, and undergo advanced diagnostic tests that are not covered by insurance. (Here is a news story from CNN on boutique health care.) The affluent aren't able to assure their health through expenditure -- but they can certainly improve their odds.

In other words, ability to pay influences the quality and extent of health care that an

individual or family is able to gain access to; and the health status of the family is affected by these variations in quality and access. So, to some meaningful extent, our social system places health care in the category of a market good.

But here is the question I'm working around to: what does justice require when it comes to health care? Is it right to look at health care as just another consumption good like shoes -- affluent people wear Gucci and poor people wear Dollar Store, but everyone has his/her feet covered? Or is health care in a special category, too closely linked to living a full human life to allow it to be distributed so unequally? (Norm Daniels has spent most of his career looking at this issue, from the points of view of philosophy and concrete policy reform. See Just Health: Meeting Health Needs Fairly for some of his findings.)

It seems a bitter but unavoidable truth that there are very substantial inequalities in the provision of health care in our society. One person's likelihood of surviving a devastating cancer may be significantly less than another person's chances, simply based on the second person's ability to pay for premium health care services. Further, it seems unavoidable that these extreme inequalities are flatly unjust in any society that believes in the equal worth of all human beings. And where this seems to lead is to the conclusion that some system of universal health insurance is a fundamental requirement of justice.

Cooperation

Thursday, October 22, 2009

How important is cooperation in a market society?

First, what is cooperation? Suppose a number of individuals occupy a common social and geographical space. They have a variety of individual interests and things they value, and they have outcomes they'd like to bring about. Some of those outcomes are purely private goods, and some can be brought about through private activities by each individual. These are the circumstances where private market-based activity can bring about socially optimal outcomes.

But some outcomes may look more like public or common goods -- for example, greater safety in the neighborhood or more sustainable uses of resources. These are outcomes that no single individual can bring about, and -- once established -- no one can be excluded from the enjoyment of these goods. (Public choice theorists sometimes look at other kinds of non-private goods such as "club goods"; see Dennis Mueller, Perspectives on Public Choice: A Handbook.)

Further, some outcomes may in fact be private goods, but may be such that they require coordinated efforts by multiple individuals to achieve them efficiently. An example of this is traditional farming: it may be that the yield on one individual's plot is greater if a group of neighbors provide concentrated labor on weeding this plot today and the neighbor's plot tomorrow than if each of us do all the weeding on our individual plots. The technical conditions surrounding traditional agriculture impose a cycle of labor demand that makes cooperation an efficient strategy.

This is where cooperation comes in. If a number of the members of a group agree to contribute our efforts to a common project we may find that the total results are greater -- for both common goods and private goods -- than if we had each pursued these goods through individual efforts. Cooperation can lead to improvement in the overall production of a good for a given level of sacrifice of time and effort. This description uses the word "agree"; but Robert Axelrod (The Evolution of Cooperation) and David Lewis (Convention: A Philosophical Study) observe that many examples of cooperation depend on "convention" and tacit agreement rather than an explicit understanding among participants.

So cooperation can lead to better outcomes for a group and each individual in the group than would be achievable through entirely private efforts.

Cooperation should be distinguished from altruistic behavior; cooperation makes sense for rationally self-interested individuals if appropriate conditions are satisfied. A cooperative arrangement can make everyone better off. So we don't have to assume that individuals act altruistically in order to account for cooperation.

So why is cooperation not ubiquitous? It is in fact pretty widespread. But there are a couple of important obstacles to cooperation in ordinary social life: the rational incentive that exists to become a freerider or easy rider when the good in question is a public good; and the risk that cooperators run that the endeavor will fail because of non-contribution from other potential contributors. There is also often a timing problem: it is common for the contribution and the benefit to be separated in time, so contributors are even more concerned that they will be denied the benefits of cooperation. If Mr Wong is asked to weed today in consideration of assistance from Mr Li in harvesting the crop four months from now, he may be doubtful about the future benefit.

The basic logic of this situation has stimulated a mountain of great social science research and theory. Garrett Hardin's "tragedy of the commons" (Managing the Commons) and Mancur Olsen's The Logic of Collective Action: Public Goods and the Theory of Groups set the negative case for thinking that cooperation is all but impossible to sustain. Elinor Ostrom's Nobel-prize winning work on common property resource regimes documents the ways in which communities have solved these cooperation dilemmas (Governing the Commons: The Evolution of Institutions for Collective Action). Douglas North essentially argues that only private property and binding contracts can do the job (The Rise of the Western World: A New Economic History). And Robert Axelrod has made the case for the rational basis of cooperation in The Evolution of Cooperation: Revised Edition. He argues that there are specific conditions that enhance or undermine cooperation and reciprocity; essentially, participants need to be able to reidentify each other over time and they need to have a high likelihood of continuing to interact with each other over an extended time. (His analysis is based on a series of experiments involving repeated prisoners' dilemmas.)

A market can "simulate" cooperation through enforceable contracts; so, for example, a peasant farming community could create a legally binding system of labor exchange among households. And organizations can create quasi-binding agreements for cooperation through "memoranda of understanding" and "inter-governmental agreements" -- written agreements that may not be enforceable through legal remedies but nonetheless create a strong incentive for each party to fulfill the obligations of cooperation. However, quite a bit of the opportunities for cooperation seem to fall outside

the sphere of these formal and semi-formal mechanisms for binding agreements.

Informal cooperation needs some kind of institutional or normative setting that encourages compliance with the cooperative arrangement. So there has been an energetic debate in the past twenty years over the feasibility of non-coercive solutions to cooperation problems; this is an area where the new institutionalism has played a key role. And in the real world, we do in fact find numerous sustainable examples of informal cooperation. Individuals work in community gardens; foundations join together in supporting urban renewal projects; villagers create labor-sharing practices. But it is an interesting question to consider: are there institutional reforms that we could invent that would allow us as a society to capture more of the benefits of cooperation than we currently realize?

Comparative life satisfaction

Saturday, October 24, 2009

We tend to think of the past century as being a time of great progress when it comes to the quality of life -- for ordinary people as well as the privileged. Advances in science, technology, and medicine have made life more secure, predictable, productive, educated, and healthy. But in what specific ways is ordinary life happier or more satisfying for ordinary people in 2000 compared to their counterparts in 1900 or 1800 -- or the time of Socrates, for that matter?

There are a couple of things that are pretty obvious. Nutrition is one place to start: the mass population of France, Canada, or the United States is not subject to periodic hunger, malnutrition, or famine. This is painfully not true for many poor parts of the world -- Sudan, Ethiopia, and Bangladesh, for example. But for the countries of the affluent world, the OECD countries, hunger has been largely conquered for most citizens.

Second, major advances in health preservation and the treatment of illness have taken place. We know how to prevent cholera, and we know how to treat staph infections with antibiotics. Terrible diseases such as polio have been eradicated, and we have effective treatments for some kinds of previously incurable cancers. So the basic health status of people in the affluent twenty-first century world is substantially better than that of previous centuries -- with obvious consequences for our ability to find satisfaction in life activities.

These advances in food security and public health provision have resulted in a major enhancement to quality of life -- life expectancy in France, Germany, or Costa Rica has increased sharply. And many of the factors underlying much of this improvement are not high-tech, but rather take the form of things like improvement of urban sanitation and relatively low-cost treatment (antibiotics for children's ear infections, for example).

So living longer and more healthily is certainly an advantage in our quality of life relative to conditions one or two centuries ago.

Improvements in labor productivity in agriculture and manufacturing have resulted in another kind of enhancement of modern quality of life. It is no longer necessary for a large percentage of humanity to perform endless and exhausting labor in order to feed the rest of us. And because of new technologies and high labor productivity, almost everyone has access to goods that extend the enjoyment of life and our creative talents. Personal computing and communications, access to the world's knowledge and culture through the Internet, and ability to travel widely all represent opportunities that even the most privileged could not match one or two centuries ago.

But the question of life satisfaction doesn't reduce to an inventory of the gadgets we can use. Beyond the minimum required for sustaining a healthy human body, the question of satisfaction comes down to the issue of what we do with the tools and resources available to us and the quality of our human relationships. How do we organize our lives in such a way as to succeed in achieving goals that really matter?

Amartya Sen's economic theory of "capabilities and realizations" supports a pretty good answer to these questions about life satisfaction (Development as Freedom). Each person has a bundle of talents and capabilities. These talents can be marshalled into a meaningful life plan. And the satisfying life is one where the person has singled out some important values and goals and has used his/her talents to achieve these goals. (This general idea underlies J. S. Mill's theory of happiness as well in Utilitarianism.)

By this standard, it's not so clear that life in the twenty-first century is inherently more satisfying than that in the eighteenth or the second centuries. When basic needs were satisfied -- nutrition, shelter, health -- the opportunities for realizing one's talents in meaningful effort were no less extensive than they are today. This is true for the creative classes -- obviously. The creative product of J. S. Mill's or Victor Hugo's generation was no less substantial or satisfying than our own. But perhaps it is true across the board. The farmer-gardener who shapes his/her land over the course of a lifetime has created something of great personal value and satisfaction. The mason or smith may have taken more pride and satisfaction in his life's work than does the software programmer or airline flight attendant. The parent who succeeded in nurturing a family in 1800 County Cork may have found the satisfactions as great or greater than parents in Boston or Seattle today. (Richard Sennett explores some of these satisfactions in The Craftsman.)

So we might say that the chief unmistakable improvement in quality of life in the past century is in the basics -- secure nutrition, improved health, and decent education during the course of a human life. And the challenge of the present is to make something meaningful and sustaining of the resources we are given.

Fair prices?

Wednesday, October 28, 2009

We live in a society that embraces the market in a pretty broad way. We accept that virtually all goods and services are priced through the market at prices set competitively. We accept that sellers are looking to maximize profits through the prices, quantities, and quality of the goods and services that they sell us. We accept, though a bit less fully, the idea that wages are determined by the market -- a person's income is determined by what competing employers are willing to pay. And we have some level of trust that

competition protects us against price-gouging, adulteration, exploitation, and other predatory practices. A prior posting questioned this logic when it comes to healthcare. Here I'd like to see whether there are other areas of dissent within American society over prices.

Because of course it wasn't always so. E. P. Thompson's work on early modern Britain reminds us that there was a "moral economy of the crowd" that profoundly challenged the legitimacy of the market; that these popular moral ideas specifically and deeply challenged the idea of market-defined prices for life's necessities; and that the crowd demanded "fair prices" for food and housing (Customs in Common: Studies in Traditional Popular Culture). The moral economy of the crowd focused on the poor -- it assumed a minimum standard of living and demanded that the millers, merchants, and officials respect this standard by charging prices the poor could afford. And the rioting that took place in Poland in 1988 over meat prices or rice riots in Indonesia in 2008 are reminders that this kind of moral reasoning isn't merely part of a pre-modern sensibility. (For some quotes collected by E. P. Thompson from "moral economy" participants on the subject of fair prices see an earlier posting on anonymity.)

So where do contemporary Americans show a degree of moral discomfort with prices and the market? Where does the moral appeal of the principles of market justice begin to break down -- principles such as "things are worth exactly what people are willing to pay for them" and "to each what his/her market-determined purchasing power permit him to buy"?

There are a couple of obvious exceptions in contemporary acceptance of the market. One is the public outrage about executive compensation in banking and other corporations that we've seen in the past year. People seem to be morally offended at the idea that CEOs are taking tens or hundreds of millions of dollars in compensation -- even in companies approaching bankruptcy. Part of the outrage stems from the perception that the CEO can't have brought a commensurate gain to the company or its stockholders, witness the failing condition of many of these banks and companies. Part is a suspicion that there must be some kind of corrupt collusion going on in the background between corporate boards and CEOs. But the bottom line moral intuition seems to be something like this: ***nothing*** could justify a salary of $100 million, and executive compensation in that range is inherently unfair. And no argument proceeding simply along the lines of fair market competition -- "these are competitive rational firms that are offering these salaries, and therefore whatever they arrive at is fair" -- cuts much ice with the public.

Here is another example of public divergence from acceptance of pure market outcomes: recent public outcries about college tuition. There is the common complaint that tuition is too high and students can't afford to attend. (This overlooks the important fact that public

and private tuitions are almost an order of magnitude apart -- $6,000-12,000 versus $35,00-42,000!) But notice that this is a "fair price" argument that would be nonsensical when applied to the price of an iPod or a Lexus. People don't generally feel aggrieved because a luxury car or a consumer device is too expensive; they just don't buy it. It makes sense to express this complaint in application to college tuition because many of us think of college as a necessity of life that cannot fairly be allocated on the basis of ability to pay. (This explains why colleges offer need-based financial aid.) And this is a moral-economy argument.

And what about that other necessity of life -- gasoline? Public complaints about $4/gallon gas were certainly loud a year ago. But they seem to have been grounded in something different -- the suspicion that the oil companies were manipulating prices and taking predatory profits -- rather than an assumption of a fair price determined by the needs of the poor.

Finally, what about salaries and wages? How do we feel about the inequalities of compensation that exist within the American economy and our own places of work? Americans seem to accept a fairly wide range of salaries and wages when they believe that the differences correspond ultimately to the need for firms to recruit the most effective personnel possible -- a market justification for high salaries. But they seem to begin to feel morally aggrieved when the inequalities that emerge seem to exceed any possible correspondence to contribution, impact, or productivity. So -- we as Americans seem to have a guarded level of acceptance of the emergence of market-driven inequalities when it comes to compensation.

One wonders whether deeper resentment about the workings of market forces will begin to surface in our society, as unemployment and economic recession settle upon us.

Causal realism for sociology

Friday, October 30, 2009

The subject of causal explanation in the social sciences has been a recurring thread here (thread). Here are some summary thoughts about social causation.

First, there is such a thing as social causation. Causal realism is a defensible position when it comes to the social world: there are real social relations among social factors (structures, institutions, groups, norms, and salient social characteristics like race or gender). We can give a rigorous interpretation to claims like "racial discrimination causes health disparities in the United States" or "rail networks cause changes in patterns of habitation".

Second, it is crucial to recognize that causal relations depend on the existence of real social-causal mechanisms linking cause to effect. Discovery of correlations among factors does not constitute the whole meaning of a causal statement. Rather, it is necessary to have a theory of the mechanisms and processes that give rise to the

correlation. Moreover, it is defensible to attribute a causal relation to a pair of factors even in the absence of a correlation between them, if we can provide evidence supporting the claim that there are specific mechanisms connecting them. So mechanisms are more fundamental than regularities.

Third, there is a key intellectual obligation that goes along with postulating real social mechanisms: to provide an account of the ontology or substrate within which these mechanisms operate. This I have attempted to provide through the theory of methodological localism (post) -- the idea that the causal nexus of the social world is constituted by the behaviors of socially situated and socially constructed individuals. To put the claim in its extreme form, every social mechanism derives from facts about institutional context, the features of the social construction and development of individuals, and the factors governing purposive agency in specific sorts of settings. And different research programs target different aspects of this nexus.

Fourth, the discovery of social mechanisms often requires the formulation of mid-level theories and models of these mechanisms and processes -- for example, the theory of free-riders. By mid-level theory I mean essentially the same thing that Robert Merton meant to convey when he introduced the term: an account of the real social processes that take place above the level of isolated individual action but below the level of full theories of whole social systems. Marx's theory of capitalism illustrates the latter; Jevons's theory of the individual consumer ss a utility maximizer illustrates the former. Coase's theory of transaction costs is a good example of a mid-level theory (The Firm, the Market, and the Law): general enough to apply across a wide range of institutional settings, but modest enough in its claim of comprehensiveness to admit of careful empirical investigation. Significantly, the theory of transaction costs has spawned major new developments in the new institutionalism in sociology (Mary Brinton and Victor Nee, eds., The New Institutionalism in Sociology).

And finally, it is important to look at a variety of typical forms of sociological reasoning in detail, in order to see how the postulation and discovery of social mechanisms play into mainstream sociological research. Properly understood, there is no contradiction between the effort to use quantitative tools to chart the empirical outlines of a complex social reality, and the use of theory, comparison, case studies, process-tracing, and other research approaches aimed at uncovering the salient social mechanisms that hold this empirical reality together.

Assurance game

Sunday, November 01, 2009

How does a group of people succeed in coming together to contribute to a collective project over an extended period of time? For example, what leads a group of unemployed workers to travel to the capital to lobby for an extension of unemployment benefits, or a group of expatriate Burmese people in London to attend demonstrations against the junta? What motivations are relevant at the individual level? And what circumstances are most conducive to creating

and sustaining collective action?

Purely self-interested egoists won't make it -- that is the message of Mancur Olson's Logic of Collective Action: Public Goods. The maximizing egoist will reason that the activity will either succeed or fail independent of his/her own participation. If it succeeds then he will enjoy the benefits of cooperation; and if it fails he will have avoided the wasted costs of participation. Either way the egoist does better by refraining from participation. So collective action in pursuit of a public good is all but impossible within a society of rationally disinterested egoists. As Amartya Sen observes in "Rational Fools" (link), "The purely economic man is indeed close to being a social moron."

But we know that this conclusion does a bad job of describing real social life. People in villages, communities, political parties, religious organizations, public television audiences, and ethnic groups do in fact often succeed in getting themselves organized and mobilized in pursuit of a public good for the group. Often the level of mobilization is below the level that would be optimal for production of the good for the population; often it is fairly straightforward to identify the symptoms of incipient free-riding; but ordinary social experience and history alike are replete with examples of voluntary collective action.

Many theories can be articulated in order to account for the spontaneous occurrence of collective action. People may be irrational; they may be motivated entirely by non-utility considerations; they may be governed by norms of solidarity beyond their rational control; they may be disciplined by grassroots organizations that punish defectors; there may be an evolutionary basis hard-wired into the human cognitive-deliberative system that favors cooperation; or, for that matter, there may be a hard-wired impulse towards punishing defectors from common projects that tips the balance of utility calculation for would-be free-riders.

But here is a factor that seems to be a credible observation about social motivation and that still makes sense of the behavior in deliberative terms. Many real social actors seem to be what might be called "conditional altruists": they are willing to contribute some effort or personal resource to a collective project **if** they have grounds for confidence that a reasonable number of other members of the group will contribute as well. (Jon Elster explores the idea in The Cement of Society: A Survey of Social Order.) And it isn't that these actors make a calculation error along the lines of the fallacy of unanimity -- "I want the benefits of the collective action, and it won't occur without me." Instead, they seem to ***reason*** in ways that would please a communitarian: "I'm a member of this group, I believe that other members will do what's good for the group, and I'm willing to do my part as well." This is a fairly explicit willingness to sacrifice the benefits of free riding. But the ***conditional*** part is important as well: the conditional altruist is calculating about the likelihood of success in the collective undertaking, and is willing to participate only if he/she judges that enough other people will contribute as well to make the undertaking feasible.

Conditional altruism thus attributes a common moral psychology to social actors, which we might refer to as the "fairness factor." Individuals are willing to factor collective goods into their calculation of the costs and benefits of action, and they have some degree of motivation to act in accordance with a proposed collective action that would benefit them even if they could evade participation. They are disposed to act fairly: "If I benefit from the action, I should take my fair share of creating the benefit." (Allan Gibbard's Wise Choices, Apt Feelings: A Theory of Normative Judgment offers an effort to bring together the evolutionary history of the species with a philosopher's analysis of moral reasoning.)

If fairness or conditional altruism are real components of human agency (for all or many human beings), then we can identify a few factors that are likely to increase the likelihood of cooperation and collective action. Measures that increase the actor's **assurance** of the behavior of others will have the effect of eliciting higher levels of collective action. And it is possible to think of quite a few social circumstances that have this effect. A shared history of success in collective action is clearly relevant to current actors' level of assurance about future cooperation. Shared history can be made more powerful in the present through the currency of songs, stories, and performances that highlight earlier successes (Michael Taylor, Community, Anarchy and Liberty). Researchers who study peasant village communities emphasize the importance of face-to-face relations among villagers; individuals know a good deal about the past behavior of their neighbors, which can provide a better basis for predicting their future cooperative behavior (Robert Netting, Smallholders, Householders: Farm Families and the Ecology of Intensive, Sustainable Agriculture). And members of small, stable communities also know that they will need to interact with each other long into the future -- increasing the cost of non-cooperation today (Robert Axelrod, The Evolution of Cooperation: Revised Edition).

What is particularly interesting about this topic is the fact that actual social outcomes show a wide range of variations in the degree of self-interest and fairness that seems to be present. Some groups seem to act more like Mancur Olson egoists; others (like Welsh coal miners) seem to act as though they have a very high "solidarity and fairness" quotient. So no single answer to the question of collective action seems to work: "people are rational **egoists**," "people are **altruists**," or "people are **conditional altruists**." Rather, a given opportunity for collective action seems to display a mix of all these styles of reasoning. These variations could be the result of several independent factors: differences in the formation of individuals' moral psychology (emphasizing individualism or community from infancy); differences in current institutional settings (arrangements that make future interactions seem more likely to each participant); even potentially differences in personality or the genetic basis of decision-making across individuals.

I'm sure that there is work in experimental economics that probes the boundaries of this feature of practical reasoning. Ordinary social experience informs us that people have different levels of willingness to undertake sacrifice for a group's projects. And having a more nuanced empirical understanding of how people behave in the settings of potential cooperation and collective action would help refine our understanding of the thought-processes and styles of reasoning through which individuals decide what to do. Here is an interesting paper by Ernst Fehr and Klaus Schmidt titled "The Economics of Fairness, Reciprocity and Altruism – Experimental Evidence and New Theories."

A modern world-system?

Tuesday, November 03, 2009

Source : Minard’s Map of Port and River Tonnage

Immanuel Wallerstein created a huge stir in the 1970s with the publication of The Modern World-System: Capitalist Agriculture and the Origins of the European World-Economy in the Sixteenth Century (1974). The book is an intellectual masterpiece, synthesizing a vast range of fundamental literature on the economic history of Europe and the world. You could look at the book as the first serious and extended effort to theorize

globalization -- a term that barely existed at the time of publication. Or you could look at it as a general theory of colonialism -- an account of the pathways and influences through which the metropole dominated and exploited the periphery. It is worth looking back at this work today to tease out some of the guiding assumptions about history, sociology, and globalization it reflected.

The concept of "world system" is itself a key component of our current understanding of globalization, in that it captures the idea of causal interconnectedness across the globe among major organizations, firms, populations, and states. Wallerstein observes that earlier social scientists had usually centered their analysis at the level of the political unit -- the nation-state; whereas his own approach is different:

This book makes a radically different assumption. It assumes that the unit of analysis is an economic entity, the one that is measured by the existence of an effective division of labor, and that the relationship of such economic boundaries to political and cultural boundaries is variable, and therefore must be determined by empirical research for each historical case. Once we assume that the unit of analysis is such a "world-system" and not the "state" or the "nation" or the "people", then much changes in the outcome of the analysis. (xi)

But what, more exactly, did he mean by a system? Did he imagine something analogous to a mechanical system in which the relations among the parts were governed by a few simple laws? He seems to suggest this possibility when he asks the question, "What do astronomers do? As I understand it, the logic of their arguments involves two separate operations. They use the laws derived from the study of smaller physical entities, the laws of physics, and argue that ... these laws hold by analogy for the system as a whole. Second, they argue a posteriori. If the whole system is to have a given state at time **y**, it most porrobably had a certain state at time **x**" (7). Here he seems to suggest that social systems are tied together by the working of governing laws -- a particularly unconvincing starting point.

But Wallerstein's practice as a sociologist is far more defensible than this language would suggest. He was in fact sensitive to causal heterogeneity, contingency, and variation in the systemic relations he meant to capture -- particularity as well as universality. So he doesn't actually treat the modern world system as if it were analogous to a set of gravitational objects governed by fixed laws of nature.

I think the clue to an answer to his working definition of a system is found in his definition of scope in terms of an "effective division of labor": a set of regions constitute a system in his framework if there is significant exchange and dependence among various of the regions for products, people, knowledge, skills, and resources from other regions. If Europe, Asia, or the Americas had been "autarkic" in 1700 -- that is, if one or more of these continental regions had been a closed economy and society making no substantial use of products, knowledge, resources, or people from other regions -- then there would not have been one "world system" but rather several independent macro-regional systems. And Wallerstein explicitly affirms this point late in the book:

By saying that in the sixteenth century there was a European world-economy, we indicate that the boundaries are less than the earth as a whole. But how much less? We cannot simply include in it any part of the world with which "Europe" traded. In 1600 Portugal traded with the central African kingdom of Monomotapa as well as with Japan. Yet it would be *prima facie* hard to argue that either Monomotapa or Japan were part of the European world-economy at that time. And yet we argue that Brazil (or at least areas of the coast of Brazil) and the Azores were part of the European world-economy. (199)

So in postulating the concept of world system as a framework for analysis of the modern period (let's say 1700), Wallerstein is laying a few important cards on the table; he is indicating his judgment that there was significant and necessary exchange among virtually all accessible places on the planet. There were economically meaningful movements of resources, people (emigrants and slaves), crops (cotton, sugar), finished products, and ideas throughout the system of places defining the system of transport and trade. This in turn implies that we cannot properly understand the workings of the regional economy without taking into account its exchange relations with other regions -- or in other words, we need to place the regional economy into the system of international division of labor in which it is located. And in fact, historians like Ken Pomeranz make a substantial case for the empirical accuracy of that judgment (see for example The Great Divergence: China, Europe, and the Making of the Modern World Economy and The World That Trade Created: Society, Culture, And the World Economy, 1400 to the Present).

If we begin with this assumption -- the idea of the substantial interdependence of continental regions in the early modern period -- then we are naturally drawn to the question, what were the terms of trade? Was exchange among regions mutually beneficial, as trade theory would have it? Or was it extractive and exploitative, as the theory of colonialism would have it? This is where Wallerstein makes substantial use of the core-periphery framework in his analysis.

The periphery of a world-economy is that geographical sector of it wherein production is primarily of lower-ranking goods ... but which is an integral part of the overall system of the division of labor, because the commodities involved are essential for daily use. The external arena of a world-economy consists of those other world-systems with which a given world-economy has some kind of trade relationship ... what was sometimes called the "rich trades." (199-200)

Wallerstein was particularly interested in interconnections between places that were the expression of power and commerce. Core and periphery are linked by relations of subordination -- military and economic domination, leading to the persistent disadvantage of the latter in favor of the former. These features define the "general attributes of a colonial situation" (5).

This analysis lays a theoretical and historical foundation for a theory of globalization. Wallerstein writes late in the book:

One of the persisting themes of the history of the modern world is the seesaw between "nationalism" and "internationalism." I do not refer to the ideological seesaw ... but to the organizational one. At some points in time the major economic and political institutions are geared to operating in the international arena and feel that local interests are tied in some immediate way to developments elsewhere in the world. At other points of time, the social actors tend to engage their efforts locally, tend to see the reinforcement of state

boundaries as primary, and move toward a relative indifference about events beyond them. (147)

Where has the effort to theorize globalization gone in the thirty-five years since Wallerstein's book appeared? A particularly important contemporary voice on this subject is that of Saskia Sassen. Her recent A Sociology of Globalization (2007) represents a current cutting-edge effort to provide a vocabulary and set of theoretical premises in terms of which to understand the global interconnectedness that characterizes the contemporary world. And she wants to provide a *sociology* of these processes -- that is, she wants to provide a theoretical vocabulary and a set of hypotheses about the causal mechanisms that are involved that are adequate to the problem of describing and explaining the workings of this system. One thing this means is providing a framework within which the empirical details and structures of global networks can be investigated. Another key point in her approach is her attention to differentiation across institutions and mechanisms.

A deeply important part of her analysis is her effort to overturn the assumption of "linearity" and hierarchy among levels of analysis -- the line of thought that assumes that neighborhoods are encompassed by cities, which fall within regions, which fall within states, which fall within international relations. She argues repeatedly and effectively that this linear scheme doesn't work for today's global relationships. The local neighborhood may be implicated in extra-national relations of immigration, crime, and trade that make it a global place. More importantly, what she calls "global cities" have crucial relationships at many levels in these supposed hierarchies -- local, national, and supra-national. So the question of scale cannot be defined within a simple hierarchy of relationships of locality, nationality, and globality. (Significantly, Wallerstein opens his treatment of the modern world system by wrestling with this issue -- a discussion that he frames in terms of the idea of the appropriate unit of analysis in considering colonialism.)

Sassen is particularly interested in the networks of communication, finance, and service organizations that constitute the fabric joining what she calls "global cities" (link; see also an earlier posting on regional interdependence). But in this book Sassen broadens considerably the angle of view in order to consider social networks at many levels of scale, including sub-national as well as supra-national.

Sassen makes an important point about international economic power that has a Wallerstein-like feel to it but that would probably not have been true in 1700 or 1970. This is her view that there has been an important process of "de-nationalization" that has removed traditional powers of the state and placed them in the scope of international economic and finance institutions that are significantly controlled by large economic actors and firms. We sometimes refer to this process as one of "liberalization"; Sassen makes the point that the construction of the new supra-national regulatory regimes is an extended historical process that can be studied in detail. She refers to the result of this process as the global corporate economy. One of Wallerstein's key arguments is that nations in the periphery were dominated and controlled by an economic system run by European nations. Sassen argues for the reality of a world system of regulatory arrangements that subordinates the sovereignty of even previously hegemonic nations to a non-democratic set of institutions and rules that implicitly favor one set of economic actors over others. But Sassen's inference from this fact about international economic power is less about north-south exploitation and more about the rising likelihood of global exploitation of all ordinary citizens by powerful extra-national economic forces that are beyond the reach of democratic processes (what she refers to as the "democratic

deficit").

Sassen's book warrants a close reading. It proposes a significantly different way of conceptualizing the meaning of globalization, and one that will suggest many new research agendas.

(The Minard trade map above is borrowed from the fascinating blog Cartographia. The blog has many great discussions of some very interesting maps.)

Singular and generic causal assertions

Friday, November 06, 2009

It is worthwhile to notice that we can ask causal questions at two extremes of specificity and generality. We can ask why the Nicaraguan Revolution occurred—that is, what was the chain of circumstances that led to the successful seizure of power by the Sandinistas? This is to invite a specific historical narrative, supported by claims about causal powers of various circumstances. And we can ask why twentieth-century revolutionary movements succeeded in some circumstances and failed in others—that is, we can ask for an account of the common causal factors that influenced the course of revolution in the twentieth century. In the first instance we are looking to put forward a causal hypothesis about a particular event; in the latter we are seeking a causal explanation concerning the behavior of a class of events.

Take the idea that the outbreak of hostilities in World War I was ***caused*** by the assassination of Franz Ferdinand of Austria in 1914. This claim might be supported by identifying a chain of events that proceeded from the assassination, to decisions in various capitals, to the mobilization of troops, to the outbreak of fighting. The assassination was the spark that led to the conflagration. But this is a purely singular chain of events, and there is no regular connection between occurrences of this set of events and the outbreak of war. The sequence of causal links in this story involves pure contingency at many stages. Assassinations don't generally cause wars; sometimes they do and sometimes they don't. Events in the category of "political assassination" do in fact have a set of causal powers -- through the influence that a political assassination can have on powerful decision-makers and public opinion. But there is no single mechanism that links assassinations to the outbreak of war.

Consider an analogy with professional basketball. We might ask the question, "What circumstances permitted the Pistons to defeat the Celtics in Game Seven of the NBA playoffs?" And the answer may include a mix of general and particular factors: their guards were quicker, their center shut down the lane, the Piston's coach had a great game plan; as well as the entirely contingent events: two Celtics players collided at a critical moment, a three-point shot at the buzzer banged off the rim, there was a clock malfunction that gave the Pistons a breather. The former types of factors are the sorts of things that might be used to attempt to explain basketball success over the course of a

season and a full range of teams; these are common causal factors explaining success and failure. The latter types of factors are fundamentally contingent and non-repeatable. These are random events with respect to a basketball season.

Much inquiry in the social sciences has to do with singular causal processes (historical outcomes): individual revolutions, specific experiences of modernization and development, specific histories of collective action. Charles Tilly‘s career-long treatment of the collective political behavior of the French is a case in point; Tilly attempts to identify a characteristic tradition of French political action, and attempts to identify the historical occurrences which gave this tradition its specificity (Tilly 1986). But Tilly is also interested in identifying common social mechanisms of contention; and this allows him to identify general causes as well as singular causes.

Historical investigation and "process tracing" permit us to analyze particular singular causal sequences—for example, "a floating iceberg caused the sinking of the Titanic." This kind of singular historical analysis permits discovery of the causal mechanisms and contingent happenings that were involved in the production of the event to be explained.

A ***general*** hypothesis about causation is based on a discovery of a pattern across a number of similar cases. For example, Theda Skocpol's States and Social Revolutions: A Comparative Analysis of France, Russia and China attempts to discover causal regularities leading to the occurrence of revolution that emerge from study of a small number of particular revolutions, and Jeffrey Paige's Agrarian Revolution offers a large-N study of cases of revolution and rebellion to attempt to discover common causal conditions. And through either type of study we might arrive at evidence supporting general causal claims like these: "the occurrence of subsistence crises is a causal factor in the occurrence of rebellion," "a strong state inhibits the occurrence of rebellion," and "international crises make rebellions more likely."

To assert that A’s are causes of B’s is to assert that there is a typical causal mechanism through which events of type A lead to events of type B. Here, however, we must note that there are rarely single sufficient conditions for social outcomes; instead, causes work in the context of causal fields. So to say that revolutions are causally influenced by food crisis, weak states, and local organization, is to say that there are real causal linkages from these conditions to the occurrence of revolution in specific instances. If we have enough cases, then these causal mechanisms will also produce some regularities of association between the hypothesized causal factors and the outcome; but without a large number of cases these regularities will be difficult or impossible to discern.

To what extent is such a causal analysis of a unique event ***explanatory***, rather than merely true? The account is explanatory if it identifies influences that commonly exert causal power in a variety of contexts, not merely the case of the French in 1848 or Russia in 1917. And a case study that invokes or suggests no implications for other cases, falls short of being explanatory.

I will put it forward as a methodological maxim that a causal assertion is explanatory only if it identifies a causal process that recurs across a family of cases. A historical narrative is an answer to the first sort of question (“why did this particular event come about?”); such a narrative may or may not have implications for more general causal questions. A true causal story is not always explanatory.

There is another issue raised by this topic of general and particular causal hypotheses,

which has to do with the idea of "over-determination." Return to the case of World War I. It might be argued that there were broad structural forces at work that were steadily increasing the likelihood of war throughout 1912-1914 -- deepening economic and geographical conflicts of interest among the great powers, large-scale military planning by various governments, and a worsening arms race, for example; so war was "inevitable" with or without the spark created by the assassination of the Archduke. If this event had not occurred, some other instigating event would have cropped up; so the conflagration was inevitable. On this interpretation, the assassination of the Archduke was a critical part of the actual pathway leading to the outbreak of war; but there were many other hypothetical pathways that would have led to the same result. So it is the background structural conditions that were the real and substantive causes of World War I -- not the contingent and accidental fact of the assassination in 1914.

Are social networks fundamental?

Monday, November 09, 2009

There are several natural starting points when we begin thinking seriously about the social world and how it works. For example, we can begin with individual agents and try to understand social patterns as the expression of common features of reasoning and motivation by stylized agents. This is roughly the strategy underway in rational choice theory, neoclassical economics, game theory, and methodological individualism. Or we might begin with an account of group attributes -- race, class, gender, ethnicity, religion. This is roughly the way in which Durkheim, Giddens, and Du Bois begin -- with a kind of macro-social set of categories in terms of which we attempt to understand social structure and behavior.

The concept of a social network doesn't fit neatly into either category. It is larger than a collection of individuals, in that we have to specify a set of ***relationships*** among individuals in order to define a social network. But it is much more concrete and agent-based than the super-categories of race, class, or gender turn out to be. So my question here is a fundamental one: Is the concept of a social network one of a very small number of concepts that must be invoked in virtually every kind of social explanation? As such, is the concept of a social network, and the associated concepts of concrete social relationships it brings with it, a fundamental component of any satisfactory social ontology? And does the concept of a social network define a crucial space between the micro and the macro? (A good recent effort to link social networks theory to an important area of social science research is Mario Diani and Doug McAdam, Social Movements and Networks: Relational Approaches to Collective Action.)

A couple of points are pretty obvious. One is that social networks do in fact constitute a key causal mechanism underlying many social processes. We can explain important features of social and political life by identifying the concrete social networks that exist within the population: the transmission of ideas, knowledge, and styles through a population; the selection of important leaders in government and industry; the effective

reach of the state; the course of mobilization within a community around an important issue; and the effectiveness of a terrorist group, to name a few examples. A second point is that networks have specific features of topology and functioning that have causal consequences that are largely independent from the personal characteristics of the people who constitute it. For example, information may travel more quickly through a network of people containing many midsized nodes than one containing just a few mega-hubs. And this structural fact may suffice to explain some social outcomes: for example, this rebellion succeeded (because of rapid transmission of information) whereas that one petered out (because of ineffective communications).

Consider two very different examples of group behavior: synchronized cheering in a stadium and the spread of boycotts in Alabama in the early 1960s. The first case involves no social network at all. Cheerleaders stationed around the field initiate the chant as the noise moves to their part of the stadium, and many fans respond when called. Fan behavior is explained by the fan's observation of the behavior of other fans and the motions of the cheerleader. The boycotts had a different dynamic. Organizations emerged which set about to mobilize support for the strategy of boycott. Some of this effort took the form of public calls to action. But a larger part of the mobilization occurred through the workings of extended networks of engaged people -- ministers, union activists, student organizations, and civil rights groups. And the effectiveness and pattern of dissemination of the call to action depended critically on the scope and structure of each of these networks of networks -- networks among leaders of diverse organizations and subordinate networks clustered around each leader. (Doug McAdam describes these processes in detail in Political Process and the Development of Black Insurgency, 1930-1970.)

These examples seem to lead to a couple of observations. One is that social networks are not critical for ***every*** form of social action. But the exceptions are pretty simple cases of spontaneous coordination. And second, the example of civil rights mobilization illustrates very clearly why we should expect that social networks are usually crucial. The reason is straightforward: almost all social outcomes require a degree of coordination, communication, and mobilization. A social network is not the only way of bringing these factors about -- cheerleaders and television stations can do it too. But the causal importance of social networks is likely to be great in many cases. And for this reason it seems justified to conclude that social networks are in fact fundamental to social explanation. Likewise, it appears correct to say that they function as bridging mechanisms from micro to macro, in that they help to convey the actions of local agents onto larger social outcomes (and back!).

(Several earlier posts are relevant to this topic: agent-based modeling, transnational protest, ethnic strife.)

Methodological localism

Thursday, November 12, 2009

I offer a social ontology that I refer to as **methodological localism** (ML). This theory of social entities affirms that there are large social structures and facts that influence social outcomes. But it insists that these structures are only possible insofar as they are embodied in the actions and states of socially constructed individuals. The “molecule” of all social life is the ***socially constructed and socially situated individual***, who lives, acts,

and develops within a ***set of local social relationships, institutions, norms, and rules***.

This account begins with the ***socially constituted person***. Human beings are subjective, purposive, and relational agents. They interact with other persons in ways that involve competition and cooperation. They form relationships, enmities, alliances, and networks; they compose institutions and organizations. They create material embodiments that reflect and affect human intentionality. They acquire beliefs, norms, practices, and worldviews, and they socialize their children, their friends, and others with whom they interact. Some of the products of human social interaction are short-lived and local (indigenous fishing practices); others are long-duration but local (oral traditions, stories, and jokes); and yet others are built up into social organizations of great geographical scope and extended duration (states, trade routes, knowledge systems). But always we have individual agents interacting with other agents, making use of resources (material and social), and pursuing their goals, desires, and impulses.

At the level of the socially constituted individual we need to ask two sorts of questions: First, what makes individual agents behave as they do? Here we need accounts of the mechanisms of deliberation and action at the level of the individual. What are the main features of individual choice, motivation, reasoning, and preference? How do these differ across social groups? How do emotions, rational deliberation, practical commitments, and other forms of agency influence the individual's deliberations and actions? This area of research is purposively eclectic, including performative action, rational action, impulse, theories of the emotions, theories of the self, or theories of identity.

Second, how are individuals formed and constituted? Methodological localism gives great importance to learning more about how individuals are formed and constituted—the concrete study of the social process of the development of the self. Here we need better accounts of social development, the acquisition of worldview, preferences, and moral frameworks, among the many other determinants of individual agency and action. What are the social institutions and influences through which individuals acquire norms, preferences, and ways of thinking? How do individuals develop cognitively, affectively, and socially? So methodological localism points up the importance of discovering the microfoundations and local variations of identity formation and the construction of the historically situated self.

So far we have emphasized the socially situated individual. But social action takes place within spaces that are themselves socially structured by the actions and purposes of others—by property, by prejudice, by law and custom, and by systems of knowledge. So our account needs to identify the **local social environments** through which action is structured and projected: the inter-personal networks, the systems of rules, the social institutions. The social thus has to do with the behaviorally, cognitively, and materially embodied reality of social institutions. An institution is a complex of socially embodied powers, limitations, and opportunities within which individuals pursue their lives and goals. A property system, a legal system, and a professional baseball league all represent examples of institutions. Institutions have effects that are in varying degrees independent from the individual or "larger" than the individual. Each of these social entities is embodied in the social states of a number of actors—their beliefs, intentions,

reasoning, dispositions, and histories. Actors perform their actions within the context of social frameworks represented as rules, institutions, and organizations, and their actions and dispositions embody the causal effectiveness of those frameworks. And institutions influence individuals by offering incentives and constraints on their actions, by framing the knowledge and information on the basis of which they choose, and by conveying sets of normative commitments (ethical, religious, interpersonal) that influence individual action.

It is important to emphasize that ML affirms the existence of social constructs beyond the purview of the individual actor or group. Political institutions exist—and they are embodied in the actions and states of officials, citizens, criminals, and opportunistic others. These institutions have real effects on individual behavior and on social processes and outcomes—but always mediated through the structured circumstances of agency of the myriad participants in these institutions and the affected society. This perspective emphasizes the contingency of social processes, the mutability of social structures over space and time, and the variability of human social systems (norms, urban arrangements, social practices, and so on).

This approach highlights the important point that all social facts, social structures, and social causal properties depend ultimately on facts about individuals within socially defined circumstances. Social ascriptions require ***microfoundations*** at the level of individuals in concrete social relationships. According to this way of understanding the nature of social ontology, an assertion of a structure or process at the macro-social level (causal, functional, structural) must be supplemented by two things: knowledge about what it is about the local circumstances of the typical individual that leads him or her to act in such a way as to bring about this relationship; and knowledge of the aggregative processes that lead from individual actions of that sort to an explanatory social relationship of this sort. So if we are interested in analysis of the causal properties of states and governments, we need to arrive at an analysis of the institutions and constrained patterns of individual behavior through which the state's characteristics are effected. We need to raise questions such as these: How do states exercise influence throughout society? What are the institutional embodiments at lower levels that secure the impact of law, taxation, conscription, contract enforcement, and other central elements of state behavior? If we are concerned about the workings of social identities, then we need to inquire into the concrete social mechanisms through which social identities are reproduced within a local population—and the ways in which these mechanisms and identities may vary over time and place. And if we are interested in analyzing the causal role that systems of norms play in social behavior, we need to discover some of the specific institutional practices through which individuals come to embrace a given set of norms.

The microfoundations perspective requires that we attempt to discover the pathways by which socially constituted individuals are influenced by distant social circumstances, and how their actions in turn affect distant social outcomes. There is no action at a distance in social life; instead, individuals have the values that they have, the styles of reasoning, the funds of factual and causal beliefs, etc., as a result of the structured experiences of development that they have undergone as children and adults. On this perspective, large social facts and structures do indeed exist; but their causal properties are entirely defined by the current states of psychology, norm, and action of the individuals who currently exist. Systems of norms and bodies of knowledge exist—but only insofar as individuals (and material traces) embody and transmit them. So when we assert that a given social structure causes a given outcome, we need to be able to specify the local pathways

through which individual actors embody this causal process. That is, we need to be able to provide an account of the causal mechanisms that convey social effects.

It is evident that methodological localism implies a fairly limited social ontology. What exists is the socially constructed individual, within a congeries of concrete social relations and institutions. The socially constructed individual possesses beliefs, norms, opportunities, powers, and capacities. These features are socially constructed in a perfectly ordinary sense: the individual has acquired his or her beliefs, norms, powers, and desires through social contact with other individuals and institutions, and the powers and constraints that define the domain of choice for the individual are largely constituted by social institutions (property systems, legal systems, educational systems, organizations, and the like). Inevitably, social organizations at any level are constituted by the individuals who participate in them and whose behavior and ideas are influenced by them; sub-systems and organizations through which the actions of the organization are implemented; and the material traces through which the policies, memories, and acts of decision are imposed on the environment: buildings, archives, roads, etc. All features of the organization are embodied in the actors and institutional arrangements that carry the organization at a given time. At each point we are invited to ask the question: what are the social mechanisms through which this institution or organization exerts influence on other organizations and on agents' behavior?

Localism and assemblage theory

Thursday, November 12, 2009

Several earlier posts have described the idea of "methodological localism" (post). This is part of an argument I want to defend in support of the idea that we need new and better ways of thinking about the "stuff" of society. We need to thoroughly question and rethink the assumptions we make about social objects -- groups, mentalities, structures, forces, power, states, and organizations. In short, we need a better social ontology -- one that is free from the patterns of thinking we have inherited from positivism and the natural sciences (post).

Here is the thrust of methodological localism. The only ontologically stable stuff that exists in the social world is the socially constructed and socially situated individual actor, embedded within a set of relationships with other concrete social actors. There are higher-level social frameworks -- police departments, professional soccer leagues, and civil wars. But these higher-level structures and events derive all their properties and powers from the extended systems of local activity

that they encompass. And they are plastic and deformable in their properties over time (post, post).

One way to put this point is to say that higher-level social structures and entities are only composites or assemblages of lower-level structures, all tracing back ultimately to an extended set of local contexts of activity (post).

And this paraphrase brings the view into some kind of relationship with the theory of "***assemblage***" that has emerged from several strands of continental thought, including especially some writings of Gilles Deleuze. Manuel DeLanda's book A New Philosophy of Society: Assemblage Theory And Social Complexity presents an appealing and accessible version of the perspective. Nick Srnicek's master's thesis "Assemblage Theory, Complexity and Contentious Politics" is a good exposition and critical discussion of the theory. And Bruno Latour's book Reassembling the Social: An Introduction to Actor-Network-Theory provides a coherent and useful reconstruction of "actor-network theory" (ANT) within the general framework of assemblage theory.

Latour's theory stems significantly from the tradition of "social construction of technology" and recent sociology and history of science and technology. ***Reassembling the Social*** is a radical call to action in the social sciences. Latour wants us to dispense entirely with traditional sociological concepts when they purport to refer to fixed, stable social things. And he wants a new conceptual scheme that puts the emphasis on relationships and associations, on dynamic patterns of action and coordination, rather than on structures and institutions.

The argument of this book can be stated very simply: when social scientists add the adjective ‘social’ to some phenomenon, they designate a stabilized state of affairs, a bundle of ties that, later, may be mobilized to account for some other phenomenon. There is nothing wrong with this use of the word as long as it designates what is already assembled together, without making any superfluous assumption about the nature of what is assembled. Problems arise, however, when ‘social’ begins to mean a type of material, as if the adjective was roughly comparable to other terms like ‘wooden’, ‘steely’, ‘biological’, ‘economical’, ‘mental’, ‘organizational’, or ‘linguistic’. At that point, the meaning of the word breaks down since it now designates two entirely different things: first, a movement during a process of assembling; and second, a specific type of ingredient that is supposed to differ from other materials.(1)

The key task for social science research, according to Latour, is systematic tracing of compound associations among diverse elements. Here is a description of what this might mean:

In such a view, law, for instance, should not be seen as what should be explained by ‘social structure’ in addition to its inner logic; on the contrary, its inner logic may explain some features of what makes an association last longer and extend wider. Without the ability of legal precedents to draw connections between a case and a general rule, what would we know about putting some matter ‘into a larger context’? Science does not have to be replaced by its ‘social framework’, which is ‘shaped by social forces’ as well as its own objectivity, because its objects are themselves dislocating any given context through the foreign elements research laboratories are associating together in unpredictable ways.

...

And the same is true for all other domains. Whereas, in the first approach, every activity—law, science, technology, religion, organization, politics, management, etc.—could be related to and explained by the same social aggregates behind all of them, in the second version of sociology there exists nothing behind those activities even though they might be linked in a way that does produce a society—or doesn't produce one. Such is the crucial point of departure between the two versions. To be social is no longer a safe and unproblematic property, it is a movement that may fail to trace any new connection and may fail to redesign any well-formed assemblage. (7,8)

The social realities of "law", "science", or "technology", then, are to be understood in terms of the network of associations that they encompass among actors and other elements. These social "things" are not static realities, but rather assemblages of dynamic actor relationships or "associations".

John Law provides a similar statement of some of the fundamental starting points of ANT in "Notes on the Theory of the Actor Network" (link), emphasizing the same skepticism about existing assumptions of social ontology:

Here is the argument. If we want to understand the mechanics of power and organisation it is important not to start out assuming whatever we wish to explain. For instance, it is a good idea not to take it for granted that there is a macrosocial system on the one hand, and bits and pieces of derivative microsocial detail on the other. If we do this we close off most of the interesting questions about the origins of power and organisation. Instead we should start with a clean slate. For instance, we might start with interaction and assume that interaction is all that there is. Then we might ask how some kinds of interactions more or less succeed in stabilising and reproducing themselves: how it is that they overcome resistance and seem to become "macrosocial"; how it is that they seem to generate the effects such power, fame, size, scope or organisation with which we are all familiar. This, then, is the one of the core assumptions of actor-network theory: that Napoleons are no different in kind to small-time hustlers, and IBMs to whelk-stalls. And if they are larger, then we should be studying how this comes about -- how, in other words, size, power or organisation are generated.

I said above that there is a convergence between methodological localism and assemblage theory. But it is an uneasy convergence, on both sides. What the two perspectives have in common is easiest to identify. Each calls for a radical rethinking of social ontology. Each emphasizes plasticity, heterogeneity, and contingency in social life and structure. And each works with a metaphor of construction or composition as a way of understanding complex social stuff -- cities, for example (post). So far, so good.

But I have a suspicion that Latour would have more to criticize than to applaud in my approach. For one thing, it may appear to be reductionist: it attempts to ground social statements and theories in facts about the local circumstances of action. And it is unsympathetic to the idea of "emergent" social properties -- properties of the social whole that do not derive from the properties of the underlying social actors and their behavior. (Though see this post for a qualified defense of holism.) Further, contrary to Latour, my perspective asserts that there is a distinctive domain of social stuff; it is the domain of purposive actors in interaction, cooperation, and competition with each other. Third, the ML approach provides a basis for attributing relatively stable causal powers to higher-

level social structures -- provided we can offer appropriate microfoundations for these powers (post). Finally, in spite of my insistence on not reifying higher-level structures, Latour would probably still feel that I'm giving a degree of "thing"-ness to states and organizations that is inconsistent with his view of sociology as a study of associations among actors rather than a study of social entities and forces.

These considerations suggest there are important disagreements between the views. However, it still seems to me that there are important areas of convergence between the two bodies of thought as well: the need for a new social ontology, emphasis on the composition of the social, and an insistence on the fluidity of social life.

What seems particularly worthwhile is to probe in detail how either perspective may turn out to have real utility when it comes to framing an empirical research programme in sociology. How does either perspective help to contribute to a more successful empirical study of society? If it is just philosophical theory with no implications for doing better science, then neither framework should be taken seriously by working social researchers. But I think there is concrete practical value in these ideas; most fundamentally, if we misconceptualize a domain of inquiry, we are not likely to succeed in understanding it. Delanda, Latour, and other theorists of *assemblage* are worth reading carefully.

Variation as a social fundamental

Sunday, November 15, 2009

1966年8月，清华大学红卫兵在砸毁牌坊上的“清华园”题字。

Over 700 historians, sociologists, demographers, and political scientists enjoyed a splendid program of panels at the Social Science History Association in Long Beach this week (link). There were panels on recent historical demography, comparative historical analysis, and social mobilization research, as well as a pair of great panels on the work of Charles Tilly. There was even a smattering of papers suggesting possible opportunities for innovation in theory and research methods in historical sociology. (A book panel on Neil Smelser's recent The Odyssey Experience: Physical, Social, Psychological, and Spiritual Journeys illustrates this point: the book is highly original and demonstrates the value of seeking out new perspectives and angles of view on social behavior and social change.)

Here is one strong impression that emerges from the program. ***Variation*** within a social or historical phenomenon seems to be all but ubiquitous. Think of the Cultural Revolution in China, demographic transition in early modern Europe, the ideology of a market society, or the experience of being black in America. We have the noun -- "Cultural Revolution" -- which can be explained or defined in a sentence or two as an extended social phenomenon of mobilization and conflict that took place in China from 1966-76; and we have the complex underlying social realities to which it refers, spread out over many cities, villages, and communes across China (The Chinese Cultural Revolution as History). Or consider another general noun, "demographic transition," defined as a period in which a population experiences abrupt decline in mortality, followed by a decline in

fertility. Using a variety of statistical methods, historical demographers can document the occurrence of a demographic transition in different periods in Sweden, Italy, Britain, and China. And it turns out that there are both common features and distinguishing characteristics that emerge from detailed study -- differences in timing, differences in social composition, differences in the mechanisms bringing these changes about.

In each case there is a very concrete and visible degree of variation in the factor over time and place. Historical and social research in a wide variety of fields confirms the non-homogeneity of social phenomena and the profound location-specific variations that occur in the characteristics of virtually all large social phenomena. Social nouns do not generally designate uniform social realities (post). These facts of local and regional variation provide an immediate rationale for case studies and comparative research, selecting different venues of the phenomenon and identifying specific features of the phenomenon in this location. Through a range of case studies it is possible for the research community to map out both common features and distinguishing features of a given social process.

This description focuses on locational variation in processes -- village to village, country to country. But social scientists often also highlight variations across social segments ***within*** a given location: class, race, gender, religion, occupation. Do sharecroppers have a different fertility profile over time than the wealthy in a particular region at a particular time? Are there significant differences in survival strategies for distinct groups defined by race or ethnicity in a city or a group of cities?

This situation of variation and case-specific research raises a number of challenging questions. One is the question of whether the phenomenon designated by the noun is one integrated social reality, with varied expressions across locations, or whether instead the different locations are simply loosely similar but independent occurrences. Simon Schama's radical question -- was there a French Revolution, or were there simply a congeries of periods and locations of disturbance? -- illustrates this question (post), as does a previous discussion of the revolutions of 1848 (post).

A second major question is the challenge of discovering causal and social mechanisms connecting the various social locations encompassed by the phenomenon. How did the activism and ideology of Cultural Revolution spread from Beijing to Nanjing and other locations? How did activism spread from city to rural locations? How did local circumstances cause changes and variations in the political movement? How much path dependency existed in the spread of revolutionary ideas and strategies?

There is a more epistemic set of questions as well, concerning generalizability. Fundamentally, if there is substantial variation across locations and instances of a given phenomenon, then to what degree can we say anything about the phenomenon as a whole? And what does the study of one location allow us to say about the larger processes? Does study of the Tsinghua student Red Guard movement tell us anything about Red Guard mobilization in other places? Or is it simply one of many different and contingent develoments of contentious politics during the period? Can we generalize from case studies and comparative research?

We can also look at the problem from the other end of the telescope: are there any social phenomena that occur fairly homogeneously across all places where this phenomenon occurs? Candidates might include:

- Anti-Semitic violence across 19th-century Ukraine villages

- Marriage / fertility practices across rural Sweden 1700-1800
- Peasant revolts in medieval Germany
- Process of protoindustrialization in villages and towns in Low Countries 1300-1600 (Industrialization Before Industrialization)

For examples like these we can ask a symmetrical set of questions to those posed above. What factors explain the uniformity of results for these processes across separate locations? Various explanations are possible:

- There is a common set of conditions across the regions (e.g. famine or drought)
- There are common causes that mobilize people in many separate places (tax protests, land confiscations)
- There are common political traditions
- There is substantial inter-location communication and influence
- There are no large institutional or circumstantial variations that would drive significant variations in outcomes across locations

This is where the appeal to social mechanisms seems once more to be highly relevant and helpful. If we work on the assumption that any large social process -- the dispersed locations of contention associated with the French Revolution, say -- is the compound result of a set of underlying causal social mechanisms, and if we hypothesize that many of these mechanisms are in play in some places but not in others; then we can explain both similarity and difference in the occurrence of the phenomenon across time and place. Now the work of historical investigation can be put in these terms: identify some of the social mechanisms that evidently recur in various locations; identify some of the mechanisms that lead to significantly different results in some places; and identify some of the cross-location mechanisms that are at work to secure a degree of synchrony and parallel in the developments observed in different locations (communication systems, networks of leaders, dissemination of activists). Case studies and comparative research permit both a degree of generalization and an explanation of variation.

In other words, the intellectual strategy here is to disaggregate the large social factor into the results of a larger number of underlying mechanisms; and then to attempt to discover how these mechanisms played out differently in different settings throughout the range of the French Revolution, protoindustrialization, or ethnic conflict in South Asia. Significantly, this is exactly the strategy of research and explanation that Charles Tilly was led to in his emphasis on discovering the component social mechanisms that underlie social contention (McAdam, Tarrow, Tilly, Dynamics of Contention).

Was Durkheim a professional sociologist?

Monday, November 16, 2009

At some point in the history of sociology there was a transition from the founding non-professional genius to the professional disciplinary researcher. Marx and Tocqueville certainly fall in the former category; Robert Merton, Mayer Zald, and Neil Smelser fall clearly in the latter. By some time in the mid-twentieth century sociology had become "professionalized." What is the situation of the "professional" sociologist? To what extent and why is this an improvement? And where do Durkheim and Weber fall in this transition?

We might characterize a discipline as --

a complex set of social institutions that organize, validate, and evaluate the work

products of knowledge seekers.

This means several things: organized processes for identifying and ranking important research problems; institutions for selecting and training young scientists; formal processes for evaluating scientific work; institutions for valorizing and disseminating scientific results; and ways of prioritizing certain methods of knowledge formation and discouraging others. As Andrew Abbott shows in Department and Discipline: Chicago Sociology at One Hundred, the discipline of sociology is an amalgam of journals and editorial boards, annual conferences, associations, research universities, departments of sociology, tenure processes and standards, and funding mechanisms. And the discipline succeeds to a substantial degree in fostering certain forms of scientific behavior among young sociologists while discouraging other forms. Heterodox researchers and innovators -- counter-disciplinary thinkers -- have a harder time in building a career in the discipline at every stage: dissertation, job seeking, promotion and tenure, and publication in high-value journals. So we might say that an academic field has become professionalized when it has created the institutions and norms that serve to guide, constrain, and regulate the scientific activities of its practitioners. (Abbott offers an extensive sociology of the professions in The System of Professions: An Essay on the Division of Expert Labor. And he analyzes academic disciplines in Chaos of Disciplines. Here is an earlier post on the sociology of the professions.)

We should begin by asking this basic question: why might professionalization of sociology be thought to be a good thing? Why is the formalization of a scientific or academic discipline a good step forward? The answers, if there are any, ought to be epistemic. We'd like to think that the professionalization of science leads to an improvement in the quality of the product -- the veridicality, scope, depth, and practical value of the products of the social activity of science. And disciplines might do this in at least two ways.

First, they might serve to embody and enforce standards of scientific rigor; they might give institutional expression to valid methods of scientific research and inference. And on the people side, they might create mechanisms of evaluation of researchers and their products that consistently identify talent and sort out high quality researchers. This promotes the high achievers, motivates everyone, and winnows out the unproductive.

And second, the institutions of a discipline might serve to enhance the collective effectiveness of the research community by establishing and organizing a scientific division of labor; they might serve to focus collective attention on a limited set of problems selected to be important -- cognitively or practically. In other words, the rules and norms of the discipline might be epistemically virtuous: they might serve to ratchet up the veridicality and scope of science as a social activity.

But do the norms and institutions of the social science disciplines actually achieve these good results? Not always. In fact, we can identify directly dysfunctional features of the disciplines: a dogmatic insistence on some methods over others, a myopic focus on research problems that are ideologically selected; a tendency to discourage innovators. (See several earlier posts on the negative potential of disciplines in the social and human

sciences; sociology, political science.)

So now let's return to the cases of Tocqueville and Durkheim. How do these beacons of French sociology fare on the spectrum of the academic professions? Tocqueville is the easier case. He was an innovative and rigorous thinker when it came to understanding the social world around him. But he was clearly not a "professional," for several reasons. He was not immersed in an evaluative framework in the context of which his scientific work was to be judged. His research questions were of his own design, not part of an active community of sociologists with considered judgments about what topics were important. His reasoning about society and history followed his own intuitions about inference and explanation, not a community-based set of norms dictating answers to these questions. There was no professional discipline of sociology in 1835, and Tocqueville was not a professional.

The case of Durkheim is a bit more difficult. (Steven Lukes's Emile Durkheim: His Life and Work: A Historical and Critical Study is a superb critical discussion of Durkheim's intellectual development (google books). Robert Nisbet's The Sociology of Emile Durkheim is also valuable.) Durkheim was highly credentialed, with degrees from the École Normale Supérieure -- and of course credentialing is a crucial component of professionalization. At the same time he was a ***founder***; he was a highly original thinker with his own intuitions about what society consists of and how to research it. This implies that he was a "genius founder" or a *sui generis* amateur. But he was also embedded within a tradition of thought that was beginning to look more like an emerging discipline of sociology. His thought fit logically and clearly -- albeit with originality -- into a tradition of teachers and writers like Fustel de Coulanges and Hyppolite Taine -- another mark of being part of a discipline or research tradition. And he distinguished himself from Comte and Spencer by committing himself to specialized studies of particular social phenomena -- yet another sign of professionalism (Lukes, 137-38; 289).

And what about publications and external standards of quality assessment? Here again, Durkheim was on the cusp of a transition. He himself was the creator and long-time editor of one of the first sociological journals in 1896, *L'Année Sociologique*. His goal was to establish a working collaboration of young sociologists to contribute to the progress and specialization of the new science of sociology. Other young sociologists associated with the journal included Célestin Bouglé, Marcel Mauss, Henri Hubert, Robert Hertz, Maurice Halbwachs, and François Simiand. Durkheim was a prolific reviewer of other people's academic work in the journal (a discipline-like activity), and he did so on the basis of standards that were clearly sociological. And of course he published numerous important and influential books on different aspects of social order, and these books helped to set the research agenda for French sociology for the next generation -- yet another disciplinary activity.

So perhaps we can say that Durkheim played a dual role with respect to sociology as a professional social science. He both contributed to the definition and articulation of a discipline of sociology, and he also fell within that discipline. He was a professional sociologist in the somewhat unusual sense that Bob "Barky" Barkhimer was a professional NASCAR driver: he helped to create the very institutional processes and institutions that would eventually validate his work.

Defining the university curriculum

Saturday, November 21, 2009

What is the purpose of a university education? And who ought to answer this question when it comes to the practical business of maintaining and reforming a university curriculum?

The second question is the easier of the two. In the United States university, the faculty generally have the responsibility and authority to make decisions about the curriculum -- from the content of a particular course to the requirements of a disciplinary major, to the nature of the general education requirements to the university's graduation requirements. To be sure, there are other significant sources of influence and constraint on this faculty-centered process. Accreditation agencies like the HLC (Higher Learning Commission), ACS (chemistry), AACSB (business), and ABET (engineering) constrain various levels of curricular design at the university level and the professional or disciplinary levels. Schools of business, colleges of engineering, and chemistry departments are constrained and guided by the agencies that control their accreditation. But it is the faculty of a particular university, school, or department that fundamentally drive the process of curriculum design and maintenance.

It could have been otherwise, of course. Other nations have implemented more centralized processes where ministries of education determine the structure and content of a university program of study. And we could imagine vesting this authority in the hands of local academic administrators -- deans and provosts. But in the United States the role of the academic administrator is largely one of persuasive collaborator rather than authoritative decision-maker when it comes to the curriculum. And the reason for this is pretty compelling: faculty are experts on the content and structure of knowledge and it makes sense to entrust them with the responsibility of organizing the educational experience.

But let's go back to the harder question: what is our society trying to accomplish through a university education? Why is this a worthwhile goal? And how can we best accomplish the goal?

Most fundamentally universities exist to continue the intellectual and personal development of young people; to help them gain the skills and knowledge they will need to carry out their plans of life; and to help them fulfill their capacities as citizens, creators, and leaders. A university education ought to be an environment in which the young person is challenged and assisted in the process of expanding and deepening his or her intellectual capabilities.

We might put these ideas in more practical terms by saying that a university education should allow the student to develop the capabilities he or she will need to succeed in a career and to make productive contributions to the society of the future.

And what do these goals require in terms of a curriculum? What are those skills, capabilities, and bodies of knowledge that young people need to cultivate in order to achieve the kinds of success mentioned here?

This is the point at which there is often disagreement among various academic voices and non-academic stakeholders. There is a very career-oriented perspective that holds that there are specific professional skills that should be the primary content of a university education. On this approach, the specialized major needs to be the focus of the undergraduate's work, and the bulk of the student's effort should be directed towards acquiring these specific skills.

But there is also an approach that emphasizes the importance of breadth and pluralism within the university curriculum. On this "liberal learning" philosophy, the university student needs to be broadly exposed to the arts, humanities, mathematics, and the social and natural sciences. Here the emphasis is on helping the student acquire a broad set of intellectual capacities, not tied to a particular professional body of knowledge.

The reasons offered for this answer to the question are pragmatic ones. A leader or creator -- in whatever career -- needs to have an understanding of the social and historical context of the problems he or she confronts. He/she needs to have a rich imagination as he confronts unprecedented challenges -- within a startup company, a non-profit organization, or a state legislature. He/she needs to have the ability and confidence needed to arrive at original approaches to a problem. And he/she needs a broad set of skills of analysis, reasoning, and communication, as he works with others to discover and implement new solutions. So a liberal education is a superb foundation for almost any career -- engineer, accountant, doctor, community activist, or president.

This picture argues for breadth in the undergraduate experience. It also argues for two other curricular values: interdisciplinarity and multicultural breadth. It is evident that the difficult problems our civilization faces do not fit neatly into specific academic disciplines. Climate change, mortgage crises, and the legacy of racism all pose dense, "wicked" problems that demand cross-discipline collaboration. And likewise, the advantages created for US society by the racial and ethnic diversity of our population will be wasted if our young adults don't learn how to see the world through multiple perspectives of different human circumstances. A university isn't the only place where multicultural learning takes place, but it is one very important place. And to date universities have only scratched the surface in creating a genuinely multicultural learning environment.

So these are a few leading values that can serve to guide decisions about what an effective university education for the twenty-first century ought to include: breadth, imagination, historical and social context, rigorous reasoning, and a genuine ability to live and work in a multicultural world. And most great universities in the United States have placed their bets on some version of this philosophy of liberal learning. This bundle of features should lead to flexibility of mind, readiness for innovation, preparation for working collaboratively, and a set of intellectual skills that support effective problem solving. (Martha Nussbaum's Cultivating Humanity: A Classical Defense of Reform in Liberal Education lays out a very similar educational philosophy; her book is worth reading by everyone with an interest in university curriculum reform.)

Marc Bloch and the French social sciences

Tuesday, November 24, 2009

Marc Bloch was one of the twentieth century's most important and pathbreaking historians. Several features of his work are particularly important: his attention to the specifics of medieval economic institutions, his interest in historically specific customs and practices, and his interest in uncovering the social and technical characteristics of medieval agriculture. He helped to define contemporary social history and economic history. (See an earlier post on Bloch's historical writings.) Somehow Bloch developed a way of thinking about the history of France that deeply incorporated some of the mental frameworks of the emerging social sciences -- geography and sociology, for example -- at a time when mainstream French history was still very much driven by the chronicling of events and personages. As a discipline, history in France was very specifically defined in terms of its definition of subject matter and historical method, and Bloch's historiography challenged some very important pillars of this framework. Along with Lucien Febvre he created the intellectual impetus that led to several generations of deeply innovative historical research within the *Annales* school. So it is an interesting question for the sociology of knowledge to trace out some of the influences that were present in the 1890s and 1900s in French intellectual life that propelled Bloch's development. (The topic has some parallels to an earlier posting on "The history of sociology as sociology.")

Susan Friedman's Marc Bloch, Sociology and Geography: Encountering Changing Disciplines provides an excellent and detailed study of the intellectual and academic context in which Bloch's development occurred. (The book is also available in a much more affordable Kindle edition, and here is a link to the Google Books version.) Friedman documents a major methodological debate, extended over roughly the decade surrounding 1903, concerning the relevance of geography and sociology to academic history. The debate was in part intellectual -- how should the new ideas emerging from these social-science disciplines be incorporated into history? But it was also institutional: how should the new disciplines of geography and sociology be represented within the university and the qualification system? The École Normale Supérieure (ENS), the Collège de France, and the Sorbonne and their students and faculty played crucial roles throughout the debates. The key figures in these debates were Durkheim and his followers, including especially François Simiand; Vidal and the young scholars who wanted to extend Vidal's ideas of human geography; and the defenders of traditional French historiography, centered around Charles Seignobos. (Interestingly enough, Marc Bloch's father, Gustave Bloch, was an important voice on the side of history in this debate.)

Friedman sets up the institutional context of the French university (and the process of reform that was underway) at roughly the turn of the twentieth century, and she skillfully and knowledgeably traces through the intellectual debates and networks that provided the context to Bloch's development. The book is of great value for any reader wanting to come to a better knowledge of the intellectual and institutional currents that shaped

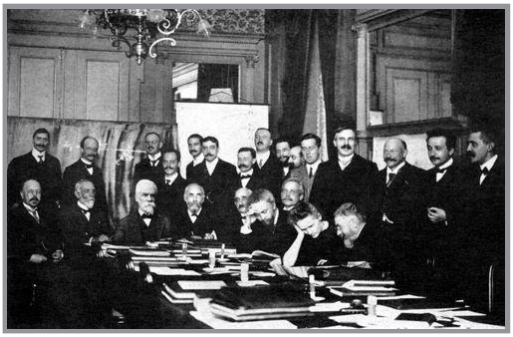
French intellectual life in the early twentieth century -- and particularly valuable if we are interested in learning more about the micro-development of Durkheimian sociology. The book offers a detailed account of the development of the Durkheimian school of sociology and the approach to "human geography" championed by Paul Vidal de la Blache, and the controversies that arose between both schools and mainstream history. (Here is a summary description of Vidal's theories of human geography and parallel thinking by Friedrich Ratzel.)

The central divides in these debates have a strikingly contemporary sound to them. Main themes included:

- Can history be a "scientific" discipline? What does this require?
- Is sociology subsumed under history or is history subsumed under sociology?
- Can social facts be explained by anything other than social facts (Durkheim)? (This cuts against both the historians, who want to explain social outcomes in terms of individual motives; and the geographers, who want to explain social outcomes in terms of physiographic features such as mountains, soil fertility, or river systems.)
- Should history study "events" or "processes, customs, and institutions"?
- What is a social or historical cause? Is there a distinction between causes and conditions?
- Should history focus its attention on the particulars of a given historical event or period; or should it use methods of comparison to arrive at generalizations and laws?

In reading Friedman's account of these debates, it is tempting to consider which positions were the most productive in the long term. The Durkheimians' insistence on the autonomy of social facts, their inflexible holism, and their insistence on discovering general social laws all seem like mis-steps from the contemporary point of view. They leave little room for social contingency and variation across social circumstances; and they leave no room whatsoever for an "agent-centered" approach to social and historical explanation. Given these shortcomings, it is perhaps a good thing that the Durkheimians never fully dominated the history profession. The Vidalians -- the human geographers -- seem like an improvement in each of these respects. Their approach emphasizes regional variation; they are eclectic in their openness to a variety of types of historical causes; and they emphasize the crucial importance of paying attention in detail to the particulars of a case. Their weakness, however, is a relative lack of attention to the specifics of social institutions. But best of all is the historian who learns something from each perspective but then constructs his own intellectual framework for the historical setting of interest to him.

And in fact, this latter position seems to be the one that Bloch took. Friedman argues that Bloch's historical sensibilities and methods were deeply influenced by these debates among the historians, sociologists, and geographers; but that ultimately his thinking remains "historical."



Even in his later years when he came closest to Durkheimian sociology, Marc Bloch remained essentially an historian. He was an historian in the sense that his primary interests lay in change and differences rather than laws and theory and that the problems which he chose to address were human ones rather than those of the physical environment. (chapter 10)

It is interesting to observe that the writings of Marx and the ideas of historical materialism do not come into this story at any point. These currents do not appear to have played a significant role in the academic debates over the future of French history in 1900. Friedman observes that Bloch was impressed by Marx. She notes that he wrote to

Febvre "that he was considering using Marx to bring some 'fresh air into the Sorbonne' and that though he suspected that Marx was a 'poor philosopher' and probably also an 'unbearable man,' Marx was without a doubt a great historian" (Kindle loc 223-35). But there is no indication in this book about what role Marx's writings played in his development. And even the statement about being a "great historian" is somewhat mysterious, since the bulk of Marx's work was plainly theoretical and immersed in political economy rather than historical research and narrative. (See an earlier posting on primitive accumulation and a posting on Marx's strengths and weaknesses as an historian.)

The German mandarins

Thursday, November 26, 2009

Fritz Ringer's The Decline of the German Mandarins: The German Academic Community, 1890-1933 is a key source on the content and social location of German academic and intellectual culture in a crucial period of its development, 1870-1933. The book appeared in German in 1967, and it presents a detailed intellectual and institutional history of the issues and actors. The concept of mandarin is Ringer's shorthand for "influential educated elite." Humanistically educated in a system that emphasized literature, classical languages, and philosophy, the mandarins played the role of the educated and powerful elites of late nineteenth-century Germany, as officials, professors, and other highly educated professionals. These were men of letters who played key roles in German social and political life. Ringer concentrates on one important segment of this elite group: Germany's professors and university leaders, primarily in the humanities and social sciences. And Ringer's central finding is that there was a highly distinctive mentality and set of social emotions that pervaded this group, and these ideas and emotions had dramatic consequences both for the nature of their theories and the direction of their political behavior as Germany's crisis deepened in the twentieth century.

Ringer's approach differs from other more internalist conceptions of intellectual history in several important respects. First, he gives a great deal of attention to the social and political context of German academic culture, essentially implying a significant degree of social causation of thought. And second, he tries to understand much of the thinking and action of this group in terms of a set of shared emotions towards the present and towards German culture. He identifies the rapid processes of economic change, industrialization, and political upheavals as being key sources of impetus for the sense of intellectual upheaval that pervaded the period. And the most important current of social emotion that he highlights is a progression from enthusiasm for a Romantic conception of education, to a profound pessimism and malaise about the current and future prospects for German culture in the face of mass democratization of society.

One way of reading this approach is to say that Ringer is functioning as a sociologist rather than strictly as an historian in his analysis of this period of intellectual history. What makes Ringer's analysis *sociological* is his effort to locate the social position of the mandarin intellectual within a theory of comparative social and political development of

early modern societies. His way of approaching the task recalls that of Karl Mannheim or Max Weber himself: situating an intellectual tradition within a broad and pervasive set of social circumstances. This approach leads to an understanding of a particular social segment -- the mandarin -- that is highly sensitive to changing social conditions: "Thus all will go well for the mandarins until economic conditions around them change radically enough to introduce powerful new groups upon the social scene" (12).

Key to the development of academic culture is the educational system, and Ringer shows how different Germany's educational institutions were from other European nations. He provides a detailed treatment of the evolution of German educational institutions during the nineteenth century, including especially the elite gymnasium and the university. His treatment demonstrates how elite academic culture and the associated institutions incorporated the romantic and idealist strains of philosophy and literature through the theory of ***Bildung***, or personal intellectual development. The cultivation of the individual is the central goal of education. (This assumption has some similarity to the theory of liberal learning mentioned in an earlier post; but current ideas about liberal learning do not insist on a sharp separation between intellectual and practical activities.)

Ringer also documents the very sharp forms of social stratification that these educational institutions created within German society, particularly towards the end of the nineteenth century. So the academic elites were separated from the rest of society by the exclusive institutions through which they were educated and by an academic philosophy that was contemptuous of practical or utilitarian skills. The mandarins were defensive of German high culture, and they were hostile to the social processes of industrialization and democratization that seemed to threaten that culture.

Another distinctive feature of Ringer's treatment is his interest in providing a ***psychological*** account of how Germany's circumstances shaped the values and goals of its intellectual class. Contrasting "logical", "traditional", and "ideological" explanations of beliefs, he argues that German intellectuals were shaped by their "emotional group preferences" (4). Ringer attempts to explain quite a bit of the development of social theory during this period in terms of the fit between a given theoretical position and the emotional perspective of the mandarin on current history.

Ringer's interpretations of the thoughts and values of these German intellectuals display a fascinating combination of assumptions about sources of influence on the character of an intellectual's thought. First, there is the fact of situatedness and limited perspective. Ringer often characterizes a thinker's choices of theories and topics in terms of the unquestioned background assumptions of this particular historically situated group. The person who grows up surrounded by the unlimited, flat horizons of Illinois will probably think differently from the one who experienced the mountain villages of the Alps since childhood -- and likewise with unquestioned social verities that differ from epoch to epoch. Second, there is the factor of self-interest. The mandarins favored a particular theory of education because it supported their positions of distinction within the university. And finally, of course, there is logic and the rational development of a particular line of thought. Ringer's presentation of Weber's exploration of the concept of the Protestant ethic is a case in point.

The first kind of intellectual influence is unconscious and invisible. The second is closer to being conscious to the thinker. And the third is analytical and intentional on the part of the thinker. These frameworks bear some analogy to the three perspectives mentioned above -- "logical", "traditional", and "ideological" explanations. But the correspondence is

not exact. We might say that the three perspectives correspond to the three different ideas about how thought corresponds to the world: that thought reflects social reality; thought advocates for social position; and thought interrogates social reality. Ringer echoes this in his coda on Weber by suggesting that Weber was able to transcend the limitations of perspective and interest to some degree, permitting him to exercise some independent critical intelligence:

Max Weber and a few other leading social scientists in the modernist camp hold a special place in the intellectual history of the mandarin community. They apparently shared some of the emotions with which the majority of their colleagues viewed the social transformations of their time. But their intellectual response to these changes far surpassed the orthodox norm in subtlety, critical control, and precision. Though never without a certain pessimism, they put their ambivalence at the service of analysis. They became at least partly conscious of their own situation. (180)

What is particularly tragic in Ringer's account is how poorly this mandarin culture prepared universities and academics for the onslaught of National Socialism and antisemitism in the 1930s. The nostalgia and pessimism that were the dominant themes of the mandarin social psychology left intellectuals unequipped for the struggle against fascism within the university and within German society. Their ideas and emotions left them ready for "conservative revolution" during the Weimar period, and provided no positive basis for mobilizing society against fascism when the time came.

These differences of tone and emphasis played a role in the political struggles of the early 1930's, in which the National Socialists triumphed over their rivals among the enemies of the Republic. ... Most academics realized at last that this was not the spiritual revolution they had sought. It was too violent and too vulgar. It declared itself the master of geist, not its servant. ... The wrote in defense of historical continuity and tradition, as if they sensed that the minimal restraints of civilization were under attack. Their tone was one of helplessness and pessimism. In 1931 Karl Jaspers warned of a coming abyss of individual nullity and unfreedom. Typically enough, he regarded the mass and machine age as the ultimate source of the approaching disaster. (436-7)

As a bit of contrast it is worth reading Arthur Koestler's autobiography, The Invisible Writing, in which he describes his experience as a radical journalist in Berlin in the early 1930s. Koestler describes his own experience and that of other politicized European intellectuals in the face of the rise of National Socialism. These too were intellectuals; but they were intellectuals who clearly perceived the deadly threat presented by the Nazi rise to power, and they were willing to fight.

Throughout the long, stifling summer of 1932 we fought our ding-dong battles with the Nazis. Hardly a day passed without one or two being killed in Berlin. The main battlefields were the *bierstuben*, the smoky little taverns of the working-class districts.... Among the Communist intellectuals who were prominent in pre-Nazi Berlin, my favourite was Hans Eisler, the composer. His family belonged to the high Comintern aristocracy and deserves a brief description. (29, 48)

(See an earlier post on Koestler's recollections.)

Comparative history

Monday, November 30, 2009

One of Marc Bloch's most important contributions was to reinvigorate the idea of "comparative history." Bloch believed that we could understand French feudalism better by putting it into the context of European legal and property regimes; and more broadly, he believed that the careful comparison of agrarian regimes across time and space could be an important source of insight into human societies. Moreover, he did not believe that the cases needed to be sociologically connected. He thought that we would learn important new truths by comparing medieval French serfdom with bonded labor in Senegal in the twentieth century, and one of the innovations developed in Bloch's editorship of ***Annales d'histoire économique et social*** was precisely his openness to this kind of comparison. (Bloch's ideas about comparative history are presented in his 1928 article, "Toward a Comparative History of European Societies," reprinted in Frederick C. Lane and Jelle C. Riermersma, eds., Enterprise and Secular Change: Readings in Economic History. See William Sewell's article, "Marc Bloch and the Logic of Comparative History" (link), for a sophisticated discussion of Bloch's theory of comparative history. Another useful resource is Colleen Dunlavy's syllabus for seminar on comparative history at the University of Wisconsin (link).)

What is "comparative history"? Most basically, it is the organized study of similar historical phenomena in separated temporal or geographical settings. The comparative historian picks several cases for detailed study and comparison, and then attempts to identify important similarities and differences across the cases. Theda Skocpol's treatment of social revolution is a case in point (States and Social Revolutions: A Comparative Analysis of France, Russia and China); Skocpol is interested in examining the particulars of the French, Chinese, and Russian Revolutions in order to discover whether there are similar causal processes at work in these three cases.

Other possible comparative research projects might include --

- Slave-based agriculture in Rome and the antebellum United States South
- Rituals of royal healing in medieval France and Bali
- Religious pilgrimages in Islam and Christianity

- Periods of rural unrest in Britain and Malaysia
- Modern economic development in England, France, and China
- Frontier societies in nineteenth-century North America and seventeenth-century Russia
- Feudal legal institutions in eastern and western Europe
- Processes of urban development in London, Mumbai, and Berlin

What is the intellectual purpose of comparative history? What might we expect to learn through careful examination of sets of cases like these? What sorts of knowledge can comparative historical research provide?

There might be several goals. First, we might imagine that some of these phenomena are the effect of ***similar causal processes***, so comparison can help to identify causal conditions and regularities. This approach implies that we think of social structures and processes as being part of a causal system, where it is possible to identify recurring causal conditions. This seems to be Skocpol's approach in *States and Social Revolutions*, though she later extends her views in an article mentioned below. Researchers often make use of some variant of Mill's methods in attempting to discover significant patterns of co-variation of conditions and outcomes. See an earlier posting on "paired comparisons."

Second, we might have a theory of ***social types and subtypes*** into which social formations fall. The purpose of comparison would be to identify some of the sub-types of a general phenomenon such as "slave economy". This sounds pretty much like the approach that Comte and Durkheim took; it corresponds to a social metaphysic that holds that there are finitely many distinct types of society, and the central challenge for sociology is to discover the structural characteristics of the various types.

Third, we might have a fundamentally ***functionalist view of social organization***, along with a basic repertoire of social functions that need to be performed. We might then look at religious systems as fulfilling one or more social functions -- social order, solidarity, legitimacy -- in alternative ways. Comparison might serve to identify functional alternatives -- the multiple ways that different social systems have evolved to handle these functional needs.

Another possible purpose of comparative history is to attempt to discover ***historical and social connections*** across separate historical settings. For example, examining different methods of labor control in different fascist countries in the 1930s may give us a basis for assessing some of the forms of influence that existed between these movements and governments (post). And Victor Lieberman's comparative study of the rise and fall of state power in France and Burma falls in this category as well; see an earlier posting on his metaphor of "strange parallels".

Finally, we might have a social metaphysics that emphasizes ***contingency and difference***. This perspective differs from the first several ideas, in that it looks at structured comparative study as a vehicle for identifying ***difference*** rather than underlying similarity. Examining the histories of Berlin and Delhi may shed a great deal of light on the range of social forces and historical contingencies that occurred in these ostensibly similar cases of "urbanization". Here the goal of comparison is more to discover alternatives, variations, and instances of path dependency. Charles Sabel and Jonathan Zeitlin's analysis of alternative forms of capitalist development in "Historical Alternatives to Mass Production" illustrates this possibility (link; see also World of Possibilities: Flexibility and Mass Production in Western Industrialization).

So there are a number of different intellectual purposes we might have in undertaking comparative historical research. How have other social scientists understood these issues?

Theda Skocpol and Margaret Somers address precisely this issue in "The Uses of Comparative History in Macrosocial Inquiry" (link). Their analysis highlights three distinct models of analysis that can underlie comparative inquiry:

There are, in fact, at least three distinct logics-in-use of comparative history. One of them, which we shall label comparative history as *macro-causal analysis*, actually does resemble multivariate hypothesis-testing. But in addition there are two other major types: comparative history as the *parallel demonstration of theory*; and comparative history as the *contrast of contexts*. Each of the three major types of comparative history assigns a distinctive purpose to the juxtaposition of historical cases. Concomitantly, each has its own requisites of case selection, its own patterns of presentation of arguments, and--perhaps most important--its own strengths and limitations as a tool of research in macrosocial inquiry. (175)

R. Bin Wong offers a different view of the value of comparison in historical studies in his important comparative study of Chinese economic and political development (China Transformed: Historical Change and the Limits of European Experience). Wong argues that comparison allows the historian to discover what is distinctive about a particular series of historical developments. Features which perhaps looked inevitable and universal in European economic development look quite different when we consider a similar process of development in China; we may find that Chinese entrepreneurs and officials found very different institutions to do the work of insurance, provision of credit, or long-distance trade. Likewise, elements that might have been taken to be *sui generis* characteristics of one national experience may turn out to be widespread in many locations when we do a comparative study.

Ultimately it seems that there are really only two fundamental intellectual reasons for being particularly interested in historical comparisons. One is the hope of discovering recurring social mechanisms and structures. This is what Charles Tilly seems to be about in his many studies of contentious politics. And the second is the hope of discovering some of the differentiating pathways that lead to significantly different outcomes in ostensibly similar social settings. The first goal serves the value of arriving at some level of generalization about social phenomena, and the second serves the goal of tracing out the fine structure of the particular.

(The images above represent rice cultivation in Bali and grain cultivation in France. As Marc Bloch might have observed, they depict landscapes that reflect fundamentally different agrarian regimes: intensive cultivation in small plots in Bali, versus extensive cultivation making use of a considerable amount of animal or machine traction in France. And Bloch would have been likely to spend a great deal of effort at discovering the legal, cultural, religious, and technical characteristics of the two regimes.)

Styles of epistemology in world sociology

Tuesday, December 01, 2009

Table 2. Theory and Evidence in Mexico and the United States

	United States (%)	Mexico (%)
Use of theory		
Mertonian "middle-range" logic	77	0
Draw "freely" on grand-theory	10	50
Do not explicitly employ theories	0	47
Other	13	3
Statement that theories should be tested by data		
Yes	87	0
No	13	100
General proposition among central claims		
Yes	87	7
No	13	93
Role of the empirical problem		
Empirical problem in itself is the main concern	7	93
Empirical problem speaks to a broader theoretical issue	93	7
Justification of problem in terms of a broader theoretical issue		
Yes	90	0
No	10	100
Deductivism		
Yes	60	0
No	40	100
Number of cases	30	30

One of the basic organizing premises of the sociology of science is that there are meaningful differences in the conduct of a given area of science across separate communities, all the way down. There is no pure language and method of science into which diverse research traditions ought to be translated. Rather, there are complex webs of assumptions about ontology, evidence, observation, theory, method, and reasoning; and there are highly significant differences in the institutions through which scientific activities are undertaken and young scientists are trained. Sociologists and philosophers such as Thomas Kuhn, David Bloor, Paul Feyerabend, Bruno Latour, and Wiebe Bijker have attempted to lay out the reasons for thinking these forms of difference are likely to be ubiquitous, and several of them have done detailed work in specific areas of scientific knowledge to demonstrate some of these differences. (Here is a post on Kuhn's approach to the history of science.)

In this vein is a genuinely fascinating and important article by Gabriel Abend with the evocative title, "Styles of Sociological Thought: Sociologies, Epistemologies, and the Mexican and U.S. Quests for Truth" (*Sociological Theory* 24:1, 2006). Abend attempts to take the measure of a particularly profound form of difference that might be postulated within the domain of world sociology: the idea that different national traditions of sociology may embody different ***epistemological*** frameworks that make their results genuinely incommensurable. Abend offers an empirical analysis of the possibility that the academic disciplines of Mexican and U.S. sociology embody significantly different assumptions when it comes to articulating the role and relationships between "evidence" and "theory." Here is how he summarizes his findings:

[The] main argument is that the discourses of Mexican and U.S. sociologies are consistently underlain by significantly different epistemological assumptions. In fact, these two *Denkgemeinschaften* are notably dissimilar in at least four clusters of variables ... : their thematic, theoretical, and methodological preferences; their historical development and intellectual influences; the society, culture, and institutions in which they are embedded; and the language they normally use.(2)

The core of Abend's analysis is an empirical study involving content analysis of four leading sociology journals in Mexico and the U.S. and sixty articles, randomly chosen through a constrained process. He analyzes the articles with respect to the practices that each represents when it comes to the use of empirical evidence and sociological theory. And he finds that the differences between the Mexican articles and the U.S. articles are

highly striking. Consider this tabulation of results on the question of the role of evidence and theory taken by the two sets of articles:

His central findings include these:

- U.S. and Mexican sociologists have very different understandings of "theory" and the ways in which theories relate to data. U.S. sociologists conform to Merton's idea of "theories of the middle range" in which a theory relates fairly directly to empirical observations through its deductive consequences. Mexican sociologists tend to use theories and theoretical concepts as ways of interpreting or thematizing large social phenomena.
- U.S. sociologists see the burden of their work to fall in the category of testing or confirming sociological hypotheses. Mexican sociologists see the burden of their work in detailing and analyzing complex social phenomena at a fairly factual level. "93 percent of M-ART are principally driven by the comprehension of an empirical problem" (10).
- U.S. sociologists are strongly wedded to the hypothetico-deductive model of confirmation and explanation. This model plays very little role in the arguments presented in the sample of articles from Mexican sociologists.
- U.S. and Mexican sociologists have very different assumptions about "scientific objectivity". U.S. authors aspire to impersonal neutrality, whereas Mexican authors embrace the fact that their analysis proceeds from a particular perspective.
- U.S. authors attempt to exclude value judgments; Mexican author incorporate value judgments into their empirical analysis. "Among U.S. sociologists, the standard reference is Weber's purportedly sharp distinctions between value and fact, *Wertfreiheit* (value freedom or ethical neutrality) and *Wertbezogenheit* (value relevance or value relatedness), and context of discovery and context of justification" (22). Concepts such as "oppression," "exploitation," and "domination" are used as descriptive terms in many of the Mexican research articles.

Table 3. Epistemic Objectivity in Mexico and the United States

	United States (%)	Mexico (%)
Rational reconstruction of research process		
Yes	80	0
No	20	100
Sections		
Standard	93	0
Nonstandard	7	80
Two or no sections	0	20
Average number of tables	4.40	0.33
Data discussion		
Yes, in a section	67	0
Yes	20	10
No	13	90
Methods discussion		
Yes, in a section	63	0
Yes	7	0
No	30	100
Number of cases	30	30

Here is a striking tabulation of epistemic differences between the two samples:

Abend believes that these basic epistemological differences between U.S. and Mexican sociology imply a fundamental ***incommensurability*** of results:

To consider the epistemological thesis, let us pose the following thought experiment. Suppose a Mexican sociologist claims p and a U.S. sociologist claims not-p. Carnap's or Popper's epistemology would have the empirical world arbitrate between these two theoretical claims. But, as we have seen, sociologists in Mexico and the United States hold different stances regarding what a theory should be, what an explanation should look like, what rules of inference and standards of proof should be stipulated, what role evidence should play, and so on. The empirical world could only adjudicate the dispute if an agreement on these epistemological presuppositions could be reached (and there are good reasons to expect that in such a situation neither side would be willing to give up its epistemology). Furthermore, it seems to me that my thought experiment to some degree misses the point. For it imagines a situation in which a Mexican sociologist claims p and a U.S. sociologist claims not-p, failing to realize that that would only be possible if the problem were articulated in similar terms. However, we have seen that Mexican and U.S. sociologies also differ in how problems are articulated—rather than p and not-p, one

should probably speak of p and q. I believe that Mexican and U.S. sociologies are perceptually and semantically incommensurable as well. (27)

Though Abend's analysis is comparative, I find his analysis of the epistemological assumptions underlying the U.S. cases to be highly insightful all by itself. In just a few pages he captures what seem to me to be the core epistemological assumptions of the conduct of sociological research in the U.S. These include:

- the assumption of "general regular reality" (the assumption that social phenomena are "really" governed by underlying regularities)
- deductivism
- epistemic objectivity
- a preference for quantification and abstract vocabulary
- separation of fact and value; value neutrality

Abend is deliberately agnostic about the epistemic value of the two approaches; he is explicit in saying that he is interested in discovering the differences, not assessing the relative truthfulness of the two approaches. But we cannot really escape the most basic question: where does truth fall in this analysis? What is the status of truth claims in the two traditions? Are there rational grounds for preferring one body of statements over the other, or for favoring one of these epistemologies over its alternative north or south?

This is important and original work. Abend's research on this topic is an effort well worth emulating; it adds a great deal of depth and nuance to the effort to provide a philosophy of sociology. I hope there will be further analysis along these lines by Abend and others.

(There is a lot of social observation and theory in the image above -- and no pretense of academic objectivity. Class opposition, global property systems, and a general impression of deep social conflict pervade the image.)

Messy regional problems and collaborative leaders

Wednesday, December 02, 2009

Regions are highly complex social formations: millions of people, thousands of businesses, hundreds of non-profit organizations, and lots of problems. Some problems are relatively simple to deal with. If the local river is being polluted by sanitary system overflows during heavy storms, the solution is costly but straightforward: the region needs to invest in a sewer separation infrastructure project.

What is more difficult for a region to handle is a situation where it is confronted by a complex of problems that are substantially inter-related and that fall outside the scope of traditional policy-making organizations. These are sometimes referred to as "wicked" problems, and they are difficult both scientifically and practically. They are difficult scientifically because it is hard to trace the various interlinked forms of causation that have created the problem. And they are difficult

practically because their solution requires the cooperation of groups and actors whose interests and understandings of the situation are often at odds. And this cooperation may need to persist over a very extended period of time -- longer than the attention span of many of the politicians, business leaders, and university presidents who have taken an interest in the problem.

Take the problem of job losses in the Detroit metropolitan region. This is a situation that is caused by a complex set of conditions and occurrences of long and short duration: business decisions about plant closings, national trends in consumer behavior, the financial crisis of 2008, family traditions of college attendance, cultural expectations about blue-collar and white-collar work, patterns of racial segregation, fiscal problems for state and local governments, and deterioration of the natural and built environment. This problem is particularly difficult to deal with for several important reasons:

- the causes of the problem are interdependent
- high unemployment itself reinforces some of the causes of rising unemployment
- the policies that would reverse job losses are not easy to identify or implement
- solutions fall outside the scope of authority of the individual decision-making organizations
- solutions may require legislative action, business decisions, and mass behavioral changes that are difficult to elicit or coordinate

Solutions that have been proposed include --

- increase the percentage of college-educated adults
- make the metropolitan area more attractive to talented young people
- encourage entrepreneurship
- create a more business-friendly environment
- lower the tax burden on businesses
- restructure state and municipal government to reduce public costs
- encourage investment in high-tech industries such as alternative energy and bioengineering
- create an "arts corridor" that links Motown and the design talents of the auto industry

But notice this important fact: these recommendations do not add up to a coherent and actionable strategy. This is true for several reasons. The relationship between the factor and the intended result is not a certain one in any of these cases; the actors who would need to take concrete actions in order to bring the factor into being are different in most of these cases; each intervention is costly, so we can't actually do all of these at once; the operational timeframes of these strategies are very different, from months to decades; and some of the strategies here would interfere directly with the efficacy of others.

More abstractly, interventions that might have a positive effect on employment may be difficult to achieve for a number of different reasons:

- they require coordinated action by multiple actors: for example, the legislature, the county executive, and several major corporations; and coordination is difficult to achieve
- the promising interventions may be conditional on achievement of several other difficult actions as well by other actors
- there may be a "blocking" actor whose interests would be harmed by the intervention in spite of its otherwise positive effects

It seems evident that a region that faces "wicked" and strongly interlinked problems like these needs to manage to create a ***plan*** for addressing the problem and a ***coalition*** of actors who have the resources and decision-making authority to take the steps specified by the plan. The plan needs to be based on the best possible ***analysis*** of the economic

and social effects of various ***interventions***, based on sound social science and social policy analysis. The actors might include: a group of legislators and the governor and mayor; multiple business groups; a cohesive set of labor leaders; and a few regional foundations which are prepared to commit significant resources to the plan.

Every step of this description poses new challenges for the region, because essentially we are faced with a public-goods problem at the level of a large, complicated public with a number of independent actors: there are costs associated with the formulation of a plan and the marshalling of a coalition, and the benefits of the effort will be broadly shared by the public as a whole. So no single organization or actor has an incentive to play the lead as agent of change, and the incentives for collaboration are weak as well.

This is where "leaders" come in. One would hope that a region has a cohort of individuals and organizations with a specific set of characteristics:

- an evidence-based vision concerning the way forward -- the changes that are needed in order to address the problem and the sorts of interventions that would bring these changes about
- a broad conception of the balance of public and private interests
- a willingness to engage in costly collaborations that promote the public good
- a practical ability to create and sustain collaborations among other powerful actors
- access to the resources of an organization: money, staff, prestige, and influence with other actors

The traditional categories of leaders are easy to understand. Their positions might include "elected official," "corporate CEO," "non-profit CEO," "foundation president," "newspaper publisher," "labor leader," or "university president." These individuals stand at the head of formal organizations, and their organizational positions give them ready-made channels of influence on public policy. Their experiences in leading their organizations may also give them a degree of insight into how to approach the broad problems that a region often faces -- disaster recovery, loss of major industries, a rising trend in social or ethnic conflict.

Some of these leaders are officially charged with the responsibility of formulating strategies and policies that will assist in the solution of problems; so mayors and governors need to be actively involved in the formulation of plans for dealing with these sorts of challenges. But most of these leaders are not charged in this way; instead, their formal responsibilities include specific organizational goals: "maximizing stockholder value," "achieving the philanthropic goals established by the board of directors," "increasing readership and advertising revenues," "protecting the interests of the members." There will always be a wide distribution of balance points between private and public interest that are chosen by these leaders; some are more public-spirited, and some are more single-minded about the interests of the organization they lead.

In addition to these traditional categories, there are sometimes leaders in a complicated community who don't fit into the usual boxes. They don't have executive authority in corporations, foundations, or labor unions, and they aren't elected to positions of official leadership. What they do have is a set of assets that fall in the category of ***social capital***:

- a big rolodex filled with relationships to powerful and influential people
- a strong and positive reputation in the leadership community
- an ability to be persuasive in dealing with a wide range of actors
- a passionate commitment to "making the region better"
- a philosophy of collaboration that they can make compelling to other actors

We might call this kind of leader a "high-level socially connected broker" (HLSCB) -- a

person who is well positioned to broker relationships among other powerful "elite" actors. The influence these leaders wield does not derive from the dollars they can commit from their own organizations (foundations, corporations), or the votes they can marshall (labor unions, student organizations), or the direct legislative influence they can wield (lobbyists, large law firms, business associations). Instead, their influence stems from ideas, passion, and relationships, and their ability to facilitate durable collaboration among actors with somewhat divided interests. The size of the rolodex is a measure of the density of the networks within which this actor functions; the HLSCB is unusually rich in a set of network relationships that permit him/her to make contact with an unusually large number of other influential actors. And the HLSCB has a set of personality characteristics that lead him/her to make use of the networks and personal charisma he/she possesses to form working coalitions dedicated to solving difficult problems. These leaders can be successful in helping a region address its wicked problems -- and perhaps more successful than the more traditional varieties of leaders are likely to be.

Why is this an interesting set of topics for ***UnderstandingSociety***? For several important reasons: it casts a spotlight on some of the most difficult types of problems that a region can face; it highlights some of the reasons that actors in a single sector are unlikely to be able to solve such problems; it underlines the question of motives and incentives for leaders and stakeholders that plague efforts to solve these types of problems; and it postulates one of the conditions that may be most important for securing meaningful collaboration around efforts to solve these large problems. And it would appear that the broker-leader is one of those ingredients for successful collaboration.

Current historical sociology: George Steinmetz

Thursday, December 03, 2009

George Steinmetz, professor of sociology at the University of Michigan, is a leading scholar in the contemporary field of historical sociology. His most recent book is The Devil's Handwriting: Precoloniality and the German Colonial State in Qingdao, Samoa, and Southwest Africa, and his volume The Politics of Method in the Human Sciences: Positivism and Its Epistemological Others is a major contribution to current debates on the methods and aims of the social sciences today. Here is a video interview and conversation I conducted with George at the University of Michigan this month. Quite a few of George's academic papers are available on his website.

This is part of an ongoing series of interviews I am conducting with innovative social scientists. The goal of the series is to provide a forum in which some very innovative and productive thinkers are able to reflect on some of the ideas and perspectives that are creating innovative work in sociology today. Visit my research page for links to prior interviews. All the videos are available on YouTube.

The German debate over method

Friday, December 04, 2009

A prior post described a major debate around 1900 in the French academic world over the terms of exchange among history, geography, and sociology. The debate also involved disagreements among France's academic elites over the structure of the future French university system. This was sometimes referred to as the "new Sorbonne" debate, and it had important implications for future developments in French social and historical thinking (post on French sociology).

Germany underwent its own debates about similar issues at about the same time. At stake was the fundamental question, how should the human sciences be construed? The central axes of these debates were ***positivism*** and the search for general causal explanations, and ***historicism*** and the search for hermeneutic understanding of specific individuals and historical moments. The several schools of thought offered very different ideas about how best to understand the social world. A central point of debate was the famous distinction drawn by Wilhelm Windelband between nomothetic and idiographic sciences. Fritz Ringer formulates Windelband's distinction (1894) in these terms:

> Methodologically, the empirical disciplines in fact fall into two groups: the *Gesetzeswissenschaften* pursue "nomothetic" knowledge of the general in the form of invariant "laws"; the *Ereigniswissenschaften* strive for "idiographic" knowledge of singular patterns or events. (Ringer, 32)

Within the terms of this distinction, the historicists were offering idiographic knowledge, whereas the natural scientists were offering nomothetic knowledge. And the more positivist theorists of the human sciences argued that the social sciences should aspire to the kind of generality and universality that is required by nomothetic science.

These German debates played key roles in the development of twentieth-century sociology. Just as Durkheim played centrally in the French debate, Max Weber was a key actor in the German debates. His own treatment of the historical school is contained in several essays in Roscher and Knies and Critique of Stammler, and his later development was deeply influenced by his engagement with these controversies. (G. H. von Wright's Explanation and Understanding provides a philosopher's analysis of the two traditions.)

Fritz Ringer's Max Weber's Methodology: The Unification of the Cultural and Social Sciences is a good source on the content and importance of the German methodology debate about the cultural sciences. Ringer attempts to understand the logic of Weber's conception of methodology and theory in sociology through his responses to historicism, positivism, and *verstehen* theory. Weber was committed to contributing to a scientific study of society; but what does science require when it comes to human society? These strands of historical and social thought in German intellectual life imply rather different answers to this question. And Ringer argues that Weber's methodology is designed to

make sense of the valid insights of each current of thought. Ringer holds that Weber's approach is both causal and interpretive; both general and particular.

Another important study of this set of debates is Woodruff Smith's 1991 book, Politics and the Sciences of Culture in Germany, 1840-1920 (Google Books link). Here is how Smith describes his subject:

In the nineteenth century, there appeared a new group of academic disciplines that took culture as a primary object of scientific study. These included anthropology in its many varieties, human geography, culture history, and branches of psychology that focused on culture. In other fields, the concept of culture became a significant part of the apparatus of interpretation. Bodies of theory about culture emerged, often overleaping the boundaries between disciplines. The development of these "cultural sciences" was an international phenomenon to which people of all major European nations and the United States contributed. But distinctive national approaches also revealed themselves, each largely shaped by the public context of intellectual life in a particular country.

This book is concerned with the cultural sciences in Germany between the 1840s and about 1920. During those years, German academia exercised its most profound influence on the rest of the world -- an influence that is generally acknowledged in some cultural sciences, for example geography, but to which rather little attention is paid in others, such as cultural anthropology. In the German intellectual setting, *Kulture* and *Kulturwissenschaft* came to have many meanings. Here we shall concentrate on cultural scientists who believed that they were practicing a nomothetic science (i.e., searching for the laws of human society as revealed in culture) and who regarded culture itself mainly in its anthropological sense. (3)

Ringer is writing as an historian of ideas, and he borrows an important concept from Bourdieu as an intellectual framework for his analysis -- the idea of an ***intellectual field***. He explains the idea in these terms:

I have elsewhere drawn upon Pierre Bourdieu's writings to define the "intellectual field" as a constellation of positions that are meaningful only in relation to one another, a constellation further charactrized by differences of power or authority, by the opposition between orthodoxy and heterodoxy, and by the role of the cultural preconscious, of tacit "doxa" that are transmitted by inherited practices, institutions, and social relations. Specifying the vague notion of "context" in this way, one can see that individuals may stand in a variety of specific relationships to their intellectual and social environment. (5)

This concept works well for Ringer's purposes, because it permits analysis of both the intellectual and the institutional settings of the debates that shaped Weber's thinking about the human sciences. The structure of the university and the relations of power that existed within the academic world are relevant -- as was equally true in the case of the French debate; and the inherent logic and rational force of a given school of thought is determining as well for the formation of the young investigator's understanding of "sociology." To borrow a metaphor from Marx, "intellectuals make their own thoughts, but not in circumstances of their own choosing." So the concept of intellectual field works well as a framework for the sociology of knowledge.

The historicist tradition included writers such as Ranke, Roscher, Knies, Schmoller, and Sombart. (Joseph Schumpeter offers some notes on the historicist school in his massive

volume on the history of economics, History of Economic Analysis (IV:4); Google Books link.) Historicists reject the idea that the social sciences (or economics) should aspire to the discovery of universal laws of society or universal and unchanging human institutions. The concrete study of specific economic institutions of the past -- economic history -- is a more insightful way of understanding the workings of economies than pure mathematical theories of competitive equilibria that are intended to apply in all times and places. Johann Gustav Droysen was a particularly articulate critic of the positivist strand of thought. "[Droysen's] main argument had to do with the divide between the search for regularities and the historian's predominant concern with the interpretive understanding of the unique and particular" (Ringer, 12). Instead of general laws and uniform structures, the historicists argue that human society illustrates historical particularity and individuality -- in structures and institutions as well as persons.

Often this insistence on historical particularity converged with the hermeneutic view that social understanding always involves the interpretation of meaningful human action and motivation. (Here is an earlier post on interpretation theory, and here is a post on the ways in which Alasdair MacIntyre and Charles Taylor have adapted these ideas.) Wilhelm Dilthey (1883) argued that the human sciences were profoundly different from the natural sciences because they involved interpretive understanding of human action rather than mechanical explanation of a system of causes. Ringer observes, further, that another of the founders of modern sociology, Georg Simmel, arrived at a very similar theory of *verstehen* in the 1890s, and that Simmel's influence on Weber was greater than that of Dilthey. Even more important for Weber, though, was a book by Heinrich Rickert, The Limits of Concept Formation in Natural Science: A Logical Introduction to the Historical Sciences (1902). Rickert's theories reconsider the distinction proposed by Windelband, proposing that the distinction between nomothetic and idiographic knowledge does not correspond to the distinction between natural and social knowledge.

The positivist framework became important in German intellectual life in the middle of the nineteenth century, though Ringer observes that "positivism" in the Comtean sense had virtually no advocates in German intellectual life prior to the Vienna Circle (post). But there was a current of thought in Germany in the late nineteenth century that took its lead from the logic of the natural sciences and attempted to apply this model to the human sciences. Mid-century philosophers such as Friedrich Albert Lange advocated for a philosophy that combined the methods of the natural sciences with a neo-Kantian metaphysics (19). Ringer singles out a stratum of what he calls "scientist-philosophers" -- Rudolf Virchow, Wilhelm Ostwald, Friedrich Ratzel, Adolf Bastian, Karl Lamprecht, and Wilhelm Wundt, as a group of intellectuals who brought the epistemic values of the natural sciences into an effort to construct the human sciences (20). If there is to be such a thing as a social science, positivism maintains that it should have the same logical characteristics as natural sciences like physics and chemistry; and this was taken to mean that it should seek out lawlike generalizations that are independent of space and time.

One important voice representing a broadly naturalistic perspective on the social sciences was Carl Menger. His critique of the historicist school from the point of view of pure economic theory is an important stage in the debate.

Our cognitive interest is directed either at the concrete phenomena in their position in space and time and at their concrete interrelationships, or else ... at the recurrent patterns in which they appear. The former research direction aims at knowledge of the concrete or, more correctly, the individual, the latter at knowledge of the general.

(Investigations into the Methods of the Social Sciences, quoted in Ringer, 16)

It appears that we could summarize the development of the two traditions as including a few branching streams of thought:

- Positivism =====> science seeks to discover universal laws
- =====> science offers causal explanations

Historicism =====> the historical and human sciences study particular human institutions in specific historical settings

- =====> the human sciences proceed through systematic interpretation of the subjective meanings and intentions of individual actors

The two major ideas associated with historicism can certainly be separated; one can accept the point that institutions are historically variable without accepting the unavoidably hermeneutic nature of social knowledge; and one could be a thorough-going hermeneutic without committing to the point about the historical boundedness of institutions or human nature. And there is a similar disconnect on the side of positivism; as Ringer points out, it is possible to be a causalist without assuming that causes are ahistorical and universal. One might take the view that a given kind of cause has a set of social powers within the context of one set of institutions but not another -- in the context of the Roman empire but not in the context of British colonialism. So both schools of thought have important distinctions collapsed within them.

Fundamentally we might say that these debates raised a small number of key questions: Is there a sharp distinction between the natural and social sciences? Is causation relevant to the interpretation of human affairs? Is there a distinctive method of interpretation of human action that underlies the scientific study of society and culture? Are there laws that govern social phenomena? Should the social sciences make use of universal concepts that apply in all times and places, or should its concepts be tailored to specific historical settings? In what ways are "history" and "nature" distinguished? Taking positions on these topics also sets the parameters for the kind of research and knowledge the social scientist will pursue.

From the vantage point of the present, it seems that we can provide some fairly compelling answers to these questions. Social institutions are plastic, heterogeneous, and contingent; so the historicists were right about this point. Human action and human nature are historically conditioned as well, in the concrete and ordinary sense that "character," "motivation," "knowledge," and "identity" are all historical products; once again, the historicists were right. The social sciences do not need to discover universal, timeless laws of society; such a quest is futile and inspired by a bad philosophy of science. So the positivists and naturalists were wrong on this point, and the historicists were closer to the truth.

But this doesn't mean that we are forced to conclude that the social sciences are idiographic and particularistic. Rickert was right in doubting the sharp distinction between human action and the natural world; it is entirely coherent to assert that human mentality and action are natural phenomena. And there is plenty of room in the human sciences for a causal analysis of social change and social persistence. But we should not understand these causal judgments as resting on an as-yet unknown set of causal laws. Instead, we are better off working with an ontology of causal mechanisms, embodied in institutions and actions of persons. And, finally, we are not forced to choose between idiographic and nomothetic science; instead, the social sciences should aspire to an empirical analysis of the world that is sensitive to the particularity of social institutions and identities, while at

the same time discovering the limited generalizations that are made possible through the discovery of common social mechanisms. In a sense, we might say that current historical sociology represents the resolution of these debates that took place in Germany in the 1870s through 1920s. Researchers such as Tilly, Moore, Steinmetz, Adams, and Skocpol have made a great deal of progress in defining the balance between the particular and the general in their studies of complex historical processes.

(These historicism debates have also been of interest in recent Japanese social science research. An interesting pair of contributions from a Japanese perspective are Yuichi Shionoya's The Soul of the German Historical School: Methodological Essays on Schmoller, Weber and Schumpeter and The German Historical School: The Historical and Ethical Approach to Economics.)

Alleviating rural poverty

Monday, December 07, 2009

What theories and values ought to underlie our best thinking about global economic development? Along with Amartya Sen (Development as Freedom), I believe that the best answer to the ethical question involves giving top priority to the goal of increasing the realization of human capabilities across the whole of society (The Paradox of Wealth and Poverty: Mapping the Ethical Dilemmas of Global Development). We need to put the poor first. However, I also believe that our ability to achieve this goal is highly sensitive to the distributive structures and property systems that exist in poor countries. The property institutions of developing countries have enormous impact on the full human development of the poor. As a result, ethically desirable human development goals are difficult to attain within any social system in which the antecedent property relations are highly stratified and in which political power is largely in the hands of the existing elites.

The fundamental question of poverty is this: how do people earn their livings? The economic institutions of the given society (property relations and market institutions, for example) determine the answer to this question. An economy represents a set of social positions for the men and women who make it up. These persons have a set of human needs—nutrition, education, health care, housing, clothing, etc. And they need access to the opportunities that exist in society—opportunities for employment and education, for example. The various positions that exist within the economy in turn define the entitlements that persons have—wages, profits, access to food subsidies, rights of participation, etc. The material well-being of a person—the “standard of living”—is chiefly determined by the degree to which his or her “entitlements” through these various sources of income provide the basis for acquiring more than enough goods in all the crucial categories to permit the individual to flourish (Sen, Poverty and Famines: An Essay on Entitlement and Deprivation). If wages are low, then the consumption bundle that this income will afford is very limited. If crop prices are low, then peasants will have low incomes. If business taxes are low, then business owners may retain more business income in the form of profits, which will support larger consumption bundles and larger

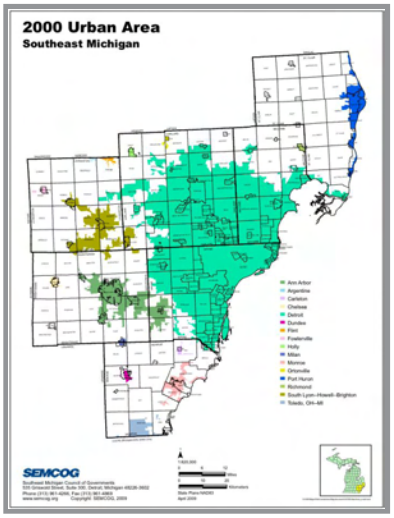
savings. There is thus a degree of conflict of interest among the agents within the economic system; the institutions of distribution may favor workers, lenders, farmers, business owners, or the state, depending on their design. And it is very possible for economic development to proceed in a way that gives the greatest benefit to the upper levels of society without leading to much change at the bottom.

Here I want to review an important empirical example of economic development without commensurate gain for the poor of the region: the effects of the Green Revolution in the rice-growing regions of Malaysia. James Scott provides a careful survey of the development process in Malaysia in Weapons of the Weak: Everyday Forms of Peasant Resistance (1985). The chief innovations were these: a government-financed irrigation project making double-cropping possible; the advent of modern-variety rice strains; and the introduction of machine harvesting, replacing hired labor. Scott considers as relevant factors the distribution of landholdings, the forms of land tenure in use, the availability of credit, the political parties on the scene, and the state's interests in development.

Scott's chief finding is that double cropping and irrigation substantially increased revenues in the Muda region, ***and*** that these increases were very unequally distributed. Much of the increase flowed to the small circle of managerial farmers, credit institutions, and outside capitalists who provided equipment, fertilizers, and transport. Finally, Scott finds that the lowest stratum—perhaps 40%—has been substantially marginalized in the village economy. Landlessness has increased sharply, as managerial farms absorb peasant plots; a substantial part of the rural population is now altogether cut off from access to land. And mechanized harvesting substantially decreases the demand for wage labor. This group is dependent on wage labor, either on the managerial farms or through migration to the cities. The income flowing to this group is more unstable than the subsistence generated by peasant farming; and with fluctuating consumption goods prices, it may or may not suffice to purchase the levels of food and other necessities this group produced for itself before development. And these circumstances have immediate consequences for the ability of poor households to achieve the development of their human capabilities. Their nutritional status, their health, their literacy, and their mobility are all directly impaired by the fact of low and unstable household income. Finally, the state and the urban sector benefits substantially: the increased revenues created by high-yield rice cultivation generate profits and tax revenues that can be directed towards urban development.

Scott draws this conclusion:

> The gulf separating the large, capitalist farmers who market most of the region's rice and the mass of small peasants is now nearly an abyss, with the added (and related) humiliation that the former need seldom even hire the latter to help grow their crops. Taking 1966 as a point of comparison, it is still the case that a majority of Muda's households are more prosperous than before. It is also the case that the distribution of income has worsened appreciably and that a substantial minority—per-haps 35-40 percent—have been left behind with very low incomes which, if they are not worse than a decade ago, are not appreciably better. Given the limited absorptive capacity of the wider economy, given the loss of wages to machines, and given the small plots cultivated by the poor strata, there is little likelihood that anything short of land reform could reverse their fortunes. (Scott 1985:81)



This example well illustrates the problems of distribution and equity that are unavoidable in the process of rural development. The process described here is one route to

"modernization of agriculture," in that it involves substitution of new seed varieties for old, new technologies for traditional technologies, integration into the global economy, and leads to a sharp increase in the productivity of agriculture. Malaysia was in effect one of the great successes of the Green Revolution. At the same time it created a sharp division between winners and losers: peasants and the rural poor largely lose income, security, and autonomy; while rural elites, urban elites, and the state gained through the increased revenues generated by the modern farming sector.

Gillian Hart, Andrew Turton, and Benjamin White's Agrarian Transformations: Local Processes and the State in Southeast Asia (1989) provides detailed case studies of these sorts of processes of property and power in development in Thailand, the Philippines, Malaysia, and Indonesia.

Measuring recession's impact: Michigan

Wednesday, December 09, 2009

Michigan has been in a rolling crisis since 2002 or so: the state has experienced the loss of manufacturing jobs, mortgage foreclosures, and plummeting state and municipal revenues at a pace that has left the region badly shaken. What have been some of the macro-level effects? How have population, income, employment, and housing changed since 2000? In particular, what effects has the recession had on southeast Michigan, where almost half of the state's population lives?

The Southeast Michigan Council of Governments (SEMCOG) has released a preliminary analysis of the data collected in the 2008 American Community Survey (a periodic resurvey conducted by the US Census Bureau; link). Some of the results are startling. Most dramatic is what has happened to income, but the region also shows important changes in residential occupancy, poverty rates, and unemployment.

The report considers data for seven counties in southeast Michigan -- Livingston, Macomb, Monroe, Oakland, St. Clair, Washtenaw, and Wayne. (This corresponds loosely to the definition of the Detroit Metropolitan Statistical Area, which consists of the six counties of Lapeer, Livingston, Macomb, Oakland, St. Clair, and Wayne.) The population of this region was 4.8 million in 2008, essentially unchanged since the 2000 census. So the region had not experienced significant net out-migration as of 2008 (post). But the age structure of the population has changed noticeably, from a median age of 35.2 in 2000 to a median age of 38.1 in 2008.

The most striking change in this period is a dramatic drop in household and per capita

income. In 2000 the median household income was $64,590, which fell to $54,184 in 2008 -- a 16% decline in household income. And per capita income fell from $40,993 to $34,665 -- a 15% decline in per capita income. This is a very large decline in a short time.

The report also documents a wide income gap based on race. In 2008 median white household income was $63,183, whereas in black households it was $40,021 and in Hispanic households it was $44,548. White households were about 50% more affluent than black households.

Both parts of these findings are important. The overall decline in personal and family income in eight years is quite remarkable; it certainly represents a very significant decline in the standard of living in the region as a result of recession-related job losses and wage cuts. And the racial disparities indicated by the gaps between white, black, and Hispanic households demonstrate the persistent racial disadvantages that seem to be hard-wired into the region.

The decline in family income has other harmful consequences as well. The net purchasing power of the region dropped by a significant percentage -- which translates into the loss of revenues for small businesses whose revenues depend on consumer purchases. And state revenues based on income taxes and sales taxes in the region fell as well by a comparable percentage -- leading to a fiscal crisis for the state and for municipalities.

Not surprisingly, the ACS data demonstrate that there was a significant upsurge in the poverty rate in the region between 2000 and 2008. In 2000 10.6% of the population lived below the poverty line; and in 2008, this group had risen to 13.9% -- a 31% increase. The percentage of families with children in poverty rose from 11.5% to 15.7%, an even greater increase than in the general population.

The effects of the foreclosure crisis are visible in this report as well. Changes in residential vacancy rates are an indicator of rising frequency of foreclosures. In 2000 there were 106,680 vacant housing units (5.5%). In 2008 this number had risen to 260,974 units (12.6%). This reflected large increases in both homeowner and rental vacancy rates over the time period.

Another noteworthy feature of the report is the light it sheds on differences by county in some important variables across the region. Most striking is the percentage of adults with a college degree. The region as a whole has 28% of its adults with a bachelor's degree or higher. And this number has increased from 25% in 2000. (At the other end of the spectrum, 12.4% of the adult population lacks a high school degree in 2008.) But this average masks a very wide range of college attainment rates by county, from a low of 13.9% in St. Clair County (the extreme northeast of the map above) to highs of 42.3% in Oakland County and 51.3% in Washtenaw County. Wayne County has a college completion rate of 19.5%.

Also striking are the income differences across counties. Median household incomes

ranged from a low of $42,376 (Wayne County) to a high of $71,486 (Livingston County). Washtenaw County (home of Ann Arbor and the University of Michigan) is somewhat anomalous: it has the highest percentage of college-educated adults, but its median household income is in the middle, at $57,848.

Predictably, poverty rates varied across counties as well. Livingston County had the lowest poverty rate in 2008 (7.6%), while Wayne County had the highest poverty rate by a significant margin (20.1%). So a person in Wayne County had almost three times the likelihood of living in poverty as a person in Livingston County. Washtenaw County's poverty rate is also surprisingly high, at 14.6%.

Finally, it appears that the foreclosure crisis had differential impact across the region as well. Wayne County shows the highest residential vacancy rate in 2008 (17.9%), whereas Livingston, Macomb, Monroe, and Washtenaw Counties fall between 7.6% and 8.6%. So the residential vacancy rate in Wayne County is at least double that of other parts of the region.

This set of data from the 2008 American Community Survey sheds light on two very important facts. First, southeast Michigan has suffered deeply and rapidly as a result of the recession. The loss of jobs and shrinking of business activity resulted in rapid and sharp declines in family income; the recession greatly increased the number of home foreclosures; and it resulted in placing another 155,000 people in poverty -- a 31% increase in the number of people in poverty. And second, the 2008 data demonstrate that these effects are not uniformly distributed across the region. Several counties weathered the recession relatively well. The worst effects have been experienced in Wayne County and the city of Detroit. And, given the degree of racial segregation that is demonstrated in Southeast Michigan, this implies that the recession had disproportionately harmful effects on the African-American population of the state.

Koestler's nightmares

Thursday, December 10, 2009

Image: book burning by National Socialist paramilitaries, 1933

Image: Ukraine peasants fleeing famine

Image: street battle, Spanish Civil War

Arthur Koestler was an articulate witness of the atrocities of the twentieth century; and much of what he witnessed was terrible. Reading his books gives one an intense and personal vision of fascism, dictatorship, mass murder, starvation, and cruelty on a monstrous scale. As George Orwell wrote of Koestler's books in 1944, "The subject-matter of all of them is similar, and none of them ever escapes for more than a few pages from the atmosphere of ***nightmare***" (link). Koestler worked as a Communist journalist in Berlin in the early 1930s during the rise of the brown shirts; he was the first European journalist to travel through the Ukraine to witness the results of famine in Stalin's war against the Kulaks (Lynne Viola, The War Against the Peasantry, 1927-1930: The

Tragedy of the Soviet Countryside); and he observed the Spanish Civil War, where he was arrested after the fall of Malaga, imprisoned, and sentenced to death as a Red. (Here is an earlier post on Koestler.)

These experiences are described in his autobiography, The Invisible Writing, and the narrative of his experiences in Spain is presented in Dialogue With Death. But Koestler's best known book is a novel, Darkness at Noon, which is the story of the final weeks of life of the fictional Soviet revolutionary Rubashov in Stalin's purges of the 1930s and the Moscow show trials. After a life as leader, theorist, and agent in service of the Soviet Union and the Communist Party, Rubashov is arrested for fictitious crimes of conspiracy and betrayal against the State. He is arrested before dawn; it takes him quite a while to find his pince-nez. He is thrown into a Soviet political prison -- it is reminiscent to him of the fascist prisons in which he had suffered beatings and torture years earlier. He is brought to confess to these crimes and others under interrogation by his former comrade-in-arms, Ivanov, and the new Soviet thug, Gletkin. Ivanov is psychologically manipulative; Gletkin is brutal; but both strive to break Rubashov and compel his confession. They are successful; Rubashov confesses to betraying the Revolution; and like Bukharin, he is convicted and summarily shot in the back of the neck. Along the way there is quite a bit of debate about history, the individual, the Party, and the Future of Humanity. The key question of the novel is the puzzle: why did Rubashov confess rather than following the secret advice of the prison barber -- "die in silence!"?

Koestler himself was a committed Communist agent in Berlin in the 1930s; so his descriptions of Rubashov's activities in eastern Europe have the ring of truth -- including Rubashov's betrayals of Richard and Little Loewy in the name of socialism. The novel recreates the Moscow show trials of 1937 with uncanny insight. Rubashov is loosely based on Nikolai Bukharin, one of the intellectual and political leaders of the Russian Revolution. Koestler's novel was written only two years after the trial and execution of these leaders of the Russian Revolution at the hands of Stalin's functionaries. Here is what he says about the central character:

The characters in this book are fictitious. The historical circumstances which determined their actions are real. The life of the man N. S. Rubashov is a synthesis of the lives of a number of men who were victims of the so-called Moscow Trials. Several of them were personally known to the author. This book is dedicated to their memory. Paris, October, 1938-April, 1940

But here is what I find fascinating. Koestler's fictional recreation of the arrest and trial of the top Party officials, in the person of Rubashov, and the background assumptions and rationalizations assumed by the prosecutors and interrogators, is remarkably close to the

historical reality. Here is Koestler's description of his own arrest and arrival in a Spanish fascist prison in Malaga:

It is a unique sound. A cell door has no handle, either outside or inside; it cannot be shut except by being slammed to. It is made of massive steel and concrete, about four inches thick, and every time it falls to there is a resounding crash just as though a shot has been fired. But this report dies away without an echo. Prison sounds are echo-less and bleak.

When the door has been slammed behind him for the first time, the prisoner stands in the middle of the cell and looks round. I fancy that everyone must behave in more or less the same way.

First of all he gives a fleeting look round the walls and takes a mental inventory of all the objects in what is now to be his domain:

- *the iron bedstead,*
- *the wash-basin,*
- *the W.C.,*
- *the barred window.*

His next action is invariably to try to pull himself up by the iron bars of the window and look out. He fails, and his suit is covered with white from the plaster on the wall against which he has pressed himself. (*Dialogue with Death*, 59)

And now turn to Rubashov's first few minutes in Stalin's jail cell:

Rubashov walked up and down in the cell, from the door to the window and back, between bunk, wash-basin and bucket, six and a half steps there, six and a half steps back. At the door he turned to the right, at the window to the left. It was an old prison habit; if one did not change the direction of the turn one rapidly became dizzy. .... Rubashov stood hesitantly in the middle of the cell, then put his pince-nez on again and propped himself at the window. (*Darkness at Noon*, 14, 18)

Much of the drama of *Darkness at Noon* is the series of interrogations Rubashov undergoes, and the mental transformation that they bring about in this courageous man to bring him to confess to the most farfetched and unbelievable crimes. The transcripts of Bukharin's prosecution exist; Robert Tucker and Stephen Cohen's THE GREAT PURGE TRIAL provides extensive transcripts of the interrogation of Bukharin and other show trial victims. It is striking to compare the interrogation of Bukharin with the interrogation of Rubashov. Consider this bit of interrogation of Rubashov, beginning with the voice of prosecutor Ivanov:

"To return to more tangible things: you mean, therefore, that 'we' -- namely, Party and State -- no longer represent the interests of the Revolution, of the masses or, if you like, the progress of humanity."

"This time you have grasped it," said Rubashov smiling. Ivanov did not answer his smile. "When did you develop this opinion?"

"Fairly gradually: during the last few years," said Rubashov.

"Can't you tell me more exactly? One year? Two? Three years?"

"That's a stupid question," said Rubashov. "At what age did you become adult? At seventeen? At eighteen and a half? At nineteen?"

"It's you who are pretending to be stupid," said Ivanov. "Each step in one's spiritual development is the result of definite experiences. If you really want to know: I became a man at seventeen, when I was sent into exile for the first time." (69)

And now a similar moment in the actual transcripts of the interrogation of Bukharin.

Vyshinsky: Allow me to begin the interrogation of the accused Bukharin. Formulate briefly what exactly it is you plead guilty to.

Bukharin: Firstly, to belonging to the counter-revolutionary "Bloc of Rights and Trotskyites."

Vyshinsky: Since what year?

Bukharin: Roughly since 1928. I plead guilty to being one of the outstanding leaders of this "Bloc of Rights and Trotskyites." Consequently I plead guilty to what directly follows from this, the sum total of crimes committed by this counter-revolutionary organization, irrespective of whether or not I knew of, whether or not I took a direct part, in any particular act. Because I am responsible as one of the leaders and not as a cog in this counter-revolutionary organization.

Vyshinsky: What aims were pursued by this counter-revolutionary organization?
Bukharin: This counter-revolutionary organization, to formulate it briefly ...

Vyshinsky: Yes, briefly for the present.

Bukharin: The principal aim it pursued, although, so to speak, it did not fully realize it, and did not dot all the "i's" -- was essentially the aim of restoring capitalist relations in the U.S.S.R. (Tucker, 328)

And now, back to *Darkness at Noon* and Rubashov; the porter's daughter reads aloud the newspaper account of the last minutes of Rubashov's testimony:

"Asked whether he pleaded guilty, the accused Rubashov answered 'Yes' in a clear voice. To a further question of the Public Prosecutor as to whether the accused had acted as an agent of the counter-revolution, he again answered 'Yes' in a lower voice ...."

Here seems to be Koestler's own explanation of the puzzle of the confessions:

Some were silenced by physical fear, like Hare-lip; some hoped to save their heads; others at least to save their wives or sons from the clutches of the Gletkins. The best of them kept silent in order to do a last service to the Party, by letting themselves be sacrificed as scapegoats -- and, besides, even the best had each an Arlova on his conscience. They were too deeply entangled in their own past, caught in the web they had spun themselves, according to the laws of their own twisted ethics and twisted logic; they were all guilty, although not of those deeds of which they accused themselves. There was no way back for them. Their exit from the stage happened strictly according to the rules of their strange game. The public expected no swan-songs of them. They had to act according to the text-book, and their part was the howling of wolves in the night.... (DN, 105)

Fiction and reality are deeply intertwined here. I don't believe that Koestler had access to transcripts of the show trials at the time he wrote *Darkness at Noon* in 1940, though he had read accounts of the trials. So the convergence of the fictional Rubashov and the historical Bukharin is remarkable. And the transformation of Koestler's own experiences -- in Communist activism and in fascist prison under sentence of death -- into the fiction of Rubashov is very striking.

The state prosecutor who conducted the show trial of Bukharin was Andrei Vyshinsky. Following his success in the show trials, Vyshinsky became a prominent diplomat under Stalin. And after World War II he served as permanent representative to the United Nations during the period that the Universal Declaration on Human Rights was drafted and adopted. He led the Soviet Bloc nations in abstention from the vote adopting the Universal Declaration on Human Rights. Here is a fragment of the outrageous speech he gave on this occasion:

Human rights could not be conceived outside the State; the very concept of right and law was connected with that of the State. (The Universal Declaration of Human Rights: Origins, Drafting, and Intent, 21-22)

I am drawn to Koestler's writings -- both his fiction and his autobiographical writings -- in part because he provides such a powerful example of an engaged mind attempting to make sense of the history around him. Much of his work is a first-person effort to "understand society" -- to make sense of the social forces and individual behavior that the twentieth century presented. George Orwell is another of my favorites in this aspect of literature, including especially Homage to Catalonia and A Collection of Essays; so it is very interesting to me that Orwell wrote the short essay about Koestler mentioned above. It is also interesting that they were both published in England by Victor Gollancz, along with E. P. Thompson.

(Louis Menand has an interesting profile of Koestler in the *New Yorker* this month.)

Sewell on history

Saturday, December 12, 2009

William Sewell, Jr., is a particularly talented historian of French social history. His study of the guild mentalities of workers in Marseille ***after*** the Revolution breaks many preconceptions about "class" and the definition of labor (Structure and Mobility: The Men and Women of Marseille, 1820-1870). But he is also a philosophically minded observer

and critic of historical writing. In Logics of History: Social Theory and Social Transformation he offers a singular contribution to historiography by an innovative interdisciplinary historian and sociologist. The book is a contribution to what I would call "applied philosophy of history": careful, analytical attention to some of the problematic constructs and frameworks that underlie the ways in which scholars attempt to characterize and explain historical change. The issues Sewell raises resonate strongly with comparative historical sociologists — scholars who are concerned with analyzing social processes in a variety of settings over an extended period of time.

Why do historians and social scientists need this kind of analysis? Because the logic and constructs involved in thinking historically are still incompletely understood. We will do a better job of understanding and probing the past, if we are more self-conscious about some of the assumptions and frameworks that we bring to our work. What is a historical “period”? What is an "event"? How are large historical constructs to be defined (revolutions, Tudor state, Marseillaise working class)? For that matter -- is there anything of historical importance captured in the snapshot of a Marseille street scene in 1914 pictured above?

Many historians have judged that the social sciences should somehow be relevant to their work of explaining historical outcomes. But what is involved in making use of social science theories in historical research and explanation? It has been evident for several decades that social processes are diverse, messy, and heterogeneous. So the impulse towards finding general laws of social transformation has been discouraged. But what is to take the place of a generalizing, universalizing approach within a “social science” study of social transformation? The best answer available at present is, an extensive borrowing from a wide range of the human sciences. The social sciences can provide a toolbox of mid-level theories of mechanisms, mentalities, and institutions that can provide resources for historians as they attempt to analyze and explain particular historical episodes. What can anthropologists tell historians about the challenge of reconstructing the mentalities of people in the past? What can the geographers of place tell us about the logic of trading and transport networks? What can researchers on collective action tell us about some of the factors that may have accelerated or inhibited popular protest in particular historical settings?

Some philosophers have offered to shed light on these abstract questions about the ontology of history and the logic of historical explanation through philosophical analysis -- for example, Ian Hacking's Historical Ontology. Sewell’s approach to these meta-historical questions is not from the point of view of philosophy, but rather from that of the methodologically sophisticated practitioner. And the results are noteworthy. *Logics of History* makes a very substantive contribution to the revitalization of the field of the philosophy of history.

Sewell's volume provides a reading of the intellectual development of social history as a discipline since the 1960s: the currents of Marxism, anthropology, and post-modernism, and the themes of underclass history, local meanings, and multiple texts. Sewell's central goal is to shed light on some of the core theoretical constructs that are used in historical research. There are chapters on the concepts of temporality, structure, culture,

synchrony, the event, and historical duration.

A recurring topic in the book is the question of "temporality". Sewell points out that social scientists often give short shrift to the temporal properties of a set of social changes or processes. In "Three Temporalities: Towards an Eventful Sociology" he carefully teases apart the different ways in which historically minded sociologists have treated historical processes, and he singles out teleological temporality, experimental temporality, and "eventful" temporality. The first approach places historical events into a supposed necessary series of stages; the second takes events out of historical settings in order to use them as the fodder of quasi-experiments in causal reasoning; and the third approach emphasizes the path dependence of historical sequences. Events in their particular historical settings have causal consequences for the shaping and occurrence of later events. Sewell characterizes events in this way: "Events may be defined as that relatively rare subclass of happenings that significantly transforms structures. An eventful conception of temporality, therefore, is one that takes into account the transformation of structures by events" (100). Sewell returns to his understanding of events in several later essays in the book as well, including "A Theory of the Event" and "Historical Events as Transformations of Structures."

Other important topics that Sewell considers include the intellectual foundations of our conceptions of structure ("A Theory of Structure") and culture ("The Concept(s) of Culture"), and the involvement of both these concepts in historical cognition. In both instances Sewell takes up a large meta-concept within the social sciences and subjects it to careful analytical attention. The results are substantial; both essays suggest new ways of thinking of the role of social structures and cultures within historical processes—not as fixed, uniform causal influences, but as flexible and plastic constructs within which historical actors live and act.

These topics are important because their nuances can significantly affect the practitioner's process of reasoning and inquiry as he or she treats historical processes. If the investigator begins with an assumption of fixed causal laws, then he or she is inclined to regard specific historical developments as instances of historical regularities. If, on the other hand, one approaches historical processes as involving a high degree of contingency and plasticity of historical events and structures, then one will give substantially greater attention to the specifics of the case.

Who invented the totalitarian state?

Tuesday, December 15, 2009

The world has known ruthless, violent, and murderous rulers for centuries. Queen Elizabeth ran a secret service that ruthlessly pursued her enemies in the Catholic underground. Isabella and Ferdinand persecuted and expelled the Jews of Spain. And the French government was perfectly ready to use deadly force against workers and rebels in Paris in 1848 and 1871. But the totalitarian state was a creation of the twentieth century. The fascist states of Italy, Spain, and Germany as well as the Soviet state seem to have been

qualitatively different from even the most repressive of their nineteenth century predecessors. By comparison, Bismarck's Prussia, Napoleon III's France, Czar Alexander's Russia, and Victor Emmanuel's Italy were quaint amateur affairs when it came to organized coercion and mass politics.

The differences are striking -- the apparatus of political prisons, the extensive secret police networks, the purposive use of violent organizations, the ideologies of national and ethnic purity. Most fundamental, though, is the degree and depth of bureaucratic control that the modern totalitarian state achieved. This is what made the modern fascist or soviet state "total" -- an ability to monitor and intimidate civil society down to the street level.

The distinction between the realm of the state and the realm of civil society has been fundamental to political theory. Civil society encompasses the private activities of individuals and their associations, and the realm of the state involves the political apparatus of law, enforcement, and coercion. We can roughly estimate the degree to which the apparatus of the state is able to penetrate down into civil society. And European states prior to the twentieth century were objectively limited in their capacity to rule civil society. This is true for the imperial Chinese state in the nineteenth century as well; it was commonly said that the power of the Emperor ended at the yamen wall (or at the county level). As Mark Allee puts it in Law and Local Society in Late Imperial China: Northern Taiwan in the Nineteenth Century,

The limited effectiveness of yamen runners as police prompted local administrators in Danshui and Xinzhu to search for ways to augment and supplement their runner cadre. In so doing, sub-prefecture and county heads aimed to create more intimate linkages to the people in their jurisdiction and to extend the reach of local government beyond the yamen wall into the countryside. (197)

Weak states have only a limited ability to enforce their will against the mass populations of city and countryside; mechanisms such as tax farming and collective tax liability are therefore called upon in order to secure the resources needed by the central authorities. And the scope of law and the effective enforcement of laws and decrees is limited as well in a weak state. European polities of the nineteenth century were generally weak states; Britain, France, Germany, and Italy had central governments with only limited administrative capacity and limited ability to impose their authority at the local level. But there was a dramatic increase in the beginning of the twentieth century in the administrative capacity of the state and its ability to govern local society. The scope of the political grew much broader, and the domain of civil society -- the relatively safe and insulated zone of individual activity and choice -- grew more limited. The creation of the totalitarian state depended on this radical increase in state power and state coercive capacity.

A striking feature of the totalitarian states of the twentieth century is their aggressiveness and brutality towards all opposition. These fascist states were ruthless and effective in their ability to attack and dismantle oppositional groups -- including communists, labor unions, radical peasants, rent resistance organizations, liberals, and anarchists. Chuck Tilly's discussion of "trust networks" is relevant here; the balance of power between the

trust networks of civil society and the central power of the state apparatus shifted profoundly with the advent of the modern dictatorship; Trust and Rule.

One index of the administrative and coercive capacity of the state is the degree to which it is successful in exacting a greater percentage of the national wealth in taxes. Weak states are relatively inefficient at collecting taxes. So careful historical study of systems of taxation is an important contribution to the topic of the power of the state. Isaac Martin, Ajay Mehrotra, and Monica Prasad's The New Fiscal Sociology: Taxation in Comparative and Historical Perspective provides a good exposure to the field of comparative fiscal sociology. With a foreword and article by Charles Tilly, it examines the ways in which states since the early modern period have intensified their ability to collect tax revenues.

One piece of this new capacity was organizational. Fascist states in the 1930s created bureaucracies of surveillance, enforcement, punishment, and killing that went vastly beyond the capacity of nineteenth century state organizations. The organizations of police and army in Italy, Spain, and Germany took major steps forward in size and complexity in the twentieth century. The personnel of the forces of coercion -- police and other armed state forces such as militias -- were few in the early nineteenth century; but by the middle of the twentieth century these numbers had grown exponentially.

Improved communication and transportation were also key to the possibility of the totalitarian state. The telephone and the railroad allowed fascist states to collect information quickly and to move their forces around the cities and countryside efficiently; functionally, this meant that rural groups and ordinary people were no longer buffered from the state by poor roads and rudimentary communication.

Another technological advance that was crucial for the totalitarian state was a substantial improvement in the technology of record keeping and retrieval. James Scott argues that the modern state's imperative to regiment and record its population is fundamental to its capacity to collect taxes and conscript soldiers -- and therefore fundamental to the nature of modern political power (Seeing Like a State: How Certain Schemes to Improve the Human Condition Have Failed). The technology of organized record keeping improved dramatically in the first several decades of the twentieth century -- thus making the state's goal of closely monitoring its subjects more attainable. (Edwin Black describes the use of IBM punch card systems to manage National Socialist records of Jews and other enemies in IBM and the Holocaust.) So communication, transportation, and record-keeping were crucial to the creation of the totalitarian state.

Of course greater state capacity is not synonymous with totalitarianism. Liberal democratic states too increased their capacity to impose their will at the local level. What distinguished totalitarian regimes was the set of ideological and political goals that fascist states sought to accomplish on the basis of their greater repressive capacity and the cult of violence that each embodied. Other states took some of these sorts of steps forward in the twentieth century; the "reach of the state" increased dramatically in the United States, France, and Britain as well. The administrative functions of the state and the ability to extract revenues through taxation increased exponentially. It would be interesting to compare the total tax percentages in 1860 and 1930 for the United States and France; surely the increase is dramatic. And likewise, the personnel of these states increased dramatically during the same time period as a percentage of population. But this broad increase in state capacity did not lead to repression and dictatorship in these countries.

This topic is historically interesting; much turns on how we explain the power and human

tragedies associated with Franco's Spain or Mussolini's Italy. But it is also interesting today when we consider the undisguised efforts of the Iranian state, and its Republican Guard military organization, to dominate the whole of Iranian civil society. Here too we see the use of surveillance, intimidation, mass arrests, forced confessions, and political murder as tactics in the effort to control civil society.

(There is quite a bit of scope for new comparative historical research on this topic. Chuck Tilly has always emphasized these issues in his analysis of the development of the modern state. Michael Mann's findings in The Sources of Social Power, Vol. 2: The Rise of Classes and Nation States, 1760-1914 are certainly relevant as well to this line of thought. But there isn't much empirical detail available at present. Simply attempting to measure the dimensions highlighted here for a number of countries -- scale of tax collections, size of state apparatus, size and complexity of police organizations, and overall state capacity to regulate local society -- requires research that doesn't appear to exist at present.)

Merton's sociology of science

Thursday, December 17, 2009

The organized study of "science" as an epistemic practice and a knowledge product has taken at least three major forms in the past century: the ***philosophy*** of science, the ***history*** of science, and the ***sociology*** of science. Philosophers have been primarily interested in the logic of scientific inquiry and the rational force of scientific knowledge. Historians have been interested in the circumstances, both external and internal, through which important periods of the growth of scientific knowledge have occurred -- the Newtonian revolution, the Darwinian revolution, the "discovery" of cold fusion (above). And sociologists have been interested in examining the norms and organizations through which "science" is practiced -- how young scientists are trained, how collaboration and competition work within a scientific discipline or a laboratory, how results are assessed and communicated.

And because the intellectual frameworks within which philosophers, historians, and sociologists have been educated differ substantially, these meta-disciplines of the study of science are significantly different as well. The philosophers are largely interested in the quality of the product -- the rational force of a given body of scientific knowledge. The historians are interested in the contingencies of development of a given field. And the sociologists are interested in the social processes that lead to the creation of a body of scientific knowledge; they are inclined to "bracket" the epistemic standing or truth-value of the theories and hypotheses that a tradition has produced.

Robert Merton was one of the giants of American sociology. One of his core contributions had to do with his efforts to define the subject matter and methodology of the sociology of science. A volume of Merton's essays from the 1930s through 1960s on the sociology of

science appeared in 1971, The Sociology of Science: Theoretical and Empirical Investigations, and these essays are worth re-reading today. Here are some of Merton's formulations of the task of the sociology of science in "The Neglect of the Sociology of Science" (1952):

Numerous works ... have variously dealt with one or another part of the subject [of the sociology of science]. But these ... have not examined the linkage between science and social structure by means of a conceptual framework that has proved effective in other branches of sociology. (210)

Among current introductory textbooks in sociology ... all deal at length with the institutions of family, state, and economy, many with the institution of religion, but very few indeed with science as a major institution in modern society. (211)

Unlike the pattern in solidly established disciplines, in the sociology of science, facts are typically divorced from systematic theory. Empirical observation and hypothesis do not provide mutual assistance. Not having that direct bearing on a body of theory which makes for cumulative knowledge, the empirical studies that have been made, from time to time, by natural scientists have resulted in a thin scattering of unconnected findings rather than a chain of closely linked findings. (212-13)

So the goal of the sociology of science is to examine the linkage between science and social structure using the "conceptual frameworks" of sociology. The sociology of science needs to be based on empirical observation -- i.e. it cannot be a purely conceptual discipline. But it must possess an appropriate framework of sociological theory within the context of which empirical observations of scientific practice can be explained.

Several ideas were particularly important in Merton's efforts to conceptualize the processes of science:

- the importance of discovering the norms that underlay the research and thinking of scientists in a given field (the ethos of science); ("the emotionally toned complex of rules, prescriptions, mores, beliefs, values and presuppositions that are held to be binding upon the scientist")
- the internal social structure of various scientific disciplines (training, communication, information flow, evaluation)
- the incentives that exist within the scientific disciplines that constitute the driving force for scientists to aggressively pursue publishable results; the reward system. How do the imperatives of the ethos and the institutions of science come together to determine the patterns of behavior of the individual working scientist?

One of Merton's key methodological contributions was the idea that it was possible to observe and measure the institutions of science through careful empirical examination of the biographies, journals, and other objective markers of scientific activity. (This is what he refers to as the conceptual framework of sociology.) He repeatedly attempts to quantify and measure the activities of science -- publication rates, inventions, numbers of scientists in a field, and so forth. For example, in "Changing Foci of Interest in the Sciences and Technology" (1938) he attempts to estimate the pattern of shifting scientific interest in England over the period of 1665-1702 by counting the numbers of articles to be published in various areas of science (tables 3-4). He finds that the physical and formal sciences fall in frequency during this time period, while the life sciences rise significantly (201). How should we explain this shift in the interests of the scientific

community? Merton advocates a sociological cause. Referring back to Rickert and Weber, he argues that this shift is likely to be linked to the broader societal interests of the time period:

Scientists often choose problems for investigation that are vitally linked with major values and interests of the time. Much of this study will examine some of the extra-scientific elements which significantly influenced, if they did not wholly determine, the foci of scientific interest. (203)

Another of Merton's key ideas is the role of the reward system of science, which he takes to be the motor of scientific change:

Like other institutions, the institution of science has developed an elaborate system for allocating rewards to those who variously live up to its norms.... The evolution of this system has been the work of centuries, and it will of course never be finished. (297)

And he finds that this reward system gives great weight to originality and priority -- which leads to the recurring phenomena of priority disputes, fraud, and plagiarism in science (309). And it leads as well to the phenomenon of multiple discovery by independent researchers:

The pages of the history of science record thousands of instances of similar discoveries having been made by scientists working independently of one another. Sometimes the discoveries are simultaneous or almost so; sometimes a scientist will make anew a discovery which, unknown to him, somebody else had made years before. Such occurrences suggest that discoveries become virtually inevitable when prerequisite kinds of knowledge and tools accumulate in man's cultural store and when the attention of an appreciable number of investigators becomes focused on a problem, by emerging social needs, by developments internal to the science, or by both. (371)

A final topic of interest in Merton's sociology of science is his treatment of "peer review". Here is how he describes this part of the institutions of science in "Institutionalized Patterns of Evaluation in Science" (1971):

The referee system in science involves the systematic use of judges to assess the acceptability of manuscripts submitted for publication. The referee is thus an example of status judges who are charged with evaluating the quality of role-performances in a social system. They are found in every institutional sphere. (460)

So we might encapsulate Merton's intellectual framework for the sociology of science in a few basic ideas: the sociologist needs to find ways of observing scientific practice empirically; the conduct of science is driven by the values that the institutions of science inculcate and enforce; the incentives created by the scientific institutions shape and motivate the behavior of scientists; and the product of science is the result of the constrained activities of scientists shaped and motivated in these particular ways. So the sociologist needs to discover and document the values, he/she needs to uncover the evaluation mechanisms, and he/she needs to discover in detail how innovations and theories have emerged in specific research environments.

What this description leaves out from a contemporary perspective might include:

- analysis of social networks of collaboration and communication among scientists
- analysis of the institutions of training through which scientists learn their craft

- content analysis of the results of scientific inquiry -- recurring features of theory and explanation within specific research traditions

(Trevor Pinch is an important contemporary contributor to current sociology of science and is one of the editors of the 1995 volume, Handbook of Science and Technology Studies. Here is a link to his syllabus for a seminar on the sociology of science that indicates how he conceptualizes the discipline.)

What makes a sociological theory compelling?

Sunday, December 20, 2009

In the humanities it is a given that assertions and arguments have a certain degree of rational force, but that ultimately, reasonable people may differ about virtually every serious claim. An interpretation of *Ulysses*, an argument for a principle of distributive justice, or an attribution of certain of Shakespeare's works to Christopher Marlowe -- each may be supported by "evidence" from texts and history, and those who disagree need to produce evidence of their own to rebut the thesis; but no one imagines there is such a thing as an irrefutable argument to a conclusion in literature, art history, or philosophy. Conclusions are to some degree persuasive, well supported, or compelling; but they are never ineluctable or uniquely compatible with available evidence. There is no such thing as the final word, even on a well formulated question. (Naturally, a vague or ambiguous question can always be answered in multiple ways.)

In physics the situation appears to be different. Physical theories are ***about*** a class of things with what we may assume are uniform characteristics throughout the range of this kind of thing (electrons, electromagnetic waves, neutrinos); and these things come together in ensembles to produce other kinds of physical phenomena. So we often believe that physical theories are deductive systems that attribute a set of mathematical properties to more-or-less fundamental physical entities; and then we go on to derive descriptions of the behavior of things and ensembles made of these properties. And the approximate truth of the physical theory can be assessed by the degree of success its deductive implications have for the world of observable ensembles of physical things. So it seems that we can come to fairly definitive conclusions about various theories in the natural sciences: natural selection is the mechanism of species evolution; gravitational force is the cause of the elliptical shapes of planetary orbits; the velocity of light is a constant. And we are confident in the truth of these statements because they play essential roles within deductive systems that are highly confirmed by experiment and experience.

So what about the empirical domains of sociology or history? Is it possible for careful empirical and theoretical research to provide final answers to well formulated questions in these fields? Is it possible to put together an argument in sociology on a particular question that is so rationally and empirically compelling that no further disagreement is possible?

There is a domain of factual-empirical questions in sociology where the answer is probably affirmative. What is the population of Detroit in 2000? What percentage of likely voters supported McCain in October 2008? What is the full unemployment rate among African-American young people in Ohio? When was the International Brotherhood of Teamsters recognized in Cleveland? There are recognized sources of data and generally accepted methods that would allow us to judge that a particular study definitively answers one or another of these questions. This isn't to make a claim of unrevisability; but it is to assert that some social inquiries have as much empirical decidability as, say, questions in descriptive ecology ("what is the range of the *Helicinidae* land snail in North America?") or planetary astronomy ("what is the most likely origin of the planetary body Pluto?").

But most major works in sociology do not have this characteristic. They do not primarily aim at establishing a limited set of sociological or demographic ***facts***. Instead, they take on larger issues of conceptualization, explanation, interpretation, and theory formation. They make use of empirical and historical facts to assess or support their arguments. But it is virtually never possible to conclude, "given the available body of empirical and historical evidence, this theory is almost certainly true." Rather, we are more commonly in a position to say something like this: "Given the range of empirical, historical, and theoretical considerations offered in its support, theory T is a credible explanation of P." And it remains for other scholars to either advance a more comprehensive or well-supported theory, or to undermine the evidence offered for T, or to provisionally accept T as being approximately correct. Durkheim put forward a theory of suicide based on the theoretical construct of ***anomie*** (Suicide). He argued that the rate of suicide demonstrated by a population is caused by the degree of anomie characteristic of that society; and he offered a few examples of how the theoretical construct of anomie might be operationalized in order to allow us to measure or compare different societies in these terms. But his theory can be challenged from numerous directions: that it is monocausal, that it assumes that suicide is a homogeneous phenomenon across social settings, and even that it overstates the degree of consistency that exists between "high anomie" and "high suicide" social settings.

Take Michael Mann's analysis of fascism (Fascists). He considers a vast range of historical and sociological evidence in arriving at his analysis. His theory is richly grounded in empirical evidence. But numerous elements of his account reflect the researcher's best judgment about a question, rather than a conclusive factual argument. Take Mann's view that "materialist" and class-based theories of fascist movements are incorrect. I doubt that his richly documented arguments to this conclusion make it rationally impossible to continue to find support for the materialist hypothesis. Or take his definition of fascism itself. It is a credible definition; but different researchers could certainly offer alternatives that would lead them to weigh the evidence differently and come to different conclusions. So even such simple questions as these lack determinate answers: What is fascism? Why did fascist movements arise? Who were the typical fascist followers? There are credible answers to each of these questions, and this is exactly what we want from a sociological theory of fascism; but the answers that a given researcher puts forward are always contestable.

Or take Howard Kimeldorf's analysis of the different political trajectories of dock-workers' unions on the East and West Coasts (Reds or Rackets?: The Making of Radical and Conservative Unions on the Waterfront). Kimeldorf provides an explanatory hypothesis of the differences between the nature of these unions in the east and west in the United States, and he offers a rich volume of historical and factual material to fill in the case and support the hypothesis. It is an admirable example of reasoning in comparative historical

sociology. Nonetheless, there is ample room for controversy. Has he formulated the problem in the most perspicuous way? Are the empirical findings unambiguous? Are there perhaps other sources of data that would support a different conclusion? It is reasonable to say that Kimeldorf makes a credible case for his conclusions; but there are other possible interpretations of the facts, and even other possible interpretations of the phenomena themselves.

These are both outstanding examples of sociological theory and analysis; so the point here isn't that there is some important defect in either of them. Rather, the point is that there is a wide range of indeterminacy in each of these examples: in the way in which the problem is formulated, in the basic conceptual assumptions that the author makes, and in the types and interpretation of the data that the author provides. Each provides a strong basis, in fact and in theory, for accepting the conclusions offered. But each is contestable within the general framework of scientific rationality. And this seems to suggest that for the difficult, complex problems that arise in sociology and history, there is no basis for imagining that there could be a final and rationally compulsory answer to questions like "Why fascism?" and "Why Red labor unions on the Pacific Coast?" And perhaps it suggests something else as well: that the logic of scientific reasoning in the social sciences is as close to arguments in the humanities as it is to reasoning in the physical sciences. It is perhaps an instance of "inference to the best explanation" rather than an example of hypothetico-deductive testing and confirmation.

Repression in China

Friday, December 25, 2009

The Chinese government signaled a major escalation in its policy of repressing dissidents with this week's conviction of dissident intellectual Liu Xiaobo on charges of subversion (New York Times link). Liu's eleven-year sentence on charges of subversion sends a chilling message to all Chinese citizens who might consider peaceful dissent about controversial issues. Other dissidents have been punished in the past year, including environmental protesters, advocates for parents of children killed in the Sichuan earthquake, and internet activists. But Liu is one of the first prominent activists to be charged with subversion. Liu is a major advocate of Charter 08, and his conviction and sentencing represent a serious blow to the cause of political liberalization in China. Regrettably, the regime of citizen rights of expression, association, and dissent has not yet been established in China.

What is Charter 08? It is a citizen-based appeal for the creation of a secure system of laws and rights in China, and has been signed by several thousand Chinese citizens (New York Review of Books translation). The central principles articulated in the Charter include:

- Freedom
- Human rights

- Equality
- Republicanism
- Democracy
- Constitutional rule

The specific points included in the Charter include:

1. A New Constitution
2. Separation of Powers
3. Legislative Democracy
4. An Independent Judiciary
5. Public Control of Public Servants
6. Guarantee of Human Rights
7. Election of Public Officials
8. Rural-Urban Equality
9. Freedom to Form Groups
10. Freedom to Assemble
11. Freedom of Expression
12. Freedom of Religion
13. Civic Education
14. Protection of Private Property
15. Financial and Tax Reform
16. Social Security
17. Protection of the Environment
18. A Federated Republic
19. Truth in Reconciliation

What is involved in advocating for "legality" and "individual rights" for China's future? Most basically, rights have to do with protection against repression and violence. These include freedom of association, freedom of action, freedom of expression, freedom of thought, and the right to security of property. History makes it clear that these rights are actually fundamental to a decent society -- and that this is true for China's future as well. Moreover, each of these rights is a reply to the threat of violence and coercion.

Take the rights of expression and association. When a group of people share an interest -- let's say, an interest in struggling against a company that is dumping toxic chemicals into a nearby river -- they can only actualize their collective interests if they are able to express their views and to call upon others to come together in voluntary associations to work against this environmental behavior. The situation in China today is harshly inconsistent with this ideal: citizens have to be extremely cautious about public expression of protest, and they are vulnerable to violent attack if they organize to pressure companies or local government to change their behavior.

The use of private security companies on behalf of companies, land developers, and other powerful interests in China is reasonably well documented. And these companies are largely unconstrained by legal institutions in their use of violence and gangs of thugs to intimidate and attack farmers, workers, or city dwellers. It's worth visiting some of the web sites that document some of this violence -- for example, this report about thugs attacking homeowners in Chaoyang. Similar reports can be unearthed in the context of rural conflicts over land development and conflicts between factory owners and migrant workers.

So this brings us to "legality." What is the most important feature of the rule of law? It is to preserve the simple, fundamental rights of citizens: rights of personal security, rights of property, rights of expression. What does it say to other people with grievances when

private security guards are able to beat innocent demonstrators with impunity? What it says is simple -- the state will tolerate the use of force against you by powerful agents in society. And what this expresses is repression.

It is also true that the state itself is often the author of repression against its own citizens for actions that would be entirely legitimate within almost any definition of core individual right: blogging, speaking, attempting to organize migrant poor people. When the state uses its power to arrest and imprison people who speak, write, and organize -- it is profoundly contradicting the core rights that every citizen needs to have.

It should also be said that these legal rights cannot be separated from the idea of democracy. Democracy most fundamentally requires that people be able to advocate for the social policies that they prefer. Social outcomes should be the result of a process that permits all citizens to organize and express their interests and preferences -- that is the basic axiom of democracy. What this democratic value rules out is the idea that the state has a superior game plan -- one that cannot brook interference by the citizens -- and that it is legitimate for the state to repress and intimidate the citizens in their efforts to influence the state's choices. A legally, constitutionally entrenched set of individual civil and political rights takes the final authority of deciding the future direction of society out of the hands of the state.

Give the Chinese people democratic rights and they can make some real progress on China's social ills -- unsafe working conditions, abuse of peasants, confiscation of homeowners' property, the creation of new environmental disasters. Deprive them of democratic rights, and the power of the state and powerful private interests can create continuing social horrors -- famine, permanent exploitation of workers, environmental catastrophes, development projects that displace millions of people, and so on. The authoritarian state and the thugocracy of powerful private interests combine to repress the people.

(Here is a very interesting audio interview with Perry Link on the NYRB website about the context of Charter 08. Also of interest is a piece by Daniel Drezner (post) on Charter 08 on the ForeignPolicy blog. See also this very extensive analysis of the Charter by Rebecca MacKinnon at Rconversation.)

The finish line

Tuesday, December 29, 2009

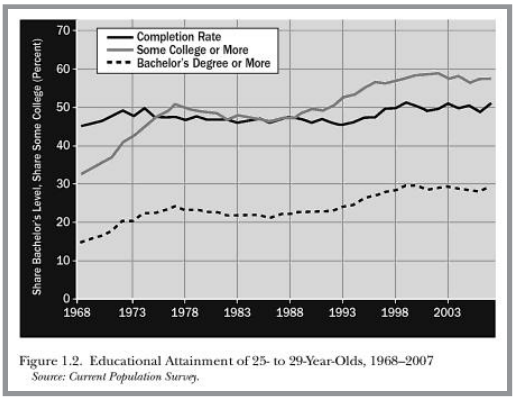

Figure 1.2. Educational Attainment of 25- to 29-Year-Olds, 1968–2007
Source: Current Population Survey.

Source: Bowen, Chingos, and McPherson, C*rossing the Finish Line*

For quite a long time the United States had a global advantage in its educated population. No more. The US now ranks low among OECD nations for percentage of adults with a baccalaureate degree. And the increases in this percentage witnessed in the United States in the 1950s leveled off in the 1970s. These facts have major consequences -- both for quality of life in

the United States for individual citizens and for the ability of the US to compete globally in a knowledge-based economy.

William Bowen, Matthew Chingos, and Michael McPherson have completed another important piece of research on the current social realities of higher education in the US with Crossing the Finish Line: Completing College at America's Public Universities. This research goes significantly beyond the prior important work Bowen and his collaborators have done. Here Bowen, Chingos, and McPherson have shifted focus from the issue of ***access*** (the core issue in Equity and Excellence in American Higher Education) to ***degree completion***, and they have shifted from elite private colleges and universities to public universities -- flagships and regionals. The book is mostly concerned with first-time freshmen, but also provides valuable data on the educational careers of transfer students. (Chapter seven looks at transfer student outcomes in particular.)

The heart of their research here is the creation of a pair of large databases of students that permit tracking the outcomes of a large student population over time. They have collected data on several hundred thousand students who entered universities in 1999. One data set is the "flagship" database including records of over 120,000 students enrolled in 21 leading public universities. The second is the "state systems" database with over 60,000 students enrolled in 47 regional campuses in four states. Here is how they describe the two databases:

The Flagships Database was assembled between September 2005 and August 2006. The core of the database is an institutional file that contains detailed demographic, academic, and financial aid data on essentially every student who entered one of 21 selective public universities in the fall of 1999 (although most universities excluded from their data students who began their studies on a part-time basis).1 The institutional file is linked with secondary data files provided by the College Board, ACT, the National Student Clearinghouse, and the Higher Education Research Institute (HERI). Additionally, the home addresses of the students have been matched to their corresponding geographical codes (“geocodes”) and can be linked to census data down to the block level.

The State Systems Database, which covers a wider range of institutions in four states—Maryland, North Carolina, Ohio, and Virginia—was assembled between June 2006 and June 2008. This database, also on the 1999 entering cohort, includes institutional files from every public university in Maryland, North Carolina, and Ohio as well as every public and private college and university in Virginia.2 Additionally, we have data on every North Carolina student who was a high school senior in 1999. These files are linked with secondary data files provided by the College Board and the National Student Clearinghouse, and the students’ home addresses have been linked to their corresponding geocodes. (Appendix B, pp. 5-6)

(The authors and the publisher have posted a 150-page PDF document on the publisher's website providing extensive details on the data sets and chief quantitative results (link).)

A particularly important data source they employ is the National Student Clearinghouse (link), which permits tracking the same student from one institution to another. NSC now encompasses over 90% of undergraduates in the United States, so it serves as an existing national tracking system. It allows us to answer the important question, what

happens to a student when he/she leaves a given institution? Does she become a permanent dropout, or does she go on to graduate from another university? Another large data source they employ is the National Education Longitudinal Study (NELS) of the 1992 high school class.

Using these databases they are able to probe for significant differences in outcomes based on SES, race/ethnicity, gender, parental education, and type of institution. The outcomes they are particularly interested in are completion rates, time to degree, field of study, and grades. This represents a real breakthrough in empirical studies of higher education; no existing data source had the size needed to break out these sub-populations meaningfully. The data permit the construction of a segmented national profile of college attendance and completion, and the data sets are large enough to allow for a significant degree of testing of causal hypotheses about differences across groups.

The logical structure of the questions posed in the research looks a lot like this:

- Are there significant differences across ***{demographic features -- e.g. ethnicity}*** with respect to ***{outcome feature -- e.g. completion rate}***?
- how much of the observed variation can be explained by ***{readiness feature -- e.g. SAT/ACT score}***?

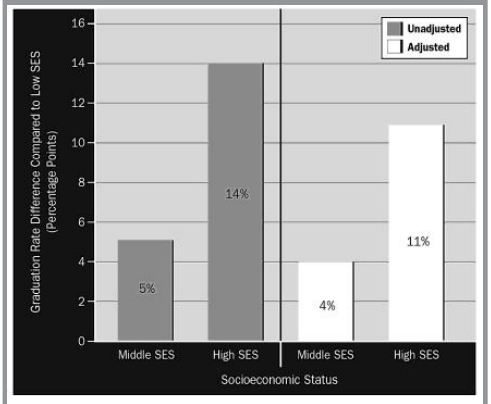

Figure 3.7. Differences in Six-Year Graduation Rates by Socioeconomic Status (Compared to Low SES), 1999 Entering Cohort, Flagships, Unadjusted and Adjusted
Source: Flagships Database.
Note: Adjusted differences control for SAT/ACT scores, high school GPA, state residency status, race/ethnicity, gender, and university attended.

Their approach to the second type of question is to control for the readiness feature(s) using a regression or other statistical technique and examine the residual differences in an adjusted data graph. Here is an example:

There are many striking findings in the research that speak to the profound effects of stratification on life prospects. Take bachelor's degree attainment broken out by family income (fig. 2.3a) and race/ethnicity (fig. 2.5). A young person from the bottom quartile of family income has an 11% chance of receiving a bachelor's degree, compared to a 52% chance for the person from the top quartile. There is also a major disparity between white and black young adults. The data indicate strikingly different bachelor's degree attainment rates across race and gender: white males 29%, white females 36%, black males 10%, black females 21%. One way of reading these results is this: the cumulative disadvantages associated with poverty and race in the United States have permanent effects on the opportunities available to disadvantaged people later in life. And our education system is not succeeding in erasing these disadvantages. The research offered here can at least help to design institutions that are more successful in doing exactly that; and this is one of the key goals that Bowen and his colleagues have for the work:

We want to end this first chapter by reiterating that the purpose of the research reported in this book is not only to improve our understanding of patterns and relationships but also--as a high priority--to search for clues about ways to make America's colleges and universities more successful in moving entering students on to graduation. Protests in China

Tuesday, December 29, 2009

Carrefour protest in Beijing

China has witnessed a visible increase over the past ten years in the number of protests, demonstrations, and riots over a variety of issues. Areas of social problems that have stimulated collective protests include factory conditions, non-payment of wages, factory closures, environmental problems (both large and small), and land and property takeovers by developers and the state.

It isn't surprising that social conditions in China have given rise to causes of protest. Rapid growth has stimulated large movements of people and migrant workers, development has created massive environmental problems for localities, and opportunities for development have created conflicts between developers and local people over land and property rights. Following the terrible earthquake in Sichuan and the collapse of many buildings and schools with tragic loss of life, there was a wave of angry protests by parents against corrupt building practices. So there are plenty of possible causes for protest in China today.

What is more surprising, though, is that the state has not been successful so far in muzzling protest, or in keeping news of local protests from reaching the international public.

YouTube provides a surprisingly wide window on protests in China and other parts of the world. It is worth viewing a sampling of clips from YouTube that surface when one searches for Chinese protest. The following clips were collected in January 2009. But here is a sobering fact: most of these clips have disappeared from YouTube with a message indicating that they violate "terms of use." One is forced to speculate about the pressures that brought this about.

Unemployment for Chinese migrant workers

Labor protest in Shanghai

Shoe factory protest for back wages

Environmental protest in Xiamen

Protest about water pollution in Xiamen

Parents protesting children's death in Sichuan

Will the sociology of the future be able to use the contents of YouTube, Twitter, or Facebook as an important empirical indicator of social change in societies such as China, Malaysia, or Russia? One thing is evident from this small experiment: YouTube is not an archive, and researchers are well advised to capture and document the items they want to study.

The Brenner debate revisited

Saturday, January 02, 2010

One of the defining controversies in the field of economic history in the past 35 years is the Brenner debate. Robert Brenner published "Agrarian Class Structure and Economic Development in Pre-Industrial Europe" in Past and Present in 1976 (link) and "The Agrarian Roots of European Capitalism" in 1982. In between these publications (and following) there was a rush of substantive responses from leading economic historians, including M. M. Postan and Emmanuel Le Roy Ladurie. (Many of the most significant articles are collected in Aston and Philpin's The Brenner Debate: Agrarian Class Structure and Economic Development in Pre-industrial Europe.) Brenner's theories injected important new impetus into the old question: what led to the advent of capitalism? (Maurice Dobb had stimulated a similar burst of scholarship on this topic with his 1963 Studies In The Development Of Capitalism (link). Brenner's discussion of the Dobb debate can be found in his essay, "Dobb on the transition from feudalism to capitalism" here.)

The core issue of the debate is large and important: what were the social factors that brought about the major economic transformations of the European economy since the decline of feudalism? Feudalism was taken to be a stagnant economic system; but in the sixteenth century things began to change. There was something of an agricultural revolution in England, with technological innovation, changes of cropping systems, and significant increase in land productivity. There were the beginnings of manufacture, leading eventually to water- and steam-powered machines. There was a population shift from the countryside to towns and cities. There was industrial revolution. (Marx describes much of this process in *Capital*; here's an earlier post of his concept of "primitive accumulation.") So what were the large social factors that caused this widespread process of social and economic change? What propelled these dramatic changes of economic structure?

The great economic historian M. M. Postan offered a simple theory: “Behind most economic trends in the middle ages, above all behind the advancing and retreating land settlement, it is possible to discern the inexorable effects of rising and declining population” (Medieval Economy and Society: An Economic History of Britain in the Middle

Ages, p. 72). Against this view, Brenner writes: "Under different property structures and different balances of power, similar demographic or commercial trends, with their associated patterns of factor prices, presented very different opportunities and dangers and thus evoked disparate responses, with diverse consequences for the economy as a whole. Indeed, . . . under different property structures and balances of class forces . . . precisely the same demographic and commercial trends yielded widely divergent results" (Brenner 1982:16-17). Key to Brenner's argument is the fact that agricultural change was substantially different in England and France; so he insists that an adequate causal explanation must identify a factor that varies similarly.

From the distance of several decades, the dividing lines of the Brenner debate are pretty clear. One school of thought (Postan, Ladurie) attempts to explain the economic transformations described here in terms of facts about population, while the other (Brenner's) argues that the central causal factors have to do with social institutions (social-property relations and institutions of political power). The demographic theory focuses its attention on the factors that influenced population growth, including disease; the social institutions theory focuses attention on the institutional framework within which economic actors (lords, peasants, capitalist farmers) pursue their goals. The one is akin to a biological or ecological theory, emphasizing common and universal demographic forces; the other is a social theory, emphasizing contingency and variation across social space.

A voice that doesn't come into the debate directly but that is highly relevant is that of Douglass North. His book (with Robert Paul Thomas), The Rise of the Western World: A New Economic History, offers a theory of modern economic development that falls within the category of "social institutional theory" rather than demographic theory. But whereas Brenner finds primary causal importance in the institutions that define local class relations (a Marxian idea), North argues that property relations that create the right kinds of incentives will stimulate rapid economic growth (a Smithian idea). And North finds that this is the innovation that took place in England in the early modern period. It was the creation of capitalist property relations that stimulated economic growth.

This schematic representation of the strands of argument in the Brenner debate suggests competing causal diagrams:

- population growth => economic activity => sustained economic growth (Postan)
- weak peasant farmers, strong capitalist farmers => enclosure and farming innovations => rapid agricultural growth (Brenner)
- enhanced protections of property rights => incentive for profitable activity => sustained economic growth (North)

But it seems clear in hindsight that these are false dichotomies. We aren't forced to choose: Malthus, Marx, or Smith. Economic development is not caused by a single dominant factor -- a point that Guy Bois embraces in his essay (Aston and Philpin, 117). Rather, all these factors were in play in European economic development -- and several others as well. (For example, Ken Pomeranz introduces the exploitation of the natural resources, energy sources, and forced labor of the Americas in his account of the economic growth of Western Europe (The Great Divergence: China, Europe, and the Making of the Modern World Economy). And I suppose that it would be possible to make a climate-change argument for this period of change as well.) Moreover, each large factor (population, prices, property relations) itself is the complex result of a number of great factors -- including the others on the list. So we shouldn't expect simple causal diagrams of large outcomes like sustained economic growth.

Not all the heat of this debate derives from a polemic between a neo-Marxist theorist and the Malthusians; there is also a significant disagreement between Brenner and another important Marxist economic historian, Guy Bois. Bois' Crisis of Feudalism appeared in 1976 -- the same year as Brenner's first paper in the debate. The crisis to which Bois refers is an analogy with a classic Marxist claim about capitalism: where Marx discerned a crisis in capitalism deriving from the falling rate of profit, Bois found a crisis in feudalism deriving from a falling rate of feudal levy. (Here is an interesting review by Chris Harman of another of Bois' books, The Transformation of the Year One Thousand: The Village of Lournard from Antiquity to Feudalism.) Bois criticizes Brenner's account for being excessively theory-driven. He argues that Brenner begins with a commitment to class struggle as a fundamental explanation, and then forces the facts of French and English rural life into this framework. Better, he argues, to let the complexity of the historical situations emerge through careful evaluation of the evidence. "Brenner's thought is, in fact, arranged around a single principle: theoretical generalization always precedes direct examination of historical source material" (Aston and Philpin, 110). And Bois argues that the evidence will suggest that it is the declining feudal levy rather than the capacity for resistance by French peasants that best explains the course of events in France.

In short, one important consequence of the Brenner debate was the renewed focus it placed on the question of social causation. Brenner and the other participants expended a great deal of effort in developing theories of the causal mechanisms that led to economic change in this period. And in hindsight, it appears that a lot of the energy in the debates stemmed from the false presupposition that it should be possible to identify a single master factor that explained these large changes in economic development. But this no longer seems supportable. Rather, historians are now much more willing to recognize the plurality of causes at work and the geographical differentiation that is inherent in almost every large historical process. So the advice that Bois extends -- don't let your large theory get in the way of detailed historical research -- appears to be good counsel.

Separate social worlds

Saturday, January 02, 2010

It is an interesting and important fact that most of us live our lives on orbits that seldom intersect with the orbits of some other categories of people in society. The boundaries of our social worlds are often marked by major forms of social separation -- race, income, residence, work, region, or age. And this creates the result that we have very little understanding of how people from other social segments think, reason, feel, and organize their experiences. We think in terms of stereotypes about other people in other segments of society, rather than having a concrete experiential basis in common with them.

When geography is a large part of this separation it is easy to understand -- a suburban tax accountant in Massachusetts has very little daily experience that would permit him/her to gain knowledge of the thoughts, values, and experiences of rural Thai

villagers. But the striking fact is that there is often an equally deep separation between the phenomenal worlds of the suburban tax accountant and the homeless person in the nearby city or the blue collar woman who drives the local school bus.

This wouldn't matter too much if everyone's experiences and mental worlds were essentially similar. But they plainly are not. Take poverty and affluence: the things that a poor person thinks about first when confronted with a small cash windfall are surely quite different from the affluent person. Chronic deprivation probably gives the poor person a very clear recognition of his/her priorities for consumption that look very different from the affluent person. Being offered a pair of basketball tickets to a Pistons game, for example: the poor person is likely enough to see the resale value of the tickets and the more pressing needs that he/she has for cash -- and therefore is more likely to come to the decision to sell the tickets rather than attend the game. Or take ethnic differences -- a Yemeni immigrant in urban Michigan is likely to see the visit of a census worker in very different terms than does the middle-class suburbanite.

So the differences in worldview and values of people in different social segments are probably quite large. And here is the important part of the story: it is valuable and interesting to find ways of reaching across these forms of separation and come to see how other people experience their worlds. Each person's experiences and perspectives on the world are enriched by deep, extensive engagement with people very different from him/herself. This is one of the chief values of a diverse but interconnected social community. And it is one of the most regrettable costs of a highly divided society.

Social institutions that help to allow people to connect meaningfully across these social divides are particularly valuable. This is how the social value of "diversity" gets actualized. Sometimes religious organizations offer this possibility to their members, when different economic or national communities come together to worship. Military service can also have this effect -- especially in countries with wide or universal military obligations such as Israel. Community service organizations like CityYear and AmeriCorps provide young people with an environment where they can have the opportunity of coming to know other people from very different social backgrounds. And universities have this potential as well -- though colleges haven't been as successful as they should be at gaining this kind of cross-group understanding. Service-learning courses are one way that faculty in some universities have found to give their students meaningful exposure to the social realities that surround them -- and therefore to give them a broader avenue through which to encounter the experiences and worldviews of the segments of society that don't wind up in their middle-class orbits.

One of the reasons that Studs Terkel was such a fascinating writer and radio personality, was his ability to connect with people from widely different worlds. His understanding of working America was dramatically different from that of most of us -- because he had great curiosity about other people, and he had the motivation to go out and talk to them. Here is Studs talking about the experience of the Great Depression -- and the recession of 1997.

The disciplines of economics

Sunday, January 03, 2010

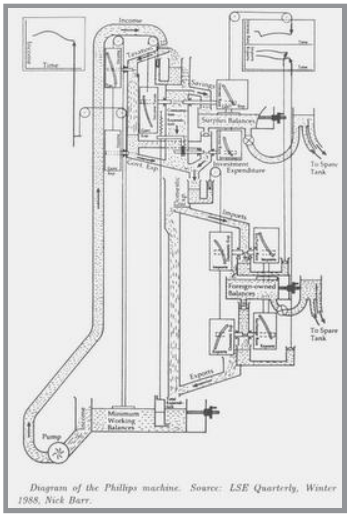

Diagram of the Phillips machine. Source: LSE Quarterly, Winter 1988, Nick Barr.

Economics is sometimes presented as the most "scientific" of the social science disciplines. It is mathematical, it involves sophisticated models, it makes use of enormous data sets, and it is invoked in the formulation of social and economic policies in much the way that the science of mechanics is invoked in the building of bridges. So one might imagine that the foundations, objectivity, and empirical credibility of modern economics are now beyond question.

Each of these assumptions is debatable, however. Daniel Hausman, a sympathetic critic and the leading authority in the philosophy of economics, casts doubt on the claims for precision and comprehensiveness of economic theory in The Inexact and Separate Science of Economics. Essays in my volume, On the Reliability of Economic Models: Essays in the Philosophy of Economics, cast doubt on the validity and reliability of some of the computational models that are used in current economics, including especially the computable general equilibrium models (CGE). And economists like Bruce Pietrykowski have pointed out that there are multiple traditions bundled into the history of contemporary economics, some of which have been overlooked to the detriment of the science of economics (The Political Economy of Consumer Behaviour: Contesting Consumption). (See an earlier post on Pietrykowski's work).

We need to have a better history and sociology of the formation of the disciplines of economics in order to have a better understanding of the scope and limits of current theory. There is, of course, a major literature on the history of economic thought, including such beacons as Joseph Schumpeter's History of Economic Analysis, Mark Blaug's Economic Theory in Retrospect, and I. I. Rubin's History of Economic Thought. (Rubin saw the muzzle-end of economic history, by being executed by Stalin in 1937 for crimes against the state.) But traditional approaches to the history of economic thought almost always look for synthesis and logical progression; so the account that we often get represents the development of economics as a fairly linear evolution from the physiocrats to the classical political economists to the marginalist revolution to Keynes and general equilibrium theory. The differences, contingencies, and choices that occurred along the way tend to disappear.

What the ***sociology*** of science can add to the history of science is a detailed, empirical examination of the institutions, processes, networks, and knowledge systems of a discipline. Sociologists like Robert Merton (link) and Andrew Abbott (Chaos of Disciplines) attempt to provide a micro-level account of the development and workings of a scientific discipline, using the empirical and theoretical tools of sociology. And this approach sheds a great deal of light on the way the particular field of science works, as well as providing greater granularity to the status of scientific claims within various disciplines. (It should be said that the current generation of historians of science also sometimes take this kind of micro-level view -- for example, Peter Galison's treatment of Einstein and Poincaré in Einstein's Clocks, Poincare's Maps: Empires of Time. But to date this hasn't been true of historians of the social sciences.)

Marion Fourcade's profoundly innovative book, Economists and Societies: Discipline and Profession in the United States, Britain, and France, 1890s to 1990s, takes a sociologist's toolkit to work on the disciplines of economics. Here is a good statement of her fundamental thesis:

Economics arose everywhere. But everywhere it was distinctive. If we look back just a few decades, we see that the institutionalization of economics expertise in science, policy, or business took different routes across nations. Scientific and practical knowledge about the economy was conceptualized and institutionalized in different ways in different places, and for identifiable reasons. (3)

What is some of the evidence for thinking that "economics" is different in different national settings? Here is a good example of an empirical approach a sociologist can take to this question. Fourcade cites opinion surveys that have been conducted of "professional economists" in seven European and North American countries, on topics relevant to economic theory and policy. For most of these questions there are significant differences between U.S., French, U.K., and Canada economists -- documenting the idea that there are meaningful differences in the theoretical presuppositions of economists in those national cultures. Here are a couple of questions from table 0-2 (p. 6):

*Tariffs and quotas reduce welfar*e

Agree U.S. 95% France 70% U.K. 84%

Disagree U.S. 3% France 27% U.K. 15%

Reducing the influence of regulatory authorities (e.g., in air traffic) would improve the efficiency of the economy

Agree U.S. 75% France 37% Canada 56%

Disagree U.S. 21% France 56% Canada 43%
On these two questions (only a subset of eight in the table), economists in the U.S. and France demonstrate very significant differences of judgment on very basic economic policy issues, with U.K. and Canada falling between them. The regulatory question is particularly revealing. So survey research -- a very basic tool of sociological research -- turns out to have useful and surprising results when directed at the profession of economics.

Another tool that Fourcade uses to good advantage is something that Merton emphasized as well: examination of scientific biographies and interviews with current practitioners. How did specific influential individuals develop into professional economists? And what can the sociologist learn about the profession from these detailed intellectual itineraries?

Fourcade is careful and reflective in formulating the methodology she pursues in the book. She makes use of the comparative framework employed by comparative historical sociologists in other fields as well; she singles out the U.S., U.K., and France as specific

national cases within which she attempts to reconstruct the specific values, attitudes, and institutions that defined "economics" as a profession. (This is methodologically similar to Frank Dobbin's study of "policy cultures" in these same three countries; Forging Industrial Policy: The United States, Britain, and France in the Railway Age.) She calls her approach "critical organized comparison" (13).

This approach defines the bulk of the book; Fourcade provides chapters on the economic cultures of professional economics in the U.S., U.K., and France, in which she examines in detail the academic institutions, policy environments, and epistemic assumptions that went into the creation of economics as a discipline of knowledge and expertise in each country. She argues that each national setting represents a "constellation of practices" that distinguishes it from the others; so that the profession of economics is defined differently in the three settings. Here are the components of the French constellation as she sorts it out: limited private jurisdiction, segmentation of economics training, legitimacy of technocratic generalist discourse, state jurisdiction dominant, and late and piecemeal institutionalization (16).

A key insight in the book is Fourcade's insistence that economic knowledge, economic policies, economic expertise, and the profession of economics are jointly specified within a specific national culture. They are socially constructed in ways that she makes perfectly understandable. These social products are interrelated, and they are differently understood in the separate cultures studied. "In short, we want to examine the historical conditions that helped crystallize the very idea of what economics is, and attend closely to changing local classifications and representations of this idea over time" (13).

She also pays close attention to the institutions through which economists are trained and validated -- another key sociological insight:

The structure of the academic system and the place of economics education and research within it are particularly relevant to understanding the nature of economic knowledge production in each country. As an academically organized form of knowledge, and a training ground for a vast array of business and administrative professions, economics is shaped by broader research and higher education ecologies. (22-23)

Here is a nice statement of how she sees her work hanging together:

This book has been particularly concerned with one specific type of affinity, that which ties knowledge to its social setting. Instead of focusing--in Foucault's manner-- on what makes particular sorts of knowledge possible at a given historical moement, I have thus tried to analyze interactions between forms of political organization and forms of knowledge making within specific social contexts. (239)

Economists and Societies is a very appealing piece of sociology, and it is a highly insightful contribution to a very fundamental question: what is the status of economic knowledge?

(Related work on the significant differences that can be discerned across national traditions of a social science discipline is being done for the discipline of sociology as well; see this post on national differences in the discipline of sociology, highlighting work by Gabriel Abend.)

Labor abuses in China

Thursday, January 07, 2010

The world press has begun to find ways of documenting the conditions of workers in many of the factories in China devoted to manufacturing goods for export to the United States and other countries (for example, In Chinese Factories, NYT, 1/5/08). The reportage is eye-opening but not surprising. Reporters have documented excessive hours of work, pay that is lower than what Chinese law requires, working conditions that are chronically unsafe, and persistent exposure to the very dangerous chemicals that American toy consumers have been so concerned about. One of the authorities sometimes quoted in these articles is Professor Anita Chan from the Australian National University, and Professor Chan has been documenting these conditions for years. Her book, China's Workers Under Assault: The Exploitation of Labor in a Globalizing Economy, is a detailed and factual examination of some of these conditions. She documents the fact that the most vulnerable groups of workers -- in the range of tens of millions! -- are the internal migrants of China, who have left their home regions in search of jobs. Very significantly, Professor Chan bases some of her fact-finding on the slowly emerging field of local investigative journalism in China.

Why do these abuses occur? For several related reasons. First, the motive of generating profits in the context of a rapidly growing economy. Since China's industrial economy was reformed in the 1990s, permiting private ownership of factories and enterprises, there have been strong incentives to be successful in business and to become rich. There has been tremendous demand for low-cost Chinese-manufactured goods, and great fortunes are being made in consumer electronics, toys, clothing, and dozens of other sectors. And in the downturn of world demand, equally abusive practices have been used to reduce costs. The profit motive leads factory owners and managers to strive hard to keep wages and factory expenses as low as possible; and the vast population of poor rural people in China who are available for unskilled factory work makes the bargaining position of the factory owner very strong. (Chan documents some of the forms of coercion and intimidation that are used in some Chinese factories to keep workers on the job and to prevent them from leaving or resisting.) And the global purchasers are insistent about cost-cutting and price-cutting on the finished goods. So the result is -- a chronic competitive "race to the bottom" in which each factory tries to produce at the require level of quality with the absolutely lowest level of cost; and this means continuous pressure on working conditions, health and safety conditions, and environmental effects. (C. K. Lee describes the situation of protest and resistance in "sunbelt" and "rustbelt" factories in Against the Law: Labor Protests in China's Rustbelt and Sunbelt.)

So part of the story has to do with the economic incentives and advantages that factory owners have relative to a large working population that has few alternatives. But this part of the story is familiar from other economies as they have developed through intensive industrialization. It has been learned elsewhere in the world that the imperatives of profitability by themselves almost mandate the abuse of labor; so government regulation and inspection are a necessary part of a manufacturing system if it is to succeed in

treating all the population fairly and humanely. We might have imagined that the Chinese government would have been prepared to provide the regulatory environment that was necessary to protect the best interests of farmers and workers; it is, after all, governed by the party of farmers and workers. However, this is not the case. China has been so concerned to support economic growth that it has been very slow to implement effective regulatory systems to protect labor and the environment. Moreover, the balance of power between factory owners and local officials seems to be tilted towards the owners; other Times reporting has documented the fact that local officials cannot impose their will upon the owners. And, of course, there is ample opportunity for corrupt collusion between owners and officials.

This failure to regulate has been evident in other areas besides labor; the Chinese government has shown itself to be unwilling or unable to enact effective environmental regulations or to establish an effective regime of inspection and regulation for foods, drugs, and other potentially harmful products. It appears that middle-class Chinese consumers themselves are now expressing anxiety about the absence of this kind of regulation within their food and drug system.

So what other avenues exist for improving the conditions of workers in China?

There are three possibilities -- all mutually compatible. First, workers themselves can protect their interests in fair wages, safe working conditions, and limited hours of work -- if they are permitted to organize in unions. Woody Guthrie had it right: as individuals, workers are weak, but together they are strong. It seems inescapable that a major part of the problem is the enormous imbalance that exists between the powers associated with ownership and management, and those assigned to workers and their organizations. So a more just China will need to permit the development of real independent labor unions that work hard for the interests of their members.

Second, labor mobility can improve the conditions of labor everywhere. It is not an accident that some of the worst abuses documented by Professor Chan have to do with the forms of coercion that factory owners use to keep workers in their factories. If workers can vote with their feet, then we would expect that they will migrate to factories and other employers who offer better conditions of work and pay. And this will force employers to bid for qualified labor on the basis of improved working conditions.

And finally, there is obviously a role for consumers and companies in North America and Europe in all of this. North American consumers benefit from the low manufacturing costs currently available in China; but these low costs are unavoidably associated with the labor abuses we see today. We have a model for how international companies can take responsibility for the conditions of labor and environmental behavior, in the form of the Fair Labor struggles of the 1990s on university campuses in the United States. Large apparel manufacturers took on the responsibility of subjecting their suppliers to standards of conduct, and they subscribed to third-party organizations that undertook to "audit" the level of compliance with these standards by the supply chain. (Visit the Fair Labor website for an example of such an organization.) As the Times story observes, this is a tricky business, given the substantial degree of sub-contracting that occurs in the manufacturing process in China. But it can have a measurable effect.

China is plainly destined to be a major economic and political power in the coming fifty years. But to succeed in creating a society in which everyone has a continuing stake in a good quality of life and a fair deal from society, it will have to solve the problems of

regulation of labor, health, and environment. And this will mean a degree of redistribution of China's wealth and power towards its poorest people.

Image: resistance to Spanish fascism, Abraham Lincoln Brigade

The crimes of fascist governments in Spain, Italy, and Germany are among the most terrible pages of twentieth-century history. And these governments commonly came to power by long mass-based mobilization by right-wing nationalist parties rather than by seizure of power by a strategically located minority. How was it possible for parties based on hatred and violence to be able to gain support from large parts of the populations of these states? And how should the social sciences proceed in efforts to diagnose and explain these processes?

Appendix Table 3.1: *Occupational Backgrounds of Italian Fascists (%)*

Sample	Landlords	Peasants	Agricultural laborers	Businessmen	Professionals	Public employees	White-collar	Petty bourgeois	Workers	Students	*N*
Italian labor force		31	22	1	1	2	1	12	26	1	
PNF (Fascist Party), Italy, 1921	–	12	24	3	7	6	10	9	16	13	151,644
PNF, Udine, 1922	1	3	–	3	8	c18	c12	10	25	16	539
PNF, Reggio Emilia, 1922	5	7	3	–	13	c8	c8	33	18+	2	265
Squadristi, Bologna and Florence, cities, 1921–22	4	0	0	3	10	11	15	6	5	46	381
Squadristi, Bologna Province, 1922	2	13	c25	5	2	5	8	5	c22	10	281
Fascist "Martyrs," Italy	?	8	?	9		19	5	5	27	27	145
MVSN paramilitaries, 1923–33	5	11	–	0	1	29	6	17	18	12	574
PNF deputies, 1924	4	1	5	6	68	17	2	1	0	0	313
Catholic PPI party deputies, 1921	5	3	6	5	60	21	3	3	3	0	117

Sources: Row 1: Sylos Labini, 1978: 61, Weiss, 1988: 33; Rows 2 and 6: Revelli 1987. In row 5 public sector includes 16 percent military and self-employed are almost entirely artisans. Row 3: Preziosi 1980: appendix 1. "Clerks" distributed 50 percent public, 50 percent private sector. Row 4: Corvaglia 1972: 152–4. Public and private white-collar workers not separated in source. I have divided them into 50 percent public, 50 percent private. The worker figure is probably an underestimate; see text. Row 5: Sarti Valli 2000: 136–7. "Baker," "mechanic," and so on divided 50 percent petty bourgeois, 50 percent workers. Rows 6 and 7: Reichardt 2002: 279–81, 306–7, 344. Workers in agriculture and industry cannot always be distinguished, while for the martyrs the "upper classes" are lumped together. Rows 8 and 9: Linz 1976: 57–8.

Map 2.1. The two interwar Europes.

In Fascists Michael Mann offers a thorough and nuanced account of the rise of fascist movements in many countries in Europe in the early part of the twentieth century. And in The Dark Side of Democracy: Explaining Ethnic Cleansing he looks at the processes that have led to genocidal violence by a range of modern states. These are important books by a particularly acute historical sociologist of political power and the state. It is particularly interesting to examine Mann's research strategy -- the empirical research he brings to bear to his research questions and the assumptions he makes about what is needed in order to arrive at an explanation of various aspects of fascism. (Another important sociological contribution to the study of fascism is Juan Linz, Totalitarian and Authoritarian Regimes.)

Mann's approach is through the people, ideologies, and social movements that led to the establishment of fascist regimes:

This book seeks to explain fascism by understanding fascists -- who they were, where they came from, what their motivations were, how they rose to power. I focus here on the rise of fascist movements rather than on established fascist regimes. I investigate fascists

at their flood tide, in their major redoubts in interwar Europe, that is, in Austria, Germany, Hungary, Italy, Romania, and Spain. To understand fascists will require understanding fascist movements. We can understand little of individual fascists and their deeds unless we appreciate that they were joined together into distinctive power organizations. (9)

Here is Mann's definition of fascism:

I define fascism in terms of the key values, actions, and power organizations of fascists. Most concisely, fascism is the pursuit of a transcendent and cleansing nation-statism through paramilitarism. (13)

Mann disputes the common dichotomy between "idealist" and "materialist" theories of large movements and structures such as fascism. Instead, he brings forward his own long-developed analysis of the four major sources of power in complex societies:

But my own approach to fascism derives from a more general model of human societies that rejects the idealism-versus-materialism dualism. My earlier work identified four primary “sources of social power” in human societies: ideological, economic, military, and political. ... To attain their goals, social movements wield combinations of control over ultimate meaning systems (ideological), control over means of production and exchange (economic), control over organized physical violence (military), and control over centralized and territorial institutions of regulation (political). (5)

His analysis of the fascisms of Europe attempts to assess each of them in terms of these sources of power. This analysis also plays into his account of the failure of fascism in countries such as France or Sweden. Mann makes an important point when he observes that fascism never prevailed in countries where parliamentary democracy had developed a secure base. There were fascist parties and leaders in France, Great Britain, and Sweden; but democratic institutions held, and fascism did not prevail in these countries.

Mann makes a very important point when he emphasizes that fascism was not an historical anomaly; rather, it was the expression of forces and crises that can recur in the twenty-first century as well. "Fascists have been at the heart of modernity.... Fascists only embraced more fervently than anyone else the central political icon of our time, the nation-state, together with its ideologies and pathologies" (9).

The largest single topic in each of the country studies is Mann's effort to understand the motivations of the fascist followers themselves. Who were the committed followers? Who were the sympathetic but less-engaged followers?

As in all my case studies I examine in some detail the social backgrounds of the fascists. They offer the best evidence regarding ordinary fascists. Yet social movements are not mere aggregations of individuals, each of whom can be counted equally and statically. Movements contain particular social structures and processes. This fascist movement greatly respected order and hierarchy, and the attainment of substantial power within the movement was an important part of the “career” of fascists. Moreover, paramilitary violence conferred distinctive powers on a “mass” (though less than “majority”) movement committed to violence. (100)

Mann uses a variety of empirical sources to answer simple questions: what were the occupational backgrounds of the members? What can we infer about their values and motivations?

Which particular social groups within these countries were most attracted to fascism? I spend many pages over several chapters examining the social backgrounds of fascist leaders, militants, members, fellow-travelers, coconspirators and voters – compared (wherever possible) with their counterparts in other political movements. How old were fascists, were they men or women, military or civilian, urban or rural, religious or secular, economic winners or losers, and from which regions, economic sectors, and social classes did they come? (25-26)

He goes to some effort to refute the Marxist interpretation of fascist movements: that they were led and supported by the lesser bourgeoisie. Instead, he finds that there was significant support for fascist ideology and movements across a wide range of social-class locations.

Ideology and values play a large role in Mann's interpretation and explanation of the program of fascism. He rejects the view that fascism was wholly opportunistic and succeeded solely through its adeptness with propaganda; rather, he takes fascist social and political theory seriously, judging that fascist parties offered plausible solutions to perceived social problems (p. 2). These parties attracted followers because they persuaded large numbers of Italians, Germans, or Spaniards that they had the ability to solve the problems their societies faced. Key ideological themes were nationalism (the aggressive values and emotions of ethnicity and the nation) and "state-ism" (the legitimacy and necessity of a strong state with few limits on its power as an institution for solving "modern" problems). "Fascists were motivated by a highly emotional struggle to cleanse their nation of “enemies,” and so they indulged in reckless aggression and terrible evil" (22).

Another key characteristic of fascist movements in the 1930s was the role played by paramilitary organizations as tools of intimidation, coercion, and mobilization.

Paramilitarism also conferred a concrete and enveloping social identity. The returning soldiers were young, mostly unmarried with little labor market experience, poorly integrated into local communities centered on family, occupation, and religion, prone to identify with the nation as a whole – which the mass army had claimed to “represent” (104).

Mann also spends some time assessing the role that "crisis" played in the rise of fascism: war, defeat, economic crisis. He does not believe that crisis was the primary cause of the rise of fascism; rather, it was a contributing condition that helped to accelerate processes that were underway already. And Mann notes that there is a pronounced geographical dimension to fascism and authoritarianism, as indicated in the following map representing the state of affairs in 1929.

So what does Mann's explanatory scheme amount to? It comes down to something like this: fascist parties and leaders articulated a vision of the current problems and their solutions. A significant proportion of the young adults (18-35) were receptive to these messages, including the call for radical change and the use of street violence. War, financial crisis, class conflict, and insecure parliamentary institutions created an environment in which the ideology of fascism could flourish and fascist mobilization was feasible. In several countries demobilized and defeated veterans represented a population of prospective recruits to fascist groups. Paramilitary violence could not defeat the military arm of the state; but it could intimidate other parties and pressure

governments. The experience of a fascist organization was itself a reinforcing one; young people who found their way into a fascist group were reinforced in the attitudes that had brought them there in the first place. State and military organizations varied in effectiveness across the map of Europe, and those states whose governments were weak and unstable were less able to repress the rising fascist challenge.

There is a deep question implicated in the effort to provide a ***definition*** of fascism. Is the definition Mann offers a stipulative statement about how Mann will use the word "fascism"? Or is it a condensed empirical theory, abstracted from the small number of clear cases -- Italy, Austria, Germany? Is it an inductive discovery that "fascism is the extreme version of nation-ism and state-ism"; or is it a purely conventional stipulation? Put it another way; does it make a difference that Mann finds that Spain is not "fascist" by this definition? Does such a finding provide any genuine sociological/empirical insight? Does it allow us to judge that "Spain's regime was likely to have other important behavioral differences relative to Italy"? I am tempted to think that Weber's conception of the ideal type is relevant here; the definition offered above is a description of the ideal type of fascism, and each of the existing fascisms differ in various ways from this description. The empirical issue is one level lower: not at the level of "fascism", but rather at the cluster of characteristics that are invoked in the ideal-type theory (paramilitary organizations, ideology of nationalism, authoritarian theory of the state, anti-democratic rhetoric).

It is interesting to think back to Fritz Ringer's analysis of the intellectual climate of the German mandarins (link) and relate his interpretation to Mann's treatment of the conservative-authoritarian ideologies of central Europe. Ringer's treatment singles out many of the same ideological themes and dissatisfactions that Mann identifies -- hostility to class conflict and mass democracy and the main elements of liberal modernity. Ringer's narrative serves as something like a snapshot of the educated elites going through the intellectual-ideological progressions Mann describes.

These crises were exacerbated by an ideological crisis. On the right, though only in one half of Europe, this became a sense that modernity was desirable but dangerous, that liberalism was corrupt or disorderly, that socialism meant chaos, that secularism threatened moral absolutes – and so cumulatively that civilization needed rescuing before modernization could proceed further. So there emerged a more authoritarian rightist view of modernity, emphasizing a more top-down populist nationalism, developmental statism, order, and hierarchy. (355)

The book also suggests something else about the present: that there are good reasons to pay close attention to the claims, complaints, values, and resentments of the American right today. As Mann discovered a coherent worldview and programme for the future in the rightist authoritarian movements he discusses, so we may find there is greater coherence, greater popular appeal, and greater danger in the rightist movements today. Conservative Christian values, hostility to government and to social welfare provisioning, hostility to unions, antipathy to immigrants, and hateful, inflammatory rhetoric give talk radio and cable television a worrisome coherence.

Here is a sobering and tragic video (in Spanish) documenting the Spanish Nationalist government's expulsion of thousands of Republican veterans to the Austrian concentration camp Mathausen, where most of them were murdered. There is a Facebook group, Plataforma Memoria Histórica - Guerra Civil Español (link), which is collecting materials on the Civil War. This is a great collective effort to remember and to

make sense of that struggle with fascism.

High modernism and expert knowledge

Saturday, January 16, 2010

James Scott is one of the really exceptional social scientists of his generation. His contributions to peasant studies have been transformative -- his ideas of the "moral economy of the peasant" and "weapons of the weak" are now part of the tool set that we all use in trying to make sense of agrarian societies (The Moral Economy of the Peasant: Rebellion and Subsistence in Southeast Asia, Weapons of the Weak: Everyday Forms of Peasant Resistance, Domination and the Arts of Resistance: Hidden Transcripts). And his historical and ethnographic accounts of peasant life and struggle have given us a strong basis for understanding these movements that were so important during the anti-colonial struggles of the mid-twentieth century. (I've treated several of these contributions in earlier posts here, here, here, and here.)

What is particularly striking about Scott's work is the range of his sociological imagination. He is a genuinely creative thinker when it comes to making sense of some of some very complex human phenomena -- peasant mobilization, agricultural modernization, and large-scale efforts to transform the world. Each of his books introduces something new (for example, his treatment of Gramsci and hegemony in *Weapons of the Weak*, or his use of "hidden transcripts" in *Domination and the Arts of Resistance*). He is a master at coming up with a concept, theory, or metaphor that can help to explain complex forms of social behavior, from the points of view of the actors. And he does a great job of overcoming the dichotomy between "material circumstances" and "culture"; the peasant communities and movements that he treats are both materially situated and culturally specific.

A more recent book that makes a number of important new contributions is Seeing Like a State: How Certain Schemes to Improve the Human Condition Have Failed (1998). Here

Scott shifts focus in two ways. His analysis here differs from his earlier books in that it is both more *macro* -- he examines the ways that states think; and more *micro* -- he also examines the nature of individually situated expert local knowledge. Both parts of the analysis are interesting and novel.

The book explores what Scott calls "high modernism" -- essentially, the effort to use science and theory to order and regularize the social world, and to use theories of the future to remake the present. Scott defines high modernism in these terms:

It is best conceived as a strong, one might even say muscle-bound, version of the beliefs in scientific and technical progress that were associated with industrialization in Western Europe and in North America from roughly 1830 until World War I. At its core was a supreme self-confidence about continued linear progress, the development of scientific and technical knowledge, the expansion of production, the rational design of social order, the growing satisfaction of human needs, and, not least, an increasing control over nature. (89)

Initially he puts the point in terms of the modern state's agenda of "sedentarianization" -- reducing the mobility and anonymity of nomadic peoples and organizing them into "legible" formations.

The more I examined these efforts at sedentarization, the more I came to see them as a state's attempt to make a society legible, to arrange the population in ways that simplified the classic state functions of taxation, conscription, and prevention of rebellion. (2)

Much of early modern European statecraft seemed similarly devoted to rationalizing and standardizing what was a social hieroglyph into a legible and administratively more convenient format. The social simplifications thus introduced not only permitted a more finely tuned system of taxation and conscription but also greatly enhanced state capacity. (Introduction)

The core thesis of the book is the damage that states have done when they have attempted to implement antecedent theories of social change:

I believe that many of the most tragic episodes of state development in the late nineteenth and twentieth centuries originate in a particularly pernicious combination of three elements. The first is the aspiration to the administrative ordering of nature and society, an aspiration that we have already seen at work in scientific forestry, but one raised to a far more comprehensive and ambitious level.... The second element is the unrestrained use of the power of the modern state as an instrument for achieving these designs. The third element is a weakened or prostrate civil society that lacks the capacity to resist these plans. (88-89)

High modernism was evident in agriculture; but it was also visible in urban planning.

Le Corbusier had no patience for the physical environment that centuries of urban living had created. He heaped scorn on the tangle, darkness, and disorder, the crowded and pestilential conditions, of Paris and other European cities at the turn of the century ... He was visually offended by disarray and confusion. (106)

The French-inspired urban design of colonial-era Saigon is pictured above.

Scott's view is that the central development disasters of the twentieth century derived from this toxic combination of epistemic arrogance and authoritarian power, including especially an excessive confidence in the ability of principles of "scientific management" to order and organize human activity. He provides case studies of the creation of Brasilia as a completely planned city; Soviet collectivization of agriculture in 1929-30; villagization in Tanzania; and the effort to regularize and systematize modern agriculture (266). And we could add China's Great Leap Forward famine to the list. In each case, the high-modernist ideology led to a catastrophic failure of social development.

In sum, the legibility of a society provides the capacity for largescale social engineering, high-modernist ideology provides the desire, the authoritarian state provides the determination to act on that desire, and an incapacitated civil society provides the leveled social terrain on which to build. (5)

A constant contrast in the book is between the objectifying knowledge of modernist science -- social and natural -- and the particular knowledge systems of practitioners and locals about the nature of their local environment -- what he calls "metis". "Throughout this book I make the case for the indispensable role of practical knowledge, informal processes, and improvisation in the face of unpredictability" (6). A particularly clear instance of these two perspectives comes in through Scott's discussion of scientific forestry and the local knowledge of forest ecology possessed by villagers. Beekeeping, traditional farming, and the cultivation of the mango tree (333) are other good examples. Two forests are pictured below; the first is an old-growth forest, and the second is the result of scientific forestry. And Scott documents the ecological destruction that resulted when these principles of scientific forestry were exported from Germany to Southeast Asia.

Scott's perspective here is not anti-scientific or anti-modern. Instead, it is fundamentally anti-*authoritarian*: the high-modernist impulse coupled with the power of the modern state has led to massive human disasters. And confidence in comprehensive, abstract theories -- whether of forests, bees, or cities -- has been an important element of these destructive endeavors. So the conclusion is a moderate one: pay attention to local knowledge, be suspicious of totalizing experiments in transforming society or nature, and trust the people who are affected by policies to contribute to their design.

Scott's arguments in *Seeing Like a State* provide some resonance with two other insightful writers discussed in earlier postings: Michael Polanyi (on the importance of tacit knowledge) and Karl Popper (on the hazards associated with comprehensive social engineering).

(Scott's most recent book is The Art of Not Being Governed: An Anarchist History of Upland Southeast Asia. Here is a very interesting working paper by Grant Evans reviewing Scott's contributions; From moral economy to remembered village: The sociology of James C. Scott (Working paper / Centre of Southeast Asian Studies, Monash University).)

Civic engagement and formative institutions

Sunday, January 17, 2010

A disposition towards civic engagement and community service seems to be a very fundamental component of social psychology that differs significantly across cohorts and populations. But the frequency of this motivation across the population is also surely a key component of the health of social order. One would hypothesize that this is an aspect of individual motivation and identity that determines the level at which a community will succeed in accomplishing its most critical tasks such as poverty alleviation, remedies for poor schools, or addressing homelessness. If a city has a significant level of high-poverty schools, with associated low levels of student academic success in the early grades, surely it is helpful when a significant number of adults and young people experience a desire to help address the problem through mentoring and tutoring programs.

But the question of how this component of social psychology works is a complex one. What are the influences in daily life through which children and young people acquire this sensibility? What are the value systems and institutional arrangements that encourage or discourage a disposition towards civic engagement? What kinds of experiences increase (or reduce) an individual's motivation to be involved in community service? (Here is an earlier posting on this question.)

Doug McAdam and Cynthia Brandt have addressed part of this question through a study of young people who have been involved with Teach for America (NYT story). Their article, "Assessing the Effects of Voluntary Youth Service: The Case of Teach for America," appeared in Social Forces this month. Here is how the authors describe their project:

We use survey data from all accepted applicants to Teach for America (TFA) between 1993-98 to assess the longer-term effect of youth service on participants' current civic attitudes and behaviors.

Their survey includes individuals who were accepted into Teach for America in the relevant years. They break the population into three groups: graduates, drop-outs, and non-matriculants. Their central findings are these:

- "The graduates seem to have emerged from their TFA experience with an enhanced attitudinal commitment to service and civic life."
- "Bottom line: relative to their age peers, our subjects participate at very high levels in all the forms of civic/political participation we examine."
- "The graduates lag significantly behind one or both of the other groups in their current levels of participation in “civic activity,” “institutional politics” and “social movements.”"

- "On all seven dimensions of civic life—service, civic activity, institutional politics, social movements, voting, charitable giving and pro-social employment—the graduates lag significantly behind one or both comparison groups."

These are surprising findings. The TFA population as a whole shows a higher level of civic engagement than the general population. But within the TFA population, the graduates lag. This seems to cast doubt on one of the central claims for community service: that the experience leads young people to develop characteristics that make them ***more*** engaged in the future.

McAdam and Brandt offer a few hypotheses about how we might explain these findings: burnout, delay in transition to career, a feeling of "having done my part," a sense of disillusionment with service; and the possibility that non-matriculants may have had other experiences that are even more conducive to lifetime civic engagement.

Here is their summary conclusion:

What, in the end, are we prepared to say about the significantly lower levels of current service on the part of matriculants relative to non-matriculants? Temporary exhaustion on the part of recent graduates (and drop-outs) appears to be a part of the story. But so too are negative reactions to TFA and, for many, the isolating nature of the teaching experience. Whatever the mix of these (and unmeasured) explanatory factors, the stark fact remains: far from increasing subsequent civic involvement, the TFA experience appears, for some, to depress current service participation.

But here is another striking conclusion based on their data: the gap evidenced in the civic engagement of the graduates is entirely explained by the 15% of graduates whose experience with TFA left them dissatisfied. The 85% who were satisfied with the program demonstrate the same levels of civic engagement as the drop-outs and non-matriculants. "It is the 15 percent of the graduates who have a retrospectively negative view of their TFA experience who account for the service/civic “gap” between graduates and the other two subject groups." This suggests that a program for community service needs to work hard to assure that the expectations of its volunteers are met.

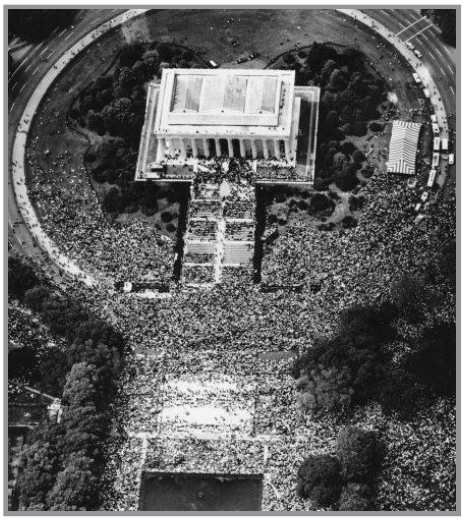
McAdam and Brandt go out of their way to indicate that their research should not be understood as a foundation of criticism of TFA or of programs of civic engagement more broadly. Rather, their goal is to find ways of assessing causal claims that are made on behalf of programs of youth engagement and community service. In order to influence attitudes and behavior, we need to have evidence-based analysis of how a variety of relevant institutions actually work. This kind of survey research is one such instrument of assessment.

The largest national service program in the US today is AmeriCorps (including CityYear). Here is a link to an ongoing study of AmeriCorps members and their levels of civic engagement following their period of service. McAdam and Brandt summarize the most recent findings of the AmeriCorps study:

The 2008 results are representative of the findings from the study as a whole. While AmeriCorps members differ from those in the comparison group on some attitudinal items, behavioral effects are few and far between. The two groups—AmeriCorps and comparison—were compared on fourteen measures of civic participation, including voting, charitable giving, and volunteer service. They differed on only four, with one of the differences favoring members of the comparison groups. In short, the modal behavioral

effect appears negligible.

The survey research that McAdam-Brandt have done is one interesting and important way of trying to gauge the impact of a certain kind of institution on a feature of social psychology. It is intriguing to wonder whether other tools might also shed light on the transformative and developmental processes that occur within the experience of intensive community service. For example, how does the experience of working together in a racially and socially mixed group affect the social understandings and motivations of the young people who are involved? How does the experience of spending a summer in a public health clinic in Chiapas influence the college students who participate? Are there qualitative methodologies available that would shed more light on these concrete mechanisms of identity formation? Would a study based on interviews and focus groups provide some insight into the processes of change that young people undergo in an AmeriCorps placement, a CityYear team, or an intense two months in a poor community in Mexico?



Suppose a researcher carried out a focus-group study on a group of CityYear corps members from September to April, and suppose the research provided evidence suggesting that Corps members had acquired specific competences of inter-community understanding. Suppose interviews and focus group videos show that white corps members had demonstrated a growing ability to understand the situations and worldviews of their black or brown fellow corps members, and vice versa. This would be evidence for judging that the CityYear environment leads to social-psychological development in the area of inter-cultural and inter-racial competence. The young people who have undergone these experiences have become more attuned to racism, racial disadvantage, and the nuances of difference that exist in the perceptions of white, black, and brown young people. They have increased their skill and confidence in interacting with a wider range of people. And, presumably, they will live their adult lives with greater commitment to inter-group dialogue and struggle to reduce the inequalities associated with race in our country. How might this set of facts relate to the framing of a longitudinal survey of CityYear alumni?

Essentially we would reason along these lines. If the changes and developmental mechanisms that were documented in the qualitative study are real and durable, then there should also be differences in the attitudes and behaviors of CityYear alumni five, ten, and fifteen years later. So a survey of alumni, along with an appropriately defined control group, should demonstrate significant differences in attitude and behavior. And if there are no such differences, then we would be pushed towards concluding either that the developmental changes identified in the qualitative study were spurious, or they were indurable. So there is a close logical relationship between the hypotheses suggested by the qualitative study (about processes and effects of social development) and the longitudinal study (about the attitudes and behaviors of a population at later moments in time).

This is important work if we are interested in helping young people acquire the attitudes, values, and practices that will make them good citizens and caring members of communities. And ultimately, it is a question that can be usefully investigated using a variety of tools of social and behavioral research.

The March on Washington, August 1963

Monday, January 18, 2010

African-American citizens and a host of supporters made some of this country's most important history almost forty-seven years ago in the mobilization that resulted in the March on Washington in August, 1963. Dr. Martin Luther King, Jr. gave his most famous speech on the occasion, and of course many of us are remembering Dr. King's legacy today as thousands of people throughout the country give a day of service in his memory.

(Over eight million people have viewed this YouTube video of the speech.)

The civil rights movement created deep and permanent changes in our country, and they were hard won. And what is clear today is the depth of change that was needed -- not at the margin, not gradually, but at the core and rapidly. The attitudes and structures that constituted racial inequality and racism in this country in the 1950s and 1960s were a profound, coercive social reality. Only a concerted, courageous, and sustained social movement involving millions of people could have broken the roots of that system of thought and power. (Doug McAdam's Freedom Summer and Taylor Branch's Parting the Waters: America in the King Years 1954-63 provide vivid narratives of the depth of these challenges and responses.)

It is hard to think of many historical social movements that had as much impact and success as the U.S. civil rights movement. Its objective was not to change a temporary situation -- a war, a military occupation, an egregious dictatorship, or a famine -- but to create a thorough change in attitudes, ideas, and institutions; and to do that in a nation in which racism was organic. Laws, public schools, housing, jobs, universities, hospitals, and transportation -- all were racialized, all demanded change. And then to create a movement that deliberately worked through nonviolent change -- this was exceptional.

A rich tradition of leadership within the black community is one part of the story of success of this struggle for equality. Of course many of the leaders and agents of change of that movement are now household names -- Martin Luther King, Medgar Evers, Malcolm X, Rosa Parks, Ralph Abernathy. But many other key figures are not so well remembered. One man in particular deserves recognition, ***Bayard Rustin***. Rustin was a civil rights activist throughout the 1940s and 1950s. He was one of the earliest organizers of what became known as the Freedom Rides, and he served 22 days on a chain gang in North Carolina for violation of segregation laws in transportation in 1947. (He also was sentenced in 1944 to two years in the Lewisburg Federal Penitentiary for violations of the Selective Service Act as a Quaker pacifist and war resister.)

Rustin was the key organizer of the 1963 March on Washington, and he was an invaluable strategist for Dr. King. But because of his open homosexuality he kept his visible role in the mobilization of the March on Washington to a minimum. Numerous

participants credit his organizational abilities and acute perception of what the moment required as crucial to the success of the March and what followed from it. He went on to become an outspoken advocate for gay and lesbian rights in the 1980s. Rustin is a great example of the persistence and courage shown by so many civil rights activists and leaders throughout America's struggles. (Here is some basic information about Rustin's biography. The NPR program ***State of the Re:Union*** ran an excellent piece on Rustin this morning; link. Here is a film based on Rustin's life.)

Rustin stands out as a particularly vivid example of a kind of leader who was common throughout the early decades of the modern civil rights movement: articulate, smart, passionate, committed, and courageous in the face of prejudice and threat. And there were hundreds of such men and women. For example, Doug McAdam provides an appendix in Political Process and the Development of Black Insurgency, 1930-1970 listing well over 150 leaders from churches, NAACP local chapter, independents, and students who were important protest leaders during the late 1950s. And the networks and organizational capabilities of these men and women translated into successful mobilizations throughout the South.

McAdam's account of the rise of the civil rights movement in the late 1950s and early 1960s also gives particular emphasis to the organizations that existed within African-American society, and the millions of people who supported those organizations. Particularly important were the churches, the local NAACP chapters, and the universities. "Perhaps the most important resource supplied by these institutions wa a potentially mobilizable body of participants. By virtue of their integration into the most organized segments of the black community, the students, church members, and NAACP personnel were readily available for recruitment into the movement" (128). The movement was successful in the face of often violent opposition, because hundreds of thousands of African-American people supported its efforts with courage and tenacity.

As we reflect on the legacy of Martin Luther King, Jr., it is crucial to remember how steep the challenges were and how much we all owe to the activists and followers who joined with King and brought us closer to a society embodying racial justice and equality. And as an observation about history, we can marvel at the magnitude of change that these men and women brought about.

Defining and specifying social phenomena

Sunday, January 24, 2010

Insect (df): a class within the arthropods that have a chitinous exoskeleton, a three-part body (head, thorax, and abdomen), three pairs of jointed legs, compound eyes, and two antennae.

What is involved in offering a definition of a complex social phenomenon such as "fascism", "rationality", "contentious politics", "social capital", or "civic engagement"? Is there any sense in which a definition can be said to be correct or incorrect, given the facts we find in the world? Are

some definitions better than others? Does a definition correspond to the world in some way? Or is a definition no more than a conventional stipulation about how we propose to use a specific word?

There are several fundamental questions that need answering when we consider the meaning of a term such as "fascism" or "contentious politics". What do we intend the term to refer to? How is the term used in ordinary language? What are the paradigm cases? What are the ordinary criteria of application of the term -- the necessary and sufficient conditions, the rules of application? What characteristics do we mean to pick out in using the term? What is our proto-theory that guides our use and application of the concept?

From the scientific point of view, the use of a concept is to single out a family of objects or phenomena that can usefully be considered together for further analysis and explanation. "Metals" are a group of materials that have similar physical properties such as conductivity and ductility. And it turns out that these phenomenologically similar materials also have important underlying physical properties in common, that explain the phenomenological properties. So it is possible to provide a physical theory of metals that unifies and explains their observable similarities. The scientist's interest, then, is in the phenomena and not the concept or its definition.

In order to investigate further we need to do several kinds of work. We need to specify more exactly what it is that we are singling out. What is "civic engagement"? Does this concept single out a specific range of behaviors and motivations? Would we include a spontaneous gift to a fund for a family who lost their home to a fire "civic engagement"? What about membership in a college fraternity? So we have to say what we mean by the term; we have to indicate which bits of the world are encompassed by the term; and perhaps we need to give some reason to expect that these phenomena are relevantly similar.

Several semantic acts are relevant in trying to do this work. "Ostension" is the most basic: pointing to the clear cases of civic engagement or fascism and saying "By civic engagement I mean things like these and things relevantly similar to them." If we go this route then we put a large part of the burden of the semantics in the world and in the judgment of the observer: is this next putative example of the stuff really similar to the paradigm examples?

But there is also an intensional part of the work: what do we ***intend*** to designate in pointing to this set of paradigm cases? Is it the motivation of the activity, the features of social connections involved in the activity, or the effects of the activity that are motivating the selection of cases? Is fascism a kind of ideology, a type of social movement, or a type of political organization? These questions aren't answered by the gesture of ostension; rather, the observer needs to specify something about the nature of the phenomena that are intended to be encapsulated by the concept.

Once we have stipulated the extension and criteria of application of the term, we can then take a further step and offer a theory of this stuff. It may be a theory in materials science intended to explain the workings of some common characteristics of this stuff -- electrical or thermal conductivity, melting point, hardness. Or it may be a social theory of the origins and institutional tendencies of the stuff (fascism, social movements, civic engagement). Either way, the theory goes beyond semantics and makes substantive empirical statement about the world.

It is not the case that all scientific concepts are constructed through a process of abstraction from observable phenomena. A theoretical concept is one whose meaning exceeds the observable associations or criteria associated with the concept. It may postulate unobservable mechanisms or structures which are only indirectly connected to observable phenomena, or it may hypothesize distinctions and features that help to explain the gross behavior of the phenomena. The value of a theoretical concept is not measured by its fit with ordinary language usage or its direct applicability to the observable world; instead, a theoretical concept is useful if it helps the theorist to formulate hypotheses about the unobservable mechanisms that underlie a phenomenon and that help to provide some empirical order to the phenomena.

In order to support empirical research, theoretical concepts need somehow to be related to the world of observation and experience. An important activity is “operationalizing” a theoretical concept. This means specifying a set of observable or experimental characteristics that permit the investigator to apply the concept to the world. But the operational criteria associated with a concept do not exhaust its meaning, and different investigators may provide a different set of operational criteria for the same concept. And a specific scheme of operationalization of a concept like "social capital" or "civic engagement" may itself be debated.

The idea of a "natural kind" arises in the natural sciences. Concepts like metal, acid, insect, and gene are linguistic elements that are thought to refer to a family or group of entities that share fundamental properties in common. Kinds are thought to exist in the world, not simply in conceptual schemes. So having identified the kind, we can then attempt to arrive at a theory of the underlying nature of things like this. (It is an important question to consider whether there are any "social kinds;" in general, I think not.)

These reflections raise many of the intellectual problems associated with defining a field of empirical research in the social sciences. Research always forces us to single out some specific body of phenomena for study. This means specifying and conceptualizing the phenomena. And eventually it means arriving at theories of how these sorts of things work. But there is a permanent gap between concept and the world that means that certain questions can't be answered: for example, what is fascism **really**? There are no social essences that definitions might be thought to identify. Instead, we can offer analysis and theory about specific fascist movements and regimes, based on this or that way of specifying the concept of fascism. But there is nothing in the world that dictates how we define fascism and classify, specify, and theorize historical examples of fascism. The semantic ideas of family resemblance, ideal type, and cluster concept work best for concepts in the social sciences.

What exists in the social realm?

Tuesday, January 26, 2010

What sorts of social things exist? Does the "proletariat" exist as a social entity? There are certainly workers; but is there a "working class"? What is needed in order to attribute existence to a social agglomeration?

We might want to say that things exist when they have enough persistence over time to admit of re-identification and study from one time to another. Persistence involves some degree of stability in a core set of properties. A cloud shaped like a cat has a set of visible

characteristics at a given moment; but these characteristics disappear quickly, and this collection of water droplets quickly morphs into a different collection in a short time. So we are inclined not to call the cat-shaped cloud an entity. On the other hand, "the Black Forest" exists because we can locate its approximate boundaries and composition over several centuries. The forest is an agglomeration of trees in a geographical space; but we might reasonably judge that the forest has properties that we can investigate that are not simply properties of individual trees (density and canopy temperature, for example). The forest undergoes change over time; the mix of types of trees may shift from one decade to another, the density of plants changes, and the human uses of forest products change. And we can ask questions like: "How has the ecology of the Black Forest changed in the twentieth century?" So it seems reasonable enough that we can refer to the forest as a geographical or ecological entity.

We can also classify individual forests into **types** of forests: temperate rain forest, tropical rain forest, coniferous forest, etc. (Here is a 26-fold classification of forests by UNEP-WCMC; the map below represents the global distribution of these types of forests.) And we can ask ecological questions about the properties and processes that are characteristic of the various types of forests.

So what characteristics should a putative social entity possess in order to fall within the working ontology of the social sciences? Here are a few possible candidate ontological features that might be associated with thing-hood in the social realm:

- persistence of basic characteristics over time -- spatio-temporal continuity and social analogs such as nucleated population with shared norms and identities
- an internal structural-functional organization
- some sort of regulative social process that maintains the thing's identity over time, either internal or external
- social cohesion among the individuals who constitute the entity deriving from their social orientation to the entity (labor union, religious community, ethnic group)
- an account of the particular material-social mechanisms through which the identity and persistence of the entity are maintained

According to these sorts of criteria, we might say that social things like these examples exist:

- United Auto Workers
- General Motors corporation
- First Presbyterian Church of Dubuque
- Missouri Synod
- Kylie Minogue Facebook fan club

- 18th Street gang of Los Angeles
- Michigan Legislature
- Internal Revenue Service
- University of Wisconsin
- apprentice system for electrical workers
- social practice of Islamic charity

Here is a slightly more abstract formulation. We might say that these kinds of social entities exist: organizations, both formal and informal; networks of individuals oriented to each other and/or a social goal; social groups unified by features of consciousness or existential circumstance; bureaucracies of the state; enduring social practices; institutions possessing internal organization, rules, and purposes.

Social entities are composed of socially constituted individuals. So the sinews of composition are important. We can recognize a wide range of ways in which individuals are composed into larger social entities: agglomeration, adherence, mutual recognition, coercion, contractual relationships, marketing, recruitment, incentive systems, ... This is one place where "assemblage" theory seems to be useful (Manuel DeLanda, A New Philosophy of Society: Assemblage Theory And Social Complexity.)

Part of the confusion in this topic is the distinction between things and kinds of things. We might agree that the Chicago Police Department exists as a social entity. But we may remain uncertain as to whether "police departments" or "state coercive apparatuses" exist as higher-order categories of social things. And perhaps this is a confusion; perhaps the issue of existence applies only to individual entities, not kinds or classes of entities. On this approach, we would stipulate the minimum characteristics of existence we would want to require of individual social entities and then be "nominalistic" about the higher-level categories or concepts into which we classify these singular individuals.

In considering the ontology of the social world it is important to be attentive to the fallacy of reification: the error of thinking that the fact that we can formulate an abstract noun (proletariat, fascism) allows us to infer that it exists as a persistent, recurring social entity. So when we identify a given social entity as an X, we need to regard it as an open question, "What do X's have in common?" We can avoid the fallacy of reification by focusing on the importance of providing microfoundations for the enduring characteristics of social entities. It is the underlying composition of the entity rather than its location within a classificatory system that provides an explanatory foundation for the behavior of the entity.

Relations, processes, and activities

Thursday, January 28, 2010

An earlier post asked what sorts of social entities exist. Posing the question this way leads us to think of persistent abstract things populating the social world -- for example, structures, organizations, or institutions. But as a commentator to the earlier post pointed out, there are persistent phenomena in the social world that don't look much like **things** and look more like **activities** and **processes**. Grammatically they have more in common with verbs than nouns. And when many such social phenomena are described using nouns, we are often forced to interpret them in a non-referential way.

Take the social realities of friendship, solidarity, and inflation.

The first is a characteristic of social relationships; it is a relational concept. It doesn't make sense to think of "friendship" as a concatenation of monadic atoms of "friend units"; rather, the concept of friend evinces a set of relational characteristics between persons. So "friendship" doesn't designate a continuing "thing" in the world; instead, it designates a complex relational and psychological feature of pairs of persons, widely separated across population and space. Our theory of friendship encapsulates our interpretation of the mental and behavioral states of persons who are in the relationship of friendship with each other.

Solidarity has this feature of relationality, and it adds a feature of social motivation and psychological orientation to a group. We can ask whether solidarity exists in the social world, and we can reasonably answer that it does. But when we affirm that "solidarity exists", we really mean that "there are numerous instances of groups and individuals in which members of the group willingly conform their behavior to the needs and purposes of the group." Our explanation of "solidarity" is likely to invoke abstract ideas about individuals within consciously constituted groups rather than something analogous to a social substance. So solidarity is not a thing, but rather a dynamic feature of consciousness shared in varying ways by individuals who orient themselves to a group.

"Inflation" is a different sort of social noun. It refers to a complex social state of affairs reflecting a set of ***processes*** in which prices of goods are determined by market forces and prices are rising across a range of commodities. We cannot define the social reality of "inflation" without specifying a set of distributed social facts and identifying a number of social processes. So inflation too doesn't look at all like a social thing.

Each of these social nouns corresponds to a social reality. But this reality doesn't look much like a set of fixed entities or composites of entities. The semantics of objects and things doesn't work well for this range of social vocabulary. And yet each of these terms identifies a domain that is perfectly well suited to empirical inquiry and discovery. The social reality of friendship practices differs across cultures; friendship practice has some degree of stability over time; and we can discover quite a bit about the culture, norms, and practices of friendship in a particular culture. And likewise with solidarity and inflation. Each is a legitimate object of empirical inquiry; and neither conforms to the ontology of "thing" with fixed location and properties.

What this discussion suggests is that our ontology of the social world needs to encompass not only a range and variety of ***entities*** -- structures, institutions, organizations, but also ontological categories that reflect a more fluid set of social realities: processes, practices, rules, relations, and activities. This observation converges with the styles of thought of thinkers as various as Charles Tilly and Norbert Elias; Tilly refers to "relational realism," and Elias is an advocate of "process sociology".

Conceptual schemes and social ontology

Thursday, February 04, 2010

What does grammar tell us about the nature of our representations of the world? Do the linguistic categories that we use fundamentally shape the way we organize our understanding of the world? Do different cultures or different linguistic communities possess different "conceptual schemes"? Are different conceptual schemes incommensurable or can we translate from one to the other? These questions come up in the context of any discussion of social ontology -- what does the social realm consist of? In an earlier post we noticed that "thing" and "object" are ontological categories that perhaps don't work as well in the social realm. Perhaps more fluid categories such as process, relation, or activity work better.

First, what is a conceptual scheme? It is an interrelated set of high-level, abstract concepts that allow us to break the empirically or historically given into a discrete set of cognitive boxes. We might think of it as our highest-level concept vocabulary, within which more specific descriptors are arranged. Our conceptual scheme gives us the mental resources needed to represent, describe, and explain the empirical reality we encounter. Color, shape, mass, position, and force might be examples of components of a conceptual scheme for the realm of ordinary empirical experience. Structure, group, ideology, and network might be components for the realm of ordinary sociological experience. A conceptual scheme is thought in some way to be ***comprehensive***: all the phenomena in a certain domain ought to find a place within the conceptual scheme.

Peter Strawson offered a very focused analysis of the everyday metaphysics involved in the ways we analyze and represent the world around us. He proposes in Individuals (1959) that we can do "descriptive metaphysics" by examining the conceptual schemes we actually use. And he argues that there are core conceptual categories that are universal. (Paul Snowdon provides a useful discussion in his article in *Stanford Encyclopedia of Philosophy*).

Here is Strawson's preliminary description of a conceptual scheme:

We think of the world as containing particular things some of which are independent of ourselves; we think of the world's history as made up of particular episodes in which we ourselves may or may not have a part; and we think of these particular things and events as included in the topics of our common discourse, as things about which we can talk to each other. These are remarks about the way we think of the world, our conceptual scheme. A more recognizably philosophical, though no clearer, way of expressing them would be to say that our ontology comprises objective particulars.... Part of my aim is to exhibit some general and structural features of the conceptual scheme in terms of which we think about particular things. (*Individuals*, 15)

How might we begin to provide a "descriptive metaphysics" for social knowledge along the lines of what Strawson describes? It is clear, to begin, that sociological analysis generally involves a rich and intertwined set of concepts and ontological assumptions

about social phenomena. Consider the range of approaches we might take in analyzing a complex historical phenomenon such as fascism: as a social movement, as a political psychology, as an expression of psychopathology, as an ensemble of ideological currents, as a set of political institutions, as a collection of social constituents, and so on, indefinitely.

More fundamentally, what conceptual choices do we need to make when we consider the swirling, fluid complexity of politics, culture, and struggle in Europe in the 1930s? We might place ideological and cultural change at the center; we might focus on the artistic and literary creations of the period; we might emphasize power or social class; we might give primary emphasis to economic change; or we might be drawn particularly to differences in behavior and regime across countries and regions of Europe. Each represents a different way of conceptualizing the historical reality of the 1930s in Europe.

So how can we make some progress towards analyzing social grammar or social conceptual frameworks? We can ask this sort of question at two levels -- ordinary social cognition and language, and organized empirical social science. At the ordinary-language level, we can ask questions like these: how do ordinary speakers represent the social world in which they live? What is the nature of the American-English social vocabulary, the descriptive and referential terms that American people use to make statements, draw distinctions, and offer generalizations about the social world they inhabit? At the level of theory, we can consider a given area of research and ask about the semantics and logical relationships associated with the terms that theorists use to describe and explain the phenomena of interest.

For ordinary language, we might find a list of common terms such as these:

- Washington [the Federal government, the bureaucracy, the political system of the Congress, the major Federal agencies]
- Lansing [state government and its bureaucracy]
- justice / injustice [of taxation, affirmative action, executive salaries]
- corruption [misuse of powers of office in private or public sectors]
- major economic institutions [banks, banking system, corporations]
- major economic facts and circumstances [unemployment, poverty, recession]
- religious institutions
- religious / ethnic identities
- facts about race, racial differences, racial inequalities
- interpretations of socially oriented behavior by others [altruism, egoism, pride, shame, rudeness]
- judgments about unfavorable social change ["kids have no values anymore"]

Ordinary people use these concepts and other to organize and criticize their social world; and they are often articulate about what they mean by the various concepts. But ordinary social cognition is perhaps less able to sketch out the relations that exist among the various social phenomena; this, perhaps, is one of the key tasks of social theory. (Here is an earlier post on ordinary social cognition.)

Second, we might consider the vocabulary and conceptual resources of a given sociologist or sociological tradition. For example, here are the main concepts Michael Mann uses in his description and analysis of European fascism in Fascists:

- fascism [to be defined as "the pursuit of a transcendent and cleansing nation-statism through paramilitarism"]
- socialism
- fascist followers and activists

- power organizations
- social movement
- nation-state
- nationalism
- ideology
- social constituency [groups characterized by status, class, occupation]
- individuals
- modernity
- paramilitarism
- authoritarian regime
- democratic regime
- capitalism [as an industrial social whole]
- social power [ideological, economic, military, political]
- individualism, racism, ethnic purity ideology [as components of ideology]
- major events and crises -- World War I, the Great Depression
- religious institutions and ideologies

These specific concepts could be related to a fairly short list of higher-level social concepts or what we might call social ***categories***: individuals and their characteristics; social groups; structures; ideologies; events; influence terms [power, prestige, status]. But almost all the concepts on the list drawn from Mann's work involve a conceptual assemblage from the higher-level categories. Capitalism is a set of structures, a set of social movements, and a set of ideologies. Racism depends upon both structure and ideology. Modernity is an ideological-cultural formation, a technological-scientific stage, and a socio-economic formation. So the relation between the higher-level category system and mid-level sociological concepts is not one of subsumption but rather one of assembly, combination, or construction.

It is sometimes thought that our conceptual systems are simultaneously contingent and deeply influential in determining how we analyze the world around us. Different conceptual systems lead to different and incommensurable representations of the world. Donald Davidson wrote a pivotal essay on some of these questions ("On the very idea of a conceptual scheme" (1974; link)). Here is how Davidson summarizes the conceptual-relativist view:

> Conceptual schemes, we are told, are ways of organizing experience; they are systems of categories that give form to the data of sensation; they are points of view from which individuals, cultures, or periods survey the passing scene. There may be no translating from one scheme to another, in which case the beliefs, desires, hopes and bits of knowledge that characterize one person have no true counterparts for the subscriber to another scheme. Reality itself is relative to a scheme: what counts as real in one system may not in another. (5)

But ultimately Davidson argues that conceptual relativism and incommensurability are unintelligible. They are claims that cannot be stated coherently. And more positively, Davidson argues that we can understand each other's concepts and words by making use of a principle of charity: we interpret the other's speech, vocabulary, and syntax in such a way as to maximize the truth of statements he/she utters.

> We do this sort of off the cuff interpretation all the time, deciding in favor of reinterpretation of words in order to preserve a reasonable theory of belief. As philosophers we are peculiarly tolerant of systematic malapropism, and practised at interpreting the result. The process is that of constructing a viable theory of belief and meaning from sentences held true. (18)

We get a first approximation to a finished theory by assigning to sentences of a speaker conditions of truth that actually obtain (in our own opinion) just when the speaker holds those sentences true. The guiding policy is to do this as far as possible, subject to considerations of simplicity, hunches about the effects of social conditioning, and of course our common sense, or scientific, knowledge of explicable error. (18)
(Here is a good discussion of Davidson's view in the *Stanford Encyclopedia of Philosophy*.)

What is the situation in the field of social knowledge? Are there deeply divided conceptual beginnings for the analysis of the social realm? Or can we be confident in the mutual comprehensibility across practitioners of Marxist sociology, Durkheimian sociology, and ethnomethodology?

We can get some leverage on this question by asking whether we can provide concrete examples of candidates for alternative sets of social conceptual schemes. For example, are individualism and holism distinct conceptual schemes for social cognition? The first identifies human individuals as the fundamental "particular"; whereas the second identifies the social whole (structure, morality, ideology, class, way of life) as the fundamental particular. The first requires that we define or specify higher-level social entities or conditions in terms of a compound of features of individuals; the second takes the social whole as irreducible and specifies individuals in terms of their relations to a set of social factors.

Here is another possible example -- perhaps materialism and idealism are distinct conceptual schemes within which to organize social experience. The materialist scheme identifies a set of circumstances of the human organism (needs), the natural and build environment, and the forms of social activity that transform the environment as fundamental to social analysis. The idealist scheme takes states of consciousness -- ideas, ideologies, moralities, wants, preferences, modes of reasoning -- as fundamental to social analysis and undertakes to characterize social facts in these terms.

Or consider a third possible example: structure and process. A structure is an enduring configuration of social characteristics and positions, reproducing a set of powers and constraints for individuals enmeshed in these social relations. A process is an ensemble of things in circumstances of change over time. Structures emphasize permanence and stability; processes emphasize change and impermanence. So perhaps the "structure" lens leads sociologists to a very different representation of the social world than the "process" lens.

These examples make it credible that there are in fact alternative conceptual beginnings from which we can analyze the social world. What does not seem to be true, however, is the idea that these beginnings are incommensurable. Instead, it seems persuasive that ideas and statements that originate in an ontology of social wholes can be effectively restated in an ontology that originates in a world of individuals; likewise, materialist and ideological approaches to the social world seem compatible and mutually constructive rather than contradictory and incommensurable. The dichotomies considered here are not exclusive or incompatible. In fact, any adequate explanation of a social process or outcome is likely to need to refer to both sets of categories. And this implies something very similar to the position Strawson and Davidson arrive at: the idea of inter-translatability and mutual comprehension across these large conceptual divides.

(These questions converge to some extent with several other lines of thought -- the Whorf hypothesis (Language, Thought, and Reality: Selected Writings of Benjamin Lee Whorf), Quine's theories of indeterminacy of translation and ontological relativity (Word and Object, Ontological Relativity), Kant's view that all knowledge is structured through a set of "categories" including cause, space, time, and objects (Critique of Pure Reason), and Kuhn's view of the incommensurability of scientific paradigms (The Structure of Scientific Revolutions). Significantly, Strawson discusses Kant at length in The Bounds of Sense: An Essay on Kant's Critique of Pure Reason, and Davidson takes up the debate with Quine, Whorf, and Kuhn.)

The inexact science of economics

Saturday, February 06, 2010

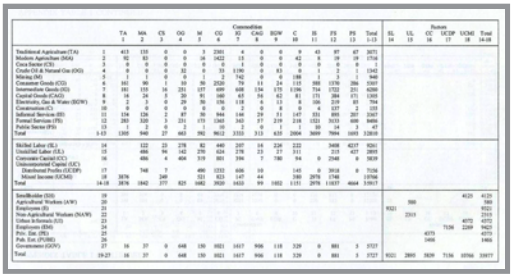

Image: social accounting matrix, Bolivia, 1997

Economics is an "inexact" science; or so Daniel Hausman argues in The Inexact and Separate Science of Economics (Google Books link). As it implies, this description conveys that economic laws have only a loose fit with observed economic behavior. Here are the loosely related interpretations that Hausman offers for this idea, drawing on the thinking of John Stuart Mill:

1. Inexact laws are approximate. They are true within some margin of error.
2. Inexact laws are probabilistic or statistical. Instead of stating how human beings always behave, economic laws state how they usually behave.
3. Inexact laws make counterfactual assertions about how things *would be* in the absence of interferences.
4. Inexact laws are qualified with vague *ceteris paribus* clauses. (128)

Economics has also been treated by economists as a ***separate*** science: a science capable of explaining virtually all the phenomena in a reasonably well-defined domain of social phenomena. Here is Hausman's interpretation of a separate science:

1. Economics is defined in terms of the causal factors with which it is concerned, not in terms of a domain.
2. Economics has a distinct domain, in which its causal factors predominate.
3. The "laws" of the predominating causal factors are already reasonably well-known.
4. Thus, economic theory, which employs these laws, provides a unified, complete, but inexact account of its domain. (90-91)

These characteristics of economic theories and models have implications for several important areas: truth, prediction, explanation, and confirmation. Is economics a scientific theory of existing observable economic phenomena? Or is it an abstract, hypothetical model with only tangential implications for the observable social world? Is economics an empirical science or a mathematical system?

Let's look at these questions in turn. First, can we give a good interpretation of what it would mean to believe that an inexact theory or law is "true"? Here is a possible answer: we may believe that there are real but unobservable causal processes that "drive" social phenomena. To say that a social or economic theory is true is to say that it correctly

identifies a real causal process -- whether or not that process operates with sufficient separation to give rise to strict empirical consequences. Galilean laws of mechanics are true for falling objects, even if feathers follow unpredictable trajectories through turbulent gases.

Second, how can we reconcile the desire to use economic theories to make predictions about future states with the acknowledged inexactness of those theories and laws? If a theory includes hypotheses about underlying causal mechanisms that are true in the sense just mentioned, then a certain kind of prediction is justified as well: "in the absence of confounding causal factors, the presence of X will give rise to Y." But of course this is a useless predictive statement in the current situation, since the whole point is that economic processes rarely or never operate in isolation. So we are more or less compelled to conclude that theories based on inexact laws are not a useable ground for empirical prediction.

Third, in what sense do the deductive consequences of an inexact theory "explain" a given outcome -- either one that is consistent with those consequences or one that is inconsistent with the consequences? Here inexact laws are on stronger ground: after the fact, it is often possible to demonstrate that the mechanisms that led to an outcome are those specified by the theory. Explanation and prediction are not equIvalent. Natural selection explains the features of Darwin's finches -- but it doesn't permit prediction of future evolutionary change.

And finally, what is involved in trying to use empirical data to confirm or disconfirm an inexact theory? Given that we have stipulated that the theory has false consequences, we can't use standard confirmation theory. So what kind of empirical argument would help provide empirical evaluation of an inexact theory? One possibility is that we might require that the predictions of the theory should fall within a certain range of the observable measurements -- which is implied by the idea of "approximately true" consequences. But actually, it is possible that we might hold that a given theory is inexact, true, and wildly divergent from observed experience. (This would be true of the application of classical mechanics to the problem of describing the behavior of light, irregular objects shot out of guns under water.) Hausman confronts this type of issue when he asks why we should believe that the premises of general equilibrium theory are true. But here too there are alternatives, including piecemeal confirmation of individual causal hypotheses. Hausman refers to this possibility as a version of Mill's deductive method.

I take up some of these questions in my article, "Economic Models in Development Economics" link, included in On the Reliability of Economic Models: Essays in the Philosophy of Economics. This article discusses some related questions about the reliability and applicability of computable general equilibrium models in application to the observed behavior of real economies. Here are some concluding thoughts from that article concerning the empirical and logical features that are relevant to the assessment of CGE models:

"The general problem of the antecedent credibility of an economic model can be broken down into more specific questions concerning the validity, comprehensiveness, robustness, reliability, and autonomy of the model. I will define these concepts in the following terms.

- Validity is a measure of the degree to which the assumptions employed in the construction of the model are thought to correspond to the real processes underlying

the phenomena represented by the model.

- **Comprehensiveness** is the degree to which the model is thought to succeed in capturing the major causal factors that influence the features of the behavior of the system in which we are interested.
- **Robustness** is a measure of the degree to which the results of the model persist under small perturbations in the settings of parameters, formulation of equations, etc.
- **Autonomy** refers to the stability of the model's results in face of variation of contextual factors.
- **Reliability** is a measure of the degree of confidence we can have in the data employed in setting the values of the parameters.

These are epistemic features of models that can be investigated more or less independently and prior to examination of the empirical success or failure of the predictions of the model."

(Hausman's book is virtually definitive in its formulation of the tasks and scope of the philosophy of economics. When conjoined with the book he wrote with Michael McPherson, Economic Analysis, Moral Philosophy and Public Policy, the philosophy of economics itself becomes a "separate science": virtually all the important questions are raised throughout a bounded domain, and a reasonable set of theories are offered to answer those questions.)

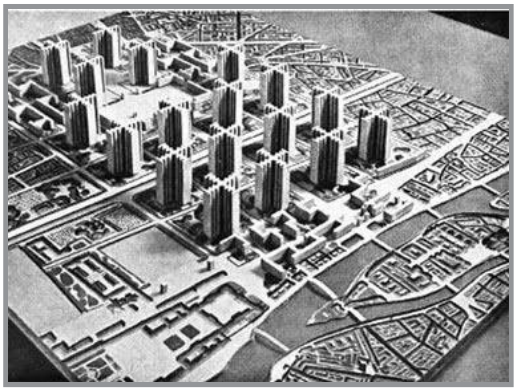
Scott's social imagination

Monday, February 08, 2010



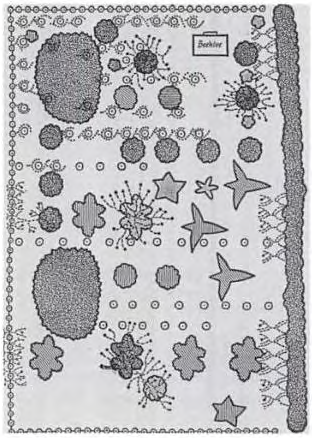


Image: Le Corbusier, Paris plan What is most remarkable about Seeing Like a State: How Certain Schemes to Improve the Human Condition Have Failed is the texture and grain of the argument that Scott makes. This is a high-resolution argument that leaves little to doubt.

The guiding thesis is original and striking enough -- that a mental framework of "high modernism" guided the thinking of a wide range of twentieth-century reformers, from agricultural specialists to city planners to revolutionaries; and that this framework led to predictable disasters. Ecology, social behavior, and cityscapes are complex, involuted systems that demand locally tailored knowledge, and the abstract simplifications of scientific forestry or le Corbusier's geometric abstractions lead to unidimensional disasters. This is powerful and insightful stuff. (See an earlier post for more discussion of the main argument of the book.)

What I'd like to highlight here is something beyond this. It is the remarkable density and variety of the evidence upon which Scott draws to illustrate and confirm his thesis. This is a kind of research and discovery that seems to have virtually no counterpart in either the social sciences or the humanities.

His discussion of tropical agriculture is detailed and exact. He finds Edgar Anderson writing on Guatemalan gardens -- complete with diagrams; and it precisely confirms the

36. Edgar Anderson's drawing of an orchard garden in Santa Lucia, Guatemala

point that traditional cultivator cultures have finetuned their crops and patterns of cultivation to the specific features of the micro-environment. He describes in great detail the goals, values, and drawings of le Corbusier and the plans he developed for Brasilia -- and these precisely capture the high modernist values that he has described. So Scott's thesis doesn't look like a hypothetical theory that needs to be confirmed through its consequences so much as an extended empirical interpretation that can be directly established or refuted.

It seems that Scott's thinking in this book -- the origins of the empirical, historical, and textual research that Scott eventually carried out -- began with the idea of legibility and state power, his insight that states seek to increase their ability to see and record the situations of their subjects. This is how he begins the book --

Originally, I set out to understand why the state has always seemed to be the enemy of "people who move around," to put it crudely. In the context of Southeast Asia, this promised to be a fruitful way of addressing the perennial tensions between mobile, slash-and-burn hill peoples on one hand and wet-rice, valley kingdoms on the other. .... Much of early modern European statecraft seemed similarly devoted to rationalizing and standardizing what was a social hieroglyph into a legible and administratively more convenient format. (Introduction)
(This topic becomes the central focus in his next book, The Art of Not Being Governed: An Anarchist History of Upland Southeast Asia.)

But two other main insights accumulated as well. A second and somewhat independent source of inspiration is Scott's longstanding respect for the knowledge systems and agency of ordinary people. Several strands of his research experience in Malaysia show up here --the mango tree and the ants, the local ecological wisdom of peasant farmers, and even the capacity of peasant communities to organize themselves. Scott has been face-to-face with local peasant knowledge, and he respects it. This knowledge he seeks to theorize as "Metis".

A third component of the inspiration and guiding thrust of the book is the puzzle of well-intentioned development disaster. Colonial agriculture and monocropping, Soviet collectivization, and city modernization all had some component of good intentions for human welfare; so why did they go so badly wrong?

Scott has taken these interests and has built a highly original, factual, and insightful argument. He offers an interpretation of states, modernism, change, knowledge, and material culture that is exquisitely well matched to the historical details he provides.

It is as if we are watching a great art historian working through the corpus of a Picasso, shedding new light and insight on every page. But Scott isn't working with a previously defined corpus of paintings; he is pulling together wildly different areas of human behavior and building in the twentieth century. His canvas is the historical experience of twentieth century "modernization". And he demonstrates a depth knowledge of each of these areas sufficient to nail the interpretation cold. In Scott's hands the high modernism thesis isn't just a sketchy hypothesis or theory; it becomes close to an established fact.

Perhaps the best analogy to the kind of work Scott has done here is a great synthetic historian of medieval France who maintains that this period was driven by a very specific set of guiding ideas -- and then demonstrates in micro-level detail the impact and manifestation of these ideas in the early kings, the Burgundian city, the Loire estate, and the Norman village. But I'm not aware of any historian who has offered this level of depth interpretation of France -- not Bloch, not Pirenne, not Braudel. Perhaps Le Roy Ladurie comes close in Montaillou: Cathars and Catholics in a French Village, 1294-1324; but Ladurie's canvas is small. A different parallel is with Schama's interpretation of France during its revolution in Citizens: A Chronicle of the French Revolution -- illustrating an interpretive point with small but deeply telling historical events like the Goncourts' balloon flight or the revolutionary monuments of Paris.

So what kind of work is this? Certainly not straight "political science". There is a good reason why Scott is named in the perestroika manifesto (post). It is not philosophy -- though it is admirably reflective, and in fact offers some original and valuable ideas about epistemology and ordinary knowledge. It has some similarity to historical interpretation of an epoch -- though it is thoroughly empirical and detail-oriented. And in some ways it resembles a careful, innovative piece of interpretive work in the humanities -- literature, art history, music criticism -- in that it works back and forth between an interpretive hypothesis and careful, detailed work at the micro-level (text, painting, farming culture). This is a powerful and original effort towards "understanding society" -- or at least important bits of the twentieth century.

Works councils and US labor relations

Tuesday, February 09, 2010

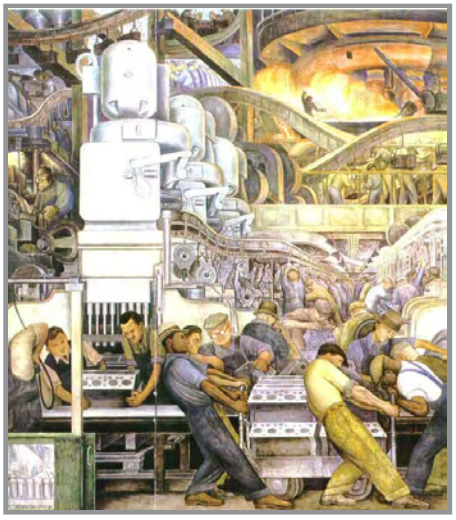

image: Diego Rivera, Rouge Plant mural, Detroit Institute of Arts

The United States has one of the lowest rates of union representation of all developed countries. The 1994 level of unionized workers in the US had fallen to about 12 percent of private sector employment, and the trend is downward. And the sole institutional form through which representation occurs in the US context is the union. So the vast majority of American workers are left with no formal representation within the firm when it comes to wages, benefits, or work practices.

This situation contrasts strikingly with the labor-management institutions in place in much of Europe and Japan. In most other countries legislation establishes the opportunity or the mandate for a second form of worker representation within the workplace, the **works council**. Industry-wide unions establish wage levels; public policy stipulates the level of the "social wage"; and works councils provide an institutionalized context in which management and employees consult with each other, exchange workplace information, and work out firm-specific implementations of industry-wide agreements. And, as Kathleen Thelen demonstrates, differences in the institutions surrounding labor in a market society can have major effects on important social and economic factors in the

societies in which they are embedded (How Institutions Evolve: The Political Economy of Skills in Germany, Britain, the United States, and Japan).

Joel Rogers and Wolfgang Streek's Works Councils: Consultation, Representation, and Cooperation in Industrial Relations is the result of an extensive NBER cross-country study of the economic and social effects of broadly implemented works councils in Europe and Japan. The bottom line is fairly clear: where they exist, these formal institutions of labor representation within the firm have clear theoretical and empirical benefits for productivity, worker skill levels, and willing patterns of cooperation between workers and management. (Richard Freeman's America Works: Critical Thoughts on the Exceptional U.S. Labor Market (2007) is a more general discussion of the singular nature of the American labor system.)

Generally speaking a works council system can be defined in these terms:

We define works councils as institutionalized bodies for representative communication between a single employer ("management") and the employees ("workforce") of a single plant or enterprise ("workplace"). (Rogers and Streek, 6)

This involves several aspects:

- It is a system of mandatory consultation by management to give organized expression to the considered views of employees to contemplated changes.
- Works councils do not have the authority to negotiate for wages and benefits; this is typically done by sectoral unions.
- Works councils are typically firm-specific, limited to consultation and exchange of information about local decision-making.

The benefits associated with works councils in Europe and Japan are many and well documented More specifically, the contributors found that works councils facilitate a number of welfare-enhancing outcomes:

- Exchange of information
- Enforcement of regulations
- Improvement of mutual trust and labor productivity
- Greater democracy and freedom for workers
- Enhancement of productivity
- Incentives for both management and employees to increase skill levels

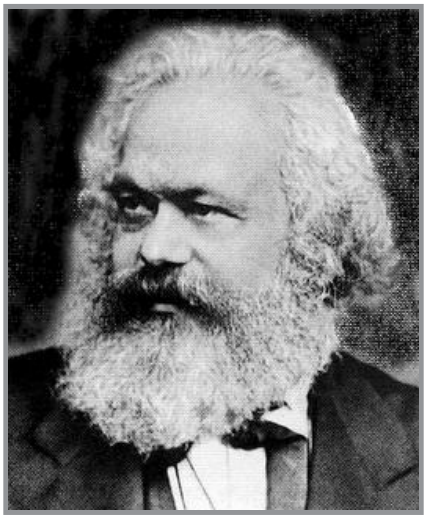
Each of these outcomes is a substantial benefit within a market-based economic system. Take the issue of the enforcement of regulations, including OSHA rules, environmental regulations, and food safety assurance regimes. The inspectorate of the agencies responsible for these regulatory regimes cannot be sized to the levels needed to ensure enforcement through inspection and fines. There are simply too many workplaces and firms. And the only other current mechanism, private litigation when violations lead to individual damages, is too sporadic to constitute an effective enforcement regime. So, for example, workplace accident rates are dramatically higher in the United States than Japan and Sweden; the US death rate is 3.5 times that of Japan and 5.8 times that of Sweden (398). Works councils specifically empowered to gain knowledge about the regulatory requirements combined with detailed workplace knowledge can change this situation.

Or take the area of a cooperative exchange of information within the firm. When various actors have the opportunity and incentive to hoard information to further their particular interests -- whether management or employee -- then decisions will be faulty, efficiencies will be overlooked, and the production process will be less efficient than it could be. Works councils give employees a greater degree of confidence and trust in management and therefore a greater willingness to share useful workplace information. And management has a legal mandate to share pertinent information and to consult with employees about prospective decisions. These intersecting incentives and obligations promote a valuable cooperative exchange of information.

Richard Freeman and Edward Lazear go into detail in laying out the reasons grounded in microeconomics for expecting that works councils will be welfare-enhancing but need to be mandatory rather than voluntary. Central to their analysis is the issue of information flow within a firm:

Economic theory recognizes that asymmetries in information between labor and management can produce inefficient social outcomes. Different levels of a firm's hierarchy can use private information opportunistically, possibly through coalitions against other levels of the hierarchy. ... Legal requirements that management disclose information to elected works councils raises the possibility that councils may help resolve the communication problem and raise rents. (33)

They also emphasize the benefits for quality of decision making that flow from the obligation to consult with employees. "Consultation can increase enterprise surplus when workers offer solutions to firm problems that management fails to see ... and when management and labor together discover solutions to company problems that neither would have conceived separately" (44).



On first principles it would seem that the US economy would be better served by a system that incorporates works councils as a supplement to union representation. And workers are likely to be benefited in very specific ways --greater satisfaction in the workplace, greater involvement in a high-skills (and high-wage) economy, and a greater level of democratic equality. So what stands in the way of reforms leading in this direction? Joel Rogers considers this question in discouraging detail in the concluding chapter. The foundations of US labor law directly prohibit these forms of workplace representation, and the political will for implementing these policy changes is lacking on both sides. And it is difficult to see a gradual process of evolution in this direction based on voluntary establishment of these institutions by employers; the history of labor relations after both world wars suggest that these forms tend to extinguish when based on voluntary choices by enterprise owners. So it is difficult to see where the political will for this major reform of US labor relations might originate.

There is another consideration that favors the establishment of works councils that is not highlighted in this report -- the terrible situation of workers in the informal sector in the United States. Restaurant workers, day laborers, taxi drivers, non-unionized hotel workers, nannies, and housekeepers have very little ability to protect their interests and defend their legal rights. Health and safety standards apply to informal workplaces; all workers have a right to receive their wages in a timely way; and physical or verbal abuse should not be accepted in any workplace. But informal sector workers have very few means at their disposal to secure their rights in even these basic ways. Often undocumented, always in desperate need for a job, they are often at the mercy of bosses and managers who take advantage of them. There are emerging efforts to create analogs for works councils to help workers in these sectors to defend their rights and their livelihoods. Intriguing experiments have emerged; for example, Restaurant Opportunity Centers in several cities (link) and Domestic Workers United in New York City (link). See Janice Fine, Worker Centers: Organizing Communities at the Edge of the Dream. Here is an extended description of the book (link) and here is a link to her Economic Policy Institute working paper, "Worker Centers: Organizing Communities at the Edge of the Dream". Also of interest is the website for WorkingAmerica, the policy organization associated with the AFL-CIO. Progress along these lines would sigificantly improve basic features of social justice in our society.

"Theory" in sociology

Thursday, February 11, 2010

What is a sociological theory? And how does it relate to the challenge of providing explanations of social facts?

In the natural sciences the answer to this question is fairly clear. A theory is a hypothesis about one or more entities or processes and a specification of their operations and interactions. A theory is articulated in terms that permit rigorous and unambiguous derivation of implications for the behavior of a body of phenomena -- perhaps through specification of a set of equations or through a set of statements with deductive consequences. A theory may specify deterministic properties of a set of entities -- thus permitting point predictions about future states of the relevant system; or it may specify probabilistic relations among entities, giving rise to statements about the distribution of possible future states of the system. And a theory is provided with a set of "bridge" statements that permit the theorist to connect the consequences of the theory with predictions about observable states of affairs.

So in the natural sciences, theories are expected to have precise specification, deductive consequences, and specific bridge relationships to observable phenomena.

Is there anything like this construct in the social sciences?

The question of the role of theory in social thinking is a complex one, and the concept of theory seems to be an ambiguous one (as Gabriel Abend points out in an article mentioned below). At one end of the spectrum (is it really a spectrum?) is the idea that a theory is a hypothesis about a causal mechanism. It may refer to unobservable processes (and is therefore itself "unobservable"), but it is solidly grounded in the empirical world. It postulates a regular relationship between or among a set of observable social factors; for example, "middle class ideology makes young people more vulnerable to mobilization in XYZ movements."

At a much more abstract level, we might consider whether a theory is a broad family of ideas, assumptions, concepts, and hypotheses about how the world works. So Marxism or feminism might represent a theory of the forces that are most important in explaining certain kinds of phenomena. We might refer to this broad collection of ideas as a "theory". Or we might instead regard this type of intellectual formation as something more than a theory -- a paradigm or mental framework -- or something less than a theory -- a conceptual scheme.

Consider this taxonomy of the field of social knowledge-creation:

- **concepts** -- a vocabulary for organizing and representing the social world
- **theory** -- one or more hypotheses about causal mechanisms and processes

- **mental framework / paradigm** -- a set of presuppositions, ontological assumptions, guiding ideas, in terms of which one approaches a range of phenomena
- **epistemology** -- a set of ideas about what constitutes valid knowledge of a domain

And we might say that there is a generally rising order among these constructs. We need concepts to formulate hypotheses and theories; we need theories to give form to our mental frameworks; and we need epistemologies to justify or criticize theories and paradigms. In another sense, there is a descending order from epistemology to framework to concepts and theories: the framework and epistemology guide the researcher in designing a conceptual system and a set of theoretical hypotheses.

Where do constructs like feminism, critical race theory, or Marxism fall within this scheme? We might say that each of these bodies of thought involves commitments in each of these areas: specialized concepts, specific causal hypotheses, an organizing framework of analysis, and an epistemology that puts forward some specific ideas about the status of knowledge and representation.

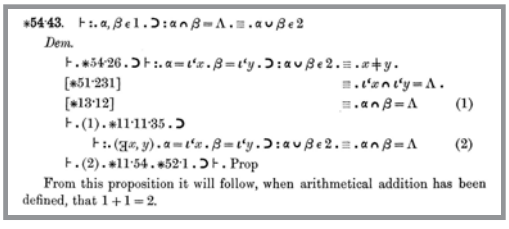
The theory of "resource mobilization" and social movements is somewhat less comprehensive (McAdam and Snow, Readings on Social Movements: Origins, Dynamics, and Outcomes; McAdam, McCarthy, and Zald, Comparative Perspectives on Social Movements: Political Opportunities, Mobilizing Structures, and Cultural Framings ; link, link, link). It functions as a linked body of hypotheses about how social movements arise. So RMT is a good example of the limited conception of theory. Zald, McCarthy, Tilly, McAdam, and others purport to identify the controlling causal variables that explain the success or failure of mobilization around grievance. Their theories reflect a mental framework -- one that emphasizes purposive rationality (rational choice theory) and material factors (resources). And they offer specific hypotheses about mobilization, organization, and social networks.

Gabriel Abend's article "The Meaning of Theory" (link) in *Sociological Theory* (2008) is a valuable contribution on this subject. Abend offers explications for seven varieties of theories and shows how these variants represent a wide range of things we might have in mind by saying that "theory is important." Here are his formulations:

1. ***Theory1****. If you use the word 'theory' in the sense of theory1, what you mean by it is a general proposition, or logically-connected system of general propositions, which establishes a relationship between two or more variables.*
2. ***Theory2****. A theory2 is an explanation of a particular social phenomenon.*
3. ***Theory3****. Like theory1 and theory2, the main goal of a theory3 is to say something about empirical phenomena in the social world. However, the main questions that theory3 sets out to answer are not of the type 'what x causes y?' Rather, given a certain phenomenon P (or a certain fact, relation, process, trend), it asks: 'what does it mean that P?,' 'is it significant that P?,' 'is it really the case that P?,' 'what is P all about?,' or 'how can we make sense of or shed light on P?'*
4. ***Theory4****. The word 'theory' and some of its derivatives are sometimes used to refer to the study of and the students of the writings of authors such as Marx, Weber, Durkheim, Simmel, Parsons, Habermas, or Bourdieu.*
5. ***Theory5****. A theory5 is a Weltanschauung, that is, an overall perspective from which one sees and interprets the world. Unlike theories1, theories2, and theories3, theories5 are not about the social world itself, but about how to look at, grasp, and represent it.*
6. ***Theory6****. Lexicographers trace the etymology of the word 'theory' to the late Latin noun 'theoria,' and the Greek noun 'the¯oria' and verb 'the¯orein' (usually translated as "to look at," "to observe," "to see," or "to contemplate"). The connotations of these words include detachment, spectatorship, contemplation, and vision. This etymology*

notwithstanding, some people use the word 'theory' to refer to accounts that have a fundamental normative component.

7. ***Theory7****. Many sociologists have written about issues such as the 'micro-macro problem,' the 'problem of structure and agency,' or 'the problem of social order.' This type of work is usually thought to fall within the domain of sociological theory. One may also use the word 'theory' to refer to discussions about the ways in which 'reality' is 'socially constructed'; the scientific status of sociology (value freedom, the idea of a social law, the relations between explanation and prediction, explanation and understanding, reasons and causes, and the like); or the 'relativity' of morality. In these examples the word 'theory' assumes a distinct meaning, which I distinguish as theory7.* (177-181)



Abend comes to a very good conclusion about the ways we should think about theory -- and refrain from legislating the forms that theory can take. He argues for a principle of "ontological and epistemological pluralism":

I believe that a satisfactory solution to SP [semantic predicament] should make as few ontological and epistemological demands as possible. The set of conditions under which the word 'theory' can be correctly used should not have too much built-in ontological and epistemological baggage. I call this the 'principle of ontological and epistemological pluralism.' The reason why I advocate this principle is, very roughly put, the following. Suppose sociologists made a certain picture of the world or idea about what can be known a prerequisite for something being a sociological theory at all. Consider some examples. We may demand that theories be underlain by the assumption that "the social world consists of fixed entities with variables attributes" (Abbott 1988:169). We may require that causality be taken to be the cement of the universe, the most important relation that can hold between two entities. Or, we could build into the definition of 'theory' the idea that social processes are regulated by laws of nature. Alternatively, we may demand the belief that the distinction between text and reality is misleading, or even the belief that there are no such things as 'reality' and 'objectivity.' Or else, we may demand the assumption that nothing exists but what can be actually observed or otherwise grasped by our senses, thereby denying existence to such 'mysterious' things as causality and similar 'underlying theoretical mechanisms' (Steinmetz 2005). In any of these scenarios, only to the extent that you shared the required ontology or epistemology, could you be said to have a theory of the social world. You could have other things about the social world—opinions, views, beliefs, ideas—but not a theory. By definition, that particular ontology or epistemology would be obligatory for one to be allowed to enter a theoretical discussion, make a theoretical contribution, or theorize at all. (195)

Symbolic logic and ontology

Sunday, February 14, 2010

*54·43. $\vdash :. \alpha, \beta \in 1 . \supset : \alpha \cap \beta = \Lambda . \equiv . \alpha \cup \beta \in 2$

Dem.

$\vdash . *54·26 . \supset \vdash :. \alpha = \iota'x . \beta = \iota'y . \supset : \alpha \cup \beta \in 2 . \equiv . x \neq y .$

[*51·231] $\equiv . \iota'x \cap \iota'y = \Lambda .$

[*13·12] $\equiv . \alpha \cap \beta = \Lambda$ (1)

$\vdash . (1) . *11·11·35 . \supset$

$\vdash :. (\exists x, y) . \alpha = \iota'x . \beta = \iota'y . \supset : \alpha \cup \beta \in 2 . \equiv . \alpha \cap \beta = \Lambda$ (2)

$\vdash . (2) . *11·54 . *52·1 . \supset \vdash .$ Prop

From this proposition it will follow, when arithmetical addition has been defined, that $1 + 1 = 2$.

image: theorem from Russell and Whitehead, *Principia Mathematica*

In what ways do the abstract features of symbolic logic reflect characteristics of thought?

The syntax of symbolic logic is illustrative. First order predicate theory provides syntactic categories for ***individuals*** (a, b, c; x, y, z), ***properties*** (Fx, Gx), ***relations*** (xRy), ***n-place relations*** (R(x1, ..., xn)), logical connectives (∧, ∨, ~, ⊃), and ***quantifiers*** (∀x, ∃x). We also need to introduce the notation of mathematical ***functions*** (x = f(w,y,z)) -- though this represents a significant expansion of the formal power of symbolic logic. Individuals are objects that possess properties and fall within relations with other objects. Properties and relations may be interpreted intensionally or extensionally: in terms of a verbal definition or in terms of a class of objects possessing the property or relation. Functions are mathematical relations specifying the value of the dependent variable for all settings of the independent variables.

This syntax permits us to formulate statements about individuals and their properties and relations:

- Bj (John is bald)
- jTa (John is taller than Alice)
- ∃x(xTa) (there exists some x such that x is taller than Alice; someone is taller than Alice)
- ∀x(Cx ⊃ xTa) (for all x, if x is C then x is taller than Alice; all members of the choir are taller than Alice)
- p = nRT/v (pressure equals n times R times temperature divided by volume)

So the syntax of symbolic logic has a relationship to a small subset of English syntax: nouns (singular and generic), adjectives, and relation terms. What this syntax lacks is a direct way of expressing "doing" or becoming -- verbs or process terms. To express a thought like "The Roman Empire was becoming more corrupt over time" we would need to do some gymnastics. If we restrict ourselves to the predicate core of symbolic logic, then we would need to introduce a new predicate:

- Cx = x is becoming more corrupt over time
- r = Roman Empire
- Cr = The Roman Empire is becoming more corrupt over time

This solution is unsatisfactory because it leaves elements of the statement that are inferentially relevant in English, invisible in the logical paraphrase. This is precisely the idea of change over time. If we make use of the conceptual machinery of mathematical functions and differential equations, then we can provide a more refined analysis of the sentence:

- r = Roman Empire
- C(x,t) = the degree of corruption possessed by x at time t
- dC(r,t)/dt > 0 = the value of C for r is increasing over time

Here we have been able to represent change or process as a derivative: the rate of change of the value of the function with respect to time. This gives us a way of representing action, process, and change; though it is an open question whether this formalism will suffice for all types of change. Consider this statement: "Robert's personality has changed a lot over the past decade." In order to capture this idea we need a set of characteristics that constitute personality -- that is, we need a theory or definition of personality; and we need to represent these characteristics as functions of time. Suppose this is our working analysis of "personality":

- A(x,t) = degree of agreeableness x shows at time t
- E(x,t) = degree of extroversion x shows at time t
- O(x,t) = degree of openness x shows at time t
- N(x,t) = degree of neuroticism x shows at time t
- C(x,t) = degree of conscientiousness x shows at time t

To say that Robert's personality is unchanging is the simplest case:

- dA(r,t)/dt = dE(r,t)/dt = dO(r,t)/dt = dN(r,t)/dt = dC(r,t)/dt = 0

And to say that Robert's personality is changing in that he is becoming less agreeable

and more neurotic might be paraphrased this way:

- $dA(r,t)/dt < 0 \wedge dN(r,t)/dt > 0$

It is a premise of logical positivism, including Bertrand Russell in Principia Mathematica, Ludwig Wittgenstein in the Tractatus, and Rudolph Carnap in The Logical Structure of the World, that all the knowledge claims of science can be formulated using only these syntactic elements. (In fact, it is possible to reduce the logical connectives to a single connective, the sheffer stroke ("not and"), and the quantifiers to a single quantifier and the negation sign.) The vocabulary of a science consists of a finite number of primitive (undefined) terms and a number of terms defined in terms of logical compounds of primitive terms. For example, mass, time, and location might be primitive terms in classical mechanics; then velocity and momentum are defined as logical compounds of these primitives. And this view of the adequacy of first-order predicate logic for the whole of science implies something like claim of "concept neutrality": the vocabulary of any science can be reformulated in terms of these simple logical elements.

Does this formulation help when it comes to inquiring about our "conceptual schemes" when we attempt to categorize the social world (link)? Not very much. The hard questions that arise when we attempt to articulate a conceptual system for analyzing personality, social movements, revolutions, or ideologies are not aided by the putative fact that we could represent any adequate scheme of concepts in terms of the formalism of first order predicate theory plus mathematical functions. If we were willing to treat revolutions as discrete historical individuals with fixed properties, then of course it is true that we can formulate our theories of revolution in terms like these:

- "All revolutions involve either widespread social unrest or defeat in war."
- $\forall x(Rx \supset (Ux \vee Dx))$ [all historical things are such that if they are revolutions then either they possess social unrest or experience defeat in war]

The ontological problem is simply this: revolutions are not uniform across instances or across time. Revolutions do not have fixed, invariant properties. So we cannot really treat revolutions as individuals over which we can quantify. And the syntactical choice of representing "revolutions" as unchanging individuals is unsatisfactory.

Two observations seem justified. First, the syntax of first-order predicate theory plus functions probably succeeds as a "grammar" within which we can express any knowledge claim in science. (The most obvious exception is modal logic: claims that express necessity and possibility. But many philosophers and scientists would argue that modal claims are not necessary to the vocabulary of science.) But second, this logical syntax does not help to solve the deep conceptual and theoretical problems that must be addressed in real exercises of social science. To define "revolution," "corruption," or "anomie" requires conceptual work that goes beyond the task of representing a given system of scientific statements in terms of a set of predicates and functions. So symbolic logic is simply a scheme of representation, not a master system of concepts and syntax.

(See an earlier posting on these issues under the rubric of "Knowledge Claims in the Social Sciences".)

Scientific realism for the social sciences

Thursday, February 18, 2010

What is involved in taking a realist approach to social science knowledge? Most generally, realism involves the view that at least ***some*** of the assertions of a field of knowledge make true statements about the properties of unobservable things, processes,

and states in the domain of study. Several important philosophers of science have taken up this issue in the past three decades, including Rom Harre (Causal Powers: Theory of Natural Necessity) and Roy Bhaskar (A Realist Theory of Science). Peter Manicas's recent book, A Realist Philosophy of Social Science: Explanation and Understanding, is a useful step forward within this tradition. Here is how he formulates the perspective of scientific realism:

The real goal of science ... is understanding of the processes of nature. Once these are understood, all sorts of phenomena can be made intelligible, comprehensible, unsurprising. (14)

Explanation ... requires that there is a "real connection," a generative nexus that produced or brought about the event (or pattern) to be explained. (20)

So realism has to do with discovering underlying processes that give rise to observable phenomena. And causal mechanisms are precisely the sorts of underlying processes that are at issue. Here is how Manicas summarizes his position:

Theory provides representations of the generative mechanisms,including hypotheses regarding ontology, for example, that there are atoms, and hypotheses regarding causal processes, for example, that atoms form molecules in accordance with principles of binding. We noted also that a regression to more fundamental elements and processes also became possible. So quantum theory offers generative mechanisms of processes in molecular chemistry. Typically, for any process, there will be at least one mechanism operating, although for such complex processes as organic growth there will be many mechanisms at work. Theories that represent generative mechanisms give us understanding. We make exactly this move as regards understanding in the social sciences, except that, of course, the mechanisms are social. (75)

Manicas's illustrations of causal powers and mechanisms are most often drawn from the natural world. But what basis do we have for thinking that social entities have stable causal properties -- let alone a profile of causal powers that are roughly invariant across instances?

Consider an example, Theda Skocpol's definition of social revolutions:

Social revolutions are rapid, basic transformations of socio-economic and political institutions, and--as Lenin so vividly reminds us--social revolutions are accompanied and in part effectuated through class upheavals from below. It is this combination of thorough-going structural transformation and massive class upheavals that sets social revolutions apart from coups, rebellions, and even political revolutions and national independence movements. (link)

Realism invites us to consider whether "social revolutions" really have the characteristics she attributes to them. Do social revolutions have an underlying nature distinctive causal powers that might be identified by a social theory? More generally, what basis do we have for thinking that certain ***types*** of social entities possess a specific set of causal powers?

The answer seems to be, very little. Types of social entities -- revolutions, states, riots, market economies, fascist movements -- are heterogeneous groupings of concrete social formations rather than "kinds" along the lines of "metal" or "gene". Each of the extended historical events that Skocpol offers as instances of the category "social revolution" is unique and contingent in a variety of ways; these historical episodes do not share a common causal nature. It is legitimate to group them together under the term "social revolution"; but it is essential that we not commit the error of ***reification*** and imagine that the group so constituted must share a fundamental causal nature in common. So the most direct application of this kind of realism to the social sciences seems somewhat unpromising.

But we are on firmer ground when we consider a particularly central type of assertion in the social sciences: claims about underlying causal mechanisms or social processes. So what does it mean to assert that a given social mechanism "really exists"?

Take the idea of "stereotype threat" as one of the mechanisms underlying an important social fact, the racial and gender differences in performance that have been observed on some standardized tests (Claude Steele and Joshua Aronson, "Stereotype Threat and the Intellectual Test Performance of African Americans" (link); see also this article in the *Atlantic*). We can summarize the theory along these lines: "Prevalent assumptions about the characteristics and performance of various salient social groups can depress (or enhance) the performance of members of those groups on intellectual and physical tasks. This provides a partial explanation of the observed differentials in performance." This mechanism is hypothesized as one of the ways in which performance by individuals in various groups is socially influenced in such a way as to lead to differential performance across groups. It postulates a set of internal psychological mechanisms surrounding cognition and problem-solving, all related to the individual's self-ascribed social identity.

The realism question is this: do these hypothetical psychological effects actually occur in real human individuals? And do these differences in cognitive processes lead to differential performance across groups? If we confirm both these points, then we can conclude that "stereotype threat is a real social psychological mechanism." The microfoundations of this mechanism reside in two locations: the concrete cognitive processes of the individuals, and the social behaviors of persons around these individuals, giving subtle cues about stereotypes that are discerned by the test-taker.

So we might say that we can conclude that a postulated social mechanism "really" exists if we are able to provide piecemeal empirical and theoretical arguments demonstrating that the terms of the mechanism hypothesis are confirmed in the actions and behavior of agents; and that these patterns of action do in fact typically lead to the sorts of outcomes postulated. In other words, we need to look at our hypotheses about social mechanisms as small, somewhat separable theories that need separate empirical, historical, and theoretical evaluation. And when we are successful in providing convincing support for these mechanism-theories, we are also justified in concluding that the postulated mechanism really exists. The social world really embodies stereotype threat if individuals are really affected in their cognitive performances by the sorts of subtle behavioral cues mentioned by the theory, in roughly the ways stipulated by the theory. And we will feel most confident in this assertion if we also find new areas of behavior where this mechanism also appears to be at work.

This approach has an important implication about social ontology. The reality of a social mechanism is dependent on facts about agents, their characteristics of agency, and the

environment of social relationships within which they act. So there is a close intellectual relationship between the ontology of methodological localism and realism about causal mechanisms.

(The smokestack image above illustrates a different kind of social mechanism -- the workings of externalities in a market economy, creating pollution by dumping public harms to save private costs.)

What do we want from sociology?

Sunday, February 21, 2010

Let's say we've absorbed the anti-positivism argued many times here -- sociology should not be modeled on the natural sciences, we shouldn't expect social phenomena to have the homogeneity and consistency characteristic of natural phenomena, and we shouldn't expect to find social laws. What remains for the intellectual task of post-positivist sociology? What do we want from sociology?

Here are a handful of topics that are both important and feasible.

- description and theory of social movements / collective action / popular politics
- comparative study of large historical social-political formations such as fascism, colonialism, fiscal systems
- descriptive analysis of social inequalities (race, gender, class, ethnicity) and their mechanisms
- descriptive and theoretical accounts of major social institutions (corporations, unions, universities, governments, religions, families) and how they work (mechanisms)
- Concrete studies of identity formation

So there is plenty for a post-positivist sociology to do. But more specifically, what can the science of sociology offer us? To start, we would like to understand some of the myriad social processes that surround us. We would like to understand how social stratification works; how economic power is translated into political power; why racial disadvantage persists from one generation to another; and what leads people to behave as they do in specific social settings. To put a name on this, we would like to have convincing theories of social mechanisms and processes, and some idea of how these aggregate into larger social processes.

Second, to whatever degree possible, we would like to have theories of social behavior that will permit us to intervene to prevent undesirable outcomes. We would like to greatly reduce the rate of teen violence in cities like Detroit and Chicago. And this requires theories of the factors that lead to the behavior so we can have some hope of designing solutions. So we would like for sociology to provide a degree of theoretical support for the design of helpful social policies.

Third, we would like for sociology to be an empirical discipline. And thus means that we want to "test" or otherwise empirically evaluate the hypotheses and theories produced by sociologists.

All three of these goals seem to point in the direction of a sociology of the middle range (as Robert Merton put it) -- theories that attempt to capture mid-range social processes such as racial discrimination in housing, power brokerage, or identity formation. The value of this level of focus is parallel to the three points just made. Mid-level analysis is

suitable to investigation and discovery of social mechanisms. Mechanisms and processes at this level are likely to be most useful when it comes to designing policies and social interventions. And, finally, this level of sociological theory is most likely to admit of empirical investigation and validation through piecemeal inquiry.

What this suggests to me is that piecemeal inquiry into specific social phenomena is a more promising approach than grand unifying sociological theories. And this in turn suggests the metaphor of toolbox rather than orrery -- a collection of explanatory hypotheses rather than a unifying theoretical system.

Equality and violence in Alabama, 1960s

Wednesday, February 24, 2010

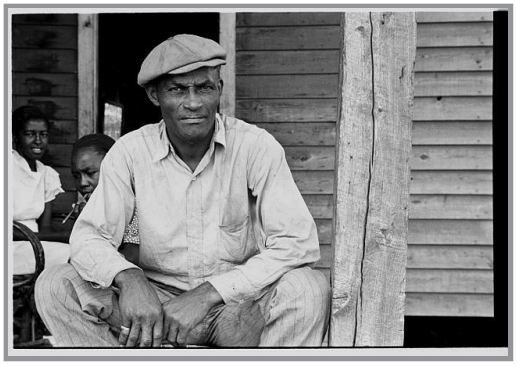

image: Ben Shahn photo of Arkansas sharecropper

Creating civil and political rights for African Americans in the 1960s required courage and persistence by hundreds of thousands of ordinary people. The system of Jim Crow assured subordination in fundamental rights and needs for millions of rural southern black people -- the right to vote, the right to own property, the right to use public amenities, and the right to a decent education. This system was held in place by the threat and reality of violence -- beatings, lynchings, shootings, and pervasive threats against individuals and families. This kind of violent environment made it particularly difficult to see the road from subordination to equality. The people of Lowndes County, Alabama, played a key role in this journey. This is the core message of Hasan Kwame Jeffries' excellent recent book, Bloody Lowndes: Civil Rights and Black Power in Alabama's Black Belt. "Bloody Lowndes" was considered the most repressive and most violent area of black suppression in the South. So success in achieving African American voter registration and elected representation would be an important step forward.
Here is how Jeffries describes the county:
Jim Crow was a grim reality in Lowndes County, Alabama, at the beginning of 1965. African Americans attended separate and unequal schools, lived in dilapidated and deteriorating housing, and toiled as underpaid and overworked domestics and farm laborers. They were also completely shut out of the political process. There were five thousand African Americans of voting age in the overwhelmingly black rural county, but not a single one was registered. (Introduction)
Jeffries tells the story of the Lowndes County Freedom Organization (LCFO) and its effort to succeed in registering the black population of the county. The struggle for equal rights in Lowndes County was nationally important, and SNCC activist Stokely Carmichael played a central role in the sustained effort. This independent political party struggled to register black voters in order to gain elected offices for black candidates. The LCFO -- represented by the image of the black panther -- struggled for two years against violent opposition, attempting to exercise rights created by the 1965 Voting Rights Act. (Huey Newton and Bobby Seale eventually drew inspiration from the LCFO and its symbol in the establishment of the Black Panther Party in Oakland.)

Racist violence in Lowndes County was common, and it is instructive to listen to oral histories of people who were there. One example is Professor Gloria House, who participated in the SNCC effort to mobilize the county as a young Berkeley graduate student who "went south". Here is an interview in which she offers a first-hand account of one particularly violent incident in Lowndes County. It is an important and dramatic testimony about the period. Dr. House describes the arrest of a small group of SNCC workers; their imprisonment in the local jail for two weeks; their release; and the murder of one of the SNCC workers at the hands of white extremists.

A crucial part of the story of Lowndes County that Jeffries tells is the role that forcible resistance played. The example of nonviolent protest was available, of course, through the strategies and actions of the Southern Christian Leadership Conference and Dr. Martin Luther King, Jr. But in the face of shotguns, torches, and ropes, the tactics of vigils, demonstrations, and boycotts seemed inadequate to the task. Part of the success of the LCFO movement in Lowndes County was the clear statement by ordinary people in the county that they would not be intimidated, and that they would defend their rights and their lives with force if necessary.

It is interesting to compare Jeffries' detailed study of the struggle in Lowndes County with the more general treatment of the movement in Doug McAdam's Political Process and the Development of Black Insurgency, 1930-1970. McAdam looks in detail at the factors across the South that facilitated or impeded the movement for civil and economic rights. But Lowndes County doesn't come into his narrative directly. More generally, the factor of "forcible resistance" doesn't play much of a role in his theoretical analysis. Generally his view appears to be that forcible resistance was largely counter-productive to the movement, in that it stimulated vastly greater white supremacist response (142). This question is worth examining in detail; there is a commonsense logic that implies that a population that makes clear its willingness to use force to defend itself against violence would deter violent attack. So we might speculate that populations with this willingness to use force in self-defense would be more successful in establishing a zone of rights in local society.

It is important to recognize clearly and honestly the degree of violence that was exercised through the rule of the Jim Crow South, and the role that armed self-defense sometimes played in the struggle for equal rights. It is one of the remarkable achievements of the American civil rights movement that its leaders and followers were able to steer their course towards freedom in a way that ultimately quieted the appeal to violence on all sides.

(Here is some background on Lowndes County, Alabama (link). The *ChangeDirection* blog has a good multi-part series of posts on Stokely Carmichael's evolution as a leader in Lowndes County and nationally.)

Business interests and democracy

Saturday, February 27, 2010

The central ideal of democracy is the notion that citizens can express their political and policy preferences through political institutions, and that the policies selected will reflect those preferences. We also expect that elected officials will act ethically in support of the best interests of the public. This is their public trust.

The anti-democratic possibility is that popular debates and expressions of preference are only a sham, and that secretive, powerful actors are able to secure their will in most circumstances. And in contemporary circumstances, that sounds a lot like corporations and business lobbying organizations. (Here is an earlier post on a report about corrupt behavior at the Department of the Interior.)

The January Supreme Court decision affirming the status of corporations as persons, and therefore entitled to unfettered rights of free speech, is the most extreme expression of the power of business, corporations, and money. As distinguished law professor Ronald Dworkin argues in the *New York Review of Books* (link), this decision dramatically increases the ability of corporations to influence elections and decisions in their favor -- vastly disproportionately to citizens' organizations. And, as Dworkin points out, corporations don't need to exercise this right frequently in order to have enormous impact on candidates and issues. The mere threat of a well-financed media campaign against key representatives will suffice to sway their behavior.

There are too many examples of pernicious influence of business interests on public policy. Take a useful policy that many states and cities have tested, pretrial release programs. It appears that the public interest has been defeated by ... the bail bondsmen. NPR ran a story on the pretrial release program in Broward, Florida (link). The program was successful, with a high appearance rate for court appearances and annual savings of $20 million for the county. But this program cost the bail bondsmen business. They hired a lobbyist, and in the dead of night the county commission scaled back the program. Here is how the "industry" describes the issue (link). It is a pretty shocking story:

According to campaign records, Book [the lobbyist] ... and the rest of Broward's bondsmen spread almost $23,000 across the council in the year before the bill was passed. Fifteen bondsmen cut checks worth more than $5,000 to commissioner and now-county Mayor Ken Keechl just five days before the vote.

Keechl and several other commissioners declined NPR's repeated requests for an interview. At the meeting last January, they said they were concerned that Broward's pretrial program cost more than other counties' programs, and they vigorously denied that campaign contributions played any role.

Book had his work cut out for him. Broward's own county attorney wrote a memo warning commissioners that cutting back pretrial could be unconstitutional. But Book worked behind the scenes.

He met with commissioners, and according to county records, he had unusual access. That's because at the same time he was hired by the bondsmen to lobby commissioners, he was also hired by the commissioners to be their lobbyist. (transcript from NPR report)
The story makes the sequence pretty clear: Through the use of campaign contributions and influence of votes by commissioners, the bondsmen groups have prevailed to abandon the policy which was unmistakably in the public interest. The commission acted in deference to the narrow financial interests of a business group; campaign contributions by that group played a decisive role; and an overburdened county government was denied a tool that was good public policy from every point of view. And similar efforts are taking place in many cities. So where is the public's interest?
Or take the largest issues we face today in national politics -- cap-and-trade policy, healthcare reform, and the nation's food system. The influence of large financial interests in each of these areas is perfectly visible. Energy companies, coal companies, insurance companies and trade associations, and large food companies and restaurant chains pretty much run the show. Regulations are written in deference to their interests, legislation conforms to their needs and demands, and elected officials calculate their actions to the winds of campaign contributions. And the Supreme Court reverses a century of precedent and accords the rights of freedom of expression to corporations and unions that are enjoyed by individual citizens. So the influence of financially powerful corporations and industry groups will become even greater.

It would be deeply interesting if we had a sort "influence compass" that would allow us to measure the net deviation created by the private interests of companies and industries for a number of policy areas. How far from the due north of the public's interest are we when it comes to --

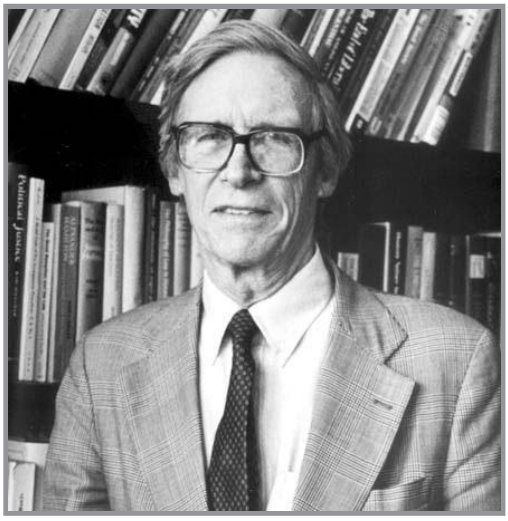
- Environmental protection
- Banking regulation
- Insurance regulation
- Energy policy
- Cost-effective military procurement
- Urban land use policy
- Airline safety
- Licensing of public resources such as gas and coal leases

Of course the metaphor of "north" doesn't really work here, since there is no purely objective definition of the public good in any of these areas. That is the purpose of open democratic debate about policy issues -- what are the facts, what do we want to achieve, and what are the most effective ways of achieving our ends? But when private interests can influence decision makers to adopt X because it is good for the profits of industry Y -- in spite of the clear public interest in doing Z -- then we have anti-democratic distortion of the process.

Where are the democratic checks on this exercise of power? A first line of defense is the set of regulations most governments and agencies have concerning conflict of interest and lobbying. These institutions obviously don't work; no one who pays attention would seriously think that agencies and governments are uninfluenced by gifts, contributions, promises of future benefits, and the blandishments of lobbyists. And these influences range from slight deviations to gross corruption. Moreover, influence doesn't need to be corrupt in order to be anti-democratic. If an energy company gets a privileged opportunity

to make the case for "clean coal" behind closed doors, this may represent a legitimate set of partial arguments. The problem is that experts representing the public are not given the same opportunity.

A related strategy is publicity: requiring that decision-making agencies make their deliberations and decision-making processes transparent and visible to the public. Let the public know who is influencing the debate, and perhaps this will deter decision-makers from favoring an important set of private interests. Then-Vice-President Cheney's refusal to make public the list of companies involved in consultations to the National Energy Policy Development Group (link) is an instructive example; it is very natural to suspect that the recommendations put forward by the NEPDG reflected the specific business concerns of an unknown set of energy companies and lobbyists (link). So greater publicity of process can be a tool in enhancing the fit between policy and the public's interests. (Here are earlier posts on the capacity of publicity to serve as a check on bad organizational behavior (post, post).)



Another line of defense is the independent press and media. Our newspapers and magazines have historically had the resources and mission to track down the influence of private interests on the formulation of legislation, regulation, and policy. Bill Moyers is a great example (link); for example, his recent story on the role of campaign contributions in the election of judges (link). But the resources are disappearing and the cheerleaders at Fox News are gaining influence by the month. So relying on the investigative powers of an independent media looks like an increasingly long-odds bet.

So we have our work cut out for us to validate the main premise of democracy: that the interests of the public will be served faithfully by government without significant distortion by private business interests.

(Here is a recent post on C. Wright Mills' analysis of power elites and the influence accorded to corporations in the United States.)

Rawls and decision theory

Sunday, February 28, 2010

John Rawls's A Theory of Justice was a strikingly original contribution to political philosophy upon its appearance in 1971. Against the prevailing preference for "meta-ethics" in the field of philosophical ethics, Rawls made an effort to arrive at substantive, non-tautological principles that could be justified as a sort of "moral constitution" for a just society. The theory involves two fundamental principles of justice: the liberty principle, guaranteeing maximal equal liberties for all citizens, and the difference principle, requiring that social and economic inequalities should be the least possible, subject to the constraint of maximizing the position of the least-well-off. (The principle also requires equality of

opportunity for all positions.)

Two elements of Rawls's philosophical argument were particularly striking. The first was his adoption of the anti-foundationalist coherence epistemology associated with Quine and Goodman (SEP article by Jonathan Kvanvig); so Rawls conceded that it is not possible to provide logically decisive arguments for moral positions. Though his theory of justice has much in common with the ideas of Kant and Rousseau, Rawls rejected the Kantian idea that moral theories could be given secure philosophical foundation. It is rather a question of the overall fit between a set of principles and our "considered judgments" about cases and mid-level moral judgments. He refers to the situation of "reflective equilibrium" as the state of affairs that results when a moral reasoner has fully deliberated about his/her considered moral judgments and tentative moral principles, adjusting both until no further changes are required by the requirement of consistency.

Another and perhaps even more distinctive part of Rawls's approach is his use of the apparatus of decision theory to support his arguments in favor of the two principles of justice against plausible alternatives (including especially utilitarianism). Essentially the argument goes along these lines. Suppose that representative individuals are brought together in a situation in which they are expected to make a unanimous and irreversible decision about the fundamental principles of justice that will regulate their society; and suppose they are profoundly ignorant about their own particular characteristics. Participants do not know whether they are talented, strong, intelligent, or eloquent; and they do not know what their fundamental goals are (their theories of the good). Rawls refers to this situation of choice as the ***original position***; and he refers to the participants as deliberating behind the ***veil of ignorance***. Rawls argues that rational individuals in these circumstances would unanimously choose the two principles of justice over utilitarianism. And this conclusion is taken to be a strong basis of support for the two principles as correct. This is what qualifies Rawls's theory as falling within the social contract tradition; the foundation of justice is the fact of unanimous rational consent (albeit hypothetical).

Once we connect the question, "what is the best theory of justice?", with the question, "what principles of justice would rationally self-interested persons choose?", there are various ways we might proceed. Rawls's description of the original position is just one possible starting point out of several. But if we begin with Rawls's assumptions, then it is natural to turn to formal decision theory as a basis for answering the question. How should rational agents reason in these circumstances? How should they decide which of several options will best serve their future interests? And one point becomes clear immediately: the choice of a decision rule makes a critical difference for the ultimate choice. If we were to imagine that decision-making under conditions of uncertainty mandates the "maximize expected utility" rule, then one choice follows (utilitarianism). But Rawls argues that the expected utility rule is not rational in the circumstances of the original position. The stakes are too high for each participant. And therefore he argues that the "maximin" rule would be chosen by rational participants in the circumstances of the original position. The maximin rule requires that we rank options by their worst possible outcome; and we choose that option that comes with the least bad outcome. In other words, we "maximize the minimum." (The maximin rule was described by von Neumann and Morgenstern in 1944 in their Theory of Games and Economic Behavior.)

Notice that this analysis involves a question of second-order rationality: not "what outcome would the rational agent choose?", but rather "what decision rule would the rational agent follow?". So it is the rationality of the decision rule rather than the rationality

of the choice that is at issue.

Another important qualification has to do with defining more carefully what part of the theory of rationality Rawls is using in this argument. It is sometimes said that Rawls applies game theory to the situation of the original position; and there is a certain logic to this interpretation. Game theory is the theory of strategic rationality; it pertains to that set of situations in which the payoff for one participant depends on the rational choices of other participants. And the original position seems to embody this condition. However, the requirement of unanimity and the complete absence of a context of bargaining makes the situation non-strategic. So Rawls's use of rational choice theory does not involve game theory per se, and he is not interested in demonstrating a Nash equilibrium in the OP. Instead, he believes that there is a single best strategy that will be chosen by each individual--the two principles of justice. (Here is a good brief description of the main assumptions of game theory.)

One might ask whether the two features singled out here -- anti-foundationalism and decision theory -- are consistent. If Rawls's theory of justice depends on an argument within formal decision theory, then why is it not a foundationalist argument? (And in fact, Rawls on occasion refers to his argument as reflecting a "kind of moral geometry".) What makes Rawls's use of decision theory "anti-foundationalist" is the fact that this argument itself is philosophically contestable. Reasonable decision theorists may differ about the rationality of the maximin rule (as John Harsanyi argued against Rawls). So the appeal to decision theory does not obviate the need for a balance of reasons in favor of the approach and the particular way in which it is specified in this situation; and this in turn sounds a lot like the role of physical theory and methodology within Quine's notion of "The Web of Belief."

(A mountain of words have been written about Rawls's moral epistemology. Here is Samuel Freeman's excellent article on the original position in the *Stanford Encyclopedia of Philosophy*; here is a useful compendium of the history of rational choice theory; and here is an old article of mine on the epistemology of reflective equilibrium.)

Democracy and agency in development ethics

Tuesday, March 02, 2010

Development ethics is an area of applied ethics that attempts to explore the moral issues involved in global social and economic transformation. Key to the urgency of the field is the fact of massive global poverty, hunger, and inequality. The current situation of the world's poor -- in Egypt, India, Mexico, Sudan, or Brazil, for example -- is entirely unacceptable from a human point of view. And governments, organizations, and individuals have positive moral obligations to work towards reducing these forms of massive suffering, and helping construct social and economic institutions that systematically reduce poverty. So much is clear from the 60,000 foot level. But how much more specificity can we provide about the bad of poverty, the principles of global justice, or the goals of development, so that moral theory can provide something of a

guide to policy and action? To what extent can we usefully connect moral theory to the practical challenges of designing workable development strategies?

Philosophers and social scientists have made a series of efforts at formulating a foundation for development ethics since the end of World War II. Early contributors were Denis Goulet (Development Ethics: A Guide to Theory and Practice) and Robert Chambers (Rural Development: Putting the last first). But the major progress in the field occurred through the writings of Amartya Sen and Martha Nussbaum, in the formulation of the "capabilities approach" to development. Sen argued that the fundamental goal of development should be to create social and economic institutions within which every individual is enabled to fulfill his/her capabilities and to realize the functionings of a full human life (Development as Freedom). And Nussbaum extended this idea with particular emphasis on the ways in which gender inequalities in development have deeply harmed women in the developing world (Women and Human Development).

There is now a third generation of thinking in the field of development ethics, well represented by David Crocker's excellent recent book, Ethics of Global Development: Agency, Capability, and Deliberative Democracy. (Other important examples include Sabina Alkire, Valuing Freedoms: Sen's Capability Approach and Poverty Reduction and Bina Agarwal, A Field of One's Own: Gender and Land Rights in South Asia.) Crocker has been actively involved in the formulation of theories of development ethics for decades, and is the founder of the International Development Ethics Association (IDEA). This is an important forum for philosophers and practitioners to come together to discuss the ethical issues of development. Crocker has been an exponent of the capabilities approach throughout his career, and has succeeded in deepening the debate by insisting on the importance of bringing the moral theories into direct engagement with the realities and practices of development.

The current book takes an important step forward. It is framed around the foundation of the capabilities approach; but it goes beyond existing capabilities theory by emphasizing the crucial role of agency and democracy within development. The capabilities approach focuses on achieving a form of society in which individuals can realize their capabilities and enjoy high quality of life. This is a focus on the ***outcome*** of development. Crocker refocuses this picture to emphasize the intrinsic and instrumental importance of the ***agency*** of the people involved in development -- the ***process*** of development. And people best exercise their agency through a deliberative, participative process -- through a ***democratic*** process. So Crocker's ethics of development might be described as a joining of the capabilities approach with current theorizing about deliberative democracy. (Here is an earlier post on deliberative democracy.)

So what does this emphasis on agency and democracy involve? Here is a concrete example: Indian economist V. K. Ramachandran's description of how the development process works in West Bengal and Kerala.

Here and elsewhere in the interview Ramachandran describes a process through which the West Bengal development agencies conduct their work. They consult broadly with social groups, labor organizations, feminist organizations, and local communities and villages. Proposals, goals, and strategies are developed through these consultations and deliberations; and the ultimate policy package is intended to represent a synthesis of the insights and claims of the various groups involved in the process. So the process

represents a practical illustration of the approach advocated by Crocker.

Why is a deliberative process along these lines appealing? First, it captures a set of social ideals associated with Rousseau and Marx about the value of individuals and groups self-constituting their goals and values through reflection and deliberation. Rather than the World Bank or the OECD Development Assistance Committee imposing a set of goals on a country or region (liberalization, more rapid urbanization, improvement of markets), the people of the region should have the opportunity and responsibility of setting their course and choosing the strategies they will pursue. Development should proceed through a process of local self-determination, and such a process is itself an intrinsic good.

Second, there is the idea is that the goals chosen through such a process will be in better alignment with the needs of the region, and will be better embraced by the people affected, because they have been refined and chosen through a deliberative, democratic process. Policies developed through a democratic process have a greater level of legitimacy with those affected by the policies.

Third, there is the expectation that the people of the community will have a better factual understanding of their natural and social circumstances, and will therefore be better able to formulate strategies that will work in the given environment. So Crocker and others expect that a process of deliberative democracy through which development goals and strategies are selected by a given community will have a higher probability of succeeding. (Notice the convergence between this set of ideas and Scott's critique of "high modernism"; link.)

This set of values suggests several institutional features: decentralization of decision-making, massive consultation, and a requirement of equality among citizens. Can we be confident that such a process will work well to reform society and reduce poverty and inequality? Ramachandran highlights one obstacle to this process in the interview posted above: the fact of extreme inequalities of wealth and poverty in rural India. But if the social setting is one of great inequalities between landlords, tenants, and landless workers, then to what extent can the requirements of democratic deliberation take place? Ramachandran argues for the necessity of agrarian reform (land reform and caste reform) as a necessary precondition for just economic development in India.

Decentralization of decision-making raises another potential problem -- the myopia of the local. A development plan that may be best for West Bengal as a whole may be undesirable to many communities; so how can we expect the process of deliberative democracy to arrive at a good outcome for the state as a whole? (The collapse of the Tata Motor Nano project in West Bengal perhaps illustrates this possibility.) And the massive consultation involved in this ideal poses its own problems of practicality. Can we be confident that such a process will come to a resolution, or will debate continue indefinitely?

Archon Fung and Erik Olin Wright address practical responses to some of these issues in Deepening Democracy: Institutional Innovations in Empowered Participatory Governance. Here is how they set the stage for their analysis:

As the tasks of the state have become more complex and the size of polities larger and more heterogeneous, the institutional forms of liberal democracy developed in the nineteenth century -- representative democracy plus techno-bureaucratic administration -

- seem increasingly ill suited to the novel problems we face in the twenty-first century. "Democracy" as a way of organizing the state has come to be narrowly identified with territorially based competitive elections of political leadership for legislative and executive offices. Yet, increasingly, this mechanism of political representation seems ineffective in accomplishing the central ideals of democratic politics: facilitating active political involvement of the citizenry, forging political consensus through dialogue, devising and implementing public policies that ground a productive economy and healthy society, and, in more radical egalitarian versions fo the democratic idea, assuring that all citizens benefit from the nation's wealth. (3)
David Crocker's focus on the importance of the values and practices of deliberative democracy within the development process is an important step forward. It helps to make more tangible the implications of the capabilities approach for specific development challenges; and it gives substance to the priority that Sen and Nussbaum accord to "freedom" as a central development value.

(Some readers may also be interested in my 2003 book, The Paradox of Wealth and Poverty: Mapping the Ethical Dilemmas of Global Development. This book likewise places the capabilities approach at the center of the analysis.)

Appearance and reality in public life

Wednesday, March 03, 2010

So what kind of democracy do we have? Do our institutions do a great job of establishing the public interest over the medium term, or have our institutions been captured by private interests, leaving essentially no real power in the hands of citizens?

The way it is supposed to work, according to Civics 101:

- Elected officials faithfully consider proposed legislation, based on their expressed political values, the interests of their constituents, and their perception of the best longterm interest of the polity.
- Decisions are made in public view.
- Legislative debates turn on the public presentation of reasons in favor of or against proposed legislation, invoking only rational assessment of likely consequences, fitness of proposed legislation to the longterm best interests of the polity, and consistency with existing law and constitution.
- Agencies use experts to faithfully create regulations that implement legislation in ways that are consistent with legislative intent, grounded in rational study of relevant scientific findings, and impartially applied without regard to persons or specific private interests.
- Lobbyists are able to influence legislation and regulation only through compelling rational arguments based on cost-benefit analysis, legitimate expression of a given set of affected interests, and public knowledge of their advocacy.

This sounds pretty much like the way that Rousseau would have expected the legislative process to have worked within the ideal polity; legislation enacts the "general will".

The not-so-ideal case:

- Elected officials give excessive importance to the impact their positions will have on the voters back home -- thereby paying less attention to the facts and consequences for the public good of various legislative initiatives.
- Elected officials sometimes permit themselves to be influenced by campaign

contributions and other personal advantages from industries and other private interests, thereby supporting or opposing initiatives for reasons other than the overall goodness or badness of the legislation for the public good.
- Regulative agencies are influenced by industry "experts" in writing regulations, with the result that regulatory regimes are tilted towards the private interests of the regulated industries rather than neutrally establishing public health and safety.
- Lobbyists have substantial access to legislators and regulators, with the result that they are able to move the dial in their favored direction.

We might describe this scenario as the pluralism scenario, along the lines of Robert Dahl's theories of democracy. Various interests contend through the use of various legal tools of influence, and the resulting set of laws, policies, and regulations represent a rough-and-ready balance of the many interested parties in a complex society. Private interests have weight on this scenario, but they don't determine the outcomes.

The nightmare scenario for democracy:

- Elected officials have no sincere adherence to the public good; they pursue their own private and political interests through all the powers available to them. (Senator Jim Bunning's unembarrassed willingness to block extension of unemployment legislation for narrow personal and political reasons falls in this category.)
- Elected officials are sometimes overtly corruptible, accepting significant gifts in exchange for official performance.
- Elected officials are intimidated by the power of private interests (corporations) to fund electoral opposition to their re-election. (The Supreme Court decision on corporate free speech makes this much more likely.)
- Regulatory agencies are dominated by the industries they regulate; independent commissioners are forced out of office; and regulations are toothless when it comes to environmental protection, wilderness protection, health and safety in the workplace, and food safety.
- Lobbyists for special interests and corporations have almost unrestricted access to legislators and regulators, and are generally able to achieve their goals.

This is the nightmare scenario if one cares about democracy, because it implies that the apparatus of government is essentially controlled by private interests rather than the common good and the broad interests of society as a whole. It isn't "pluralism", because there are many important social interests not represented in this system in any meaningful way: poor people, non-unionized workers, people without health insurance, inner-city youth, the environment, people exposed to toxic waste, ...

The fact that healthcare reform, regulation of CO2 emissions, and significant reform of the financial system have all been essentially blocked in the current legislative process seems to point to one of these scenarios; and it isn't the first or the second.

I'll quote an idea used in the previous posting to suggest one possible way forward for our democracy: a movement towards substantially greater participatory democracy in this country. Archon Fung and Erik Olin Wright address the future of our democracy in Deepening Democracy: Institutional Innovations in Empowered Participatory Governance. Here is how they set the stage for their analysis:

As the tasks of the state have become more complex and the size of polities larger and more heterogeneous, the institutional forms of liberal democracy developed in the nineteenth century -- representative democracy plus techno-bureaucratic administration -- seem increasingly ill suited to the novel problems we face in the twenty-first century. "Democracy" as a way of organizing the state has come to be narrowly identified with

territorially based competitive elections of political leadership for legislative and executive offices. Yet, increasingly, this mechanism of political representation seems ineffective in accomplishing the central ideals of democratic politics: facilitating active political involvement of the citizenry, forging political consensus through dialogue, devising and implementing public policies that ground a productive economy and healthy society, and, in more radical egalitarian versions fo the democratic idea, assuring that all citizens benefit from the nation's wealth. (3)

It is an interesting question to consider whether a participatory process surrounding the issue of healthcare reform would have led to a more satisfactory outcome. Given the results of the raucous, aggressive, and incivil disruption of town-hall meetings that occurred last summer around this issue, it is hard to be too optimistic about this approach either.

Essentializing race?

Friday, March 05, 2010

PBS is running a program this month called "Faces of America" (link), hosted by distinguished African-American Studies professor Henry Louis Gates, Jr. The program focuses on a handful of celebrity guests, a genetic profile for each, and then a variety of "surprising" discoveries about the genealogies of various of the guests.

What I found surprising and jarring in viewing Episode 3 is the degree of essentialism about race the script seems to presuppose. Gates's script seems to suggest that one's racial or ethnic identity is a function of one's genotype and one's ancestral (though unknown) history. At one point Professor Gates has a discussion with Kristi Yamaguchi, the Japanese figure skater. Pointing out that her genetic profile indicates descent from a particular genetic group that originated in far northern Asia some hundred thousand years ago, he makes a joke to the effect that perhaps her skating talent is a reflection of her ancestry in an extremely cold climate. It's a joke, of course; but it is a telling one. It conveys the idea that genes make the person; that one's biological ancestry constitutes one's race or ancestry and one's current characteristics.

What is surprising about this biological essentialism is the fact that most scholars who think deeply about race have decisively concluded that race is ***not*** a biological category but a cultural one. A person's race is socially constructed, deriving from the cultural communities in which he/she was formed and ***not*** primarily from his/her genotype or biological ancestry. Population geneticists find that there is as much genetic variation within a "racial" group as across racial groups; which seems to imply directly that the race of each group is not determined by the genetic profile of the group. Instead, racial or ethnic identity is created by the cultural environment in which one forms his/her most basic psychological dispositions.

The American Anthropological Association has had good reason to think deeply and critically about the concept of "race." In 1998 the AAA released a careful statement on

race. Here are a few specific claims included in the statement:

In the United States both scholars and the general public have been conditioned to viewing human races as natural and separate divisions within the human species based on visible physical differences. With the vast expansion of scientific knowledge in this century, however, it has become clear that human populations are not unambiguous, clearly demarcated, biologically distinct groups. Evidence from the analysis of genetics (e.g., DNA) indicates that most physical variation, about 94%, lies within so-called racial groups. Conventional geographic "racial" groupings differ from one another only in about 6% of their genes. This means that there is greater variation within "racial" groups than between them. In neighboring populations there is much overlapping of genes and their phenotypic (physical) expressions. Throughout history whenever different groups have come into contact, they have interbred. The continued sharing of genetic materials has maintained all of humankind as a single species.

...

At the end of the 20th century, we now understand that human cultural behavior is learned, conditioned into infants beginning at birth, and always subject to modification. No human is born with a built-in culture or language. Our temperaments, dispositions, and personalities, regardless of genetic propensities, are developed within sets of meanings and values that we call "culture." Studies of infant and early childhood learning and behavior attest to the reality of our cultures in forming who we are.

It is a basic tenet of anthropological knowledge that all normal human beings have the capacity to learn any cultural behavior. The American experience with immigrants from hundreds of different language and cultural backgrounds who have acquired some version of American culture traits and behavior is the clearest evidence of this fact. Moreover, people of all physical variations have learned different cultural behaviors and continue to do so as modern transportation moves millions of immigrants around the world.

So fundamentally, my reaction to the "Faces of America" script is that it seriously misrepresents the social reality of race and ethnicity, implying that identity follows from biology. Now, of course Henry Louis Gates, Jr. is perfectly well aware of this view of the status of the category of race; he is in fact one of the country's leading thinkers on this subject. So it is surprising that he would have permitted the simplistic version of the facts of race, ethnicity, and ancestry that the series conveys.

The most convincing voice I heard in the program was a statement by Ojibwe novelist Louise Erdrich who declined to undergo the genetic screening for the program. Her explanation of her thinking, roughly, was that her Ojibwe identity was constituted by her experience of family and community, not by ancestry; and she preferred not to confuse that identity by conflating it with facts about her distant ancestors.

The point I am making here is not that the genetic techniques to which the program refers are scientifically invalid; I would be willing to assume that there is good science behind the inferences from one person's genotype to conclusions about distant ancestry (including the gimmick of discovering that several of the guests have an ancestor in common). But my point is that this doesn't tell us anything at all of much interest about race or ethnicity; these are cultural constructs rather than biological facts.

Personally the conclusion I would rather come to goes along these lines: our genotypes

matter very little to our current experience and social location. The origins of our most distant ancestors is of some scientific interest but not much social significance. If we take pride in being "Asian-American," "Irish," or "African-American," it is because we have had specific social, family, and community experiences that lead us to identify with those groups and to give special importance in their struggles and achievements through history. The child who was a foundling in New York in 1900 and was raised in an Irish-Catholic family is no less Irish and no less Catholic if it turns out her father was an Italian anarchist and her mother was a Swedish Protestant. It is the particular communities into which we have socialized that constitute our identities, and I think that extends to racial and ethnic identities. Of course, some readers may think that this perspective also leads to somewhat paradoxical conclusions -- for example, the foundling who is "Irish" without a bit of Celtic ancestry, or that one could be Native American without any tribal ancestry.

Rawls on Marx; December 1973

Wednesday, March 10, 2010

John Rawls taught a course on the history of political philosophy throughout much of his career at Harvard University. The course contained his description and analysis of the most important figures in modern political philosophy, including Mill, Locke, Rousseau, Kant, and Marx. The course evolved over time; the final version from 1994 is edited in Samuel Freeman's Lectures on the History of Political Philosophy. I served as graduate assistant in Rawls's lectures on this subject in fall 1973, and recently reread my notes of the course. Here are my notes of a particularly important lecture towards the end of the course: Rawls's treatment of Marx's ideas about economic justice. This lecture demonstrates Rawls's understanding of the fundamentals of Marx's economic theories and the labor theory of value. (I am inclined to think that Joseph Schumpeter's History of Economic Analysis (1954) was an important source for Rawls on the history of economic thought, including Marx's economics, though I can't at this moment confirm this.) This lecture is particularly significant in that it is roughly simultaneous with the emergence of "analytical Marxism" announced by the publication of an important article by Allen Wood, "The Marxian Critique of Justice" in *Philosophy and Public Affairs* in 1972 (link).

MARX'S ATTITUDE TOWARDS THE THEORY OF JUSTICE

John Rawls, History of Political Philosophy, Phil 171, fall 1973
Notes from lecture, December 11, 1973
[notes taken by Daniel Little; intended to capture Rawls's formulations of the main points presented in the lecture]

[Quoting Rawls:]

Capital seems to be a description of an unjust society. The owners of the means of production live in relative abundance and idleness at the expense of the ever-growing

class of wretched laborers. But Marx doesn't make any attempt to present an argument that capitalism is unjust, nor any concept of justice which would back up such an argument. Moreover, we have vitriolic criticisms of utopian socialists who did condemn capitalism on the grounds of justice. Marx asserts on the contrary, that capitalism is perfectly fair, perfectly just. Why so?

(a) It is not enough to say Marx is averse to preaching or moralizing. He is so averse; but judgments of justice can be reasoned and hence not properly described as "preaching".

(b) It is not enough to say that he didn't want the critique of capitalism to rest on some social ideal. He does reject the utopian socialists' program; but that would not prevent him from stating his own opinion. And he doesn't do that either. He reproaches the utopians for not realizing that some major social change must precede an adjustment along moral lines.

Here is my conjecture as to why Marx didn't judge capitalism unjust. He thinks of justice as a political and juridical conception which is associated with a particular conception of the state and society; so it belongs to the prehistory of mankind. Given his picture of human society, these political and juridical institutions belong to the superstructure, and reflect the workings of the mode of production. For each mode of production there is a conception of justice appropriate to it, at least in prehistory. A further qualification: It is worthwhile to distinguish between the high time of a form and its low period -- where the form is a progressive force and where it stands in contradiction to the mode of production.

Here is a brief discussion of justice in *Capital III*:

To speak here of natural justice, as Gilbart does, is nonsense. The justice of the transactions between agents of production rests on the fact that these arise as natural consequences out of the production relationships. The juristic forms in which these economic transactions appear as wilful acts of the parties concerned, as expressions of their common will and as contracts that may be enforced by law against some individual party, cannot, being mere forms, determine this content. They merely express it. This content is just whenever it corresponds, is appropriate to the mode of production. It is unjust whenever it contradics that mode. Slavery on the basis of capitalist production is unjust; likewise fraud in the quality of commodities. (*Capital III*, 339-40)

Here Marx conceives of justice in terms of adequacy to the mode of production. **(1) The justice of legal forms cannot be discovered on the basis of those forms alone. Rather it depends upon their adequacy to the mode of production. The juridical institution is formal; to give it content we must look to the way of life and its requirements. A consequence: There is no universal theory of justice which allows us to evaluate generally the social institutions of any society. There is no general principle like "slavery is always unjust." There are thus no general rules of natural rights, no universal justice. (2) This adjustment of justice to the mode of production doesn't mean there are no injustices. Slavery is unjust under capitalism; wage labor is just under capitalism, provided that the worker is paid the value of his labor power.**

This view seems to suggest a sort of relativism; but this would be a faulty conclusion. We have a theory matching theories of justice with modes of production, and we might at some time find a function systematically linking them.

Let's now try out this suggestion on the conception of surplus value. The utopians argued

that workers ought to be paid the value of their contribution to the firm. Since they are not, capitalism is unjust. Marx rejects this view. It makes the appropriation of surplus value appear accidental -- as if the capitalists could act differently. Marx required a theory of value which made the appropriation of surplus value a necessary part of the capitalist system. On the theory of value every commodity is exchanged for a strict equivalent.

Marx distinguishes between the product of labor and labor power. The worker is given the value of his labor power, not his product. It is on this ground that he is fairly treated. Thus he is undercutting the Ricardian socialist position by rejecting and replacing the principle of contribution. It is the system itself which brings about surplus value, not the behavior of individuals who violate moral principles. Surplus value is an intrinsic part of the working of the social institutions of capitalism.

Consider the description of the production of surplus value in *Capital*.

Every condition of the problem is satisfied, while the laws that regulate the exchange of commodities, have been in no way violated. Equivalent has been exchanged for equivalent. For the capitalist as buyer paid for each commodity, for the cotton, the spindle and the labour-power, its full value. He then did what is done by every purchaser of commodities; he consumed their use-value. ... This metamorphosis, this conversion of money into capital, takes place both within the sphere of circulation and also outside it; within the circulation because it is conditioned by the purchase of the labour-power in the market; outside the circulation, because what is done within it is only a stepping-stone to the production of surplus value. (*Capital I*, p. 194)

The fact that surplus value arises is a piece of good fortune for the buyer, but no injustice to the seller.

Marx thus rejects the Ricardian principle of contribution. He finds it a bourgeois notion, basing property rights on one's labor.

Summing up. (1) Marx views the notion of justice as a virtue of legal forms and institutions, and thus perhaps it is a notion which belongs to prehistory. The state depends upon the mode of production. (2) Marx doesn't deny that the various conceptions of justice have formal features in common -- exchange of equivalents for equivalents -- but the notion of what is equivalent is determined in different ways. Marx would be prepared to admit that capitalism in its high period is just. One reason he rejects the utopian's argument is that it is misleading. It rests on a misapprehension of where the essential problem lies: not in the superstructure, but in the mode of production. He felt that the key enterprise is to give a scientific theory of the mode of production.

A second point: justice is a distributive notion. The appeal to justice suggests that we can separate the mode of distribution from the mode of production. This is for Marx incorrect. Appeals to justice are thus supposed to be superficial. Moreover, appeal to justice suggests that important social change can be achieved by legislation.

[Other relevant materials from the course:]

From the syllabus:

(a) Marx's criticism of the liberal state; (b) His attitude towards theories of justice; (c) The theory of alienation and exploitation; (d) The conception of rational human society

Final exam questions on Marx:

4. Present and discuss Marx's theory of alienation (as developed in the *Economic and Philosophic Manuscripts*)
5. Present and discuss Marx's theory of historical materialism (as developed in the *German Ideology*)
6. Present and discuss Marx's analysis of historical change in the *Communist Manifesto*.
7. Outline Marx's analysis of the basic characteristics of capitalism: the social relations which define it and the nature of the form of economic production.

The moral sentiments

Thursday, March 11, 2010

One of Adam Smith's contributions to the study of philosophical ethics is his book, The Theory of Moral Sentiments. It is an interesting work, one part descriptive moral psychology, one part theory of the emotions. Here is the opening paragraph (link):

How selfish soever man may be supposed, there are evidently some principles in his nature, which interest him in the fortune of others, and render their happiness necessary to him, though he derives nothing from it except the pleasure of seeing it. Of this kind is pity or compassion, the emotion which we feel for the misery of others, when we either see it, or are made to conceive it in a very lively manner. That we often derive sorrow from the sorrow of others, is a matter of fact too obvious to require any instances to prove it; for this sentiment, like all the other original passions of human nature, is by no means confined to the virtuous and humane, though they perhaps may feel it with the most exquisite sensibility. The greatest ruffian, the most hardened violator of the laws of society, is not altogether without it.
So Smith asserts as a matter of empirical fact that there are common moral emotions and feelings -- sympathy, pity, compassion -- that underlie human social and moral behavior. And the most basic kinds of morally motivated behavior -- altruism in particular -- are explained by the workings of these natural emotions of empathy with other human beings. So Smith posed a fundamental question: is there an innate human moral psychology, beyond the reach of training and teaching, that accounts for our willingness to give to others and sometimes sacrifice important interests for the good of others? Why do firemen rush into the highly dangerous environment of a large fire in order to rescue the people inside?

Now fast-forward to the post-Darwinian world; look at the human organism from the point of view of the study of primate behavior; and ask this key question: Is there an evolutionary basis for social behaviors? Are there emotions supporting cooperation that were selected for through our evolutionary history? Is a moral capacity hardwired?

Philosophers have treated this question in the past. Allan Gibbard's Wise Choices, Apt Feelings: A Theory of Normative Judgment is a particularly good example. Here is how Gibbard describes the situation.

Consider now human beings evolving in hunting-gathering societies. We could expect them to face an abundance of human bargaining situations, involving mutual aid, personal property, mates, territory, use of housing, and the like. Human bargaining situations tend to be evolutionary bargaining situations. Human goals tend toward biological fitness, toward reproduction. The point is not, of course, that a person's sole goal is to maximize his reproduction; few if any people have that as a goal at all. Rather, the point concerns propensities to develop goals. Those propensities that conferred greatest fitness were selected; hence in a hunting-gathering society, people tended to want the various things it was fitness-enhancing for them to want. Conditions of primitive human life must have required intricate coordination--both of the simple cooperative kinds involved, say, in meeting a person, and of the kind required for bargaining problems to yield mutually beneficial outcomes. Propensities well coordinated with the propensities of others would have been fitness-enhancing, and so we may view a vast array of human propensities as coordinating devices. ***Our emotional propensities, I suggest, are largely the results of these selection pressures, and so are our normative capacities.*** (67)
One of Gibbard's key points is an analytical one. He argues against the idea of there being specific moral content, ethical principles, or moral emotions that are embodied in the central nervous system (CNS) as a result of variation and selection. Instead, he argues for there being a hardwired set of more abstract capacities that have CNS reality and selection advantage: the ability to learn a norm and to act in accordance with it. (Richard Joyce makes a similar point: "Evolutionary psychology does not claim that observable human behavior is adaptive, but rather that it is produced by psychological mechanisms that are adaptations. The output of an adaptation need not be adaptive" (5).)

This is the part that seems counter-intuitive from a simple Darwinian point of view. Wouldn't an organism possessing a genetically determined disposition to act contrary to its mortal interests almost necessarily have less reproductive success? So shouldn't such a gene quickly lose out to a more opportunistic alternative? Gibbard considers the evolutionary arguments surrounding the topic of altruism (including Richard Dawkins' Selfish Gene), and concludes -- not necessarily. It is possible to mount an evolutionary argument that establishes the fitness-enhancing characteristics of some specific kinds of altruistic behavior.

So what does the current research on this topic add to what we already knew? And, can we draw any interesting connections back to the venerable Smith?

In fact, there seems to be a new surge of interest in the topic. A number of philosophers and psychologists are now interested in treating moral psychology as an empirical question, and they are interested in working back to the evolutionary environment in which these human capacities emerged. (For example, Richard Joyce, The Evolution of Morality and Walter Sinnott-Armstrong, ed., Moral Psychology, Volume 1: The Evolution of Morality: Adaptations and Innateness.) Particularly interesting is research by Michael Tomasello and his collaborators. Tomasello is the co-director of the Max Planck Institute for Evolutionary Anthropology. He argues that human beings are hardwired for cooperation, empathy, and social intensionality in a very interesting recent book, Why We Cooperate. A great deal of his research has to do with experiments and observations of human children (9-24 months) and of young non-human primates. He finds, essentially, that infants and children display a range of behaviors that seem to reveal a natural readiness for altruism, sharing, coordination, and eventually following of norms. "I only propose that the kinds of collaborative activities in which young children today engage are the natural cradle of social norms of the cooperative variety. This is because they contain the seeds of the two key ingredients" (89-90). He presents a range of experimental data supporting these ideas:

- Human infants have a pre-cultural disposition to be helpful and empathetic (12-14 months)
- Human toddlers adjust their cooperative and normative behavior to be more attentive to the behavior of others: generous to the generous and not to the ungenerous.
- Human infants and toddlers have a precultural disposition to absorb and enforce norms.
- The emotions of guilt and shame to be hardwired to conformance to norms.
- Infants appear to take a "we" intentional stance without learning. They are able to quickly figure out what another agent is trying to do.
- Chimps differ from human infants in virtually each of these areas.

Here is a particularly interesting piece of evidence that Tomasello offers in support of the idea that human evolution was shaped by selection pressures that favored social coordination: the whites of the eyes in the human being. Almost all non-human species have eyes that are primarily dark; whereas human eyes feature a large and conspicuous circle of white (the sclera). The whites of the eyes permit an observer to determine what another individual is looking at -- allowing human individuals to achieve a substantially greater degree of shared attention and coordination. "My team has argued that advertising my eye direction for all to see could only have evolved in a cooperative social environment in which others were not likely to exploit it to my detriment" (76).

So does this recent work on the evolutionary basis of moral emotions have anything to do with Smith and the moral sentiments? What the two bodies of thought have in common is the idea that there is a psychological foundation to moral behavior, cooperation, altruism, and helping. Pure maximizing rationality doesn't get you to "helping"; rather, there needs to be some psychological impulse to improve things for the other person. Where evolutionary psychology differs from Smith is precisely in the nature of the explanation that is offered for this moral psychology; we have the advantage of having a pretty good idea of how natural selection works on biological traits, and we are therefore in a better position than Smith was to explain why human beings possess moral sentiments. What we cannot yet answer is the question of the nature of the mechanism at the level of the central nervous system or the cognitive system, of how these moral sentiments are embodied in the human organism.

(It is interesting to contrast this line of argument with that of Tom Nagel in The Possibility of Altruism. Nagel argues against the moral psychology of Hume -- very similar to that of

Smith -- and argues that altruism is actually a feature of rationality. We behave altruistically, fundamentally, because we have a rational representation of the reality of the external world and of other persons; and to recognize the reality of another person is immediately to have a reason to help the other person. So no "motor" of moral emotion is needed in order to explain altruistic behavior. On this approach, we don't need to postulate moral sentiments to explain moral behavior; all we need is a rich conception of practical rationality.)

Marx's influence on Rawls

Tuesday, March 16, 2010

John Rawls and Karl Marx shared a number of core intellectual concerns. Both were interested in the question of what features a good and just society should have; both had theories about the good human life; and both understood that the benefits of modern life depend upon social cooperation. So it is interesting to ask whether Marx's thought had an influence on Rawls. In brief, the answer seems to be largely "no." In particular, Marx's economic writings and his theory of exploitation seem to have been of no special interest to Rawls during the period leading up to the publication of A Theory of Justice in 1971.

I didn't have the opportunity to study with Marx; but I did have that opportunity with Rawls. I attended both of his lecture series on the history of moral philosophy and the history of social and political thought in 1972 and 1973, and I served as a graduate assistant in the latter course. And eventually Rawls agreed to serve as primary advisor on my dissertation, "Marx's *Capital*: A Philosophical Study" (1977). (This eventually became the germ of my first book, The Scientific Marx.) Rawls's two primary lecture series have now been compiled by former students of Rawls's: Samuel Freeman's edition of Lectures on the History of Political Philosophy and Barbara Herman's edition of Lectures on the History of Moral Philosophy. The lectures continued into the 1990s, and they certainly evolved significantly during that time. In particular, the lectures on Marx are substantially more extensive by the time of the 1990s than they were in the 1970s. (An earlier posting provides the notes I took on a lecture that Rawls gave in 1973 on Marx's critique of justice.)

Rawls's teachings about Marx in his courses on ethics and social and political philosophy focused primarily on the early Marx -- the "philosophical Marx". He taught and reflected upon the theory of alienation and species being, and the main texts he focused on were the *Economic and Philosophical Manuscripts*, *On the Jewish Question*, and *Contribution to a Critique of Hegel's Philosophy of Right*. He gave little serious attention to *Capital* or Marx's own economic theories. It was Marx's theory of the human person, Marx's philosophical anthropology, that he seems to have found of the greatest philosophical interest and value. (Robert Tucker's The Marx-Engels Reader (Second Edition) remains a good source on Marx's writings. and Rawls used it as the primary source of Marx's writings in his course. Rawls also used Tom Bottomore's collection, Karl Marx: Early Writings.)

There is only one substantive comment about Marx in the lectures on moral philosophy:

A difference between Hegel and Marx in this respect is that Hegel thinks that the citizens of a modern state are objectively free now, and their freedom is guaranteed by its political and social institutions. However, they are subjectively alienated. They tend not to

understand that the social world before their eyes is a home. .... By contrast, Marx thinks that they are both objectively and subjectively alienated. For him, overcoming alienation, both subjective and objective, awaits the communist society of the future after the revolution. (Herman, 336)
(Shlomo Avineri's Hegel's Theory of the Modern State, which appeared in 1972, provides a similar treatment of Hegel view of the modern state and the citizen's freedom.)

Rawls gave his primary attention to Marx in his lectures on the history of social and political philosophy. (This occupied roughly two weeks of the 12-week course.) Here are the selections of Marx's writings that Rawls assigned in this course: *On the Jewish Question*, *Contribution to the Critique of Hegel's Philosophy of Right*, selections from the *German Ideology*, selections from *Capital*, the *Economic and Philosophic Manuscripts*, *Capital*, Vol. I, chs I: sec. 4; VI-VII; IX, sec. 1; X, sec.1; XIII-XIV; and *Critique of the Gotha Program*. (These are the assignments listed in the syllabus for Philosophy 171, fall 1973-74.)

The materials assigned from the early Marx in this syllabus provide a fairly complete exposure to Marx's theories of species being, true human emancipation, and alienation. *On the Jewish Question* and the *Economic and Philosophic Manuscripts* contain rich bodies of argument in which Marx lays out his conception of human activity and freedom. Sections from the *German Ideology* provide some exposure to the theory of historical materialism. And the *Critique of the Gotha Program* is a vehicle for discussing Marx's ideas of a socialist society. So this batch of materials offer a reasonably thorough exposure to Marx's thought prior to his political economy and his formulation of an economic theory of capitalism.

By contrast, the imprint of Marx's political economy in this set of lectures is very limited. The readings from *Capital* break out this way:

- Vol I, ch I, sec. 4: The Fetishism of Commodities and the Secret Thereof
- VI: The Buying and Selling of Labour-Power
- VII, sec. 1: The Labour-Process or the Production of Use-Values
- X, sec.1: The Limits of the Working-Day
- XIII: Co-Operation
- XIV: Division of Labour and Manufacturing

This amounts to about 55 pages of reading from *Capital*, out of the 774 pages of volume 1. These readings introduce a few fundamental ideas such as the fundamentals of the labor theory of value, the idea of commodity fetishism, and some of the basics of Marx's sociological description of capitalist society and the economic process within capitalism. But it is a very sketchy introduction to Marx's thinking in *Capital*. And the most extensive discussion that Rawls provided of any ideas from *Capital* in his 1973 course -- the discussion of Marx's conception of justice in the 1973 lectures -- is largely a paraphrase of Allen Wood's analysis in "The Marxian Critique of Justice" (*Philosophy & Public Affairs*, 1972, link). This is true all the way down to the two passages that Rawls mentions from *Capital* in the course of this lecture; both were previously discussed in Wood's article. So there is nothing original in the 1973 lecture; Rawls has pretty much adopted Wood's frame of analysis in treating the question of Marx's conception of justice. This isn't surprising, in that Wood's article was highly original and rigorous, and opened up a largely new line of interpretation of Marx's theories. But Rawls didn't have much to add to the debate in this lecture.

In other words: As of 1973, two years after the publication of A Theory of Justice, Rawls's references to the economic theories and sociological descriptions contained in *Capital*

were very slender indeed. It is hard to avoid the conclusion that Rawls had not been significantly immersed in a reading of Marx's economic and sociological writings during the formative period of his development of the theory of justice.

This breakdown of topics and readings gives a clue to what Rawls found appealing about Marx. The conception of individuals forging themselves through labor is central; it reflects a line of thought extending from Aristotle to Hegel to Marx, and it seems to be foundational for Rawls himself when he describes his theory of the good.

But there are other core ideas in Marx's thought that plainly did not appeal to Rawls. Central are the ideas of ***critique*** and ***exploitation***. Both ideas are absolutely core to Marx; but they play no role in Rawls's theories.

The idea of critique involves the notion that there are hidden presuppositions underlying a given theory, and critical philosophy can uncover them. Ludwig Feuerbach represents on ideal along these lines; Feuerbachian criticism of religion "lays bare" the hidden agendas represented by official religion. Marx's own arguments in the *German Ideology* reflect this method. And in fact, many of Marx's titles have the subtitle "towards a critique of political economy". Does Rawls ever give attention to this intellectual style? In a word, no. Rawls pays no attention to Marx's philosophical method when it comes to "critique" as a tool of intellectual discovery.

The other unspoken Marxian concept in Rawls's writings and teachings is exploitation. Marx believed, as a matter of objective economic analysis, that capitalism is a system of exploitation in a specific technical sense: the capitalist is enabled to expropriate the unpaid surplus labor of the worker. This perspective on modern economic relations as representing a set of fundamentally unfair economic relations between the powerful and the weak is not one that Rawls found compelling, apparently. And the fundamental "ontological" framework of Marx's thinking -- the idea of capitalism as a system of relations of production through which economic activity transpires -- never comes in for detailed description or discussion in Rawls.

This aspect of Marx's theory of capitalism became central in the debate in the 1970s and 1980s over "Marx's theory of justice" (for example, Allen Buchanan, Marx and Justice: The Radical Critique of Liberalism and Allen Wood, Karl Marx). If capitalism is exploitative in its most fundamental institutions, then presumably Marx would judge that capitalism is unjust. Debate raged.

The topic of justice comes up directly in Rawls's 1973 lectures. But significantly, Rawls's analysis here is taken almost point-by-point from Wood; Rawls doesn't seem to have given the question much thought himself. So the theory of exploitation, in spite of its relevance to Rawls's central topic, is not an area of influence on the development of Rawls's thought.

And why is this? Apparently because both ideas are fundamentally anti-liberal. As Rawls writes in his lectures on political philosophy, "I will consider Marx solely as a critic of liberalism" (Freeman, 320). The two ideas mentioned here both fall in the category of fundamental critique of liberalism. The first discredits the philosophical foundations of Smithian political economy, promising to lay bare the underlying and contradictory assumptions it rests upon. The second lays out an explicit theory purporting to demonstrate the explicit inequality and unfairness of market institutions at their core. Perhaps it was cognitive dissonance that kept Rawls from giving more attention to the

later Marx.

It is interesting to note that the explosion of interest in Marx by analytic philosophers took place in the early 1970s -- about the time of publication of A Theory of Justice. Philosophers such as Allen Wood, George Brenkert, Allan Buchanan, John McMurtry, Gerald Cohen, Jon Elster, Adam Przeworksi (a political scientist), and John Roemer (an economist) began taking Marx's writings seriously and offering extensive analysis and criticism of his theories. This resurgence began in discussions of "Marx's theory of justice," but extended quickly into many other areas of Marx's thought -- the theory of exploitation, the labor theory of value, the theory of historical materialism, and his theory of capitalism as a distinctive mode of production. (I myself argued for a "rational choice" interpretation of Marx's theory of capitalism in The Scientific Marx.) Early arguments discrediting the labor theory of value fall in this category as well. Examples of some of this work are included in John Roemer, ed., Analytical Marxism: Studies in Marxism and Social Theory. This work was referred to as "rational choice Marxism" or "analytical Marxism," and it represented an intellectual agenda that took Marx seriously as a thinker but often came to conclusions that offended orthodox Marxist theorists.

Detroit: Taking charge of our story

Thursday, March 18, 2010

New Detroit (link) and Wayne State University are putting on a major and significant conference on how the story of Detroit is being told today. Detroit is getting a lot of press these days --and it's mostly about crisis, decline, and despair. It is hard for a city to move forward in the context of such a negative picture. And many in Detroit find this national story to be superficial and misleading. So how can we do a better job of understanding and presenting our story? (Here is a link: Ourdetroitstory.)

There is a persistent feeling in the region that the national press is writing the story of Detroit in ways that retell the myths about the past and sensationalize the present. And it makes a difference. We need more nuanced stories, and today's conference is an important effort in that direction.

The lead speaker was Tom Sugrue, author of the 1997 book, The Origins of the Urban Crisis: Race and Inequality in Postwar Detroit. Sugrue made several key points. Most importantly, he points out that the received wisdom about Detroit is wrong. It's not mostly about the 1967 uprising, the white flight of the 1960s, or the racialized politics of Mayor Coleman Young. Instead, our current situation is the result of racial discrimination in employment in the 1940s through 1960s, the flight of industry from the city that began following World War II, and the patterned and systematic racial segregation that followed from Federal home loan policies, real estate steering, and violent and harrassing homeowner associations aimed at intimidating black home buyers.

So Sugrue argues that telling today's story requires an honest understanding of 70 years of our past. The past has created a set of social forces and patterns of economic and

political inequality that profoundly affect the present and future. And he argues that the boundaries that divide our region have become a deep barrier to our progress.

The next panel involved lively presentations and discussions by distinguished observers: Robin Boyle (Wayne State University), Malcolm Dade (former political strategist for Coleman Young), David Freund (University of Maryland and author of Colored Property: State Policy and White Racial Politics in Suburban America), and Marcella Wilson (Matrix Human Services). There is a strong theme of needing to achieve a greater reality of racial justice to our city -- and that so many other forms of progress won't be achieved without this important dimension of change.

The discussions today are an important part of Detroit's efforts to reinvent itself in a more equitable and affluent way. And this means understanding our history and our patterns of systemic racial disadvantage more fully.

Influences and arguments

Sunday, March 21, 2010

Lately I've been writing about the influences that can be discerned in the theories of John Rawls. Rawls was a "social contract theorist"; to what extent were his theories shaped and framed by his reading of the great contract theorists such as Locke, Rousseau, or Kant? He was also influenced by the history of economic thought; so is it possible to find parallels or echoes of the thought systems of Adam Smith or Karl Marx in Rawls's thinking? And to what extent were there more local influences in the 1940s and 1950s that created fairly specific directions and characteristics in Rawls's thinking?

This is an interesting question in application to one particular philosopher. But it also raises a more general question: where do philosophical theories come from? To what extent is it the case that a given philosopher is working within a "micro-tradition" -- a particular and specific field of influence -- and to what extent is the thinker "original", bringing forward new ideas on a topic? And once a fundamental topic has been established for a thinker -- e.g., "What defines the principles of justice for a property-owning democracy?" -- to what extent does the theory then develop autonomously according to the arguments and analysis of the philosopher?
This way of formulating the problem invokes several related ideas: influence and tradition; originality and creativity; and orderly, logical development of a position or theory.
I suppose that there are many instances of philosophers who fall mostly in the "influence" part of the map: their philosophical work largely takes the form of carefully working out the ideas of their influencers. (This might be part of the legacy of Rawls; I suppose there has been quite an ocean of philosophical work dedicated to specifying more exactly what "primary goods" are, or how "reflective equilibrium" works.) This might be described as "normal science" -- taking the foundations of a field of study as being unquestioned, and then attempting to work out the details more exactly.

There are also some good examples of philosophers who were largely driven by the "logical analysis" part of the map: formulate a good, difficult question, and then spend the rest of one's career working out analytically sound answers to the problems this question spawns. "Naturalized epistemology" might fall in this sector; we might say that the philosophers who have tried to give a biological interpretation of the conditions of knowledge are taking one fundamental question -- how do biological organisms arrive at knowledge of their environment? -- and attempt to apply the findings of cognitive science and evolutionary biology to the issues that arise. Kant's philosophy also seems to have this character: once having chosen the topics "What can we know metaphysically?" or "What creates moral duty?", his mind seems to have proceeded analytically and logically, without correction or stimulus from a contemporary literature.

And what about originality? Are there examples of philosophers who have largely invented a set of questions and approaches that defined a new philosophy for a given domain? Wittgenstein is commonly recognized as a highly original philosopher; but certainly his theories were embedded in a tradition of philosophy. Several things are apparently true about Wittgenstein when it comes to influence and argument. (a) Many of his ideas and assumptions in the Tractatus Logico-Philosophicus derived from careful readings of Frege and Russell; (b) his insights and assertions in Philosophical Investigations were responsive to a surrounding set of ideas about language, behavior, and meaning, but his solutions and theories still strike one as being highly original; and (c) for certain themes and problems he continued to work carefully to move his position forward through analytical discovery and inference. So Wittgenstein seems to illustrate all three dimensions of philosophical theory formation and knowledge construction.

Several things seem to be true about the formation of the theories and perspectives of individual philosophers:

- They are introduced into a fairly specific "philosophical research community" through graduate education that provides paradigm examples of philosophical questions and issues and prescriptive advice about the nature of philosophical argument and analysis.
- They are introduced to their field at a particular moment in social history: World War II, the Holocaust, the Vietnam War, the civil rights period, 9-11; and historical events and shifts have an influence on the formation of their thought.
- "Originality" can take the form of arriving at new questions ("How is group mentality possible?"); new methods of analysis (Frege-Russell's formal deductivism as a solution to the question of the nature of mathematical truth); or new substantive approaches to philosophical theory (Kant's Copernican Revolution in thought).

An interesting contribution to this set of topics is an innovative series of volumes posing "5 Questions" to philosophers in a variety of fields (link). A recent volume is Philosophy of the Social Sciences: 5 Questions, edited by Diego Rios and Christoph Schmidt-Petri. Contemporary philosophers were asked to respond to five important questions about their approaches to the field of the philosophy of social science. The format offers the beginning of a triangulation among "beginnings," "fundamental assumptions," and "future directions" for each of these philosophers. The questions that were provided to the philosophers are these:

1. How did you get interested in the philosophical aspects of the social sciences?
2. Which social sciences do you consider particularly interesting or challenging from a philosophical point of view?
3. How do you conceive the relation between the social sciences and the natural sciences?
4. What is the most important contribution that philosophy has made to the social sciences?

5. Which topics in the philosophy of social science will, and which should, receive more attention than in the past?

Contributors include David Bloor, Raymond Boudon, Mario Bunge, Nancy Cartwright, Margaret Gilbert, Daniel Hausman, Harold Kincaid, Daniel Little, Steven Lukes, David Papineau, Philip Pettit, Alexander Rosenberg, David-Hillel Ruben, John Searle, and Raimo Tuomela. This list includes quite a few of the people who have helped to shape current thinking in this sub-discipline of philosophy; so it is very interesting to have a chance to see what they have to say about some of the original influences on their thinking about the social sciences, as well as their own definitions of the frameworks they have arrived at. I found it very interesting to think seriously about these questions in my own case, because it forces one to reflect on the ideas, events, and ideologies that led one to choose one set of topics and approaches rather than another. I would have added a sixth question for each of the contributors: "What are the most basic ideas that you have come to in the course of your studies of the social sciences?"

What I would like to see is a next step conducted by a gifted sociologist of the professions, who would attempt to map out the streams of influence and contribution that are documented within the essays in this volume. Andrew Abbott's careful analysis of the currents of thought constituting the discipline of sociology in the 1960s and 1970s is a good case in point (Chaos of Disciplines). Another good example is William Sewell's attempt to provide a geography of the discipline of social history in the 1960s (Logics of History: Social Theory and Social Transformation).

Zomia -- James Scott on highland peoples

Wednesday, March 24, 2010

James Scott opens his most recent book with quotations from frustrated pre-modern administrators and missionaries whose territories included the peoples of inaccessible highland regions -- Guizhou, highland Burma, and Appalachia. Scott finds that the geographical circumstances of highland peoples mark them apart from the political organizations of the valleys; states could control agriculture, surplus, and labor in the lowlands, but were almost entirely incapable of exerting sustained rule in the highlands. And he finds that highland cultures and systems are more or less deliberately shaped to elude the grasp of the state; linguistic variety, swidden agriculture, and ethnic opacity all work to make the art of rational administration all but impossible. The book is The Art of Not Being Governed: An Anarchist History of Upland Southeast Asia, and it is a significant contribution to the social and political analysis of very large swatches of the world. (Here are the table of contents and introduction to Edmund Leach's classic book, Political Systems of Highland Burma: A Study of Kachin Social Structure.)

Scott makes use of the concept of "Zomia" to capture the highland peoples of Southeast Asia.

One of the largest remaining nonstate space in the world ... is the vast expanse of uplands, variously termed the Southeast Asian *ma s-si f* and more recently, Zomia. This great mountain realm on the marches of mainland Southeast Asia, China, India, and Bangladesh sprawls across roughly 2.5 million square kilometers -- an area roughly the size of Europe. As one of the first scholars to identify the massif and its peoples as a single object of study, Jean Michaud has traced its extent: "From north to south, it includes southern and western Sichuan, all of Guizhou and Yunnan, western and northern Guangxi, western Guangdong, most of northern Burma with an adjacent segment of extreme [north]eastern India, the north and west of Thailand, practically all of Laos above the Mekong Valley, northern and central Vietnam along the Annam Cordillera, and the north and eastern fringes of Cambodia." (chapter 1)
(The Michaud citation refers to Historical Dictionary of the Peoples of the Southeast Asian Massif.)

Scott estimates the population of the minority peoples of Zomia at 80-100 million. Here is a map posted by Martin Lewis on GeoCurrents.Info.

What is intriguing about this definition of space and social reality is that it is not defined by nation-state boundaries and jurisdiction, by linguistic groupings, or by ethnic and national identities. Scott emphasizes the enormous linguistic and ethnic variation that occurs across this expanse of space. "In the space of a hundred kilometers in the hills one can find more cultural variation--in language, dress, settlement pattern, ethnic identification, economic activity, and religious practices--than one would ever find in the lowland river valleys" (chapter 1; Kindle location 343).

Two central arguments take up much of Scott's attention in the book. One is an argument about the logistics of state power in a pre-modern agrarian society. Essentially he argues that pre-modern agrarian societies were only able to impose their rule over a tight radius of perhaps 300 kilometers, when it came to collecting taxes, grain, and manpower. Moreover, this radius of power reduced significantly when population was distributed over mountainous country. So as a practical matter, the pre-modern states of Burma, Thailand, and Cambodia were river-valley states, and the peoples of the highlands were rarely subject to central rule. This argument resonates with Michael Mann's analysis of pre-modern state power in The Sources of Social Power: Volume 1, A History of Power from the Beginning to AD 1760. On this scale, the Kingdom of Chicago would barely be able to exert its will over the peasants of Peoria or Milwaukee; and Indianapolis would be a distant and irrelevant place.

The precolonial state, when it came to extracting grain and labor from subject populations, could project its power only within a fairly small radius of the court, say, three hundred kilometers, and that undependably and only during the dry season. (Kindle loc 610)
And, he argues, the peoples of the highlands deliberately organized their activities in ways that made the power of the state least effective.

Virtually everything about these people's livelihoods, social organization, ideologies, and (more controverially) even their largely oral cultures, can be read as strategic positionings designed to keep the state at arm's length. (Kindle loc 26)

The very diversity, fluidity, and mobility of their livelihoods meant that for an agrarian state adapted to sedentary agriculture, this ungoverned landscape and its people were fiscally sterile. (Kindle loc 217)
The other central theoretical argument that Scott offers concerns the question of ethnicity and identity. Like Ben Anderson (Imagined Communities: Reflections on the Origin and Spread of Nationalism), Scott believes that the identities of Burman, Mon, Khmer, Tai, or Shan are constructed identities, not essential or ancient.

Identity at the core was a political project designed to weld together the diverse peoples assembled there. Bondsmen of allied strongmen, slaves captured in warfare or raids, cultivators and merchants enticed by agricultural and commercial possibilities: they were in every case a polyglot population. (Kindle loc 1166)

The central plain of what would become Siam was, in the thirteenth century, a complex mix of Mon, Khmer, and Tai populations who were an "ethnicity-in-the-process-of-becoming" Siamese. (Kindle loc 1172)
The book takes up the argument that Scott began in Seeing Like a State: How Certain Schemes to Improve the Human Condition Have Failed: that a central task of the state it to render its territory and population "legible". The state needs to be able to regiment and identify its subjects, if it is to collect taxes and raise armies; so sedentary, mobile, peripheral peoples are antithetical to the needs of the state. This argument begins in *Seeing Like a State*; and it gains substantial elaboration here. And it is a fundamental call for a different approach to conceptualizing and studying the cultures and populations of Southeast Asia: not by ethnic group, not by national boundaries, but rather by the common circumstances of material and political life in high, rugged terrain.

As I've suggested in treating Scott's other contributions to "peasant studies", Scott's work almost always takes the form of an imaginative re-framing of problems that we thought we had understood. But once looking at the facts from Scott's point of view, we find that the social phenomena are both more complex and perhaps more obscure than they initially appear to be.

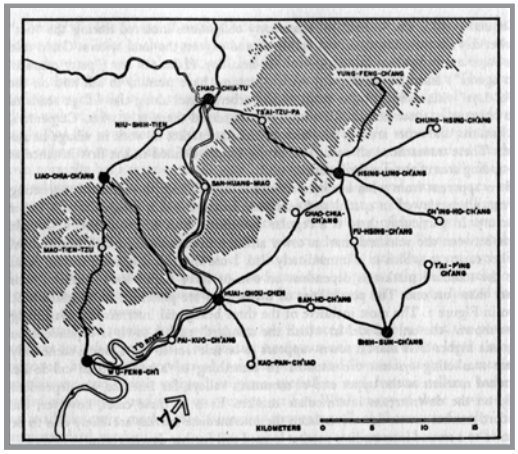
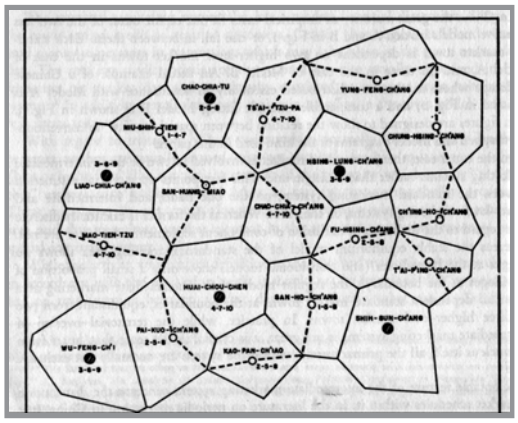
Skinner's spatial imagination

Saturday, March 27, 2010

images: presentations of Skinner's data by Center for Geographic Analysis, Harvard University, AAS 2010



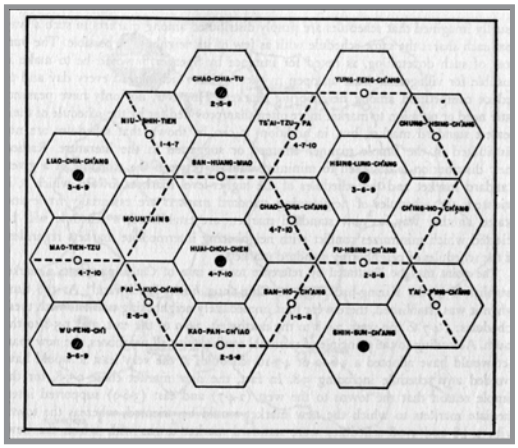
G. William Skinner was a remarkably generous scholar who inspired and assisted several generations of China specialists. (Here is a link to a remembrance of Bill.) He was prolific and fertile, and there is much to learn from rereading his work. There is quite a corpus



of unpublished work in the form of research reports and conference papers. Rereading this work is profoundly stimulating. It holds up very well as a source of ideas about social science analysis of concrete historical and social data, and there are many avenues of research that remain to be further explored.

Skinner is best known for his efforts to provide regional systems analysis of spatial patterns in China. He thought of a social-economic region as a system of flows of people, goods, and ideas. He argued for the crucial role that water transport played in knitting together the economic activities of a region in the circumstances of pre-modern transport.

Skinner's work demonstrated the great value of spatial analysis. Patterns emerge visually once we've selected the appropriate level of scope. Mapping social and economic data is tremendously insightful. He was also highly sensitive to the social and cultural consequences of these flows of activity. For example, patterns of gender ratios show a pronounced regional pattern; Skinner demonstrates the relevance of core-periphery structure to social-cultural variables such as this one.



Skinner plainly anticipated the historical GIS revolution conceptually. And this is a feature of imagination, not technology.

A classic series of articles on the spatial structure of the Chinese countryside in the 1960s provided an important basis for rethinking "village" society. They also provided a rigorous application of central place theory to the concrete specificity of China. Here are several maps drawn from these essays ("Marketing and Social Structure in Rural China." *Journal of Asian Studies* 24 (1-3), 1964-65). Here Skinner is trying out the theories of central place theory, and the theoretical prediction of economic space being structured as a system of nested hexagons with places linked by roads.

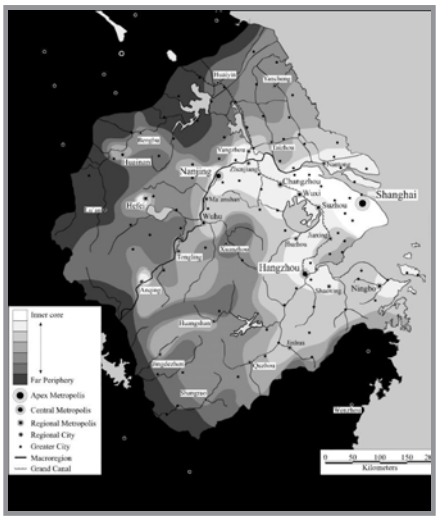
Another key contribution of Skinner's work is his analysis of China in terms of a set of eight or nine "macroregions". He argues that China was not a single national economic system, and it was not a set of separate provincial economies. Instead, it consisted of a small number of "macroregions" of trade, commerce, and population activity, linked by water transport. And macroregions were internally differentiated into core and periphery. Skinner used meticulous county-level databases to map the economic and demographic boundaries of the region. Skinner identified core and periphery in terms of population density, agricultural use, and other key variables. And he then measured a host of other variables – female literacy, for example – and showed that these vary systemically from

core to periphery. There is also an important ecological dimension to the argument; Skinner demonstrated that there is a flow of fertility from periphery to core as a result of the transfer of food and fuel from forests to urban cores. (This analysis is developed in "Regional Urbanization in Nineteenth-Century China" in *The City in Late Imperial China*, edited by G. W. Skinner, Stanford University Press, 1977.) Here are three maps developed by Skinner and his collaborators on the basis of the macroregions analysis.

Map 1. China's macroregional systems in relation to provinces, showing metropolitan cities, 1990

This is a particularly expressive map of the Lower Yangzi macroregion, differentiated into 4 levels of core and periphery. This is pretty much the full development of the macroregional analysis.

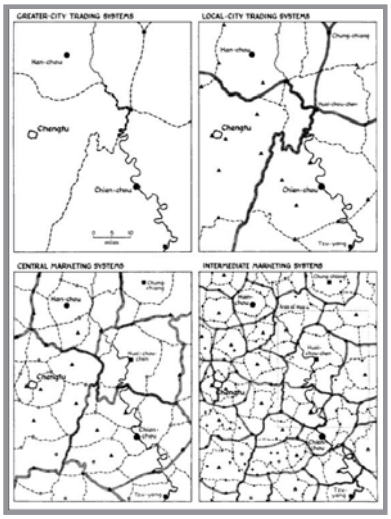
Another key idea in Skinner's work is his analysis of city systems into a spatial and functional hierarchy. He argued that it is possible to distinguish clearly between higher-level and lower-level urban places, and that there is an orderly arrangement of economic functions and marketing scope associated with the various urban places in a macroregion.



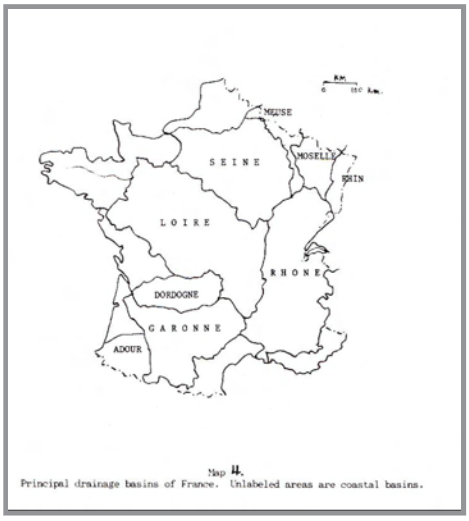
So regional analysis of China is a key contribution in Skinner's work. But Skinner did not restrict his research to China alone. He also did significant work on Japanese demography and family structure and female infanticide in the 1980s (for example, "Reproductive Strategies and the Domestic Cycle among Tokugawa Villagers," an AAS presentation in 1988).

And he brought his regional systems analysis to bear on France in an extended piece of research in the late 1980s. The maps that follow are drawn from an unpublished conference paper titled "Regional Systems and the Modernization of Agrarian Societies: France, Japan, China," dated 1991. This paper builds upon a 1988 paper titled "The Population Geography of Agrarian Societies: Regional Systems in Eurasia."

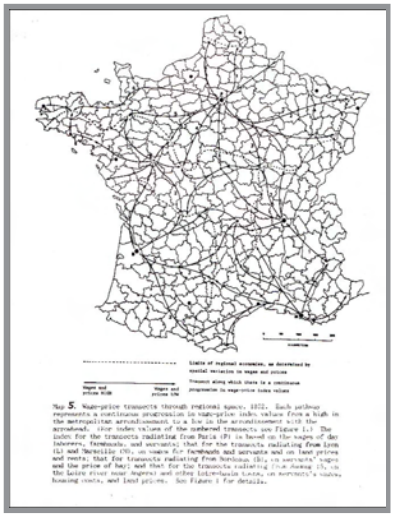
This analysis builds a view of France as a set of interrelated regions with core-periphery stucture. Through the series of working maps Skinner painstakingly constructs an empirically based analysis of the economic regions of France in mid-nineteenth century. And Skinner then asks one of his typically foundational questions: how do these geographical features play a causal role in cultural and demographic characteristics?



This map of never-married/married female ratios is one illustration of Skinner's effort to relate social, cultural, and demographic variables to the core-periphery structure of a region. The pattern of high ratio corresponds fairly well across the map of France to the

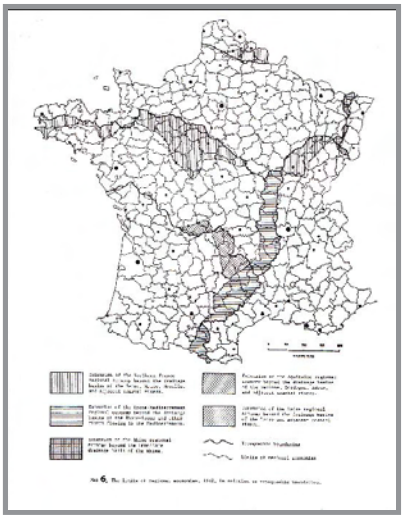


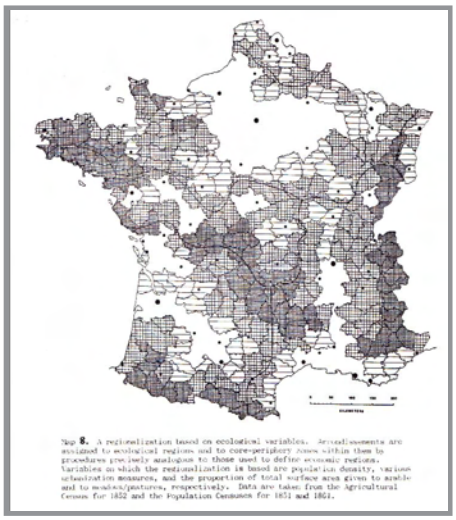
regions identified by demographic and agricultural factors. And this serves to confirm the underlying idea -- that economic regionalization has major consequences for cultural and demographic behavior.



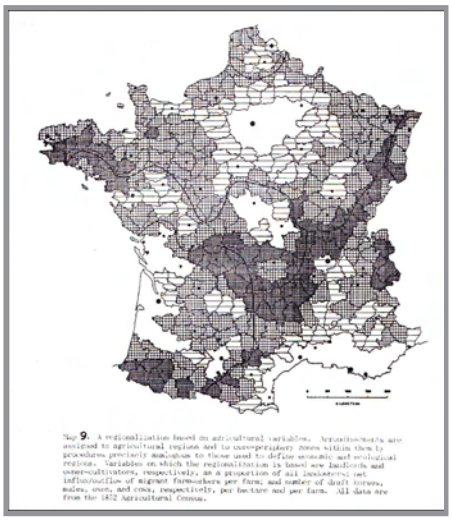
Likewise patterns of female life expectancy and net migration; here again we find the kind of regionalization of important social variables that Skinner documents in great detail in late imperial China.

Finally, Skinner also played an important role as a "macro-historian" of China. His 1985 Presidential Address to the Association for Asian Studies was a tour-de-force, bringing his macroregional analysis into a temporal framework (Skinner, G. William. 1985. Presidential Address: The Structure of Chinese History. *Journal of Asian Studies* XLIV (2):271-92). In this piece he demonstrates a "long-wave" set of patterns of economic growth and contraction in two widely separated macroregions. And he argues that we understand China's economic history better when we see these sub-national patterns. He analyzes the economic and population history of North China and Southeast Coast, two widely separated macroregions, over several centuries. And he demonstrates that the two regions display dramatically different economic trajectories over the long duree. Skinner brings Braudel to China. Here is the pattern he finds for two macroregions over a centuries-long expanse of time. And significantly, if these patterns were superimposed into a "national" pattern, it would show pretty much of a flat performance, since the two macroregions are significantly out of phase in their boom and bust cycles.

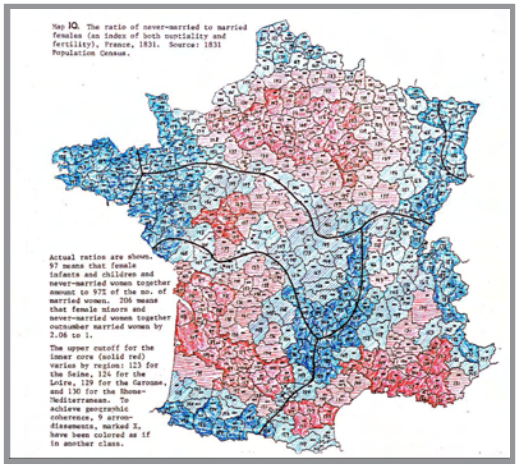




Finally, an enduring contribution that Skinner made is his cheerful disregard of discipline. Economic anthropology, regional studies, demography, urban studies, history … Skinner moved freely among all these and more. It was topics and questions, not disciplinary strictures, that guided Skinner's fertile and rigorous imagination. And area specialists and social scientists alike can fruitfully gain from continued study of his research. Fortunately, work is underway to make Skinner's unpublished research and data available to other scholars. Here are some major projects:

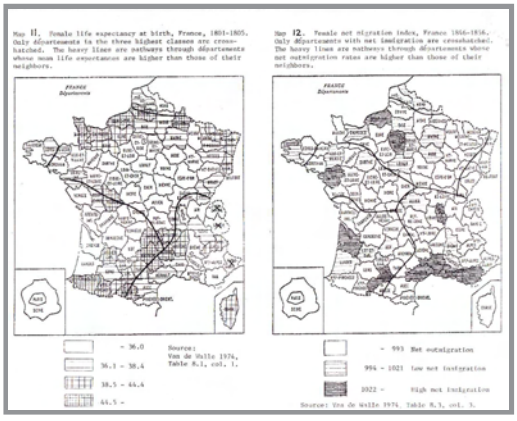


Map 5. Wage-price transects through regional space, 1852. Each pathway represents a continuous progression in wage-price index values from a high in the metropolitan arrondissement to a low in the arrondissement with the arrowhead. (For index values of the numbered transects see Figure 1.) The index for the transects radiating from Paris (P) is based on the wages of day laborers, farmhands, and servants; that for the transects radiating from Lyon (L) and Marseille (M), on wages for farmhands and servants and on land prices and rents; that for transects radiating from Bordeaux (B), on servants' wages and the price of hay; and that for the transects radiating from Nancy (N), on the Loire river near Angers and other intermediate areas, on servants's wages, housing rents, and land prices. See Figure 1 for details.



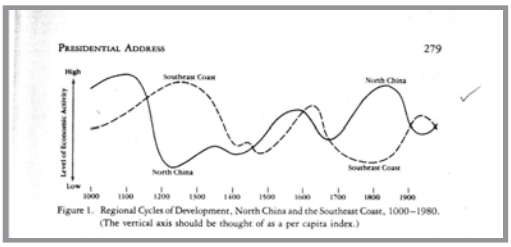
Map 6. The Limits of regional economies, 1852, in relation to topographic boundaries.

Map 8. A regionalization based on ecological variables. Arrondissements are assigned to ecological regions and to core-periphery zones within them by procedures precisely analogous to those used to define economic regions. Variables on which the regionalization is based are population density, various urbanization measures, and the proportion of total surface area given to arable and to meadow/pastures, respectively. Data are taken from the Agricultural Census for 1852 and the Population Censuses for 1851 and 1861.



Map 9. A regionalization based on agricultural variables. Arrondissements are assigned to agricultural regions and to core-periphery zones within them by procedures precisely analogous to those used to define economic and ecological regions. Variables on which the regionalization is based are landlords and owner-cultivators, respectively, as a proportion of all inhabitants; net influx/outflux of migrant farmworkers per farm; and number of draft horses, mules, oxen, and cows, respectively, per hectare and per farm. All data are from the 1852 Agricultural Census.

Map 10. The ratio of never-married to married females (an index of both nuptiality and fertility), France, 1831. Source: 1831 Population Census.



Actual ratios are shown. 97 means that female infants and children and never-married women together amount to 975 of the no. of married women. 206 means that female minors and never-married women together outnumber married women by 2.06 to 1.

The upper cutoff for the inner core (solid red) varies by region: 123 for the Seine, 124 for the Loire, 129 for the Garonne, and 130 for the Rhone-Mediterranean. To achieve geographic coherence, 9 arrondissements, marked X, have been colored as if in another class.

Map 11. Female life expectancy at birth, France, 1801-1805. Only départements in the three highest classes are cross-hatched. The heavy lines are outlines through départements whose mean life expectancies are higher than those of their neighbors.

Map 12. Female net migration index, France 1866-1936. Only départements with net immigration are cross-hatched. The heavy lines are outlines through départements where net outmigration rates are higher than those of their neighbors.

- Data and maps are being curated and presented at Harvard. Here is a beta site and here is the platform the China GIS team is using at AfricaMap.
- The Skinner Archive at Harvard (link)
- Skinner's unpublished papers and research materials are being digitized and presented at the University of Washington. Here is a link.
- The China Historical GPS project at Fudan University is presenting an ambitious digital mapping collection as well (link).

Contentious politics in China

Sunday, March 28, 2010

By official count, the incidence of popular protest in China has increased ten-fold in the past fifteen years. Kevin O'Brien and Rachel Stern report that the Chinese state reported 8,700 "collective incidents" in 1993, and this number had grown to 87,000 by 2005 (12). And the issues that have evoked protest have expanded as well: land seizures, egregious local corruption, lay-offs and labor mistreatment, ecological and environmental concerns, and the Sichuan earthquake and building collapses, for example. (The photo above is drawn from a 2008 story on factory protests in Dongguan in the *Telegraph* (link).) A recent volume by O'Brien and Stern, Popular Protest in China, is a collection of some of the best current work by China scholars on popular protest in contemporary China. Contributors include some of the researchers who are doing the most detailed work on this topic today, including William Hurst (The Chinese Worker after Socialism), Kevin O'Brien (Rightful Resistance in Rural China), Guobin Yang (The Power of the Internet in China: Citizen Activism Online), and Yongshun Cai (Collective Resistance in China: Why Popular Protests Succeed or Fail). So the volume offers an excellent perspective on the state of the field.

(It is mildly ironic to note that the conference on which the volume is based was held in 2006 -- several years ***before*** the global financial collapse that threw millions of Chinese workers out of work. The incidence and severity of factory protests has certainly increased in the intervening years.)
Sidney Tarrow frames the volume by observing that there has been a welcome recent convergence between China studies and the field of contentious politics. The contributors to the volume have made productive use of some of the core concepts of the theories of

contentious politics that have been developed in the past two decades -- resource mobilization, political opportunity, issue framing, social networks, issue escalation, etc., that have proven so productive in the analysis of a range of instances of contention and collective action. And Tarrow poses a comparativist's challenge: to what extent is it possible to discern similar processes of mobilization and escalation in the China case? Further, Tarrow points out that much of the theorizing about contentious politics has taken place in the context of more democratic regimes; so how much of a difference does the fact of China's authoritarian political system make for the occurrence and character of social contention?

One of the important insights offered by several of the contributors is the importance of disaggregating structures like "political opportunity," "actor," and "issue." O'Brien and Stern put it this way in their introduction:

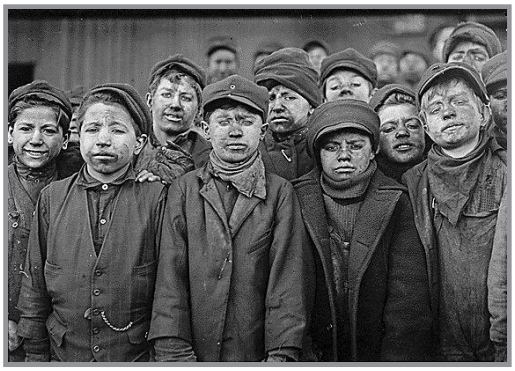
The essays in this volume show that political opportunity in China depends (at a minimum) on the identity of the participants, the region, the grievance at hand, and the level of government engaged. (14)

The Chinese state is not a "monolith" but a "hodge-podge of disparate actors," an "attractive, multidimensional target." (14, quoting O'Brien and Li, Rightful Resistance in Rural China)

And, of course, we have to recognize the widely different circumstances facing potential contentious actors in different regions and segments of the country. The point is an important one: we should not look to the intellectual framework of contentious politics research as a set of conceptual recipes for deductively explaining contention. Rather, we are better off looking at the literature on contentious action as a toolbox of "mechanisms and processes" that recur across contexts and that aggregate differently in different circumstances. (This is, of course, the methodology that Tarrow, McAdam, and Tilly advocate in Dynamics of Contention.)

Each chapter focuses, by and large, on a different thread within the current literature on contentious politics: framing (William Hurst), trust (Teresa Wright), transnational actors (Patricia Thornton), leadership (Feng Chen), networks (Yanfei Sun and Dingxin Zhao), repression (Yongshun Cai), communication (Guobin Yang), and opportunity (Yanfei Sun and Dingxin Zhao). As such, the volume also serves as something like a tutorial on current theories of contentious politics.

Liz Perry's concluding essay frames the argument around "rebellion" (protest against particular officials) versus "revolution" (protest against principles and structures of government). And she is inclined to think that the rise in protest in China today falls in the former category -- mostly harmless from the point of view of the power and structure of the regime.



Despite its remarkable frequency, then, contention in contemporary China remains limited in size, scale, and scope. With few exceptions, the social composition, territorial reach, and endurance of individual protests have all been highly circumscribed. (206)

But I'm inclined to think that this misses one of the most important implications of the contentious politics literature, and the import of its most important case. Small-scale mobilization and protest can escalate to fundamental and widespread demands for justice. And a broad movement can emerge that is not **revolutionary** -- devoted to the overthrow of the state -- and yet is persistently **transformative**: dedicated to the long, slow transformation of society and state in the direction of equality and dignity for all members of society. The great historical example of this -- the example that motivated some of the best work in the literature of contentious politics -- is the American civil rights movement. This movement demanded a fundamental change of law and of culture, and it succeeded. And we might say that this is what ordinary people in China today demand and deserve. The demand for voice and legal protections of lawful activities that swims

throughout the more specific claims currently being made has the potential of becoming a very widespread movement.
(There are a number of earlier posts on these issues, collected under the tag CAT_collective action.)

Public health estimates in Marx's Capital

Friday, April 02, 2010

Long stretches of Marx's *Capital* take the form of an effort at developing and defending an economic model of capitalism, based on the theories of value and surplus value. But there are also recurring efforts at providing a descriptive ***sociology*** of capitalism: the forms of day-to-day life that British economic relations imposed upon the working class. This dimension of the book is descriptive and detailed; it has much in common with Engels's approach in The Condition of the Working Class in England.

Marx was very interested in these descriptive investigations -- Dr. Simon, Dr. Julian Hunter, Mr. Smith, Dr. Bell, and the inquiries and Acts of Parliament in the 1860s that shed light on the depth of English poverty. The index for *Capital* includes a section, "Parliamentary Reports and Other Official Publications," which includes references to over a hundred reports on factories, poverty, nutrition, and health. These range from a Report of Select Committee, London, 1855, on "Adulteration of Bread", to "Reports of the Medical Officer of the Privy Council on Public Health" (1861-66). And these reports constitute the core of empirical evidence that Marx brings to bear for his economic assertions throughout the work. In fact, we might describe some parts of *Capital* as a sort of "meta-study" of current investigations of the public health status of England's cities.

This interest is particularly evident late in *Capital* where Marx turns to the topic of "The General Law of Capitalist Accumulation." Consider one fairly detailed section, "The Badly Paid Strata of the British Industrial Class" (link). Here Marx is offering the best information available, at the household level, concerning the standard of living of this stratum of the British working class. Consider this passage:

During the cotton famine of 1862, Dr. Smith was charged by the Privy Council with an inquiry into the conditions of nourishment of the distressed operatives in Lancashire and Cheshire. His observations during many preceding years had led him to the conclusion that “to avert starvation diseases,” the daily food of an average woman ought to contain at least 3,900 grains of carbon with 180 grains of nitrogen; the daily food of an average man, at least 4,300 grains of carbon with 200 grains of nitrogen; for women, about the same quantity of nutritive elements as are contained in 2 lbs. of good wheaten bread, for men 1/9 more; for the weekly average of adult men and women, at least 28,600 grains of carbon and 1,330 grains of nitrogen. His calculation was practically confirmed in a surprising manner by its agreement with the miserable quantity of nourishment to which want had forced down the consumption of the cotton operatives. This was, in December, 1862, 29,211 grains of carbon, and 1,295 grains of nitrogen weekly.

Marx then quotes a Privy Council inquiry in 1863, which finds that

"in only one of the examined classes of in-door operatives did the average nitrogen-supply just exceed, while in another it nearly reached, the estimated standard of bare sufficiency [i.e., sufficient to avert starvation diseases], and that in two classes there was defect — in one, a very large defect — of both nitrogen and carbon. Moreover, as regards the examined families of the agricultural population, it appeared that more than a fifth were with less than the estimated sufficiency of carbonaceous food, that more than one-third were with less than the estimated sufficiency of nitrogenous food, and that in three counties (Berkshire, Oxfordshire, and Somersetshire), insufficiency of nitrogenous food was the average local diet."

In other words, the Privy Council finds that important segments of the English working class were undernourished by the prevailing scientific standard of the day. This official report is fundamentally damning of the current economic system; it led to conditions of near-starvation for its workers.

Marx goes on to describe other components of the standard of living -- housing, crowding, sanitation, and clothing, for which the working class are seriously deprived. And in each case he believes that independent, disinterested observers have documented the conditions of misery in which the working class lived in England in the 1860s.

Consider another interesting example, Marx's use of the Select Committee's report on the adulteration of bread. This occurs in an extended footnote in Chapter VI, "The Buying and Selling of Labour-Power."

In London there are two sorts of bakers, the "full priced," who sell bread at its full value, and the "undersellers," who sell it under its value. The latter class comprises more than three-fourths of the total number of bakers.... The undersellers, almost without exception, sell bread adulterated with alum, soap, pearl ashes, chalk, Derbyshire stonedust, and such like agreeable nourishing and wholesome ingredients. (note 3)

Marx goes on to describe in a little bit of detail the specific timing of the payment of wages, demonstrating the economic coercion that leads workers to agree to buy this adulterated bread.

Or we might notice that Marx's index refers to a series of Parliamentary reports on child labor, and then consider the use that Marx makes of these reports. Here is one example of his use of the child labor reports in the chapter on "The Working-Day":

The potteries of Staffordshire have, during the last 22 years, been the subject of three parliamentary inquiries.... For my purpose it is enough to take, from the reports of 1860 and 1863, some depositions of the exploited children themselves. ... William Wood, 9 years old, was 7 years and 10 months when he began to work. He "ran moulds" (carried ready-moulded articles into the drying-room, afterwards bringing back the empty mould) from the beginning. He came to work every day in the week at 6 a.m., and left off about 9 p.m. "I work till 9 o'clock at night six days in the week." (*Capital I*, chap 7, sect. 3)

What is of special interest in these passages is the way that Marx's mind seems to have worked on these questions. He was genuinely interested, it would seem, in the concrete details of the conditions of the English working class; and he was fortunate that there was something of an explosion of official and non-official interest in the same set of questions, including especially Parliamentary Blue Books. These inquiries fall in the category of what we would today call the field of public health, and Marx was plainly an avid reader of the reports that resulted from these investigations.

It is not accident that brings Marx's detailed discussion of the nutritional status of the industrial poor into Part VII of *Capital*, "Accumulation." It is Marx's view that the production of surplus value, and the accumulation of wealth that it enables, is directly

related to the production of the poverty of the worker. So the circumstances that Marx describes in this section do not constitute simply an unfortunate current reality; they are the apotheosis of a system of production that was working well.

Norbert Elias on the individual

Sunday, April 04, 2010

Norbert Elias opens his 1987 book The Society of Individuals with these words:

The relation of the plurality of people to the single person we call the "individual", and of the single person to the plurality, is by no means clear at present. But we often fail to realize that it is not clear, and still less why. We have the familiar concepts "individual" and "society", the first of which refers to the single human being as if he or she were an entity existing in complete isolation, while the second usually oscillates between two opposed but equally misleading ideas. Society is understood either as a mere accumulation, an additive and unstructured collection of many individual people, or as an object existing beyond individuals and incapable of further explanation. In this latter case the words available to us, the concepts which decisively influence the thought and action of people growing up within their sphere, make it appear as if the single human being, labelled the individual, and the plurality of people conceived as society, were two ontologically different entities.
This Preface was written around the time of the publication of the volume in 1987; but the core of the book was originally written in the context of the composition of Elias's 1939 book, The Civilizing Process: Sociogenetic and Psychogenetic Investigations. So the ideas expressed in the primary essay of the book belong to the classic period of the development of his thought.

What is striking about this paragraph is Elias's insistence, essentially, that we don't know what we are referring to when we use the terms "individual" and "society." He rejects the twin views of "individualism" and "holism", and he wants to arrive at a conception of "individual/society" that avoids the polarity between the two.

I interpret Elias's analysis here in a way that roughly parallels the intuition I was grappling with in formulating the idea of "methodological localism" (link). Fundamentally, the idea is that we can't take the individual out of society or society out of the individual; instead, we begin with the socialized individual and build up more complex social processes and structures. Here is a passage from the Preface that anticipates this idea of the socially constructed individual:

The entire stock of social patterns of self-regulation which the individual has to develop within himself or herself in growing up into a unique individual, is generation-specific and thus, in the broader sense, society-specific. My work on the civilizing process therefore showed me very clearly that something which did not arouse shame in an earlier century could be shameful in a later one, and vice versa - I was well aware that movements in the opposite direction were also possible. But no matter what the direction, the evidence of

change made clear to what extent individual people are influenced in their development by the position at which they enter the flow of the social process. (viii)
So individuals are socially and historically constructed; there is no such thing as the "pre-social" or "extra-social" individual. Here is another statement of this point:

At birth individual people may be very different through their natural constitutions. But it is only in society that the small child with its malleable and relatively undifferentiated mental functions is turned into a more complex being. Only in relation to other human beings does the wild, helpless creature which comes into the world become the psychologically developed person with the character of an individual and deserving the name of an adult human being. (21)
But there are also dynamic and individuating features of societies; societies are distinct in ways that ultimately derive from the characteristics of existing individuals:

Society, as we know, is all of us; it is a lot of people together. But a lot of people together in India and China form a different kind of society than in America or Britain; the society formed by many individual people in Europe in the twelfth century was different from that in the sixteenth or the twentieth century. And although all these societies certainly consisted and consist of nothing other than many individuals, the change from one form of living together to another was clearly unplanned by any of these individuals. (3)

What we lack - let us freely admit it - are conceptual models and an overall vision by which we can make comprehensible in thought what we experience daily in reality, by which we could understand how a large number of individuals form with each other something that is more and other than a collection of separate individuals - how they form a "society", and how it comes about that this society can change in specific ways, that it has a history which takes a course which has not been intended or planned by any of the individuals making it up. (7)
And here is how Elias suggests that we commonly think about social reality:

One section of people approaches sociohistorical formations as if they had been designed, planned and created, as they now stand before the retrospective observer, by a number of individuals or bodies. ... The opposing camp despises this way of approaching historical and social formations. For them the individual plays no part at all. ... A society is conceived, for example, as a supra-individual organic entity which advances ineluctably towards death through stages of youth, maturity and age. (4-5)
It appears that Elias frames a false dichotomy here when he asks how society came about: **either** specific individuals planned and intended that social institutions should have specific functions, **or** a society is a whole that possesses its own dynamics of development. But there is a third possibility: social institutions have their current characteristics because of the actions and choices of countless individuals; but these characteristics are largely the **unintended** consequence of the strategic interactions among many individuals. So individual agency lies behind social institutions and structures; but these agents are usually operating within the framework of a limited set of goals and beliefs that have nothing to do with the eventual shape of the social institution.

So we need to follow Elias's suggestion and look for new metaphors for understanding the relation between "society" and "individual." We need metaphors that work better for the third option -- society as the unintended assemblage of many strategic activities of individuals. Here is one: we might think of a social institution as a potlach supper rather than a seven-course meal designed by a chef. Or, to use a metaphor explored in an earlier posting, we can understand society along the lines of a flea market: a somewhat

orderly affair that derives from the separate and sometimes coordinated actions of hundreds of participants (link). And in fact, Elias actually uses a similar metaphor:

> And even in each present moment, people are in more or less perceptible motion. What binds the individuals together is not cement. Think only of the bustle in the streets of a large city: most of the people do not know each other. They have hardly anything to do with each other. They push past each other, each pursuing his or her own goals and plans. They come and go as it suits them. Parts of a whole? The word "whole" is certainly out of place, at least if its meaning is determined solely by a vision of static or spatially closed structures, by experiences like those offered by houses, works of art or organisms. (13)

Here is another interesting metaphor that Elias explores as a way of capturing "the social" -- the complex intertwining of behavior in formal dance.

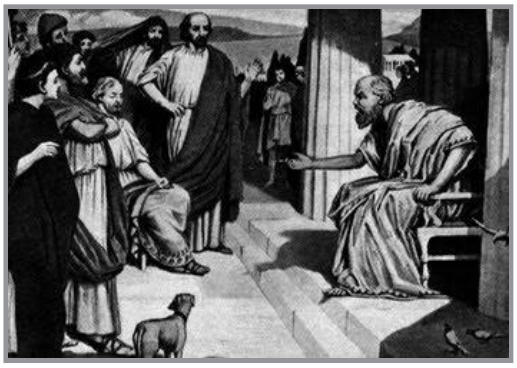
> Let us imagine as a symbol of society a group of dancers performing court dances, such as the frangaise or quadrille, or a country round dance. The steps and bows, gestures and movements made by the individual dancer are all entirely meshed and synchronized with those of other dancers. If any of the dancing individuals were contemplated in isolation, the functions of his or her movements could not be understood. The way the individual behaves in this situation is determined by the relations of the dancers to each other. (19)

But within the bustle of the street or the coordination of the dance there is an underlying order (just as we found in thinking about the flea market analogy):

> The invisible order of this form of living together, that cannot be directly perceived, offers the individual a more or less restricted range of possible functions and modes of behaviour. By his birth he is inserted into a functional complex with a quite definite structure; he must conform to it, shape himself in accordance with it and perhaps develop further on its basis. (14)

And this order poses a problem for individualism:

> This network of functions within a human association, this invisible order into which individual purposes are constantly being introduced, does not owe its origin simply to a summation of wills, a common decision by many individual people. (15)



But here the false dichotomy mentioned above is important. It doesn't take an announced master plan to create a peasant militia or an age-specific practice of dating and courtship; rather, a series of opportunistic choices are made over time, by a number of different actors, leading to an institution that has characteristics that were intended by no one (see illustrations in Elizabeth Perry, Rebels and Revolutionaries in North China, 1845-1945).

This is an interesting and important contribution to the philosophy of society. I'm inclined to think, though, that Elias does a better job of situating the "socialized, civilized individual" than he does in conceptualizing the social institution or structure. There is a persistent structural-functionalism in the language, and a persistent attempt to attribute intentional design to social institutions, that fail to deliver on the promise of arriving at a better way of understanding both aspects of the "individual-society" relationship.

Teaching philosophy

Tuesday, April 06, 2010

What is it that we expect students to learn when we teach philosophy? Is philosophy an arcane and charmingly useless vestige of a nineteenth-century university education? Or does it have something crucial to add to the liberal education of the twenty-first century -- whether in the arts and sciences or in pre-professional schools?

Philosophers would probably answer this question in a wide variety of ways. In my own case, I have several high-level goals in mind when I approach a new group of undergraduate students in philosophy. I hope to help them to develop in several ways:

- to gain a set of intellectual skills: analysis, reasoning, clarity of thinking and exposition, open-mindedness and a readiness to try to see a problem from multiple points of view
- to learn some of the developed approaches to "philosophical" problems: knowledge, ethical behavior, individual rights, social justice, the authority of the state, the nature of rationality, the meaning of human life
- to gain an engaged involvement in some great thinkers and their theories and reasoning in detail
- to gain some meaningful acquaintance with some important philosophical theories (utilitarianism, empiricism, mind-body materialism, ordinary language philosophy ...)
- to gain an ability to see the connections between philosophical reasoning and real human problems -- scientific knowledge, addressing poverty or racism, resolving conflicts of value or conflicts of interest or desire, ...

Most of these goals have to do with developing intellectual capacity -- imagination,

reasoning, analytical ability, critical capacity to probe behind ordinary assumptions -- more than gaining specific bits of knowledge about the history of philosophy. Students are exposed to pieces of philosophical traditions that result in exam questions such as these: What was Anselm's ontological argument? What was Russell's paradox? What were the higher pleasures according to J. S. Mill? But the real learning goal isn't that the student should have the ability to draft a short Wikipedia entry on one of these topics. Rather, the goal is that he/she has enough of a set of analytical and critical skills so that she can pick up a philosophical problem; explore and develop the problem with insight and imagination; consider a variety of ways of addressing the problem; and put forward a philosophical argument that attempts to resolve the problem. The student needs to learn how to **think** -- philosophically, imaginatively, and critically.

It is true, of course, that being able to formulate and resolve a philosophical problem requires a degree of acquaintance with the systems and theories that previous generations of philosophers have brought to bear on the problems they raise. So it is important to have grappled seriously with Anselm, Russell, or Mill. And this means taking seriously the positions these philosophers and others advanced and the intellectual frameworks within which they reasoned. So a degree of knowledge of some of the fields and traditions of philosophy is an important intellectual attainment for a philosophy student. But the goal of pursuing this knowledge is not so that the student can become a mini-expert on Anselm or Russell; rather, the goal is to broaden the set of intellectual frameworks and reference points on the basis of which the student's philosophical imagination can address new problems.

This approach addresses one of the large dichotomies that we have to face in designing a university curriculum: the split between "intellectual skills and capacities" and "mastery of content". My position puts primary emphasis on the former over the latter. One might ask, in good philosophical fashion, why we might want to make this choice? My own reason has to do with the highest goal I think universities ought to pursue: to help their students to gain a rich range of skills, tools, and intellectual resources on the basis of which they can address the widest range of problems they will face in their civic and professional lives. When a philosophy student graduates, attends law school or business school, and enters the world of professional activity, he/she may not be able to reproduce specific arguments from the course she took in epistemology or the philosophy of science. But what we hope is that the challenge of working with those arguments as an undergraduate, challenging and dissecting the assumptions the philosopher made, and considering alternative solutions to the problem, will have given him/her a broad intellectual range and acuity, and a flexible and imaginative ability to think through a set of issues. And, we would hope, these skills are highly transportable, from the context of philosophy to the practical intellectual challenges of being a good doctor, lawyer, or engineer. Ultimately the intellectual capacities of imagination, analytical ability, critical insight, and intellectual rigor are the best and most enduring attainments of a good liberal education.

This goal has to do with intellectual capacity and imagination. But we have another and equally important goal as well in designing a university education or a philosophy course. This is the goal of helping our students become engaged and morally motivated members of the organizations and communities to which they belong. We would hope that our students have cultivated an ability to think independently and seriously about the issues of social justice and personal conduct that arise in the society that they are helping to constitute; and we would hope that they have acquired some of the components of personal seriousness that lead them to act with conviction on the basis of their moral

ideas. The transition from narcissism to engagement is not an automatic or inevitable one, and a suitable learning environment in the university can have a large impact on this process of personal development. So my hope in my own philosophy classroom is that students will have an opportunity to explore and challenge their own moral ideas; to come to see how the contemporary world measures up with respect to those ideas; and to see that their own engagement in issues of community, justice, and social progress can make a meaningful difference in the state of their world.

Some of this process of critical self discovery can happen in the classroom. But some of it is best stimulated by the other activities that can help students get engaged in the important social issues of their day -- poverty alleviation, literacy, racial disparities, etc. Involvement in organizations such as Habitat for Humanity or Amnesty International can give students a genuine understanding of the needs their world presents to them, and the difference that their engagement can make. And the teamwork that unavoidably accompanies all these activities gives a concrete illustration to the student of the value of collaboration.

This line of thought converges with one of the common refrains of current thinking about pedagogy: the idea of the student as an "active learner." As Socrates and Habermas illustrate in the images above, a very large part of teaching philosophy is the challenge of getting the student to think for himself/herself. The student needs to take on the intellectual challenge as a serious one; and he/she needs to expend the real mental effort required to understand and deal with the problem. This can't be distilled into an artful lecture by the professor; rather, it seems to require dialogue and intellectual exchange. The student needs to be engaged in the debate; and he or she needs to be brought to see the stakes of the issue. (In spite of the vast lecture hall that Michael Sandel confronts in the third image above, he too is capable of engaging and challenging the students in his classroom. Here is a video of a lecture from his Harvard course on justice.)

Trust networks

Friday, April 09, 2010

Chuck Tilly had a fascination with the mechanisms of social interaction at all levels. His 2005 book, Trust and Rule, picks up on one particular feature of social organization that is often instrumental in political and social episodes, including especially in the everyday workings of predation and defense. This is the idea of a *trust network*: a group of people connected by similar ties and interests whose "collective enterprise is at risk to the malfeasance, mistakes, and failures of individual members" (chapter 1, kindle loc 186). Here is a definition:

Trust networks, then, consist of ramified interpersonal connections, consisting mainly of strong ties, within which people set valued, consequential, long-term resources and

enterprises at risk to the malfeasance, mistakes, or failures of others. (chapter 1, kindle loc 336)

A band of pirates, a group of tax resisters, or a village of non-conformists in a period of religious persecution fall in the category of trust networks. The stakes are high for all participants. On the other hand, the American Medical Association, the League of Women Voters, and the pickpockets who work the Gare St Lazare train station do not represent trust networks, though they have the properties of social action networks more generally. There is little real risk for any particular physician even if other members of the AMA don't play their parts in a lobbying campaign. The willingness of members of the extended group to commit their own actions to a risky common effort depends on their level of trust in other members -- trust that they will make their own contributions to the collective enterprise, and trust that they will not betray their comrades. (French historian Marc Bloch belonged to a trust network, the French Resistance, that led to his death in 1944 by the Gestapo; link.)

The general idea is that there are numerous examples of networks of people who share substantial interests in common, and who have a high level of trust in one another that permits them to undertake risky joint activities. Here is a more complete statement of Tilly's conception:

How will we recognize a trust network when we encounter or enter one? First, we will notice a number of people who are connected, directly or indirectly, by similar ties; they form a network. Second, we will see that the sheer existence of such a tie gives one member significant claims on the attention or aid of another; the network consists of strong ties. Third, we will discover that members of the network are collectively carrying on major long-term enterprises such as procreation, long-distance trade, workers' mutual aid or practice of an underground religion. Finally, we will learn that the configuration of ties within the network sets the collective enterprise at risk to the malfeasance, mistakes, and failures of individual members. (chapter 1, kindle loc 186)

Trust networks are particularly relevant in the context of efforts at violent extraction and domination -- both on the side of predators and prey. Predators -- bandits, pirates, and gangs -- need to establish strong ties within their organizations in order to be able to effectively coerce their targets and to escape repression by others. And prey -- farmers in ranch country, rural Jews in Poland, or home owners in central Newark -- are advantaged by the existence of strong ties of family, religion, or ethnicity through which they can maintain the collective strategies that provide some degree of protection. But Tilly makes the interesting point that the workings of trust networks cross over both contentious and noncontentious activities. Here is a general statement that frames much of Tilly's discussion in the book:

Noncontentious politics still make up the bulk of all political interaction, since it includes tax collection, census taking, military service, diffusion of political information, processing of government-mediated benefits, internal organizational activity of constituted political actors, and related processes that go on most of the time without discontinous, public, collective claim making. Trust networks and their segments get involved in noncontentious politics more regularly -- and usually more consequently -- than in contentious politics. (chapter 1, Kindle loc 208)

The idea of a trust network represents a different way of getting a handle on the contrast between self-interested agency and group-oriented agency, which in turn corresponds to "economistic" and "sociological" approaches to social behavior. Is it ***interests*** or ***norms*** that guide social behavior? By introducing the idea of a trust network, Tilly is able to find a position someplace else on the spectrum -- neither purely self-interested behavior nor

routine normative conformance. Instead, agents within trust networks behave as purposive, goal-directed actors; but they have commitments and resources that people in other social settings lack, and they are thereby enabled to achieve forms of collective action that are impossible elsewhere. We might say that Tilly is offering an account of the microfoundations of collective action, or of a certain kind of collective action.

In line with Tilly's lifelong interest in taxation and state-building, the idea of resource extraction plays a central role in his analysis of trust networks. A central theme is the struggle between the tax-collecting state and the elusive, tax-evading trust networks that exist in civil society. "Rulers have usually coveted the resources embedded in such networks, have often treated them as obstacles to effective rule, yet have never succeeded in annihilating them and have usually worked out accommodations producing enough resources and compliance to sustain their regimes" (kindle loc 229).

It is interesting to connect this dialectic of predation and evasion with the arguments Jim Scott puts forward in The Art of Not Being Governed: An Anarchist History of Upland Southeast Asia (link). Part of the effectiveness of the highland peoples of Burma in Scott's account is the density of their social relationships and a consequent ability to sustain a degree of collective resistance that would be impossible in a less dense society. And, in fact, Tilly's analysis of the tactical situation of a trust network subject to the superior coercive power of some other entity is enlightening in Scott's story as well. Consider these avenues that Tilly advances as collective strategies for protecting a given trust network against the pressures of the surrounding state: concealment, dissimulation, clientage, predation, enlistment into the regime, bargaining, and dissolution (chapter 2, kindle loc 794). We can find examples of each of these strategies in Scott's analysis of Burma. More pointedly, we can see instances of almost all these strategies in the current conflicts between the Burmese junta and the cease-fire groups such as the Kachin Independence Organization (link, link).

So what kind of analysis is Tilly offering here? What is the use of this concept from the point of view of the social sciences, beyond the metaphor and analytical specifics? Are there concrete historical or sociological hypotheses in play? Does this concept provide a better basis for explaining some puzzling outcomes than existing theories? Or, possibly, is the concept of a trust network another example of a part of the sociologist's toolkit: an ideal-typical description of a real social mechanism whose workings can be discerned in a variety of contexts?

Tilly is relatively explicit about several of these questions. To start: he does not believe that "trust networks" constitute a homogeneous social kind. We cannot offer a general account of the essential features of a trust network (kindle loc 823). We can do a certain amount of classification within the group of social configurations that we call "trust networks". So "trust networks" are socially real, and we can use ordinary methods of social and historical inquiry to map out some of their properties.

Further, he believes, we can state some mid-level regularities about trust networks and political regimes: for example,

- Trust networks survive and hold off predators when they generate enough resources to reproduce themselves;
- trust networks are absorbed into systems of rule when existing autonomous trust networks disintegrate or cease to provide substantial benefits;
- variations in the kinds of trust networks that exist help explain the variety of the consolidation of rule that occurs in given settings. (loc 1096)

- trust networks that mark, maintain, and monitor sharp boundaries between insiders and outsiders generally operate more effectively than others (loc 1238)
- trust networks most commonly defend themselves from predation by adopting some combination of the strategies of concealment, clientage, and dissimulation (loc 1724)

Another important question is the role of evidence in this treatment. Tilly offers dozens of examples of significant historical instances of trust networks at work -- as predators, as prey, and as potential subjects of extractive rule. And we can ask this question: what is the evidentiary value of the examples? Are they merely illustrative? Do they serve to pinpoint some of the specifics of discrete social mechanisms? Or are they more like suggestive heuristic cases that may point us in the direction of a more developed theory?

I think that Tilly's view would be something close to the second option here: the examples are valuable and insightful because they provide relatively transparent instances in which the mechanisms are fully exposed. They are a bit like the observations of "animalcules" through van Leeuwenhoek's microscope: glimpses of an underlying mechanism that proves to be an important constituent of more macro-level processes.

At the same time, the analysis doesn't add up to a "theory" of trust networks; it is more analogous to descriptive ecology than it is to the theory of the gene. When Darwin documents the variety of finches in the Galapagos Islands, or when Wallace painstakingly describes the myriad distinct species of beetles he finds in the jungles of the Malay archipelago, each is involved in a kind of scientific work that stands between pure description and explanatory theorizing. And this seems to be roughly where Tilly's dissection of trust networks falls as well.

It is also interesting to consider whether there are important examples of trust networks in the world today. And it seems clear that there are. The situation of the ethnic movements in contemporary Burma is one good example. Domestic terror groups and right-wing militias provide another clear set of examples. The American Civil Rights movement, the Freedom Riders, and SNCC's organizing efforts offer another good set of examples as well (link). So the concept of a trust network is in fact a valuable contribution to the study of collective action and social mobilization.

Marx on Russia

Wednesday, April 14, 2010

In 1881 Marx wrote a letter to Vera Zasulich, an important Russian follower, that addresses the question of theory and prediction when it comes to thinking about the future course of history. In particular, he denies that his theories have determinate predictive implications for the development of capitalism or socialism in Russia. Here is a link to the letter, and below are a few paragraphs.

The issue is an important one: did Marx think of his body of knowledge as constituting a general predictive theory? And the letter clearly implies that he did not.

The letter is interesting in several respects. First, it explicitly rejects the notion that Marx's economic and historical theories are suited to the task of identifying the necessary or inevitable course of historical development. It summarily dismisses the idea of a necessary sequence of modes of production. Instead, Marx shows himself to recognize the contingency that exists in historical development, as well as the degree to which history creates new conditions in its course that influence future developments.

The other important feature of the letter is its substantive analysis of the material characteristics of the Russian peasant commune, and the potential that this social form has for constituting the material core of an alternative route to socialism in Russia. As the letter makes clear, Marx thinks that the social relations associated with the peasant commune provide a possible social foundation for a modern socialist economy; and this would be an economy that was not "post-capitalist" but nonetheless technologically and socially advanced.

In a way Marx's argument anticipates the theory of "late developers" -- for example, Gerschenkron's Economic Backwardness in Historical Perspective. Marx argues that a socialism in Russia was possible through an alternative pathway. A version of socialism in Russia based on the "archaic" commune can take advantage of the developments in technology and social organization created by advanced capitalism. It is not necessary for Russian society to go throughout the several-centuries long process of agricultural and technological modernization that England underwent; rather, Russia can simply adopt the modern technologies now available.

The interest of this letter is not to be found in the historical predictions it makes, but rather in the example it offers of the way that Marx's mind worked. The reasoning here represents a good example of Marx's materialist approach to history. He wants to arrive at a fairly detailed level of understanding of the social and economic relations -- the property relations -- that constituted a historical form of the rural commune. And he then seeks to provide an analysis of the way in which those relations might be expected to develop under a specific set of historical circumstances. And key within this analysis is the workings of the specific form of property that corresponded to this social system -- the social relations of production.

I suppose the letter illustrates something else as well: Marx's interest at the end of his life in finding an alternative pathway to socialism. The revolutions of 1848 were long in the past, and a proletarian revolution had not ensued. The Paris Commune had been decisively and violently repressed in 1871. Working-class militancy was not propitious in the advanced capitalist countries -- France, Germany, or Britain. So the prospects of revolution in the advanced capitalist world were not encouraging to Marx. And so finding some hope for an alternative process of social development through which the ends of socialism might be achieved was an appealing prospect for Marx.

Here are the first few paragraphs of the letter, which is worth reading in full:

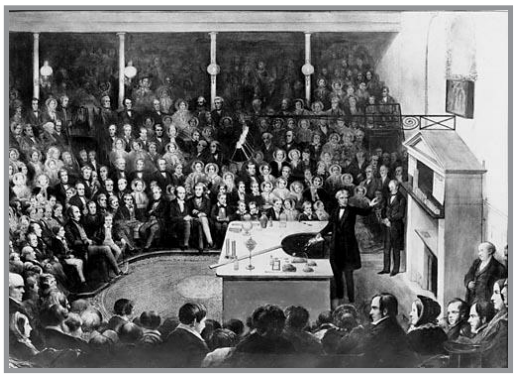
1) In dealing with the genesis of capitalist production I stated that it is founded on “the complete separation of the producer from the means of production” (p. 315, column 1, French edition of *Capital*) and that “the basis of this whole development is the expropriation of the agricultural producer. To date this has not been accomplished in a radical fashion anywhere except in England... But all the other countries of Western Europe are undergoing the same process” (1.c., column II).

I thus expressly limited the “historical inevitability” of this process to the countries of Western Europe. And why? Be so kind as to compare Chapter XXXII, where it says:

The “process of elimination transforming individualised and scattered means of production into socially concentrated means of production, of the pigmy property of the many into the huge property of the few, this painful and fearful expropriation of the working people, forms the origin, the genesis of capital... Private property, based on personal labour ... will be supplanted by capitalist private property, based on the exploitation of the labour of others, on wage labour” (p. 341, column II).

Thus, in the final analysis, it is a question of the transformation of one form of private property into another form of private property. Since the land in the hands of the Russian peasants has never been their private property, how could this development be applicable?

2) From the historical point of view the only serious argument put forward in favour of the fatal dissolution of the Russian peasants’ commune is this: By going back a long way communal property of a more or less archaic type may be found throughout Western Europe; everywhere it has disappeared with increasing social progress. Why should it be able to escape the same fate in Russia alone? I reply: because in Russia, thanks to a unique combination of circumstances, the rural commune, still established on a nationwide scale, may gradually detach itself from its primitive features and develop directly as an element of collective production on a nationwide scale. It is precisely thanks to its contemporaneity with capitalist production that it may appropriate the latter’s positive acquisitions without experiencing all its frightful misfortunes. Russia does not live in isolation from the modern world; neither is it the prey of a foreign invader like the East Indies.
And here is an important summary statement:



Theoretically speaking, then, the Russian “rural commune” can preserve itself by developing its basis, the common ownership of land, and by eliminating the principle of private property which it also implies; it can become a direct point of departure for the economic system towards which modern society tends; it can turn over a new leaf without beginning by committing suicide; it can gain possession of the fruits with which capitalist production has enriched mankind, without passing through the capitalist regime, a regime which, considered solely from the point of view of its possible duration hardly counts in the life of society. But we must descend from pure theory to the Russian reality.
There is a major irony in rereading Marx's analysis of the emancipatory possibilities inherent in the social form of the "peasant commune" in Russia. Most striking is the experience of the collectivization of Soviet agriculture in the 1920s and Stalin's war on the kulaks. Rather than representing a bright new future for the peasants, collectivization represented a cruel war by starvation against rural society (Lynne Viola, The War Against the Peasantry, 1927-1930: The Tragedy of the Soviet Countryside, Volume one (Annals of Communism Series) (v. 1)).

It is also also interesting to recall that one of the disputes among the Bolsheviks within Soviet leadership in the 1920s and 1930s was the issue of cooperatives in agriculture. A. V. Chayanov advocated for a more democratic route to Soviet socialism, through the mechanism of locally established rural cooperatives (link). His reasoning had quite a bit in common with Marx's analysis in this letter to Vera Zasulich; and, of course, it led to his persecution and execution in 1937.

Feyerabend as artisanal scientist

Friday, April 16, 2010

I've generally found Paul Feyerabend's position on science to be a bit too extreme. Here is one provocative statement in the analytical index of Against Method:

Thus science is much closer to myth than a scientific philosophy is prepared to admit. It is one of the any forms of thought that have been developed by man, and not necessarily the best. It is conspicuous, noisy, and impudent, but it is inherently superior only for those who have already decided in favour of a certain ideology, or who have accepted it without having ever examined its advantages and its limits. And as the accepting and rejecting of ideologies should be left to the individual it follows that the separation of state and church must be supplemented by the separation of state and science, that most recent, most aggressive, and most dogmatic religious institution. Such a separation may be our only chance to achieve a humanity we are capable of, but have never fully realised.

Fundamentally my objection is that Feyerabend seems to leave no room at all for rationality in science: no scientific method, no grip for observation, and no force to scientific reasoning. A cartoon takeaway from his work is a slogan: science is just another language game, a rhetorical system, with no claim to rational force based on empirical study and reasoning. Feyerabend seems to be the ultimate voice for the idea of relativism in knowledge systems -- much as Klamer and McCloskey seemed to argue with regard to economic theory in The Consequences of Economic Rhetoric.

This isn't a baseless misreading of Feyerabend. In fact, it isn't a bad paraphrase of Against Method. But it isn't the whole story either. And at bottom, I don't think it is accurate to say that Feyerabend rejects the idea of scientific rationality. Rather, he rejects one common interpretation of that notion: the view that scientific rationality can be reduced to a set of universal canons of investigation and justification, and that there is a neutral and universal set of standards of inference that decisively guide choice of scientific theories and hypotheses. So I think it is better to understand Feyerabend as presenting an argument against a certain view in the philosophy of science rather than against science itself.

Instead, I now want to understand Feyerabend as holding something like this: that there is "reasoning" in scientific research, and this reasoning has a degree of rational credibility. However, the reasoning that scientists do is always contextual and skilled, rather than universal and mechanical. And it doesn't result in proofs and demonstrations, but rather a preponderance of reasons favoring one interpretation rather than another. (Significantly, this approach to scientific justification sounds a bit like the view argued about sociological theories in an earlier posting.)

Here are a few reasons for thinking that Feyerabend endorses some notion of scientific rationality.

First, Feyerabend is a philosopher and historian of science who himself demonstrates a great deal of respect for empirical and historical detail. The facts matter to Feyerabend, in his interpretation of the history of science. He establishes his negative case with painstaking attention to the details of the history of science -- Newton, optics, quantum mechanics. This is itself a kind of empirical reasoning about the actual intellectual practices of working scientists. But if Feyerabend were genuinely skeptical of the enterprise of offering evidence in favor of claims, this work would be pointless.

Second, his own exposition of several scientific debates demonstrates a realist's commitment to the issues at stake. Take his discussion of the micro-mechanisms of reflection and light "rays". If there were in principle no way of evaluating alternative theories of these mechanisms, it would be pointless to consider the question. But actually, Feyerabend seems to reason on the assumption that one theory is better than another, given the preponderance of reasons provided by macro-observations and mathematical-physical specification of the hypotheses.

Third, he takes a moderate view on the relation between empirical observation and scientific theory in "How to Be a Good Empiricist":
The final reply to the question put in the title is therefore as follows. A good empiricist will not rest content with the theory that is in the centre of attention and with those tests of the theory which can be carried out in a direct manner. Knowing that the most fundamental and the most general criticism is the criticism produced with the help of alternatives, he will try to invent such alternatives. (102)
This passage is "moderate" in a specific sense: it doesn't give absolute priority to a given range of empirical facts; but neither does it dismiss the conditional epistemic weight of a body of observation.

So as a historian of science, Feyerabend seems to have no hesitation himself to engage in empirical reasoning and persuading, and he seems to grant a degree of locally compelling reasoning in the context of specific physical disputes. And he appears to presuppose a degree of epistemic importance -- always contestable -- for a body of scientific observation and discovery.
What he seems most antagonistic to is the positivistic idea of a universal scientific method -- a set of formally specified rules that guide research and the evaluation of theories. Here is how he puts the point in "On the Limited Validity of Methodological Rules" (collected in Knowledge, Science and Relativism).
It is indubitable that the application of clear, well-defined, and above all 'rational' rules occasionally leads to results. A vast number of discoveries owe their existence to the systematic procedures of their discoverers. But from that, it does not follow that there are rules which must be obeyed for every cognitive act and every scientific investigation. On the contrary, it is totally improbable that there is such a system of rules, such a logic of scientific discovery, which permeates all reasoning without obstructing it in any way. The world in which we live is very complex. Its laws do not lay open to us, rather they present themselves in diverse disguises (astronomy, atomic physics, theology, psychology, physiology, and the like). Countless prejudices find their way into every scientific action, making them possible in the first place. It is thus to be expected that every rule, even the most 'fundamental', will only be successful in a limited domain, and that the forced application of the rule outside of its domain must obstruct research and perhaps even bring it to stagnation. This will be illustrated by the following examples. (138)
It is the attainability of a universal, formal philosophy of science that irritates him. Instead, he seems to basically be advocating for a limited and conditioned form of local rationality

-- not a set of universal maxims but a set of variable but locally justifiable practices. The scientist is an artisan rather than a machinist. Here is a passage from the concluding chapter of *Against Method*:

The idea that science can, and should, be run according to fixed and universal rules, is both unrealistic and pernicious. It is unrealistic, for it takes too simple a view of the talents of man and of the circumstances which encourage, or cause, their development. And it is pernicious, for the attempt to enforce the rules is bound to increase our professional qualifications at the expense of our humanity. In addition, the idea is detrimental to science, for it neglects the complex physical and historical conditions which influence scientific change. It makes our science less adaptable and more dogmatic: every methodological rule is associated with cosmological assumptions, so that using the rule we take it for granted that the assumptions are correct. Naive falsificationism takes it for granted that the laws of nature are manifest and not hidden beneath disturbances of considerable magnitude. Empiricism takes it for granted that sense experience is a better mirror of the world than pure thought. Praise of argument takes it for granted that the artifices of Reason give better results than the unchecked play of our emotions. Such assumptions may be perfectly plausible and even true. Still, one should occasionally put them to a test. Putting them to a test means that we stop using the methodology associated with them, start doing science in a different way and see what happens. Case studies such as those reported in the preceding chapters show that such tests occur all the time, and that they speak against the universal validity of any rule. All methodologies have their limitations and the only 'rule' that survives is 'anything goes'.

His most basic conclusion is epistemic anarchism, expressed in the "anything goes" slogan, but without the apparent relativism suggested by the phrase: there is no "organon," no "inductive logic," and no "Scientific Method" that guides the creation and validation of science. But scientists do often succeed in learning and defending important truths about nature nonetheless.

(Here is an online version of the analytical contents and concluding chapter of Against Method. And here is a link to an article by John Preston on Feyerabend in the *Stanford Encyclopedia of Philosophy*.)

Ideal types, values, and selectivity

Monday, April 19, 2010

image: cover of Max Weber, The History of Commercial Partnerships in the Middle Ages

I've never really understood why the exposition of one of Max Weber's most important methodological ideas, his theory of ideal types, occurs in the context of an essay that is primarily about the role of values in the social sciences. This is his essay, "'Objectivity' in Social Science and Social Policy" in The Methodology of The Social Sciences. The central thrust of the essay is to attempt to spell out the ways that objectivity and truth relate to partisanship and values within the course of social science research and teaching. And Weber draws a sharp distinction between what can be known and demonstrated (empirical facts and causal relationships) and what can be internally tested for consistency but not demonstrated (fundamental value commitments). Here is how Weber puts the point early in the essay:

What has been the meaning of the value-judgments found in the pages of the *Archiv* regarding legislative and administrative measures, or practical recommendations for such

measures? What are the standards governing these judgments? What is the validity of the value-judgments which are uttered by the critic, for instance, or on which a writer recommending a policy founds his arguments for that policy? In what sense, if the criterion of scientific knowledge is to be found in the "objective" validity of its results, has he remained within the sphere of *scientific* discussion? We will first present our own attitude on this question in order later to deal with the broader one: in what sense are there in general "objectively valid truths" in those disciplines concerned with social and cultural phenomena? (50-51)

The theory of ideal types is an important contribution to the specification of the nature of concepts in the human and historical sciences. But why is this subject particularly relevant in the context of a discussion of values and social policy?

One reason for the conjoining of ideal types and values is the unavoidable fact of **selectivity** in the social sciences. Weber makes the point repeatedly in this essay that there is an infinite depth to social phenomena -- even to a single phenomenon or event -- and therefore it is necessary to **select** a finite representation of the object of study if we want to approach a problem scientifically. But how do we select a specific aspect of a phenomenon for study? We do so on the basis of a judgment of what aspects are important -- and this is a value judgment, either directly or indirectly. In a very specific sense, our **interests** (material and intellectual) guide the formation of our social-science research projects. "The quality of an event as a 'social-economic' event is not something which it possesses 'objectively.' It is rather conditioned by the orientation of our cognitive interest, as it arises from the specific cultural significance which we attribute to the particular event in a given case" (64). And a few pages later: "Social economic problems do not exist everywhere that an economic event plays a role as cause or effect -- since problems arise only where the significance of those factors is problematical and can be precisely determined only through the application of the methods of social-economics" (66).

Or in other words: what constitutes an economic situation as a "problem" is the fact that it has consequences that intersect with things we care about -- or our fundamental scheme of values. So the subject matter of "social-economics" is doubly dependent on our interests: our cognitive interests in how things work, and our practical interests in how to promote "good" outcomes and avoid "bad" outcomes.

This is where the issue moves into connection with the theory of ideal types. Weber makes it clear that he regards the formulation of a scientific research topic as being generated by a set of ***interests*** -- cognitive and practical. And this is where the idea of an ideal type is relevant. Because an ideal type is a selective, one-sided representation of an aspect of social life. Here is the foundational description that Weber offers in conjunction with the idea of a "commodity-market":

This conceptual pattern brings together certain relationships and events of historical life into a complex, which is conceived as an internally consistent system. Substantively, this construct is itself like a utopia which has been arrived at by the analytical accentuation of certain elements of reality. Its relationship to the empirical data consists solely in the fact that where market-conditioned relationships of the type referred to by the abstract

construct are discovered or suspected to exist in reality to some extent, we can make the characteristic features of this relationship pragmatically clear and understandable by reference to an ideal-type. It is not a description of reality but it aims to give unambiguous means of expression to such a description. It is thus the "idea" of the historically given modern society, based on an exchange economy, which is developed for us by quite the same logical principles as are used in constructing the idea of the medieval "city economy" as a "genetic" concept. ... An ideal type is formed by the one-sided *accentuation* of one or more points of view and by the synthesis of a great many diffuse, discrete, more or less present and occasionally absent *concrete individual* phenomena, which are arranged according to those one-sidedly emphasized viewpoints into a unified *analytical* construct. In its conceptual purity, this mental construct cannot be found empirically anywhere in reality. (90)

This specification of the concept of an ideal type links back to Weber's discussion of the value of specialization in the social sciences: "the justification of the *one-sided* analysis of cultural reality from specific 'points of view' -- in our case with respect to its economic conditioning -- emerges purely as a technical expedient from the fact that training in the observation of the effects of qualitatively similar categories of causes and the repeated utilization of the same scheme of concepts and hypotheses offers all the advantages of the division of labor" (71). In other words, the specialization of research methods and training that is implied by the establishment of disciplines in the social sciences is justified pragmatically rather than epistemically -- it is the practical advantage in research productivity rather than the nature of the social world that justifies the establishment of disciplines.

There is no absolutely "objective" scientific analysis of culture -- or put perhaps more narrowly but certainly not essentially differently for our purposes -- of "social phenomena" independent of special and "one-sided" viewpoints according to which -- expressly or tacitly, consciously or unconsciously -- they are selected, analyzed and organized for expository purposes. (72)

This locates the role and justification of the "ideal type" very precisely. An ideal type -- of a market economy, of a university, or of a banking institution -- creates a selective model of social organization that can then be explored analytically and empirically by specialists. The ideal type is not intended to be a general representation of a category of phenomena; but rather as a heuristic model that permits exploration and extension of some of the characteristics of the concrete social institutions and behaviors that it partially represents.

Throughout this discussion is woven the methodological debate between advocates of nomothetic and idiographic interpretations of the social sciences (link). Weber indicates his own understanding of the crucial importance of the individuality and particularity of historical phenomena -- without abandoning the viability of discovering limited generalizations and regularities.

Laws are important and valuable in the exact natural sciences, in the measure that those sciences are universally valid. For the knowledge of historical phenomena in their concreteness, the most general laws, because they are most devoid of content are also the least valuable. The more comprehensive the validity -- or scope -- of a term, the more it leads us away from the richness of reality since in order to include the common elements of the largest possible number of phenomena, it must necessarily be as abstract as possible and hence devoid of content. In the cultural sciences, the knowledge of the universal or general is never valuable in itself. (80)

Here again, the historically detailed ideal type is a better basis for historical and social

analysis.

Here is one additional qualification that Weber offers that is very important to his understanding of social-scientific knowledge:

We have designated as "cultural sciences" those disciplines which analyze the phenomena of life in terms of their cultural significance. The *significance* of a configuration of cultural phenomena and the basis of this significance cannot however be derived and rendered intelligible by a system of analytical laws, however perfect it may be, since the significance of cultural events presupposes a *value-orientation* towards these events. The concept of culture is a *value-concept*. (76)

This makes a final important connection between the two themes of the essay, objectivity and values. Values come into the social science at the stage of defining and examining social-economic-cultural problems; they come into the choice of subject matter by establishing the framework in terms of which a phenomenon is a "problem"; and they must be invoked in our interpretations of the phenomena when we attribute cultural meanings to the participants. The construct of the ideal type provides conceptual resources for each of these zones of intersection between social-science inquiry and the schemes of values that we humans endorse.

UnderstandingSociety Facebook page

Wednesday, April 21, 2010

You are invited to participate in the new UnderstandingSociety Facebook page. The page has links to recent posts on the blog, news items on recent developments in Burma, Thailand, and China, and updates on earlier topics concerning the social sciences in the blog. Best of all, readers can participate by offering their own observations and posting photos that capture their own social insights.

Readers of UnderstandingSociety come from all over the world. It would be great if you would post occasional photos from your location that speak to the processes of social change you observe where you live. Readers in France, India, Italy, Thailand, or Argentina -- what images can you share with us that would cast a light on social conditions there?

This can be a powerful tool for better understanding our global, complex society. Each person has daily experiences that are relevant to getting a better understanding of the social processes that envelop us. The Facebook page for UnderstandingSociety can be a location for pooling some of those insights.

Citizens' assemblies

Friday, April 23, 2010

There is quite a bit of interest today in exploring better mechanisms for implementing the goals of democracy in more effective and broadly legitimate ways than most electoral democracies have succeeded in doing to date. A core democratic goal is to create deliberation and decision mechanisms that permit citizens to become sufficiently educated about the issues that confront the polity that they can meaningfully deliberate about them, and to find decision-making processes that fairly and neutrally permit each citizen to contribute equally to the final outcome.

The deficiencies of current democratic processes are fairly visible around the television dial, the Internet, and the town-hall meeting and state house: demagogic leaders who deliberately whip up the most negative emotions in their followers, citizens who take almost no effort to learn the details of the issues, strident and verbally violent attacks against one's political adversaries, the excessive power possessed by economic interests to prevail through influence on agencies and legislators, and an overall lack of civility and trust within the polity. (Many of these deficiencies are highlighted in an earlier post.) It is hard to see that the public's considered interests are the ultimate guide to our democratic actions. Some people are now referring to these flaws as the "democratic deficit" -- a set of structural flaws in existing democratic institutions that lead to disappointing results.

So how can we do better? There are several important kinds of experiments underway that seem to have a lot going for them, both in principle and in practice, and these generally fall within the category of experiments in "deliberative, participatory democracy." (Here is a link to an earlier post on some of these issues.)

Particularly interesting is an experiment undertaken a few years ago in British Columbia in Canada. Following several elections that generated a great deal of popular complaint about the nature of the voting processes that led to the perverse outcomes, the Liberal Party pledged to create a "Citizens' Assembly for Electoral Reform" to consider the existing procedures and feasible alternatives and to recommend a single reform if warranted. The LP came to power in the next election in 2000 and the government of British Columbia kept its pledge. A citizens' assembly was created in 2004, composed of 160 citizens selected quasi-randomly from each of the province's districts. The body was asked to deliberate carefully about existing voting procedures and feasible alternatives, and to make a recommendation to be presented in a referendum to the voters of the province as a whole. The deliberations of the assembly occurred over an eleven-month period. They were supported by a professional staff and sufficient resources to conduct their work. And in 2005 they duly issued a considered recommendation to be presented to the BC electorate. This was the single transferable vote recommendation (STV). (The Wikipedia article on the "single transferable vote" system provides a good background on the Citizens' Assembly process as well; link.)

Here is a good video that describes the process in some detail; the full playlist is found here, and is worth watching in full:

This whole process was observed carefully by a team of social scientists at the Centre for the Study of Democratic Institutions at the University of British Columbia, and their assessment of the process is documented in Mark Warren and Hilary Pearse, eds., Designing Deliberative Democracy: The British Columbia Citizens' Assembly (Theories of Institutional Design). The book is a fascinating work in "experimental democracy." Here are the central questions posed by the researchers:

1. "What role should citizen bodies play in representative democracies generally, and what kind of legitimacy do citizen bodies have to decide questions of constitutional reform?
2. In what sense was the CA a representative body? How did CA design choices affect the representation of social groups within the Assembly and the empowerment, participation, and deliberation of CA participants?
3. Did the Citizens' Assembly transform citizens into competent decision-makers?
4. How did deliberations within the CA relate to deliberation and decisionmaking by the broader public?" (xii)

The summary conclusions are quite favorable to the process: citizen participants took their task seriously, they learned a great deal about different voting mechanisms, they debated the values that ought to guide selection of a mechanism, and they came to near-unanimity about the eventual recommendation -- a system of proportional representation referred to as "single transferable vote" (STV). Briefly, it is a system in which voters are permitted to rank candidates, and their votes are passed on to lower-ranked choices once the first choice has received sufficient votes. This permits minority groups to achieve representation when they would otherwise be entirely shut out of government.

Here is a summary statement about the CA process provided by the editors:

The authors of this volume are far from uncritical of the CA process. But they lend strong support to the judgment that the CA represents the first time a democratic institution has been deliberately and relatively successfully designed to address a constitutional issue. And if there is a broad lesson, it is that new democratic institutions can be successful if their design is closely related to broadly legitimate goals as well as to the specific characteristics of the issue at hand. (xii)

An important issue is the status of a citizens' assembly as a representative institution. It is not representative in the traditional electoral sense; citizens of British Columbia did not elect them as their representatives in this process. Instead, the quasi-random process of selection that was used ensured a different kind of representativeness in the resulting body. It was representative of the gender composition of the province, and it was modestly representative of the range of income, age, and education that was present in the province. It was necessary to add several slots to provide representation for indigenous groups. And, most important, it was a process that essentially excluded the likelihood of over-representation of "special interests", whether business, labor, or social issues. It was credible to expect, therefore, that this group would be able to consider the specific issues presented to it in a reasonably neutral and representative way.

Another important empirical question is whether a group of citizens will succeed in educating themselves about a complex issue and arrive at well considered opinions that bring together their understanding of the relevant values they share and the facts of institutional design that can be discovered. Here again, the CA example is a heartening one. The authors of *Designing Deliberative Democracy* give ample evidence, based on

ethnographic data, of the effectiveness of this forum in stimulating this kind of values reflection and learning that good decisions by a group of typical citizens require. The process appears to have worked very well, even by the high standards of philosophical theories of deliberative democracy. Habermas would be pleased!

What was the eventual result of this effort? The proposal did not reach the 60% super-majority required for adoption, but it came close with about 57.7%. A second referendum was conducted in 2009, and the proposal failed again, gaining only 38.8%. But in spite of electoral failure, the experiment appears to be a very important one, and one that other polities may well want to attempt to emulate.

It is deeply interesting to consider whether mechanisms like the citizens' assembly might help to repair the democratic deficit we experience in the United States. Are there mechanisms that we can adopt at the local, regional, or national level that would permit us to arrive at a better understanding of complex issues, a better ability to find common ground with each other, and an ability to arrive at recommendations for public policies that are feasible and fair? Could we address issues of healthcare reform, social security reform, financial regulation, budget planning, or environmental protection through mechanisms like this? And would the result be something that we could all find to be superior to the current processes of legislation, referendum, and cable television rants? The evidence of British Columbia suggests a favorable answer to all these questions.

(Another piece of research in this general vein is Archon Fung and Erik Olin Wright, Empowered Participation: Reinventing Urban Democracy. This will be the topic of a future post.)

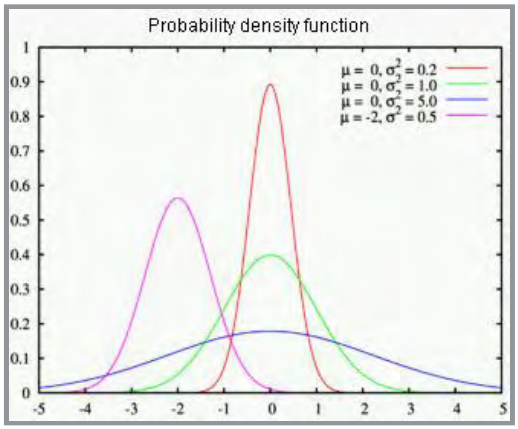
Sociology in time: cohorts



Sunday, April 25, 2010

What difference does it make to a person's personality, values, agency, or interpretive schemes that she was born in 1950 rather than 1930 or 1970? How does a person's place in time and in a stream of historical events influence the formation of his or her consciousness? (I've raised some of these questions in prior posts, here and here.)

If we thought of people as being pretty much uniform in their motivations and understandings of the world, then we wouldn't be particularly interested in the micro-circumstances that defined the developmental environment of a cohort; these circumstances would have been expected to lead to pretty much the same kinds of actors. We don't think it is useful to analyze ants or cattle into age cohorts.

If, on the other hand, we think that a person's political and social identity, the ways in which she values a range of social and personal outcomes, the ways in which she organizes her thinking about the world -- if we think that these basic features of cognition, valuation, and motivation are significantly influenced by the environment in which

development and maturation take place, then we are forced to consider the importance of cohorts.

The ideas of the "Great Generation" the "Children of the Depression," or the "Sixties Generation" have a certain amount of resonance for us. We think of the typical members of these cohorts as having fairly important features of personality, memory, and motivation that are different from members of other cohorts. Americans born in the 1920s were thrown into social environments that were very different from those of people born twenty years earlier or later. And their political consciousness and behavior seem to reflect these differences.

But here is the difficult question raised by these considerations: how should sociologists attempt to incorporate the possibility of cohort differences in behavior and outlook? Here is one possible way of conceptualizing cohort differences with respect to a personality characteristic -- let's say "propensity to trust leaders." Suppose we have conducted a survey that operationalizes this characteristic so that the trust propensity of each individual can be measured. We might postulate that every individual has some degree of trust, but that different cohort groups have different mean values and different distributions around the mean.

The graph below represents four **hypothetical** cohorts: purple, blue, green, red. Blue, green, and red cohorts have the same mean value for trust (normalized to 0). But they differ in terms of the degree of variation there is within the cohort with respect to this feature. The red cohort is tightly scattered around the mean, whereas the blue cohort is very widely distributed. The "average" red individual has the same degree of trust as the average blue individual; but there is a much wider range of the blues than the reds. Members of the purple cohort show a fundamentally different behavior. They have a significantly lower level of trust, with a mean of -2. And the degree of distribution around the mean is moderate for the purple cohort -- not as tight as the reds, not as broad as the blues. Finally, it should be noted that there are reds, greens, and blues who are as untrusting as some purples, and there are some purples who are more trusting than some reds, greens, and blues. In other words, the distributions overlap.

If we were confronted with data like these, our next question would be causal and historical: what were the circumstances of development in which the generation of people in the purple cohort took shape that caused them to be less trusting than other cohorts? And what circumstances led the blue cohort to have such a wide distribution of variation in comparison to the green and red cohorts?

Now let's put some dates on the curves. Suppose that the purple cohort is the baby-boom generation -- people born between 1945 and 1954. Red is the "Greatest Generation", born between 1915 and 1924. And blue is the "me-generation", born between 1955 and 1964. We might speculate that growing up in the sixties, with a highly divisive war in Vietnam underway, a government that suffered a serious credibility gap, and a youth culture that preached the slogan, "trust no one over 30!", would have led to a political psychology that was less inclined to trust government than generations born earlier or later. So the Purple cohort has a low level of trust as a group. The social necessity of

sticking together as a country, fighting a major world war, and working our way out of the Great Depression, might explain the high degree of unanimity of trust found in the Red cohort. And the Blue generation is all over the map, ranging from a significant number of people with extremely low trust to an equal group of extremely high trust. We might imagine that the circumstances of maturation and development following the wild and crazy sixties imposed little structure on this feature of political identity, resulting in a very wide distribution of levels of trust.

It is also important to consider some of the factors that vary across time that might have important influences on the development of different cohorts. Circumstances like war, famine, or economic crisis represent one family of influences that are often markedly different across age cohorts. Ideologies and value systems also change from decade to decade. The turn to a more conservative kind of Christianity in the United States in the 1990s certainly influenced a significant number of young people coming of age during those decades, and the value system of nationalism and patriotism of the 1940s and 1950s influenced the young people of those decades. Third, institutions change significantly over time as well. Schools change, the operations and culture of the military change, and the internal workings of religious institutions change. So the institutions in which children and young adults gain their perspectives, motives, and allegiances are often significantly different from one decade to another. And presumably, all these factors are involved in the formation of the consciousness and identity of the young people who experience them. Difference in settings (events, ideologies, institutions) lead to differences in psychology across cohorts.

Andrew Abbott raised some of these questions in his presidential address to the Social Science History Association in 2004 (link). The title he chose is illuminating -- "The Historicality of Individuals". And the central point here could be put in the same terms: it is important for us to attempt to understand processes of social and historical change, through the shifting characteristics of the age-specific populations that make these processes up. The historicality of individuals adds up to the sociological importance of cohorts.

Revitalizing our cities

Wednesday, April 28, 2010

It is hard to think of an American city that is doing really well these days. Dense urban poverty in the core, super-high rates of unemployment, failing schools for many urban children, high rates of crime, chronic and overwhelming fiscal crises resulting from too little public revenue for needed public services, and health outcome discrepancies that mark debilitating life disadvantages for urban people -- these seem to be fairly widespread features of cities from Miami to Cleveland to Los Angeles to Chicago to Detroit.

The most recent victim of the urban crisis in the area of publicly provided social services

in my city, Detroit, is indicative; this week it was announced that Detroit's Neighborhood Services Organization would lose 2/3 of its funding effective immediately (link). This program reaches out to Detroit's homeless people and provides transition assistance permitting 1000 people per year to return to housed status. It is now forced to close down its operations entirely until October 1, since the program has already expended 1/3 of its budget for 2009-10. No one disputes that NSO is doing great work and returning multiples of benefits relative to its budget; but the state's fiscal crisis has been passed on to this effective, people-oriented program. (CEO Sheilah Clay was featured as a guest on the Craig Fahle show on WDET today -- one of the best parts of the urban Detroit dial. Thanks, Craig!)

So cities are suffering from very significant structural disadvantages in the United States today. And yet, as Richard Florida argues so persistently and so correctly, cities are crucial to the future of the United States and the rest of the world (link). When they are healthy, they create a concentration of talent, innovation, and synergy that simply cannot be beaten. So we need healthy cities and metropolitan regions if we are to thrive in the twenty-first century.

So what can be done, given that the deck seems to be stacked against our cities? This evening Judith Rodin, president of the Rockefeller Foundation and former president of the University of Pennsylvania, gave an important lecture on this subject at Wayne State University in its Van Dusen Forum on Urban Issues. Rodin is an ideal speaker on this subject, because the University of Pennsylvania developed very strong urban renewal strategies aimed at West Philadelphia during her tenure, and because the Rockefeller Foundation has taken urban revitalization as one of its core goals for quite a few decades. Rodin is the author of an important book about the process that unfolded in Philadelphia around the University of Pennsylvania (The University and Urban Revival: Out of the Ivory Tower and Into the Streets), and it is worth reading. She estimates that there are roughly 50 "megaregions" in the United States -- Detroit Metro, Chicago-Land, ... -- and that these megaregions represent 65% of the population and a higher percentage of all economic activity. So healthy development of American cities is enormously important. But likewise, the institutions that find themselves deeply integrated into the geography of these cities urgently need a future in which their cities begin to grow more habitable, healthy, and equitable. Here is a memorable line from the speech -- "Blight of the city becomes the plight of the university."

What actors and strategies can help attain a positive trajectory of urban revitalization? Rodin's central thrust is that universities and health systems can serve as "anchor" institutions in cities, and that they can design strategies that substantially improve the economic development and quality of life of the cities they inhabit. (She calls these institutions "***eds and meds***".) They provide very significant employment opportunities and purchasing power in the city; and more important, they necessarily make significant investments in real estate and infrastructure in the city. So in principle, it is credible that the resources of these institutions could be used in ways that leverage positive change in the cities in which they live.

But Rodin draws several very important lessons from the example of Penn and

Philadelphia. There needs to be a broad and sustained institutional commitment to making strategic decisions around the goal of enhancing the process of urban development. The strategies can't be "one-off" -- they need to be sustained and thoughtful. Strategies need to be coherent and comprehensive -- not piecemeal and stop-and-go. Third, she emphasizes that successful revitalization strategies require us to think innovatively. Existing solutions haven't worked; we need to bring fresh thinking to the situations we confront and the outcomes we want to achieve. And, finally, she emphasizes over and over the need for partnership and community participation in the plans that the institution arrives at. Full, uninhibited partnership is essential if any of these strategies are to work. So communication, partnership, and genuine collaboration with all stakeholders is essential to a successful strategy. Another memorable line -- "Urban revitalization can't be done **for** the community or **to** the community; it must be done **with** the community."

The examples that Rodin offered from Philadelphia largely had to do with neighborhood revitalization and investments by the university in stabilizing the neighborhoods surrounding it in West Philadelphia. For example, the university bought dozens of homes and buildings in the neighborhoods, renovated them, and leased them back to residents and businesses; and, significantly, it did so at a loss. The idea was to make attractive properties available to city residents and businesses, bringing housing, children, and consumers into once-blighted neighborhoods. Another example -- she highlighted crime and safety on the streets as a key issue; so the university organized a program for street lighting in a number of neighborhoods. The new lighting system invited people back into the streets; but more people in the streets in turn reduced the prevalence of crime. A third example -- she talked about a mortgage incentive program the university offered to faculty and staff, to give them an incentive to live in the targeted neighborhoods. In other words, through a targeted and sustained investment strategy in real estate and neighborhoods the university was able to help Philadelphia achieve meaningful change.

The upshot of these examples comes down to two basic causal ideas: invest in real estate in ways that invite people to live and work in the central city; and find ways of changing behaviors so that the neighborhoods will be increasingly attractive. Crucially, Rodin suggests that the university's investment is a sizable one; but it is a small fraction of the total investment in these neighborhoods that eventually comes about as residents, business owners, and investors acquire more confidence in the safety and stability of the neighborhoods. So the change of behavior is really essential to the whole plan; unless people begin occupying homes, purchasing in grocery stores and other businesses, and enjoying parks and cinemas in these neighborhoods, nothing fundamental will change. No single institution has the resources to turn West Philadelphia into Back Bay, but early investments by "anchor institutions" may pay off through their ability to leverage many times those resources through other sources.

What Rodin didn't talk about so much in her lecture is how the research energies of the university can be a positive factor in urban revitalization. But this aspect of the university's ability to contribute is crucial. The social problems that modern cities face are "wicked" problems -- big, messy, complex, and multi-sectoral problems (link). Everyone wants to improve the quality of urban schools. But what interventions might actually work? This requires a broad research effort, incorporating teacher training, pedagogy, curriculum, the cultural and social environments that poor children live in, school leadership, system bureaucracy and governance, and a host of other complex causal processes. So 800-word editorials in the local newspaper won't be able to provide a guide to policy reform. The remedies won't be simple. Or take racial disparities in health outcomes. Why are

certain diseases so much more prevalent in poor neighborhoods? Some of the answers are fairly simple; but overall, this is a complex phenomenon that requires careful, detailed applied research. And schools of public health have exactly the right constellations of talent and expertise to help sort out the causal processes leading to these outcomes -- and the kinds of policy interventions that can reverse them. Here again, the research capacity of a university is crucial to the solution or amelioration of the problems our cities face.

Another major impact that a university can offer a city is in the form of an engaged student body. If students are motivated to support community service organizations, they can have an immediate impact. If they are encouraged to take service-learning courses that give them a better understanding of the city, this will deepen their ability to contribute. And both these forms of engagement will produce something even more important: adults who are prepared to extend themselves in forms of community service throughout their lives. Learning the habit of engagement can be a lifelong change.

Significantly, a number of urban and metropolitan universities are adopting institutional missions that highlight the kinds of partnership, engagement, and urban/metropolitan impact that is described here. In particular, the Coalition of Urban and Metropolitan Universities represents a group of universities with precisely those commitments. Here is the Declaration that members of the coalition endorse. Another important recent development is the establishment of a new Carnegie classification of universities, the classification for Community Engagement (link).

Outcast London

Monday, May 03, 2010

A city is a complex social agglomeration, and all too often it represents a concentration of social ills that are very difficult to eradicate. Poverty, violence, and poor public health are three social problems that seem to be almost synonymous with "urban." We might ask two rather different sorts of questions about these facts. One is "Why so?", and the other is, "Under what circumstances not?"

The "why" question has a number of fairly obvious answers -- not all consistent with each other. A city is often a magnet for extremely poor people looking for better opportunities than those afforded in their current locations. A city is often segregated and stratified, with high barriers to exit; so poor people are concentrated in their cores. Extreme poverty reproduces extreme poverty, as businesses and other social activities exit the core.

The question, "what circumstances help a city to avoid these outcomes?" also has some obvious answers. Robust business growth promotes jobs at a range of skill levels, so unemployed unskilled people (usually poor) are able to find work and to climb the ladder of economic advancement. The presence of a well funded and robust social welfare net helps the poor population. A high degree of civic pluralism in the population facilitates

easy movement across the neighborhoods and jobs of the city. And there are virtuous circles at work among these factors: more job growth enables more pluralism, and helps to fund more social welfare spending; which in turn stimulates more job growth.

As we contemplate these social processes in the contemporary U.S. city, it is instructive to think about an important historical example as well. In this context it is interesting to reread Gareth Stedman Jones' Outcast London: Study in the Relationship Between Classes in Victorian Society, a brilliant piece of social and urban history first published in 1971.

Stedman Jones frames his narrative around the shocking puzzle that London presented to the English nation in the first half of the nineteenth century. London was the cultural, financial, and political center of England, a world city with a privileged and affluent population. But at the same time it was the home to a large population of extremely poor people who fell under the general label of "casual labor." And, as Stedman Jones points out repeatedly, educated London had almost no conceptual framework within which to categorize the social reality of the slum.

In fact, there was a growing perception of "two Englands" and two races of English people -- the poor and the rest. As Stedman Jones makes clear, the political economists of the mid-nineteenth century devoted a good deal of their time to the effort to decipher this paradox of wealth and poverty. Malthus placed much of the responsibility for the slums of London on over-population; slum dwellers represented the cutting edge of "positive checks" on population growth. Alfred Marshall, on the other hand, took a more benign view of the possible future of the working class; he argued for a gradual process of improvement that lifted the quality of life for many poor people.

Economic institutions are the product of human nature, and cannot change much faster than human nature changes. Education, and the raising of our moral and religious ideals, and the growth of the printing press and the telegraph have so changed English human nature that many things which economists rightly considered impossible thirty years ago are possible now. (S-J, 9, quoting Marshall in "How far do Remediable causes influence prejudicially (a) continuity of employment, (b) the rates of wages?")
But there was a lower end of the lower class in Marshall's worldview: the "residuum" of people who would never benefit from the rising tide.

Marshall expressed the prevailing opinion when he characterized the 'residuum' as those who are limp in body and mind'. The problem was not structural but moral. The evil to be combated was not poverty but pauperism: pauperism with its attendant vices, drunkenness, improvidence, mendicancy, bad language, filthy habits, gambling, low amusements, and ignorance (11).
So Marshall's diagnosis of extreme poverty came down to something akin to a biological moral theory: there is a segment of humanity who cannot benefit from the progress of civilization and the economy. And London was ground zero for this segment:

London was regarded as the Mecca of the dissolute, the lazy, the mendicant, 'the rough' and the spendthrift. The presence of great wealth and countless charities, the unparalleled opportunities for casual employment, the possibility of scraping together a living by innumerable devious methods, all were thought to conspire together to make London one huge magnet for the idle, the dishonest, and the criminal. (12)
Dock labor was the largest source of casual-labor employment in these decades, and it was notoriously prone to fluctuation. And the collapse of traditional industries left even

more people unemployed. S-J quotes George Godwin in an ethnographic mode:

At the corners of the streets may be seen groups of youths of the age from 16 to 20 (evidently not of the vicious class), lean, wan and ragged. On speaking to these lads, they will tell you that they are sons of silk weavers: they have no employment: some have tried to get into a man of war, but being over 15 years of age have been refused: they have tried to enlist into the army, but their chest or height would not pass inspection. (102)

In order to treat these conditions rigorously Stedman Jones provides a careful analysis of the dynamics of the casual labor market in London in the mid-nineteenth century and its high degree of seasonality, and demonstrates that economic insecurity and immiseration were the foundation of slum culture. He quotes Henry Mayhew from London Labour and the London Poor:

Where the means of subsisence occasionally rise to 15s. per week, and occasionally sink to nothing, it's absurd to look for prudence, economy, or moderation. Regularity of habits are incompatible with irregularity of income... it is a moral impossibility that the class of labourers who are only occasionally employed should be either generally industrious or temperate. (263)

An interesting feature of *Outcast London* is the dual perspective that Stedman Jones takes: he offers a narrative of economic change and social class; but he also dissects the intellectual frameworks through which economists and policy makers sought to understand these processes. So the book does a good job of both describing the economic circumstances as well as the shifting theories through which British intellectuals and the public tried to make sense of these circumstances.

Here is the interesting and relevant conclusion of Stedman Jones's argument: in the end, it was not dissoluteness or poor morals that condemned the extreme poor to their stations, but simply the lack of economic opportunity presented by the urban environment of London in the 1850s. It was the lack of jobs, not the lack of morals, that constructed the great slums of London.

Mental models for the social world

Wednesday, May 05, 2010

What is involved in being prepared to understand what is going on around you?

In a sense this is Kant's fundamental question in the Critique of Pure Reason: what intellectual resources (concepts, categories, frameworks) does a cognitive agent need in order to make sense of the contents of consciousness, the fleeting experiences and sensations that life brings us? And his answer is pretty well known: we need concepts of fixed objects in space and time, subject to causal laws. The stream of experiences we have is organized around a set of persistent objects located in time and space with specific causal properties. Space, time, cause, and object are the fundamental categories of cognition when it comes to understanding the natural world. This line of thought leads to an esoteric philosophical idea, the notion of transcendental metaphysics. (P. F. Strawson's work on Kant is particularly helpful; The Bounds of Sense: An Essay on Kant's Critique of Pure Reason.)

But we can ask essentially the same kind of question about the ordinary person's ability

to make sense of the social world around him or her. Each person is exposed to a dense stream of experiences of the social world, at various levels. We have ordinary interactions -- with friends, bus drivers, postal carriers, students -- and we want to interpret the behavior that we observe. We read news reports and tweets about happenings in the wider world -- riots in Athens, suicide attacks in Pakistan, business statements about future sales, ... -- and we want to know what these moments mean, how they hang together, and what might have caused them. In short, we need to have a set of mental resources that permit us to organize these experiences into a representation of a coherent social reality.

So is it possible to provide a transcendental metaphysics for ordinary social experience? Can we begin to list the kinds of concepts we need to have in order to cognize the social world?

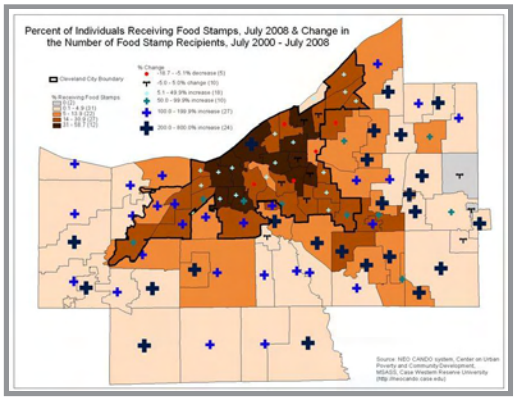
We might say that a very basic building block of social cognition is a set of scripts or schemas into which we are prepared to fit our observations and experiences. Suppose we observe two people approach each other on the street, exchange words, bow heads slightly, and part. This interaction between two strangers might be categorized as "courtesy" during a chance meeting. But it might be construed in other ways as well: ironic insults, sexual innuendo, or condescension from superior to inferior. Each of these is an alternative interpretive frame, a way of conceptualizing and "seeing" a complex series of behaviors. So the scripts or frames that we bring to the observations impose a form of organization on the observations.

Or take the current rioting in Greece: we might construct these masses of collective behavior as rationally directed economic protest, righteous resistance, or opportunistic anarchism. Each alternative has different implications, and each corresponds to a somewhat different set of background assumptions about how social interactions unfold. Each corresponds to a different social metaphysic. Different observers bring a different set of assumptions about how the social world works to their observations. And these frameworks lead to different constructions of the events.

Or consider the question of the social "things" around which we organize our social perceptions: nations, financial markets, cities, parties, and ideologies, for example. How much arbitrariness is there in the ontological schemes into which we organize the world? Could we have done just as well at making sense of our experience with a substantially different ontology? Is there a most basic ontology that underlies each of these and is a scheme that cannot be dispensed with?

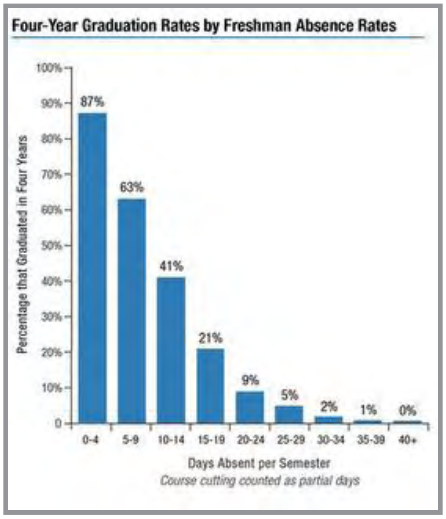
We might try a "fundamental" ontology along these lines: we must identify individuals as purposive, intentional agents; we must recognize relations among individuals -- giving us social networks, knowledge transmission, and groups; and we must recognize social processes with causal powers, constituted by individuals within specific social relations. And we must recognize the situation of consciousness -- beliefs, desires, values, and ideologies. And, we might hypothesize, we can build up all other more specific social entities out of aggregations of these simple things.

This is one possible way of formalizing a social ontology. But there are others. For example, we might give priority to relations rather than individuals; or we might give priority to processes rather than structures. So it is hard to justify the notion that there is a single uniquely best way of conceptualizing the realm of the social.



An interesting collateral question has to do with the possibility of systemic error: is it possible that our metaphysical presuppositions about the social world sometimes lead us to construe our social observations in ways that systematically misrepresent reality? For example, would a "metaphysics of suspicion" (the idea that people generally conceal their true motives) lead us to a worldview along the lines of Jerry Fletcher, the central character in Conspiracy Theory?

Several things seem likely. First, there is no single and unique set of ontological "simples" for the social world. Rather, there are likely to be multiple starting points, all of which can result in a satisfactory account of the social world. So there is no transcendental metaphysics for the social world -- including the candidate sketched above.



Second, it seems that the unavoidable necessity of having a set of causal, semantic, and process schemata does not guarantee correctness. Our schemata may systematically mislead us. So the schemata themselves amount to a large empirical hypothesis; they may be superseded by other schemata that serve better to organize our experiences. The schemata are not determined by either apriori or empirical considerations. And therefore our social cognitions are always a work in progress, and our conceptual frameworks are more like a paradigm than an ineluctable conceptual foundation.

Urban inequalities and social mobility

Sunday, May 09, 2010

Most American cities commonly look a lot like the poverty map of Cleveland above, when it comes to the spatial distribution of poverty and affluence. There is a high-poverty core, in which residents have low income, poor health, poor education, and poor quality of life; there are rings of moderate income; and there are outer suburbs of affluent people with high quality of life.

We can ask two different kinds of sociological questions about these facts: What factors cause the reproduction of disadvantage over multiple generations? And what policy interventions have some effect on enhancing upward social mobility within disadvantaged groups? How can we change this cycle of disadvantage?

The persistence of inequalities in urban America was addressed in a special 2008 issue of the Boston Review in a forum on "ending urban poverty." Particularly interesting is Patrick Sharkey's article "The Inherited Ghetto." Sharkey begins with a crucial and familiar point: that racial inequality has changed only very slightly since the

passage of the Fair Housing Act in 1968. The concentration of black poverty in central cities has not substantially improved over that period of time, and the inequalities of health, education, and employment associated with this segregation have continued. And the association between neighborhood, degree of segregation, and income and quality of life is very strong: children born into a poor and segregated neighborhood are likely to live as adults -- in a poor and segregated neighborhood.

Sharkey documents these statements on the basis of his analysis of the data provided the University of Michigan Panel Study of Income Dynamics, the first major statistical study of several generations of families in terms of residence, income, occupation, health, and other important variables. Using a computer simulation based on the two-generation data provided by the Panel Study, Sharkey indicates that it would take five generations for the descendants of a family from a poor, black neighborhood to have a normal expectation of living in a typical American neighborhood. (That's one hundred years in round numbers.) In other words: the progress towards racial equality in urban America is so slow as to be virtually undetectable.

Particular frustrating is the persistence of segregation in the forty years since the passage of the Fair Housing Act. Sharkey argues that this fact is partially explained by the fact that the policy choices made by federal and local authorities concerning housing patterns have more or less deliberately favored segregation by race. Beginning with the initial Fair Housing legislation -- which was enacted without giving the Federal agencies the power of enforcement -- both federal and state policies have reinforced segregation in housing. Sharkey notes that federal housing programs have subsidized the growth of largely white suburbs, while redlining and other credit-related restrictions have impeded the ability of black families to follow into these new suburban communities. The continuation of informal discrimination in the housing market (as evidenced by "testers" from fair housing agencies) further reinforces continuing segregation between inner-city black population and the suburban, mostly white population.

So racial segregation is one important mechanism that maintains the economic and social inequalities that our society continues to embody.

How about policies that would work to speed up social progress? It is commonly agreed that improving access to higher education for disadvantaged people is the best way to speed their economic advancement. The theory is that individuals within the group will benefit from higher education by enhancing their skills and knowledge; this will give them new economic opportunities and access to higher-wage jobs; the individuals will do better economically, and their children will begin life with more economic support and a set of values that encourage education. So access to higher education ought to prove to be a virtuous circle or a positive feedback loop, leading to substantial social mobility in currently disadvantaged groups.

This theory appears to be substantially true: when it is possible to prepare poor children for admission to college, their performance in college and subsequent careers is good and lays a foundation for a substantial change in quality of life for themselves and their families (link).

However, most of our cities are failing abysmally in the task of preparing poor children for college. High school graduation rates are extremely low in many inner-city schools -- 25-50%, and performance on verbal and math assessment tests are very low. So a very substantial number of inner-city, high-poverty children are not being given the opportunity

to develop their inherent abilities in order to move ahead in our society. This is true in Detroit (link), and much the same is true in Cleveland, Oakland, Miami, Houston, New Orleans, and dozens of other cities. (Here is a survey of the issues by Charles Payne in So Much Reform, So Little Change: The Persistence of Failure in Urban Schools. And here is a striking report from 1970 prepared by the HEW Urban Education Taskforce.) High poverty and poor education go hand in hand in American cities.

One important research question is whether there are behavioral or structural factors that predict or cause low performance by groups of students. Here is a fascinating graph of high school graduation rates broken down by freshman-year absenteeism (MDRC report). Important research is being done at the Center for the Social Organization of Schools at Johns Hopkins on the dropout crisis in urban schools (link). (Here is an earlier post on CSOS and its recommendations for improving dropout rates from urban high schools.) The topic is important because research findings like these may offer indications of the sorts of school reforms that are most likely to enhance school success and graduation.

It is clear that finding ways of dramatically increasing the effectiveness of high-poverty schools is crucial if we are to break out of the multi-generational trap that Sharkey documents for inner-city America. Here is a specific and promising strategy that is being pursued in Detroit by the Skillman Foundation and its partners (link), based on small schools, greater contact with caring adults, and challenging academic curricula. This turn-around plan is based on a specific set of strategies for improving inner-city schools developed by the Institute for Student Achievement, and ISA provides assessment data that support the effectiveness of the plan in other cities. With support from the United Way of Southeast Michigan, several large high schools are being restructured along the design principles of the ISA model.

But the reality is that this problem is immense, and a few successful experiments in school reform are unlikely to move the dial. Somehow it seems unavoidable that only a Marshall Plan for addressing urban poverty would allow us to have any real confidence in the possibility of reversing the inequalities our cities reveal. And none of our political leaders -- and few of our taxpayers -- seem to perceive the urgency of the problem.

System safety engineering and the Deepwater Horizon

Sunday, May 09, 2010

The Deepwater Horizon oil rig explosion, fire, and uncontrolled release of oil into the Gulf is a disaster of unprecedented magnitude. This disaster in the Gulf of Mexico appears to be more serious in objective terms than the Challenger space shuttle disaster in 1986 -- in terms both of immediate loss of life and in terms of overall harm created. And sadly, it appears likely that the accident will reveal equally

severe failures of management of enormously hazardous processes, defects in the associated safety engineering analysis, and inadequacies of the regulatory environment within which the activity took place. The Challenger disaster fundamentally changed the ways that we thought about safety in the aerospace field. It is likely that this disaster too will force radical new thinking and new procedures concerning how to deal with the inherently dangerous processes associated with deep-ocean drilling.

Nancy Leveson is an important expert in the area of systems safety engineering, and her book, Safeware: System Safety and Computers, is a genuinely important contribution. Leveson led the investigation of the role that software design might have played in the Challenger disaster (link). Here is a short, readable white paper of hers on system safety engineering (link) that is highly relevant to the discussions that will need to occur about deep-ocean drilling. The paper does a great job of laying out how safety has been analyzed in several high-hazard industries, and presents a set of basic principles for systems safety design. She discusses aviation, the nuclear industry, military aerospace, and the chemical industry; and she points out some important differences across industries when it comes to safety engineering. Here is an instructive description of the safety situation in military aerospace in the 1950s and 1960s:

Within 18 months after the fleet of 71 Atlas F missiles became operational, four blew up in their silos during operational testing. The missiles also had an extremely low launch success rate. An Air Force manual describes several of these accidents:

An ICBM silo was destroyed because the counterweights, used to balance the silo elevator on the way up and down in the silo, were designed with consideration only to raising a fueled missile to the surface for firing. There was no consideration that, when you were not firing in anger, you had to bring the fueled missile back down to defuel.

The first operation with a fueled missile was nearly successful. The drive mechanism held it for all but the last five feet when gravity took over and the missile dropped back. Very suddenly, the 40-foot diameter silo was altered to about 100-foot diameter.

During operational tests on another silo, the decision was made to continue a test against the safety engineer's advice when all indications were that, because of high oxygen concentrations in the silo, a catastrophe was imminent. The resulting fire destroyed a missile and caused extensive silo damage. In another accident, five people were killed when a single-point failure in a hydraulic system caused a 120-ton door to fall.

Launch failures were caused by reversed gyros, reversed electrical plugs, bypass of procedural steps, and by management decisions to continue, in spite of contrary indications, because of schedule pressures. (from the Air Force System Safety Handbook for Acquisition Managers, Air Force Space Division, January 1984)

Leveson's illustrations from the history of these industries are fascinating. But even more valuable are the principles of safety engineering that she recapitulates. These principles seem to have many implications for deep-ocean drilling and associated technologies and systems. Here is her definition of systems safety:

System safety uses systems theory and systems engineering approaches to prevent foreseeable accidents and to minimize the result of unforeseen ones. Losses in general, not just human death or injury, are considered. Such losses may include destruction of property, loss of mission, and environmental harm. The primary concern of system safety is the management of hazards: their identification, evaluation, elimination, and control

through analysis, design and management procedures.
Here are several fundamental principles of designing safe systems that she discusses:

- System safety emphasizes building in safety, not adding it on to a completed design.
- System safety deals with systems as a whole rather than with subsystems or components.
- System safety takes a larger view of hazards than just failures.
- System safety emphasizes analysis rather than past experience and standards.
- System safety emphasizes qualitative rather than quantitative approaches.
- Recognition of tradeoffs and conflicts.
- System safety is more than just system engineering.

And here is an important summary observation about the complexity of safe systems:
Safety is an emergent property that arises at the system level when components are operating together. The events leading to an accident may be a complex combination of equipment failure, faulty maintenance, instrumentation and control problems, human actions, and design errors. Reliability analysis considers only the possibility of accidents related to failures; it does not investigate potential damage that could result from successful operation of the individual components.

How do these principles apply to the engineering problem of deep-ocean drilling? Perhaps the most important implications are these: a safe system needs to be based on careful and comprehensive analysis of the hazards that are inherently involved in the process; it needs to be designed with an eye to handling those hazards safely; and it can't be done in a piecemeal, "fly-test-fly" fashion.

It would appear that deep-ocean drilling is characterized by too little analysis and too much confidence in the ability of engineers to "correct" inadvertent outcomes ("fly-fix-fly"). The accident that occurred in the Gulf last month can be analyzed into several parts. First is the explosion and fire that destroyed the drilling rig and led to the tragic loss of life of 11 rig workers. And the second is the uncalculated harms caused by the uncontrolled venting of perhaps a hundred thousand barrels of crude oil to date into the Gulf of Mexico, now threatening the coasts and ecologies of several states. Shockingly, there is now no high-reliability method for capping the well at a depth of over 5,000 feet; so the harm can continue to worsen for a very extended period of time.

The safety systems on the platform itself will need to be examined in detail. But the bottom line will probably look something like this: the platform is a complex system vulnerable to explosion and fire, and there was always a calculable (though presumably small) probability of catastrophic fire and loss of the ship. This is pretty analogous to the problem of safety in aircraft and other complex electro-mechanical systems. The loss of life in the incident is terrible but confined. Planes crash and ships sink.

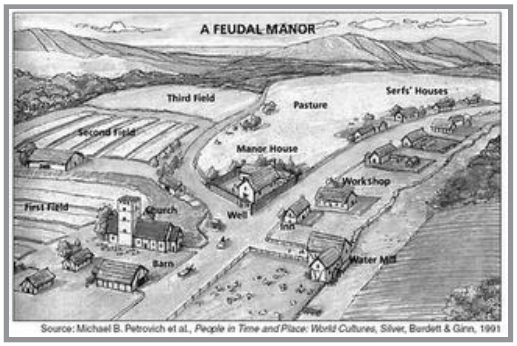
What elevates this accident to a globally important catastrophe is what happened next: destruction of the pipeline leading from the wellhead 5,000 feet below sea level to containers on the surface; and the failure of the shutoff valve system on the ocean floor. These two failures have resulted in unconstrained release of a massive and uncontrollable flow of crude oil into the Gulf and the likelihood of environmental harms that are likely to be greater than the Exxon Valdez.

Oil wells fail on the surface, and they are difficult to control. But there is a well-developed technology that teams of oil fire specialists like Red Adair employ to cap the flow and end the damage. We don't have anything like this for wells drilled under water at the depth of this incident; this accident is less accessible than objects in space for corrective

intervention. So surface well failures conform to a sort of epsilon-delta relationship: an epsilon accident leads to a limited delta harm. This deep-ocean well failure in the Gulf is catastrophically different: the relatively small incident on the surface is resulting in an unbounded and spiraling harm.

So was this a foreseeable hazard? Of course it was. There was always a finite probability of total loss of the platform, leading to destruction of the pipeline. There was also a finite probability of failure of the massive sea-floor emergency shutoff valve. And, critically, it was certainly known that there is no high-reliability fix in the event of failure of the shutoff valve. The effort to use the dome currently being tried by BP is untested and unproven at this great depth. The alternative of drilling a second well to relieve pressure may work; but it will take weeks or months. So essentially, when we reach the end of this failure pathway, we arrive at this conclusion: catastrophic, unbounded failure. If you reach this point in the fault tree, there is almost nothing to be done. And this is a totally irrational outcome to tolerate; how could any engineer or regulatory agency have accepted the circumstances of this activity, given that one possible failure pathway would lead predictably to unbounded harms?

There is one line of thought that might have led to the conclusion that deep ocean drilling is acceptably safe: engineers and policy makers might have optimistically overestimated the reliability of the critical components. If we estimate that the probability of failure of the platform is 1/1000, failure of the pipeline is 1/100, and failure of the emergency shutoff valve is 1/10,000 -- then one might say that the probability of the nightmare scenario is vanishingly small: one in a billion. Perhaps one might reason that we can disregard scenarios with this level of likelihood. Reasoning very much like this was involved in the original safety designs of the shuttle (Safeware: System Safety and Computers). But several things are now clear: this disaster was **not** virtually impossible. In fact, it actually occurred. And second, it seems likely enough that the estimates of component failure are badly understated.



What does this imply about deep ocean drilling? It seems inescapable that the current state of technology does not permit us to take the risk of this kind of total systems failure. Until there is a reliable and reasonably quick technology for capping a deep-ocean well, the small probability of this kind of failure makes the use of the technology entirely unjustifiable. It makes no sense at all to play Russian roulette when the cost of failure is massive and unconstrained ecological damage.

There is another aspect of this disaster that needs to be called out, and that is the issue of regulation. Just as the nuclear industry requires close, rigorous regulation and inspection, so deep-ocean drilling must be rigorously regulated. The stakes are too high to allow the oil industry to regulate itself. And unfortunately there are clear indications of weak regulation in this industry (link).

(Here are links to a couple of earlier posts on safety and technology failure (link, link).)

Social theory and the empirical social world

Thursday, May 13, 2010

How can general, high-level social theory help us to better understand particular historically situated social realities? Is it helpful or insightful to "bring Weber's theory of religion to bear on Islam in Java" or to "apply Marx's theory of capitalism to the U.S. factory system in the 1950s"? Is there any real knowledge to be gained by applying theory to a set of empirical circumstances?

In the natural sciences this intellectual method is certainly a valid and insightful one. We gain knowledge when we apply the theory of fluid dynamics to the situation of air flowing across a wing, or when we apply the principles of evolutionary theory to the problem of understanding butterfly coloration. But do we have the same possibility in the case of the social world?

My general inclination is to think that "applying" general social theories to specific social circumstances is not a valid way of creating new knowledge or understanding. This is because I believe that social ensembles reflect an enormous degree of plasticity and contingency; so general theories only "fit" them in the most impressionistic and non-explanatory way. We may have a pure structural theory of feudalism; but it is only the beginning of a genuinely knowledge-producing analysis of fourteenth-century French politics and economy or the Japanese samurai polity. At best the theory highlights certain issues as being salient -- the conditions of bonded labor, the nature of military dependency between lord and vassal. But the theory of feudalism does not permit us to "derive" particular features or institutions of French or Japanese society. "Feudalism" is an ideal type, a heuristic beginning for social analysis, rather than a general deductive and comprehensive theory of all feudal societies. And we certainly shouldn't expect that a general social theory will provide the template for understanding all of the empirical characteristics of a given instance of that theorized object.

Why is there this strong distinction between physical theory and social theory? Fundamentally, because natural phenomena really ***are*** governed by laws of nature, and natural systems are often simple enough that we can aggregate the effects of the relevant component processes into a composite description of the whole. (There are, of course, complex physical systems with non-linear composite processes that cannot be deductively represented.) So theories can be applied to complicated natural systems with real intellectual gain. The theory helps us to predict and explain the behavior of the natural system.

The social world lacks both properties. Component social mechanisms and processes are only loosely similar to each other in different instances; for example, "fealty" works somewhat differently in France, England, and Japan. And there is a very extensive degree of contingency in the ways that processes, mechanisms, agents, and current circumstances interact to produce social outcomes. So there is a great degree of path dependency and variation in social outcomes, even in cases where there are significant similarities in the starting points. So feudalism, capitalism, financial institutions, religions,

ethnic conflicts, and revolutions can only be loosely theorized.

That is my starting point. But some social theorists take a radically different approach. A good example of a bad intellectual practice here is the work of Hindess and Hirst in Pre-Capitalist Modes Of Production, in which they attempt to deduce the characteristics of the concrete historical given from its place within the system of concepts involved in the theory of the mode of production.

Is this a legitimate and knowledge-enhancing effort? I don't think that it is. We really don't gain any real insight into this manor, or the Burgundian manor, or European feudalism, by mechanically subsuming it under a powerful and general theory -- whether Marx's, Weber's or Pareto's.

It should be said here that it isn't the categories or hypotheses themselves that are at fault. In fact, I think Marx's analysis and categories are genuinely helpful as we attempt to arrive at a sociology of the factory, and Durkheim's concept of anomie is helpful when we consider various features of modern communities. It is the effort at derivation and subsumption that I find misguided. The reality is larger and more varied than the theory, with greater contingency and surprise.

It is worthwhile looking closely at gifted social scientists who proceed differently. One of these is Michael Burawoy, a prolific and influential sociologist of the American labor process. His book, Manufacturing Consent: Changes in the Labor Process Under Monopoly Capitalism, is a detailed study of the American factory through the lens of his micro-study of a single small machine shop in the 1940s and 1970s, the Allied/Geer factory. Burawoy proceeds very self-consciously and deliberately within the framework of Marx's theory of the capitalist labor process. He lays out the fundamental assumptions of Marx's theory of the labor process -- wage labor, surplus labor, capitalist power relations within the factory -- and he then uses these categories to analyze, investigate, and explain the Allied/Geer phenomena. But he simultaneously examines the actual institutions, practices, and behaviors of this machine shop in great participant-observer detail. He is led to pose specific questions by the Marxist theory of the labor process that he brings with him -- most importantly, what accounts for the "consent" that he observes in the Allied workers? -- but he doesn't bring a prefabricated answer to the question. His interest in control of surplus labor and coercion and consent within the workforce is stimulated by his antecedent Marxist theory; but he is fully prepared to find novelty and surprise as he investigates these issues. His sociological imagination is not a blank slate -- he brings a schematic understanding of some of the main parameters that he expects to arise in the context of the capitalist labor process. But his research assumptions are open to new discovery and surprising inconsistencies between antecedent theory and observed behavior.

And in fact, the parts of Burawoy's book that I find most convincing are the many places where he allows his sociological imagination and his eye for empirical detail to break through the mechanism of the theory. His case study is an interesting and insightful one. And it is strengthened by the fact that Burawoy does not attempt to simply subsume or recast the findings within the theoretical structure of Marx's economics.

(Burawoy addresses some of these issues directly in an important article, "Two Methods in Search of Science" (link). He advocates for treating Marxist ideas as a research program for the social sciences in the sense articulated by Imre Lakatos.)

So my advice goes along these lines: allow Marxism, or Weber or Durkheim or Tilly, to function as a suggestive program of research for empirical investigation. Let it be a source of hypotheses, hunches, and avenues of inquiry. But be prepared as well for the discovery of surprising outcomes, and don't look at the theory as a prescription for the unfolding of the social reality. Most importantly, don't look to theory as a deductive basis for explaining and predicting social phenomena. (Here is an article on the role of Marxism as a method of research rather than a comprehensive theory; link.)

Underdetermination and truth

Sunday, May 16, 2010

We say that a statement is underdetermined by available facts when it and an alternative and different statement or theory are equally consistent with that body of facts. It may be that two physical theories have precisely the same empirical consequences -- perhaps wave theory and particle theory represent an example of this possibility. And by stipulation there is no empirical circumstance that could occur that would distinguish between the two theories; no circumstance that would refute T1 and confirm T2. And yet we might also think that the two theories make different assertions about the world. Both statements are underdetermined by empirical facts.

Pierre Duhem further strengthened the case for the underdetermination of scientific theories through his emphasis on the crucial role that auxiliary hypotheses play in the design of experiments in The Aim and Structure of Physical Theory. Individual theoretical hypotheses -- "light is a wave," "people behave on the basis of their class interests" -- do not have definite empirical implications of their own; rather, it is necessary to bring additional assumptions into play in order to design experiments that might support or refute the theoretical hypothesis. And here is the crucial point: if an experimental result is inconsistent with the antecedent theory and auxiliary hypotheses, we haven't demonstrated that the hypothesis itself is false, but rather that at least one among the premises is false. And it is possible to save the system by modifying the theory or one or more of the auxiliary assumptions. As W. V. O. Quine put the point, scientific knowledge takes the form of a "web of belief" (The Web of Belief).

On the extreme assumption that both statements have precisely the same consequences, we might infer that the two theories must be logically equivalent, since the logical content of a theory is the full range of its deductive consequences and the two theories are stipulated to have the same deductive consequences. So it must be possible to derive each theory from the other. And if T1 and T2 are logically equivalent, then we wouldn't say that they really express different assertions about the world.

A more problematic case is one where two theories have distinct bodies of deductive consequences; but where the subset of deductive consequences that are empirically

testable are the same for the two theories. In this situation it is no longer the case that the two theories are logically equivalent but rather "empirically equivalent." And here it would be credible to say that the two make genuinely different assertions about the world -- assertions that cannot be resolved empirically.

A third and still weaker case is one in which T1 and T2 have distinct consequences for both theoretical statements and a specific subset of empirical statements; but they overlap in their consequences for a second body of empirical statements. And consider this possibility: Because a given level of instrumentation and inquiry limit the types of empirical statements that can be evaluated, this body of data does not permit us to differentiate between the theories. So we can distinguish between "currently testable" and "currently not testable". For this third case, we are to imagine that T1 and T2 have distinct implications for theoretical statements and for currently not testable empirical statements; but they have the same consequences for currently testable statements. In this case, T1 and T2 are currently underdetermined -- though advances in instrumentation may result in their being empirically distinguishable in the future.

It is worth noting how heroic is the notion of "determination" of theory by evidence. If we thought that science should issue in theories that are determined by the empirical evidence, we would be committed to the idea that there is one uniquely best theory of everything. This assumption of ultimate theory uniqueness might be thought to follow from scientific and metaphysical realism: the world has a specific and determinate structure and causal properties; this structure gives rise to all observations; well-supported theories are approximately true descriptions of this hidden structure of the world; and therefore there is a uniquely best scientific theory -- the one that refers to this set of entities, processes, and structures. And if an existing theory is false in description of this unobservable reality, then there must be observational circumstances where the false assumptions of the theory give rise to false predictions about observation. In other words, well-confirmed theories are likely to be approximately true, and the hidden structure of the world can be expected to create observations that refute out false theories.

However, this foundational approach is implausible in virtually every area of science. Our theories rarely purport to describe the most fundamental level of reality; instead, they are meso-level descriptions of intermediate levels of phenomena. Take the effort to understand planetary motion. The description of the orbits of the planets as ellipses generated by the gravitational attraction of the planet and the sun turned out to be only approximately true. Did this refute the pure theory of gravitation? Certainly not; rather, it raised the possibility of other causal processes not yet identified, that interfere with the workings of gravitational attraction.

So how do these general considerations from the philosophy of science affect the situation of knowledge claims in the social sciences?

It would seem that social science claims are even more subject to underdetermination than the claims of mechanics and physics. In addition to the problem of unidentified interfering causes and the need for auxiliary hypotheses, we have the problems of vagueness and specification. We commonly find that social science theories offer general statements about social causes and conditions that need to be further specified before they can be applied to a given set of circumstances. And there are almost always alternative and equally plausible ways of specifying the concept in a particular setting.

Take the idea of class conflict as a theory of political behavior. The theory may assert that "workers act on their material interests." Before we can attempt to evaluate this statement in particular social settings, we have to specify several things: how to characterize "material interests" in the setting and how to represent the cognitive-behavioral models the worker uses as he/she deliberates about action. Is retaining support from City Hall a material interest? Or are material interests restricted to wages and the workplace? Are workers thought to be rational maximizers of their interests, or do they also embody social commitments that modulate the dictates of maximization? And here is the crucial point: different specifications lead to different predictions about political behavior; so the general theoretical assertion is underdetermined by empirical observation.

This discussion seems to lead us into surprising territory -- not the limited question of underdetermination but the large question of truth and correspondence and the question of the rationality of scientific belief. Do we think that social assertions are true or false in the semantic sense: true by virtue of correspondence to the facts as they really are; or do we think that social assertions are simply ways of speaking about complexes of social phenomena, with no referential force? Is the language of class or ideology or ressentiment just a way of encompassing a range of social behaviors, or are there really classes and ideologies in the social world? And if we affirm the latter possibility, does the evidence of social observation permit us to unambiguously select the true theories?

I suppose one possible approach is to minimize the scope of "truth" when it comes to the social sciences. We might say that there is a limited range of social statements that are unambiguously true or false -- Jones robbed a store, Jones robbed a store because he was economically desperate, people sometimes commit crimes out of economic necessity -- but there is a broader class of statements that have a different status. These are more akin to interpretive schemes in literary criticism or to a set of metaphors deployed to describe a complex social situation. The language of class may fall in this category. And we might say that these statements are not truth claims at all, but rather interpretive schemes that are judged to do a better or worse job of drawing together the complex phenomena to which they are applied. And in this case, it seems unavoidable that statements like these are radically underdetermined by the empirical facts.

(See Kyle Stanford's essay on underdetermination in the *Stanford Encyclopedia of Philosophy*.)

Red shirts as a social movement

Wednesday, May 19, 2010

The redshirts in Thailand have moved onto the world stage in the past several months. Massive protests in Bangkok have stymied the Thai government and have held the army and police forces at bay for months. Demands from redshirt leaders and posters include removal of the military-backed government of Prime Minister Abhisit and a commitment to prompt elections. In the background seems to be a demand for a shift in the playing field in Thailand, with meaningful attention to social inequalities. And

exiled former prime minister Thaksin plays a continuing role in the background, offering video messages at protest meetings and veiled instructions to redshirt demonstrators. Efforts at clearing the protest encampment led to dozens of deaths in April, and a major crackdown this week seems to have succeeded in breaking the protest in Bangkok with another handful of deaths and a great deal of arson in the center of the city. But there are indications that protests and violence may spread to other parts of Thailand.

What all of this implies is the presence of a major social movement in Thailand, supported by many thousands of rural and urban Thai people, mostly from the lower end of the socioeconomic order. This much is clear through the journalism that has developed around the current turmoil. What we haven't yet seen, though, is a careful analysis of the dynamics and processes of this movement. How is it organized? How are followers recruited? What resources are leaders able to call upon? What are the grievances that motivate potential followers? The time is ripe for a careful, analytical study of the movement. And intellectual resources exist for such a study, in the form of the extensive literature on social movements and contention that exists in the current social science literature. However, that literature largely focuses on social movements in the democratic West, and scholars in this tradition generally lack deep knowledge of the politics of Asian countries. So we need to find ways of crossing boundaries if we are to make use of social movement theory in the context of the Redshirt movement.

One of the most important voices in the current literature on social contention is Doug McAdam. His study of the black insurgency in the United States is a sophisticated and extensive analysis of the dynamics of the US civil rights movement in the South (Political Process and the Development of Black Insurgency, 1930-1970), and perhaps there are some parallels between the two movements. McAdam's work is entirely focused on examples of protests and mobilization in the United States. But in the introduction to the second edition of this work he provides a clear and powerful statement of the state of the field, and his synthesis of the best current thinking about how to analyze social movements is of general interest. So perhaps this is one place to begin the search for an empirically and theoretically informed study of the Redshirt movement.

Here are a few of McAdam's central points.

Increasingly, one finds scholars from various countries and nominally different theoretical traditions emphasizing the importance of the same three broad sets of factors in analyzing the origins of collective action. These three factors are: 1) the political opportunities and constraints confronting a given challenger; 2) the forms of organization (informal as well as formal) available to insurgents as sites for initial mobilization; and 3) the collective processes of interpretation, attribution and social construction that mediate between opportunity and action. (viii)
Or in short: ***political opportunities***, ***mobilizing structures***, and ***framing processes*** (viii-ix). Here are brief descriptions of each of these axes of analysis.

Expanding political opportunities. Under ordinary circumstances, excluded groups or challengers face enormous obstacles in their efforts to advance group interests.... But the particular set of power relations that define the political environment at any point in time hardly constitutes an immutable structure of political life. Instead, the opportunities for a challenger to engage in successful collective action are expected to vary over time. It is these variations that are held to help shape the ebb and flow of movement activity. (ix)

Extant mobilizing structures. ... By mobilizing structures I mean *those collective vehicles,*

informal as well as formal, through which people mobilize and engage in collective action. This focus on the meso-level groups, organizations, and informal networks that comprise the collective building blocks of social movements constitutes the second conceptual element in this synthesis. (ix)

Framing or other interpretive processes. ... Mediating between opportunity, organization and action are the shared meanings, and cultural understandings -- including a shared collective identity -- that people bring to an instance of incipient contention. At a minimum people need to feel both aggrieved about some aspect of their lives and optimistic that, acting collectively, they can redress the problem. (ix-x)

So how can these basic sets of questions help in forming a careful analysis of the Redshirt movement? McAdam's general point is that these angles of analysis have emerged as key within dozens of studies of collective action and social movements. They represent an empirically informed set of theoretical perspectives on collective action. We shouldn't look at these three sets of factors as setting a blueprint for collective action; but it is a good bet that new instances of social movements will involve each of these factors in some way.

Putting the point another way: we can read McAdam's synthesis as posing a research framework in terms of which to investigate a new example of a social movement -- whether the Falun Gong in China, the monks' movement in Burma, the Maoist insurgency in India, or the Redshirt movement in Thailand. It is certainly possible that a given case won't fit very well into this set of questions; but McAdam's hunch is that this is unlikely.

So it would be very interesting to initiate a careful study of the Redshirt movement along these lines. Such a study would need to review the shifting circumstances of political power over the past ten years or so in Thailand, both at the national level and at the state level. Certainly the military overthrow of the Thaksin government created "ebbs and flows" of the sort to which McAdam refers. And the Yellowshirt demonstrations of 2008 also shifted the fields of power in Thailand. What openings did these various events create for Redshirt mobilization? Second, we would need to know a great deal more about the local and regional organizations through which Redshirt mobilization occurs. What are those organizations? What resources do they control? How do they manage to succeed in mobilizing and transporting many tens of thousands of rural supporters to the center of Bangkok? And how do they manage to continue to supply and motivate these supporters through several months of siege? Finally, and most importantly, we need to know much more about the mentality and social identities of the Redshirts. What do they care about? What are their local grievances? What are their most basic loyalties and motivations? McAdam points out that most studies of successful social movements have found that activists and supporters usually possess dense social networks and deep connections to their communities; will this turn out to be true for the Redshirt movement?

There is a cynical reading of the movement that would almost certainly not stand up to this kind of careful analysis: the idea that the Redshirts are simply the pawns of Thaksin, and that Thaksin's financial support to individual followers is sufficient to explain their behavior. This doesn't seem credible on its face; it makes the movement out to be an automaton controlled by a distant leader. Surely Thaksin plays a role; but equally certainly, leaders and followers have their own issues, agendas, and passions.

The kind of study suggested here does not yet exist, so far as I can tell. It would be necessary to pull together a great deal of local knowledge about the social constituencies and local organizations that are involved in the movement -- information that isn't

presented in any detail in the journalism that has been offered to date about events in Thailand. But once a researcher has pulled together preliminary answers to questions in each of these areas, he/she will be much better positioned to answer pressing questions of the day: will the movement survive the repression in Bangkok this week? Will it spread to other locations in Thailand? Will the government succeed in preserving the status quo? And schematic answers to these questions would provide a much more substantial basis for understanding the movement and its location within Thai society.

Here is one small contribution to the effort. McAdam emphasizes the importance of "identity shift" in the evolution of a social movement. He thinks that a very substantial part of a movement's strength and staying power derives from the new forms of collective identity that it creates. There is evidence of shifting identities along these lines within the Redshirt movement. Consider this interesting analysis of language from Thailand's Troubles:

ไพร่, which sounds like prai, was a dusty word which rarely saw the light of day. Now on every other t-shirt worn by people of the Red movement printed large and proud is prai.

Prai has perhaps a dozen meanings including cad, citizen, plebian and proletariat. In the context of the Red movement protest, which includes an element of class conflict and rebellion over inequality, prai frequently means commoner and peasant.
This sounds quite a bit like a shift of identity, from disregarded poor person to proud member of a movement.

(Several earlier posts have focused on events in Thailand. Here is a post from about a year ago on civil unrest in Thailand. See also the social movements thread in *UnderstandingSociety*.)

The dropout crisis

Thursday, May 20, 2010

The United States faces a huge dropout crisis. In some cities the high school graduation rate is less than 50% -- sometimes as low as 25%. And this means devastating poverty for the dropouts, as well as continuing social blight for their communities. We might say, though, that the graduation rate is only the *symptom* of the problem; the causes include high poverty neighborhoods and failed elementary and middle schools, and the effects extend far into the future.

So in a way, it is too simple to call it a dropout crisis; rather, it is a schooling crisis (extending back into the early grades) and a poverty crisis (extending forward for one or more generations for the young people who are affected and their eventual children). And it is a particularly serious national problem, at the beginning of a century where the most important resource will be educated people and talented creators. How can we be optimistic about the prospects for innovation and discovery in the American economy when we are wasting so much human talent?

The crisis itself is widely recognized (link). What we haven't figured out yet is a success strategy for resolving the current system of failure. Is it even *possible* to envision a system of public education in high-poverty cities that actually succeeds in achieving the 90-90-90 goal (90% graduation rate, 90% achievement at grade level, 90% continuation to post-secondary education)? Or are we forced to conclude that the problem is too great, and that 50% of inner-city children are doomed to lives of continuing poverty and social blight? If so, the future is dim for our county as a whole: rising crime, social problems, civil conflict, and increasingly gated communities are our future. And, inevitably, our economic productivity as a country will falter. So the whole country loses if we don't solve this problem.

The current environment for solving the schooling problems is unpromising. Urban school systems across the country face staggering fiscal crises -- a $300 million deficit in Detroit, $480 million in Los Angeles, and similar amounts in other cities. So school systems are forced into a cycle of cost-cutting, removing some of the critical resources that might have addressed the failure for their students. And the school systems themselves -- administrators, teachers, and unions -- are all too often resistant to change. The current Federal educational reform program, Race to the Top (link), is designed to stimulate new thinking and more successful reforms; but the jury is out.

The situation requires a whole-hearted commitment to solving this problem. Solutions will require the best available research on learning and schooling; they will require substantial resources; and they will require significant collaboration among a number of stakeholders. And the solutions can't be simply one-off demonstration projects; we need a national strategy that will work at scale. There are a million new drop-outs a year. We need to reduce that number by 80% in the next decade if we are to be successful.

These are pretty daunting challenges. So consider this proposed solution that seems to have the ability to satisfy each of these constraints. This is the Diplomas Now program that is becoming increasingly visible in education reform and the press (link). The program is a research-based strategy for helping children make academic progress at every step of the way. It recognizes the need for much more intensive adult contact for at-risk children. It acknowledges the need for providing a host of community services in high-poverty schools. And it places high academic standards at the center of the strategy.

The program is based on important research undertaken by Robert Balfanz at Johns Hopkins University (link). Balfanz finds that it is possible to identify high school drop-outs very early in their school experience. He identifies the ABC cluster of criteria as diagnostic of future high school failure: **a**bsenteeism, **b**ehavior, and **c**ourse performance. Sixth-graders who show any one of these characteristics have only a 25% likelihood of completing high school. So, he reasons, let's use these early warning signs and intervene with children when there is still an opportunity to get them back on track. This requires careful tracking of each child, and it requires that schools have the resources to address the problems these children are having in the early grades. But Balfanz argues that the payoff will be exactly what we need: these children will be back on track and will have a high likelihood of graduating from high school.

So what does the strategy need? First, it needs a good and well-implemented tracking system. Second, it needs teachers and principals who have the professional development needed to allow them to assist the progress of their students. But it needs two other things as well: it needs a corps of dedicated young people who will function as fulltime near-peer tutors and mentors for at risk children. And it needs a set of wrap-

around social and community services that are available to children and their families in the schools.

This is where community service and stakeholder collaboration come in. CityYear is a vibrant national youth service organization within Americorps (link). CityYear has always placed involvement in high-poverty schools at the core of its service agenda for the young people who give a year of their lives to change the world. Now CityYear has entered into agreements with the Diplomas Now program to support focused interventions in a growing number of schools in a number of cities. (Here is a CityYear report.) And Communities in Schools is a national organization that is able to provide the other piece (link). Communities in Schools provides several social work professionals and supervision for each DN school. Finally, the Talent Development program at Johns Hopkins provides training for DN teachers and administrators.

The Diplomas Now model has now been applied in a number of schools around the country, and the results are highly encouraging (link). Results for a sixth grade class in Feltonville School in Philadelphia are representative: from 2008 to 2009 absenteeism dropped by 80%, negative behavior dropped by 45%, and the number of students with failures in math or english dropped by about 80%. Participants and observers attribute the successes measured here to the synergies captured by the combined approach. But a key factor is the presence of caring young adults in the lives of these children. (video)

These are amazing and encouraging results. But we have to ask the question, what would it take to scale this solution for all of Los Angeles, Detroit, or Chicago? The answer is that it will require a major investment. But it will also return many times that amount in increased productivity and lower incarceration and social service costs.

Here are some estimates from CityYear planning for the challenge of scaling up the Diplomas Now solution. The goal the organization has adopted is an ambitious one: to have CityYear teams in all schools that generate 50% of dropouts in the city. In Detroit CityYear teams currently serve 8 schools and 4,600 students with 65 corps members. In order to reach the goal, CityYear Detroit will need to expand to 39 schools, serving 26,290 students, including 9,400 at-risk students, with 403 corps members. This expansion will be costly; federal, school, and private funding would increase from $3.8 million to $12.8 million. But the five-year return on investment is massive. A Northeastern University study estimates the benefit of converting one dropout into a graduate at $292,000, aggregating to a net social benefit of $686,000,000. The returns are enormous. Nationally the total annual cost of the CityYear program would be just under $200 million by 2016, with other program costs perhaps doubling this amount. But the value of success is a staggering number: net social benefits from reducing the drop-out rate estimated in the range of $10 billion.

So it seems that we now know that the skepticism that is often expressed about inner-city school failure is misplaced. There are intensive strategies for success that should work in any school. There is a cost to these programs. But there are many thousands of young people who are eager to pick up the responsibility. Their civic engagement and pragmatic idealism are inspiring. We need strong support from our government, foundations, and private sources in order to make school failure a thing of the past.

(Here are a couple of earlier posts on this topic; post, post, post.)

Doug McAdam on contentious politics and the social sciences

Saturday, May 22, 2010

Doug McAdam is hard at work shedding new light on the meso-dynamics of contention. What are the specific social and psychological mechanisms that bring people into social movements; what factors and processes make mobilization more feasible when social grievances arise? Recently he has done work on the impact of Teach for America on its participants, and he and his graduate students are now examining a set of environmental episodes that ***might*** have created local NIMBY movements -- but often didn't.

McAdam's most sustained contribution to the field of contention is his 1982 book on the dynamics of the struggle for racial equality, Political Process and the Development of Black Insurgency, 1930-1970. The book was reissued in 1999 with a substantive new introduction, and it has set the standard for sophisticated sociological study of a large, complex movement. McAdam collaborated with Sidney Tarrow and Chuck Tilly in articulating a new vision of how to approach the politics of contention in Dynamics of Contention. And he has co-authored or co-edited another half dozen books on social movements and popular mobilization. So McAdam has been one of the architects of the field of contentious politics. Most importantly, he and his collaborators have brought innovative new thinking to the definition of problems for social research.

So it is valuable to dig into some of McAdam's thoughts and his sociological imagination as we think about how the sociology of the future might be shaped. I conducted an extensive interview with Doug earlier this month, and it opened up quite a few interesting topics. The full interview is posted on YouTube (link).

There are quite a few important turns to the conversation.

1. **Segment 1:** Why is the study of contention a central topic within the social sciences?
2. **Segment 2:** How can we approach contention without looking only at the successful cases? How about the moments where contention might have developed but did not? We can combine quantitative and qualitative methods -- perhaps in an order that reverses the usual approach. Maybe we can use quantitative studies to get a general feel for a topic, and then turn to qualitative and case studies to discover the mechanisms.
3. **Segment 3:** Another important theme: "We are voracious meaning-making creatures." Human beings have a cognitive-emotional-representational ability to attempt to represent meanings and their own significance within the larger order. Rational choice theory has too narrow a conception of agency. Why did the Black

community stay off the buses in Montgomery? Because people were strongly enmeshed in communities of meaning and commitment that framed the bus boycott in terms of meaning and identity.

4. **Segment 4:** The psychology of mobilization is complex. It's not just "rational incentives". Organizers and leaders use the affinities and loyalties of the community to bring about collective action. For example, an interesting strategy by SNCC to "shame" church leaders into supporting activists. Movements happen very suddenly; this seems to reflect a process of "redefining" the situation for participants. Another interesting issue: what is the right level of analysis -- micro, meso, or macro? Doug favors the "meso" level.
5. **Segment 5:** More on the meso level: disaggregated social activity. McAdam argues that government actions are themselves often at the meso level. And he makes the point that Civil Rights reform was strongly influenced in the United States by the issues created internationally through the tensions and ideological conflicts of the Cold War. This explains why it was Truman rather than Roosevelt who endorsed the need for Civil Rights reform. You can't explain the broad currents of the Civil Rights movement without understanding the international context that was influencing the Federal government. (This is an example of a macro-level effect on social movements.)
6. **Segment 6:** Now to mechanisms and processes. There are no laws of civil wars. So we need to look downward into the unfolding of the episodes of contention. Comparative historical sociology is a very dynamic movement today. Your work isn't quite as comparative as that of Tilly or McAdam. Doug indicates that he favors comparison; but he tends to choose cases that are broadly comparable with each other. Tilly often made comparisons at a much higher level of variation. Q: Would you have been comfortable framing your study of the American Civil Rights movement as a comparison with the Solidarity Movement in Poland? A: no. There is too broad a range of differences between the cases.
7. **Segment 7:** McAdam offers some interesting observations about the relationship between general theory and the specific social phenomena under study. An important point here is a strong advocacy for eclectic, broad reading as one approaches a complex social phenomenon. We can't say in advance where the important insights are going to come from -- anthropology, political science, history, sociology, ...
8. **Segment 8:** We can dig into the social features that make certain figures very successful in bringing a group of people into a readiness to engage together. Is social status a key factor? Is it that some people are particularly persuasive? Doug wants to break open the black box and get a lot better understanding of the meso-level processes and mechanisms through which mobilization occurs. A closing topic: what about protest and mobilization in Asia? Do you think these ideas about mobilization are relevant and illuminating in China or Thailand? Or has it developed in too specific a relationship to democratic societies? Does the current understanding of popular mobilization help us when we try to understand movements like the Redshirt movement in Thailand? Doug believes the framework is relevant outside the democratic West. The ideas need to be applied loosely and flexibly.
9. **Segment 9:** So the theory is really a "sketch" of the space of mobilization, rather than a set of specific hypotheses about how mobilizations always work. And in that understanding -- the field is very relevant to research on the Thailand movement.

(Note the strong connections between this discussion and a few of the earlier interviews -- Tilly, Tarrow, and Zald in particular (link). My interview with Gloria House about her experience with SNCC in Lowndes County is very relevant as well (link).)

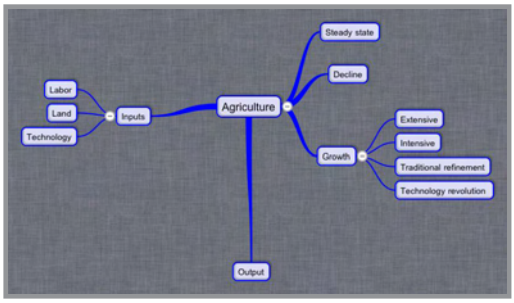
Varieties of economic progress

Tuesday, May 25, 2010



The study of economic history reveals a number of different patterns when it comes to agricultural production and the standard of living of a given population in a region. Let's think about the issue in very simple terms. Imagine that the standard of living for a population in a region is determined by the amount of grain that each household is able to acquire in a time period. Grain is produced on farms using labor and technology (water, traction, fertilizer, pesticides, harvest tools). Output is influenced by the existing agricultural technology and the quantity of labor expended in the farming process. At a given level of technology and a given practice of labor use, a certain quantity of grain Q can be produced for the population P (farmers and their families). If population is stable and if land area, technology, and labor use remain constant, then the total amount of grain produced remains constant as well and the standard of living remains level at Q/P.

Now several things can begin to change. First, consider a steady population increase over time. If land, technology and labor remain constant, then the standard of living falls, since Q remains constant while P increases. So how can this population sustain and perhaps improve its standard of living? It needs to increase the output of grain at a rate at least equal to the rate of increase in population. And this can be done in several ways.

First, the population can bring more land into cultivation. Population increase leads to more farm labor; more farmers can farm the additional land; and if agricultural technologies and practices are unchanged, then output will increase proportionally to the increase in population; so the standard of living will remain constant. This assumes, however, that the new land is of equal productivity to existing land; but as the physiocrats observed, generally new land is of lower productivity. So in this scenario, output would increase more slowly than population, and the standard of living would slowly decline. We might call this ***extensive growth***; technique and labor practices remain constant, but the arable land area increases (at the cost of deforestation and loss of common lands).

Second, more labor can be applied to the process of cultivation to increase output, using traditional farming practices. More frequent weeding and destruction of pests takes time, but it increases output. So if population is rising and land extent and productivity are constant, it is possible to offset the tendency for average output to fall, by applying more labor to the process. Family labor, including children, can be expended more and more intensively in order to achieve additional gains in output. But, of course, the marginal product of these additional hours of labor is small. This process is familiar from the history of agriculture; Chayanov calls it "self-exploitation" (The Theory of Peasant Economy) and Clifford Geertz calls it "agricultural involution" (Agricultural Involution: The Processes of Ecological Change in Indonesia). The standard of living may remain fairly constant, but the work load for the farm family increases over time. Naturally, this process reaches a limit; eight hours a day of farm labor is sustainable; twelve hours is difficult; and eighteen hours is unsupportable. (Here is an explanation and application of Chayanov's theory to the circumstances of Sri Lanka; link.) We can call this ***involutionary growth or labor-intensive growth***.

A third possibility is somewhat more positive for the standard of living and quality of life. Intelligent farmers can recognize opportunities for improving and refining existing techniques and practices. A better kind of sacking material may do a better job of protecting the harvest from rats; a bicycle-powered irrigation pump may increase the amount of water available for crops, thus increasing the harvest; a different form of labor cooperation across households may permit more effective seeding during the appropriate season. So the traditional practices can be refined, permitting an increase of output with a constant quantity of land and labor. This is what Mark Elvin refers to as "***refinement of traditional practices***" in his pathbreaking analysis of the "high-level equilibrium trap" (The Pattern of the Chinese Past). It is an incremental process through which the productivity of the traditional farming system is increased through a series of small refinements of practice and technique. Improvement in productivity permits an improvement in output per person; but if population continues to increase, then soon these gains are erased and the standard of living begins to decline again.

A fourth possibility is even more dramatic. The fundamental technologies in use may be qualitatively improved: manure may be replaced by bean curd, which in turn may be replaced by chemical fertilizers; seed varieties may be significantly improved through selective breeding; electric-powered pumps may improve the availability of irrigation; small tractors may replace oxen and many person-hours of labor. This kind of improvement in productivity can be represented as a jump from one of the heavy curves above to a higher "production possibility frontier." And this enhancement of agricultural productivity can result in massive increases in the quantity of grain relative to the farming population -- thereby permitting a significant improvement in the standard of living for the farming population. This can be referred to as ***modern technological productivity growth***.

Two problems arise at this point, however. First is Elvin's fundamental point about Chinese agriculture: these significant technological improvements require a significant social investment in scientific and technical research. And if a population has already approached a subsistence trap -- a level of population at which intensive labor and existing farm technology only permits a near-subsistence diet for the population -- then

there is no source of social surplus that can fund this research investment. (This is the core of his theory of the high-level equilibrium trap: farming techniques and practices have been refined to the maximum degree possible, and population has increased to the point of subsistence.)

Another problem is equally important. The sorts of productivity improvements described here are "labor-expelling": the size of the labor force needs to fall (unless more land is available). So the standard of living may rise for the farm population; but there will be a "surplus population" that is excluded from this improvement in productivity. (This is a process that James Scott describes in Green-Revolution Malasia in Weapons of the Weak: Everyday Forms of Peasant Resistance.) And at this point, the only hope for improvement of the standard of living for this segment of the population is for economic growth in another sector -- manufacturing or service -- where the labor of displaced farmers can be productively used.

So there are three large patterns, with several structural alternatives among the growth scenarios.

(See several earlier posts on farming, agriculture, and development; link, link, link.)

Prosperity based on commodities

Friday, May 28, 2010

An earlier post looked at economic prosperity and standard of living from the point of view of a grain-based agricultural economy. There I singled out intensive, extensive, and technology-based growth, and the effects these scenarios had on the standard of living for a farming population. This is a particularly simple case, since it equates standard of living with food availability per capita. (This is enough, however, to arrive at credible estimates of the standard of living over long stretches of Chinese history, as Bozhong Li has demonstrated in Agricultural Development in Jiangnan, 1620-1850.) This simplification leaves out markets, prices, and trade; so it doesn't shed much light on economies based substantially on the production of commodities (including farm products, but also including manufactured goods). So how does the situation change when we postulate production for exchange and consumption based on cash income?

Let's once again consider an isolated region, where all products consumed are produced in the region. So there is no interregional trade. And let's suppose there are three goods: grain, shirts, and beer. Every household needs some of each, and households acquire income through ownership of resources: land, capital, and labor power. The income available to a household is the net return it achieves through use of its resources. Goods are produced by "firms" and are bought and sold through competitive markets.

Now to estimate a household's standard of living we need to do a more complex estimation: we need to estimate the household's income and we need to estimate the

"purchasing power" of this income in terms of the baskets of goods this income can purchase at prevailing prices. So we need an income model and a price model for the three goods. (See Robert Allen's detailed efforts at answering these questions across Eurasia (link, link).)

Production requires access to resources. Each resource can be used in two basic ways: it can be used directly by its owner in production, or it can be "rented" to a firm for use by the firm in production. So there is also a competitive market for resources: rent for land, interest for capital, and wages for labor. And at any given time there is a specific distribution of resources across population; some households have dramatically more of each resource than others.

We can begin our thought experiment by taking as fixed the techniques of production that exist for the three basic commodities. In order to produce at a given level of output, the firm needs access to a known quantity of resources, in a specific proportion. Firms amd households with lots of resources can begin producing shirts, beer, and grain immediately. Poor firms and households will either rent access to more resources through promise of future rents; or they will rent out the resources they currently possess, including labor time. So landless, propertyless households have no choice but to sell their labor time; they become workers. So now let's picture our region as populated by firms and households producing commodities, and all persons functioning as consumers purchasing a bundle of commodities for life needs.

So far we've provided a scene very familiar from the classical political economists and Marx. Much of subsequent economic thought went into solving various parts of this story: what determines prices, what does the distribution of income look like, and how do innovation and organizational and technological change fit into this story? What does an equilibrium of production, consumption, and price look like with static technology? What are the dynamic processes of adjustment that occur when there is a substantial change in the process of production?

My question here is a limited one: what needs to occur in this scenario in order for there to be a rising trend in the average and median standard living for this society?

Let's define the standard of living as the size of the wage basket available to the ***median*** consumer: the sets of baskets of grain, shirts, and beer that the median income earner is able to purchase. In order for the standard of living to rise in this isolated region, there needs to be an overall increase in the efficiency and productivity of the production process for the three goods. And the money wage of the median consumer needs to rise. (Amartya Sen provides quite a bit of analysis of the meaning of the standard of living in The Standard of Living.)

Let's refer to the concrete production process at a given time as the current practice; this is the specific way that inputs are organized in order to create the output. As we saw in the graph of output against time borrowed from Mark Elvin (link), we can think of progress here in two ways. First, there is refinement of practice, as producers gradually recognize small modifications that permit removal of costs from the process. And, as Marx and Smith agree, firms and households producing goods for a market have a powerful incentive to seek out these improvements: they can continue to sell their products at the old price until the rest of the producers catch up.

Second, producers can introduce substantial, revolutionary changes in technology. They

may replace skilled sewing-machine operators with sewing robots that reduce each of the inputs into the good. Productivity takes a big stride forward.

There is a third mechanism of cost reduction available: the firm/household may speed up the labor process, lengthen the working day, or lower the wage. Volume I of *Capital* goes into detail on each of these mechanisms within a market-governed firm. And each of these approaches is negative for the quality of life of the working class.

Now let's get back to the question of the standard of living. Does the process of competition, rising productivity, and falling prices imply an improvement in the standard of living? Or, conceivably, does it lead to a paradoxical immiseration of the bulk of the population? Both outcomes are possible. Rising efficiency and productivity have permitted our little society to produce a rising quantity of beer, grain, and shirts. And this on the basis of a fixed level of basic resources. So in principle everyone may be better off. But it is possible as well that the benefits of rising productivity have been disproportionately captured by a small advantaged group. So income may have become increasingly concentrated at the top. The average wage basket will have increased. But the median consumer may have declined through that process of concentration.

What this story tells us is something fairly simple: the effects of productivity improvement within a commodity economy depend critically on the prior distribution of assets and the institutions through which income and the gains of efficiency are distributed. And this in turn suggests a point much like that of Robert Brenner: the social-property relations embedded within an economy are critical in determining the fate of the median person, and they are subject to profound political struggle (post).

It would be very interesting to use agent-based modeling software to represent a series of scenarios based on this description of a commodity-based economy undergoing growth. What do distributive outcomes look like when the prior distribution is relatively equal? How about when they are substantially unequal? How much difference does the timing of growth make on the eventual distributive and welfare characteristics of the scenario?

(Piero Sraffa's Production of Commodities by Means of Commodities : Prelude to a Critique of Economic Theory picks up some parts of this story in a neo-Ricardian way; Marxian economists have looked at Sraffa's work as also providing a novel basis for the labor theory of value. The framework provided here also leads into an argument for a new definition of exploitation by John Roemer in A General Theory of Exploitation and Class.)

Real Utopias

Tuesday, June 01, 2010

It is worth thinking a bit about the intellectual project of envisioning a utopia. By definition, a utopia is a vision of a social order that is profoundly different from the real historical circumstances and institutions in which we live. It would correct important flaws in the social world we currently inhabit. It is a social order that does not yet exist. And there is an implication that this better social order is not simply a marginal improvement over the

current world, but rather a sweeping revamping of the institutions and practices that create the social order. To be a utopian thinker is usually to have an intellectual disposition of impatience for small, gradual change. Mill was patient and gradualist -- and not utopian; Marx was impatient and revolutionary -- and utopian.

So to think about a utopia, we need to have a set of values that specify the features that we would like to see in the social institutions that govern us. Such a system of values provides the basis for social criticism. These might include moral equality of all human beings, or the freedom of all human beings, or the intrinsic importance of community, or a preference for a world in which each individual is in a position to realize his/her full human potential. As social critics, we hold up the values, and we measure the current functioning of social relations and institutions to see how well or badly they conform to the value prescriptions. How free or equal are individuals within these institutions? How good is the sense of community that actually exists? And we criticize the actual on the grounds of its divergence from our moral ideals.

So envisioning a utopia requires that we have a basis for social criticism, grounded in a social philosophy specifying some system of important values. But it requires something else as well: a credible argument for the feasibility of a concrete and specific set of institutions that do a better job with respect to the values -- without simultaneously creating new harms that are even more terrible. This is a call for a science of the hypothetical alternative: "Here is how this complex set of institutions should be expected to work if they were established and were populated by ordinary human beings." This is one part of the story where the social sciences can help; social scientists have a lot to say about how institutions work, and how alternatives might function as well.

Here is an example. A Chinese social critic in the 1930s might have observed tenant peasant farming in North China; he/she might have argued that the system was exploitative, unfair, and inefficient (three different social values); and he/she might have argued that the collective farm was a superior alternative, being more democratic, fair, and efficient. The collective farm might have been offered as a utopian alternative to tenant farming.

This is where careful institutional analysis is required, and the analysis needs to be rigorous and empirically and theoretically informed. What incentives would be established by the collective farm? How would authority be exercised? Who would make important decisions? And how would ordinary human behavior be conducted when it came to labor, consumption, and power relations? We might hope that this careful effort at analysis would have arrived at some important results:

"There will be a lot of 'easy riding' because of public goods problems; there will be a lot of

petty tyranny because of the vacuum created by the institutions when it comes to collective decision-making; and there will be chronic over-consumption because food is a common resource."
So the collective farm is likely not to be a utopian solution to China's rural problems in 1930. And in fact, subsequent history confirms this conclusion; the Great Leap Forward famine was the consequence of many of these institutional failures.

But let's say that our institutional analysis indicates that a given system of institutions would work as advertised. The next thing we need is a theory of a feasible pathway through which these institutions could be established; a pathway of how we might get from here to there. It may be that there is a stable equilibrium of stacked dominoes embodying a certain topological structure; stable simply means that, once established, the configuration will survive small shocks. But this isn't very useful information if there isn't any way to get the dominoes into that configuration through a series of incremental steps. So to engage in "real utopian" thinking, we need to have some theories of pathways of change that are realistic when applied to real people.

So utopian thinking requires critique; envisioning of alternatives; and discovery of pathways from here to there.

How can social theory and social research help inform our thinking about "utopian alternatives"? And what is a "real utopia"? The Real Utopias project has been going for almost twenty years now (link). And some of the most interesting thinkers writing today in social philosophy and criticism have been involved -- Erik Olin Wright, Josh Cohen, Joel Rogers, John Roemer, and Archon Fung, for example. One of the most recent titles to come out of the project is Deepening Democracy: Institutional Innovations in Empowered Participatory Governance (Real Utopias Project) (v. 4), by Archon Fung and Erik Olin Wright.

Erik Olin Wright talks about the underlying rationale for the project in this fascinating interview by Valerio Bacak (link). Here is how Wright sets up the problem:

The Real Utopias Project is, in a sense, a response to a deep problem within the Marxist tradition. Here’s the issue: Marxism is, above all, an emancipatory critique of capitalism. It identifies an array of oppressions and harms generated by capitalist relations and dynamics and then makes the extraordinary claim that these harms could be eliminated if capitalism was radically transformed. This kind of system-level, radical critique of the basic structures of society requires a huge leap of imagination: how is it possible that the basic institutions of society, which seem so natural to most people, could be radically changed without generating chaos and massive perverse consequences?
And here is his preferred approach:

Develop a coherent, positive social scientific theory of feasible alternative institutions without attempting a prediction of their likely emergence. The idea is to explore alternative designs of institutions in terms of three criteria: first, to what extent would the institutional design, if implemented, contribute to the realization of emancipatory values of one sort or another; second, in what ways might the institutional design generate perverse side-effects and are their plausible strategies for countering these; and third, if implemented, is the institutional design sustainable, does it generate a social dynamic that reinforces rather than systematically undermines its own conditions of possibility. I refer to this strategy as envisioning real utopias: “utopias” insofar as the agenda is anchored in vision of emancipatory social change; “real” insofar as the analysis revolves

around institutional feasibility. This is a wide-open theoretical and empirical agenda. It involves explorations of theoretical proposals which have no immediate real-world exemplars as well as empirical cases in which efforts at constructing, not just envisioning, real utopias have occurred. The premise of this third strategy is that while there are real limits on the possibilities of emancipatory futures that cannot be breached simply by an act of will, those limits are not fixed independently of our beliefs about what is possible. While it is false that “where there is a will there is a way” it is nevertheless the case that without a “will” many “ways” become impossible, and envisioning real utopias is part of the process of creating a will for change.

What the Real Utopias project is aimed at validating, most fundamentally, is the idea of emancipatory agency: that it is possible for us humans to restructure our social institutions in a direction that fits our fundamental values better than the present institutions do. And it is worth underlining how important, but also how risky, this effort is: important, because it gives a basis for thinking that we can create a better world; and risky, because many of the worst historical experiences of modern memory came from "utopian" efforts to redefine society. (This is a point that James Scott makes in Seeing Like a State: How Certain Schemes to Improve the Human Condition Have Failed (link).)

What now for Michigan?

Monday, June 07, 2010

The Detroit Regional Chamber Leadership Conference at Mackinac has come and gone. Leaders from all sectors in Southeast Michigan participated in discussions about how the state might move forward and regain the vitality and quality of life that the state has lost in the past decade. All agree that the state faces very tough challenges. And solutions and strategies were put forward. Central themes included a range of strategies -- Create more jobs.... Improve K-12 schooling.... Create and retain more college graduates.... Improve the climate for business and entrepreneurs.... So there are ideas about what is needed, and there are organizations investing effort in achieving some of these goals.

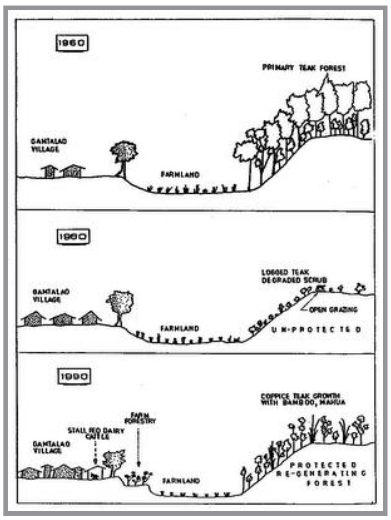
So why might one board the ferry from the island with a sense of disappointment? For a few reasons. First, there are a number of critical social issues that got no public discussion at all: the persistence and depth of urban poverty in each of Michigan's cities, the continuing reductions the state is imposing on the social services budgets, the enduring inequalities the state accepts along racial lines, and the state's stubborn refusal to face up to its fiscal crisis, to list several. One might imagine that these problems would disappear if and when the state's economic crisis abates; but I'm not persuaded of that.

A more fundamental source of disappointment is the lack of serious, realistic analysis of the problems we face in the state and what interventions might actually succeed in addressing them. The lack of realism in these discussions is often truly staggering. There are exceptions, of course; for example, Lou Glazer's efforts at Michigan Future are data-driven (link), and the Citizens' Research Council has done great work on the fiscal crisis

of the state (link). But all too often various political and business leaders have picked out one small issue and have tried to present it as a comprehensive strategy. For example, leaders in state government tout the opportunity represented by alternative energy and the manufacture of windmills. But there is no honest calculation of the likely scope of labor force demand created by this sector; and to date, the numbers are tiny. The state has lost over 800,000 jobs in the past eight years, and windmill manufacture has the potential to employ a few thousands. So how can this be a realistic avenue for "putting Michigan to work again"?

Similar comments might be made about the idea that Michigan should focus on biotechnology. The state has assets in this field, to be sure, including world-class researchers in many of its universities. But how many states and regions have already declared themselves for the future of biotechnology (including Pittsburgh, several of whose leaders spoke at the conference); and how many are likely to succeed? So picking out alternative energy and biotech as the primary areas of growth in the state sounds sexy but unrealistic.

More credible is a broad strategy of improving the human capital and quality of life of the state. Logically, it makes sense that dramatic improvement in K-12 education, educational attainment, and college graduation will add a broad-based and fungible resource to the state's arsenal for productive activity in the future. And equally, it seems very logical that creating appealing, safe, and fun cityscapes will be conducive to productivity, quality of life, and business growth. (These are Richard Florida's central insights in the CreativeClass.) So investments in education and the urban environment seem to be very practical ways of increasing the prosperity of the state in the medium run. (The unemployment rate of baccalaureate adults is about 1/3 that of high school graduates in the state right now.)



But significantly, each of these areas of public investment has declined in the past 8 years. State support for K-12 and post-secondary education has declined significantly over the past eight years. All cities and municipalities in Michigan are facing a current and severe fiscal crisis because of declining property values and revenue sharing, and this crisis will get dramatically worse in the next 5-10 years. So improving urban quality of life is not being supported either. (Proposal A makes matters worse, since it means that it will take many years for cities to regain the tax base they lost during the real estate meltdown in the past several years; link.) So the result is that Michigan is disinvesting in exactly the factors that hold out the greatest promise for improvement in the next 15 years.

It is possible that there is no intelligent solution to Michigan's crisis -- no smart strategy that could be pursued by public and private organizations that would do this set of things in order to bring about that set of good results. It is possible that regions come out of economic tailspins only through a lot of trial and error, and sometimes they come out in a much reduced state. Nothing guarantees that the end of this story will be a happy one, resulting in a prosperous society of 10-12 million people moving forward confidently. In other words, it may be that repairing deep economic and social damage is essentially beyond our ability. But one would want to think otherwise. We would want to think that there are investments and reforms that can be adopted now that will make recovery most likely and full. And we would want to think that it is possible to identify some of the broad structural obstacles to productive growth, and work to remove these. Each of these efforts is likely to bear fruit -- much as a baseball team increases the odds of success by recruiting and cultivating strong players, working on the essentials of teamwork, and removing the process issues that may be in the way of success.

Social progress

Tuesday, June 08, 2010

What is involved in "making society better"? What do we have in mind when we aspire to improving society? I suppose there are several things we might mean by this idea. Superficially we might say that a society is better off when its members are better off; but is there more to the story? There seem to be several different lines of thought to pursue.

First, we might have a small number of dimensions of goodness in mind -- something like a social welfare function -- and we might understand social progress as ***aggregate improvement with respect to these dimensions of welfare***. Social progress is defined as "aggregate improvement in quality of life for the population" (income, health status, freedom), and it is achieved through a series of steps in which one or more of these measures is improved. This definition is potentially more complex than a utilitarian moral theory, but it shares the basic structure with utilitarianism. It defines the good of society as the sum of the goods of individuals in society. (We might also have a theory about the processes through which these improvements need to take place; for example, we might say that all improvements need to be Pareto-improving: making some better off without reducing the welfare of anyone.)

Second, we might have a list of specific current social defects in mind -- the widespread fact of urban homelessness, the incidence of childhood obesity, or the incidence of violence in society -- and we might define progress as the reduction or elimination of these defects. Social progress is the result of ***sequential reduction of social harms***.

Third, we might have a set of moral-structural theories in mind: fairness, equality, democracy, self-determination. And we might define progress as a reform of institutions that increases one or more of these features of society. We might be thinking here along the lines that Rawls suggests in talking about imperfect justice; improving society means ***reforming unjust institutions and practices***. Or it means reforming institutions that unnecessarily interfere with citizens' freedoms. Or it means reducing the ways in which institutions treat citizens unequally. This differs from the standard-of-living definition, in that it looks at the characteristics that need to be addressed as relational and systemic characteristics, not simply aggregates of the wellbeing of the individual members of society. A society is better when it is more just or more free. Here we might find ourselves in a position of saying that "Society A is in a better position than society B, even though citizens of B have a higher level of material wellbeing than those in society A." Apartheid was a particularly egregious example of a systemic defect in a society, and it required fundamental structural change to improve the apartheid society. Current discussions of democratic institutions fall in this category; the idea is that institutional reforms can create new procedures that better embody the ideals of democracy.

Fourth, we might have in mind the important point that social institutions and practices

work in very specific ways and have differential effects on different groups of people in society. So we might have in mind the idea of improving the workings of the basic institutions of society -- improve their ***effectiveness and efficiency***, or improve their ***equity*** in terms of their effects on different groups. This is analogous to the goal of "making the air transport system better": we look at the goals the system serves and the practices and procedures through which it does this, and we try to design better procedures to accomplish the goals of the system. We might notice that the environmental regulations governing the siting of hazards tend to disfavor poor people, and we might try to make them more democratic. Or we might notice that land-use permitting processes are very cumbersome in many cities, thus discouraging new and productive uses of land, and we might try to change them in the direction of greater efficiency. Each effort could be described as "making society better."

Fifth, we might try to locate "social progress" entirely in terms of the wishes and preferences of the members of society. This is a liberal and democratic definition of social wellbeing: the wellbeing of society, and what counts as an improvement in social wellbeing, is entirely specified once we know what the citizens prefer. So on this approach we might say that "social progress" is entirely procedural: a set of changes represent progress just in case they were arrived at through a ***fair and equal process of collective decision making***.

An important issue that arises in thinking about social progress is the question of myopia and design. Think of the analogy with the evolution of species: natural selection is a myopic process in which each change is fitness-improving, but there is no longterm plan for what the species will eventually look like. Coming up with a better bicycle, on the other hand, is usually the result of a far-sighted design process, in which the architecture of the bicycle is reconceived so as to achieve certain design goals. The thing about a myopic process of improvement is that it is possible to get trapped in a local maximum, unable to take one step back in order to achieve a higher nearby equilibrium. (Richard Dawkins describes this possibility in Climbing Mount Improbable.)

So what about social progress: should we think of social improvement as the net result of many small, myopic reforms; or should we think about it ideally as the result of a comprehensive policy design process? To what extent are we in a situation of improvement resulting from a large number of small adjustments, versus the possibility of large designed reforms leading to discontinuous jumps in quality and equity? The constraints of democracy strongly suggest the former rather than the latter. Building legislative and democratic majorities for change seems to imply piecemeal reform and a degree of myopia. It is difficult to see how a comprehensive, multi-decade plan for social reform could be implemented and sustained. (Adam Przeworski considers some of these issues in Democracy and the Market: Political and Economic Reforms in Eastern Europe and Latin America.) So piecemeal and gradual reform on several fronts may be the best we can do.

Generically the concept of reform fits into these ideas very tightly. Reforms are intended to improve the social situation in one way or another; and the cumulative effect of an extended series of reforms may be a significant enhancement in equity, democracy, equality, and quality of life. But two things are usually true: first, reforms are generally selective and partial; and second, the cumulative effects of an extended series of reforms may lead to outcomes that were never anticipated. A reform process is not a utopian process: it is generally not guided by a comprehensive vision of what the ideal society ought to look like, and the results of reform are generally pragmatic and limited rather

than sweeping and socially transformative.

(The image above is drawn from a manual on forestry management in Karnataka, India (link). It depicts a sequence of social systems of land use governing farm land, cattle husbandry, and forests. The middle panel represents degradation of the system and the worsening of the standard of living of the population; the final panel represents the improvement of the system of land use and a major step forward in the standard of living as a result of a major legal reform, confined cattle and protected regenerated forests.)

Marx's relevance as a social scientist

Saturday, June 12, 2010

What was Karl Marx's enduring contribution to the social sciences? Does he deserve the status of being one of the founders of sociology, along with Durkheim and Weber? Did he put forward substantive hypotheses about the workings of the modern world that continue to illuminate our social world? Is there anything important for sociologists, political scientists, or economists of the current generation to absorb from Marx as they construct their own hypotheses about social processes and organizations?

Below are the concluding paragraphs of my 1986 book, The Scientific Marx. Here I tried to assess whether the theories and frameworks that Marx advanced in *Capital* and his other scientific writings were of continuing relevance today. The question for me in 1986 was this: does Marx still have important scientific and theoretical insights into the structures, institutions, and behavior of modern capitalism? And I came to a tentative conclusion: that Marx's most important insights were about the institutions and mechanisms of capitalism (not a formal economic theory), and that these insights continue to have some validity and importance today. Here is the conclusion:

Throughout this work I have examined the logical features of Marx's social science, not its correctness as an analysis of capitalism. In discussing Marx's use of empirical evidence, for example, I have not been concerned to discover whether the available evidence confirms or falsifies Marx's account, but rather the logical question, namely, whether Marx uses evidence in such a way as to permit him to empirically evaluate his account. Thus my primary endeavor has been to examine Marx's practice as a scientist and to determine whether his efforts at explanation, inquiry, and justification are reasonable ones within social science. It may be appropriate in closing, however, to offer a view of the status of *Capital* as a body of theory about a social and economic system that continues to dominate our lives in the West. Is *Capital* still capable of offering scientific insights into the nature of twentieth-century capitalism?

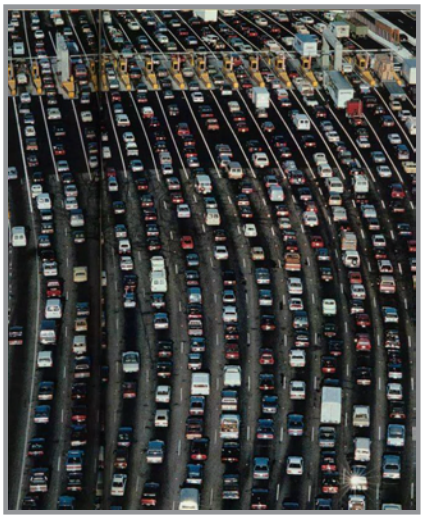
There is a sense in which Marx's own views would make him suspicious of the claim that an investigation of the social relations of production of nineteenth-century capitalism should remain valid for the social system that emerges from that mode of production over

a century later. For Marx is insistent on the historical specificity of the relations that define any mode of production. He raises this point in connection with cross-modal judgments of timelessness (for example, the idea that precapitalist modes of production must "really" have been based on bourgeois exchange relations). But the point is equally valid in application to the development of a single mode of production over time. To the extent that the social relations of production that define twentieth-century capitalism are significantly different from those that defined nineteenth-century capitalism, Marx's analysis must be modified before it can offer relevant commentary on the present.

There are unmistakable differences between capitalist property relations in 1850 and in the mid-1980s. On the side of capital, at least these changes have occurred: the accelerated separation of ownership and management, the increasing role of finance and credit within capitalist enterprises, the creation of the modem multinational corporation as the basic unit of capital, and the increased involvement of the state in the affairs of capitalist enterprises. Changes have emerged on the side of labor power as well: increasing government regulation of work conditions, the shift from industrial to service employment, the creation of effective units of organized labor in all capitalist countries, the rise of mass-based socialist parties with proletarian support in Western Europe, and the emergence of much more extensive social welfare systems in all capitalist systems. All these factors potentially may influence the dynamics of modem capitalism, and they all were of only minor importance in the economic structure Marx investigated.

At the same time there are substantial continuities between nineteenth-century and twentieth-century capitalism. (It is these continuities that justify our identification of the modern American or Western European economies as "capitalist.") The fundamental requirements of capitalist property still exist, namely, the effective separation between a minority class that owns and controls the vast majority of all productive wealth and a majority class that possesses no productive wealth and is obliged to sell its labor power. Capitalism remains a system of class power and privilege -- witness the uninterrupted power and influence of the minority class that owns and directs the productive wealth in each capitalist nation. Capitalism remains a system in which class power and privilege derive from ownership of wealth -- witness the sharp inequalities of wealth and income that persist to the present day. Moreover capitalism continues to depend on the accumulation of capital, and it continues to reflect a deep conflict of interest between owners and workers in the productive process. Finally -- in Marx's technical meaning of the term -- capitalism remains an exploitative system: The social surplus is still expropriated from the class of immediate producers by the class of owner of productive wealth.

Given these important similarities and differences between the property relations of nineteenth- and twentieth-century capitalism, it becomes a problem of continuing research -- of the sort Marx provided so extensively in *Capital* -- to determine whether the fundamental dynamic of contemporary capitalism should be predicted to resemble that of nineteenth-century capitalism. Only detailed empirical and theoretical analysis will permit us to determine whether the continuities are sufficiently fundamental to offset the alterations introduced by changes in the social relations of property and class. For we have seen that Marx's arguments for the "laws of motion" of capitalism depend essentially on assumptions about the details of capitalist relations of production, and those relations have not remained fixed.



This finding suggests that the application of the findings of *Capital* to contemporary capitalism must be somewhat tentative; it is surely not possible to derive particular laws

of motion of contemporary capitalism from Marx's analysis alone. Rather, Marxist social scientists and political economists must provide the sort of detailed account of modem property relations and economic institutions that Marx provides for nineteenth-century relations and institutions. This is not to say that Marxist social science must begin de novo. The continuities between modern capitalism and nineteenth-century capitalism are crucial to understanding modem capitalist phenomena, and Marx's analysis of those basic features of capitalism remains profoundly illuminating. But it is necessary to supplement, modify, and extend his account to draw particular conclusions about the course of modem capitalism.

Significantly, contemporary Marxist social science conforms to this view of the relevance of *Capital* today. Thus Marxist political economists have put forward detailed studies of modem capitalist relations of production--e.g. Ernest Mandel's Late Capitalism and James O'Connor's The Fiscal Crisis of the State. Other Marxist social scientists have offered analyses of particular post-capitalist modes of production -- Rudolph Bahro's The Alternative in Eastern Europe or Donald Hodges's The Bureaucratization of Socialism, to name two. And Marxist political sociologists have refined and extended his treatment of class, property, and politics, for instance, Erik Olin Wright's Class Crisis & the State and Ralph Miliband's The State in Capitalist Society. What these works have in common is not pious deference to Marx's texts -- in *Capital* or elsewhere. Rather, they are unified in being vigorous attempts, using extensive contemporary data, to offer theoretical accounts of modem social institutions within a framework of analysis that is greatly indebted to Marx's treatment of capitalism. Contemporary Marxist social science is rooted in Marx's insights, but it is not confined to his conclusions or to the particular features he singled out for fine-grained analysis. Thus Marx's *Capital* established a research program for twentieth-century social science, and it is a program that has borne fine fruit indeed.
So how does Marx hold up in the first decade of the twenty-first century? And how does this assessment of my own, written almost twenty-five years ago, hold up as well?

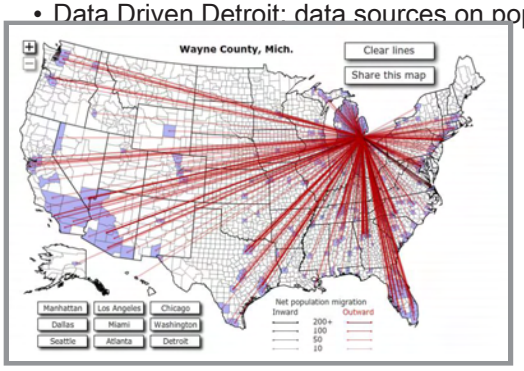
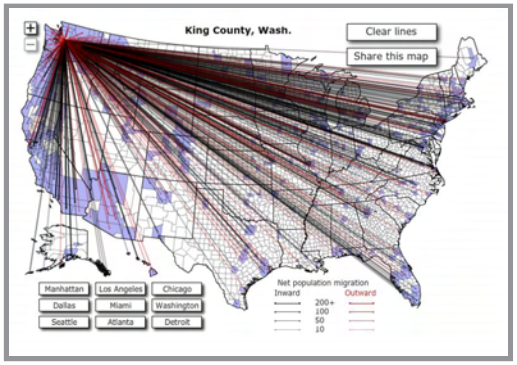
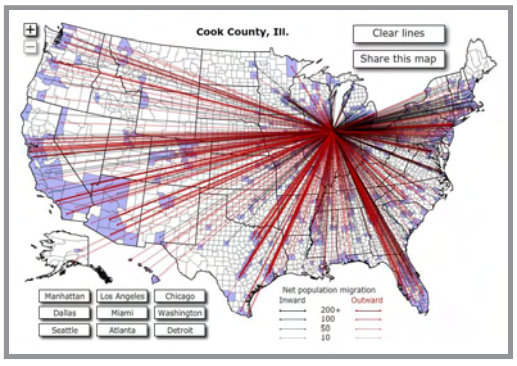
Michigan's population loss



Saturday, June 12, 2010





Earlier posts have raised the possibility that Michigan's jobs crisis will lead to significant population loss (link, link, link). The basic idea is this: Michigan has lost more than 800,000 jobs since 2002. Its population in 2002 was about 10 million. The current unemployment rate in the state is about 15%, or just under. In order to bring the unemployment rate back to the 2002 levels (~6%), roughly 800,000 jobs need to be created; or else the working population needs to decline by about that much. Assuming one dependent for each worker, that amounts to a loss of about 1.6 million people. Other combinations are possible; create 400,000 jobs and only 800,000 Michigan residents would leave; etc.

So what is the situation of out-migration today? Here are some recent reports over the past twelve months:

- Detroit News 4/2009: Eight-year population exodus staggers state (link)
- AnnArbor.com: 89,844 residents lost 2005-2008 link
- CrainsDetroit 12/23/09: population falls below 10 million; low birthrate and high out-migration responsible link
- Michigan State University report on population loss 12/09 link
- Toledo Blade: Michigan is tops in 1-year population loss 12/09 link
- Detroit Free Press: Rochelle Riley, City's rebirth at risk over lack of births link
- Data Driven Detroit: data sources on population in Detroit link

And where are Detroit metro families going? Here is a map Forbes published (link) showing the destinations in 2008:

Notice that almost all the lines are red, indicating out-migration. Compare that with the pattern of migration for Seattle:

And Chicago:

In other words, a significant amount of out-migration has already occurred in Michigan, and there is no indication that this process will slow down.

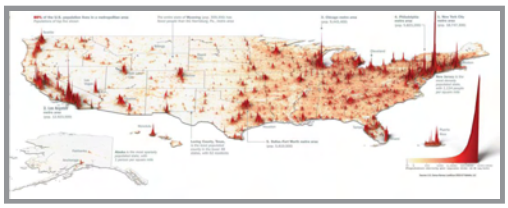
In fact, some observers have argued that Michigan's population losses have been less than expected in the past 18 months because of the generally bad economic conditions in other parts of the country (and because of the difficulty of selling a house). But if this is a factor, then we should expect an increase in out-migration when job creation takes hold in other parts of the country.

There is another worrisome part of this story: the fact that the best-educated and most talented people are likely to be the first to go. They are nationally competitive with skills that can bring value to employers in other parts of the country; so population loss is likely enough to be talent-drain as well.

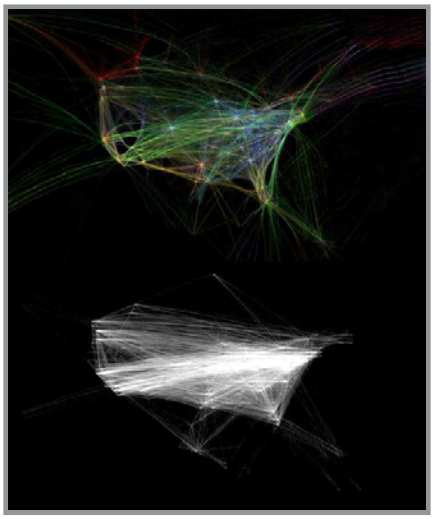
It is hard to find any political or business leader in the state of Michigan who believes that it is possible to create 100,000 new jobs a year in the state over a prolonged period. This seems to imply chronic high unemployment in the state for a very long time, with all the features of poverty, poor health, and low quality of life that comes along with this scenario.

So is there a different possible future for Michigan that assumes a different paradigm: a smaller population; smaller cities; but a more robust and diverse economy and a higher overall standard of living? Is it time, perhaps, to be planning for a smaller but more

prosperous and healthy state?



There are many serious challenges that this transformation would create. A declining population implies a declining tax base; so state and municipal revenues would decline as well. School systems were built for a certain level of capacity; take 15-25% of the children out of a school system and you have a funding crisis in the schools as well. Detroit's Mayor Dave Bing is grappling with the need to consolidate the land area of the population served by the city of Detroit, in order to achieve a balance between resources and needs. And, of course, the state would continue to lose representation in the House of Representatives. So designing a strategy for "smaller, healthier, wealthier" is not simple. But it may be time to begin thinking along these lines.



UPDATE December 28, 2010

The results of the 2010 census are now available, and Michigan is the only state in the country to have lost population since 2000. The country as a whole gained 9.6%, whereas Michigan lost .6% of its population -- roughly 60,000 people. Here is a news article from AP (link).

Spatial patterns in the US

Tuesday, June 15, 2010

Here are four interesting graphics representing different kinds of activity in the United States. The top panel represents population concentrations across the United State. The second image is air traffic across the country, and the third image is internet traffic across the country. The final image is a photograph of the United States from space at night, showing the concentration of lights across the country. Basically the images correspond to where people live; where they travel; and where they exchange data. Unsurprisingly, the maps line up very well. The most interesting question to consider is **not** the structure of the networks represented by air travel and internet activity. The nodes of both air travel and internet traffic line up exactly with the cities and metropolitan areas represented in the population map, and they align well with the concentration of lighted areas in the bottom frame as well. The patterns of both air travel and internet traffic take the form of a swath extending from the dense eastern corridor of the US (Boston to Washington) to California (San Francisco to San Diego), with Chicago standing out as a significant node in the middle of the country. This is entirely obvious and predictable; travel and communication follow population density.

Rather, the more interesting question is this: to what extent is there evidence of internet

and air traffic at a node that is **disproportionately greater** than would be expected given the population of that node? This is the kind of question that drives Saskia Sassen's classification of cities as local, regional, national, and global (The Global City: New York, London, Tokyo and Global Networks, Linked Cities). (Here is an earlier post on Sassen's work.)

Fundamentally, a city that originates 10 times the volume of internet traffic compared to other cities of similar size is worth looking at in detail. Its activity level suggest an exceptional concentration of organizations and people that are unusually integrated into global networks of communication and data exchange. It is a location for knowledge-intensive activity: high-end services, banking, universities; and it is a place with intensive relations to other nodes. Likewise, a city that originates 5 times as many air-travel passengers as comparably sized cities elsewhere is likely to be a specialized location for business and high-end service activity (or else a population of very dedicated tourists). In other words, the most interesting feature that these data sets might show us about the economic roles of US cities is not visible in the graphics presented here.

So it would be very interesting to be able to "divide" the activity levels represented by the middle two graphs by the populations represented by the top graph, so we could see which cities in the US are "super data exchangers" and "super travel generators". And this would give us an indication of the degree of high-end, knowledge-intensive activity that is concentrated in the place -- thereby providing a measure of its importance in the national and global economy. It is possible, for example, that Ann Arbor or Madison would show up as spikes of internet activity relative to their relatively small populations; and Raleigh-Durham might show up as a spike of air travel relative to population, reflecting an unusual concentration of high-end service businesses in this region. The above-average data and air-traffic nodes are perhaps the dynamic centers of 21st-century economic activity.

Likewise, it would be interesting to identify the cities that have lower-than-expected levels of travel or internet activity; this would suggest local economies that are somewhat more self-contained and less integrated into the national economy than other locations. And it would be interesting to see if there are significant pairings among locations for either kind of transaction; for example, is the volume of data exchange between Los Angeles and New York significantly greater than that between New York and Chicago or Boston? And would this serve as an indicator of the degree of economic and business integration between these specific locations?
These views of the United States are interesting because they allow us to see the country as an inter-connected system of places and activities. They serve as something like a dynamic CT scan of the brain: certain connections between places "light up", providing an indication of systemic activities that warrant further investigation.

(The middle panel was published in the Harvard Alumni Magazine (link). The population map comes from Urbanomnibus (link).)

More on jobs and people in Michigan

Thursday, June 17, 2010

Olivier Blanchard and Lawrence Katz did an important empirical study of regional adjustment to employment shock in 1992 (link). Here is their central conclusion:

"We have shown that most of the adjustment of states to shocks is through movements of labor, rather than through job creation or job migration." (54)

In other words, they find that the US labor market is fairly well integrated, and an extended period of unemployment and low wages leads workers to seek new opportunities in other regions. (Here is a recent book by Katz and a collaborator; The Race between Education and Technology.)

What implications does this have for Michigan? Let's say that Michigan's unemployment rate will adjust to approximately the national rate by 2020, and that the national rate will recover to 6% by then. This implies 6% unemployment for Michigan, compared to 14% today. Let's assume that less than half of the recovery comes from new and imported jobs. What does this imply for out-migration and population loss for the state?

The arithmetic is straightforward. There are currently about 4.2 million jobs in Michigan and 681,000 unemployed workers, for a labor force of about 4.9 million. (Here is a page of data from the Bureau of Labor Statistics for Michigan; link.) What would it take to bring Michigan's unemployment rate down to 6% by 2020? Here is one solution: 150,000 new jobs and 250,000 out-migrants from the labor force. And assuming that each worker has one dependent on average, this means a loss of about 500,000 people from Michigan's current population of about 9.9 million--for a total population of 9.4 million in ten years.

This is a significant but not overwhelming loss of population -- about 5%. And the number of jobs required on this scenario is moderate and achievable -- 150,000 new jobs in ten years. This amounts to about 4% jobs growth per year. We can make some educated guesses about the demographics of the population that leaves the state -- they are likely to be young, they are likely to have children, and they are likely to be better educated than the general population. So the economic and social impact of this exodus is likely to be greater than their 5% share of the general population. But all of that conceded, it would appear that there is a reasonably achievable pathway for Michigan to dig itself out of its current crisis.

So let's get serious about preparing the ground for a healthy recovery; let's enhance K-12 education, extend the reach of university attainment, improve the quality of life in our cities, and get serious about redesigning our state's fiscal system.

Short thoughts from Clifford Geertz

Saturday, June 19, 2010

Clifford Geertz was a frequent contributor to the New York Review of Books, and he succeeded remarkably well in bridging the gap between the university and the public in many of his "postings." (I think of these contributions as a pre-web version of a blog.) Many of these contributions are collected in a superb recent volume, Life among the

Anthros and Other Essays, edited by Fred Inglis. These range from his first contribution to NYRB in 1967, "Under the Mosquito Net," on Malinowski, to his last in 2005, "Very Bad News," a review of Jared Diamond, Collapse: How Societies Choose to Fail or Succeed and Richard Posner, Catastrophe: Risk and Response. A common theme across the essays is the often surprising and sometimes comic misunderstandings that have occurred across major geo-cultural cleavages, including especially the west and Islam.

Geertz had a splendid eye for making sense of ideas and meanings -- pulling out the figure from the ground. Here are a few lines on the significance of Foucault:

Foucault's leading ideas are not in themselves all that complex; just unusually difficult to render plausible. The most prominent of them, and the one for which he has drawn the most attention, is that history is not a continuity, one thing growing organically out of the last and into the next, like the chapters in some nineteenth-century romance. It is a series of radical discontinuities, ruptures, breaks, each of which involves a wholly novel mutation in the possibilities for human observation, thought, and action.... Under whatever label, they are to be dealt with "archaeologically," That is, they are first to be characterized acording to the rules determining what kinds of perception and experience can exist within their limits, what can be seen, said, performed, and thought in the conceptual domain they define. That done, they are then to be put into a pure series, a genealogical sequence in which what is shown is not how one has given causal rise to another but how one has formed itself in the space left vacant by another, ultimately covering it over with new realities. The past is not prologue, like the discrete strata of Schliemann's site, it is a mere succession of buried presents. ("Stir Crazy," 1978, 30)
This is a very concise, insightful statement of Foucault's position, and certainly more understandable than any particular stretch of The Archaeology of Knowledge & The Discourse on Language.

Or consider a key and enduring topic for Geertz: the difficulties that intrude on gaining a single, consistent, and fact-based representation of another culture. "In Search of North Africa" was published in NYRB in 1971, and poses many of the questions of plural interpretation and perspective that are hallmarks of Geertz's own meta-view of ethnography.
Academic monographs, social realism documentaries, and belletristic essays compete to develop a representational form in which Maghrebi society can be caught and communicated. The first result of the dawning realization that though society doubtless exists independently of the activity of sociologists, sociology does not, is a proliferation of genres. The second, still so faint as to be scarcely visible, is the development of the sort of radically experimental attitude toward modes of representation that set in so much earlier elsewhere in modern culture. (62)
Here Geertz raises the questions of objectivity and perspective that are unavoidable in the human sciences. "The document makers [of films and books] are, if anything, even more bound to the notion that social reality is presented to them directly and that the main thing is to look at it with sufficient care and the appropriate attitude." But, Geertz suggests, the relationships between social reality, representation, and knowledge are more complicated than this.

Here is one reason why the simplistic realism of the documentarian won't work:

North Africa doesn't even divide into institutions. The reason Maghrebi society is so hard to get into focus and keep there is that it is a vast collection of coteries. It is not blocked out into large, well-orgaized, permanent groupings -- parties, classes, tribes, races -- engaged in a long-term struggle for ascendancy. It is not dominated by tightly knit bureaucracies concentrating and managing social power; not driven by grand ideological movements seeking to transform the rules of the game; not immobilized by a hardened cake of custom locking men into fixed systems of rights and duties. (63)

Or, in other words, the business of choosing a conceptual scheme and then applying it objectively to Maghrebi society is doomed from the start; the social activities, groupings, and transactions themselves are fluid and ever-changing. "Structure after structure -- family, village, clan, class, sect, army, party, elite, state -- turns out, when more narrowly looked at, to be an ad hoc constellation of miniature systems of power, a cloud of unstable micro-politics, which compete, ally, gather strength, and, very soon, overextended, fragment again" (63). (This perspective converges closely with the ideas offered in the plasticity and heterogeneity threads here.)

And what about catastrophe? Geertz takes up Jared Diamond and Richard Posner in one of his last contributions to NYRB in 2005. Geertz acknowledges the bad news all around us, when it comes to the ways in which human society seems to be capable of destroying itself through its own activities. But he has a bone to pick with both of them: they really don't get down into the sociology, the psychology, and the cultural frames of the people who make up our modern societies. And yet these contextual, local details matter enormously in how a group responds to catastrophe. Here is Geertz's critique of both Diamond and Posner:

What is most striking about both Diamond's and Posner's views of human behavior is how sociologically think and how lacking in psychological depth they are. Neither the one, who seems to regard societies as collective persons, minded super-beings intending, deciding, acting, choosing, nor the other, for whom there are only goal-seeking individuals, perceiving and calculating rational actors not always rational, has very much to say about the social and cultural contexts in which their disasters unfold. Either heedless and profligate populations "blunder" or "stumble" their way into self-destruction or strategizing utility maximizers fail to appreciate the true dimensions of the problems they face. What happens to them happens in locales and settings, not in culturally and politically configurated life-worlds--singular situations, immediate occasions, particular circumstances. But it is within such life-worlds, situations, occasions, circumstances, that calamity, when it occurs, takes intelligible shape, and it is that shape that determines both the response to it and the effects that it has. (165)

In a word, Geertz puts it forward that even our largest concerns about our social futures require the kind of detailed, meaning-inflected and locally specific understandings that a certain kind of ethnographic imagination brings forward. We need "local knowledge" to navigate a global future.

This volume is a great example of the role that a certain kind of publishing can play in our intellectual lives: capturing and refreshing the insights of thinkers and observers over a period of decades. Geertz's ideas in this volume were the product of his evolving mind from the sixties to the end of his life; and it is enormously stimulating to keep that long evolution in front of our minds as we grapple with our own issues and innovations. We tend to think only of the most recent ideas and contributions as "cutting edge"; but there is a hugely important dimension of historical depth that we can discover by returning to the insights of earlier generations.

(See an earlier post on Robert Darnton that illustrates another important intellectual corpus laid out in the pages of decades of the NYRB. The image above is, of course, a photo of a Balinese cockfight, one of Geertz's ethnographic icons.)

Concrete sociological knowledge

Monday, June 21, 2010

Is there a place within the social sciences for the representation of concrete, individual-level experience? Is there a valid kind of knowledge expressed by the descriptions provided by an observant resident of a specific city or an experienced traveler in the American South in the 1940s? Or does social knowledge need to take the form of some kind of generalization about the social world? Does sociology require that we go beyond the particulars of specific people and social arrangements?

There is certainly a genre of social observation that serves just this intimate descriptive function: an astute, empathetic observer spends time in a location, meeting a number of people and learning a lot about their lives and thoughts. Studs Terkel's work defines this genre -- both in print and in his radio interviews over so many years. A particularly good example is Working: People Talk About What They Do All Day and How They Feel About What They Do. But Studs is a journalist and a professional observer; does he really contribute to "sociological knowledge"? (See this earlier post on Studs.)

Perhaps a better example of "concrete, individual-level experience" for sociology can be drawn closer to home, in Erving Goffman's work. (Here is an earlier discussion of some of Goffman's work; link.) Here are the opening words of The Presentation of Self in Everyday Life (1956):

I mean this report to serve as a sort of handbook detailing one sociological perspective from which social life can be studied, especially the kind of social life that is organised within the physical confines of a building or plant. A set of features will be described which together form a framework that can be applied to any concrete social establishment, be it domestic, industrial, or commercial.

The perspective employed in this report is that of the theatrical performance; the principles derived are dramaturgical ones. I shall consider the way in which the individual in ordinary work situations presents himself and his activity to others, the ways in which he guides and controls the impression they form of him, and the kinds of things he may and may not do while sustaining his performance before them. In using this model I will attempt not to make light of its obvious inadequacies. The stage presents things that are make-believe; presumably life presents things that are real and sometimes not well rehearsed. More important, perhaps, on the stage one player presents himself in the guise of a character to characters projected by other players; the audience constitutes a third party to the interaction -- one that is essential and yet, if the stage performance were real, one that would not be there. In real life, the three parties are compressed into two; the part one individual plays is tailored to the parts played by the others present, and yet these others also constitute the audience. Still other inadequacies in this model will be considered later.

The illustrative materials used in this study are of mixed status: some are taken from respectable researches where qualified generalisations are given concerning reliably recorded regularities; some are taken from informal memoirs written by colourful people; many fall in between. The justification for this approach (as I take to be the justification for Simmel's also) is that the illustrations together fit into a coherent framework that ties together bits of experience the reader has already had and provides the student with a guide worth testing in case studies of institutional social life. (preface)

Goffman's text throughout this book relies on numerous specific descriptions of the behavior of real estate agents, dentists, military officers, servants, and medical doctors in concrete and particular social settings. Here are a few examples:

[funerals] Similarly, at middle-class American funerals, a hearse driver, decorously dressd in black and tactfully located at the outskirts of the cemetery during the service, may be allowed to smoke, but he is likely to shock and anger the bereaved if he happens to flick his cigarette stub into a bush, letting it describe an elegant arc, instead of circumspectly dropping it at his feet. (35)

[formal dinners] Thus if a household is to stage a formal dinner, someone in uniform or livery will be required as part of the working team. The individual who plays this part must direct at himself the social definition of a menial. At the same time the individual taking the part of hostess must direct at herself, and foster by her appearance and manner, the social definition of someone upon whom it is natural for menials to wait. This was strikingly demonstrated in the island tourist hotel studied by the writer. There an overall impression of middle-class service was achieved by the management, who allocated to themselves the roles of middle-class host and hostess and to their employees that of maids -- although in terms of the local class structure the girls who acted as maids were of slightly higher status than the hotel owners who employed them. (47-48)

[hospitals] Thus, if doctors are to prevent cancer patients from learning the identity of their disease, it will be useful to scatter the cancer patients throughout the hospital so that they will not be able to learn from the identity of their ward the identity of their disorder. (The hospital staff, incidentally, may be forced to spend more time walking corridors and moving equipment because of this staging strategy than would otherwise be necessary.) (59)

[hotel kitchens] The study of the island hotel previously cited provides another example of the problems workers face when they have insufficient control of their backstage. Within the hotel kitchen, where the guests' food was prepared and where the staff ate and spent their day, crofters' culture tended to prevail, involving a characteristic pattern of clothing, food habits, table manners, language, employer-employee relations, cleanliness standards, etc. This culture was felt to be different from, and lower in esteem than, British middle-class culture, which tended to prevail in the dining room and other places in the hotel. The doors leading from the kitchen to the other parts of the hotel were a constant sore spot in the organization of work. (72)

So Goffman's sociology in this work is heavily dependent on the kind of concrete social observation and description that is at issue here. Much of the interest of the book is the precision and deftness through which Goffman dissects and describes these concrete instances of social interaction. This supports one answer to the question with which we began: careful, exacting and perceptive description of particular social phenomena is an important and epistemically valid form of sociological knowledge. Studs Terkel contributes to our knowledge of the social world when he accurately captures the voice of

the miner, the hotel worker, or the taxi driver; and a very important part of this contribution is the discovery of the singular and variable features of these voices.

At the same time, it is clear that Goffman goes beyond the concrete descriptions of restaurants, medical offices, and factory floors that he offers to formulate and support a more general theory of social behavior: that individuals convey themselves through social roles that are prescribed for various social settings, and that much social behavior is performance. (This performative interpretation of social action is discussed in an earlier post.) And this suggests that there is a further implicature within our understanding of the goals of sociological knowledge: the idea that concrete descriptions should potentially lead to some sort of generalization, contrast, or causal interpretation.

Truth and reconciliation commissions

Thursday, June 24, 2010

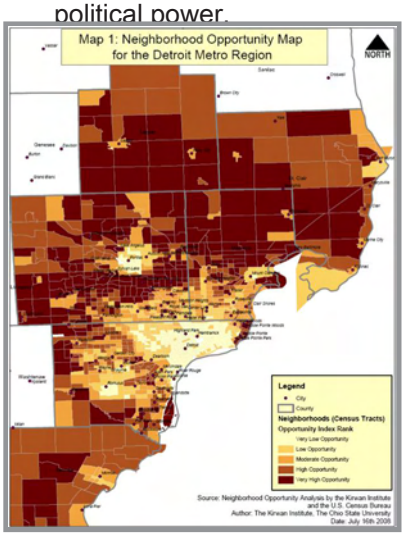
When does a society need a process of "truth and reconciliation" along the lines of such processes in South Africa, El Salvador, and Argentina? Here are some recent examples of truth and reconciliation processes: the fate of the "disappeared" in Argentina (link); Indian Residential Schools in Canada (link); Korean War civilian casualties (link); Liberian civil conflict (link); lynchings in the US South (link); and, of course, the Truth and Reconciliation Commission in South Africa (link).

The general theory of TRC is that a society is sometimes grievously divided over events and crimes that have occurred in the past, and that honest recognition of those crimes may lay a foundation for reconciliation within the society. Here is a summary statement of the purpose of a Truth and Reconciliation Commission from the South African Ministry of Justice:

... a commission is a necessary exercise to enable South Africans to come to terms with their past on a morally accepted basis and to advance the cause of reconciliation.
But what more can we say about what facts might trigger the need for a TRC process?

First, such a process is only invoked when there is a serious history of injustice within the community, leading to a situation in which one group has been badly treated by other groups or powerful institutions. The stakes need to be high for current members of society in order to justify establishing a TRC.

Second, a TRC process seems to be most needed when the consequences of the past injustice persist into the present: the bad things that happened in the past continue to burden some groups in the present.



Third, there is an implication of abiding resentment and rancor within the current population. The injustice of the past continues to be a source of emotional division between members of the relevant groups. This is the reconciliation part of the agenda: by honestly confronting the facts about the past injustices, the groups subject to this

treatment may be in a better place to resolve their rancor. And more practically, honest recognition of the past may lead to concrete steps in the present to restore the interests and rights of affected groups.

Fourth, there is a common feature of violence and subjugation in the instances where TRC processes have been invoked to date: pogroms, mass killings, lynchings, and other forms of inter-group violence.

So what are some important examples of historical circumstances where TRC is called for? There are many:

- The expatriation of French Jews by the French government into the hands of the Nazis, leading to the deaths of thousands of people from this community.
- The Rwandan genocide.
- The Argentine military's policy of "disappearing" large numbers of its opponents, involving secret imprisonment, torture, and murder.
- White violence against black people in the American South, enforcing white power through lynchings, shootings, and violent intimidation.
- Organized ethnic cleansing and mass murder in Croatia, Bosnia, and Slovenia.
- The fact of slavery as practiced in the United States through Emancipation.
- The crimes of death squads in El Salvador in the 1980s, including a degree of US support and involvement.
- Robert Mugabe's use of ZANU-PF paramilitary thugs in Zimbabwe to maintain his political power.

Here is the immediate question of interest in this posting: how do the facts of northern race relations fit into the parameters of truth and reconciliation? In the Detroit area the Michigan Roundtable for Diversity and Inclusion is calling for a Truth and Reconciliation Commission to honestly examine the history of race and residence in the region (link). The Roundtable states that --

The establishment of a Truth and Reconciliation Commission, inspired by the process that took place in South Africa, will allow us to develop an appropriate understanding of past injustices and to envision constructive remedies to create a new regional culture of fairness, equal opportunity and prosperity.

(Here is a link to the Facebook page for the organization in which the initiative is launched.)

So let's ask the crucial question: are the patterns of racial segregation and inequality of opportunity that are unmistakably involved in most US large cities an appropriate cause for a process of truth and reconciliation?

In many ways the answer appears to be "yes." Urban segregation was and is a source of massive injustice for black Americans. It embodied a quasi-permanent pattern of inequality of opportunity and outcome on African-American citizens. It was the result of specific but often hidden social practices that embodied a pattern of white privilege. And these practices sometimes involved actual and threatened violence. So entrenched discrimination and segregation constitute social harms that meet most of the criteria

mentioned above, and the truth about the underlying mechanisms is not widely known.

In short, most honest observers would probably agree that the history of racial segregation in Southeast Michigan reflects serious injustice and continues to inflict harms on people in the region today. These harms include disproportionate levels of poverty, unemployment, inadequate education, and differential health outcomes. And many would agree as well that social injustices of this magnitude need to be addressed openly and honestly.

The map of the Detroit metropolitan area below represents a measure of "neighborhood opportunity" across the region. It is published in an important report, "Opportunity for All," by john a. powell and the Kirwan Institute for the Study of Race and Ethnicity at Ohio State University (link). What it documents in a very visual way is the current effects of past and present practices of residential segregation: the areas of high African-American population line up very precisely with the areas of low "neighborhood opportunity". (Here is a keynote address by john a. powell to the Michigan Roundtable for Diversity and Inclusion (link) that lays out the data in great detail.)

So a sustained and honest effort to uncover and disseminate the historical causes of these patterns of racial segregation in the region is a positive step forward.

What is perhaps more difficult to answer is the question of efficacy. Do these TRC processes actually work? Do they succeed in changing attitudes in the populations in which they operate? Do they help communities develop more harmonious and collaborative approaches to the problems they face? And does "truth" lead to "reconciliation" in a significant number of cases? The Michigan Roundtable conducted a survey of racial attitudes in Michigan in 2009, and one question in particular stands out. In 2009 56% of residents said that we will have racial equality "in 100 years" or "never," compared to 48% in 2008. In other words, well over half of all Michigan citizens despair of achieving racial equality within five generations. And 68% of African American citizens in Michigan expressed the same lack of hope. We need to do better than this at achieving real racial equality; the question is, whether the proposed Truth and Reconciliation Commission can help us move forward in practical and effective ways.

Public intellectuals in France and the US

Saturday, June 26, 2010

What is the role of the intellectual in France in 2010? And has that role declined in the past several decades? Have the media and the internet profoundly eroded or devalued the voice of the intellectual in public space? The *Nouvel Observateur* takes up these questions in a recent issue devoted to "Le pouvoir intellectuel" (link).

The line of thought is a complicated one. Jacques Julliard frames the question by proposing that the public imagination of the intellectual involves a narrative of precipitous decline since the active engagements of Sartre, Beauvoir, and Camus. There was a conception of the engaged intellectual who brought his/her ideas and convictions into opposition when state and society were going wrong -- Algeria, Vietnam, capitalism. And, Julliard suggests, the common view is that the current generation of intellectuals have not succeeded -- perhaps have not even attempted -- at bringing theory, critique, and value into the public sphere. Jean Daniel captures the idea in his editorial: "*Faut-il rire des*

'intellos'?"

But -- here is the complexity -- Julliard refutes this idea. The tradition of the public intellectual is ***not*** attenuated or corrupted in France; rather, the current generation of intellectuals are in fact engaged and involved. It is nostalgia for a golden age -- the age of Liberation, Communism, and Existentialism -- that foreshortens the reputation of the intellectual today. But the golden age is a myth.

Tout cela est faux, archifaux, et prouve seulement que Saint-Sulpice n'est séparé de Saint-Germain que par quelques enjambées et par la piété du souvenir. Et revenons aux faits. [All this is false, badly false, and only proves that Saint-Sulpice is only separated from Saint-Germain by a few steps and the piety of memory. Let us return to the facts.]

Julliard points out five salient facts. **First**, we sometimes confuse the intellectual and the literary artist. The artist is valued for the aesthetic quality of his/her works, whereas the intellectual is valued for the significance of the impact of his/her ideas. **Second**, the impact of Sartre and Camus on France's wars in Algeria or Vietnam was minimal, and later generations of French intellectuals have actually exercised greater influence. In fact, Julliard argues that Lévy, Glucksmann, and Finkielkraut were more effective in their own interventions about policy in Bosnia than Sartre or Camus on the colonial wars. **Third**, Julliard argues that modern media, including the blogosphere, have provided the contemporary intellectual with a much more powerful platform for disseminating ideas and values than was available to Zola, Sartre, or Camus. He cites debates on the Israel-Palestine conflict, global warming, immigration, European governance, and even philosophy and literature, as locations of debate where modern media have amplified the voices of intellectuals. **Fourth**, there is the question of designation: who decides who the "intellectuals" are? The media select their talking heads; what confidence can the public have that these are the best voices available? Julliard even suggests that there has been an inversion of quality; the telegenic pundit acquires reputation as a savant, rather than the savant being sought out as a pundit. And **fifth**, there was a tendency of the "engaged" philosophers of the generation of Sartre, Merleau-Ponty, and Camus, to be engaged in service to a cause -- Communism, most commonly. So the positions offered by these intellectuals were often enough not "intellectual" at all; they did not follow from the principles, ideas, and methods of the thinker, but rather derived from the position of a party or camp. Today's intellectuals, Julliard suggests, are interested in ideas rather than ideologies. And with this commitment they have returned to the real vocation of the intellectual:

En rompant avec l'idéologie abstraite au profit de l'universel concret, les intellectuels, du moins les plus novateurs d'entre eux, sont revenus à leur fonction essentielle : la critique sociale, et d'abord la critique de leur propre pratique. [Dispensing with abstract ideology, today's intellectuals have returned to their essential function: social criticism, and especially criticism of their own practice.]

So Julliard's telling of the story expresses several key points: France needs public intellectuals; there are several overlapping generations of thinkers who are filling this role (and more to come); and in fact, the decline of ideology and the rise of media and the Internet makes the voices of intellectuals more effective rather than less. In his editorial in this issue Jean Daniel reaches a similar conclusion: "*En un mot: depuis que nous n'avons*

plus confinace dans des idéologies, nous avons un frénétique besoin des idées. C'est-a-dire des intellectuels." [In a word: since we no longer have confidence in ideologies, we have urgent need of ideas; which is to say, intellectuals.]
In continuing the theme, *Nouvel Obs* returns to the debate of 1980 by talking again with several of the young intellectuals it consulted in that year. Pascal Bruckner, Luc Ferry, and Gilles Lipovetsky offer their perspectives on the role of ideas and intellectuals in French society from the vantage point of 2010 (link). And there is a challenging interview-discussion with Alain Badiou and Alain Finkielkraut on communism (link). So *Nouvel Obs* is doing its part -- it is helping to bring to the fore debates and thinkers who can help France navigate into the twenty-first century.

There is one form of practical proof of the importance of intellectuals in contemporary France that is not so visible from the United States: the depth and pervasiveness of the presence of deeply thoughtful scholars and writers on French radio and television. For a taste of the breadth and depth of the voices of intellectuals in French society today, consult the list of podcasts made available from radio programming at *France Culture* (link). Particularly rich are *Les nouveaux chemins de la connaissance* (link) and *Repliques* (link). These programs exemplify serious voices, serious debates, and nuanced and extensive discussions.

In the United States it seems that the whole issue of the public intellectual plays out differently than in France. To begin -- the great majority of the "public" have virtually no interest in or respect for academic discussions of issues. Fox News, talk radio, and blistering political blogs fill that space.

Second, however, there is a subset of the American public that does have an appetite for more detailed and nuanced treatment of the issues that face us. Slate.com has between 5 and 8 million unique readers a month; the Huffington Post logged about 10 million visitors in December, 2009; and NationalReview.com logs about 4.5 million readers a month. The Facebook page for "Give me some serious discussion and debate about crucial issues!" could be huge.

Looking at the question from another angle -- the academic world in the United States is itself a meaningful segment of the workforce. There are about 1.5 million post-secondary teachers (professors and lecturers) in the United States, and the majority of these have doctoral degrees. Of these, a smaller number fall into traditional "intellectual" disciplines: English literature (74,800), Foreign literature (32,100), History (26,000), Philosophy and Religion (25,100), and Sociology (20,300), for a total of 178,300. In engineering, mathematics, and the sciences there are another 262,600 post-secondary teachers. (These data come from a Bureau of Labor Statistics snapshot for 2008 (link).) So a small but meaningful proportion of the US population have advanced degrees and intellectual credentials. They are a core segment of the audience for public intellectuals. And, of course, you don't have to be an academic to be an intellectual.

Further, there are a host of specialists and experts on specific crises -- environment, finance, globalization, war -- who are called upon to comment on specific issues, and there are specialized "think tanks" that promote and disseminate research on critical public issues. Moreover, voices like that of Bill Moyers have offered critical and nuanced perspectives on public television (link) (regrettably, now off the air). And the United States has a number of prominent academics who speak to a broad public -- Henry Louis Gates, Jeffrey Sachs, Martha Nussbaum, Cornel West, Michael Walzer, and James Gustave Speth, to name a few. So there is a domain of intellectual discourse that succeeds in

escaping the confines of the academic world and the limiting echo-chamber of cable television; this domain helps to create and feed an intellectual public.

Overall, it seems fair to say that public intellectuals have little influence on public opinion and public policy in the US today. Perhaps Richard Hofstadter's Anti-Intellectualism in American Life (1963) still has a lot of validity. But maybe, just maybe, it is also possible that the Internet is beginning to offer a bigger footprint for serious analysis and criticism for the American public and American policy makers. Perhaps there is a broadening opportunity for intellectuals to help define the future for the United States and its role in the world. And perhaps we can be more like France in this important dimension.

The Chinese-American Left in the early 20th century

Thursday, July 01, 2010

There hasn't been much historical scholarship on the forms of political activism that existed within the Chinese-American communities in the US in the early part of the twentieth century. Historical research on the Chinese-American community has more often focused on poverty, discrimination, employment, immigration law, and racism. A very important exception to this is the life-long research of Him Mark Lai, collected in a fascinating recent book (Chinese American Transnational Politics, edited by Madeline Hsu). And, as Lai demonstrates, it is a fascinating and important story.

Lai was an independent scholar who devoted a lifetime to historical and archival research on the history of the Chinese communities in the United States. He was trained as an engineer and had a career as a mechanical engineer for Bechtel in San Francisco. But what he really cared about was history. And he became a founding pioneer in the field of Chinese-American studies. Here are several links to biographies and archives of Lai's contributions (link, link). Here is how Lai frames his analysis of the Chinese-American Left:

The different Chinese left movements from the later nineteenth through the greater part of the twentieth century were offshoots of important political and social movements of the West. Probably because the Chinese population constituted only a small minority in the United States, little scholarly attention has focused on the historical development of these movements among them. This essay strives to piece together information scattered among many publications and oral sources to reconstruct this history and the varying roles of the individuals involved. This essay emphasizes activities concerning Chinese people in America rather than interpreting the inner workings, conflicts, or ideological leanings of global left movements.

Two factors stimulated the emergence and rise of left-wing activities among Chinese in America: the desire to improve their status in America, where they faced exploitation and racial oppression, and the hope of modernizing China into an internationally respected nation. (53)

The topic of interest here is the political identities that began to emerge within Chinese-American communities in the 1920s and 1930s. This is interesting for several reasons: the fact of an indigenous left in the US during these decades, which poses the questions of influence and alliance within the American left and radical working class movement; and the fact of rapid political development for reform and revolution in China itself, which raises the question of influence of Chinese radical thought on American Chinese intellectuals and activists. Lai documents the appearance of anarchist, socialist, and communist thought in leaders and intellectuals in leading Chinese-American communities, and he attempts to tease out the intellectual and political influences that created this efflorescence of the Chinese left in the US. (Here is an interesting link to short texts referring to Chinese anarchists in the United States in the 1920s.)

One potential influence that conspicuously did **not** occur was deliberate recruitment of Chinese people by left labor organizations in the US. "Even the Socialist Party, despite its emphasis on the common interests of the proletariat regardless of race or nationality, was hostile toward Chinese labor" (53). Only the IWW was able to genuinely embrace the anti-racist principles of the theory of socialism; only the Wobblies made determined efforts to organize and mobilize exploited Chinese workers in the US.

A key influence on Chinese-American activists was the impact that had been created in China by exposure to socialist and anarchist critiques of modern society.

During this period, Chinese Marxists and anarchists were chiefly intellectuals and students who had gone abroad to study and become politically active reformers and revolutionaries. Through Japanese and European writings, they learned about the ideas of Bakunin, Kropotkin, Marx, Engels, and others. Many articles touching on these doctrines appeared in newspapers and periodicals established by reform and revolutionary organizations in Hong Kong and Japan (54).
(Here is an online review by Jason Schultz of Arif Dirlik's book, Anarchism in the Chinese Revolution. Dirlik gives a good representation of the thread of non-communist radicalism in China.)

These developments among Chinese activists and intellectuals diffused to the Chinese diaspora and concentrated Chinese populations abroad. "Around the turn of the twentieth century, first the reformers, then the Hongmen, followed by the revolutionaries, founded newspapers in major New World Chinese communities such as San Francisco, Honolulu, Vancouver, and New York City" (55). "The teachings of Proudhon, Bakunin, and Kropotkin gained in popularity as petty bourgeois Chinese intellectuals embraced the concept of committing acts of terrorism to help destroy the old order" (55). "Around 1907-08 the IWW recruited two Chinese sympathizers in San Francisco to translate some of their literature. In 1909 a Honolulu book club was already in existence and met periodically to discuss such works as 'A Critique of Socialism,' 'Scientific Socialism,' and 'Marx'" (55-56).

Some of these political-social theories began to have an influence on ordinary working people in the Chinese communities of the United States. "Immigrants from China, many influenced by anarcho-syndicalist philosophies, were active in labor issues among the Chinese population on the North American mainland. The widespread labor unrest in the United States and Canada that peaked during the years following World War I probably contributed to such developments" (58). "One of the first major labor organizing efforts occurred in Vancouver, with the founding of the Zhonghua Gongdang [Chinese Labour Association] in 1916 and that group's efforts to organize sawmill workers in the area. In

1918 and 1919 the association led successful strikes that won on such issues as shortening the workday from ten to eight hours" (58). "In the United States, Chinese spearheaded a major labor organizing effort in 1918, when Chicago waiters organized the Mon Sang Association to demand better working conditions. However, the largest group of Chinese organized workers was the Sanfanshi Gongyi Tongmeng Zonghui [Workers' League of San Francisco, or Unionist Guild], founded in 1919 in San Francisco, which at the time had the largest population of Chinese shirt-factory workers" (58).

Anarcho-syndicalist ideas appear to have the earliest appeal to Chinese-American activists; but Marxism soon came along as well. "Chinese in America showed interest in Marxism as early as December 1919, when Oi-won Jung, a KMT party member who had also been active in the Chinese Socialist Club, helped organize Xin Shehui [New Society] in San Jose, California, 'to study capitalism and communism and the radical politics of the New Russia'" (61). But, Lai argues, this influence did not reflect a connection between Chinese activists and the Communist Party of the United States of America; rather, the influence proceeded from debates occurring in China around the direction and strategies of the KMT. And the mortal split that eventually occurred between the KMT and the CCP forced division between radical Chinese groups in the US as well (70).

This summary only touches upon the complex and fascinating narrative that Lai constructs, interweaving the local grievances expressed by the Chinese-American community and the increasingly complex political relationships that evolved in China between KMT and CCP groups as China struggled towards revolution. It is a history well worth reading, and gives a good illustration of the power of "micro-history" as a way of discovering the underlying complexities of macro-level, world-historical phenomena -- revolution, ideology, racism, injustice, and resistance.

(And now, for something completely different -- Monty Python's version of anarcho-syndicalism:)

International social science

Sunday, July 04, 2010

Last month the International Social Science Council (ISSC) launched a major review of the status of the social sciences worldwide (link). The report was commissioned and partially funded by UNESCO. The full report is available as a PDF file, and it is an important piece of work. It includes review essays by leading social scientists and chiefs of social science research organizations in Europe, North America, the Middle East, Africa, and Latin America and the Caribbean, and it makes an effort to provide a fairly comprehensive snapshot of the current state of affairs in the institutions, funding, and patterns of collaboration that currently drive social science research programmes in almost all regions of the world. (It is interesting to observe that there is not a single mention of social science research in

Israel.)

The primary focus of the report is on the institutional settings within which social science research takes place globally: for example, funding systems, universities and institutes, peer review systems, and publication systems. To what extent are these institutions, in various regions of the world, succeeding in supporting and encouraging the kinds of social science research that will further the policy and informational needs of the publics they serve? And to what extent are there substantial differences across regions of the world with respect to the depth and effectiveness of these institutional supports for the social sciences?

Here are three high-level changes in the social sciences that are noted in the report:

Three changes in the environment of social science production are particularly likely to affect their content, role and function. These are first, globalization, leading to the parallel internationalization of some public concerns and of social science research itself; second, changes in the institutional and social organization of social sciences; and third, the increased role of new information technology (IT) in the production and dissemination of social sciences. (1)
A more pervasive finding that structures many chapters in the report is the idea of "divides" within and across the world's communities of social scientists. Most fundamental is the gap in resources and institutional capacity that exists between North and South with respect to social science research:

For any observer of social sciences worldwide, the most striking divide is between countries and regions. There is not much in common between a social science department in a well-endowed university of the global North and a social science research institute in a Southern country suffering from economic and political instability. (3)
(Here is a map indicating widely different levels of spending on tertiary education across the globe:)

But the report also highlights divides across the practices of the social sciences that reflect real differences in intellectual commitments:

From an epistemological point of view, social sciences have been diverse and are characterized by a multiplicity of methods, approaches, disciplines, paradigms, national traditions and underlying political and social philosophies. (3)
Before undertaking such a survey, it is necessary to have a working conception of the definition and role of the social sciences. The report takes a pragmatic approach; the social sciences are "the disciplines whose professional association is part of ISSC" (3). But here is the closest the report comes to framing the intellectual task of the social sciences:

The social sciences are concerned with providing the main classificatory, descriptive and analytical tools and narratives that allow us to see, name and explain the developments that confront human societies. They allow us to decode underlying conceptions, assumptions and mental maps in the debates surrounding these developments. They may assist decision-making processes by attempting to surmount them. And they provide

the instruments to gauge policies and initiatives, ‘and to determine what works and what does not’. (9)
Another organizing thread in the work of this large team of collaborators is the idea that the social sciences are most valuable when they make a contribution to the solution of important social and political problems. They specifically refer to a set of common challenges that are of concern to virtually all the regional research communities surveyed here:

Challenges such as environmental change, poverty, financial crisis and inequality, as well as trends affecting human societies such as ageing, marginalization and the rise of cities as strategic economic spaces in the global economy are occurring everywhere but take on different forms according to local contexts. The authors discuss a wide array of challenges and trends, but other challenges such as gender issues, public health concerns, security, food crisis, migrations, diversity and integration, and burning issues and trends could also have found a place in this section. (9-10)
The greatest value and interest of this report is the degree of detail it is possible to glean from the summary reports provided by the regional associations of the social sciences. This gives a cumulatively detailed impression of the ways in which the social sciences are framed in Africa, the Middle East, Asia, and Latin America, as well as North America and Europe. Here is a nice example from Huang Ping's survey of the status of the social sciences in China, where Ping provides historical context for Chinese social science:

In terms of what we see today, the status of the social sciences in China can be traced back to the late nineteenth and early twentieth centuries, when the first generation of Chinese students and scholars returned from Western countries, mostly the UK and the USA, after completing their degrees or their research.

After the Second World War and since the founding of the People’s Republic of China in 1949, social sciences in China have developed along three traditions: Chinese scholarly academia, especially Confucianism, Daoism and Buddhism; focusing on economics in line with Soviet influences and Marxist studies; and later, Western approaches.

During the Cultural Revolution (1966–76), social sciences almost disappeared and were hardly taught. After the opening-up process initiated in 1978, social sciences, along with science and research in general, were resumed and given a mandate to support the reform process. The Soviet influence gradually disappeared, and Western, especially US, social science approaches became the most influential. Sociology, for example, had been banned since 1952 and was reintroduced in 1979. During the past decade, traditional Chinese academic traditions have been reintroduced in universities and have caught the interest of an increasing number of students. (73)
The report does not explicitly attempt to map the range and diversity of research priorities in different regions of the world; but it is possible to begin to do so by paying close attention to the surveys offered by the regional associations for social science research. Topics vary across regions. What is more difficult to assess is the degree to which epistemologies, theories, and intellectual frameworks vary as well -- though Sandra Harding's contribution points in this direction. (See an earlier posting discussing work by Gabriel Abend on "Styles of Epistemology" (link).)

Particularly interesting for me are short pieces by Saskia Sassen ("Cities in today's global age"), Craig Calhoun ("Social sciences in North America"), Akhil Gupta ("Construction of the global poor"), David Harvey ("A financial Katrina?"), Jon Elster ("One social science or many?"), and Sandra Harding ("Standpoint methodologies and epistemologies: A logic

of scientific inquiry for people").

In short, this is a genuinely interesting and detailed review of the status of the social sciences in the world today, and anyone with an interest in the "sociology of the social sciences" and the globalization of social knowledge will want to read it carefully.

Feasibility conditions on social reform

Tuesday, July 06, 2010

Several earlier posts have raised the issues of social change and social progress (post, post). People sometimes want society to be different (**change**), and they want it to be better (**progress**). But not all outcomes are possible, and some possible outcomes are not sustainable over time. So how should we think about sweeping prescriptions for social change? What constraints does social reality impose upon the reformer? And what kinds of moral and political constraints should be respected as we advocate for change?

Consider an analogy with the natural sciences and engineering. Physics and the natural sciences set the boundary conditions on what kinds of structures can be built and used. Engineering design involves acquiring a detailed knowledge of the natural properties of materials and structures, and then designing artifacts that satisfy human needs. The human-built world is not **determined** by the laws of physics, since there are countless different technologies that could have satisfied human needs consistent with physics; but it is **constrained** by the laws of physics. What is the corresponding relationship between the social sciences and social reform?

Let's begin by giving a schematic definition of a reform program. A program for reform consists of several things: a representation of the existing social world; a critique of some aspects of that world; a prescription for what the reformer believes would be a better social world; and a developed strategy for moving society from here to there. Reformers think that a specified set of changes will make for a better environment for some aspect of human life, for a group or for the population as a whole. The representation of the current social world may include several different kinds of elements: representation of typical social behavior, representation of existing institutions and practices, and representations of things like justice, power, inequality, and repression.

For example, suppose one was an anti-racist reformer in the US in 1850 or 1950. The diagnosis of the present may be that current institutions and majority attitudes, behaviors, and practices systematically repress, demean, and stunt members of the racial minority. The reformer's goal may be the creation of a society in which racial oppression, discrimination, and bias do not exist. And the strategy may be to create powerful coalitions of players in society who will work effectively and quickly to disassemble racist laws and institutions and to educate the public to leave behind their racist attitudes and beliefs.

So what are some of the basic conditions of realism and feasibility that a legitimate program of reform must satisfy? For a proposed reform agenda to be rationally supportable, its goals must be ***feasible*** and ***accessible***. The institutions, practices, and behaviors it postulates as an end state need to be consistent with what we know about how a society works. And there needs to be a possible pathway through which society can move from here to there.

In other words, the social reformer needs to demonstrate that --

- The described social arrangement can be **implemented**, given ordinary people and ordinary social processes and mechanisms; in other words, the social arrangement doesn't require a miracle to be achieved.
- The arrangement will have a significant likelihood of being **sustainable and self-reproducing**, given ordinary people and ordinary social processes. No miracles are needed to sustain the new society.
- There is a **feasible pathway** that can take us from here to there, consistent with ordinary people AND some set of moral constraints (democracy, commitment to legal processes, no illegal use of force).
- The described social arrangement will be **efficacious**: it will have the social effects that it is planned to have.

A little more specifically, the program of reform needs to be consistent with our best understanding of ***how ordinary human beings behave.*** It needs to create incentives that are consistent with ordinary human behavior; and the behaviors that result from these incentives need to reinforce the stability of the institutions that the program postulates. We don't need to offer a strong theory of universal human nature, in order to maintain that there are elements of motivation and psychology that are common among human beings and that will continue to drive their behavior in the future.

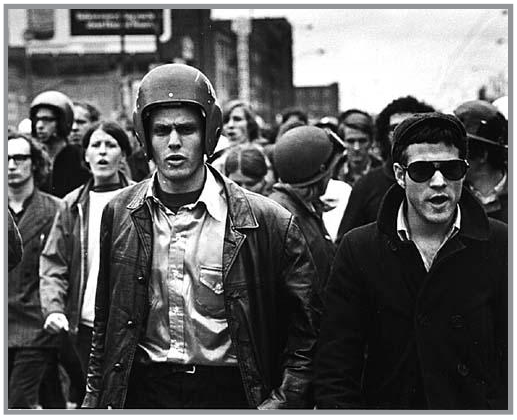
Second, the program needs to ***envision institutions that work correctly together***: they successfully coordinate behavior, motivate citizens, raise public revenues, and maintain order as a coherent system. For example, we could have little confidence in a theory of the future that postulated a wide range of public services and a fiscal model that depended entirely on voluntary contributions by citizens to society's coffers. And we would likewise be skeptical about a vision of the future that aggregated local functions like trash collection and building inspections to the national level.

Third, we would want to specify that we need to have a ***theory of democratic feasibility***: that there is a strategy of change that can be successfully executed within the constraints of a democratic society. No "dictatorship of the proletariat" on the road to a more just future; no use of violence by a minority party aiming to achieve its goals by force.

The social sciences can assist with each of these challenges. Consider first the "ordinary behavior" condition. Empirical studies of human behavior -- motivations, modes of reasoning, schemes of action -- provide a rich set of tools in terms of which to assess the likely behavior of individuals within a hypothetical social context. Ethnography, social psychology, applied rational choice theory, and the philosophy of action all have much to contribute on this issue.

Turn next to the "institutional workings" condition. One of the central tasks of the "new institutionalism" is to provide theories of the mechanisms and processes through which specific institutions interact with human actors to bring about social outcomes. So institutionalists from sociology, political science, and economics have many of the tools necessary to provide an assessment of the likely workings of a specified set of

hypothetical institutions.



The social sciences are also relevant to assessing the democratic feasibility requirement. Policies are implemented by governments, and governments are subject to a variety of political constraints. Within a democratic electoral system governments are unavoidably concerned about the effects of various policies on the electoral blocks upon which they depend. We can reason in some detail, as Adam Przeworski does in Capitalism and Social Democracy, about the feasibility of maintaining an electoral majority in favor of a given reform program over the period of time that would be required.

There is an important implication in all of this. Envisioning a better future for our society is a good thing. But in order to have a defensible plan for creating that future, we need to make the very best use possible of the social sciences in order to assess the feasibility, stability, and efficacy of the ideas for which we advocate. Not all visions for the future can be realized; and some visions turn out to have unintended and unanticipated consequences that have proven disastrous.

Protest and the politics of dissent

Thursday, July 08, 2010

There are several different moral and practical stances that people can take in relation to their social worlds. The scenes above depict one of these possibilities: vociferous protest and active opposition to specific social and political policies. Individuals and groups have ideas about justice and legitimacy. And they have specific material interests that are affected by state policies. When their values and interests are offended by the actions of their government or other collective actors, they may choose to mobilize around overt opposition and collective action. Street demonstrations, protests, boycotts, and destruction of property may be the result. Anti-globalization protests in Toronto in 2010, anti-war protests in 1968 and 2004, demands for aggressive AIDS policies in the 1990s, anti-racism protests in 1968, French protests against President Sarkozy's policies in 1999, and anti-NATO protests in Strasbourg in 2009 -- each scene represents an extensive movement against the actions of governments, international organizations, and social institutions.

What are some of the goals of public protests? One is obvious: to exert direct pressure on governments and other powerful organizations to change their policies and actions. Organizers and followers often have very concrete goals in mounting a protest, with an explicit theory of how the protest action will lead to the possibility of change of policy. This

is most evident in the demonstrations that took place in France in 2009 in opposition to the government's neo-liberal economic reform policies. Organizers, organizations, and unions had very specific notions about how mass protests in Paris, Dijon, Marseille, and Lyon could succeed in forcing the government to retreat. In this case the action is purposive and ***instrumental***: choose ***this*** strategy to bring about ***that*** result.

Another possible goal is more ***expressive*** than this description would suggest. People may mobilize around a demonstration out of their simple desire to express their moral dissent; to offer a moral example to the world of the wrongness of the targeted policy. Some strands of the US civil rights movement had this character; demonstrations served to cast a light on the fundamental injustice of US race relations and laws, and many supporters participated simply out of moral solidarity with these values.

A third possibility combines the expressive and instrumental types of collective action. Leaders and followers invested in a particular issue may want to publicize their values and their critique in order to persuade the broader public to share these values. So a goal of the demonstration is to illustrate the moral and political values that are involved, and to attempt to sway other citizens to share these values. This was part of Martin Luther King, Jr.'s theory of change: a strategy of non-violent protest could change attitudes throughout the country and eventually lead to very substantial change in law and practice. It also seems to be a part of the transnational movement of activists against neo-liberal globalization: help the mass of citizens of the developed world to see the harms created by the neo-liberal regime.

The occurrence of protest and demonstration is a commonplace. But it is also a central focus of scientific study by scholars such as Charles Tilly, Sidney Tarrow, or Doug McAdam under the topics of social movements and social contention. Here are several important recent contributions. Tarrow and Tilly published Contentious Politics in 2006. Tarrow's New Transnational Activism focuses on the anti-globalization protests that have

occurred since Seattle's WTO meetings in 1999. McAdam's Political Process and the Development of Black Insurgency, 1930-1970 offers a detailed analysis of the mobilization processes that culminated in the US Civil Rights movement. Each of these works, and dozens of others, have offered careful insights and theories about the mechanisms of social mobilization.

Social scientists have focused on several aspects of protest movements: for example, motivations of the followers; social characteristics of followers; characteristics of leaders; the organizations that serve to mobilize and coordinate protest; the networks of information and other resources that link separate organizations together; the nature of the grievances that stimulate prolonged protest movements; and the efficacy of protest movements. Quite a few important ideas have come out of these research efforts. For example, Charles Tilly introduced the important idea of "repertoires" of protest, making the point that different communities have developed different scripts for presenting their protests to the public and to the government. And Tilly, Tarrow, and McAdam have argued for an innovative approach to the study of contention, in the form of a methodology of the range of social mechanisms that can be identified in a variety of instances of mobilization.

One important fact that comparative study of protest movements and organizations demonstrates, is the common feature of ***diversity*** of purposes, goals, and strategies among the individuals and groups who support a movement. The US anti-war movement is a good example; the coalition that came together to create large demonstrations and public actions in various cities in the 1960s commonly represented a very wide range of political perspectives and goals, from Quakers to Progressive Labor activists. This range of political positions reflected significant disagreement about the goals of protest; but it also represented serious disagreement about the strategies of protest as well.

A crucial dividing line among anti-war organizations was the use of deliberate destruction of property as a tool of protest. Probably the majority of individuals and groups opposed the use of violence, whereas small organizations deliberately sought out opportunities for "trashing". The slogan, "Days of Rage," captures this perspective. This same divide was evident in the G20 demonstrations in Toronto last month, with Black Bloc activists deliberately finding opportunities for burning police cars and smashing shop windows. (Here is a manifesto from the Wombles on the subject of violence in demonstrations.) Peter Ackerman demonstrates in Strategic Nonviolent Conflict: The Dynamics of People Power in the Twentieth Century that non-violent protest has a very wide range of strategies at its disposal, and that these mechanisms have often proven very effective in achieving the goals of the protest.

(Quite a few earlier posts have focused on examples of social mobilization and theories of how groups become engaged in collective action; these can be found in the collective action thread.)

Gabriel Tarde's rediscovery

Friday, July 09, 2010

LES LOIS
DE
L'IMITATION
ÉTUDE SOCIOLOGIQUE
PAR
G. TARDE
PARIS
FÉLIX ALCAN, ÉDITEUR
1911

Gabriel Tarde was an important rival to Emile Durkheim on the scene of French sociology in the 1880s and 1890s. Durkheim essentially won the field, however, and Tarde's reputation diminished for a century. Durkheim's social holism and a search for social laws prevailed, and the sociology of individuals and the methodology of contingency that Tarde had constructed had little influence on the next several generations of sociologists in France. In the 1990s, however, several important strands of thought were receptive to a rediscovery of Tarde's thinking; Gilles Deleuze and Bruno Latour each found elements in Tarde's thinking that provided intellectual antecedent and support for ideas of their own. In the past fifteen years or so there has been a significant revival of interest in Tarde.

An important volume edited by Matei Candea represents the most extensive reconsideration of Tarde's views of sociology to date. Contributors to The Social after Gabriel Tarde: Debates and Assessments provide highly provocative and stimulating discussions of various aspects of Tarde's philosophy of sociology, and the book represents an important contribution to new thinking about the social sciences. The introductory essay by Candea is very useful and is available for free as a sample of the Kindle edition. Bruno Latour's contribution to the volume is available on Latour's website (link), as are two short pieces on Latour's thoughts about Tarde (link, link).

Several aspects of Tarde's philosophy of sociology stand out. First is his rejection of Durkheim's holism. He was consistently critical of the idea of finished social wholes; instead, he recommended a focus on the components of social interactions and practices. This might be understood as a focus on the individual and his/her psychological properties (methodological individualism); but it also might be seen as a more radical disassembly of the social into sub- and supra-individual constructions. This is where Latour finds inspiration; he suggests that Tarde is an intellectual precursor to Actor Network Theory (ANT), which does not give ontological priority to ***either*** individuals or social wholes.

Another important feature of Tarde's philosophy of the social is his emphasis on heterogeneity and contingency within the social. He revels in the fact of variation among and within social processes, and he emphasizes the deep degree of contingency that characterizes social outcomes. Here is one example in Social Laws: "Science is the co-ordination of phenomena regarded from the side of their repetitions. But this does not mean that differentiation is not an essential mode of procedure for the scientific mind" (8).

The contributors to the Candea volume illustrate this deep contingency in a different way; they ask the question of how the science of sociology might have developed differently if Tarde's views had taken deeper root. Here is how Candea puts this point in the opening words of the volume:

Some theorists have intersected with history in such an odd way that they seem to require an introduction in the form of a thought experiment: What if Durkheimian

sociology had had, from the very beginning, a thoughtful and vocal opponent; one who queries the 'thingness' of the social and the holistic, bounded nature of societies and human groups; one who accused Durkheim of disregarding the contingency of history in the search for scientific 'structure'; one who proposed a radical reversal of the organic analogy, claiming that organisms are societies and not the other way around; one who foregrounded imitations, oppositions and inventions where Durkheim saw conformism to a rule as the key component of the social; one who had already found a way to dissolve the linked contrasts between individual and society, micro and macro, agency and structure, freedom and constraint -- Durkheim's main (and for many, troublesome) legacy to twentieth-century social science?
And, of course, that critic is none other than Tarde.

Here are a few of Tarde's ideas as expressed in his 1897 volume, Social Laws: An Outline of Sociology (translated into English in 1899).

Thus science consists in viewing any fact whatsoever under three aspects, corresponding, respectively, to the repetitions, oppositions, and adaptations which it contains, and which are obscured by a mass of variations, dissymmetries, and disharmonies. The relation of cause to effect, in fact, is not the only element which properly constitutes scientific knowledge. (9)
Here is a schematic philosophy of science -- an account of what sociology consists of. Tarde emphasizes the discovery of both regularities and variations:

These reflections were needed in order to show what sociology must be, if it is to deserve the name of science, and along what paths sociologists must guide its course, if they wish to see it assume, unchallenged, its proper rank. Like every other science, it will attain this only when it has gained, and is conscious of possessing, its own domain of repetitions, its own domain of oppositions, and its own domain of adaptations, each characteristic of itself and belonging wholly to itself. Sociology can only make progress when it succeeds in substituting true repetitions, oppositions, and harmonies for false ones, as all the other sciences have done before it. And in place of repetitions, oppositions, and adaptations that are true but vague, it must find others that become ever more exact as it advances. (10)
And on a central tenet of methodological individualism--the idea of the strict determination of the whole as a consequence of the characteristics of indistinguishable individual components:

I believe that none of the above-mentioned differences, including even the mere variety of arrangement and random distribution of matter throughout space, can be explained on the theory of exactly similar atomic elements—an hypothesis so dear to chemists, who are in this respect the real metaphysicians; I do not see that Spencer’s so-called law of the instability of the homogeneous explains anything. And hence, I believe that the only means of explaining this exuberant growth of individual differences upon the surface of phenomena is by assuming that they spring from a motley array of elements, each possessing its own individual characteristics. (15)
And rather than seeking out high-level generalizations and regularities about the social world, Tarde advocates for more specific and granular studies:

Fortunately, screened and sheltered from view by these ambitious generalizations, certain less venturesome workers strove, with greater success, to formulate other more substantial laws concerning the details. Among these should be mentioned the linguists, the mythologists, and above all the economists. These specialists in sociological fields

discovered various interesting relations among successive and simultaneous facts, which recurred constantly within the limits of the narrow domain they were examining. (18)
Tarde explicitly rejects John Stuart Mill's particular version of methodological individualism:

In some quarters the feeling has existed that we must look to psychology for any general explanation of the laws and pseudo-laws of economics, language, mythology, etc. No man held to this view with greater force and clearness than John Stuart Mill. At the end of his *Logic* he represents sociology as a species of applied psychology. Unfortunately he did not analyze the concept carefully enough; and the psychology to which he looked for the key to social phenomena was merely individual psychology—the branch which studies the interrelations of impressions and imagery in a single mind, believing that everything within this domain can be explained according to the laws of association of these elements. Thus conceived, sociology became a sort of enlarged and externalized English associationism, and was in a fair way to lose its originality. (19)
And here is an explicit rejection of a particular kind of Durkheimian social fact -- the idea of a national character:

Sooner or later, one must open his eyes to the evidence, and recognize that the genius of a people or race, instead of being a factor superior to and dominating the characters of the individuals (who have been considered its offshoots and ephemeral manifestations) is simply a convenient label, or impersonal synthesis, of these individual characteristics; the latter alone are real, effective, and ever in activity; they are in a state of continual fermentation in the bosom of every society, thanks to the examples borrowed and exchanged with neighboring societies to their great mutual profit. (27)
Here is how Bruno Latour summarizes his appreciation of Tarde in "Gabriel Tarde and the End of the Social" (link):

And yet, I want to argue in this chapter, through a close reading of his recently republished most daring book, *Monadologie et sociologie* (M&S), that Tarde introduced into social theory the two main arguments which ANT has tried, somewhat vainly, to champion:

a) the nature and society divide is irrelevant for understanding the world of human interactions ;

b) the micro/macro distinction stifle any attempt at understanding how society is being generated.

In other words, I want to make a little thought experiment and imagine what the field of social sciences would have become in the last century, had Tarde's insights been turned into a science instead of Durkheim's. Or may be it is that Tarde, a truly daring but also, I have to admit, totally undisciplined mind, needed a rather different century so as to be finally understood.
Latour ends his contribution to the Candea volume with an intriguing section called "Digital traceability ... Tarde's vindication?". The key idea here is that the twenty-first century permits social scientists to go decisively and transparently beyond the primitive aggregative statistics that underlay Durkheim's approach to the "social whole." Tarde, and Latour, look at Durkheim's social whole as no more than a crude statistical aggregation of data; and, according to Latour, Tarde had envisioned a time when the statistics and quantitative data deriving from social behavior would be transparent and visible. This, Latour suggests, is becoming true. Today we can look at social data at a full

range of levels of aggregation, moving back and forth from the micro to the macro with ease. Here is Tarde's version of the vision:

If Statistics continues to progress as it has done for several years, if the information which it gives us continues to gain in accuracy, in dispatch, in bulk, and in regularity, a time may come when upon the accomplishment of every social event a figure will at once issue forth automatically, so to speak, to take its place on the statistical registers that will be continuously communicated to the public and spread abroad pictorially by the daily press.
And here is Latour's comment:

It is indeed striking that at this very moment, the fast expanding fields of "data visualization", "computational social science" or "biological networks" are tracing before our eyes, just the sort of data Tarde would have acclaimed. ... Digital navigation through point-to-point datascapes might, a century later, vindicate Tarde's insights.
This is only the briefest of samplings from Tarde's work, from one short book. But it is perhaps enough to give substance to the idea that Tarde is as much of an innovative founder of scientific sociology as Weber, Marx, or Durkheim; and he is a thinker from whom a new generation of sociologists can gain new ideas.

Knowing the population

Tuesday, July 13, 2010

At any given time there are huge areas of the unknown when it comes to the question, what do various members of our society care about? We have opinion research tools, of course. But we don't really have good answers to any of these questions:

- How do West Bloomfield teenagers think about their futures?
- Why do Kenyan truck drivers refrain from the most basic AIDS-prevention techniques?
- Are skateboarders disaffected from mainstream society?
- What does it mean when affluent suburban white kids wear hiphop gear?
- What do laid-off auto workers think about higher education for themselves?
- How do Mexican gang killers feel about their victims?

These questions fall in the general area of qualitative knowledge of social actors and groups. We want to know in some detail about the subjectivity of the members of these groups -- how they think, what they value, how they perceive the world. There can be a quantitative side as well -- once we have information about some people in a group we can ask about the distribution of these characteristics over the group.

But here is the key question at the moment: where within the disciplines of the social sciences does inquiry into these questions fall? And the simple answer is, none of them

and parts of all of them. Ethnography is relevant; but anthropologists usually seem to have larger theoretical apples to peel. Political scientists are interested in a small subset of these questions -- basically, they are interested in measuring political attitudes and preferences. And some branches of sociology have had an interest in this kind of concrete social description -- for example, Erving Goffman; but at present this kind of detailed inquiry into the lived experience of particular individuals and groups doesn't have much prestige in the field. It is hard to see AJS publishing a descriptive study of attitudes and values of West Bloomfield teenagers.

So two things seem to be true. First, there is an important kind of knowledge that we need to have in order to adequately understand society. And second, there doesn't seem to be a discipline in the social sciences that takes on this challenge.

So how should we think about the subjective experience and mental frameworks of a given social group? A group is defined by some set of characteristics -- people from a certain region ("midwesterners"), people with a certain occupation ("insurance adjustors"), people with a certain national origin ("Irish-Americans"), people from a particular age cohort (Generation X), or people with a certain religion or value scheme ("Protestants," "Populists"). So by construction, members of the group share a few characteristics in common -- the "nominal" characteristics of the group. But we also know that almost every group displays a great range of diversity with respect to other characteristics -- lifestyle, political attitudes, moral commitments, ... So how should we think about the problem of coming to better understand the distinctive features of consciousness as well as the range of diversity and similarity among members of the group? This raises a number of interesting questions. For example:

- Are there similarities that members of this group possess over and above the nominal characteristics of the group? Is there something distinctive about the experience and mentality of Gen X or "The Greatest Generation"?
- Are some groups more diverse than others with respect to a given set of social characteristics?
- Is it possible to explain some of the patterns of similarity that are discovered among members of the group?

Suppose we are interested in K-12 school teachers: what makes them choose this work, what are some of the social backgrounds from which they emerge, how do they feel about their work, are they idealistic or jaded in their work? How might we approach a subject like this from the point of view of social science research?

One possibility is to approach the task through survey research. We might design a survey intended to measure attitudes, background, degree of commitment, etc. The results of the survey can be presented as a set of descriptive statistics for each question, with standard deviations. We might have a theory of how the questions cluster, and we might classify individuals into sub-groups sharing a cluster of properties. Further, we might try to identify differences that exist among sub-populations (by race, age, or occupational group, let us say). And we would probably want to see whether there are interesting correlations among some of the recorded variables.

Another possibility is to approach the task through interviews and qualitative research. Here the investigator will work with a smaller number of cases; but he/she will get to know individuals well, and will come to see the nuance and detail of the multiple experiences that school teachers have of their work. Here we might imagine several different kinds of findings:

"There is no typical school teacher; rather, each has a different profile." This researcher may not be able to summarize or analyze his/her findings, but rather needs to provide a

descriptive narrative of a series of cases. This is perhaps the kind of knowledge that Studs Terkel produces (link).

Or: "A small set of common themes emerge from a number of the cases, so we can begin to classify teachers into a small set of similar groups."
It is also possible to code and aggregate the results of this sort of qualitative research. This may permit us to discover that there are some broad groupings among the population surveyed. We might find that there are fairly visible groupings among school teachers, with similar attitudes and commitments among individuals of group A that distinguish them sharply from individuals of group B. (For example: "Inner city teachers differ significantly from suburban teachers;" "teachers in their 50s differ significantly from teachers in their 30s;" "white and black teacher differ significantly from each other.") The researcher may then try to arrive at hypotheses about why the A's are so different from the B's: educational background, experience within a certain industry, gender or race characteristics, cohort-specific experiences, differences in the work-place environment. This represents a slide from qualitative inquiry to quantitative analysis; ethnographic and individual-level investigation is aggregated into analytical categories. Here the sociologically interesting question is that of social causation: what are the social influences that differently affected the two populations?
The key point here is that individuals have a rather specific socially constituted subjectivity -- a set of mental frameworks, concepts, modes of thinking, emotions, values, and aversions -- that distinguishes them from others. This subjective framework provides a basis for their actions, choices, and preferences. We also speculate, often, that there are important similarities in these frameworks within groups in dimensions that distinguish this group from that group. It appears to be a fundamentally important task for the social sciences, to have means of investigating these empirical realities. These questions are important, most fundamentally, because they give an indication of why people behave as they do. And yet the existing disciplines have little interest in pursuing these types of questions.

Methodological nationalism

Thursday, July 15, 2010

Are there logical divisions within the global whole of social interactions and systems that permit us to focus on a limited, bounded social reality? Is there a stable level of social aggregation that might provide an answer to the "units of analysis" question in the social sciences? This is a question that has recurred several times in prior postings -- on regions (link), on levels of analysis (link), and on world systems (link). Here I'll focus on the nation-state as one such system of demarcation.

We can start with a very compelling recent critique of current definitions of the social

sciences. Andreas Wimmer and Nina Glick Schiller offer an intriguing analysis of social science conceptual schemes in "Methodological nationalism and beyond: nation-state building, migration and the social sciences" (link). (Wimmer's Nationalist Exclusion and Ethnic Conflict: Shadows of Modernity is also of great interest.) The core idea is the notion that the social sciences have tended to conceptualize social phenomena around the boundaries of the nation-state. And, these authors contend, this assumption creates a set of blinders for the social sciences that makes it difficult to capture some crucially important forms of social interaction and structure.

Wimmer and Schiller characterize the idea of methodological nationalism in three forms:

The epistemic structures and programmes of mainstream social sciences have been closely attached to, and shaped by, the experience of modern nation-state formation.... The social sciences were captured by the apparent naturalness and givenness of a world divided into societies along the lines of nation-states.... Because they were structured according to nation-state principles, these became so routinely assumed and 'banal', that they vanished from sight altogether. (303-4)

A second variant, typical of more empirically oriented social science practices, is taking national discourses, agendas, loyalties and histories for granted, without problematizing themor making them an object of an analysis in its own right. Instead, nationally bounded societies are taken to be the naturally given entities to study. (304)

Let us now address a third and last variant of methodological nationalism: the territorialization of social science imaginary and the reduction of the analytical focus to the boundaries of the nation-state. (307)

The three variants of methodological nationalism ... are thus ignorance, naturalization, and territorial limitation. (308)
Their view is a complex one. They think that the social sciences have been trapped behind a kind of conceptual blindness, according to which the concepts of nation and state structure our perception of social reality but disappear as objects of critical inquiry. Second, they argue that there were real processes of nation and state building that created this blindness -- from nineteenth century nation building to twentieth century colonialism. And third, they suggest that the framework of MN itself contributed to the concrete shaping of the history of nation and state building. So it is a three-way relationship between knowledge and the social world.

"Nationalism" has several different connotations. First, it implies that peoples fall into "nations," and that "nations" are somewhat inevitable and compact social realities. France is a nation. But closer examination reveals that France is a social-historical construct, not a uniform or natural social whole. (Here is a discussion of Emmanuel Todd's version of this argument; link). Alsatians, Bretons, and Basques are part of the French nation; and yet they are communities with distinct identities, histories, and affinities. So forging France as a nation was a political effort, and it is an unfinished project.

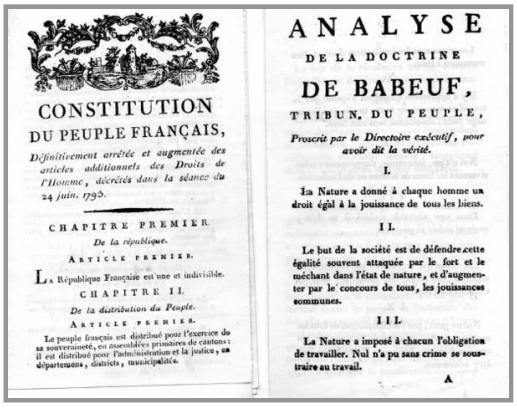
Second, nationalism refers to movements based on mobilization of political identities. Hindu nationalists have sought power in India through the BJP on the basis of a constructed, mobilized (and in various ways fictional) Hindu identity. The struggle over the Babri Mosque, and the political use to which this symbol was put in BJP mobilization, illustrates this point. But "nationalist politics" also possess a social reality; it is all too evident that even fictive "national identities" can be powerful sources of political

motivation. So nationalist politics in the twentieth century were a key part of many historical processes. (Michael Mann's The Dark Side of Democracy: Explaining Ethnic Cleansing illustrates this point.) And, of course, there may be multiple national identities within a given region; so the "nation" consists of multiple "nationalist" groups. Ben Anderson's Imagined Communities: Reflections on the Origin and Spread of Nationalism provides an extensive development of the political and constructed nature of ethnic and national identities.

What about the other pole of the "nation-state" conjunction -- the state? Here the idea is that the state is the seat of sovereign authority; the origin and enforcement of legal institutions; and the holder of a monopoly of coercive power in a region. A state does not inevitably correspond to a nation; so when we hyphenate the conjunction we make a further substantive assumption -- that nations grow into states, and that states cultivate national identities.

The fundamental criticism that Wimmer and Schiller express -- the fundamental defect of methodological nationalism -- is that it limits the ability of social scientists and historians to perceive processes that are above or below the level of the nation-state. Trans-national processes (they offer migration as an example) and sub-national processes (we might refer to the kinds of violent mobilization studied by Mann in the *Dark Side of Democracy*) are either invisible or unimportant, from the point of view of methodological nationalism. So the methodology occludes social phenomena that are actually of great importance to understanding the contemporary world. Here is how they suggest going beyond methodological nationalism in the field of migration studies:

Going beyond methodological nationalism in the study of current migration thus may require more than a focus on transnational communities instead of the nation and its immigrants. In order to escape the magnetism of established methodologies, ways of defining the object of analysis and algorithms for generating questions, we may have to develop (or rediscover?) analytical tools and concepts not coloured by the self-evidence of a world ordered into nation-states. This is what we perceive, together with many other current observers of the social sciences, as the major task lying ahead of us. We are certainly not able to offer such a set of analytical tools here. (323-24)



Wimmer and Schiller seem to point in a direction that we find in Saskia Sassen's work as well: the idea that it is necessary for the social sciences to invent a new vocabulary that does a better job of capturing the idea of the interconnectedness of social activity and social systems (for example, in A Sociology of Globalization; link). The old metaphors of "levels" of social life organized on an ascending spatial basis doesn't seem to work well today when we try to deal with topics like global cities, diasporic communities, or transnational protest movements. And each of these critiques makes a convincing case that these non-national phenomena are influential all the way down into the "national" orders singled out by traditional classification schemes.

Radicals, activists, and reformers

Sunday, July 18, 2010

Several posts have drawn attention to the acts of criticism of the present and advocacy for change. But both criticism and programs of advocacy have enormous variation when it comes to analytical and theoretical rigor. Babeuf's conspiracy of equals set the stage for radicalism during the French Revolution. But how good were his diagnosis of the

CONSTITUTION
DU PEUPLE FRANÇAIS,
Définitivement arrêtée et augmentée des articles additionnels des Droits de l'Homme, décrétés dans la séance du 24 juin. 1793.

CHAPITRE PREMIER
De la république.
ARTICLE PREMIER.
La République Française est une et indivisible.
CHAPITRE II.
De la distribution du Peuple.
ARTICLE PREMIER.
Le peuple français est distribué pour l'exercice de sa souveraineté, en assemblées primaires de cantons: il est distribué pour l'administration et la justice, en départemens, districts, municipalités.

ANALYSE
DE LA DOCTRINE
DE BABEUF,
TRIBUN, DU PEUPLE,
Proscrit par le Directoire exécutif, pour avoir dit la vérité.

I.
La Nature a donné à chaque homme un droit égal à la jouissance de tous les biens.

II.
Le but de la société est de défendre cette égalité souvent attaquée par le fort et le méchant dans l'état de nature, et d'augmenter par le concours de tous, les jouissances communes.

III.
La Nature a imposé à chacun l'obligation de travailler. Nul n'a pu sans crime se soustraire au travail.

A

present and his vision of a possible future? And what was he really trying to accomplish as a radical?

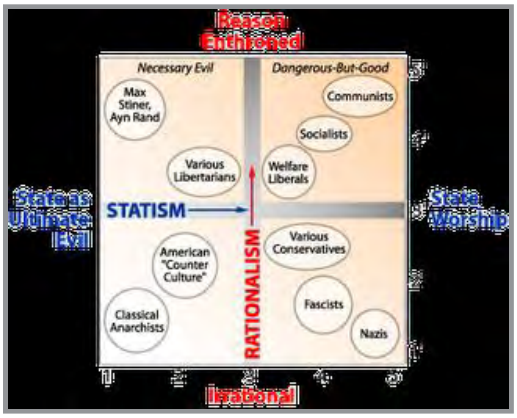
Criticism and advocacy can combine into several rather different stances -- think of Mill, Bakunin, and Lenin and the very different ways in which they combined reasoned thought and political activism. It is worth asking the question, what are the different states of mind and intentionality that characterize different kinds of social activists. Fundamentally, how do we distinguish between liberal reformers, radical activists, and revolutionaries? We might say that the difference parallels that between amelioration, opposition, and transformation; systemic change and piecemeal improvement; gradual and abrupt; but can we say more? Here are some sketches.

Radical activists are ... radical. They want largescale, rapid change in society. The radical opposition surveys the existing social world; identifies a set of institutions and practices that currently exist; judges that these institutions and practices are fundamentally flawed in some important way; and demands fundamental change or replacement for these institutions and practices. So the radical activist demands immediate, concerted action to bring this complex state of affairs about. The radical activist is not intellectually committed to proving the feasibility of alternatives; he/she is committed in the heart to the abolition of the present injustice.

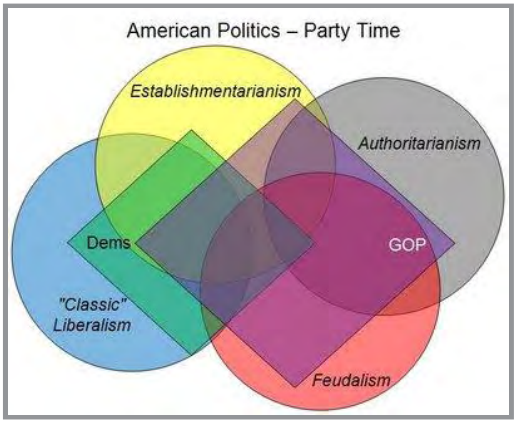
The liberal reformer is a critic as well. There are feature of the existing social world that he/she strenuously rejects. But the liberal reformer accepts the reality of the present. He/she proposes a set of immediate and mid-range reforms that will work to modify the unacceptable features of the present and move society towards a more satisfactory set of institutions and practices in the future. Gradual transformation is the model of change for the liberal reformer. Having confidence in the feasibility of a given set of pathways of reform is the highest intellectual value.

The revolutionary is an architect of change, not just a radical activist. The revolutionary wants to sweep away the bad institutions and social relations of the present. And the revolutionary has a vision of the new society which the movement is aiming at creating. The revolutionary is intellectually committed to the achievement of a concrete social order that is better than the present; and this means he/she is committed to demonstrating the feasibility of the new order. So the revolutionary, like the liberal reformer, needs to be a social engineer making good use of historical insights and social analysis into the ways that social change works.

So one way of distinguishing the radical from the liberal is in terms of the scope of change that the critic demands. The radical demands sweeping change of a wide range of institutions; the liberal demands a more limited set of changes. The revolutionary is distinct from the activist as well, in that the revolutionary is intellectually committed to the feasibility of the new order.



Here is another way of drawing the distinction -- in terms of pace and means of achieving change. The radical demands change in a very short period of change -- and therefore rejects "gradual reform and improvement".



Here is yet another way of drawing the line between liberal reformers and activists and revolutionaries. The radical activist and the revolutionary sometimes advocate for means of social change that the liberal reformer would reject: the use of violence, dictatorship of the proletariat, authoritarian use of state power. The liberal reformer advocates for a process of change that takes place within existing institutions, over an extended period of time, perhaps leading to a less sweeping transformation of society.

The distinction between liberal, activist, and revolutionary is perhaps not as sharp as indicated here. The categories are not mutually exclusive. On the topic of racial justice, for example, we might say that the abolition of slavery was a radical demand, requiring profound and discontinuous change. The movement in the 1950s and 1960s for a raft of legal reforms in support of full equality for African-Americans was a liberal and gradualist strategy. So both radical and liberal steps were involved in the quest for racial justice in the United States. And each set of demands was crucial for the achievement of racial justice.

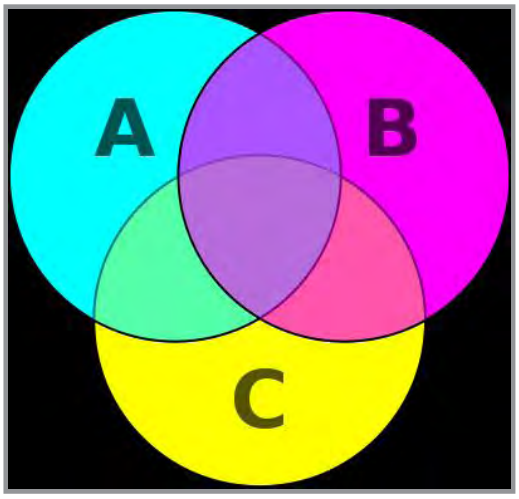
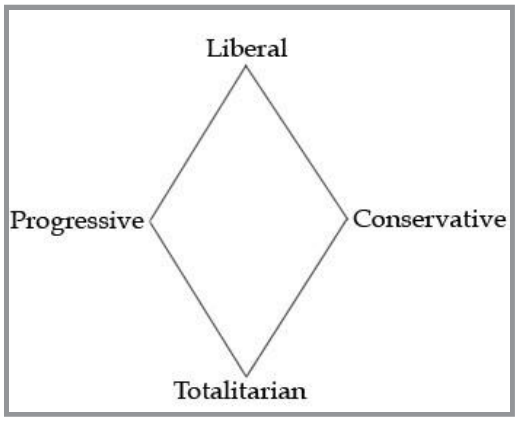
The politics color wheel

Wednesday, July 21, 2010

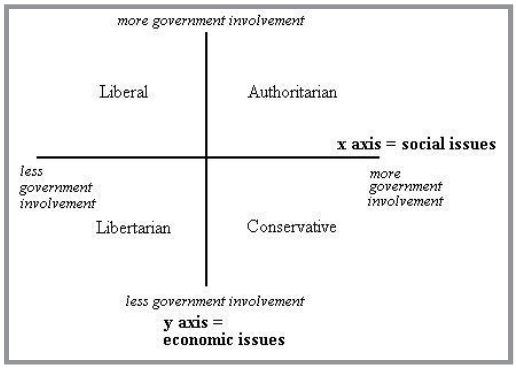


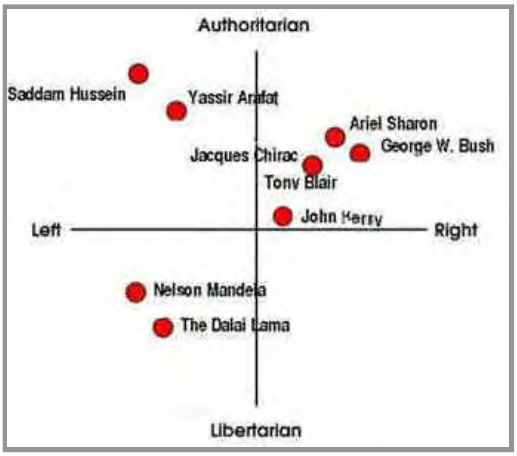


The problem of mapping or classifying people's political attitudes is more complicated than it looks. Placing people on a spectrum from left to right is convenient but over-simple. It assumes that there is a single dimension of political difference, ranging from conservative to liberal, and that everyone can be placed somewhere along that spectrum. But social and political attitudes aren't single-dimensional. So we'd like to have a way of mapping the space of attitudes that captures the separate dimensions that go into political attitudes.

Most of the schemes above take a step forward by hypothesizing two dimensions reflecting attitudes towards the involvement of the state in the economy and in individual social and moral life. An economic conservative opposes state involvement in the economy. A social liberal opposes state involvement in individual choices and lifestyle, while a social conservative favors intervention in individual behavior when it comes to certain "social" issues. A libertarian opposes both forms of state intervention and an authoritarian supports both.

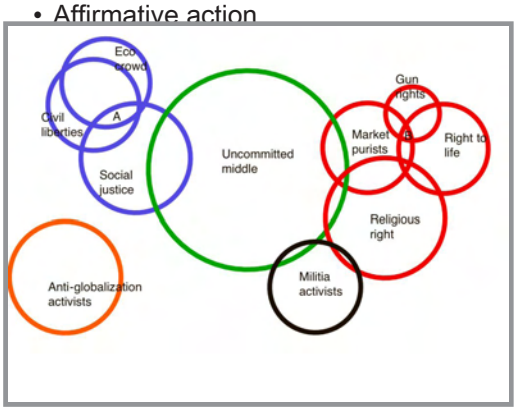
This kind of classification is an improvement, but it doesn't fully satisfy. It doesn't really capture the substantive moral ideas that might underlie these attitudes, the political





philosophy that might underlie political preferences.

A more substantive effort at classification might take the form of a cluster of values shared by various groups. Conservatives favor maintaining traditional values (religion and morality), maintaining an existing system of wealth, power, and prestige (market and social inequality), and limiting the use of state power to these functions. Progressives favor greater social equality and opportunity; they favor the free expression of individual life choices; and they favor using the authority of the state to increase the equality and freedom of ordinary people. Conservatives defend existing inequalities and oppose redistribution. Progressives condemn certain kinds of inequality and justify redistributive measures to redress these inequalities.



Yet another approach is to consider a diagnostic set of issues and classify the individual according to where he/she falls on these issues. For example:

	Pro- Tiger		Anti- Tiger		
Pro- Gvt.			A SLFP/EPDP/TMVP	B JHU/NFF	Pro-War
Anti- Gvt.	H: Elements of Tiger sympathizers	H: Elements of Tiger sympathizers	C UNP/TULF	D JVP	
Pro- Gvt.			G Elements of LSSP/CP/NLF	All-anti but pro-Gvt.	Anti-War
Anti- Gvt.	H: Elements of Tiger sympathizers	F: TNA/ peace NGOs /NLF	E UTHR/SLDF	All -anti	
	Ealam	Federalism	Pro-Devolution	Anti-Devolution	

- Guaranteeing a woman's right to choose
- Restricting the sale of assault rifles
- Carbon tax
- Inheritance tax
- Immigration reform
- Affirmative action

We might imagine grouping the population into a sort of Venn diagram. Suppose that each circle represents individuals who include the specific issue within his/her top five issues. Overlaps indicate the circumstance of individuals who share the issues of each overlapping circle. So region A represents individuals who rank civil liberties, social justice, and environmental issues in their top five; region B represents individuals who rank markets, guns, right to life, and religious fundamentalism in their top five priorities. On this diagram, there is no one who is a militia activist and a social justice advocate.

Several questions arise here: are there correlations across individuals with respect to these issues? Is there a set of philosophical principles that underlie the choices that individuals make within connected clusters? And do the clusters correspond to identifiable political groups?

A property-owning democracy

Sunday, July 25, 2010

John Rawls offered a general set of principles of justice that were formally neutral across specific institutions. However, he also believed that the institutions of a "property-owning democracy" are most likely to satisfy the two principles of justice. So what is a property-owning democracy?

In Justice as Fairness: A Restatement (2001) Rawls offered a more explicit discussion of this concept than was offered in A Theory of Justice: Original Edition (1971). Here are several important descriptions:

Let us distinguish five kinds of regime viewed as social systems, complete with their political, economic, and social institutions: (a) laissez-faire capitalism; (b) welfare-state capitalism; (c) state socialism with a command economy; (d) property-owning democracy; and finally, (e) liberal (democratic) socialism.

Regarding any regime four questions naturally arise. One is the question of right: that is, whether its institutions are right and just. Another is the question of design: that is, whether a regime's institutions can be effectively designed to realize its declared aims

and objectives. This implies a third question: whether citizens, in view of their likely interests and ends as shaped by the regime's basic structure, can be relied on to comply with just institutions and the rules that apply to them in their various offices and positions. The problem of corruption is an aspect of this. Finally, there is the question of competence: whether the tasks assigned to offices and positions would prove simply too difficult for those likely to hold them.

What we would like, of course, are just and effectively designed basic institutions that effectively encourage aims and interests necessary to sustain them. Beyond this, persons should not confront tasks that are too difficult for them or that exceed their powers. Arrangements should be fully workable, or practicable. Much conservative thought has focused on the last three questions mentionsed above, criticizing the ineffectiveness of the so-called welfare state and its tendencies toward waste and corruption. But here we focus largely on the first question of right and justice, leaving the others aside. (136-137)
(Notice that these four questions converge closely with the feasibility conditions on reforms mentioned in an earlier post.)

There is similar but less developed language in the original version of the *Theory of Justice*:
Throughout the choice between a private-property economy and socialism isleft open; from the standpoint of the theory of justice alone, various basic structures would appear to satisfy its principles. (TJ, 258)
Rawls argues that the first three alternatives mentioned here (a-c) fail the test of justice, in that each violates conditions of the two principles of justice in one way or the other. So only a property-owning democracy and liberal socialism are consistent with the two principles of justice (138). Another way of putting this conclusion is that either regime can be just if it functions as designed, and the choice between them is dictated by pragmatic considerations rather than considerations of fundamental justice.
Here is how Rawls describes the fundamental goal of a property-owning democracy:

In property-owning democracy, ... the aim is to realize in the basic institutions the idea of society as a fair system of cooperation between citizens regarded as free and equal. To do this, those institutions must, from the outset, put in the hands of citizens generally, and not only of a few, sufficient productive means for them to be fully cooperating members of society on a footing of equality (140).
Rawls isn't very explicit about the institutions that constitute a property-owning democracy, but here is a general description:

Both a property-owning democracy and a liberal socialist regime set up a constitutional framework for democratic politics, guarantee the basic liberties with the fair value of the political liberties and fair equality of opportunity, and regulate economic and social inequalities by a principle of mutuality, if not by the difference principle. (138)
This last point is important:

For example, background institutions must work to keep property and wealth evenly enough shared over time to preserve the fair value of the political liberties and fair equality of opportunities over generations. They do this by laws regulating bequest and inheritance of property, and other devices such as taxes, to prevent excessive concentrations of private power. (51)
And concentration of wealth is one of the deficiencies of a near-cousin of the property-owning democracy, welfare-state capitalism:

One major difference is this: the background institutions of property-owning democracy work to disperse the ownership of wealth and capital, and thus to prevent a small part of society from controlling the economy, and indirectly, political life as well. By contrast, welfare-state capitalism permits a small class to have a near monopoly of the means of production. (139) [also Collected Papers, p. 419]

The past thirty years have taken us a great distance away from the social ideal represented by Rawls's *Theory of Justice*. The acceleration of inequalities of income and wealth in the US economy is flatly unjust, by Rawls's standards. The increasing -- and now by Supreme Court decision, almost unconstrained -- ability of corporations to exert influence within political affairs has severely undermined the fundamental political equality of all citizens. And the extreme forms of inequality of opportunity and outcome that exist in our society -- and the widening of these gaps in recent decades -- violate the basic principles of justice, requiring the full and fair equality of political lives of all citizens. This suggests that Rawls's theory provides the basis for a very sweeping critique of existing economic and political institutions. In effect, the liberal theorist offers radical criticism of the existing order.

(Thomas Pogge's John Rawls: His Life and Theory of Justice has a good discussion of this topic.)

Area studies and social science theories

Wednesday, July 28, 2010

image: The ruins of Bagan, Myanmar

Understanding a particular place seems to involve a very specific kind of knowledge and research. It involves understanding the unique combination of historical circumstances, social processes, cultural formations, and unique institutions that give rise to the current complex social reality. And yet it also involves an effort to understand and explain the developments that are observed -- which implies some sort of appeal to social science theory. For the past four decades this space has been occupied by "area studies" -- Latin American studies, Asian studies, African studies.

Here is a nice 1998 paper by South Asian historian and former president of the Association for Asian Studies David Luddens on the epistemic foundations of area studies (link). Here is how Luddens formulates the issue:

The production of area-specific knowledge about the world has no firm theoretical foundation. It seems to be an intellectual by-product of modern state territorialism and of those state-supported institutions of area studies which became prominent during the heyday of the nation state, in the decades between 1945 and 1990. Area studies in the university find their official justification in itself because they effectively serve disciplines, professions, business and national interests. The rationale for area studies for itself derives from the need to understand the diversity of human experience, which is

increasingly embroiled in identity politics and debates about cultural pluralism. University administrators, legislators, and funding agencies now find the old rationale for area studies less compelling and institutional support for the production of area-specific knowledge depends more and more on its utility for academic globalization, as the university, like business and government, seeks to expand its operations around the world and to establish it own authority in global culture. Though scholars who produce area-specific knowledge are well endowed with talent and resources, they find it hard to adapt to this trend without sacrificing their old intellectual commitments, because they have such a weak theoretical justification for doing what they do. To sustain their enterprise, they need to theorize area-studies in relation to globalization. This is the first in a set of essays that work in that direction. It focuses on the institutional history of area studies in the long-term process of globalization. (1)
Here I'd like to focus on the relationship between area knowledge and disciplinary knowledge.

Area studies is in its nature an interdisciplinary assemblage, at two levels -- institutional and individual. For example, centers for Latin American studies commonly involve political scientists, anthropologists, literary specialists, art historians, and sociologists, each bringing a specific body of knowledge and inquiry to the collective effort. But furthermore, each individual area specialist is expected to show some degree of interdisciplinary knowledge in his or her research. This is the value-added provided by a center: individuals come together and gain insight from colleagues in other disciplines. It is commonly believed among area specialists that excessive focus on a single disciplinary perspective is likely to create a form of "aspect blindness" in the investigator -- the economic historian of China overlooks the cultural forces at work, the political scientist who studies Latin American populism may fail to see the influence of religious traditions, and so forth.

How should area studies specialists and historians employ general social theories in attempting to understand particular social and historical examples? How, for example, is social science theory pertinent to explaining the historical experience of India or Burma? In other words, how can we bring together the specific knowledge of area specialists and the more general knowledge of discipline-based social scientists?

Some theoretical frameworks -- the study of social movements, analysis of land tenure relations, analysis of local political power practices, analysis of local political traditions -- are plainly useful across studies of various societies. They offer good common questions -- so long as we recall that there are very different answers to these questions in different places and times. And they can provide suggestive ideas about the causal processes that may be underway in particular periods of social change.

One important goal of the use of social science theories is to help the researcher to arrive at descriptions of the particular institutions, traditions, mentalities, etc., through which various general factors are worked out -- to mediate the particular and the general. Social science theories provide developed conceptual schemes and vocabularies in terms of which to analyze the concrete social phenomena. What is a revolution? How does it differ from a coup or a fall of government? So social science theory is valuable as a source of ideas about how to organize and conceptualize the social given in a particular area.

Another critical contribution of the social sciences to area studies is the growing collection of common social mechanisms and processes that political scientists, sociologists, and economists have studied in detail. Social scientists aren't able to provide comprehensive

theories of society that can simply be "applied" to specific areas; there is no general theory of the state that would permit the Middle East specialist to understand and predict the behavior of the Syrian regime. But social scientists are able to identify mundane mid-level mechanisms that arise in politics, economies, and social movements; and these theories of specific mechanisms can be of great value to the area specialist. (This is a crucial contribution of Chuck Tilly's work; for example, Tilly and Tarrow, Contentious Politics.)

Consider one particular example -- the China area specialist who is trying to get a better understanding of changes in China's economic structure between 1980 and 2000. Findings having to do with the mechanisms of rent-seeking and corruption will probably shed important light on the developments; the mechanism of "bureaucratic clientelism" will be helpful; and mechanisms of social movements and labor mobilization will prove helpful as well. In one sense China's sudden economic transformation after the reforms of the early 1980s was *sui generis*. But it also consisted of a number of component processes that have been identified and studied in very different historical and cultural settings. (Jean Oi's State and Peasant in Contemporary China: The Political Economy of Village Government provides a good example.)

So there is an important sense in which the social sciences permit a basis for generalizing and explaining when we consider specific areas. But it is crucial to avoid the mistake of over-generalizing.

One such mistake is the idea that we can simply subsume a particular region's experience under a comprehensive general theory. In particular, we should avoid stereotyped contrasts and models of change: traditional-modern; capitalist-feudal; stagnant-dynamic. Constructs such as "modernization theory" are unhelpful, because they import a raft of unspoken presuppositions, they are teleological, and they are formulated at too high a level. Area specialists are better served by meso-level theories of social mechanisms. (Arturo Escobar offers a strong contemporary critique of modernization theory in Encountering Development.)

Another variety of faulty historical analysis is the intellectual error of Eurocentrism. It is critical that we not generalize from the experience of Western Europe in application to Asia or Africa. Consider the example of Asian politics. The polity of pre-colonial India was highly pluralistic, with a very wide and heterogeneous set of social relations, forms of power, ethnic conflicts, economic forms, and political and quasi-political arrangements. China, by contrast, was a more uniform political order, with a visible unified state. And neither of these states is well understood if we simply import the apparatus of political theory developed out of study of the modern European state. So there is great variety and originality in the political institutions of India, China, or Bali, and we cannot understand those institutions by simply attempting to find European analogies. (Bin Wong makes these points very powerfully in China Transformed: Historical Change and the Limits of European Experience.)

So area scholars have to aim for a delicate balance, between concrete, local knowledge and the application of relevant findings from the social sciences. But the social sciences certainly have a key role in understanding the institutions, mentalities, and behavior of particular places.

Movements for social justice

Sunday, August 01, 2010

It was argued in an earlier post that social progress is best pursued through incremental, gradual steps that can be evaluated as we go along (post). It was also suggested that programs of change that are bent on achieving huge systemic change and the establishment of a complex new set of institutions are unwise, because of the contingency and unpredictability of social processes (post).

How should these ideas be tested against historical cases of large struggles for social justice -- for example, the struggle to end apartheid in South Africa or the Civil Rights movement in the early 1960s in the United States?

Several things are clear. First, both of these movements for racial justice aimed at -- and achieved -- large, discontinuous change in their home societies. Second, each involved strategies and struggles that were inherently risky: the probability of failure and suffering for participants was high. But third, the end state towards which these struggles aimed was not a highly complex, untested and novel set of institutions. Rather, each movement aimed at securing a system of law that treated black people equally and democratically -- a system whose properties we understand well. So no one could argue in 1955 in South Africa or Alabama that a system of democratic equality within a racially neutral system of law could have catastrophic unforeseen consequences.

In other words, the major civil rights struggles were risky with respect to strategies but low-risk with respect to possible outcomes. Racial equality is not a hazardous social reality.

But here is another salient point. Even if the range of possible outcomes of a struggle against apartheid or Jim Crow might include some social disasters, it is inconceivable that we would conclude that the black population should simply accept and endure its oppression. People who are subject to enduring injustice have a right to demand justice and to mobilize so as to bringing justice about.

One of the constraints I mentioned on social change in an earlier post is that we need to test proposed new institutions in terms of how they would work, given people as they are (post). But this is slightly questionable, in that it takes existing social consciousness as a given rather than being itself an object of change.

In particular, a successful outcome of either of these struggles entailed changing more than laws and institutions; each required a change of consciousness and morality in the white population of power-holders. If the majority of the white population had remained violently racist, then democratic racial equality may not have been a sustainable social order. (This is the kind of scenario that Michael Mann takes up in The Dark Side of Democracy: Explaining Ethnic Cleansing.) So a strategy for change required changing both structures and consciousness. And this means that we have to be reflective about what sorts of factors we take as fixed rather than changeable.

This also implies a change of emphasis in the analysis of social progress argued previously. Some crucial advances in social justice have been anything but continuous and gradual; but have rather been daring, improbable, and crucial. Being deliberative about strategies of social change does not imply being slow to act or reluctant to take on large challenges.

The Real Utopias project has done really interesting and important work on new ideas about democracy and new thinking about ending economic exploitation and class power (link, link). What this project hasn't done yet is to address issues of racism and persistent racial inequity. And yet this is a pressing issue, in the United States and other countries. It would be great to see some of these activist-scholars turn their attention to racial progress.

How many Geertz's?

Wednesday, August 04, 2010

Clifford Geertz's contributions are wide-ranging, in a couple of ways. He wrote about North Africa as well as Indonesia; and he touched on Islam as well as water systems. So there was both geographical as well as topical diversity in his research life. But here is another dimension of range: Geertz demonstrated a surprisingly wide variation of methodology and theoretical framework in his many studies of Indonesia. I am particularly struck by the conceptual distance between two important studies of Bali and Java. Both these studies are relevant to long processes of economic and social development. But the perspectives taken are quite divergent. (Geertz provides an appealing account of his early career in Available Light: Anthropological Reflections on Philosophical Topics.)
The first is Geertz's 1963 book, Agricultural Involution: The Processes of Ecological Change in Indonesia, and the second is his 1981 book, Negara: The Theatre State In Nineteenth-Century Bali. The first is a close and detailed reading of agricultural practices in Java. Geertz examines the progression and the social and ecological settings of two major agricultural regimes -- *swidden* and *sawah* (slash and burn and rice paddy). It is a material ethnography, spending a great deal of effort on the nature of labor practices and the ecological setting of agriculture. It is historical, looking to identify the ways in which the Dutch colonial regime and rising population produced a distinctive social-cultural response in agricultural society. And it provides an enduring thought paradigm for understanding traditional agriculture, the idea of involution. This is basically the idea of a fine division of task to assure a place for every working adult within the farm economy.
With the steady growth of population came also the elaboration and extension of mechanisms through which agricultural product was spread, if not altogether evenly, at least relatively so, throughout the huge human horde which was obliged to subsist on it. Under the pressure of increasing numbers and limited resources Javanese village society did not bifurcate, as did that of so many other "underdeveloped" nations, into a group of large landlords and a group of oppressed near-serfs. Rather it maintained a

comparatively high degree of social and economic homogeneity by dividing the economic pie into a steadily increasing number of minute pieces. (Geertz 1963:97)

The productive system of the post-traditional village developed, therefore, into a dense web of finely spun work rights and work responsibilities spread, like the reticulate veins of the hand, throughout the whole body of the village lands. (Geertz 1963:99)

This is a strikingly materialist treatment of rural Javanese society, with essentially no symbolic interpretation. Here is how Geertz describes the book in 1991 (link):

The book was originally intended as a prolegomena to a general analysis of Indonesian society. But after I published it, such a project seemed premature, so I more or less set it aside and addressed myself to a series of other issues in Indonesian sociology. As a result, its very close relation to my work overall has tended to go unnoticed, and the book has become something of an orphan with a special history of its own.

The second book is very different. *Negara* is a thoroughly symbolic interpretation of Balinese politics and local life, and organizes its gaze through interpretation of the semiotics and history of the "theatre state." Here is one passage in which Geertz describes his view:

The expressive nature of the Balinese state was apparent through the whole of its known history, for it was always pointed not toward tyranny, whose systematic concentration of power it was incompetent to effect, and not even very methodically toward government, which it pursued indifferently and hesitantly, but rather toward spectacle, toward ceremony, toward the public dramatization of the ruling obsessions of Balinese culture: social inequality and status pride. (2)

This study is a great example of symbolic or interpretive anthropology; countless aspects of Balinese social life, behavior, and architecture are interpreted in terms of the ideas associated with the theatre state. But the book also gives a lot of attention to some of the social-material aspects of social life in Bali. Particularly interesting is Geertz's treatment of the control of irrigation water through a set of channels and gates. And this part is an exquisite example of micro-analysis of social coordination. Where the two narratives come together is in the role of symbolic hierarchy in organizing both systems.

One thing that I find interesting about the pair of books, beyond the detailed content, is the remarkable distance in thought frames that they represent. They almost give the impression of being the product of different authors. So what explains this distance? One piece of the answer is simply time. *Agricultural Involution* was researched and written in the 1960s, drawing on fieldwork from the 1950s, when Geertz was a young anthropologist. *Negara* was written in the 1980s, following the extensive development of Geertz's pathbreaking ethnographic ideas of the 1970s. So a part of the difference between the two books is simply the result of the growth and development of Geertz's ideas. But I think the two books support something else as well: that really great social scientists are not captive to their own intellectual presuppositions. It is possible for a Geertz or a Sahlins to treat a topic in a way that represents a fresh approach, an innovative set of ideas.

Another book of Geertz's that I find very interesting is Islam Observed: Religious Development in Morocco and Indonesia (1968). This work is different from each of these examples -- and again provides a strikingly original contribution to the task of thinking culture. Here again there is also a critical contribution that is useful in many areas of the social sciences: Islam is not a single, unified "thing" across the many Islamic societies and communities in which it exists. It is valuable to probe in specific detail some of the distinguishing characteristics of Islam in North Africa and in Indonesia; and the finding of heterogeneity is one that applies to a much wider swath of behavior, consciousness, and culture than simply religion.

Here is a superb archive of almost all of Geertz's corpus (link). (Thanks to Isaac for the

link!)

Links between literature and the social sciences

Saturday, August 07, 2010

Some novelists take as part of their task the description and evocation of certain social realities. James Baldwin captured one slice of African-American life in the 1950s and 60s. Tim O'Brien captured aspects of infantry life in Vietnam in The Things They Carried. And Tolstoy caught much about social attitudes and relations in elite Russia at a certain time and place. We could interpret these sorts of novels "realistically" and ask a range of questions about them: how accurate are they? Do they leave out important aspects of the picture? And what was the epistemic location of the author, such that he/she could claim to observe and portray accurately?

If we take this function of literature seriously, then it is natural to ask how this creative act relates to various areas of the social sciences. Does the knowledge offered by Baldwin complement the work of sociologists and historians of race in America? And, for that matter, can the realistically-minded novelist find valuable synergy in the research of historians and sociologists?

These questions are taken especially seriously by critics who are developing the framework of "critical realism", including especially Satya Mohanty. Particularly valuable is Identity Politics Reconsidered (Future of Minority Studies), edited by Linda Alcoff, Satya Mohanty and Michael Hames-Garcia. The topic is a core concern for the Future of Minority Studies project (link).

So, what about it? Can a work of fiction have realistic, referential content? Is a novel sometimes an empirical statement? Can a fictional character truthfully represent aspect of what it is like to be black in America, South Asian in Manchester, or gay in a suburban Illinois high school? For that matter, can a novel be faulted for "getting it wrong" -- for example, for representing an American Muslim as being completely oblivious to issues of racism? Or is "right" and "wrong" out of place when it comes to evaluating the relationship between a novel and the world?

Here is one possible answer: fiction is always fiction, and normally does not have empirical validity. If we want to make empirical statements about social relations, class attitudes, or typical social values of specific groups, we need to do so based on valid methods of social research: surveys, focus groups, interviews, and observations of behavior. And we need to analyze the data we collect according to valid methods of aggregation and inference. That is what is required in order to arrive at **knowledge** about the social world.

Another very different response goes along these lines. Novelists are sometimes skilled

social observers, and some of these are also skilled "painters" or evokers of what they have seen. A great novelist can pull together his/her many insights and observations into a powerful description of a fictional world or experience that captures an important sociological truth about the society depicted. So these novelists do in fact gain knowledge of social life through observation, and they represent that knowledge through the fiction they produce. Both parts of this epistemic process are subject to criticism; but both are valid knowledge practices.

According to the second view, readers have the possibility of gaining real knowledge about the social world through the novel. Seen in this way, a novelist is somewhat akin to an ethnographer, trying to make sense of a complex system of behaviors and meanings and expressing his/her findings in a way that is truthful to the social reality observed.
It seems that one would have to be a pretty narrow-minded epistemologist to hold that there is only one kind of knowledge, and that literature necessarily falls outside its bounds. This might have been credible when the program of logical empiricism still seemed possible -- that there are observations that can be unambiguously arrived at, and that theories are evaluated through a specific logic of confirmation marshaling a domain of observations in support of hypothetical statements. But this epistemology doesn't work well even in the sciences. And within the framework of an anti-foundationalist epistemology, it seems reasonable enough to believe that literature has the potential of revealing important aspects of the social world.
This brings us back to the question of linkage between literature and the social sciences. If we think that *Platoon* or *The Things They Carried* express some important truth about the nature of the experience of that war for American soldiers, this suggests the possibility of framing other sorts of social-science investigations to probe the extent and variation of these characteristics on the ground. In other words, there is a simple kind of synergy that can exist between novelists, sociologists, and historians, when it comes to framing interpretations and explanations of a complex social reality, and designing further empirical studies to evaluate and qualify these findings.

Rousseau the democrat

Tuesday, August 10, 2010

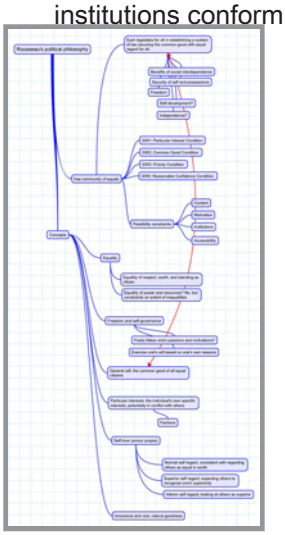
Rousseau's political philosophy probably represents the richest and most adequate view of the moral foundations of the state of any of the great figures in the history of political thought. But it is also complex and opaque. Rousseau is usually cast as falling within the social contract tradition, according to which the legitimacy of the state depends on the hypothetical consent of the governed. This puts him in discussion with Hobbes and Locke. But he had substantive and radical ideas about freedom and equality that separate him sharply from these British theorists. His ideas about freedom and equality made him a prime candidate for the title, "philosopher of the French Revolution". He offered a sometimes mysterious theory of the "general will" as the central focus of politics; but philosophers have offered wildly different interpretations of the

meaning of this concept. And, unlike Locke, Hobbes, or Mill, Rousseau had an elaborate theory of psychology -- the motivations that lead social actors to behave as they do and the processes of social construction through which they come to have these characteristics. This theory appears to fit into his social philosophy, but it isn't perfectly clear how.

It is for these reasons that Josh Cohen's recently published Rousseau: A Free Community of Equals is such an important contribution. The book is an exceptional achievement. Cohen offers a coherent, developed interpretation of Rousseau's theory; he provides clear statements of the central ideas and shows how they tie together; and he makes use of virtually all of Rousseau's enormous corpus to tease out Rousseau's intricate line of thought. Cohen demonstrates that Rousseau's theory is not simply a series of aphorisms, but is rather a detailed and subtle logical argument, with premises and inferences that can be rigorously reconstructed. It is a full philosophy of politics. Most basically, Cohen shows how philosophical principles, institutional assumptions, and psychological theories are intended to tie together into a coherent view of a democratic society.

This is an enormously difficult task to have accomplished. Just take the Social Contract as your starting point and you are inclined to emphasize chiefly the relations between institutions and freedom. Just take Emile or the Confessions as the point of origin and the emphasis will be on the individual's development. And if you begin with the more applied parts of Rousseau's work -- the constitution for Poland, for example -- and you are likely enough to get lost in a forest of institutional details. In other words -- three Rousseau's. Cohen has paid close attention to all these components of Rousseau's thought, and he has succeeded in showing how they all contribute to a single, coherent line of thought.

The key idea in Cohen's construction is the notion of a "free community of equals." (This is also the subtitle of the book.) Each part of the phrase demands analysis -- equality, freedom, and community, and unpacking them provides a basis for a nuanced and powerful political philosophy. The phrase also invokes the central problem of political philosophy, the contradiction between security and freedom: how is it possible to find personal security within a state (and therefore being subject to coercive laws), while fully maintaining one's freedom and autonomy? Here is how Cohen puts the solution he attributes to Rousseau:



The essential point about content is that Rousseau's solution requires that individuals commit to regarding themselves as belonging to a political community whose members are committed to regarding one other as equals: acknowledging one another as political equals, with equal status in establishing the laws; recognizing one another as equally subject to the laws; and agreeing to regulate their association by reference to reasons of the common good, which gives equal weight to the good of each citizen. (Kindle loc 221) This formulation captures every element of the solution: equality, the common good, and a consequent situation of full autonomy. The citizen is autonomous (self-legislating) because he/she has willed the creation of exactly this system of law. The common good referred to here is the "general will"; and Cohen makes a good case for understanding that this concept is one that comes down to the individual perceiving and willing outcomes that serve the whole of the citizenry.

Citizens also have their own particular interests; so the situation described here, where all citizens give priority to the common good over their particular interests is one that requires a fairly specific bundle of institutions and motivations. And Cohen demonstrates

that Rousseau methodically explores these institutional and behavioral requirements.

Cohen analyzes the idea of a community as being regulated by the general will into a conjunction of four conditions:

- GW1 Particular Interest Condition [citizens have separate, particular interests]
- GW2 Common Good Condition [citizens publicly share a common understanding of the common good]
- GW3 Priority Condition [each citizen gives priority to reasons having to do with the common good over those concerning particular interests]
- GW4 Reasonable Confidence Condition [citizens can be confident that their institutions conform to their shared conception of the common good]

It is evident that these are strong conditions. So it is incumbent on Rousseau (and Cohen) to demonstrate that they are singly possible and jointly consistent. If these points cannot be established, then the idea of a general will is useless. If the conditions are possible and consistent, then there is a further question to investigate: what empirical conditions (institutions, processes of individual moral development) are needed to establish and sustain them?

Another fascinating line of thought in the book is Cohen's attempt to reconstruct Rousseau's argument for the "natural goodness" of the human being. It is a complex argument and one I found highly convincing as an interpretation of Rousseau. And the issue is simply crucial; if this argument cannot be made out, then the free community of equals is an impossibility.

Much of Cohen's work here is that of philosophical reconstruction: what were Rousseau's positions and reasons? This is descriptive work, and doesn't require that Cohen evaluate the theory. (In fact, we can ask the question whether this is simply a hypothetical reconstruction of a Rousseau-like theory, or whether we are to understand that Rousseau actually had these logical connections and explications clearly in mind.) But beyond the explicative work, it is plain that there is much in Rousseau's conceptions of equality, freedom, participation, and democracy that Cohen admires deeply and regards as fruitful for contemporary discussions of democracy. There are also a few important threads that he is distinctly not pleased by: in particular, the exclusion of women, of course, and Rousseau's sometimes incipient communitarianism. The latter makes for the possibility of an ethnically or nationalistically grounded community, rather than a community of simple moral equals. And Rousseau sometimes seems to suggest that only a highly uniform community is likely to satisfy the conditions above -- a discouraging finding for those of us interested in a creating a democratic, multicultural world.

There is a particularly important meta-level point that emerges from Cohen's book and that seems to be fully embedded in Rousseau's thought process: the importance of addressing the question of social justice in full detail from three interrelated perspectives. We need a convincing set of moral principles that help to define what the most important features of a just society are. We need an analysis of some of the institutional requirements that these principles present; an idea of the kinds of institutions that could satisfy the principles. And we need an analysis of human psychology -- both the fixed parts and the malleable parts -- that would either support or undermine these institutions and principles. In other words, social philosophy requires a concrete study of institutions and psychology if we are to succeed in arriving at convincing and practical models of a

good society. And Rousseau seems to have understood this imperative in greater detail than other contributors to the traditions of political philosophy.

Here is a schematic representation of major parts of Cohen's analysis of Rousseau:

Anthropology as a discipline

Thursday, August 12, 2010

Several posts have focused recently on the meandering pathways through which the social science disciplines have developed in the past century or so -- within and across nations (link, link). Anthropology is a particularly interesting example because of its proximity to power and empire. And Gustavo Lins Ribeiro and Arturo Escobar's recent World Anthropologies: Disciplinary Transformations in Systems of Power (Wenner-Gren International Symposium Series) (2006) is a good place to start.

Ribeiro and Escobar are primarily interested in the question of "internationalizing" anthropology. The volume came out of an important conference on the topic sponsored by the the Wenner-Gren Foundation in 2003. The question of internationalization is relevant to anthropology in two separate ways: in terms of *content* (local or exotic), and in terms of *organizational structure* (a few core centers in the metropole, versus a large and diffuse research community across the globe). Ribeiro and Escobar are interested in incorporating the anthropological research traditions that have developed in the developing world into a more comprehensive and adequate world anthropology for the future. They are certainly right that there is much to be learned by looking in detail at some of the ways that social observers in Africa, Asia, or Latin America have sought to describe and theorize distinctive communities. And their premise of the non-linearity of the development of anthropology is exactly right as well. There is no "best" ethnography, methodology, or anthropological theory within which to organize observation and explanation of the social world.

Several chapters in the volume are particularly interesting; and none more so than Eduardo Archetti's detailed and nuanced telling of the story of anthropology and ethnography in France since roughly 1900. The inclusion of France in this volume's discussion of core and periphery in scientific anthropology is of course initially surprising; but it makes sense in context. Part of the story of France falls squarely in the core of the discipline; but another part falls in the periphery of the science. Archetti links his discussion to several important recent histories of anthropology that are interesting in their own right: Thomas Eriksen and Finn Nielsen (A History of Anthropology), Alan Barnard (History and Theory in Anthropology), and Robert Layton (An Introduction to Theory in Anthropology).

What Archetti finds is that there is a standard way of telling the story of French anthropology. It begins with Durkheim and Mauss and culminates in Levi-Strauss and Godelier; it is long on theory, and it interweaves periodically with the interests of the French colonial state. The standard account emphasizes the important role played by

French thinkers in constructing theoretical frameworks for comprehending cultures. And the standard history links French anthropology to the international concerns represented by France's colonial possessions. Archetti quotes Lévy-Bruhl's arguments to this effect on the occasion of the establishment of the Institute of Ethnology at the University of Paris in 1925 (117):

The first and most central of the natural resources is the indigenous population, because the other resources are dependent on it, above all in tropical regions. Does not there exist a capital interest in studying it, in a methodical way, in order to get an exact and deep knowledge of its languages, religions, and social organization, which it is not prudent to destroy irresponsibly? (Lévy-Bruhl 1925: 1)

But Archetti argues that this story of French anthropology is too simple by half. What it leaves out is crucial: the development of several traditions of regional and ethnic studies within France that were slighted with the label "folkloric." And it turns out that a number of figures within that group of traditions should be given much more attention in the history of anthropology than they have received to date. The presumption is that anthropology is concerned with the external and the exotic; and that the study of indigenous French traditions and communities is pedestrian and uninteresting. It is ethnology rather than ethnography. But this assumption is false.

Archetti singles out several figures for particular attention. Arnold van Gennep is one figure largely overlooked in the standard narrative, particularly when it comes to recognizing and extending his studies of French rural communities (114). Other figures who are marginalized are Louis Dumont, Michel Leiris, and Marcele Griaule. The latter two figures come in for more extensive treatment because of their "de-centered" treatment of anthropology (119). Griaule and Leiris were students of Mauss but did not define their efforts in terms of the formulation or elaboration of theoretical ideas. Leiris presented his African ethnographic work, *L'Afrique fantôme* in a literary form influenced by surrealism; it jarred against the ideal of dispassionate description. And Griaule's ethnography also had a deep thread of the subjective and the anti-general. Archetti quotes James Clifford's assessment of Griaule with approval: "One hears, as it were, two full chords of a Dogon symphony: a mythic explanation of the cosmos and a native theory of language and expressivity" (119). This implies that there is as much of Griaule as the Dogon in the treatment. But, Archetti suggests, both these French ethnographers captured themes of interpretation and styles of presentation that were to become important in later ethnography. "*L'Afrique fantome* is a powerful book precisely because it is centered on the explicit recognition of the subjectivity of the ethnographer" (121).

Dumont is important in Archetti's account, not for his studies of South Asia, but for his detailed studies of some specific French settings.

La Tarasque is a complex and unorthodox monograph consisting of ethnographic findings based on observations of the ritual of the feast of the dragon in the village of Tarascon, a detailed oral history of its legends, the results of exhaustive historical archival work, and a detailed iconographic presentation. (124)

Here is Archetti's explanation of Dumont's significance:

My main aim with this brief examination of *La Tarasque* is to contextualize the question of centers and peripheries with a focus on the anthropology of France and its internationalization. It is clear that the rich tradition of studies of France by ethnologists, ethnographers, and folklorists initiated before World War II remained "local" and was not integrated into the creation of an international discipline in which the "more exotic and

extreme non-European others" were privileged. (124)
Several points of interest come out of Archetti's discussion and the volume more generally. First has to do with the history of attempts to define the subject matter of anthropology through the focus on "exotic" non-western cultures. In hindsight, this is a distinction that makes no sense at all. The cultures, norms, religions, practices, and local preoccupations of an Alsatian village or a Detroit neighborhood are no more transparent than their counterparts in the Andaman Islands or the high Andes. And detailed observation and ethnographic investigation will reveal much of great interest in any of these locations. What is "exotic" is obviously a question of the familiar and one's initial perspective. So it is not in the least bit surprising that anthropology in the west has turned its attention to topics like "household practices in Soviet cities" or "nuclear weapons designers as a norm-driven community." Dissolving the notion of the exotic is a natural step.

Second, the notion that anthropology needs a few grand theories around which to organize its work is likewise bogus. The grand theories -- structural-functionalism, Freudianism, Marxism, rational choice theory -- simply can't be used as a formula in terms of which to understand a society or a culture as a whole. This isn't to say that theories are irrelevant to the investigation of communities; but they must be brought to bear in partial ways, not as general comprehensive schemes of interpretation.

Third, I suppose we might be just as skeptical about the availability of universal "ethnographic" methods. Once again, this isn't meant to doubt the need for intellectual rigor in observation and interpretation -- only to doubt that there is or should be a single best way of studying a human social groups. Objectivity qnd intellectual rigor cannot be defined simply as "adherence to the XYZ method of ethnographic observation." Ethnographic investigation can afford to be eclectic and multi-methodological; in fact, it can't afford anything else.

And finally, I think that Archetti's retelling of the story of French anthropology probably sheds light on the multiple nature of the development of scientific traditions everywhere. Many false starts, many promising avenues that were simply abandoned, and a real plurality of insightful approaches that don't cumulate to a simple, linear story.

(There is an interesting connection between this narrative of anthropology in France and the early relation of the *Annales* school to local histories of regions in France; link.)

Rawls on Rousseau 1973, 1975

Saturday, August 14, 2010

As noted in an earlier post, John Rawls delivered a fundamentally important course on the history of political philosophy at Harvard throughout much of his career. (See the earlier post for more about the course and for a set of notes on the section on Marx.) The 1973 course followed these main topics:

1. The nature of political philosophy
2. Natural law and contract theory. [kinds of natural law doctrines; Locke's account of political obligation; Hume's critique of contract theory; Rousseau's theory of the General Will]
3. The notion of the original position
4. Some principles of justice
5. J. S. Mill
6. Marx

Readers of my post on Josh Cohen's excellent recent book on Rousseau (Rousseau: A Free Community of Equals) may be interested in these course notes I took as a graduate student in Rawls's course. Cohen points out how important Rawls's lectures on this subject were for the formation of his own understanding of Rousseau. The notes are not detailed enough to give a full picture of Rawls's interpretation of Rousseau; but they give an idea of the issues he highlighted as well as an indication of how he related Rousseau's views to his own arguments in A Theory of Justice.

I attended the 1973 version of the course as a graduate student and served as a teaching assistant in the 1975 version of the course. So I have two sets of notes for most of the course, and it is interesting to compare them. (Here is a PDF document that presents the two sets of lectures side-by-side for easier comparison.)

Several things stand out upon reading both versions of the lectures. First is a very high degree of consistency between the two years. Rawls clearly worked from a very detailed lecture outline; the same topics occur in the same order, with the same breaking point between lecture 1 and lecture 2. Second, there is a great deal of consistency of content as well. Rawls's explanations of the general will, the well-ordered society, the central problem of the social contract, and the role of unanimity and voting are essentially the same in the two series. Even a somewhat puzzling statement in 1973 -- "The 'system' of the world has a general will; its object is the law of nature." -- recurs in 1975: "The law of nature is the general will of the universe." Third, both series indicate Rawls's interest in relating Rousseau's ideas to his own constructions in *A Theory of Justice*.

Finally, the availability of two independent sets of notes from different years gives some basis for judging Rawls's meaning at various points. For example, when Rawls asks, "What does the general will will?", he answers "the public good" and "justice". But Rousseau doesn't write that "the general will wills justice"; so we have to ask what Rawls means by this. The fact that he repeats the assertion in both years indicates that he has something specific in mind. And it would appear that the connection in his mind proceeds

through the idea of the well-ordered society (again, not a concept that Rousseau uses but one that is critical in Rawls's own thinking).
A synthesis of Rawls's lectures on the history of political philosophy over a number of years is provided in Samuel Freeman's edition of Rawls's lectures in Lectures on the History of Political Philosophy.

A core text for the course was Ernest Barker, ed., *Social Contract: Essays by Locke, Hume, and Rousseau*, which includes the full text of Rousseau's *Social Contract*. Here is a link to the G. D. H. Cole translation of the *Social Contract*.

John Rawls, History of Political Philosophy, Phil 171, fall 1973 and 1975

[The following are notes taken by Daniel Little; they were intended to capture Rawls's formulations of the main points presented in the lecture. Text in red is from the 1975 lectures, and text in black is from the 1973 lectures.]

[Quoting Rawls:]

Rousseau. If inequalities are between property owners and non-property owners, giving rise to political differences, it is hard to see that the have-nots have equal opportunity. Especially if the contract view allows for entrenching of privileged class and restricts equality of opportunity.

Like Locke, Rousseau offers a complex view. We will look at one aspect of the Social Contract, with an explicitly narrow approach.

Rousseau, The Social Contract. The General Will. What is the general will the will of? Every association of people is held together by some common interest. (The "system" of the world has a general will; its object is the law of nature.) Within a political association each sub-association has a general will. This is a theory of associations as general-will-bearing agents. The general will is the general will of the political association. It is the will of the public person or body politic. When active, it is the will of the sovereign. An act of sovereignty is the declaration of the General Will. The general will is the will of the citizen -- i.e. as a rational person not determined by his particularity.

The general will. Here is a question: what is it the will of? Every human association has a general will. As long as people identify themselves as belonging to a group having a common aim, the resulting group has a general will. The law of nature is the general will of the universe. If we think of factions within associations, each of them has a general will also; but this is a particular will with respect to the whole association. Normally an association has procedures for making up its collective mind. The general will is the general will of the association established by the Social Contract of the body politic. The declaration of the General Will is the act of sovereignty.

The general will is the will of each person qua member of the association. It is the will that each person would have if they were rational, undeceived, unbiased, undistracted by private interests. We can identify three selves: self as member of political community, self as member of sub-association, and self as private individual.

What does the general will will? The common good -- i.e. the good of the public person, just as private will wills the private advantage. The general will wills justice (I.4.4 [perhaps a reference to TJ I.4, "The Original Position and Justification"]). It wills the

preservation of the whole and every part. In the social contract the person only alienates as much of his liberty as is necessary for the sovereign to rule.

Political economy (P114 [*perhaps a reference to TJ V.41, "The Concept of Justice in Political Economy"*]). The general will wills justice. *The Original Position.* To ascertain the general will, conditions lead each person to put himself in the place of all others. The general will is therefore the will of all, and applies to all. It must be general in purpose and nature: spring from all and apply to all.

The general will always extends to what is right (but it may be deceived or misinformed).

What does the general will will? It wills the common good, public interest, justice. The general will aims at the preservation and welfare of the whole and every part. This is related to the fact that in the social contract each alienates only so much of his liberty as relates to the community as a whole. This creates authority within limits. (2:4:3) The general will wills justice. It is the most just of wills. To be certain of following the general will it is enough to act justly. Why is the general will right even if not always enlightened? Happiness of everyone qua citizen is wished for by everyone.

In voting no one fails to take "each" to refer to himself. This proves a notion of rights derives from a predilection to oneself. (2:4:4) Qua rational citizens what we are to do is to adopt a certain general point of view. The general will wills justice from adopting the perspective of the citizen as citizen.

By what acts does the general will act? It acts and expresses itself through enactments of basic laws -- particularly through decrees that set up fundamental conventions. It can set up privileges, but it cannot decide who gets them by name. The object of the general will is general.

By what acts does the general will act? It acts in the form of general laws and enactments. These are enactments of a constitutional sort: basic legislative agreements; fundamental laws that regulate the form of a regime.

Book II, chapter iii (link). Institutional questions. Under what conditions is it likely that the general will will express itself? No large public interests affecting voting. No coalitions. A vote is a statement of opinion, not an expression of interest or desire. As a vote approaches unanimity it tends to come closer to the expression of the general will.

The original position is a way of articulating conditions for the expression of the general will. The book describes a well-ordered society.

Institutional expression of the general will. What each citizen would will if rational, etc. We want to work out what form of institutional expression would do this. Consider the contrast between the will of all vs. general will. Former: what everyone would will if their sectional or personal interests ruled. Optimal conditions for establishing the general will within an association:

1. No large sectional interests which affect general deliberations, and personal interests cancel out and leave the vote unaffected. 2:3:1-2
2. No communication or mutual influence in deliberation. No coalitions. 2:3:2
3. Rules of order ensure that the question is perfectly put. What is most of interest of this political association?
4. Assurance that we get expression of the general will comes from unanimity or

approximate unanimity.

5. Every vote has to be counted and no one is excluded. No classes are excluded by constitution.
6. People have to be reliably informed.

The more these conditions are satisfied, the greater our assurance that the outcomes of votes is an expression of the general will. The more important and serious the matter, the greater the need for unanimity. The social contract must be unanimous.

[continued on second lecture]

Last time: What would the conditions have to be for an enactment to represent the general will?

The general will is the will of persons qua citizen. How are we to determine this will? (1) No large private interests should determine action; rather, many small interests which cancel out (II:iii). The notion of the original position is designed to represent the same idea.

One can view the society of the original contract as a description of a well-ordered society. [*"A well-ordered society is one designed to advance the good of its members and effectively regulated by a public conception of justice" (TJ chap VIII, sect 69).*] What are the characteristics of this view in Rousseau? The general will is not historical, but rather a sociological fact. The conditions of the general will must be expressed in institutional form. Rousseau's society is a natural rights type of society.

What is the content of the general will? Rousseau doesn't say in sufficient detail what the general will wills. He depends upon social institutions and education to bring about the general will, rather than trying to sketch it out a priori. But one would like at least to know what the general principles are which govern the general will.

Describing a well-ordered society: an association having some conception of the common good which has public institutional expression. Public conception of justice, as expressed in institutional enactments.

We can supplement Rousseau by trying to see what these principles might be. The principles must satisfy a mutual advantage condition. Rousseau doesn't explore details, however.

What is Rousseau's special contribution to contract theory? It is clear in Rousseau that the social contract is not historical; not a sequence of actual agreements, as Locke seems to suggest. Rather, it represents conditions on any well-ordered society.

The general will as an interest that exists in every citizen. It is the basis upon which people decide how to vote or what is in the common interest. It is Rousseau's view that these conditions are realized and secure.

It is a natural rights view of some sort. Rousseau thinks of society as generating in people as they grow up a general will. That interest then determines their public reasoning. This leads them to act as the general will requires them to act, in conjunction with other interests. The society of the social contract is therefore stable. Rousseau does not discuss what the possible conceptions are of justice. Are they many or few?

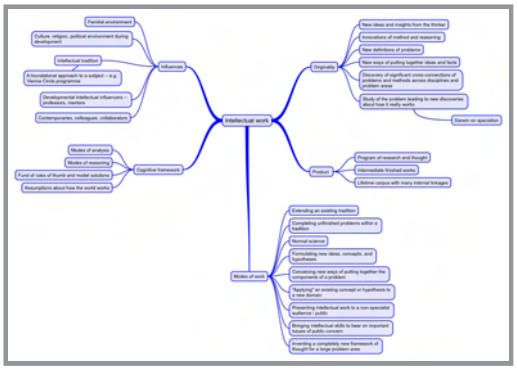
Rousseau notes a hierarchy of interests: citizen qua citizen, citizen qua bourgeois, citizen qua individual. The object of the general will is the constitutional form, that of the particular is the individual's own private goals. The higher interests regulate the lower ones. These interests need to be articulated. There is no contradiction between say willing as citizen to establish a law and say willing as individual to avoid the application of the law in my own case. Rawls's four-stage sequence in Chapter 4 of A Theory of Justice is designed to provide much the same kind of articulation of interests.

Another notion in Rousseau is a hierarchy of interests. The self is not an aggregate of interests, but rather a structure. We have interests of different orders. Higher order interests are interests having other lower-order interests. E.g. an interest or desire not to have compulsive sensuous desires. To get rid of desire we might take specific actions. Higher order interests in some way regulate the growth of lower-order desires. How does Rousseau use this notion? The general will is the highest order desire. It is not necessarily the strongest; this is a logical characteristic rather than a measure of strength. Highest order desire is the most fundamental; it regulates all others.

We might now discuss Rousseau's fundamental problem: how to find an institutional form which protects the interests of each with the weight of all and yet also leaves each autonomous and as free as before. We may interpret his solution in terms of justice. (1) Each person alienates himself totally and his rights to the whole community and the public conception of justice. This means everyone gives himself absolutely to be regulated by the public conception of justice. (2) The giving of oneself is unconditional; no one is independent of the normative force of the public conception. (3) In giving oneself to the community, he gives himself to no one. There is no one in a superior relation to him; justice is mutual. (Book 1, chap 6, paragraphs 4, 6-8; link)

The central problem of the social contract may be thought to have the following solution. The problem: How to form an association which protects all without losing freedom. Each totally alienates all his rights and freedom to the whole association absolutely and without qualification. When the association conforms to the general will it is all right. If the association is seen as regulated by the common good, then what Rousseau says can be satisfied.

No one then has any rights except those defined by this conception of justice or the common good. Each person in giving himself to the community gives himself to no one. Everyone does the same, and everyone has the same rights. Giving oneself over to being regulated by the notion of the common good.



I-8: being forced to be free. This addresses a concern with the free-rider problem. People may agree that rules are fair but prefer to be an exception. They can be compelled to comply with fair rules. Justice defines rights and defines equal freedoms.

Intellectual work

Tuesday, August 17, 2010

It is interesting to think about the work that intellectuals do. Basically, they take on thought problems -- what is justice? How does a market economy work? Why do used cars sell for less than their real value? They gather the theories and hypotheses that they have encountered and studied. They look for a new avenue of approach to the problem. They make use of styles of analysis and reasoning they have acquired during their development and education. And they formulate and develop their own attempts at a solution to a problem.

There are some intellectuals -- Descartes, for example -- who present themselves as starting *de novo*; framing a problem in purely abstract, logical terms, and addressing it through first principles alone. Possibly the philosopher mathematician Gottlob Frege falls in this category as well. He asked, "What are the foundations of arithmetic?" And he presented a constructive logical account of how the truths of arithmetic can be derived from a small set of axioms. So these thinkers pretend to a "pure thought" approach to intellectual work. But in fact, this claim doesn't hold up even in these cases. Both Descartes and Frege existed within traditions of thought; the questions they posed had historical roots, and the methods they use were historically conditioned as well.

The diagram above represents a stylized description of intellectual work: influences, an embodied cognitive framework ("skill"), important elements of originality, and a product. The diagram also provides, at the bottom, a highly incomplete inventory of some of the ways in which intellectuals proceed in their work: extending and transforming existing frameworks, introducing novel elements, crossing intellectual domains, and bringing ideas into the public arena.

This puts intellectual work into a certain kind of frame: tradition and influences; problem formulations; invention and creativity; and a new intellectual product -- a theory of justice, a theory of general equilibrium, a market for lemons. It is "work" in the Marxian sense: it begins with certain materials; the materials are shaped and transformed according to the skills and plans of the worker; the worker's skills are themselves an historical product; and the results reflect both tradition and creativity.

This analysis doesn't cover every kind of intellectual work; it doesn't fit the creation of literature, for example. But it seems to fit philosophy, social theory, the early parts of the natural sciences, and even theology.

To the extent this scheme fits an area of thought, we can then address the question of a particular thinker's contributions from several angles: looking for influences, looking for specific modes of thinking, looking for flashes of genuine originality, and looking at

finished theories. In other words, we can think of the task of *intellectual biography* through the lens of this analysis of the mature thinker's work, and the arc of development that can be perceived in his/her lifetime corpus.
So, for the individual intellectual, we can ask questions at various points of entry. **First**, can we say what some of this thinker's fundamental cognitive assumptions are. Can we identify the modes of investigation, analysis, and reasoning that he/she pursued? **Second**, can we trace backwards to some of the difference-making influences that shaped the intellectual's agenda? What was the tradition of thought into which he/she was introduced through early reading and education? Who were some of the charismatic individuals who helped this intellectual to establish a perspective and an intellectual framework? **Third**, what can we discover internally to the corpus? Is there a visible evolution of thought over time? Are there ideas and assumptions that give the corpus coherence from beginning to end? Can the corpus be reformulated into a consistent and innovative approach to a large set of problems?

Several books recently discussed in other postings are relevant to this question of the development of an intellectual. One is Clifford Geertz's autobiographical essay in Available Light: Anthropological Reflections on Philosophical Topics. Another is the biographical essay of John Rawls provided by Tom Pogge in John Rawls: His Life and Theory of Justice. Geertz highlights many of the categories mentioned here: exposure to a few influential figures in his undergraduate years, the experience of World War II, his exposure to Indonesia as a graduate student, ... Geertz's work is highly original; nonetheless, we can go some ways towards teasing out some of the ways that his mature perspectives were influenced by his educational and personal experiences. And likewise, Pogge's essay on Rawls's development as a child, youth, and adult sheds a very interesting light on Rawls's intellectual style as a mature philosopher.

Economics and the historian

Thursday, August 19, 2010

What are some of the important ways in which economic analysis is pertinent to historical research and explanation? This was the topic of a cutting-edge collection edited by Tom Rawski over ten years ago (Economics and the Historian), and it is still a unique contribution. Rawski is a good historian of China and a good economist (Chinese History in Economic Perspective, China's Transition to Industrialism: Producer Goods and Economic Development in the Twentieth Century), and the volume is genuinely useful today. The project began with a focus on Chinese history, but this volume takes a broader look at aspects of world history more generally. Here is the overriding goal:

Our book is rooted in the conviction that historians will find it useful to acquaint themselves with economics. The chapters that follow provide repeated examples of how

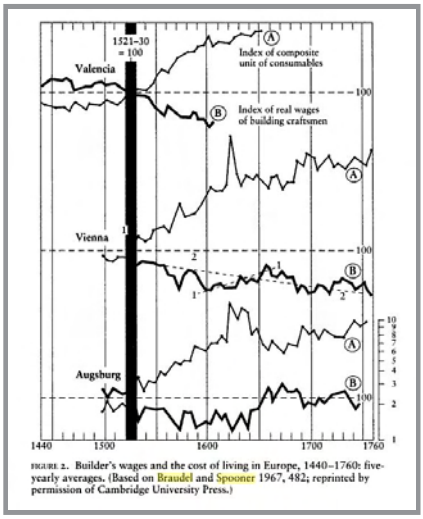

FIGURE 2. Builder's wages and the cost of living in Europe, 1440–1760: five-yearly averages. (Based on Braudel and Spooner 1967, 482; reprinted by permission of Cambridge University Press.)

standard items in the economist's intellectual arsenal extend the reach of historial source materials by revealing unexpected connections between different elements of market systems. (3) The point of the volume is not how to conduct "economic history", but rather how to bring economic data and analysis into many aspects of historical research.

So what are the important foundational insights that economics can bring to history? Here is Rawski's statement of the fundamental object of economic thinking:

Economic theory is built around the logical analysis of profit-seeking behavior by large numbers of well-informed, independent individuals in competitive markets governed by legal systems that enforce contracts and ensure the rights of private owners. (5)
But he also emphasizes that economic theory in the past thirty years has given much more extensive attention to ***institutions*** -- the sets of rules through which transactions take place within an economy and within society. Transaction costs and imperfect information fundamentally alter the logic of a pure market populated with rationally self-interested agents with perfect information. Rawski's approach, and that of many of the other contributors, is very sympathetic to the "new institutionalism in economics."

If the market system, including the whole penumbra of legal, financial, and other enabling institutions, operates within a broader socio-cultural matrix that helps to determine the course of economic evolution, then the study of any economy, past or present, must involve a range of knowledge that reaches far beyond the focal points of conventional economic theory. (11)
Rawski's substantive essay focuses on "trends" as an important historical phenomenon.

Here he presents data on the cost of living and the real wage in three cities in the sixteenth through the eighteenth centuries. And he points out that these data suggest several very interesting stories. Valencia shows a steep downward trend in the real wage through 1620; but we have no data to answer the question whether this trend continues. Vienna shows a downward trend throughout the whole three-hundred year time period; but, as Rawski points out, between 1600 and 1650 shows the opposite trend -- a fifty-year rising trend in the real wage. So we have to be very specific in defining the time period over which we are investigating these movements, before we can say anything about the trends that exist. This implies an important point: that we can't look at a "trend" as objective feature of history, but rather as a feature that is dependent on the frame of analysis.

At the same time, the phenomena recorded in the three graphs raise an important and interesting set of questions for the historian: what are the causes that pushed the prices of the basket of consumable up so sharply in all three cities between 1550 and 1650? And equally important, what social consequences might these trends have had? Was family size affected? Were mortality statistics affected? Did the incidence of bread riots and other forms of civil unrest increase?

Rawski's essay provides a fine tutorial for the historian on the difficulties of calculating the

cost of living: index problems, data blind spots and data bias, and variation across a region. But he also makes a clear case for why this kind of analysis is so important for historians generally -- not just economic historians: the circumstances of life that are indicated by rising rice prices or falling wages are fundamental to behavior. So historians who want to understand how urban Austria in the 16th century or rural China in the 19th century developed in response to political and social changes need to have a good grasp of the material circumstances of the period as well. (Robert Allen's work on the cost of living across Eurasia is an outstanding example; link.)

Other topics covered in the volume include institutions (Jon Cohen), labor economics (Susan Carter and Stephen Cullenberg), neoclassical supply and demand (Donald Deirdre McCloskey), macroeconomics (Richard Sutch), money and banking (Hugh Rockoff), and international economics (Peter Lindert).

McCloskey's treatment of economic rationality is a good place to close:

To reduce the humans in the rice market to single-minded seekers after profit does not seem to accord with common sense. It does not. We see ourselves failing every day to make the best decision about which food to buy or whether to change jobs. Considering that most of us wander in a fog of indecision and emotion the bright sunlight in which the rational man strides toward his goal is difficult to credit. (143)
However, McCloskey does not think that this element of realism about real actors does not make economic reasoning based on rationality a pointless exercise:

An English farmer choosing a reaping machine did not need detailed engineering specifications for each of the dozens of machines available in order to make up his mind to buy. Nor did he need perfect foresight about the future price of harvest labor. A crude decision is rational if information to make a more subtle one is expensive. (143)
In other words: imperfect rationality is enough to get the economic theory enterprise going.

Village life in India

Tuesday, August 24, 2010

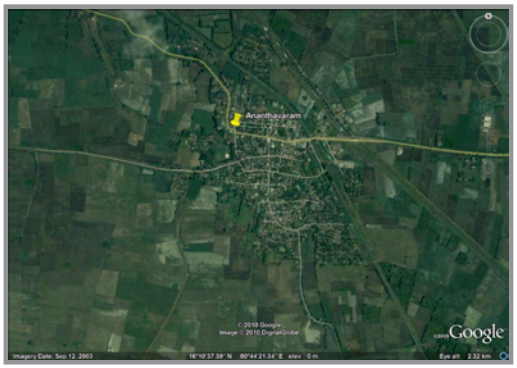
People sometimes describe India as undergoing an economic miracle in the past twenty years. After decades of indolent economic growth following independence, a number of sectors of the economy have taken off with high rates of growth and increasing income. Deepak Lal addresses this assumption in "An Indian Economic Miracle?" (link). Here is the crucial graph from Lal's paper:

As the graph indicates, starting in roughly 1980, both GDP and GDP per capita increased at a rising rate, greatly exceeding the disparaging "Hindu rate of growth" of the 1950s and 1960s. Lal's paper is worth reading. But the overall impression is that India is finally moving forward -- an impression reinforced by some of Tom Friedman's comments in The World Is Flat: A Brief History of the Twenty-first Century.

However, this impression is very misleading with respect to India's rural population; or so V. K. Ramachandran at the Indian Statistical Institute argues. (Here is an interview I conducted with Ramachandran in 2008.) Ramachandran and his collaborator, Madhura Swaminathan, have pursued an important program of research on village India under the rubric of the Foundation for Agrarian Studies (link). They and their research teams have conducted a series of village studies over the past ten years that shed detailed light on the economic, social, and caste circumstances of rural India; and the picture they find does not conform to the idea of an "economic miracle." Instead, they find patterns of social inequality and social domination that are continuing and increasing; patterns of landlessness that have worsened in the past decade or so; and levels of poverty that continue to challenge the idea of a fully developed human life for many hundreds of millions of Indian rural people.

A recent publication summarizes their studies of several villages in Andhra Pradesh (Socio-Economic Surveys of Three Villages in Andhra Pradesh: A Study of Agrarian Relations), and it is worth reading in detail. This book synthesizes the detailed surveys conducted in three villages in 2005-06. The authors describe the goals of the Project on Agrarian Relations in India in these terms: to study and analyse ...

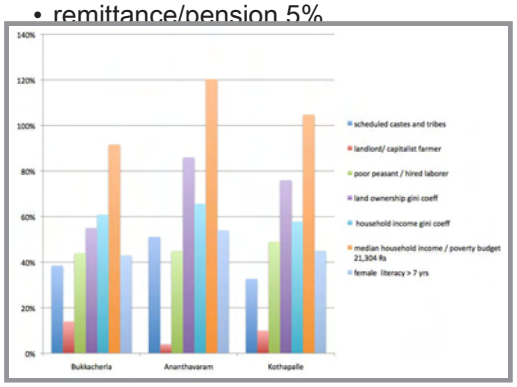
- village-level production, production systems and livelihoods, and the socio-economic characteristics of different strata of the rural population;
- sectional deprivation in rural India, particularly with regard to the Dalit and Scheduled Tribe populations, women, specific minorities and the income-poor; and
- the state of basic village amenities and the access of rural people to the facilities of modern life. (1)



Here are the three villages included in the survey (Bukkacherla, Ananthavaram, Kothapalle):

View Andhra Pradesh in a larger map

The villages are small, ranging from 292 households (Bukacherla) to 667 households (Ananthavaram). Here is a zoom view of Kothapalle village (372 households):



And here is Ananthavaram:

The surveys attempt to capture the important social and economic characteristics of the villages, including population, agricultural practices, social class composition, and caste composition. Class and caste are particularly important characteristics in the analysis. The researchers classify households as "landlord -- big capitalist farmer -- manual worker

-- peasant -- other" (chapter 2). Here is how this classification works out for Kothapalle village:

- landlord / big capitalist farmer 1%
- capitalist farmer / rich peasant 9%
- peasant: middle 13%
- peasant: poor 5%
- hired manual worker 44%
- artisan and work at traditional caste calling 1%
- business activity 8%
- rents / moneylending 1%
- salaried person 11%
- remittance/pension 5%

In other words, about 50% of households are in socially disadvantaged positions (poor peasants, landless workers, and artisans).

Here is a snapshot of the three villages extracted from the study with respect to several important socioeconomic characteristics: percent scheduled classes and tribes, percent landlord and capitalist farmer, percent poor peasant and hired laborer, land ownership Gini coefficient, household income Gini coefficient, medial household income as percent of poverty budget, and percent female literacy for persons seven years or older.

Several things are apparent from this summary. First, the distributions of land and household income are very unequal in all three villages, with a Gini coefficient of .86 for land distribution in Ananthavaram. The Gini coefficients for the distribution of income hover around .60 for all three villages -- a very high degree of income inequality by international standards (link, link)). And it is interesting to notice that Ananthavaram village enjoys the highest median household income and highest female literacy, but simultaneously the highest degree of inequality of property and income and the highest percentage of scheduled castes and tribes.

Second, all three villages represent a high degree of poverty among households. The income bar represents median household income as a percentage of a household poverty budget of 21,304 Rs. The median household in Bukkacheria falls short of this budget -- as do the 50% of households below the median, implying a poverty rate of more than 50%. The median household in Kothapalle is slightly higher than the poverty budget, and only Ananthavaram has a median income significantly higher than the poverty budget (120%). So the poverty rate ranges between 40% and 55% in all three villages --

very high.

Third, female literacy is often regarded as an important measure of overall human development in a poor region or country; and the rates observed by these surveys are quite low (42-47%), with a substantial gap to the rates for male literacy. Likewise, there are substantial variations in literacy across castes. Female literacy in Bukkacherla village is 43% for all households but is 28% for Dalit households; 37% for "backward class" households; and 53% for "other caste" households (160). In other words, the literacy rate for Dalit women is about half that of "other caste" women.

Put the point another way: these village surveys do not support the idea that social progress is occurring rapidly and broadly in India. Rather, these particular villages support the idea that inequalities in rural India are extensive and possibly increasing; that poverty is widespread; that class and caste continue to determine life prospects; and that human development is impeded by these conditions of inequality and poverty.

It is interesting to consider the question of representativeness that this volume raises. The studies provide data for only three out of thousands of villages in one Indian state. So it is productive to ask whether the findings provided here are "typical" of rural Andhra Pradesh -- let alone other parts of India. Ramachandran and Swaminathan have surveyed villages in a number of states, and will continue the project into the future. Plainly, it is important to bring these micro-studies into relation with other larger-scope studies in order to assess the degree to which these developments are typical of rural India. The authors do a good job of trying to make these connections using national and state social data sources; plainly, both methods are needed in order to arrive at justified conclusions about the state of Indian agrarian society.

Second, it is interesting to read this report as an exercise in empirical Marxist economics. The studies are highly empirical and data-rich. At the same time, the categories of analysis are drawn from Marxist economics: exploitation, class analysis, productive relations, and social relations of domination, extraction, and control. The report provides a powerful illustration of the analytical value of a Marxian sociology and political economy in this context; relations of power, privilege, and property plainly have a determining role in the processes of social change in rural India today.

(For the interested reader, Ramachandran's Wage Labour and Unfreedom in Agriculture: An Indian Case Study is an important contribution to the political economy of India.)

(Thanks to Vikas Rawal for corrections on the locations of the villages and images of Kothapalle and Ananthavaram.)

Mechanisms of contention reconsidered

Thursday, August 26, 2010

Social contention theorists Doug McAdam, Sidney Tarrow, and Charles Tilly created a great deal of interest in the "mechanisms" approach to social explanation with the publication of their Dynamics of Contention in 2001. The book advocated for several important new angles of approach to the problem of analyzing and explaining social contention: to disaggregate the object of analysis from macro-events like "civil war," "revolution," "rebellion," or "ethnic violence" into the component social processes that

recur in various instances of social contention; and to analyze these components as "causal mechanisms." Here is how they define contentious politics:

By contentious politics we mean: episodic, public, collective interaction among makers of claims and their objects when (a) at least one government is a claimant, an object of claims, or a party to the claims and (b) the claims would, if realized, affect the interests of at least one of the claimants. Roughly translated, the definition refers to collective political struggle. (5)

Here is the way they characterize the distinctive nature of the analysis offered in their new work:

This book identifies similarities and differences, pathways and trajectories across a wide range of contentious politics -- not only revolutions, but also strike waves, wars, social movements, ethnic mobilizations, democratization, and nationalism. (9)

And here is how they want to make systematic, explanatory sense of the heterogeneous examples of social contention that the world presents: to identify and investigate some common social mechanisms that work in roughly similar ways across numerous different instances of social contention.

Social processes, in our view, consist of sequences and combinations of causal mechanisms. To explain contentious politics is to identify its recurrent causal mechanisms, the ways they combine, in what sequences they recur, and why different combinations and sequences, starting from different initial conditions, produce varying effects on the large scale.... Instead of seeking to identify necessary and sufficient conditions for mobilization, action, or certain trajectories, we search out recurrent causal mechanisms and regularities in their concatenation. (13)

They offer these definitions of the key analytical terms:

Mechanisms are a delimited class of events that alter relations among specified sets of elements in identical or closely similar ways over a variety of situations.

Processes are regular sequences of such mechanisms that produce similar (generally more complex and contingent) transformations of those elements.

Episodes are continuous streams of contention including collective claims making that bears on other parties' interests. (24)

They distinguish among environmental mechanisms ("externally generated influences on conditions affecting social life"), cognitive mechanisms ("operate through alterations individual and collective perception"), and relational mechanisms ("alter connections among people, groups, and interpersonal networks") (25-26). And they offer a few examples of mechanisms: mobilization mechanisms, political identity formation mechanisms, and aggregation mechanisms.

The approach can be summarized in these terms:

Seen as wholes, the French Revolution, the American civil rights movement, and Italian contention look quite different from each other. ... Yet when we take apart the three histories, we find a number of common mechanisms that moved the conflicts along and transformed them: creation of new actors and identities through the very process of contention; brokerage by activists who connected previously insulated local clumps of aggrieved people; competition among contenders that led to factional divisions and re-alignments, and much more. These mechanisms concatenated into more complex

processes such as radicalization and polarization of conflict; formation of new balances of power; and re-alignments of the polity along new lines. (32-33)

This is roughly the conception of social ontology and explanation that was put forward in 2001, and it was a powerful challenge to a more positivistic methodology that insisted on looking for general laws of contention and uniform regularities governing things like revolutions and civil wars.

By 2007, however, Tarrow and Tilly found it necessary to reformulate their views to some degree; and this re-thinking resulted in Contentious Politics. So what changed between the theory offered in 2001 and that restated in 2007? The answer is, surprisingly little at the level of concept and method.

Tilly and Tarrow refer to three main lines of criticism of *Dynamics of Contention* to which they felt a need to respond:

Although that book stirred up a lively scholarly discussion, even specialists who were sympathetic to our approach made three justified complaints about it. First, it pointed to mechanisms and processes by the dozen without defining and documenting them carefully, much less showing exactly how they worked. Second, it remained unclear about the methods and evidence students and scholars could use to check out its explanations. Third, instead of making a straightforward presentation of its teachings, it reveled in complications, asides, and illustrations. (xi)

What did not change between the two formulations was the conceptual foundation. The key concepts of contentious politics, mechanisms, processes, and episodes are essentially the same in the 2007 book as in 2001.

Contentious politics involves interactions in which actors make claims bearing on someone else's interests, leading to coordinated efforts on behalf of shared interests or programs, in which governments are involved as targets, initiators of claims, or third parties. Contentious politics thus brings together three familiar features of social life: contention, collective action, and politics. (4)

Further, they analyze contention in the same basic terms in 2007 as in 2001:

For explanation, we need additional concepts. This chapter supplies four of them: the events and episodes of streams of contention and the mechanisms and processes that constitute them.

And their definitions of mechanisms and processes are unchanged:

By ***mechanisms***, we mean a delimited class of events that alter relations among specified sets of elements in identical or closely similar ways over a variety of situations. Mechanisms compound into processes. By ***processes***, we mean regular combinations and sequences of mechanisms that produce similar (generally more complex and contingent) transformations of those elements. (29)

One goal of the 2007 book is to simplify the discussion of mechanisms. The authors highlight three mechanisms as being particularly central to episodes of contention:

- ***Brokerage***: production of a new connection between previously unconnected sites
- ***Diffusion***: spread of a form of contention, an issue, or a way of framing it from one site to another
- ***Coordinated action***: two or more actors' engagement in mutual signaling and parallel making of claims on the same object (31)

Other mechanisms that are discussed include social appropriation, boundary activation, certification, and identity shift (34). And their key examples of processes are ***mobilization***

and ***de-mobilization*** -- each of which consists of a series of component mechanisms.

One difference between the two versions of the theory is more substantive. In 2007 Tarrow and Tilly give greater priority to the *performative* nature of contentious politics: contentious performances and repertoires have greater prominence in the story offered in 2007 than in the analysis of episodes provided in 2001. This is not a new element, since Tilly himself made extensive use of the ideas of performance and repertoire in his earlier analyses of French contentious politics; but the theme is given more prominence in 2007 than it was in 2001.

Overall, it seems reasonable to say that *Contentious Politics* expresses the same conceptual framework for researching and understanding contention as that found in *Dynamics of Contention*. There is no fundamental break between the two works. What has changed is more a matter of pedagogy and presentation. The authors have sought to provide a more coherent and orderly presentation of the conceptual framework that they are presenting; and they have sought to provide an orderly and systematic analysis of the cases, in order to identify the mechanisms that recur across episodes.

Where additional work is still needed is at the level of conceptualization of causal mechanisms. There is now a large body of discussion and debate about how to think about social causal mechanisms, and many observers are persuaded that the move to mechanisms is a very good way of getting a better grip on social explanation and analysis. But how to define a social mechanism is still obscure. The definition that MTT offer does not really seem satisfactory -- "*a delimited class of events that alter relations among specified sets of elements in identical or closely similar ways over a variety of situations.*" A mechanism is not an event (or a class of events); rather, it is a ***nexus*** between a cause and an effect; it is the ***pathway*** through which the cause brings about the effect. It is a materially embodied set of causal powers and their effects. But the specific formulation provided by MTT doesn't succeed in capturing any of these root ideas.

Various philosophers have attempted to specify more clearly the notion of a causal mechanism (Jon Elster, Explaining Social Behavior: More Nuts and Bolts for the Social Sciences; Hedstrom and Swedberg, Social Mechanisms: An Analytical Approach to Social Theory, my own Varieties Of Social Explanation: An Introduction To The Philosophy Of Social Science). We can give good examples of what we mean by a causal mechanism. But to date, it seems that we have not yet been able to come up with a fully satisfactory definition of a causal mechanism. (Here is a short conference paper by Tilly in 2007 that takes a different approach by linking the concept to Robert Merton's work; link.)

So the disaggregative approach that MTT advocate is a crucially important breakthrough in the study of complex social phenomena, and it seems convincing that it is "mechanisms" that disaggregation should lay bare. Moreover, the idea of mechanisms aggregating to processes and constituting episodes is an intuitively compelling notion of how complex social phenomena are constituted. These are genuinely important new ways of conceptualizing the complex social reality of contention and the task of providing descriptions and explanations of complex social episodes. Contentious Politics is a very good presentation of these fundamental ideas. What we don't yet have, however, is a fully convincing and fertile conception of the root idea, the notion of a causal mechanism.

(See other postings under the thread of causal mechanism for other discussions of the

topic.)

Criteria for assessing economic models

Monday, August 30, 2010

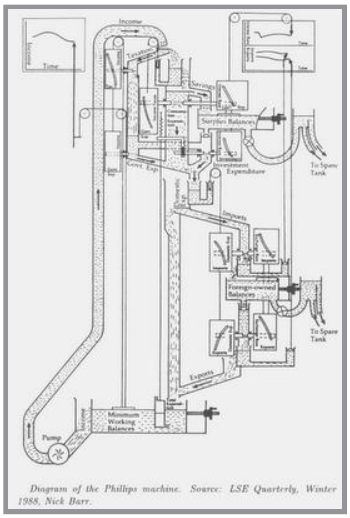

Diagram of the Phillips machine. Source: LSE Quarterly, Winter 1988, Nick Barr.

How can we assess the epistemic warrant of an economic model that purports to represent some aspects of economic reality? The general problem of assessing the credibility of an economic model can be broken down into more specific questions concerning the validity, comprehensiveness, robustness, reliability, and autonomy of the model. Here are initial definitions of these concepts.

- **Validity** is a measure of the degree to which the assumptions employed in the construction of the model are thought to *correspond to the real processes* underlying the phenomena represented by the model.
- **Comprehensiveness** is the degree to which the model is thought to succeed in capturing the *major causal factors* that influence the features of the behavior of the system in which we are interested.
- **Robustness** is a measure of the degree to which the *results of the model persist* under small perturbations in the settings of parameters, formulation of equations, etc.
- **Autonomy** refers to the *stability of the model's results* in face of variation of contextual factors.
- **Reliability** is a measure of the *degree of confidence* we can have in the data employed in setting the values of the parameters.

These are features of models that can be investigated more or less independently and prior to examination of the empirical success or failure of the predictions of the model.

Let us look more closely at these standards of adequacy. The discussion of realism elsewhere suggests that we may attempt to validate the model deductively, by examining each of the assumptions underlying construction of the model for its plausibility or realism (link). (This resembles Mill's "deductive method" of theory evaluation.) Economists are highly confident in the underlying general equilibrium theory. The theory is incomplete (or, in Daniel Hausman's language, inexact; link), in that economic outcomes are not wholly determined by purely economic forces. But within its scope economists are confident that the theory identifies the main causal processes: an equilibration of supply and demand through market-determined prices.

Validity can be assessed through direct inspection of the substantive economic assumptions of the model: the formulation of consumer and firm behavior, the representation of production and consumption functions, the closure rules, and the like. To the extent that the particular formulation embodied in the model is supported by

accepted economic theory, the validity of the model is enhanced. On the other hand, if particular formulations appear to be ad hoc (introduced, perhaps, to make the problem more tractable), the validity of the model is reduced. If, for example, the model assumes linear demand functions and we judge that this is a highly unrealistic assumption about the real underlying demand functions, then we will have less confidence in the predictive results of the model.

Unfortunately, there can be no fixed standard of evaluation concerning the validity of a model. All models make simplifying and idealizing assumptions; so to that extent they deviate from literal realism. And the question of whether a given idealization is felicitous or not cannot always be resolved on antecedent theoretical grounds; instead, it is necessary to look at the overall empirical adequacy of the model. The adequacy of the assumption of fixed coefficients of production cannot be assessed *a priori*; in some contexts and for some purposes it is a reasonable approximation of the economic reality, while in other cases it introduces unacceptable distortion of the actual economic processes (when input substitution is extensive). What can be said concerning the validity of a model's assumptions is rather minimal but not entirely vacuous. The assumptions should be consistent with existing economic theory; they should be reasonable and motivated formulations of background economic principles; and they should be implemented in a mathematically acceptable fashion.

Comprehensiveness too is a weak constraint on economic models. It is plain that all economic theories and models disregard some causal factors in order to isolate the workings of specific economic mechanisms; moreover, there will always be economic forces that have not been represented within the model. So judgment of the comprehensiveness of a model depends on a qualitative assessment of the relative importance of various economic and non-economic factors in the particular system under analysis. If a given factor seems to be economically important (e.g. input substitution) but unrepresented within the model, then the model loses points on comprehensiveness.

Robustness can be directly assessed through a technique widely used by economists, sensitivity analysis. The model is run a large number of times, varying the values assigned to parameters (reflecting the range of uncertainty in estimates or observations). If the model continues to have qualitatively similar findings, it is said to be robust. If solutions vary wildly under small perturbations of the parameter settings, the model is rightly thought to be a poor indicator of the underlying economic mechanisms.

Autonomy is the theoretical equivalent of robustness. It is a measure of the stability of the model under changes of assumptions about the causal background of the system. If the model's results are highly sensitive to changes in the environment within which the modeled processes take place, then we should be suspicious of the results of the model.

Assessment of reliability is also somewhat more straightforward than comprehensiveness and validity. The empirical data used to set parameters and exogenous variables have been gathered through specific well-understood procedures, and it is mandatory that we give some account of the precision of the resulting data.

Note that reliability and robustness interact; if we find that the model is highly robust with respect to a particular set of parameters, then the unreliability of estimates of those parameters will not have much effect on the reliability of the model itself. In this case it is enough to have "stylized facts" governing the parameters that are used: roughly 60% of workers' income is spent on food, 0% is saved, etc.

Failures along each of these lines can be illustrated easily.

1. The model assumes that prices are determined on the basis of markup pricing (costs plus a fixed exogenous markup rate and wage). In fact, however, we might believe (along neoclassical lines) that prices, wages, and the profit rate are all endogenous, so that markup pricing misrepresents the underlying price mechanism. This would be a failure of validity; the model is premised on assumptions that may not hold.
2. The model is premised on a two-sector analysis of the economy. However, energy production and consumption turn out to be economically crucial factors in the performance of the economy, and these effects are overlooked unless we represent the energy sector separately. This would be a failure of comprehensiveness; there is an economically significant factor that is not represented in the model.
3. We rerun the model assuming a slightly altered set of production coefficients, and we find that the predictions are substantially different: the increase in income is only 33% of what it was, and deficits are only half what they were. This is a failure of robustness; once we know that the model is extremely sensitive to variations in the parameters, we have strong reason to doubt its predictions. The accuracy of measurement of parameters is limited, so we can be confident that remeasurement would produce different values. So we can in turn expect that the simulation will arrive at different values for the endogenous variables.
4. Suppose that our model of income distribution in a developing economy is premised on the international trading arrangements embodied in GATT. The model is designed to represent the domestic causal relations between food subsidies and the pattern of income distribution across classes. If the results of the model change substantially upon dropping the GATT assumption, then the model is not autonomous with respect to international trading arrangements.
5. Finally, we examine the data underlying the consumption functions and we find that these derive from one household study in one Mexican state, involving 300 households. Moreover, we determine that the model is sensitive to the parameters defining consumption functions. On this scenario we have little reason to expect that the estimates derived from the household study are reliable estimates of consumption in all social classes all across Mexico; and therefore we have little reason to depend on the predictions of the model. This is a failure of reliability.

These factors--validity, comprehensiveness, robustness, autonomy, and reliability--figure into our assessment of the antecedent credibility of a given model. If the model is judged to be reasonably valid and comprehensive; if it appears to be fairly robust and autonomous; and if the empirical data on which it rests appears to be reliable; then we have reason to believe that the model is a reasonable representation of the underlying economic reality. But this deductive validation of the model does not take us far enough. These are reasons to have *a priori* confidence in the model. But we need as well to have a basis for *a posteriori* confidence in the particular results of this specific model. And since there are many well-known ways in which a generally well-constructed model can nonetheless miss the mark--incompleteness of the causal field, failure of *ceteris paribus* clauses, poor data or poor estimates of the exogenous variables and parameters, proliferation of error to the point where the solution has no value, and path-dependence of the equilibrium solution--we need to have some way of empirically evaluating the results of the model.

(Here is an application of these ideas to computable general equilibrium (CGE) models in an article published in On the Reliability of Economic Models: Essays in the Philosophy of Economics; link. See also Lance Taylor's reply and discussion in the same volume.)

Development economics in historical context

Wednesday, September 01, 2010

Hollis Chenery and T. N. Srinivasan published the Handbook of Development Economics in 1988. It was state-of-the-art in the late 1980s. It is interesting to look back at the *Handbook* twenty-two years later to see how it stands up today.

First, the contributors. The volume is a dream-team of development thinkers from the 1970s and 1980s: Amartya Sen, Arthur Lewis, Pranab Bardhan, Joseph Stiglitz, Peter Timmer, Nancy Birdsall, Paul Streeten, and Dwight Perkins, to name only a small subset of the authors. (There are 33 essays in volumes I and II.) Several currently important figures are not represented -- Arturo Escobar, Jeffrey Sachs, and Dani Rodrik, for example. Escobar's Encountering Development: The Making and Unmaking of the Third World appeared in 1994; Jeffrey Sachs's The End of Poverty: Economic Possibilities for Our Time didn't appear until 2005; and Dani Rodrik's One Economics, Many Recipes: Globalization, Institutions, and Economic Growth appeared in 2008. So it is certainly true that the field has moved forward with the emergence of new voices and perspectives since 1988. But it is also true that the volume represents a very deep body of knowledge about some of the dynamics and policy choices pertaining to economic development.

More important is the question of the range of perspectives on development represented in the volume. Development thinking has tended to swing from progressive to neo-liberal over the decades. Progressives have paid more attention to distribution, poverty, and social provisioning; whereas neo-liberals have focused on markets and "getting the prices right," with little appetite for redistribution, government subsidies, or serious efforts at poverty reduction. Gunnar Myrdal, Amartya Sen, and Arturo Escobar represent three generations of progressive development theorists; perhaps Peter Timmer, Malcolm Gillis, and Jeffrey Williamson fall closer to the neo-liberal end of the spectrum. I would judge that the *Handbook* does a pretty good job of finding the middle of the spectrum. Chenery's own emphasis on the importance of redistribution in development (Redistribution with Growth) places him closer to the progressive end, along with Pranab Bardhan, Irma Adelman, and Lance Taylor (each of whom has a contribution in the volume). The book pays attention to "alternative approaches" to economic development as well as poverty-related issues like health and nutrition. The book does a good job of combining a clear vision of the goals of economic development -- improvement of human welfare -- with technical economic analysis of growth, labor markets, and trade. And many of the authors explicitly recognize the point that development economics benefits from theoretical pluralism; the approach is not narrowly neo-classical.

Here are a few interesting observations from several contributors:

Pranab Bardhan:

Development economics as a separate branch of economics originated in a widespread perception of the limited usefulness of orthodox economics, and even though its pristine separatism has mellowed over the years it retains to this day its contrary, unruly, if

somewhat flaky, image in the eyes of mainstream economics. Standard neoclassical economics is mainly on the defensive in this terain and a number of alternative approaches clash and contend for our attention. (40)
Joseph Stiglitz:

The central questions facing development economics are: Why is it that some countries are so much poorer than others? What can be done to make them grow faster? Faster growth is needed if the gap in living standards is not to be widened even further. (94)
J.G. Williamson:

What explains the timing and the extent of the transition from a traditional rural to a modern urban society? Why does city growth speed up in early development and slow down in later stages? What role does migration play in the process, and do migrants make rational location decisions? Do urban labor markets serve to absorb urban immigrants quickly? Are rural emigrants driven by "push" conditions in the countryside or by "pull" conditions in the cities? Is the Third World "overurbanized"? (425)
T.P. Schultz:

The record of sustained modern growth in real per capita income cannot be accounted for by the accumulation of conventional units of physical capital or by the increased applicaiton of hours of labor per capita. The source of modern economic growth are sought instead in the changing quality of labor and capital, in the more comprehensive accounting of other inputs, and in change of organization, policy environment, or technology. ... Research on various aspects of the microeconomic relationshipb etween education and development has expanded rapidly, forging a consensus on questions for study and appropriate methodologies to address these questions. ... Studies across persons, households, farms, and firms have documented, first generally in the United States and then in many low income countries, strong empirical regularities between educational attainment of populations and their productivity and performance in both market and nonmarket (home) production activities. (544)
Jere Behrman and Anil Deolalikar:

Health and nutrition are important as ends in themselves and often are emphasized as critical components of basic needs in developing countries. In addition they may be channels through which productivity and distributional goals of developing societies may be pursued effectively if, as is often hypothesized, the productivity of low-income persons in work and in human- capital formation is positively affected by health and nutrition status. (633)
Several things are noteworthy in reviewing the contents and methods of the *Handbook* -- issues and perspectives that would now be regarded as crucial.

A phrase that does not occur in the volume is "Washington Consensus." This concept became current in the 1990s after being introduced by John Williamson in 1990 (link). Here is how Williamson puts his point: "The paper identifies and discusses 10 policy instruments about whose proper deployment Washington can muster a reasonable degree of consensus." He identifies ten policy goals as constituting the Washington Consensus: Fiscal Deficits, Public Expenditure Priorities, Tax Reform, Interest Rates, The Exchange Rate, Trade Policy, Foreign Direct Investment, Privatization, Deregulation, and Property Rights. It is apparent that this list is heavily tilted towards the neo-liberal end of the spectrum. By contrast, consider the Millenium Goals adopted by the United Nations in 2000 (link): End Hunger, Universal Education, Gender Equity, Child Health, Maternal Health, Combat HIV/AIDS, Environmental Sustainability, Global Partnership. The

Millenium Goals are focused on ending world poverty, while the Washington Consensus is focused on achieving effective market institutions and trading systems globally. The *Handbook* isn't a sourcebook or a polemic in support of the neo-liberal agenda; but neither is it emphatic in its treatment of poverty.

Another term that does not occur in the volume is "globalization." There are discussions of international trade, migration, capital flows, transnational corporations, and credit markets -- important components of contemporary debates about globalization. But the concept space involved in the idea of economic development had not yet fully highlighted the importance of global interconnectivity.

Third, the *Handbook* gives virtually no attention to sustainability, resource depletion, and the environment. These are now regarded as crucial aspects of the challenge of economic development. Taxation, trade, and governance come in for repeated treatments; but environmental sustainability is not raised as a significant issue.

Finally, the *Handbook* doesn't give central priority to the issues of poverty alleviation and inequality that were already becoming central for some development economists, including Amartya Sen. Sen's central ideas of functionings, freedom, and capabilities are expressed in his opening chapter to the volume. But the bulk of the contributions to the *Handbook* don't begin with poverty, but rather more specific questions about growth, modernization, trade, and population. The conceptual shift that Sen's writings would eventually bring to the field had not yet had full effect.

It is also interesting to examine the first and second editions of an important textbook on development economics that was roughly contemporary to the *Handbook*. Malcolm Gillis, Dwight Perkins, Michael Roemer, and Donald Snodgrass's Economics of Development was published a few years earlier than the *Handbook in* 1983 and 1987. There is a high degree of conceptual and organizational similarity between the two treatments of the economics of development, including topics, approaches, and models and methods. To get a sense for how the discipline of development economics has shifted since 1988, take a look at the topics and readings included in the course on Economic Development offered by Rohini Pande and Dani Rodrik (link). Addressing poverty is the central focus in this conceptualization of the field; there is lots of attention to the components of human wellbeing (health, education, nutrition); and the syllabus pays a good deal of attention to issues of institutions and governance within the development process.

The public sphere

Friday, September 03, 2010

The current issue of *Social Science History* is devoted to a series of articles in honor of Charles Tilly (link), around the general theme of the "public sphere" (the theme of the Social Science History Association annual meeting in 2007). Tilly was an active presence in the Social Science History Association, and this issue recognizes Tilly's originality and influence. The volume contains contributions by several distinguished historical sociologists, including Tilly, Andreas Koller, Craig Calhoun, Andrew Abbott, and Elisabeth Clemens.

The concept of the public sphere isn't a subject to which Tilly gave a lot of explicit attention; in fact, there is very little research on the social reality of the public sphere

within comparative historical sociology quite generally. The most directly relevant discussion of some of these topics in Tilly's work probably occurs in his 2007 book, Democracy. But the topic is ripe for consideration by comparative and historical sociologists, and for this reason the current SSH issue is a welcome start.

Andreas Koller formulates the general research question about the public sphere in his introductory essay in these terms:

Despite its central relevance for the members of modern societies for determining the course of their own history through reasoned debate and public choice, the study of the public sphere is not an integrated research field. ... This introduction seeks to provide an overview of analytic and historical dimensions that enables one to decipher a number of discussions that are spread out over many disciplines and often proceed in multiple disciplinary terminologies. Such a quest for an integrative framework is a necessary condition for well-defined comparative and historical research. (262-63)

Before a comparative historical sociologist could begin to investigate a phenomenon such as the "public sphere," it is necessary to have a preliminary conception of what we are talking about. As Koller points out, most discussions of the concept begin with the ur-text in the study of the public sphere: Jurgen Habermas's 1962 book, The Structural Transformation of the Public Sphere: An Inquiry into a Category of Bourgeois Society. Here are some preliminary descriptions of the public sphere offered by several of the contributors to this special issue of SSH:

Andreas Koller: [The public sphere] refers to a public of speaker(s) and audience that organizes itself and determines its own future by the force of the better argument, and it refers to its object, the public good. (Koller, 263)

Charles Tilly: No one has so far developed crisp measures of the public sphere's expansion and consolidation in one regime or another. In that regard, comparative-historical research faces gigantic conceptual, technical, and empirical challenges. But surely one indicator worth tracing is change in the frequency and character of gatherings in which people make collective claims on others, including public authorities. (Tilly, 292)

Craig Calhoun: It is instructive to situate the idea of the public sphere in this context. This gives the influential account of Jurgen Habermas its central pathos: the public sphere arises as part of civil society, incorporating adults who have gained maturity and intellectual autonomy in another of its parts, the family. It is oriented to forming rational-critical opinion on matters of universal interest to citizens, and through this to informing state policy. But it is debased and corrupted when the state-society division collapses amid bureaucratization, organized interest-group politics, and mass society in the twentieth century. (Calhoun, 302)

Craig Calhoun: The notion of the political public sphere centered on the idea that private persons might come together through reasoned communication to consider public issues and inform public policy. (Calhoun, 303)

Andrew Abbott: In this article I take this last as my definition of public spheres: public

spheres are symbolic spaces within which a group's normative affairs are discussed in some sense for themselves.... So I shall take public spheres as an empirical possibility while making no detailed claims about their characteristics. (Abbott, 338)

Elisabeth Clemens: At the core of the philosophical legacy of the Enlightenment lies a vision of rational individuals governing themselves through collective deliberation. By means of critical discourse, self-interested or private individuals reflect on common concerns and discover the nature of the public good, justice, and truth. (Clemens, 374)
What these snippets have in common is the idea of a ***public*** consisting of deliberative ***individuals*** engaging in ***debate*** over ***policies*** and legislation, in relation to conflicting ideas of the ***public good***. (There is an evident connection between this definition and Rousseau's theories of the general will; link.) There is the idea here that a collectivity can arrive at a publicly shared conception of its good, through open and public debate. And, in common with theorists of deliberative democracy, there is the idea that public debate can transform individual citizens' conceptions of themselves and the public good. So debate is not merely expressive of current opinions and preferences; it is potentially transformative.

These ideas are expressed in the language of political philosophy and the theory of democracy. But the subject matter becomes an object of study for sociologists when we realize that each aspect of the definition refers to a social reality that is highly variable across time, space, and culture. So it is an empirical question, to consider to what extent Qing China, pre-revolutionary Iran, or medieval England had social realities that corresponded to any of these categories: the public intellectual, the engaged citizen, public debate, or public policy. Was there a Qing public? Were matters of common concern debated openly or publicly, or were they decided behind closed doors by an Imperial bureaucracy? Did subjects of the Qing state regard themselves as public individuals?

Tilly's essay in this volume focuses on one aspect of this sociological topic: to what extent did new forms of public debate and agitation begin to emerge in England in the eighteenth and nineteenth centuries? He treats this as an empirical matter:

My collaborators and I gathered the evidence to examine how the development of British capitalism, transformation of the British state, and popular political struggle itself shaped changes in the ways that ordinary Britons made collecdtive claims -- changes in their repertoires of contention. (292)
He finds that there was a marked increase in the frequency of contentious gatherings, which he attributes to a rise in mass-based organizations and a mass-based public media. (Much of this research is presented in his more extensive contribution to Social Movements and Networks: Relational Approaches to Collective Action, "Contentious Connections in Great Britain, Britain, 1828-34", with Lesley Wood.)

So this is one empirical approach that a comparative historical sociologist could take to the problem of trying to assess the scope and growth of the public sphere. A very different approach is offered by Andrew Abbott in his contribution to the SSH volume, "Pragmatic Sociology and the Public Sphere: The Case of Charles Richmond Henderson." Abbott moves from meso to micro in this piece. He too counts things in order to assess the scope of the public sphere. But in this case, what is counted is appearances in the *Chicago Tribune*. Abbott attempts to gauge Charles Richmond Henderson's prominence in the public sphere by counting and classifying Henderson's presence in Chicago's leading newspaper. How frequently does Henderson's name

appear in the *Tribune*, in comparison to other prominent professors?

Henderson was chaplain and professor of sociology at the University of Chicago between 1892 and 1915, and it turns out that he had a remarkably high level of visibility in the *Tribune*. He was a prominent public figure. Abbott attempts to make sense of the public persona of Anderson through a brief intellectual and professional biography of the man; and he tries to arrive at some judgments about the causes and impact of his prominence. "Over his quarter century at the University of Chicago, Henderson became one of Chicago's and even America's most visible reform figures" (342). And much of his prominence was deliberate: Henderson sought out opportunities for bringing his convictions to the attention of a broader public than the university. Clubs and conferences were a frequent venue; Henderson was deeply interested in bringing his ideas to the public through these venues. And Abbott makes the important point that Chicago consisted, not of one public, but of an **archipelago** of publics: business elites, religious communities, immigrant communities, professional groups, ... (351).

Both of these empirical studies of certain aspects of the public sphere are intriguing and engaging. Taken as a whole, the SSH volume provides a diverse palette of work, and it plainly does no more than scratch the surface of the kinds of sociological research that are suggested by the topic of the public sphere. Abbott, Calhoun, Tilly, and the other contributors give an intriguing sense of the kinds of investigations that can be undertaken; there is much work to do in this area. Consider this variety of questions that need to be posed about the public sphere from a comparative sociology point of view:

- How did the public sphere evolve in England between 1600 and 1900?
- How does the public sphere differ in France, Germany, and England?
- Did China have a public sphere in the late Imperial period?
- What are some important differences in repertoire and performance within the public spheres of different countries and periods?
- How do intellectuals participate in the public sphere in different times and places?
- What role does organized public protest play in the public sphere?

(The photo above captures two historical ends of the idea of the public sphere: the polis and the protest. It captures a major protest in Athens following the 2009 financial crisis of the Greek state.)

Goffman's programme

Monday, September 06, 2010

Erving Goffman has had wide influence on American and French sociology, and I find his work highly interesting. But it is hard to characterize, because it doesn't fit easily into the standard categories of sociological research and theory. It studies individuals, but it is not individualist. And it is evidence-based, but it is not empiricist. In earlier posts I've characterized it as a particular kind of local knowledge, a sort of ethnography for micro-sociology (link, link). But there is certainly more to say than that.

One key part of his work can be described as "close observation of individual behavior in social context." This has two ends -- individual behavior and social context. And Goffman wants to shed light on both poles of this description. In particular, he almost always expresses interest in the social norms that surround action -- the expectations and norms through which other people interpret and judge the individual's conduct.

Consider these programmatic statements from several of Goffman's books:

I mean this report to serve as a sort of handbook detailing one sociological perspective from which social life can be studied, especially the kind of social life that is organised within the physical confines of a building or plant. A set of features will be described which together form a framework that can be applied to any concrete social establishment, be it domestic, industrial, or commercial. (The Presentation of Self in Everyday Life, preface)

By and large, the psychiatric study of situational improprieties has led to studying the offender rather than the rules and social circles that are offended. Through such studies, however, psychiatrists have inadvertently made us more aware of an important area of social life -- that of behavior inpublic and semipublic places. Although this area has not been recognized as a special domain for sociological inquiry, it perhaps should be, for rules of conduct in streets, parks, restaurants, theaters, shops, dance floors, meeting halls, and other gathering places of any community tell us a great deal about its most diffuse forms of social organization. Sociology does not provide a ready framework that can order these data, let alone show comparisons and continuities with behavior in private gathering places such as offices, factory floors, living rooms, and kitchens. (Behavior in Public Places: Notes on the Social Organization of Gatherings, 3-4)

Society establishes the means of categorizing persons and the complement of attributes felt to be ordinary and natural for members of each of these categories. Social settings establish the categories of persons likely to be encountered there. The routines of social intercourse in established settings allow us to deal with anticipated others without special attention or thought. When a stranger comes into our presence, then, first appearances are likely to enable us to anticipate his category and attributes, his 'social identity' – to use a term that is better than 'social status' because personal attributes such as 'honesty' are involved, as well as structural ones, like 'occupation'. (Stigma: Notes on the Management of Spoiled Identity, 11)

Within the terms, then, of the bad name that the analysis of social reality has, this book presents another analysis of social reality. I try to follow a tradition established by William James in his famous chapter "The Perception of Reality," first published as an article in *Mind* in 1896. Instead of asking what reality is, he gave matters a subversive phenomenological twist, italicizing the following question: Under what circumstances do we think things are real? (Frame Analysis: An Essay on the Organization of Experience, 2)

In 1945 Alfred Schutz took up James' theme again in a paper called "On Multiple Realities." ... Schutz's paper ... was brought to the attention of ethnographic sociologists by Harold Garfinkel, who further extended the argument about multiple realities by going on (at least in his early comments) to look for rules which, when followed, allow us to generate a "world" of a given kind. (Frame Analysis: An Essay on the Organization of Experience, 5)

I have borrowed extensively from all these sources, claiming really only the bringing of

them together. My perspective is situational, meaning here a concern for what one individual can be alive to at a particular moment, this often involving a few other particular individuals and not necessarily restricted to the mutually monitored arena of a face-to-face gathering. I assume that when individuals attend to any given current situation, they face the question: "What is it that's going on here?" (Frame Analysis: An Essay on the Organization of Experience, 8)

The study of face-to-face interaction in natural settings doesn't yet have an adequate name. Moreover, the analytical boundaries of the field remain unclear. Somehow, but only somehow, a brief time span is involved, a limited extension in space, and a restriction to those events that must go on to completion once they have begun.... The ultimate behavioral materials are the glances, gestures, positionings, and verbal statements that people continuously feed into the situation, whether intended or not. These are the external signs of orientation and involvements -- states of mind and body not ordinarily examined with respect to their social organization. (Interaction Ritual - Essays on Face-to-Face Behavior, 1)

There are several orienting themes among these statements and within Goffman's work -- frames, we might call them.

- There is the idea of face-to-face behavior, in private, in public, and in everyday life.
- There is focus on the social setting within which local behavior takes place -- the norms and constraints that are embodied in the group and constraining of the individual.
- There is emphasis on the particulars of the place -- the factory, the asylum, the hotel.
- There is the social-cognitive situation of the individual -- the way in which he or she answers the question, "What is going on here?"

So Goffman starts much of his work with fine-grained, detailed observations of behavior -- elements as subtle as the bodily signs of embarrassment in a conversation. Second, he wants to discover some of the structures of mental processing through which individuals act in social settings -- the frames, scripts, and rituals that guide social perception and action for individuals. Third, he wants to tease out the social judgments and norms that provide the normative and guiding context for the actor's movements -- the judgments surrounding "saving face," embarrassment, shame, pride, and proper performance.

There is also a psychiatric dimension of Goffman's work: "abnormal behavior" and the description and contextualization of unexpected patterns of behavior are frequent elements of Goffman's discourse. For example, in *Stigma*:

The term stigma and its synonyms conceal a double perspective : does the stigmatized individual assume his differentness is known about already or is evident on the spot, or does he assume it is neither known about by those present nor immediately perceivable by them? In the first case one deals with the plight of the discredited, in the second with that of the discreditable. This is an important difference, even though a particular stigmatized individual is likely to have experience with both situations. I will begin with the situation of the discredited and move on to the discreditable but not always separate the two. (14)

And psychiatric examples permeate Behavior in Public Places: Notes on the Social Organization of Gatherings as well.

The Erving Goffman Archive at UNLV has some very useful materials relevant to Goffman's intellectual project (link). The site is of great value and is worth studying in detail. Here is a link to one of Goffman's course reading lists from 1970. The list is titled, "The Ethnography of Symbolic Forms: Frame Analysis," and is dated Fall 1970. The list is very interesting, and particularly valuable is the first section on "Basic Materials." This

gives us an idea of some of the most important formative influences on Goffman. Included on the list are several phenomenologists (Husserl, Kockelmans); several ethnomethodologists (Garfinkel, Schutz); a handful of analytic philosophers (David Shwayder, J. L. Austin, Nelson Goodman), and a playwright (Pirandello).

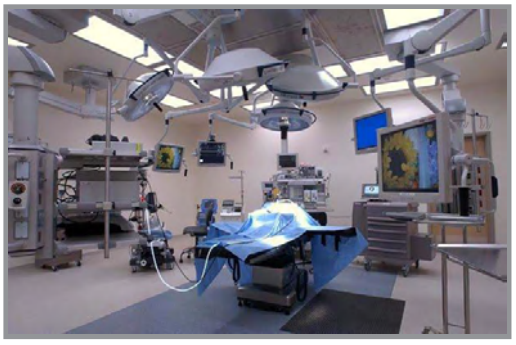
The 1960 reading list is also of interest; link. This syllabus is titled Communication and Social Contact. Goffman describes the course in these terms:

This course deals with face to face interactions in natural settings. Interest will center on the components of the communicative act, the variables and models of interaction analysis, and the natural units of interaction for which a literature is available.

The syllabus breaks the course into a series of topics: Sign Processes, Expressive Behavior, Interaction, Substantive Areas, Conversation, Task Meetings, Two-Person Psychotherapy, Performances, Play-Games, Public Behavior, and Social Occasions. This list has some of the surprising conjunctions evident in the 1970 list as well; for example, there is a significant amount of attention to game theorists (Von Neumann and Morgenstern, Schelling, Luce and Raiffa), as well as Freudian psychology.

Here is how Pierre Bourdieu distilled Goffman's originality (link):

The work of Erving Goffman is the product of one of the most original and rarest methods of doing sociology -- for example, putting on a doctor's white coat, in order to enter a psychiatric asylum and thus putting oneself at the very site of the infinity of minute interactions which combine to make up social life.... Goffman's achievement was that he introduced sociology to the infinitely small, to the things which the object-less theoreticians and concept-less observers were incapable of seeing and which went unremarked because they were too obvious, like everything which goes without saying. These entomologist's minutiae were bound to disconcert, even shock, an establishment accustomed to surveying the social world from a more distant and more lofty standpoint. ("Erving Goffman, Discoverer of the Infinitely Small," *Theory Culture & Society* 2:1 1983, 112)



This is a nice description of Goffman's work. It leaves out an important dimension, however, namely, the social and contextual side of Goffman's gaze. Goffman was always interested in the nuances of social expectation, norm, and script within particular social settings. And this makes his work thoroughly sociological.

System changes in healthcare

Sunday, September 12, 2010

One of the largest and most interesting processes of change going on in the United States today is the rapid redesign and adjustment of the American healthcare system. A key driver is this spring's passage of the Patient Protection and Affordable Care Act (PPACA), but the more fundamental causes are the twin crises we face for access and rising cost for health coverage. Somehow the country needs to find a way of including the whole population within the insured population, and we need to find ways of reducing the rate of growth of aggregate and per capita healthcare expenditures. PPACA is aimed at addressing both crises, and they are urgent.

Healthcare in the United States is provided through doctors, physician groups, and hospitals, organized into regional health systems. A given region typically has a number of hospital systems, non-profit and profit, and physician groups ranging in size from one to hundreds of physicians. And many experts describe existing health systems and hospitals as homebrew organizations that haven't changed fundamentally in thirty years. The current environment is forcing change for quality, health outcomes, and cost.

So who is forcing the changes? The requirements of the healthcare reform legislation (PPACA) are part of the answer. But other change drivers are large employers who are purchasers of healthcare services for their employees and the insurers who directly pay for services. A particularly important player is the Voluntary Employee Benefits Association trust (VEBA), a type of organization created by Federal law to administer large benefit pools. The United Auto Workers VEBA itself expends $4.6 billion annually in support of healthcare for its retirees, and it is actively managing plans and contracts so as to achieve sustainable spending for the 800,000 retirees in its pool (link). Health systems, hospital administrators, and physician group leaders are actively seeking ways of adjusting to the imminent future in the healthcare space.

The diagnoses of failure in the healthcare system often focus on a cluster of problems.

- Poorly aligned incentives for patients, physicians, and hospitals
- Incentives don't create behavior of all parties leading to greater health and lower cost
- Lack of focus on health rather than illness
- Lack of focus on the health of a population rather than a group of clients
- Lack of standardization of process within healthcare systems
- Lack of Electronic Medical Records
- Failure to involve the patient in responsibility for his/her health

The problem from the health system's point of view often comes down to reimbursement and revenue. Medicare and Medicaid reimbursement levels don't cover the costs of care, and hospital systems have large obligations for indigent (non-reimbursed) care. So hospital administrators and physician leaders face the imperative of squeezing costs out of their system while maintaining and enhancing quality and patient safety. More and more urban hospitals are approaching a critical financial status as a result.

Payers -- basically, the companies that pay for health insurance for their employees -- see the problem as one of rapidly rising costs and assuring quality. So their effort is to place pressure on providers and insurers to contain costs, to shift part of the cost to the employee, and to create effective wellness plans that incentivize employees to adopt healthier lifestyles. Payers and insurers are attempting to make highly focused use of data about providers, cost, and health outcomes to permit evaluation of health systems and doctors and their practices. That data is available in voluminous quantities, and it will allow payers to distinguish strongly between more and less efficient health systems.

So what are some of the strategies currently being pursued by system administrators to allow their systems to survive in the new fiscal and regulatory environment? The mantra

is the patient-centered medical home. Systems are seeking improvements in coordination of health care for the patient, quarterbacked by the primary care physician; a shift of emphasis towards wellness for the population rather than disease intervention; improvements in process efficiency; close attention to cost centers; competition for patients and referrals within the region; development of recognized specialty areas with higher margins and reimbursement rates; and implementation of the Electronic Medical Record and all the processes that need to surround this technology. Another visible strategy around the country is consolidation, as more successful hospitals absorb or merge with less successful ones. The goal is to create a system of "integrated and accountable care," achieving both goals of quality and cost effectiveness.

One of the current areas of focus is the concept of an "Accountable Care Organization," a concept introduced through the PPACA legislation but not explicitly defined. (Here is a 2009 discussion paper by the Urban Institute.) It is a level of organization that will figure crucially in the administration of future payment systems and regulations, and health systems are attempting to formulate their own ACOs. Here is a working definition:

An ACO is a group of providers working as a team taking fiscal responsibility for outcomes and costs for a defined population.
If one is interested in the fate of a particular regional healthcare system or hospital, now is the time to be paying close attention to the planning and reform its leaders and physicians are currently carrying out. The stakes are very high. Tthe business environment is changing rapidly and abruptly, and some community hospitals and health systems will not survive. Moreover, some experts expect a significant decline in the percentage of employers who offer health coverage -- bad news for currently insured workers.

So the next few years portend some very deep changes for almost all Americans when it comes to healthcare.

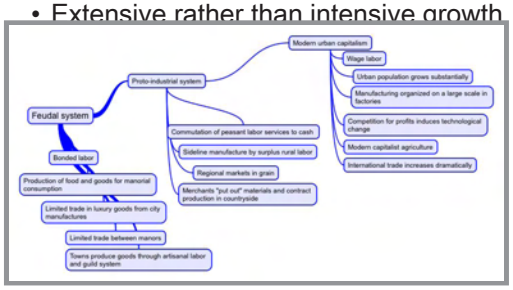
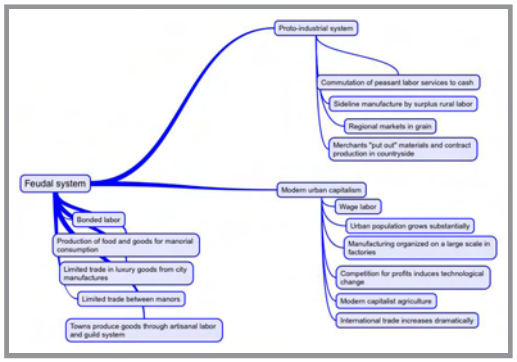
Proto-industrialization

Tuesday, September 14, 2010



The concept of proto-industrialization became an influential one in economic history in the 1970s and 1980s. The term refers to a system of rural manufacture that was intermediate between autarchic feudal production and modern urban factory production. Variously described as rural manufacturing, domestic manufacture, cottage industry, and a "putting-out" system, it was a dispersed system of production that used traditional methods of production and extensive low-paid rural labor to produce goods for the market, both domestic and international. Unlike modern capitalist manufacturing, proto-industrialization did not depend on rising labor productivity as a source of higher profits; instead,



merchants increased the scale of their businesses by extending production to additional households and workers.

One of the first to use the term was Franklin Mendels in 1970 (link), who applied the concept to extra-urban manufacturing in Flanders in the eighteenth century. Peter Kriedte, Hans Medick, and Jurgen Schlumbohm's Industrialization Before Industrialization provided an extensive historical and theoretical treatment of the phenomenon in 1977.

It has long been known that industrial commodity production in the countryside for large inter-regional and international markets was of considerable importance during the formative period of capitalism. (1)
What are the chief economic characteristics of a stylized proto-industrialization system of production?

- Rural labor, often sideline activities beside agricultural work
- Production for a market, often through urban-based merchants
- Extremely low returns to labor -- squeezed labor
- Low technology, very low rate of technological change
- Extensive rather than intensive growth

In order for rural industry to develop on a large scale in a region, several factors needed to be present: extensive demand for manufactured goods by concentrated populations and developed patterns of trade; a concentration of merchant wealth; and a population of under-employed rural householders who could be recruited into sideline manufacturing employment. Peter Kriedte explained the regional pattern of emergence of proto-industrialization in terms of the different forms of power possessed by lords in different parts of Europe:

The power-constellations and their impact on the spatial expansion of industrial commodity production were different in east-central and eastern Europe. Peasants were more directly and more firmly dominated by their lords, and there was little room for the development of rural industries....

But whether a region developed rural industries or not was determined not so much by the extent of feudal charges as by the form in which peasants paid them. And the form of payment was determined not only by the social relationship in the narrow sense between the feudal lord and his dependent peasants but also by the overall relations of production. (18)
This argument is similar to that offered by Robert Brenner in his explanation of different courses that agricultural development took in different parts of Europe (link).

The regions where proto-industrialization developed earliest, according to Kriedte, were in western Europe:

The first regions of relatively dense rural industry had developed in England, the southern

Low Countries, and southern Germany in the late Middle Ages. The decisive thrust which brought about the phase of proto-industrialization came at the end of the sixteenth and in the seventeenth centuries.... Quantitative changes in supply and demand combined to produce a cumulative process which led to a new phase. (23)

Generally speaking, a region that has made the transition to commercial agriculture is barren soil for rural manufacturing, for the simple reason that commercial farmers earn a sufficient income through farming. However, some areas of commercial agriculture also became significant concentrations of rural manufacturing:

When proto-industrialization gained a foothold in a region of commercial agriculture despite these basic assumptions, special circumstances are usually responsible. First of all, commercial agriculture, generally, could only develop in a highly urbanized region. The concentrated demand of a large town or a whole network of towns was necessary in order to induce the self-sufficient peasant family holding to enter on the path of specialization. (27)

Hans Medick emphasizes the micro-side of the equation -- the economics of the peasant household in the late Middle Ages.

The central feature of the 'rationality' underlying the family economy is the fact that its productive activity was not giverned primarily by the objective of maximizing profit and achieving a monetary surplus. The maximization of the gross produce rather than the net profit is the goal of family labour. (41)

In other words, the peasant household is governed by the dynamic that leads to "self-exploitation" in the sense described by Chayanov -- use of family labor to the point approaching a marginal product of zero (The Theory of Peasant Economy). Under these circumstances, it is economically rational to expend some family labor on sideline manufacturing if there is some income associated with this activity -- no matter how low the wage.

PI is described as transitional because its economic possibility was created by the political situation of feudal cities -- specialized manufacture in cities under a regulated guild system, self-production in the countryside. And, it is sometimes claimed, proto-industrialization prepared the ground for a full modern systems of capitalist industry. The "transition" scenario might be framed along these lines:

But it is also possible that proto-industrialization was an **alternative** to capitalist development -- a cousin rather than a grandparent. Here the diagram would look differently:

Proto-industrialization is a significant historical phenomenon, we might say, because it represented a large and marked change in the organization and volume of production of goods from the medieval period to the early modern period. Towns and cities were already economically active locations, representing both concentrated demand and concentrated production. But the rural population was almost entirely involved in farming and sideline production for home use. The emergence of a significant level of production in rural hinterlands was a shift, and so it is worth asking why this change occurred in the circumstances in which it did. The change dynamics Kriedte, Medick, and Schlumbohm describe include population change; urban economic regulations; incentives for feudal rights-holders to transition to cash obligations; and the existence of inter-regional trade and markets that extend beyond the local village.

Several questions are especially pertinent to the study of this phenomenon.

- Was proto-industrialization indeed a step on the path to modern manufacturing and capitalism?
- What were the factors that led to the regional spread of rural manufacturing in parts of Europe?
- What factors explain the geographical distribution of rural industry in the early modern period in Europe?
- How did the economic and political institutions of the feudal order set the stage for the emergence of proto-industrialization?
- What role did demographic factors play in this period of economic development?
- Was PI a distinctive "system" or simply a predictable economic adaptation to rising demand for finished goods?
- What is the connection between PI and the "modern world system" of trade?

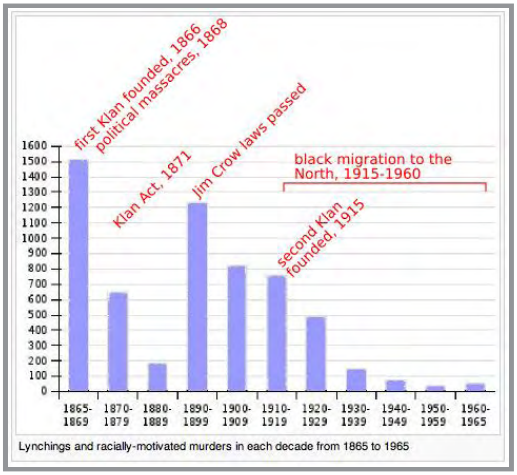
Here are some relevant causal factors that might be invoked in formulating answers to these questions:

- Rising population and population density
- Rising volumes of inter-regional trade
- Shifts in the political power of various collective actors
- Changes in political institutions -- central state, local civic arrangements
- Improvements in agricultural productivity
- Emergence of new technologies
- Persistence/change of the guild system
- ...

It is tempting to frame this problem in the terms offered by Thunen and early economic geographers in "modeling" the economic changes that would be predicted on a featureless plane populated by economically rational agents (VON THUNEN'S ISOLATED STATE an English Edition of Der Isolierte Staat). Imagine a sort of "SimCity" simulation that begins with a sprinkling of mid-sized towns and cities with given levels of production and trade regulated by guilds, located within a countryside consisting of manors with serfs and small peasant farms. There is trade between town and country, since the towns must import food for the urban population, and there are some goods needed in the countryside that cannot be produced there. But trade is limited, labor mobility is limited, and the market economy is only a small fraction of all economic production. The actors in this story are merchants, lords, bonded serfs, free peasants, and officials. Now postulate that the actors respond rationally to some set of changing circumstances. Which of various initial scenarios lead to a proliferation of rural manufacture?

We might postulate that merchants have only a few accessible strategies for achieving a return on their wealth. Investing in production and trade is one such strategy. Town-based production was heavily regulated, however, and the opportunities for profits were limited. A large under-employed labor force was available in the rural periphery of the towns. So a strategy of "putting-out" materials and paying low wages to rural producers was an attractive one.

This discussion relies heavily on a very specific set of historical and institutional characteristics -- the economic and demographic conditions of Western Europe in the early modern period. But it is interesting to compare these developments with some similar patterns in China's economic history. For example, consider Mark Elvin's description of merchant-based manufacturing in Ming China in The Pattern of the Chinese Past. It is also interesting to compare the very different analysis in Charles Sabel and Jonathan Zeitlin's World of Possibilities: Flexibility and Mass Production in Western Industrialization. Sabel and Zeitlin describe a different alternative to factory production:



high wage, high return artisanal production, surviving well into the era of modern factory production.

Race and racism

Thursday, September 16, 2010

Race has been a fundamental fact in American society for centuries, since the sixteenth century with the arrival of African slaves. And many would observe that rac***ism*** has been a part of that history from beginning to end. These are distinct statements; it is possible for race to be a factor, without racism being present. But our history does not suggest this separation. Instead, the United States has embodied a pretty deep version of racial awareness, extending back to the period of slavery and its aftermath, and it continues to embody behaviors, attitudes, and outcomes that are best described as racist.

So what do we mean when we say that a society contains a substrate of racism? Can we observe and measure the social dimensions of racism? And can we say with any confidence that there has been change over time? Most fundamentally, a society is racist if members of one racial group despise, demean, mistreat, and discriminate against members of another racial group. Assertions of racial superiority and inferiority, patterns of treatment that discriminate across individuals within different racial groups, and outcomes that show a distinct advantage to members of a dominant racial group all represent the markings of racism within a society.

We might say that there are several important social factors that represent different aspects of the social reality of racism: attitudes, behaviors, institutions, and outcomes.

The **attitudes** of racism include a bundle of emotions and beliefs: a belief in the inherent superiority or inferiority of one race relative to another; feelings of hostility, suspicion, or antipathy towards members of a different racial group; a set of stereotypes about the characteristics of the other group; and a readiness to discriminate against members of other groups when one is in a position to assign benefits, opportunities, or hardships. There is such a thing as an "ideology" of race: a set of beliefs about people and the world that validates the assumptions of superiority and inferiority and the situation of privilege of the dominant group. It is possible to use survey methodology, focus groups, and individual interviews to probe attitudes of a population, and perhaps it is possible to "map" the variations in racial thinking throughout a society. So we might have some confidence

in the possibility of developing an aggregate measure of "degree of racist attitudes" in a given society, and with effort we could monitor the direction of change of this measure over time. This might give us a basis for concluding that "racial attitudes are improving (or worsening) during a specific period."

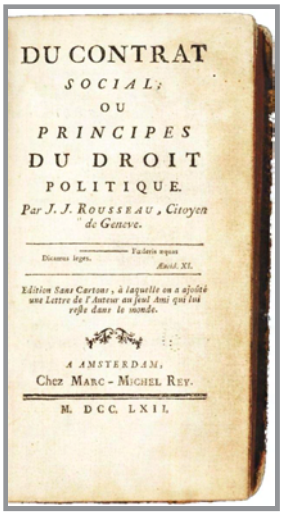
Behaviors have something to do with attitudes; we generally believe that people's behaviors derive in some way from their underlying attitudes and ideologies. But the evidence of racist behavior is more visible than inferences about attitudes. Particularly visible are facts about the incidence of racially motivated violence; facts about discrimination in employment and housing; and patterns of social behaviors in interactions between members of different racial groups. A situation in which members of a privileged group express dominance, superiority, and greater self-importance towards members of a different group is one that expresses behaviorally the logic of race relations in that society. So we can ask the question of a given society: to what extent do members of a privileged racial group engage in harmful and discriminatory behaviors towards members of another group? And we might attempt to estimate the degree of racism in a society by the relative frequency of racially motivated crimes over time (FBI hate crime statistics; link). Consider this graph of the frequency of lynchings in the United States between 1865 and 1965 (Wikipedia link):

We might speculate that decades in which there is an exceptionally high incidence of lynchings are also peak periods of racism more generally. (Though we might also explain the frequency of these acts of violence in more political-organizational terms.)

The third factor mentioned above is **institutions**: to what extent are the basic institutions in a given society "racialized"? That is, to what extent do the basic institutions automatically and systematically treat members of different races differently? The practices of real estate "steering" and mortgage redlining are clear examples of a racialized system for assigning home seekers to neighborhoods; and employment practices that disadvantage members of some racial groups are just as critical in the area of employment and wellbeing. For example, facts about residential segregation and the availability of transportation make it extremely difficult for African-American applicants to pursue job openings in the suburbs. So this is a system that discriminates against one group in favor of another -- even though the employer's personal attitudes may not be the cause of the discrimination. Here too it is plausible to imagine that we might arrive at some quantifiable judgments about the degree of discrimination and equality of basic institutions at a given time; and this would permit us to make comparisons over time as well.

The fourth factor is **outcomes.** The degree of racialization of a society might be measured by the breadth of the gap between races with respect to important life outcomes. If blacks and whites differ significantly in life expectancy, incarceration rates, health status, income, wealth, and education, we have good reason to believe that there are racialized social processes that are leading to these outcomes. So measuring the race gap with respect to important social outcomes is an important way of assessing the degree to which a given society is racialized; or in other words, to measure the degree to which racism is an important social factor in that society. Racial gaps with respect to important life outcomes can be measured; and it is meaningful to find that racial gaps have narrowed (or widened) during a given period of time.

The fundamental test of a non-racist society is this: there should be no difference in the availability of opportunities across racial groups, and -- given a reasonable assumption



about the fundamental equality of human beings -- there should be no gap in outcomes across racial groups when it comes to factors like health, education, income, or wealth. In other words, a non-racist society is one whose basic institutions do not discriminate, consciously or unconsciously, across individuals from different racial groups.

The treatment of attitudes, behaviors, institutions, and outcomes offered here suggests that it is indeed possible to chart the degree of racial progress a society has made over a number of decades. We can measure attitudes and behaviors over time, using rigorous social-science tools (survey methodology). And we can assess the workings of institutions and the distribution of outcomes using the suite of tools available to the social historian more generally. What is genuinely surprising, however, is the relative paucity of social-science research on this topic.

There is of course the crucial question of the social dynamics of racist attitudes and behavior. Are there social or psychological factors that make the appearance of racist attitudes more likely? Are there features of human nature that lead naturally to a social psychology of "in-group, out-group" discrimination? Or is racism a purely contingent accident that results from some important historical events in the past -- the slave economy, for example? What are the factors in contemporary American social life that are either conducive or inhibiting to the formation of racist attitudes and behaviors in individuals?

Did Rousseau have a sociology?

Sunday, September 19, 2010

DU CONTRAT
SOCIAL;
OU
PRINCIPES
DU DROIT
POLITIQUE.
Par J. J. ROUSSEAU, Citoyen de Geneve.
A AMSTERDAM;
Chez MARC-MICHEL REY.
M. DCC. LXII.

Political philosophers ask a small number of core questions: for example, what constitutes the moral basis of political authority? How should the values of individual liberty and community wellbeing be balanced? And we might imagine that the most insightful political philosophers work on the basis of an astute understanding of the social world. Political philosophy, we might say, ought to be grounded in a good empirical understanding of how society works. As Rousseau himself puts a similar point in the opening pages of "Considerations on the Government of Poland":

Unless you are thoroughly familiar with the nation for which you are working, the labour done on its behalf, however excellent in theory, is bound to prove faulty in practice; especially when the nation in question is one which is already well-established, and whose tastes, customs, prejudices and vices are too deeply rooted to be readily crowded out by new plantings.
Rousseau had a distinctive political philosophy -- but did he also have a sociology? What did he understand about how a society works? And why should we expect that a political philosopher might have something like a sociological theory of the society in which he/she lives? For that matter, what were some of the main characteristics of French and Swiss society in 1750?

Rousseau's political philosophy is well known (link). Rousseau's conception of society in The Social Contract is grounded in a conception of the moral psychology of the individual

and the constitutive relationship that exists between community and the individual. Rousseau distinguished between the **natural** individual (motivated by direct natural emotions and desires, along the lines of Hobbes's conception of the individual); and the **moral** individual (constituted by an understanding of his relation to other moral beings). The former is outside of society; whereas the latter is integrally integrated within a set of social relationships. Rousseau is a theorist of freedom. But freedom has these same two aspects: natural freedom and moral freedom. And his conception of social relationships is simple: there is sovereignty (the relations of the polity) and there is property (the relations of the economy).

What this philosophy does not provide is anything like an empirical understanding of real, concrete social life in Rousseau's contemporary France or Switzerland: for example, the nature of the occupational segments of eighteenth-century French society, the ways in which the state exercises its power, the social practices of farming villages, or the ways in which wealth and power are accumulated by elites. There is very little concrete empirical social detail in Rousseau's writings.

The central models of social life that Rousseau possessed fall in a couple of categories:

- stylized examples of social behavior -- cooperation, for example
- stylized examples of a legislative process (the constitution of Poland)
- the romanticized example of the Greek polis
- popular elite conceptions of the French court
- stylized conception of the relation between the governed and the ruler; forms of government

So there is a political theory -- a theory of different forms of the state -- but not much of a theory of how social life works. There is very little social description in Rousseau's work. The only institution he describes in any detail is the process of legislation. And there are only infrequent instances of hypotheses about social processes -- how social organizations work, for example. So it is hard to avoid the conclusion that Rousseau did not have much of a sociological imagination or curiosity. Unlike Tocqueville a century later, he was not a sociologist in the making.

We might expect sociological description in his A Discourse Upon the Origin and the Foundation Of The Inequality Among Mankind. But this isn't the case. He refers to the creation of property and the consequent emergence of inequalities of wealth; but he doesn't ask at all what the social processes are that preserve property. And there is nothing historically specific about his descriptions of property, wealth, and inequality; they remain apriori and general.

What might we want from a sociology from an observer like Rousseau? We would want a couple of fundamentals: an understanding of how power works in the contemporary society; an idea of how economic institutions work; an understanding of the major classes that exist in society -- and the forms of life and forms of social relations that exist within these. There is a descriptive aspect of this picture -- what are the main social groups and processes? And there is a theoretical part -- how do these institutions work? What are some of the causal processes that can be identified within society?

Moreover, we might say that a political philosophy is seriously hampered if it is not grounded in a fairly good understanding of how society works -- how individuals behave in institutional settings, how organizations work, how public opinion and shared social values influence individuals. Significantly, these are the sorts of concrete observations with which Tocqueville's work is filled (link).

We also find much more of a sociological eye in the writings of novelists. We get more of a descriptive sociology from many of the French novelists of the nineteenth century than is to be found anywhere in Rousseau. Balzac, Zola, and Stendhal all devote extensive attention to the lives and ways of the various segments of French society -- bourgeois, aristocrat, peasant, merchant, thief.

Robert Darnton describes a bit of sociological description in The Great Cat Massacre: And Other Episodes in French Cultural History in a fascinating chapter called "A Bourgeois Puts his World in Order: The City as a Text." The object of the chapter is a highly detailed description of Montpellier written during Rousseau's lifetime. Here is the opening paragraph of Darnton's essay:

If the grim folklore of peasants and the violent rituals of artisans belong to a world that seems unthinkable today, we might expect to be able to think ourselves into the skin of an eighteenth-century bourgeois. The opportunity arises thanks to another document, as extraordinary in its way as Contat's account of the cat massacre: it is a description of Montpellier written in 1768 by an anonymous but solidly middle-class citizen of the city. To be sure, the casual nonfiction of the eighteenth century was full of "descriptions," guidebooks, almanacs, and amateur accounts of local monuments and celebrities. What set our bourgeois apart from others who dealt in the genre was his obsession with completeness.

Intangible services

Tuesday, September 21, 2010

Neoclassical economics presents a pretty simple theory of the equilibrium price of a manufactured good. This theory also extends to a theory of the wage for skilled and unskilled labor. We postulate production and demand curves, and the equilibrium price is the point where supply equals demand. The supply curve is influenced by factors governing the cost of production and therefore the level of profit created at a given production level and price, and the demand curve is influenced by subjective consumer preferences. An increase in demand for a good pushes up the price, thus triggering more production; and the price falls to a new equilibrium.

Wages are affected by this calculation because labor is a factor of production, and demand for labor at a given wage is influenced by the marginal product of labor. If the marginal product is greater than the wage the employer will hire another worker, increasing demand for labor and marginally increasing the wage. The equilibrium wage is the point at which the marginal product equals the wage.
Labor is not a homogeneous substance; the marginal product is affected by skill, intensity, and experience. So we should expect different wage curves for different segments of the labor force, with the wage rate for unskilled and inexperienced workers at the lowest level. But because specialized labor is somewhat elastic in supply (through additional training) we would expect some degree of convergence between skilled and

unskilled labor rates over moderate time periods.
How does this theory apply to intangible services where the quality of the product is difficult to measure? I'm thinking of a college education; how does a consumer decide between the education offered at a private university like Rice and the lower-cost alternative at UT-Arlington? But let's think of simpler examples -- for example, architectural services, family lawyers, or studio musicians. What are the factors that influence the price a supplier can charge in the marketplace? Why do each of these sectors embody significantly tiered price structures?

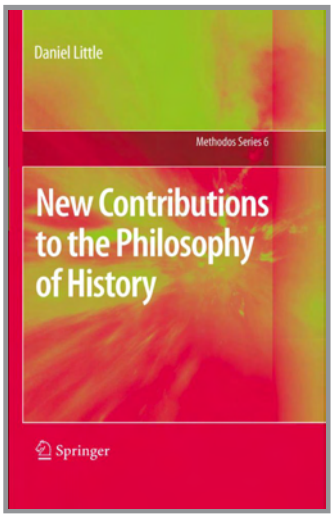
Take architectural services. There is a wide range of fees charged by architectural firms, ranging from one-person firms designing single-family homes to multi-city firms charging much higher fees. There is demand for architectural services regionally and nationally. There is good information about suppliers and rates at the national level. And the supply of services is somewhat elastic -- more students will enter architecture school when the incomes they can expect are high. So why doesn't the simple logic of supply and demand imply convergence of prices for this service that is reasonably consistent and related to the cost of production of the service? Why are some elite firms able to retain a significant and permanent price premium? In other words, why don't we witness the commodification of architectural services along the lines of the auto industry, where firms compete aggressively on price?

I suppose some of the factors that stabilize this sort of multi-tier price system in services are fairly obvious. These might include brand and reputation; quality and prestige of professional service providers within the various firms; and depth and quality of referral networks.

Consider this thought experiment. RUNOFTHEMILL is an architectural firm of 30 professionals in the Rustbelt. TOPOFTHELINE is a firm of 200 professionals in San Francisco. Detailed quality assessment by the XYZ consulting firm estimates that RUNOFTHEMILL completes a wide range of midsize projects at roughly the same level of quality as TOPOFTHELINE. However, TOPOFTHELINE charges roughly twice what RUNOFTHEMILL charges for a project of comparable size. What are the mechanisms that preserve the price differential between the two firms? Why are rational business organizations willing to pay the premium to have their buildings designed by TOPOFTHELINE?

First, it is possible that TOPOFTHELINE has succeeded in positioning itself in the marketplace as a provider of superior quality. By hypothesis, this is untrue; but if potential buyers are persuaded of the quality advantage, they may choose TOPOFTHELINE over RUNOFTHEMILL in spite of the premium. This seems to be an inverted version of the "market for lemons": because the actual quality of the good is difficult to measure, the purchaser is forced to turn to other indicators as possible signals of quality. And this may lead the purchaser to pay more for the service than necessary.

Second, TOPOFTHELINE may have pursued a deliberate and successful strategy of recruitment of architects from the most respected schools in the world, whereas RUNOFTHEMILL may pay lower fees and may recruit equally capable but less prestigious professionals. Prospective clients may take the prestige of the staff as an indicator of the quality of the product, and may therefore be willing to pay the premium. The observable prestige of the professional staff may serve as a surrogate for the inferred quality of the service.



Third, TOPOFTHELINE may have a brand that conveys significant prestige on its projects. A company whose corporate offices are designed by TOPOFTHELINE may gain from that prestige, and the gain may justify the premium in spite of the additional cost.

Finally, it may be that the market for architectural services is highly segmented as a result of the networks of referrals that exist involving the two firms. TOPOFTHELINE exists in a network of premiere organizations, both providers and purchasers; and referrals and endorsements for TOPOFTHELINE support premium prices for its services. RUNOFTHEMILL has completed equally high-quality projects, but for a second tier of companies and consumers; so its referrals more or less automatically steer its services towards a tier of companies that are more likely to compete on price. So RUNOFTHEMILL's referrals generate lower average fees.

Several of these factors are inherently irrational grounds for accepting a price premium. If purchasers had full information about quality and price, they would not pay a premium for the pedigrees of the professional staff, and they would not restrict their purchasing horizon to suppliers recommended by other elite firms. Instead, they would go with the Walmart strategy: get the best product for the lowest price. So far, however, it seems that the markets for advanced and specialized services are fairly sticky when it comes to price, quality, and prestige.

New contributions to the philosophy of history

Thursday, September 23, 2010

I am pleased at the publication this month of a book I've been working on for quite a long time, New Contributions to the Philosophy of History (Methodos Series). (Here is a link to a digital version of the book on the Springer website.) The title is self-explanatory. The book is intended to jump-start a new round of conversations within analytic philosophy about the nature of history and historical explanation. The philosophy of social science and the philosophy of biology have contributed enormously to the progress of research in both these areas, and I believe that new discussions in the philosophy of history can be equally valuable.

The book was inspired out of the thought that reflections on history and historical knowledge have not been as prominent within philosophy as they once were; and yet the issues raised under this rubric are interesting and important. We need to have a better understanding of some of the conceptual and epistemic issues raised by the attempt to understand and explain human history. So it seems timely to reopen the domain of the philosophy of history with some new questions and new approaches.

The approach that I've taken in this book is to take very seriously the innovations and intellectual turns that gifted historians have brought forward in the past thirty years. Writers such as Philip Kuhn, Jonathan Spence, Robert Darnton, Simon Schama, Peter Perdue, and Michael Kammen have brought strikingly new perspectives to the writing of history; and often their innovations suggest new ways of formulating some basic issues in

the philosophy of history. Good historians are often deeply insightful philosophers of history as well. I've tried to approach the philosophy of history along the lines of how many philosophers have approached various of the special sciences (biology, psychology, physics, sociology, anthropology): to combine good philosophical analysis and reasoning with a careful and sympathetic reading of some of the best current research efforts in those disciplines. When Simon Schama or Albert Soboul wrestle with the question, "What sort of thing was the French Revolution?", we can learn a lot about how to think about historical ontology. And when Peter Perdue or R. Bin Wong propose a shift in thinking about Eurasia, we can get a much more precise understanding of the question of defining periods, regions, and civilizations.

The table of contents of the book gives a fairly good idea of the range of topics considered in the book: "History and Narrative," "Historical Concepts and Social Ontology," "Large Structures," "Causal Mechanisms," "History of Technology," "Economic History," "The Involution Debate," and "Mentalities." These discussions circle around three different master questions:

- How can we best define or conceptualize historical things (**ontology**)?
- What issues arise in our effort to provide knowledge about the past (**epistemology**)?
- What constitutes a good historical explanation (**explanation**)?

To these core questions, we can add another important one that emerges that perhaps falls closer to historiography than the philosophy of history:

- What are some innovative ways that contemporary historians have invented as a basis for representing the past?

One aspect of *New Contributions* is especially novel: the effort I've made to combine an intellectual process of traditional academic research and writing with the work I've been doing for the past three years on this blog, *UnderstandingSociety*. I announced in 2007 that "The blog is an experiment in thinking, one idea at a time," and *New Contributions* is my first effort to test out the viability of that idea. Most of the chapters in the book began as conference presentations designed to contribute eventually to this new approach to the philosophy of history. I had a book plan in mind as I wrote these papers and chapters over a ten-year period. After the book was accepted by the excellent editors of the Springer Methodos series, Daniel Courgeau and Robert Franck, I undertook a major rewriting of the full manuscript; and I realized that I was also writing quite a few posts on various aspects of the philosophy of history in the blog. So I undertook to integrate a lot of the new material into the manuscript. In the end, roughly 40 postings have been integrated into *New Contributions*, which amounts to more than a third of the book. So this is a fairly extended test run to evaluate the notion that it is possible to make significant intellectual progress on a subject through a series of separate blog postings.

Here are a couple of key paragraphs of the book; they give something of a feel for the kind of analysis I'm trying to offer.

Why do we need a better philosophy of history? Because we think we know what we mean when we talk about "knowledge of history," "explaining historical change," or "historical forces and structures." But -- we do not. Our assumptions about history are often superficial and fail to hold up to scrutiny. We often assume that history is an integrated fabric or web, in which underlying causal powers lead to enduring historical patterns. Or we assume that historical processes have meaning -- with the result that later events can be interpreted as flowing within a larger pattern of meaning. Or we presuppose that there are recurring historical structures and entities--"states," "cultures," and "demographic regions" that are repeatedly instantiated in different historical circumstances.

I do not say that these assumptions are entirely wrong. I say that they are superficial, misleading, and simple in a context in which nuances matter. Take the idea of recurring historical structures. Is there some state "essence" possessed in common among the Carolingian state described by Marc Bloch, the theatre state of Bali described by Clifford Geertz, and the modern Chinese party state described by Vivienne Shue? If so, what is this set of essential properties that states have? If not, what alternative interpretation can we provide to "state talk" that makes coherent sense? (2)
I certainly hope the book will wind up in enough libraries around the world to allow a range of readers to get a chance to consider it! And the digital version made available by Springer is certainly a help; it allows readers to examine some of it online (link).

Skilled synchronized cooperation

Sunday, September 26, 2010

One kind of social behavior that is particularly interesting to observe is what we might call "small group skilled cooperation." This kind of social action arises when --

- there is a recurring task to be performed by a small defined group of actors;
- success in the task requires effective performance of specialized actions by members of the group;
- success in the task requires close coordination in time of the actions of the specialized actors;
- success in the task requires extensive training of individuals and the group to enhance individual skill and inter-actor coordination.

Here is one example --

Here is another:

These examples come from athletics. But we could also think of examples from other time-sensitive, rapidly unfolding scenes of social coordination: fire fighting, jazz ensembles, urban warfare, and NASCAR pit crews provide others. In each case two kinds of skillful performance are needed. Each individual needs to be highly skilled at his/her assigned activity; and the individuals need to be skilled at coordinating with other actors and handing off assignments to each other at the right time. Here are the Boston Celtics showing both kinds of skill in a playoff game against the Pistons in 1987:

So the questions here are these -- How do groups or teams get good at this kind of coordination and skilled performance? And how common is this kind of coordination in everyday social life?

Part of the "how" question is fairly obvious. The purpose of repetition and training in sports is precisely to allow players to run through possible game scenarios and perfect their individual skills and their timing and coordination. The quarterback who throws well but consistently misjudges the speed of the receiver will not be successful; and through practice he can improve his timing of the flow of the play. Each member of the team is

expected to perfect his readiness to perform accurately and to do so at precisely the right moment. Determining the "right moment" requires having a good mental representation of the play as it is developing in real time, to permit the player to make the block or make his cut at the moment needed to complete the play. This emphasis on training and repetition seems to be uniform wherever a high degree of coordination is required; we don't rely on the spontaneous decision-making of the individuals, but instead try to lay down practiced routines that are invoked when the occasion arises. And this in turn suggests the need for a sort of phenomenology of skill; we would want to explore the awareness and mental capacities that are associated with high-performance teamwork.

The fact that a team depends on both kinds of skills -- individual and coordinative -- explains why All-Star teams are not very good at basketball and are better at baseball. All the players are highly skilled as individuals. But they haven't had the practice together that would be needed for them to function at a high level as a team: recognizing each other's particular strengths and accurately judging their likely behavior and speed in the next several seconds. In the Celtics video above, we see Dennis Johnson streaking to the basket before Larry Bird steals the inbound pass -- reflecting DJ's understanding of the game situation and his anticipation of the possibility of Bird's actions. This doesn't seem likely in a team of talented strangers. Baseball, by contrast, seems like a sport that reflects the sum of the talents of the individuals rather than a "value-added" component derived from close coordination of efforts. (The double play is an exception to this point, of course.)

The "how common" question is more difficult. I'm inclined to think that skilled time-sensitive cooperation is ***not*** very common in ordinary social life. There seem to be relatively few examples of cooperative activities that require the high degree of coordination and timing specified here. There is a lot of division of task in contemporary society, and therefore a lot of coordination and cooperation. But this rarely requires the second-by-second synchronization that is found in the examples offered here. Instead, a good sales team may depend on the individual talents of the members of the team, without requiring a high degree of coordination among them. Sales is more like baseball than basketball.

Perhaps the most common example of an area of common social action that requires this kind of training, skill, and coordination is in the field of emergency response: firefighters, emergency rooms and surgical suites in hospitals, and emergency responders in large cities. By contrast, a newsroom, a factory floor, and a department store each require skill and specialization of task at the individual level; but they require little temporally precise teamwork. The teamwork required in these examples is more conceptual and communicative: one person's work product needs to be aligned with the goals and needs of the other person's work product; and this requires leadership and communication.

Sociology in China

Tuesday, September 28, 2010

1966年8月，清华大学红卫兵在砸毁牌坊上的“清华园”题字。

Social investigation has a history in China that extends into the Ming-Qing dynasties and earlier, in the form of reports by scholar-officials on local conditions. Scholars undertook to provide descriptions of agricultural conditions, farming methods, famines, drought and flooding, the conditions of the poor, banditry, and many other topics of interest to the state or potentially of value to the people. These reports often show great attention to detail and concern for veracity, and they provide important sources of data for contemporary historians. They do not constitute “scientific sociology,” any more than the writings of Mayhew or the findings of Parliamentary commissions constituted a British sociology in the 18th century. They fall in the category of careful fact-gathering, with some efforts at diagnosing causes of some of the phenomena identified. We may also refer to the tradition called “evidential research” (kaoju), which emphasized “empirically rigorous methods” by historians and linguists to gather evidence for reconstructing China’s early history.

Sociology as a science involves several more specific ideas over and above simple descriptive reportage of social behavior: the idea of empirically rigorous methods of **data gathering and analysis**, the idea of providing **explanations** of the phenomena that are discovered, the idea of formulating **theories about unobservable social processes** or mechanisms, and the idea of identifying some level of **patterns or regularities** among and across groups of phenomena.

So what were some of the main turning points in the development of modern sociology in Chinese academic institutions in the twentieth century? How did sociology first appear in China? What were the primary influences? What assumptions about social theory and social research methodology were important, at what periods in time? When did the institutions of academic sociology develop—departments, associations, and journals?

As a European intellectual development, sociology took its shape in the 19th century as a result of several important currents of thought: the development of empiricism or positivism as philosophical theories of human knowledge, the development of “classical sociological theories” of modern societies (Weber, Durkheim, Marx, Tocqueville, Simmel); and the refinement of the methods of social description and analysis associated with public policy and reform efforts. Durkheim’s theories of social solidarity and cohesion, Weber’s theory of rationality and norms as causes of large historical developments such as the emergence of capitalism, and Marx’s theory of class conflict as the historical cause of social change—these classical theories constituted a first generation of sociological theory that twentieth century sociologists worked with in their efforts to deal with complex sociological phenomena. New theories in the twentieth century acquired classical standing as well: Parsons’ structural-functionalism as a general theory of social organization, the anthropologists’ formulation of theories of culture and language, and the Chicago School’s blend of pragmatism and policy provided a reservoir of theoretical ideas in the context of which more specific sociological inquiries could be framed.

Early in the twentieth century there were several important early Chinese sociologists who studied these theories in the west and brought them back to Chinese universities. There was a “founding group” of sociologists who studied in the US, in Chicago, California, and other universities in the 1930s and who created significant pockets of social research in China. The primary fields were rural development, ethnic groups, labor issues, gender and family. These founders published in English and Chinese. Yan Fu (1853-1921) was one of China’s first scholars of sociology, and translated Herbert Spencer’s *Study of Sociology* into Chinese in 1903). Quite a few Chinese students received Wisconsin, Columbia, USC, Chicago PhDs in the 1920s and 30s, and one students received a PhD from the University of Michigan in 1936.

Following the Communist Revolution, sociology went through several serious periods of crisis. In the 1950s the “socialist” character of the revolution led officials in China to ideological objections to the science of sociology. The view was that sociology had to do with addressing social problems. But this is a socialist society, so how can we have social problems? Therefore, we don’t need sociology. Departments of sociology were disbanded in the universities. A few went to the Labor Cadre School. Others went to statistics departments. Quantitative and statistical methods were acceptable; but sociological theory and applied research were not. This was described as “bourgeois science.”

In 1956-57 there was an attempt by some professors to revive sociological research. Prof. Ma Yinchu wrote an article addressed to Chairman Mao about population issues. He advocated for research on this question, arguing that population increase could interfere with China’s economic future. There was some openness to this research, and Chairman Mao invited open thinking and ideas. There had been an important meeting of a group of social scientists to re-start sociological research. All the participants in this meeting were identified as “rightist”. Participants included Yuan, Chen, Ma, and Fei. Yuan was identified as “ultra-rightist” because he had done some organizational work for this small informal group. He was sent to Northeast China for “labor re-education” in 1957.

Some opinions that emerged during the apparent thaw in 1956 were critical of one-party rule. There was an elite of scholars and officials from pre-1949 who were critical of one-party system. An important turning point was Wang Shengquan's “Big Character Paper” in 1956 or 1957. He criticized Leninism as contrary to Marxist theory. Marx believed that socialism could only occur when the world had developed to the point of socialism; not “socialism in one country. Lenin and Stalin deviated from this belief. Wang said that Lenin was untrue to Marxism. He was consequently labeled “rightist”.

The brief emergence of critical opinions among social scientists in 1956 led to a crackdown on “Rightist thinking” and the squelching of emerging social research. The emerging sociology and social science, social reform, political reform thinkers were all identified as rightists. Even criticism from the left—e.g. “The Party is not doing enough for peasants” was identified as rightist and counter-revolutionary. In the anti-Rightist campaign in 1957 about 100,000 people were labeled as “rightist”. There were quotas for institutions to identify a certain number of rightists among them. The anti-Rightist Movement by the CCP/Propaganda Department crushed the re-emergence of social science research at this time. The fear was that social research would turn to criticism and lead to calls for changing the political system.

The period of the Cultural Revolution was also an unpropitious period for sociology as a

discipline. The universities were closed for much of the period of 1966-76, and when they reopened, sociology remained a suspect discipline. It was only in the early 1980s that sociology began to regain its place in the university and in the field of social-science research in China. "In 1980 the Institute of Sociology under the Chinese Academy of Social Sciences was established with Fei Xiao-tong as director" (Zheng and Li, 461).

Important Chinese sociologists

A particular leader in Chinese sociology was Prof. Fei Xiaotong. He was educated in the 1930s and did field research in Jiangsu and Yunnan in the 1930s-1940s. He was the first president of the Sociological Society of China, and he was a leading figure in re-establishing sociology after 1979. He became a party official in a “democratic party”. He died in 2005. Prof. Fei was a major influence after the Cultural Revolution in reviving sociology in China. An important book in English translation is *Peasant Life in China: a Field Study of Country Life in the Yangtze Valley*, based on his field survey in a village in Jiangsu province in 1930s (Google Books link). Later he did field research in Yunnan. After 1979 his best work was field research on the rise and roles of small market towns after the collapse of the people’s communes, focusing on Jiangsu Province. (See David Arkush, Fei Xiaotong and Sociology in Revolutionary China.) Fei became the first President of the Sociological Society after the CR in 1979. Yuan became the second president. (Here are obituaries from the New York Times (link) and ChinaDaily (link).)

Chen Da took a PhD at Columbia and became a specialist on Chinese labor. He was a prominent sociologist in the 30s and 40s. He became a key influence on the development of sociology at Tsinghua University, becoming founding director of the General Census Center there in 1939. After the revolution he was prohibited from research and teaching and was eventually assigned to the Labor Cadre School. His areas of research included survey methodology and surveys of workers’ households. (Here is a brief history of sociology at Tsinghua University; link.)

Another important figure is Yuan Fang. He was educated at Kumming at Southwest Union University, a university that was relocated during the anti-Japanese War. He was a student of Chen Da. He taught quantitative methods at a time that this was dangerous; “bourgeois science”. Some professors disapproved of the workshops he organized. People who participated were told to “be critical from a Marx-Mao-Lenin point of view.” After the anti-Japanese War, he went to Tsinghua as professor. He then went to Peking University as chair of sociology in 1984.

Lei Jieqiong. USC 1932. She advocated for the five-city survey. Family and marriage. After the Cultural Revolution she became Vice Mayor of Beijing, representing a “showcase democratic party.” She was also a Peking University professor. Here is a ChinaDaily article on the occasion of her 105th birthday.

Pan Guangdan. Sociology/anthropology. He studied ethnic groups. He was a professor of Fei. He was the first translator of Darwin into Chinese and became China's leading promoter of eugenics.

Yan Yangchu [James Yen]. Another renowned sociologist in the 1930s. See Charles W. Hayford, *To the People: James Yen and Village China* (Google Books link).

Li Jinghan. Ph.D. from Chicago (?) in the late 1920s. Social survey methods. Statistical study of household surveys. Both rural and urban. Major report of fieldwork: Dingxian

shehui gaikuang diaocha (a general social survey of Ding county); first published in 1934 and recently reprinted.

Wang Shengquan. Chen and Yuan educated him. His “Big Character Paper” in 1956 or 1957 was a precipitating incident leading to the Anti-Rightist Campaign. He was sent to the Cadre School.

A chronology

A History of Chinese Sociology, by Zheng Hang-sheng and Li Ying-sheng (China Renmin University Press) includes a fairly detailed appendix listing "Major Events in Chinese Sociology." Here are a few significant events from the early twentieth century:

- 1921 Xiamen University established the department of history and sociology -- first department of sociology in universities run by the Chinese
- 1922 Yu Tian-xiu set up "Association of Chinese Sociology" and started *Journal of Sociology*
- 1923 Shanghai started the department of sociology; stipulated that the teaching took the theoretical basis of Marxism and Leninism, i.e. historical materialism as its guide.
- 1924 The Fund Board of Chinese Education and Culture was established in Beijing and the Department of Social Survey was led by Tao Meng-he and Li Jing-han. Published a large number of findings reports, including *Rural Families in the Suburbs of Beiping*.
- 1926 Li Da published *Modern Sociology*.
- 1928 Chen Han-sheng conducted three large-scale surveys of rural areas in Hebei, Jiangsu and Guangdong Provinces through the early 1930s.
- 1930 The department of sociology in Yanjing University established an experimental base at Qinghe Town, where Xu Shi-lian and Yang Kai-dao directed students to survey the population trend, families, bazars, organizations of village and town in Qinghe Town (Google Books link)

The entry for 1957 is laconic:

1957 Inspired by the principle, "let a hundred flowers blossom and a hundred schools of thought contend" set forth by the Central Committee of the CPC led by Mao Ze-dong, Fei Xiao-tong published an article A Couple of Words about Sociology in Wenhuibao. Chen Da, Wu Jing-chao and other distinguished sociologists also expressed their opinions about the restoration and reconstruction of Chinese sociology at Chinese People's Political Consultative Conferences and in influential newspapers or journals in Beijing and Shanghai. The opinions of the former sociologists evoked big repercussions and attracted the attention of the leaders in departments responsible for the work. However, when the Anti-Rightist Campaign began, the opinions about restoring and reconstruction of sociology were criticized as part of the plot to restore capitalism, and a number of former sociologists were mistaken for rightists and were persecuted. From then on, sociology became a restricted academic zone.

The next entry is 1979, 22 years later.

Opportunity index

Saturday, October 02, 2010

It would be very interesting if we had something we might call an "opportunity index" that could be applied to young children to estimate their probability of later success in life. The idea would go along these lines: Take some measure of adult success -- perhaps graduation from college or success in attaining a skilled job or career by the age of 30. Then identify a series of societal developmental factors that enhance the probability of the outcome. Finally, construct an index of these factors for each child that estimates the overall likelihood of success for that child. The logic is analogous to identifying risk factors for heart disease: given this set of factors, the individual's likelihood of O is p.

The positive opportunity factors might include things like this:

- Quality of schools
- Reading level at grade 5
- Presence of caring adults and mentors
- Quality of family environment
- Adequate nutrition
- Adequate housing
- Adequate family income
- Access to healthcare

There are probably redundancies here; public health professionals and education specialists would need to chime in. But suppose we've got some set of factors that can be scored 1-5, and suppose the index aggregates the factors to an overall estimate of probability of success. Maybe it goes along these lines: children with low scores in all factors (1) have only a 20% likelihood of success. (I.e. some children survive even crushing adversity; but it is only a small percentage who do.) Children with a 3 score have a probability of success of 75%. And children with the top scores have a probability of success of 95%. (I.e. students with good schools, high reading levels, great families, and affluent circumstances are almost certain to succeed.)

Just supposing we had such an index, what would it tell us when we applied it to a large population of children? The index collects societal factors that influence the child's likelihood of success, and the aggregate index is intended to correspond to the overall likelihood of success. So looking at the distribution of the likelihood of success over a population would be sort of a CT scan of the opportunity structure that is presented to children in different social locations: affluent suburb, poor inner city, declining suburb, farm community, ... And we could then look at the index as a way of measuring "opportunity equity."

My suspicion is that the result of this thought experiment would be pretty shocking. The factors that individually contribute to success are likely to covary by neighborhood,

income, and race. It is therefore likely that whole schools full of children are likely to have similar scores. This suggests that there are gross inequalities of probability of success by race and poverty status. And this would highlight what is really a glaring source of injustice in our country: the likelihood of life success varies enormously by race and affluence.

Further, since the factors mentioned here are external social factors which are simply presented to the children, there is no sense in which we could maintain that these differences derive from things the child is responsible for. So, in other words, these gross inequalities of opportunity and outcome are fundamentally unjustifiable.

I'm led to this set of thoughts as a result of spending some time with young people in Detroit. The high school and college graduates I've been acquainted with display a remarkable set of talents and aspirations. They are on their way to success in whatever way we choose to define that term. And yet their own stories demonstrate what a difficult road it has been for them, and how many of their peers have been left behind. Fewer than 50% of Detroit school children go on to graduate from high school. Violence, hunger, homelessness, indifference, and illiteracy have prevented so many of their brothers and sisters from achieving the same kind of success. These are system characteristics, not individual failings. And these are the objective obstacles to opportunity that simply must be eliminated.

Rawls and economics

Tuesday, October 05, 2010

A topic of continuing interest to me is the role that serious engagement with economic theory played in the formation and development of John Rawls's thought (link). To what extent were important aspects of the theory of "Justice as Fairness" influenced by elements of economic theory?

I'm inclined to think that we can look at Rawls's major papers between 1955 and 1971 as a fairly reasonable sample of the intellectual influences that affected the development of his thought. His first major paper, "Two Concepts of Rules," appeared in 1955, and *A Theory of Justice* appeared in 1971. All of his major papers are included in Collected Papers, so this is a fairly convenient way of surveying his thought during this first portion of his career.

So what can we learn from these papers when it comes to the influence of the economists on Rawls?

Here is an inventory of Rawls's references to economists from 1955 to 1971, from the essays included in Collected Papers.

Two Concepts of Rules (1955)
- Lionel Robbins, The Theory of Economic Policy in English Political Economy (1952)

Justice as Fairness (1958)
- John von Neumann and Oskar Morgenstern, The Theory of Games and Economic Behavior (1947); R. Duncan Luce and Howard Raiffa, Games and Decisions (1957) (56)
- IMD Little, A Critique of Welfare Economics (1957); KJ Arrow, Social Choice and

Individual Values (1951); JR Hicks, Value and Capital (1946); Tibor Scitovsky, Welfare and Competition (1952) [66]
- Jerome Rothenberg, The Measurement of Social Welfare; JC Harsanyi, "Cardinal Utility" (1953) and "Cardinal Welfare" (1955) [85]

The Sense of Justice (1963)
- WJ Baumol, Welfare Economics and the Theory of the State; RD Luce and Howard Raiffa, Games and Decisions [104]

Legal Obligation and the Duty of Fair Play (1964)
- KJ Arrow, Social Choice and Individual Values (1951)

Distributive Justice (1967)
- RD Luce and Howard Raiffa, Games and Decisions (1957) [133]
- Wilfredo Pareto, Manuel d'economie politique (1909) [135, 160]
- Nicholas Kaldor, An Expenditure Tax (1955) [143]

Distributive Justice: Some Addenda (1968)
- JC Harsanyi, "Cardinal Utility" (1953), "Cardinal Welfare" (1955) [173]

Justice as Reciprocity (1971)
- FY Edgeworth, "The Pure Theory of Taxation" (1958) [203]
- John von Neumann and Oskar Morgenstern, The Theory of Games and Economic Behavior (1947); Luce and Raiffa, Games and Decisions (1957) [205]
- RB Braithwaite, Theory of Games as a Tool for the Moral Philosopher (1955)
- IMD Little, Critique; KJ Arrow, Social Choice; JR Hicks, Value; JC Harsanyi, "Cardinal Welfare", Tibor Scitovsky, Welfare and Competition (1963) [217]

A couple of things are noteworthy in this inventory. First, Rawls's references are highly contemporary to the 1950s. He appears to have a reasonable level of acquaintance with what was happening in economics in that decade. And there are virtually no references to earlier figures in the history of economics; Pareto is virtually the only repeat entry in the index (Pareto principle).

Second, there is a decided focus on several areas: welfare economics, social choice theory, and game theory. Von Neumann and Morgenstern are cited several times, as are Luce and Raiffa; and Kenneth Arrow and John Harsanyi are repeat visitors as well. (Amartya Sen is cited in later essays, but not prior to 1971.) Keynes is not mentioned in these early articles, and only tangentially in TJ. And there is no mention of general equilibrium theory.

Third, none of these citations corresponds to a significant or substantive discussion of the economist's views. Rather, Rawls tends to illustrate a philosophical point by finding a relevant theoretical claim in one economist or another. This indicates a degree of familiarity with the contemporary literature, but a fairly low level of intellectual engagement with the debates and analytical approaches. In contrast to his treatment of utilitarianism, Kant, or Rousseau, Rawls's treatment of economic theory is brief and non-substantive.

Significantly absent from this inventory of references is any mention of the classical political economists. The index of *Collected Papers* contains no references to Ricardo, Quesnay, or Malthus, and only one reference to Adam Smith (ideal spectator theory; 201). John Stuart Mill is discussed in some detail, but always as a utilitarian philosopher, not an economist. Marx is mentioned briefly (Critique of the Gotha Programme; 252). The labor theory of value -- the central construct of classical political economy -- is not mentioned once.

There are a few references to Smith in *A Theory of Justice*, but they are superficial and

incidental: Smith as a utilitarian, the concept of the invisible hand (57), the moral sentiments (184, 479), and impartial spectator theory (263). There is nothing to suggest a careful or extensive reading of Smith, Ricardo, or Malthus in *A Theory of Justice*.

It is hard to avoid the conclusion that the history of economic thought played a limited role in Rawls's thought. Rawls was reasonably well acquainted with contemporary economics as of the 1950s and plainly found some aspects relevant to his philosophical agenda (Arrow, Harsanyi, von Morgenstern). But I don't find much reason to believe that Rawls's important philosophical insights on justice were very much shaped by a reading of the history of economics. Contemporary economists appear to have had greater influence -- decision theory, game theory, and social choice theory in particular.

(See an earlier entry on "Rawls and decision theory" for more on this; link.)

Rawls and the history of economics

Tuesday, October 05, 2010

What did John Rawls know about the history of political economy? In particular, how much did he know about classical political economy, including especially the theories of Smith, Ricardo, Malthus, Marx, or Mill?

It appears from his writings and lectures that he was generally familiar with the most basic theoretical positions and debates in classical political economy -- the labor theory of value, the invisible hand, the theory of land rent, and the simple theory of a competitive market. And beginning with the marginal revolution (Jevons, Pareto, and Marshall), he seems to have studied economic theory more carefully. But I don't find any evidence in his corpus of a careful reading of Smith, Ricardo, or Malthus. So what was the source of his knowledge of classical political economy?

One source of exposure to the history of economics occurred during his first two years of teaching as a lecturer at Princeton. Tom Pogge indicates in John Rawls: His Life and Theory of Justice that Rawls did significant reading and study of political economy during 1950-52:

In the fall of 1950, he attended a seminar of the economist William Baumol, which focused mainly on J. R. Hicks's *Value and Capital* and Paul Samuelson's *Foundations of Economic Analysis*. These discussions were continued in the following spring in an unofficial study group. Rawls also studied Leon Walras's *Elements of Pure Economics* and John von Neumann and Oskar Morgenstern's *Theory of Games and Economic Behavior*. (16)

So there is some direct evidence of Rawls's reading in economics. Another way in which he might have gained a speaking acquaintance of the history of economics is through secondary surveys of the field. Were there standard histories of political economy in Rawls's formative years from 1950 to 1965?

One of the great historians of economic thought during those years was Joseph Schumpeter. Schumpeter's Ten Great Economists appeared in 1952. This book focuses largely on post-classical political economy; after a long chapter on Marx, Schumpeter

provides short discussions of Walras, Menger, Marshall, Pareto, von Bohm-Bawerk, Taussig, Fisher, Mitchell, and Keynes. More important than *TGE* is Schumpeter's major contribution to the history of economic thought, History of Economic Analysis, which appeared posthumously in 1954. It is possible that Rawls used these books as a sort of intellectual guide to his understanding of the history of economic thought. The only reference to Schumpeter in Rawls's corpus is a single citation of Capitalism, Socialism, and Democracy in *A Theory of Justice*. This doesn't preclude the possibility that he read Schumpeter's histories of economics. But is there any basis for supposing that Rawls was in fact acquainted with Schumpeter's work?

Here is a clue worth pursuing. Pogge notes that Rawls spent a final year of fellowship at Princeton in 1949-50, and that he spent part of this time in an economics seminar with Jacob Viner, a distinguished Princeton economics professor. (The other main area of study during that year was in the history of U.S. political thought with Alpheus Mason.) And this establishes a tenuous connection to Schumpeter and the history of economic thought. Viner was a significant contributor to economic theory and policy in the 1930s and 40s at the University of Chicago and Princeton, and he also had a sustained interest in the history of economic thought. In 1954 he wrote one of the first (and most prominent) reviews of *History of Economic Analysis* in *American Economic Review* (link).

So here is a hypothesis: it seems likely enough that part of the work that Rawls did in 1949-50 with Viner was concerned with the history of economic thought, and it seems likely as well that he would have learned of Schumpeter's ambitious research on the history of economics from Viner. Schumpeter's book existed only in extensive notes and drafts at the time of his death in 1950 and was edited for publication by his wife, Elizabeth Boody Schumpeter, following his death. Exposure to Schumpeter through Viner would have given Rawls the motivation to study *History of Economic Analysis* carefully when it appeared in 1954. Rawls was an assistant professor of philosophy at Cornell by that time, and Pogge emphasizes his discipline when it came to reading and reflecting on the materials that he found relevant to his philosophical work.

Two other books on the history of economic thought that appeared during the approximate time period are Mark Blaug's Economic Theory in Retrospect (1962) and George Stigler's Essays in the History of Economics (1965). There are two references to Blaug in *A Theory of Justice*, so Rawls was certainly familiar with this book. Maurice Dobb's Theories of Value and Distribution since Adam Smith: Ideology and Economic Theory (1973) appeared a few years later.

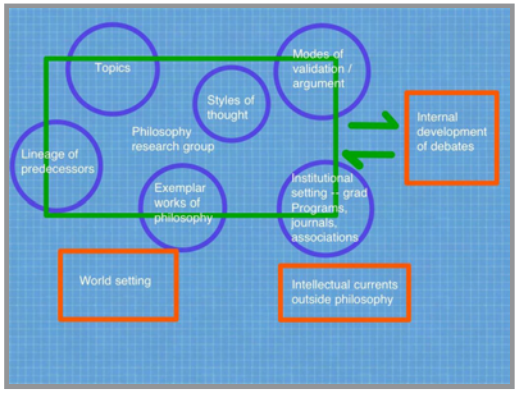
French philosophy?



Friday, October 08, 2010

Is there such a thing as "French philosophy"? Or is philosophy a purely universal discipline, raising the same abstract questions no matter whether the philosopher is Chinese, English, French, or Brazilian? One way to address this question is to consider the collective intellectual practice of "philosophy" from the point of view of sociology -- that is to say, historically and empirically.

Jean-Louis Fabiani's book Qu'est-ce qu'un philosophe français? (which was released in

France this week) addresses this question from the point of view of sociology, and it provides a fascinating and innovative approach to the history of philosophy. (Here is a link to Fabiani's academic bio.) Fabiani was a student of Bourdieu, and he approaches philosophy in something like the way that other sociologists have approached the study of science: as a socially situated intellectual activity which is amenable to sociological analysis and explication. The fact that it is ***intellectual*** implies that there is an internal logic to the development of the discourse; organized thinking moves it forward. And the fact it is ***situated*** implies that philosophy is conditioned and motivated by social circumstances external to the philosophical community.

Fabiani attempts to steer a highly original course between the idea that social context determines the content of a specific philosophical tradition, and the idea that philosophy develops wholly and solely according to its own internal intellectual logic. Crude sociology of knowledge falls in the first camp, and traditional history of philosophy often appears to fall in the second camp. Fabiani takes an approach that allows both for social influence on philosophy as well as critical, rigorous logical analysis and thought wielding its influence.

Here is a description that Fabiani provides of philosophy as an object of sociological study. (The passages quoted here are drawn from a pre-publication translation Fabiani provided in a visit this month to the University of Michigan.)

Philosophy is never limited to a collection of texts, knitted together by the threads of tradition. It also includes material objects, spaces and social practices. It includes all types of reception, including the less orthodox. As with any other type of work, philosophical texts imply different types of appropriation in space and time, and exist only through the successive pacts of reception that constitute them as valued objects in a particular culture.
He asks the questions, what is a sociology of philosophy and why is it needed? And here are some of his answers:

I wish to analyze philosophy just as what we now call science studies have analyzed processes and controversies in the various scientific disciplines. Science studies have questioned the great epistemological divide which reserved the study of contextual elements for sociologists (institutions, organizations, strategies, etc.) and removed the assertions, demonstrations and the quest for evidence from their purview (except if they are crudely determinist and seek to explain concepts entirely by contexts, to put it simply).

...

What could be interesting about a socio-historical analysis of philosophy? First, we have to suspend our belief -- at least for a while, because it is the habitual battleground of the activity -- in the existence of an abstract and universal frame for the philosophical debates, this the result of a venerable scholarly tradition. The « relocalization » of philosophical interactions is necessary in order to see that philosophical texts are also performances, not only embodiments and products of lifestyles but also their sources.

...

Studying philosophy by means of sociological methods would appear to be one of the most important challenges for the social sciences today. « The queen of disciplines,» as it is called in France (or the crown--or crowning as I once described it years ago) has long resisted any attempt at objectivation.

...

Although the most general objection to the ascription of social determinants in the shaping of social thought are now superannuated, the explanatory power of theories applied to the field of intellectual production still remains quite limited. The modes of categorization applied to products and to individual intellectual strategies are too crude and their use too poorly controlled; we no longer take for granted that society as such can be read (at least in a cryptic language) through symbolic production.
So what is in play when we ask whether philosophy (or any other intellectual discipline) is conditioned by its historical and social context? We might say that a national tradition of philosophy could be characterized according to several different criteria: topics, styles of thought, modes of validation, and lineage of predecessors. For example, British philosophy defined itself in terms of several core ideas -- the role of the senses in the acquisition and validation of knowledge, for example; and Hume, Locke, and Berkeley deployed recognizable forms of argument and styles of reasoning as well. Hume's treatises look and feel quite a bit different from Descartes' meditations. Here is a way of conceptualizing the situation of philosophical research and discovery:

The diagram is intended to be a way of visualizing a philosophy research tradition at a moment in time. The unit of production, the philosophy research group, is steeped in a conventional specification of the important **topics**; it is skilled in a specific set of **modes of argument**; it holds out a set of **exemplary philosophical works** from the history of the discipline as currently understood; it operates in a space that may include **other research groups** pursuing different topics and methods; and it functions within a **set of institutions** -- graduate programs, journals, tenure processes, associations, prizes -- that train, valorize, and rank various individuals and their products. Each aspect of these "internal" features is amenable to concrete historical and sociological investigation; we can seek to trace out the institutions, discover the order and rationale of the topics, etc.

External to these factors are circumstances in history and current social life (World War I, the Holocaust, the Civil Rights movement), and intellectual currents from outside the discipline (Freudianism, for example), that exercise influence on the development of philosophical positions and frameworks. The social context draws attention to (or away from) certain topics; context also sometimes provides institutional constraints that favor or disfavor some positions. (For example, McCarthyism and the Cold War created constraints and incentives that greatly deformed the course of research in the humanities and the social sciences.) The intellectual activities of the current research groups lead to a degree of development of the ideas, positions, and schools of philosophy at a given

moment in time. So the received setting, external environment, and application of modes of invention and argument drive forward new philosophical content, and the institutions of the profession attach credibility/lack of credibility and prestige/scorn to the results.

The diagram indicates as well several ways in which a philosophical tradition might possess a distinctive, national character. The list of valued topics may differ across national traditions; likewise the styles of reasoning and modes of argument; and different traditions may valorize very different bodies of predecessors as well. So it is fairly evident that Fabiani's question warrants a "yes" -- there are distinguishing characteristics or signatures across traditions of philosophy. And even when the topics and questions appear similar -- the focus on the conditions of knowledge in common between British and French philosophy in the 17th century, for example-- the styles of thinking, modes of reasoning, and examples of good solutions still differ widely.

Should we think of these differences as defining distinct *paradigms* of philosophy? I'm inclined to use a different term -- perhaps "*research tradition*" -- to suggest a high degree of variation within a national tradition of philosophy. Like other areas of humanities production, it seems to me that the standards and exemplars that hold together "analytic philosophy" or "hermeneutic philosophy" are much looser and less prescriptive than their counterparts in the natural sciences. So the term "paradigm" does not fit the framing of philosophy in context very well.

Fabiani's work rewards study and bears an interesting relation to other efforts to discover distinctive features of French intellectual life (the distinctiveness of French sociology (link), the development of French anthropology (link)). Johan Heilbron's work is relevant to these topics as well (The Rise Of The Social Sciences And The Formation Of Modernity). Here is the table of contents of Fabiani's current book:

Première partie L'institution d'une discipline
Chapitre premier – La philosophie en classe Chapitre 2 – Carrières et concepts Chapitre 3 – Les moments et les crises
Deuxième partie Une philosophie nationale? Chapitre 4 – Le rempart de la raison Chapitre 5 – Le spiritualisme français Chapitre 6 – Transferts conceptuels
Troisième partie Art, religion, science et philosophie Chapitre 7 – La religion ddans les limites de la simple raison? Chapitre 8 – Aux frontiers de la science Chapitre 9 – Le philosophe artiste et la tentation prophétique
(The photo above is of Alexandre Kojève. It is relevant to the current topic because of Kojève's complex philosophical heritage -- Russia, Germany, and eventually the leading *explicateur* of Hegel in post-war France.)

Strategies of economic adaptation

Sunday, October 10, 2010

Charles Sabel and Jonathan Zeitlin made a powerful case for there being alternative institutional forms through which modern economic development could have taken place in their 1985 article, "Historical Alternatives to Mass Production: Politics, Markets and Technology in Nineteenth-Century Industrialization" (link). In an important volume in 1997, World of Possibilities: Flexibility and Mass Production in Western Industrialization, they take the argument two steps further: first, that institutional variations were not merely

hypothetical, but in fact had an extended history in a variety of industries well into the twentieth century; and second, that the current situation of pervading uncertainty about our most basic economic institutions was characteristic of the earlier periods as well. The volume represents the work of an intensive seminar in economic history sponsored by the Maison des Sciences de l'Homme. Contributors include a broad swath of researchers in economic history across Europe (not Asia!). Chapters take up the processes of mechanization, specialization, and mass manufacture in a variety of industries in the nineteenth and early twentieth centuries -- silk, cutlery, watch-making, metal-working, and ship-building. (Here is part of the very good introduction to the volume provided by Sabel and Zeitlin; link.)

Sabel and Zeitlin take the view that the history of business and technology can in fact shed quite a bit of light on the economic situation we face today -- from brand new sectors (Google, Facebook, Amazon) to the abrupt decline of old industries (the US auto industry) to speculation about the next big area of business growth (biotech, alternative energy). They highlight a couple of features of the business and economic climate in the late 1990s that seem equally applicable today -- an acute sense of economic fragility and institutional plasticity. They argue that these features were also the hallmarks of earlier periods of economic change as well. So they argue that we can learn a great deal for today's challenges by considering the situation of industries like glass-making or watch-making in 1880 or 1920.

The sense of fragility goes to the once commonsensical idea that progress would lead to the gradual consolidation of particular forms of economic organization, and hence to an ever more certain sense of how best to deploy technology, allocate labor and capital, and link supply of particular products to demand. Today ... it is commonsensical to believe that the way many of these things are done depends on constantly shifting background conditions whose almost insensible mutation can produce abrupt redefinitions of the appropriate way to organize economic activity.

The second experience is one of the recombinability and interpenetration of different forms of economic organization: the rigid and the flexible, the putatively archaic and the certifiably modern, the hierarchical and the market-conforming, the trusting and the mistrustful.

...

The central theme of this book is that the experience of fragility and mutability which seemed so novel and disorienting today has been, in fact, the definitive experience of the economic actors in many sectors, countries, and epochs in the history of industrial capitalism.

...

But this double perception of mutability and fragility ... has not led them to exalt catch-as-catch-can muddling through as the organizing principle of reflection and action. What we find instead is an extraordinarily judicious, well-informed and continuing debate within

firms, and between them and public authorities, as to the appropriate responses to an economy whose future is uncertain, but whose boundary conditions at lease in the middle term are taken to be clear.

...

Our purpose here is to show that most firms in nineteenth- and early twentieth-century Europe and the United States, neither mired in tradition nor blinded by the prospect of a radiant future, carefully weighed the choices between mass production and what we would now call flexible specialization. (2-3)

One of Sabel and Zeitlin's most basic arguments is the idea that firms are strategic and adaptive as they deal with a current set of business challenges. Rather than an inevitable logic of new technologies and their organizational needs, we see a highly adaptive and selective process in which firms pick and choose among alternatives, often mixing the choices to hedge against failure. They consider carefully a range of possible changes on the horizon, a set of possible strategic adaptations that might be selected; and they frequently hedge their bets by investing in both the old and the new technology. "Economic agents, we found again and again in the course of the seminar's work, do not maximize so much as they strategize" (5).

During the eighteenth and early nineteenth centuries, for example, the silk merchants and weavers of Lyons carefully monitored but did not imitate the policies of design routinization, subdivision of labor and price competition pursued by their Spitalfields counterparts, preferring alternative strategies based on rapid style change, increasingly flexible machinery and the skillful exploitation of fashionable markets for high-value products. ... Much as they admired the efficiency of American methods, detailed accounts of the American system in trade journals and technical society proceedings typically emphasized that this efficiency depended on standardization of the product which was wholly incompatible with the current or expected organizations of their respective markets. (12)

In other words, specialized firms did not "resist change;" rather, they carefully assessed the full implications of one form of organization and one use of technology against another, and selected those innovations that represented the best match to their own business realities.

An interesting case study of an alternative way of organizing production is provided in the chapter by Peer Hull Kristensen and Charles Sabel, "The small-holder economy in Denmark." It was an example of cooperative-based agriculture and small-scale production that provided a durable alternative to private capitalism farming and manufacture:

Denmark was the exception. There in the decades before World War I peasant small holders built a technologically innovative cooperative movement that outcompeted estate-owners and urban financiers in virtually every segment of the dairy, egg and pork products industries. In so doing they created demand for particular kinds of capital goods that contributed to the modernization of the small-shop sector of industry as well. (345)

Alongside the agrarian republic there was another estate of small holders, the artisans and craftsmen. Their property was the knowledge of tools, materials, and techniques which made them independent of any one market or employer. By the outbreak of the First World War, they too had built institutions -- particularly a network of technical schools -- which allowed them to defend their place in Danish society by constantly renewing it. (365)

The history these activities in Denmark demonstrate that it was possible for voluntary

producers' cooperatives to manage the provision of specialized services, marketing services, and economies of scale to farmers and artisans that we sometimes believe can only be provided by the market. This system did not last forever -- though it proved economically durable for half a century, and it demonstrated much of the flexibility and organizational innovativeness that Sabel and Zeitlin emphasize in their introduction.

But some fifty years later, in the late 1950s, the cooperative core of this small-holder economy was coming visibly undone. First cooperative dairies, then the cooperative slaughterhouses began to combine into larger and larger units abandoning in the process many of their original constitutional features and becoming in fact and law corporations. The corporations in turn fought with one another and the remaining cooperative for control of their respective markets. (374)

I find the contributions to this volume interesting in exactly the way predicted by Sabel and Zeitlin in the introduction: for the models they illustrate of deft navigation of uncertain economic environments by firms, cooperatives, and individuals. The economic and business environment in the region where I live is unforgiving for a wide range of industries; for example, job shops and tool and die shops have largely disappeared in the Detroit metropolitan area. However, there are a number of mid-sized adaptable businesses that have continued to thrive, through exactly the kinds of intelligent, forward-scanning adaptation to new opportunities described by contributors to this volume. These businesses are in the engineering and advanced services sector, and they are innovative in two ways: they are constantly looking for new opportunities to apply existing and new technologies to new applications; and they are looking for customers in developing countries, including especially the Middle East from Lebanon to Saudi Arabia. Energy, solar power, building control systems, urban parking systems, and aviation maintenance can be found within the portfolio; and the leaders of these companies are systematically and strategically developing the relations abroad that are necessary to secure the next wave of contracts.

It is interesting to consider whether there is a difference between economic history and business history. One might say that the former has to do with the large features of economic organization, social regulation, and logistics that constitute an economic ***system***, whereas business history has to do with the tactical maneuvering and small-scale adaptations that individual firms undertake within the general framework of the existing economic structure. But I think Sabel and Zeitlin's answer would be a fairly decisive one: there is no fundamental distinction between the two levels of analysis. They frame the distinction in terms of the ideas of "epochs" and "crises"; this language distinguishes between long periods of institutional stability, and short periods of dislocation and change -- something like the theory of punctuated equilibrium. But Sabel and Zeitlin doubt the validity of this distinction. "The solution, we think, is to relax the distinction between periods of stability and periods of transition in the same way and for the same reasons that we relaxed the distinction between maximizing actor and constraining context" (29). Or, in other words, when we look closely, almost every period of economic activity is also a period that mixes elements of stability with deep and unpredictable change.

French economic inequalities

Tuesday, October 12, 2010

France is one of the more affluent countries in the OECD, but it continues to contain significant poverty and meaningful inequalities of income, wealth, and life outcomes. The past several years of rising unemployment have worsened these circumstances. A lot of this variation occurs across the lines of ethnicity and national origins; immigrant communities in France tend to have significantly higher levels of poverty, unemployment, and health disparities, often concentrated in the *banlieue* surrounding major cities. So how should concerned French citizens get a better understanding of these fundamental features of French society?

A research center and website that attempts to track these inequalities is the **Observatoire des inegalites**, directed by Louis Maurin. The website is found at inegalite.fr, and it is worthy of regular visits. The goal of the *Observatoire* project is to make sense of the social statistics of France and to communicate this information to the public in an understandable way. Right now the organization is focusing on recently released statistics on the rate of poverty on France. It would be very useful if there were similar sites in other countries, including the United States. (Here is a valuable source of information on poverty data provided by the United States Census Bureau; link.)

Two issues are particularly central when it comes to measuring poverty: first, how to define the poverty line (and how to interpret the poverty budget that this corresponds to); and second, how many people are poor in France by this criterion, and how this has been changing in the past several years.

On the first question, the official standard in France is pegged to a budget defined as half of the median income. This raises the first significant debate, because the EU pegs the poverty rate to the 60th percentile of income rather than the 50th percentile (median). Naturally, more people are classified as poor by the second criterion than the first. (In the U.S. the poverty line is calculated on the basis of an estimate of the income needed to purchase a specified "poverty budget" wage basket.)

Two features of the French definition of poverty are noteworthy. First, it is a relative rather than absolute definition of poverty; the index rises as economic growth occurs and median family rises. Rather than conceiving of poverty as absolute deprivation, it conceives of poverty in relation to the income levels of the rest of society. The poverty line will be different in Sweden and France. And the U.S. definition is more similar to an absolute definition: unless the contents of the poverty wage basket changes, people who are at the poverty line in 1970 will have the same purchasing power as people at the poverty line in 2000.

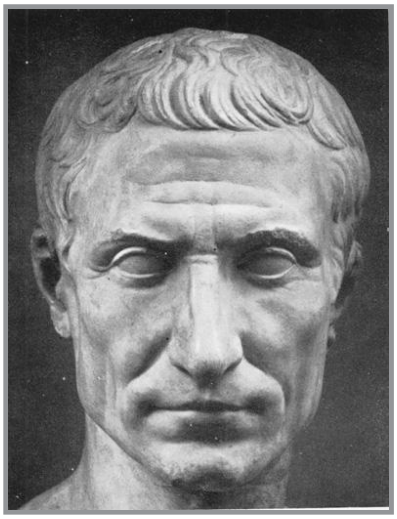
Second, this is a purely income-based criterion of poverty, rather than an all-round assessment of living standards. As Amartya Sen argues, poverty is not solely determined by low income. The poverty wage basket approach comes a bit closer to Sen's idea that it is the overall ability of the poor family's ability to satisfy its basic needs that determines its status as poor or not-poor. (The main component that Sen emphasizes in his overview of

quality of life as being overlooked by a pure income criterion of poverty is the provisioning of social services by the state; and France sets a fairly high standard with respect to this factor.)

So how does France measure up when it comes to poverty? Basically, the data suggest that the poverty rate is significant in France (7.1% in 2008, representing 4.3 million people), and, even more pressingly, it seems to have stabilized at that level. In 1970 the rate was 13.5%, falling to 7.2% in 1998. But during the next decade there was no significant change; there were 4.3 million poor people in France in 1998 and in 2008. (The poverty rate in the U.S. is estimated at a whopping **14.3%** for 2009 -- a striking increase over the previous decade (link), and an appalling counterpoint to the extreme increases that have taken place in the United States in the concentration of income at the top of the distribution.)

Measuring poverty is a very important step for any decent society. More difficult and more important is deciphering the economic mechanisms giving rise to poverty and creating the observed changes in the rate over time. Unemployment is one obvious factor, and France is experiencing high rates of unemployment along with much of the rest of Europe. But what about other mechanisms? What about discrimination in housing and employment, for example (as suggested in Didier Lapeyronnie's Ghetto Urbain). And what about the terms of the grand social compact -- the division of income and wealth among classes and educational levels? This is essentially what the conflict is about in France today, between unions and business, and between the Sarkozy government and large segments of society. And these are the mechanisms that generate inequalities of income and wealth, and they contribute to the macro-facts about poverty as well.

Another point established by data on the *Observatoire* is the fact that the mechanisms generating jobs and joblessness are very differently distributed across the map of France. The unemployment rate in France as a whole was 9.5% in 2009. But this rate encompasses a range of rates across regions of France, from 5.0% in Lozere to 13.5% and 13.6% in Herault and Aisne (link).



Also interesting on the site at present is an analysis of inequalities across social groups in terms of access to the baccalaureate degree; data provided here demonstrates sharp inequalities by group in terms of access to this valuable source of personal development and earning potential (link). Since education -- especially higher education -- is crucial to entry in higher-earning professions and occupations, the differential social processes at work here are also relevant to the distribution of income in the coming generation.

The *Observatoire* does a very good job of approximating the ideal of a transparent, understandable representation of the social data of a whole population. As such it is a very important experiment in "understanding society."

Lukes on power

Thursday, October 14, 2010

Steven Lukes's Power: A Radical View was a very important contribution when it appeared in 1974. Lukes emphasized several important points that became landmarks in subsequent discussions of the social reality of power: that power is a multi-dimensional social factor, that power and democracy are paradoxically related, and that there are very

important non-coercive sources of power in modern society. In the second edition in 2005 he left the 1974 essay unchanged, but added a substantive introduction and two new chapters: "Power, Freedom and Reason" and "Three-Dimensional Power". Also new in the second edition is substantially more attention to several other writers on the social context of power, including James Scott and Michel Foucault.

Lukes offers a generic definition of power along these lines:

I have defined the concept of power by saying that A exercises power over B when A affects B in a manner contrary to B's interests. (37)

But this definition is too generic, and Lukes attempts to provide a more satisfactory interpretation by constructing a "three-dimensional" account of power.

What are the "dimensions" of power to which Lukes refers? He begins his account with the treatment of power provided by the pluralist tradition of American democratic theory, including especially Robert Dahl in 1957 in "The Concept of Power" (link). This is the one-dimensional view: power is a behavioral attribute that applies to individuals to the extent that they are able to modify the behavior of other individuals within a decision-making process. The person with the power in a situation is the person who prevails in the decision-making process (18).

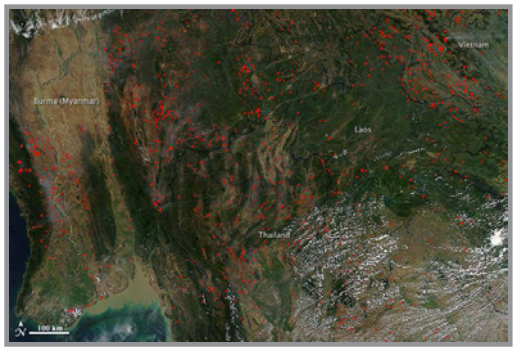
Thus I conclude that this first, one-dimensional, view of power involves a focus on *behaviour* in the making of *decisions* on issues over which there is an observable *conflict* of (subjective) *interests*, seen as expressing policy preferences, revealed by political participation. (19)

The second dimension that Lukes discusses was brought forward in rebuttal to this pluralist theory; critics pointed out that it is possible to influence decisions by shaping the agenda, not merely by weighing in on existing decision points. Lukes quotes from Peter Bachrach and Morton Baratz in their 1962 "Two Faces of Power" (link): "'to the extent that a person or group -- consciously or unconsciously -- creates or reinforces barriers to the public airing of policy conflicts, that person or group has power'" (20). So shaping the agenda is an important source of power that is overlooked in the pluralist model, the one-dimensional view.

The three-dimensional theory of power turns to a different problem -- the fact that people sometimes act willingly in ways that appear contrary to their most basic interests. So the third dimension is the set of ways in which the powerful transform the powerless in such a way that the latter behave as the former wish -- without coercion or forcible constraint -- for example, by creating a pervasive system of ideology or false consciousness. Both pluralists and their critics overlook an important point, in Lukes's view:

The trouble seems to be that both Bachrach and Baratz and the pluralists suppose that because power, as they conceptualize it, only shows up in cases of actual conflict, it follows that actual conflict is necessary to power. But this is to ignore the crucial point that the most effective and insidious use of power is to prevent such conflict from arising in the first place. (27)

And again:



What one may have here is a latent conflict, which consists in a contradiction between the interests of those exercising power and the real interests of those they exclude. These latter may not express or even be conscious of their interests, but ... the identification of those interests ultimately always rests on empirically supportable and refutable hypotheses. (28-29)
When Lukes returns to the three-dimensional theory in the final essay in the second edition, he shifts the language slightly to refer to "power as domination." Domination can occur through explicit coercive means, but it can also occur through unconscious mechanisms. This allows Lukes to address the theories of people like James Scott (Domination and the Arts of Resistance: Hidden Transcripts) and Michel Foucault (The History of Sexuality, Vol. 1: An Introduction).

In hindsight, it seems a little dubious to refer to these as "dimensions" of power, rather than aspects or forms of power. To call them "dimensions" somehow suggests that overall power is a vector of quantities in three or more orthogonal dimensions, each of which can vary independently. The features that Lukes identifies as "dimensions" seem more like tools in a toolkit or strategies in a repertoire: exercise control by doing X or Y or Z. So the language of dimensions seems inappropriate in this context.

But here is a more basic concern that is visible with the advantage of hindsight: there is very little in Lukes's treatment that sheds light on the social mechanisms of power. What are the social features that enable one individual or group to wield influence in any of these ways? Through what sorts of institutional and individual facts are individuals enabled to exercise power over others? Lukes doesn't address this question; and yet it seems to be the heart of the matter. We would like to have a way of analyzing social relations that allows us to discern how it is that some groups gain the material and social resources necessary to prevail. Marxism offers one such theory -- power derives from class position; but this answer doesn't really satisfy in the contemporary social world. (Lukes devotes a few paragraphs to the debate between Nicos Poulantzas and Ralph Miliband on the right way of understanding the exercise of power within a capitalist society; 54-58.) But generally, it seems fair to say that Lukes comes closer to offering a semantic analysis of the use of the term "power" rather than offering a sociological analysis of the causal and structural reality of power.

Zomia reconsidered

Monday, October 18, 2010

An earlier post described James Scott's recent book on the segment of Southeast Asia that he refers to as Zomia (The Art of Not Being Governed: An Anarchist History of Upland Southeast Asia). As noted there, Scott turns in his usual creative, imaginative, and innovative treatment of the subject matter; the book is an absolutely captivating argument about the push and pull between states and fugitive peoples. As such, it suggests the possibility of bringing some of the central ideas and analyses to bear on other geographies as well. But how accurate is Scott's reading of the primary

historical experience of these parts of Southeast Asia -- Burma, Thailand, Vietnam, China, Cambodia, and Bangladesh?

This is the question posed by the current issue of the *Journal of Global History* (link), with essays by C. Patterson Giersch, Magnus Fiskesjo, Sarah Turner, Sara Shneiderman, Bernard Formoso, and Victor Lieberman. All the essays are fascinating, including the editorial introduction by Jean Michaud. But particularly important is Lieberman's essay. Lieberman is one of the leading contemporary historians of Southeast Asia, and he is a very fertile and imaginative thinker himself. So his responses to Scott's arguments are worth looking at closely. (His most recent volumes, Strange Parallels: Volume 1, Integration on the Mainland: Southeast Asia in Global Context, c.800-1830 (v. 1) and Strange Parallels: Volume 2, Mainland Mirrors: Europe, Japan, China, South Asia, and the Islands: Southeast Asia in Global Context, c.800-1830, are directly relevant to Scott's analysis.)

Lieberman begins by establishing the territory on which he agrees with Scott. First, he accepts the fact of a growing separation between lowland and highland peoples in Southeast Asia during early modern times, and he agrees about the importance of analyzing this pan-Southeast Asian phenomenon.

Another point of agreement is the fact of highlander agency. Lieberman agrees with Scott's insistence that highland peoples throughout Southeast Asia crafted their own social worlds in response to the political and natural environments that faced them. He writes:

Scott's basic thesis is that highland societies, far from living in isolation, have been profoundly and continuously moulded by their relation to plains-based kingdoms. (333)
He notes that Scott's approach turns the narrative of state-building on its head; highland peoples were defined in terms of state-avoidance. The lowland states had an interest in gathering manpower and taxes, and the highland peoples had a persistent interest in evading both. Lieberman writes:

Scott claims that these processes transformed Southeast Asia's mountainous interior into a vast "shatter zone," an area of flight, a sphere of asylum and marronnage for runaways from state-making projects in the plains. (334)

Scott's central achievement, then, is to bring hill peoples into the mainstream of regional history by uncovering their relation to lowland states and societies. (336)
So Lieberman acknowledges the importance and boldness of Scott's effort at providing a comprehensive historical study of Zomia. But Lieberman offers a series of important criticisms of Scott's historical case.

First, he finds Scott's documentation to be weak, in that it makes little use of Burmese-language sources. This has led, in Lieberman's opinion, to a number of errors of fact, some more significant than others. He cites estimates of literacy, for example; Scott says less than 1 percent of people were literate in Southeast Asia, and Lieberman documents 50 percent for Burma in 1800.

More significantly, Lieberman believes Scott over-estimates the importance of manpower as a determinant of military success in the region. The degree of maritime commerce was equally important, he argues. And this is critical to Scott's argument, since competition for manpower is one of the primary reasons Scott cites for the efforts of lowland states to

attempt to dominate the highlands.

Finally, and most important, Lieberman argues that there is little documentary evidence for significant population flight from lowland to highland (339). This is key to Scott's interpretation, and Lieberman argues the evidence isn't there to support the claim. After reviewing Scott's own evidence and some additional data of his own, he writes:

All in all, outside central Vietnam perhaps, this remains a rather limited record of displacement and flight. (341)
Moreover, Lieberman argues that Scott's interpretation of the highlands becomes so dependent on one causal factor, state oppression, that it neglects the processes of development that were internal to the highland societies themselves. "Ecological and cultural conditions that were intrinsic to the hills and that were substantially or completely divorced from the valleys receive little or no attention" (343).

This point is more important when we consider an example not included in Scott's analysis -- the highland peoples of Borneo/Kalimantan. Lieberman argues that these tribes had virtually all the characteristics of culture and agriculture displayed by Zomians, including swidden cultivation and a proliferation of local languages, and Scott interprets these traits as deeply defensive. Yet these features of highland life emerged in Borneo without the pressure if a surrounding predatory lowland state (345). And this casts serious doubt on Scott's anarchist, anti-statist interpretation of Zomia.

Lieberman's point isn't that Scott's interpretation of Zomia is unsupportable. Rather, his point is that it is a bold and substantive interpretation of a complex historical domain, and it requires serious, fact-based consideration. And this is exactly what the essays in this special volume of *Global History* promise to do.

This debate is interesting and important, in part, because it sheds light on the practical empirical research challenges that arise when we consider bold new interpretations of social data. A bold hypothesis is advanced, purporting to pull together the processes of development observed in a variety of places; and then there is the practical question of evaluating whether the hypothesis is born out when we do the detailed, local historical research needed to test its basic assertions. In this case, Lieberman is suggesting that several of the components of the theory are found wanting when applied to highland Burma.

(The image above is a satellite-based survey of fires across Southeast Asia (link), relevant to the practices of swidden farming.)

Toyota in Guangzhou

Saturday, October 23, 2010

I got a chance to visit Guangdong this week, and it's a pretty amazing place. You get a very vivid feeling for globalization when you see dozens of container ships lined up off Kowloon, preparing to off-load and reload in several container ports in eastern Guangdong and the lower Pearl River delta. I visited the district of Nansha in an eastern area of Guangdong that was primarily agricultural only five years ago. Now there has been extensive development, with the population going from 40,000 to 260,000 in just a few years.

One of the largest parts of the development in Nansha District is a large Toyota factory, opened in 2006 and now producing 360,000 cars a year. This plant is a joint venture with Guangzhou Automobile Group. The factory employs about 7,000 workers in two shifts, and it embodies one of the most recent examples of the Toyota production system. A vehicle passes by every 68 seconds, so a new Toyota exits to the test track every 68 seconds as well. 1,000 cars a day roll of one of the production lines and another 500 exit the second line. (Here is a 2004 news release on the venture from *China Daily*.)

But here is the first surprise. Every car produced in Nansha is headed for the domestic Chinese market -- along with the output of the other major Toyota factory near Beijing. Toyota plans to sell more than half a million cars in the domestic Chinese market in the coming year. Compare that to European and American production for China, and you get a sense of Toyota's worldwide ambition. Fiat just celebrated its millionth car sold in China. Toyota will exceed that number from just this factory every three years.

The factory is highly automated, with numerically controlled welding machines and other robotic assists, and it appears that the skill level of shop-level workers is low. Training is brief for the regular line worker. Workers are largely recruited from Guangdong Province, and the factory boasts of its conformance to the highest standards of worldwide vehicle quality. The company representative wasn't able to share information about workers' wages, but someone familiar with the local economy estimated a monthly wage somewhere around 3,000 RMB. That works out to an income of about $5,100 a year -- significantly higher than China's per capita income, but not a middle class lifestyle either. That's about $2.33 per hour, and it works out to about $87 in direct assembly labor costs per vehicle.

This is a fairly good factory environment, though it's a bit Chaplin-esque to watch hundreds of workers rushing to return to their stations after a 10-minute break during which the line is turned off. But it's no sweatshop, and it appears that workers are likely to be grateful for their jobs. Safety, efficiency, and quality seem to be the guiding management goals. The recent strike at a Honda plant in Guangdong makes it plain, of course, that Chinese workers have important demands. But realistically, this plant is good for China's goals of improving the standard of living for poor people. It seems a bit analogous to GM or Ford in Detroit in the 40s and 50s.

At the same time, the numbers here document the challenge faced by manufacturing companies in the US and Europe. A similar factory in Michigan would have direct labor costs per vehicle in the range of $450, and no amount of labor concessions can erase that difference. So to compete on price American producers need to find more efficient ways of handling the other cost components of the manufacturing process -- but those efficiencies are equally available to producers worldwide.

I suppose one way of reading the situation is to see Guangdong as one of the leading change points in a longterm evolution towards a common global wage for unskilled or semi-skilled labor. Wages and quality of life have certainly gone up for Chinese workers in Guangdong in the past 10 years -- just as they've gone down for industrial workers in the US. And the living standard gap that existed between Hong Kong and Guangdong has substantially narrowed in the past decade as well, according to longterm observers. And this makes the point about education and talent in a very pointed way: the only thing that commands a premium in the world labor market is talent, skill, education, and innovative capability. We are certainly not doing nearly enough in the US to take the

steps needed to prepare our population for this basic reality.

So what's next for Guangdong? Will the region be content to exploit its labor cost advantage and continue to gain market share as the world's low-cost manufacturer? I don't think so. The economic development official I talked with in Guangdong was eager to discuss the region's plans for the expansion of universities, increasing support for research and development, and moving into the industries of the twenty-first century. She specifically cited growing knowledge capacity in sustainable energy and electric vehicles, advanced logistics systems, electric battery breakthroughs, and information technology enhancements in life sciences and healthcare. The province and the central government want to make the investments in education and research that will position the region for a talent-based economy of innovation. And the infrastructure investments you can observe in the region -- new sea-water port facilities, major apartment complexes, new university facilities, extension of passenger rail -- suggest the region is taking the long view about its economic future.

The global talent race

Monday, October 25, 2010

We have a lot of anxiety in the United States about the quality and effectiveness of our educational system, particularly at the elementary and secondary levels. And the anxiety is justified. A large percentage of our school-age population lives in high poverty neighborhoods, and they are served by schools that fail to allow them to make expected progress in needed academic skills, including especially reading, writing, and math. And we have high school dropout rates in many cities that exceed 25% -- leading to the creation of large cohorts of young adults who lack the basic skills necessary to do productive work in our society. So at a time when personal and social productivity depends on problem-solving, innovation, and invention, many of our young people in the US haven't developed their talents sufficiently to make these contributions.

How does this problem look from an international perspective? Other countries and regions seem to have taken more seriously the macro-role that education and talent will play in their futures, and are preparing the ground for superior outcomes on a population-wide basis. Here is one example -- Hong Kong. Though part of the People's Republic of China, Hong Kong retains a degree of autonomy in its social policies, and education is one of those areas where Hong Kong government can take special initiatives.

There is a pervasive feeling in Hong Kong that educational success is absolutely crucial. School children are strongly motivated, their families support them fully, and the city is trying to ensure that all children have access to effective schools. And there is a lot of civic focus on the quality and reach of the Hong Kong universities as well. Business and civic leaders recognize the key role that well-educated Hong Kong graduates will play in the economic vitality of the city in the future. And university leaders are keenly interested in enhancing the quality of the undergraduate and graduate curricula Here is a valuable survey report by Professor Leslie N.K. Lo, director of the Hong Kong Institute of Educational Research at Hong Kong Chinese University (http://www.hkpri.org.hk/bulletin/8/nklo.html). The report documents the priority placed on quality of education by the authorities, even as it raises concerns about the effective equality of education in the city. Here is a report on the state of education research and reform in HK (http://www.springerlink.com/content/gt11u17672j34372/fulltext.pdf). The

report raises the possibility that Hong Kong's educational system is skewed by income and language: low-income families attending Cantonese-speaking schools may not get a comparable education to that provided to middle- and upper-income families in English-speaking schools. But it isn't easy to find detailed educational research that would validate this point.

One very interesting data point concerning the equality of access provided by Hong Kong education can be located in the distribution of family incomes among students in Hong Kong's elite universities. Basically the data indicate that the Hong Kong universities are reasonably well representative of the full income spectrum of the city. About half of students in the elite universities in Hong Kong come from families in the lower half of the income distribution (or in other words, the median student's family income is equal to the median family income of the city). This compares to a markedly different picture in selective public universities in the United States, where the median student family income is at about the 85th percentile of the US distribution of family income. In other words, universities in the United States are over-represented by students and families from the higher end of the income distribution; whereas the Hong Kong university student population is relatively evenly distributed over the full Hong Kong income distribution. (These data are based on a summary report prepared by researchers at Hong Kong University of Science and Technology.)

This statistical fact gives rise to a suggestive implication: that students of all income levels in Hong Kong are roughly as likely to attend Hong Kong's elite universities. And this contrasts sharply with the situation in the United States, where attendance in elite universities is sharply skewed by family income (Equity and Excellence in American Higher Education (Thomas Jefferson Foundation Distinguished Lecture Series)).

The issue is important, because in the world-wide race for talent cultivation, those countries that do the best job of cultivating the talents of all their citizens are surely going to do the best in the economic competition that is to come. Countries that waste talent by denying educational opportunities to poor people or national minorities are missing an opportunity for innovation, creativity, and problem-solving that can be crucial for their success in the global environment. And if Hong Kong, China, and other East Asian countries are actually succeeding in creating educational systems that greatly enhance equality of opportunity across income, this will be a large factor in their future success.

China's confidence

Saturday, October 30, 2010

Traveling in China for the past two weeks has given me a different perspective on the country. The most powerful impression I've had is one of collective national confidence; the sense that China is on the move, that the country is making rapid progress on many fronts, and that China is setting its own course. We've known for twenty years about the unprecedented rate of economic development and growth in China since the fundamental reforms of the economy in the 1980s. China's manufacturing capacity is also well known throughout the world. But the story is bigger than that. What is perhaps not so well understood outside the country is the scope and purposiveness of the development plans the country is pursuing.

One aspect of this is the breadth of forms of capacity building that the country is investing

in. The nation is making long-term investments in a range of fundamental areas aimed at providing a foundation for long-term, sustained evolution. Transportation is one good example. The extension of the high-speed trains among China's important cities indicates a good understanding of the future importance of economic integration and mobility for future innovation and growth. But this high-speed rail system indicates something else as well: China's readiness to successfully design and build the most sophisticated engineering and technology projects on a large scale. The high-speed train between Hangzhou and Shanghai opened last week, with a sustained speed in excess of 350 km/hour; this brings the travel time down from 78 minutes to 45 minutes over the distance of 202 kilometers. Similar service will be completed between Beijing and Shanghai, providing 5-hour service between these key cities. So China will soon be leading the world in high-speed rail.

Higher education is another great example. The universities in and around Shanghai have built whole new campuses in the past ten years, reflecting a local and national commitment to improvement of the high-end talent base in the country. Universities in Beijing, Guangdong, Hangzhou, and Souzhou are making rapid and focused plans to enhance the quality of their faculties and the effectiveness of their curricula -- especially in the areas of mathematics, science, and engineering. My visit to the Chinese Academy of Fine Arts in Hangzhou was a great example of this dynamism. There I saw many bright, talented students from all across China studying the fine arts, design, and multimedia on a beautiful urban campus serving 9,000 students. The student work is very good, and it gives a sense of the creative potential invested in the current generation.

A more intangible aspect of China's current confidence comes from a long series of conversations with Chinese faculty, graduate students, and undergraduate students. There is a real pride in China's cultural heritage -- new friends in Hangzhou and Souzhou were eager to explain the meaning of ceramics, paintings, and gardens in terms of the Chinese value systems they represent. And there is a sense of purpose and direction in many of these conversations -- as if people in their 60s and people in their 20s alike have absorbed China's history and its half-century of turbulence, and are now looking forward to consolidation and enhancement of the cultural and economic power of their country. There also appears to be a deep underlying fear of turbulence; the people we met want to see stable, continuous progress. There was sympathy for Liu Xiabo, but not much appetite for radical changes in rights and liberties. "China needs to maintain stability."

This sense of confidence is accompanied by a lack of "Western envy." There is very little sense that any of the people I talked with over these several weeks think that their country should emulate Europe or North America -- politically or culturally. "China can create its own way ." Some of the students I talked to were very clear in their criticisms of the policies of their own government -- from educational access and equality to internet access -- but none expressed the notion that China should simply follow the European or North American models in these areas. (I was asked, why do corporations have so much influence on the government in the US?) And more importantly -- many of these young people have the desire to study abroad; but they also express a very specific intention to return to China and have their lives and careers in China. And equally important, I met leading Chinese academics who have chosen to return to China from leading universities in the US.

So -- rapid, sustained economic growth; a broadly shared sense of China's distinctive values and history; successful incorporation of advanced, largescale technology systems; the world's fastest super-computer; integrated regional and national plans for the future;

and a degree of recognition of the importance of addressing China's social problems -- this is a powerful foundation for a China-centered future for this country and its 1.3 billion citizens.

Where is the place for social criticism in this picture? China faces a number of difficult social problems that will require decades to solve. Consider some of the hardest problems: Dealing with the needs of China's aging generation; providing quality healthcare to everyone; rapidly increasing incomes to China's poorest 40%; reining in the steadily rising pressures on air and water quality; reducing the prevalence of guanxi and corruption in business and daily life; and handling the challenges of rapid rural-urban transformation, to name just a few important problems. Many of these problems affect large segments of Chinese society, and their solution will require critical demands by these groups if the government is to take appropriate action. So allowing Chinese people a genuine voice in defining the problems the country needs to tackle is crucial.

Moreover, many of the policy choices that need to be made will affect different social groups differently. Expansion of the rail network or the power grid provides large gains for many people, but it imposes important costs on other people. And often the "losers" in these policy areas are poor people with little effective voice in the policy arena. If poor people don't have open avenues through which they can express their needs and sources of hardship, these needs will not be heard. So for both these types of reasons, it is crucial that China move in the direction of creating greater space for dissent and the expression of fundamental concerns and interests.

An important part of this evolution is the development of an institutionally protected investigative press. It is crucial in a modern society that the role of the news-gathering investigator be established and secured against the pressures of government. Investigations of corruption sometimes occur in the Chinese press. But there seem to be fairly clear limits to the depth and subjects that journalists can undertake. Investigators trying to establish culpability for school building collapses during the Sichuan earthquake quickly ran into government controls for going too far. And yet it is only when the spotlight falls on corruption that it can be addressed.

So the confidence that Chinese people currently have in their future is warranted. And the path will be more direct if the Chinese political system continues to develop more institutionalized ways of allowing citizens and groups to express their concerns, desires, and criticisms. There will be a distinctively Chinese polity in the future. And it needs somehow to solve the problem of facilitating citizen voice and deliberative social problem solving.

Fresh thinking about government

Monday, November 01, 2010

The eminent neo-Confucian scholar Tu Weiming argues for the importance of bracketing our Western-centric ideas about society, progress, and justice when we think about our global futures. (Here is an interesting article by Tu titled "Mutual Learning as an Agenda for Social Development"; link.) So for a moment let us put aside the familiar rhetoric about "democracy" that usually surfaces when we talk about how societies ought to be governed. Much of that language derives from Western political theorists like Hobbes, Locke, Jefferson, and Mill, and arguably shows the signs of times and places very

different from current social realities. Can we begin to rethink the task of collective governance in a way that might help frame current discussions more fruitfully? Is it possible to rethink democracy in a way that is less Western-centric?

In order to think carefully about the idea of government, we need two different sets of assumptions: first, what the social realities or conditions are within the context of which "government" needs to function; and second, a core set of value assumptions that define the standards to which government ought to conform.

What are the fundamentals? There are several basic social realities that are hard to seriously question, and there are a few normative ideas that have credibility but could be debated.

Large social groups require governance.

Let's define a large group as a population of greater than 50,000 people living in proximity to one another, involved in a range of interactions and exchanges with each other and sharing access to a set of resources. This establishes interdependence and mutual effects among persons.

Here are some core governance needs: Maintenance of public order, management of conflicts, provision of some set of public goods, establishment of a system of rules and laws, collection of taxes to support the activities of government.

Persons have interests and commitments that they care about.

People have interests, desires, and commitments, and these interests lead to competition and cooperation, predation and defense. They behave purposively and strategically to further their interests and protect themselves against predation.

There are perhaps other basic facts about individuals that would be important from the perspective of other civilizational values systems -- for example,

Persons are psychologically and socially defined by the social relationships within which they exist.

Here is another salient fact:

Governments take actions that affect different people differently.

And another fact:

The powers of government create opportunities for corruption, preferential treatment, and favoring of the powerful by government officials.

So citizens care deeply about the outcomes of governmental action, and they are especially concerned at the possibility that others may gain great advantages through corrupt influence on officials and agencies.

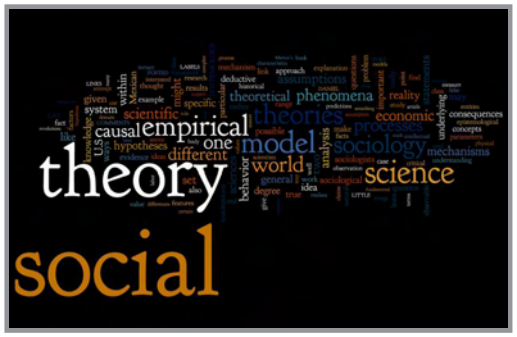
Now consider a few values that most people would probably accept.

- Government should pursue the public good, not the private good of officials or private individuals.

- Government should not favor some persons over others.
- Government should take the desires and needs of citizens into account when formulating rules, policies, and laws.
- Government policies and laws should reflect the preferences and interests of citizens.
- Government should establish a neutral framework of law and policy that is applied without regard to persons and private interests.
- Citizens should have the ability to express criticism and disagreement with government actions.

Designing government requires that we take account of these basic facts and do our best to embody the values we agree about. We need a set of institutions that will be durable, that will reinforce the fundamental values around which they are designed, and that will be difficult to distort when self-interested actors occupy roles within them. Most fundamentally, we need a set of institutions that embody pursuit of the public good; that reflect citizen preferences; and that secure a just system of law for all citizens.
So what kinds of governance institutions are compatible with this list of facts and values?

This is where the mechanisms of constitutional electoral democracy come in. Western political theorists argue that a constitution sets the regulative framework for governance -- the fundamental legal protections defining citizenship and the scope and role of government. And electoral democracy permits citizens to express their preferences and enforce good performance by officials. So policies are selected that correspond to the preferences of citizens; and they are implemented in good faith under the enforcement mechanism of representative electoral democracy.



But here is the more challenging question: are there other institutional arrangements that might fit these facts and values about as well? In particular, could we imagine a Confucian single-party state with an energetic **anti-corruption office**, an energetic and **independent "investigative journalism" office**, and a robust **social survey office** that serves the functions of gathering citizen preferences and concerns? Could such a system genuinely embody the public good in a hypothetical modern Asian society? In other words, could we imagine an administrative-authority system that effectively embodied the public good and protections of the fundamental interests and preferences of citizens? Could the "checks and balances" represented by an electoral system be established through other means?

It is easy to see objections to this hypothetical possibility; they largely come down to the problem of independence and effectiveness when a regulative office finds it necessary to criticize powerful officials or private persons. But it's worth asking the question of alternative governance design, and it's not inconceivable that solutions to these problems could be created.

(Here is an interesting collection of Tu Weiming's writings; Humanity and Self-Cultivation: Essays in Confucian Thought.)

Three years of UnderstandingSociety

Wednesday, November 03, 2010

Today marks the end of the third year of publication of ***UnderstandingSociety***. This is the 481st posting, with prior posts covering a range of themes from "social ontology" to "foundations of the social sciences" to "globalization and economic development." In beginning this effort in 2007 I had envisioned something different from the kinds of blogs that were in circulation at the time -- something more like a dynamic, open-ended book manuscript than a topical series of observations. And now, approaching 500,000 words, I feel that this is exactly what the blog has become -- a dynamic web-based monograph on the philosophy of society. It is possible to navigate the document in a variety of ways -- following key words, choosing themes and "chapters", or reading chronologically. And it is also possible to download a full PDF copy of the document up through July, 2010; this will be updated in January 2011.

I find that the discipline of writing the blog has led me into ideas and debates that I would not have encountered otherwise. For example, the thread of postings on "***world sociology***" and the epistemologies and content of sociology in China, France, or Mexico opens up a new set of perspectives for me on the social context of the disciplines of sociology. Thanks to Gabriel Abend, Marion Fourcade, Céline Béraud and Baptiste Coulmont for a range of stimulating ideas on this subject. (These discussions can be located under the "disciplines" and "sociology" tags.)

I've also been pleased at the way that the ***social ontology*** topic has unfolded. The ideas of plasticity, heterogeneity, and contingency as fundamental features of social entities are crucial when we try to understand why social entities and processes are different from natural entities. They give a basis for understanding that the distinction between natural kinds and social kinds is a crucial one. And I don't think I would have come to the particular formulations and found here without the working canvas provided by the blog. (This thread falls under the ontology theme.)

And, of course, I've been led into a number of discussion areas that I wouldn't have anticipated: Michigan's economic crisis, practical strategies of stimulating regional economic development, analysis of the schooling crisis our major cities face, and current developments in China, for example.

The writing process here is quite different from that involved in more traditional academic writing. When a philosopher starts out to write a philosophical essay for publication, he/she plans to spend many days and weeks formulating a line of argument, crafting the prose, and critically revising until it is perfect. Likewise, writing a traditional academic book involves coming up with a "story-line" of topics and key arguments, turning that into a chapter outline, and methodically drafting out the full manuscript. Creative planning, writing, and editing occupy months or years before the ideas come into public view.

Writing an academic blog has a different structure. It is a question of doing serious thinking, one idea at a time. Each post represents its own moment of thought and

development, without the immediate need to fit into a larger architecture of argument. Eventually there emerges a kind of continuity and coherence out of a series of posts; but the writing process doesn't force sequence and cumulativeness. Instead, coherence begins to emerge over time through recurring threads of thinking and writing.

I've done each of these other forms of traditional academic writing -- dissertation, conference presentation, journal article, book, and book review -- and I find this current form particularly valuable and intellectually rewarding. It stimulates creativity, it leads to new insights, it permits rigor in its own way, and it leads to new discoveries within the vast literatures relevant to "understanding society" and the space of questions this domain presents.

Writing the blog is intertwined with the web in several deep ways that are worth calling out. First, of course, is the availability of a venue for publication and the possibility of gaining a world-wide readership. The web and the search engines made this kind of readership possible, and this was a unique new capability entirely absent in the world of print. But equally important for me has been the ubiquitous availability of knowledge and writing on the web, and the ease with which we can access this knowledge through search engines and other web-based tools. This means that the web-based scholar can quickly discover other materials relevant to the current topic, leading to unexpected turns in the argument. It means that the web-based scholar is not locked into the circle of his own study and the literatures that he/she has already mastered; rather, there is an open-ended likelihood of interaction with new and important ideas previously not part of the mix. So the task of writing is no longer that of formulating one's pre-existing ideas; it is simultaneously an act of inquiry and intellectual discovery. (For me a good example of this is the interest I've developed in the theory of *assemblage* and the writings of Deleuze, Delanda, and Latour. These ideas fall far outside my own analytic philosophy comfort zone, and yet they align well with my own thinking about micro-foundations and social contingency.)

I invite readers to take this opportunity to make suggestions or observations about this experiment in academic writing. Are there topics you'd like to see addressed in future postings? Do you have suggestions for how to make the presentation of the content more useable? Can you see possibilities for this kind of inquiry and writing in your own field?

Super-high-density Shanghai

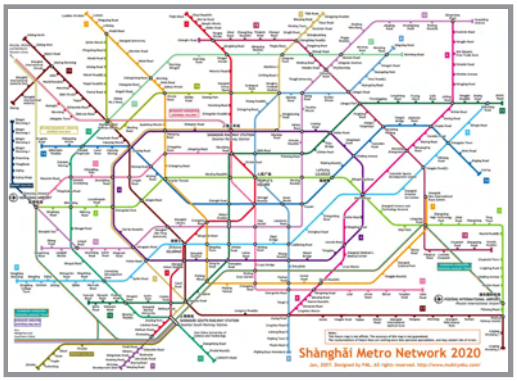
Friday, November 05, 2010

Shanghai is a city approaching 20 million people, and it is arguably the most economically dynamic city in Asia. This concentration of population and economic activity surely has important long-term consequences. There was an interesting piece in the Shanghai Daily recently by Nate Stein, called "Sky's the limit for well planned city of Shanghai." Stein makes a really intriguing point about the Shanghai metropolitan region that seems very important. He argues that the "invisible boundary" of a city is a margin that is roughly 45 minutes from the city center; and that this boundary is moving out fast in the lower Yangtze River Delta. Improvements in transportation have brought a handful of mid-sized cities into the 45-minute zone, with the result that Shanghai is fast becoming the most populous high-density metropolitan area in the world.

Here is the heart of Stein's view:

After building a subway in 1995 that has quickly grown to the world's longest and most traversed, Shanghai's invisible border moved outward significantly and drastically increased its growth potential. Instead of surrounding dense urban development with sprawling suburban homes, Shanghai's residents live in apartment buildings that do not restrict the growth of a city like stand-alone homes do.

Being built upon a backbone of compact flats and public transit, rather than homes on large lots and personal automobiles, means that the population has no upper boundary or, in a very literal sense, the sky is the limit, depending on how many people can fit in one building.



People are stacked on top of and below others as growth extends up, and not out. Concentrations of people make mass transit feasible and waste less fuel and energy. Efficiency greatly increases in compact cities and provide for the feasibility of small businesses staying in demand among residents without cars who need the convenience of small neighborhood shops.

The almost entirely urban design of Shanghai provides for impressively sustainable growth potential. The problem of overcrowding is on the horizon, but Shanghai has been effectively advancing its transit infrastructure. There is a two-level road tunnel under the Bund, the main portion of downtown, to prevent congestion and high-speed rail lines coming into existence that will further extend the reach of its invisible 45-minute boundary.

So Shanghai is a city with almost limitless density, in the sense that it can add population vertically rather than laterally and it can serve that population with a high-capacity rapid transit system.

Here is the Yangtze River Delta mega-region by night:
The transportation improvements that continue to transform the Shanghai urban landscape include both the subway system and the high-speed rail system connecting China's cities. Here is what the Shanghai Metro system looks like today:

And here is the plan for 2020:

The system currently consists of twelve lines, with new track being added rapidly. It handles something like five million passengers a day.

The other major improvement in transportation is the extension of the high-speed inter-city rail network. High-speed trains now connect Shanghai to Hangzhou and Suzhou, bringing those cities comfortably within the 45-minute radius of Shanghai. The high-speed train from Shanghai to Hangzhou takes only 25 minutes today. In practical terms, this means that there can be a tight integration among firms, knowledge workers, and universities throughout this region with a total population approaching 90 million people in the Yangtze River Delta Region. Professionals can live in Hangzhou or Souzhou and do their work in Shanghai.

Here is the intriguing question: does this development of a high-density, high-population metropolitan Shanghai have important implications for social and economic development? Is this mega-city going to represent a qualitative change in the world's urban history? Will Shanghai become a unique new kind of mega-urban place, with significantly higher growth potential than other world cities?

One reason for thinking that this may be true is the case that people like Richard Florida and Saskia Sassen have made for the synergies created by a densely interconnected urban area. Florida talks about the concentration of talent afforded by a high-density city, and Sassen focuses on the economic and informational networks that are stimulated by high-density cities. In each case there is the idea of non-linear interaction effects and positive feedback loops. Sassen's concept of a global city captures her core idea; a global city is one that has a large volume of connections to other cities around the globe, in terms of trade, services, telephone calls, internet traffic, and financial transactions (The Global City: New York, London, Tokyo.).

Shanghai is not the only large metropolitan area in the world, of course; but it appears to have features of urban system interconnectedness that take it out of the category of "sprawl" cities like Mexico City or Johannesburg.

Sassen puts some of her thinking into an interesting paper titled "Megaregions: Benefits Beyond Sharing Trains and Parking Lots?" (link). Here is how she frames her problem in the paper:

I have been asked to examine whether there are particular advantages to economic interactions at the megaregional scale and whether such interactions might play a role in enhancing the advantages of megaregions in today’s global economy. Familiar advantages of scales larger than that of the city, such as metropolitan and regional scales, are the benefits of sharing transport infrastructures for people and goods, enabling robust housing markets, and, possibly, supporting the development of office, science, and technology parks. Critical policy options identified by RPA in this regard would aim at strengthening the megaregional scale of economic interactions by investing in intercity and high speed regional rail, enhanced goods movement systems, and land use planning decisions. More complex and elusive is whether the benefits of megaregional economic interaction can go beyond these familiar scale economies and,

further, whether this would strengthen the position of such megaregions in the global economy.

And here is part of her answer:

One central argument I develop in this paper is that the specific advantages of the megaregional scale consist of and arise from the co-existence within one regional space of multiple types of agglomeration economies. These types of agglomeration economies today are distributed accross diverse economic spaces and geographic scales: central business districts, office parks, science parks, the transportation and housing efficiencies derived from large (but not too large) commuter belts, low-cost manufacturing districts (today often offshore), tourism destinations, specialized branches of agriculture, such as horticulture or organically grown food, and the complex kinds evident in global cities. Each of these spaces evinces distinct agglomeration economies and empirically at least, is found in diverse types of geographic settings –from urban to rural, from local to global. ***The thesis is that a megaregion is sufficiently large and diverse so as to accommodate a far broader range of types of agglomeration economies and geographic settings than it typically does today.*** This would take the advantages of megaregional location beyond the notion of urbanization economies. A megaregion can then be seen as a scale that can benefit from the fact that our complex economies need diverse types of agglomeration economies and geographic settings, from extremely high agglomeration economies evinced by the specialized advanced corporate services to the fairly modest economies evinced by suburban office parks and regional labor-intensive low-wage manufacturing. It can incorporate this diversity into a single economic megazone. Indeed, in principle, it could create conditions for the return of particular (not all) activities now outsourced to other regions or to foreign locations.

It would appear from a non-specialist's perspective, that Shanghai promises to have many of these multiple "agglomeration economy" dimensions, and from this we might expect that its economic growth will be accelerated with further densification.

Here is another interesting application of the idea of a global city to the case of Shanghai -- a conference paper by Professor Lin Ye, "Is Shanghai Really a 'Global City'?" (link). Ye's test involves examining three factors:

1. Central place in the national economy
2. Concentration nodes for global capital
3. Agglomeration sites to provide professional services (5)

Does Shanghai rate highly enough in these three areas to qualify as a global city?

Ye concludes that the data support a "yes" in each area. The Shanghai region represents a very significant percentage of the total Chinese GDP, and was increasing from 1992 to 2001 (7). It represented 5.16% of total GDP in 2001, with only roughly 1.5% of population. Second, Shanghai represented a significant concentration of China's foreign direct investment and exports during these years. Shipping and air traffic were concentrated in the metropolitan region as well. So Ye concludes that "Shanghai has become a strategic concentration node for global capital" (12). Finally, Sassen's most important criterion has to do with being a key node in the global network of professional services. He finds that here too, Shanghai measures up. So-called "tertiary" industries amount to 45.8% of employment -- dramatically greater than China's overall 27.7% rate (14). And the volume of financial services, insurance, and real estate (FIRE) business activity is very high as well. "Shanghai is leading the way to transform to an information-based professional service concentration place" (15). One important measure is the Globalization and World Cities Study Group assessment (link). GaWC singles out a list of 46 global firms (accounting, financial services, architecture, ...), and then ranks cities according to how many offices they possess of these firms. Ye notes that GaWC identified 55 global cities based on the concentration of global advanced producer service firms in each city, and Shanghai is on this list, with 27 offices out of the 46 global firms

(compared to 105 offices in New York). Ye concludes that Shanghai has "quickly adjusted from a traditional manufacturing center to a place that provides advanced professional services to the whole world" (17). It isn't yet in the top rank; but it is increasing its global interconnectedness rapidly.

These transitions from primary sector to tertiary sector businesses that Ye documents indicate that Shanghai is already well on its way to being a knowledge-centered global city. And the processes of densification described above should only amplify this process.

Merton's sociological imagination

Monday, November 08, 2010

Robert Merton began life as Meyer Schkolnick, son of impoverished Eastern European Jewish immigrants in Philadelphia, and he became one of the most influential American sociologists of his generation. He is most often associated with a couple of phrases that came to embody common knowledge in the social sciences -- "theories of the middle range," "unforeseen consequences," "focus group," and "standing on the shoulders of giants." But what, precisely, was his conception of sociology as a science? What sort of knowledge did he believe that sociology should aspire to? Did he offer anything like a "paradigm" for sociology as a body of research, theory, and explanation? And what does his work have to offer to today's generation of sociologists?

Craig Calhoun and others organized a conference at Columbia in 2007 involving a group of pathbreaking sociologists in a variety of sub-disciplines to consider the legacy of Merton, and the result is a highly interesting volume of essays, Robert K. Merton: Sociology of Science and Sociology as Science. Contributors include Craig Calhoun, Alehandro Portes, Charles Tilly, Robert Sampson, Cynthia Fuchs Epstein, Viviana Zelizer, Thomas Gieryn, Aaron Panofsky, Alan Sica, Ragnvald, Kallebert, Peter Simonson, Harriet Zuckerman, and Charles Camic, and jointly they consider a very wide range of themes and perspectives from Merton's work. The volume isn't presented as a *festschrift*; Gieryn provided just such a collection in 1980 during Merton's life (Science and Social Structure: A Festschrift for Robert K. Merton). Instead, this volume is conceived as a way of taking the measure of Merton's contributions to sociology as the field continues to develop, and to sound out ways in which Merton's theories and ideas have either flourished or declined in the decades since the most influential ideas were published. The volume therefore serves very well as an avenue through which to ask the analytical question: what defined Merton's sociological imagination?

In his introduction to the volume, Craig Calhoun presents one important part of Merton's work as being the job of "professionalizing" sociology. But he also believes that Merton's contributions were substantive and fundamental. He quotes Merton from "On Sociological Theories of the Middle Range" on the overall purpose of sociology:

Each to his last, and the last of the sociologist is that of lucidly presenting claims to

logically interconnected and empirically confirmed propositions about the structure of society and its changes, the behavior of man within that structure and the consequences of that behavior. (14-15)

This is a very focused statement about the nature of sociology; it involves **<empiricallyjustified> <theories>** about social **<structures>** and social **<behavior>**. It defines a method (empirical, fact-based research), a research product (a body of "logically interconnected statements"), and a subject matter (social structure and behavior). At the same time, it isn't a wholly informative statement. What falls under the topic of "social structure"? Is the theory of organizations a component of a theory of social structure? How deeply into the intricacies of social psychology should the sociologist go in researching social behavior? Calhoun makes it clear that he believes that Merton's "philosophy of sociology" becomes more concrete through his efforts to clarify the concepts and theories that sociologists advance. This is a move from the more abstract to the more concrete -- and very consistent with the idea of "theories of the middle range." And in fact, much of the value of the volume comes from the efforts made by the contributors to delve more deeply into some specific areas of research and theory formation in which Merton involved himself.

The sociology of science is certainly one of the important areas where Merton made a lasting contribution, and several essays in the volume are devoted to this field. Thomas Gieryn asks whether Merton formulated a ***paradigm*** for the sociology of science -- a good question, since Merton himself was one of the first (along with Thomas Kuhn) to use the word "paradigm" to analyze scientific and intellectual activity. Gieryn does a very useful job of collating the many things that Merton attributes to his core uses of the concept of paradigm throughout his work from 1968 to 2004 (115):

- assumptions
- problem sets
- problematics
- key concepts
- generalizable concepts
- central concepts
- conceptual apparatus
- logic of procedures procedures of inquiry
- scheme of analysis
- vocabularies
- postulates
- classification
- ideological imputations
- inference
- substantive findings
- inventory of extant findings
- types of pertinent evidence
- basic propositions
- interpretative schemes
- provisional agreement

Gieryn attempts to codify this list into three areas: "what we know about the social world ... ; how sociologists should study the social world ... ; prototheories that explain in causal fashion why society is the way it is" (115). (Another way of boiling these elements down would be along these lines: concepts and interpretive schemes; inference and evidence; broadly accepted substantive findings.)

Gieryn goes on to offer his own account of a paradigm for sociology as a series of

oppositions:

1. Science is social and cognitive
2. Science is cooperative and competitive
3. Science is institutionalized and emergent
4. Scientific objects in the world are real and constructed
5. Science is autonomous and embedded
6. Science is universal and local
7. Scientific knowledge is cumulative and ... not (120)

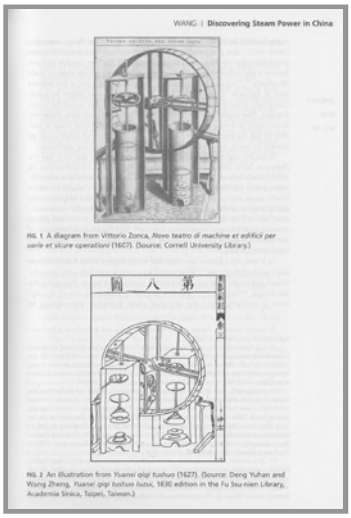
This formulation demonstrates one of the emergent values of a project like this one: inventive sociologists are led to push forward an important question ("What is a paradigm for sociology?") through careful consideration of Merton's work and its strengths and limitations.

An area where Merton is not so well known is in the area of "cultural sociology." In fact, "culture" seems entirely absent from the short definition quoted above. Merton is usually read as offering an abstract, structural-functional approach to the social world that pays little attention to cultural factors and meaningful behavior. Cynthia Fuchs Epstein and Viviana Zelizer take issue with this interpretation, however, in their chapters in the volume. Epstein puts her perspective in these terms: "Many of Merton's key concepts for the analysis of social life centered on the cultural domain, mated with structural variables" (79). And she thinks that a key part of Merton's approach to sociological thinking invokes a cultural interpretation of social life:

Learning to think like a sociologist, according to Merton, requires going beyond the individual as the unit of analysis, as is the focus of rational-choice theorists or mainstream psychologists today. The sociologist is required to consider the cultural web in which individuals are embedded, the social context that causes them to make certain choices and to act in concert with others because they share or are persuaded by social conventions that lodge them in institutional frameworks, which in turn circumscribe their options. (81)

Merton's sociology of science is perhaps a particularly clear example of Epstein's point here; Merton invokes the idea of the ethos of science, the norms and values that govern the choices of scientists, as one of the key sociological facts about science as socially embedded activity. And this ethos is plainly conveyed to scientists through concrete social arrangements of training and education.

Another area that is less familiar is "sociological semantics" and rhetoric -- basically, Merton's interest in tracing some of the metaphors and concepts that have been important in the ways that people have conceived of history and society. His book, On the Shoulders of Giants: A Shandean Postscript, traces the phrase "standing on the shoulders of giants" as a metaphor for the advancement of science. (He traces the lineage past Isaac Newton's usage of the phrase to Bernard of Chartres in the twelfth century.) Essentially, it is a phrase that captures the idea of cumulation and progress, incorporating and extending the body of knowledge received from prior generations. Charles Camic notes that Merton often insisted on a sharp delineation between the history of ideas and the sociology of ideas (275). But Camic argues that Merton actually pursued inquiries that crossed over this line repeatedly in his interest in tracing quotations, concepts, and metaphors through the history of science (278). His treatment of "serendipity" is a good example; and Camic argues that Merton regarded this kind of analysis as a serious exercise in sociological research.



That Merton himself viewed these writings in light of a larger intellectual project, rather

than as occasional amusements, is something he made increasingly explicit, however. (279)
Merton summarized this area of interest under the heading of "Neologisms as Sociological Concepts: History and Analysis" and as a "study in sociological semantics" (279, 280). Camic quotes Merton as holding that "the frequency and nature of quotations in society [serve] as objects of study in themselves" (283), and he links this kind of inquiry to the study of propaganda and mass persuasion as well.

In short, Merton is a sociologist who repays careful, extensive review, and this volume is a very good start. It proves the notion that we can not only stand on the shoulders of giants, but can also gain insights that go beyond and beside those predecessors.

Transmitting technology

Friday, November 12, 2010

How do large technological advances cross cultural and civilizational boundaries? The puzzle is this: large technologies are not simply cool new devices, but rather complex systems of scientific knowledge, engineering traditions, production processes, and modes of technical communication. So transfer of technology is not simply a matter of conveying the approximate specifications of the device; it requires the creation of a research and development infrastructure that is largely analogous to the original process of invention and development. Inventors, scientists, universities, research centers, and skilled workers need to build a local understanding of the way the technology works and how to solve the difficult problems of material and technical implementation.

Take inertial guidance systems for missiles, described in fascinating detail by Donald MacKenzie in Inventing Accuracy: A Historical Sociology of Nuclear Missile Guidance. The process MacKenzie describes of discovery and development of inertial guidance was a highly complex and secretive one, with multiple areas of scientific and engineering research solving a series of difficult technical problems.

Now do a bit of counterfactual history and imagine that some country -- say, Burma -- had developed powerful rocket engines in the 1950s but did not have a workable guidance technology; and suppose the US and USSR had succeeded in keeping the development of inertial navigation systems and the underlying science secret. Finally, suppose that Burmese agents had managed to gain a superficial description of inertial navigation: "It is a self-contained device that tracks acceleration and therefore permits constant updating of current location; and it uses ultra-high precision gyroscopes." Would this be enough of a leak to permit rapid adoption of inertial navigation in the Burmese missile program? Probably not; the technical obstacles faced in the original development process would have to be solved again, and this means a long process of knowledge building and institution building. For example, MacKenzie describes the knotty problem posed to this technology by the fact of slight variations in the earth's gravitational field over the surface of the globe; if uncorrected, these variations would be coded as acceleration by the instrument and would lead to significant navigational errors. The solution to this problem

involved creating a detailed mapping of the earth's gravitational field.

This is a hypothetical case. But Hsien-Chun Wang describes an equally fascinating but real case in a recent article in Technology & Culture, "Discovering Steam Power in China, 1840s-1860s" (link). There was essentially no knowledge of steam power in Chinese science in the mid-Qing (early nineteenth century). The First Opium War (1839-1842) provided a rude announcement of the technology, in the form of powerful steam-driven warships on the coast and rivers of eastern China. Chinese officials and military officers recognized the threat represented by Western military-industrial technology, but it was another 25 years before Chinese industry was in a position to build a steam-powered ship. So what were the obstacles standing in front of China's steam revolution?

Wang focuses on two key obstacles in mid-Qing industry and technology: the role of technical drawings as a medium for transmitting specifications for complex machines from designer to skilled workers; and the absence in nineteenth-century China of a machine tool technology. Technical drawings were an essential medium of communication in the European industrial system, conveying precise specifications of parts and machines to the workers and tools who would fabricate them. And machine tools (lathes, planes, stamping machines, cutting machines, etc.) provided the tools necessary to fabricate high-precision metal parts and components. (Merritt Roe Smith describes aspects of both these stories in his account of the U.S. arms industry in the early nineteenth century; Harpers Ferry Armory and New Technology.) According to Wang, the Chinese technical culture had developed models rather than drawings to convey how a machine works; and the intricate small machines that certainly were a part of Chinese technical culture depended on artisanal skill rather than precision tooling of interchangeable parts.

So communicating the technical details of a complex machine and creating the fabrication infrastructure needed to produce the machine were two important obstacles for rapid transfer of steam technology from Western Europe to Qing China. But perhaps a more fundamental obstacle emerges as well: the fact that Chinese technical and scientific culture was as yet simply unready to "see" the way that steam power worked in the first place. When steam warships arrived, acute Chinese observers saw smoke and fire, and they saw motion. But they did not see "steam-driven traction", or the translation of kinetic energy into rotational work. (This is evident also in the drawing of the treadmill water pump above; the maker of the drawing clearly did not perceive from the Italian drawing how the motion of the treadmill was translated into the vertical pumping action.) Wang quotes a description from an observer in Guangzhou in 1828:
Early in the third month ... there suddenly came from Bengal a *huo lunchuan* [fire-wheel ship] .... The *huo lunchuan* has an empty copper cylinder inside to burn coal, with a machine on the top. When the flame is up, the machine moves automatically. The wheels on both sides of the ship move automatically too. (37)
And another observer wrote in Zhejiang in 1840:

The ship's cabin stores a square furnace under the beam from which the wheels are hung. When the fire is burning in the furnace, the two wheels turn like a fast mill and the ship cruises as fast as if it is flying, regardless of the wind's direction. (37-38)
The give-away here is the word "automatically"; plainly these observers had not assimilated a causal process linking the production of heat (fire) to mechanical motion (the rotation of the paddle wheels). Instead, the two circumstances are described as parallel rather than causal.

So the fundamental motive force of steam was not cognitively accessible at this point, even through direct observation. By contrast, the marine utility of paddlewheel-driven warships was quickly assimilated. Chinese commanders adapted what they observed in the European naval forces (powerful paddlewheels that made sails unnecessary) to an existing technology (human- or ox-driven paddlewheels), and large "wheel-boats" saw action as early as 1842 on Suzhou Creek (40).

Wang notes that several Chinese inventors did in fact succeed in discerning the mechanism associated with steam power by the 1840s. Ding Gongchen succeeded in fabricating a model steam rail engine 61 centimeters long and a 134-centimeter model paddlewheel steamboat; so he clearly understood the basic mechanism at this point. And Zheng Fuguang appears to have mastered the basic concept as well. But here is Wang's summary:

Ding's efforts show that despite the circulating writings of a few experimenters, the steam engine remained a novelty, which was difficult to understand and probably impossible to reproduce. Interested parties were discussing it, however, but attempted to grasp it in terms of their indigenous expertise alone rather than more broadly understanding the new Western technology. (45)

In 1861, during the Taiping Rebellion, a senior military commander Zeng Guofan created an arsenal in Anqing for ammunition, and also set about to create the capacity to build steam-powered ships. With the assistance of experts Xu Shou and Hua Hengfang, the arsenal produced a partially successful full-scale steamship by 1863, and in 1864 Hua and Xu succeeded in completing a 25-ton steamship, the *Huanghu*, that was capable of generating 11.5 kilometers per hour. The Chinese-build steamship had arrived.

Here is how Wang summarizes this history of technology adaptation over a 25-year period of time:

The path from the treadmill paddlewheel boat to the Jiangnan arsenal's steamers was a long journey of discovery. Qing officials experimented with the knowledge and skills available to them, and it took time--and trial and error--for them to realize that steamboats were driven by steam, that machine tools were necessary to turn the principle of steam into a workable engine, and that drawings had to be made and read for the technology to be diffused. (53)

So perhaps the short answer to the question posed above about cross-civilizational technology transfer is this: "transfer" looks a lot more like "reinvention" than it does "imitation." It was necessary for Chinese experimenters, officials, and military officers to create a new set of institutions and technical capacities before this apparently simple new technological idea could find its way into Chinese implementations on a large scale.

(The image at the top is one of the most interesting parts of Wang's very interesting paper; it establishes vividly the difficulty of transmitting technologies across different technical cultures. The Italian drawing dates from 1607, and the Chinese copy dates from 1627. As Wang points out, the Chinese version of the drawing is visually highly similar to the Italian original; it is a good copy. And yet it fails to designate any of the technical features of how this treadmill-operated water pump works. The pair of drawings are fascinating to examine in detail.)

Eurasian time

Sunday, November 14, 2010

Victor Lieberman is probably the leading historian of Southeast Asia writing in English today. His primary focus is Burma, and throughout his career he has done a masterful job of piecing together the political, cultural, and economic history of the succession of Burmese polities over a millennium, using materials in many local languages.

His current work broadens the canvas by looking at broad temporal patterns of consolidation and turmoil across the full expanse of Eurasia, including Russia, France, Japan, China, and Southeast Asia. In two volumes of Strange Parallels: Volume 2, Mainland Mirrors: Europe, Japan, China, South Asia, and the Islands: Southeast Asia in Global Context, c.800-1830 (Studies in Comparative World History) he documents a degree of synchrony among widely separated polities that demands explanation. (Here is an earlier discussion of his programme in Volume One; link.)

Between 1240 and 1390 the principal realms of mainland Southeast Asia collapsed. The same was true of France and Kiev, whose political and economic travails merged with a general European crisis. (Kindle loc 512)
Here is how the pulsing of consolidation and disintegration looked in Southeast Asia:

In sum -- in lieu of four modest charter polities in 1240, 23 kingdoms in 1340, and 9 or 10 kingdoms in 1540 -- mainland Southeast Asia by the second quarter of the 19th century contained three unprecedentedly grand territorial assemblages; those of Burma, Siam, and Vietnam. (Kindle loc 799)
Lieberman defines consolidation as a broadening of scope of a polity, including territory, population, war-making capacity, and fiscal reach. And he notes that each of the world polities he studies shows a sequence of consolidation, followed by periods of turmoil and breakdown.

Along with territorial consolidation and administrative centralization, a third index of integration within each empire was a growing uniformity of religious and social practices, languages, and ethnicity. (Kindle loc 873)
And this was true as much in Burma as it was in 17th and 18th century France.

Moreover, and this is his key point, these periods show a remarkable degree of synchrony, from Kiev to Paris to Burma. So here is the central question: what kinds of global triggers or events could have created this synchrony?

Here are a few candidates that he considers. For the 10th-13th century, he considers the effects of global climate fluctuation, disease, Viking invasions, and the predations of Mongol armies from Inner Asia. And for the 17th and 18th centuries he considers the expansion of Eurasian trade, modern arms, and monetary uses of silver in Europe and Asia (Kindle loc 8745). Here is how the climate factor works:

Agriculture also exhibited long-term dynamism, the product of several influences. By increasing the reach and force of monsoon flows and minimizing droughts linked to El Nino events, the Medieval Climate Anomaly c. 800/850-1250/1300 contributed in some uncertain but possibly critical degree to that demographic and agricultural vigor, and associated institutional vitality, characteristic of the charter era, two of whose chief polities, Pagan and Angkor, lay in dry zones. (Kindle loc 1008)

Internal to each polity are factors that appear to be local in their effects: population change, agricultural improvements, new organizational forms in governance, military, and taxation, and the diffusion of literacy and national culture. Concerning the polities of Southeast Asia he writes:

My essential argument is this: Four phenomena -- expansion of material resources, new cultural currents, intensifying interstate competition, and diverse state interventions -- combined to strengthen privileged lowland districts at the expense of outlying areas. (Kindle loc 996)

But the logic of these processes does not imply any sort of global synchrony; so, once again, what would serve to link consolidation and disorder in France and Burma? Here is Lieberman's summary assessment.

Why, then, these loose, but increasingly close parallels over a thousand years? On current evidence, the synchronized florescence of Kiev, charter Southeast Asia, and Capetian France owed more to parallel social experiments and especially the Medieval Climate Anomaly than to long-distance trade. Political collapse in the 13th and 14th centuries reflected the intersection of institutional weakness with resource constraints caused by centuries of sustained growth, strains that were aggravated by post-1250/1300 climatic deterioration, shifting trade routes, Tai eruptions in Southeast Asia, and Mongol-Tatar mediations. The latter could be either military (in Burma, Angkor, and Kiev) or epidemiological (across Europe). Political revival after c. 1450 in all five realms reflected, in part, counterphasic trends: institutional responses to antecedent weaknesses, demographic recovery, and climatic amelioration. But post-1450 reintegration also relied on substantially novel technological and organizational factors, so that each polity started from a higher level than its 10th-century predecessor. (Kindle loc 9341)

This is world history you can get your teeth into. It is detailed, making use of the best available sources for each of the regions and polities considered. And it is bold in its effort to arrive at trans-continental, even global causes of these local developments.

New modes of historical presentation

Wednesday, November 17, 2010

Victor Lieberman's Strange Parallels: Volume 1, Integration on the Mainland: Southeast Asia in Global Context, c.800-1830 and Strange Parallels: Volume 2, Mainland Mirrors: Europe, Japan, China, South Asia, and the Islands: Southeast Asia in Global Context, c.800-1830 represent about 1000 pages of careful, dense historical prose extending over two volumes. As previously discussed (link, link), the book reviews a thousand years of history of the polities of France, Kiev, Burma, Japan, and China, it documents a significant correlation of timing across the extremes of Eurasia, and it offers some historical hypotheses about the causes of this synchronicity. It is a long and involved story.

My question here is perhaps a startling one: Is it possible that some alternative modes of

presentation would permit the author to represent the heart of the historical findings much more efficiently in the form of a complex animated visual display? Could the empirical heart of the two volumes be summarized in the form of a rich data display over time? Is the verbal narrative simply a clumsy way of representing what really ought to be graphed? What would be gained, and what would be lost by replacing the long complex text with a compact series of graphs and maps?

This thought experiment is possible because Lieberman's argument lends itself to a quantitative interpretation. Essentially he is focusing on factors that can be estimated over time: degree of scope of a regime, degree of integration of institutions, economic productivity, agricultural intensity, rainfall, temperature, population level and density, mortality by disease, and transport capacity, for example. And he is looking for one or more factors whose temporal variations can be interpreted as a causal factor explaining correlations across the graphs. So we could imagine a master graph representing the factual core of the research, with six groups of graphs over time, representing the chief variables for each region over time. Here is Lieberman's initial effort along these lines, graphing his estimate of "scope and consolidation" of the states of SE Asia and France. And we can imagine presenting different data series representing his findings about agricultural productivity, mortality, population, climate change, etc., arranged around a single timeline.

We might imagine supplementing these superimposed data series with a series of dated maps representing the territorial scope of the states of the various regions, arranged along a timeline:

France T1 France T2 France T3
(A similar series would be constructed for the states of SE Asia.)

What this coordinated series of graphics represents, then, is the core set of facts that Lieberman has synthesized and presented in the book. By absorbing the social, political, and economic changes represented by this graphical timeline, the reader has gained access for the full set of empirical claims offered by Lieberman. And, one might say, the presentation is more direct and comprehensible than the verbal description of these

changes contained in the text. Moreover, we might expect that patterns will emerge more or less directly from these graphic presentations -- for example, the synchrony between state crisis and accumulating climate change.

As for what is lost in this version of the story -- several things seem clear. First, much of the narrative that Lieberman provides is synthetic. He attempts to pull together a wide variety of sources in order to arrive at a summary statement such as this: "The Capetian state increased dramatically in scope and administrative competence between 1000 and 1250." So the narrative serves to justify and document a particular inflection point in the long graph of "French polity". It provides the evidentiary basis for the estimate at this period in time.

Second, of course, the packet of graphs I've just described lacks the eloquence and vividness of the prose that Lieberman or other talented historians are able to achieve in telling their stories. It represents only the abstract summary of conclusions, not the nuance of the reasoning or the drama of the story. The prose text is inherently enjoyable to read, and it engages the reader to share the historical puzzle. But, one might argue, the epistemic core of the book is precisely the abstract factual findings, not the prose style. And the reasoning can be captured as a hypertext lying behind the graph -- a sort of annotated hyper-document.

Finally, this notion of arriving at an abstract, schematic representation of a history of something doesn't work at all for many kinds of historical writing. Michael Kammen's Mystic Chords of Memory: The Transformation of Tradition in American Culture is an inherently semiotic argument, working out the ways that public ceremonies and monuments work in the consciousness of a population. Robert Darnton's The Great Cat Massacre: And Other Episodes in French Cultural History is a deft interpretive inquiry, arriving at a complex interpretation of a puzzling set of actions. These examples of great historical writing are evidence-based; but they are not designed to allow estimation of a set of variables over time. And I don't see that there is the possibility of a more abstract and symbolic representation of the historical knowledge they represent.

One might say that what we have encountered here is an important fissure within contemporary historical writing, between "***cliometric***" research and knowledge (Reflections on the Cliometrics Revolution: Conversations with Economic Historians) and ***hermeneutic*** historical knowledge (Paul Ricoeur, Memory, History, Forgetting). The former is primary interested in the processes of change of measurable human or social variables over time, whereas the latter is concerned with interpreting human actions and meanings. The former is amenable to quantitative representation -- graphs -- while the latter is inherently linguistic and interpretive. The former has to do with estimation and causal analysis, while the latter has to do with interpretation and narrative.

Often, of course, historians are involved in both kinds of interpretation and analysis -- both measurement and interpretation. So when Charles Tilly describes four centuries of French contention in The Contentious French, he is interested in charting the rising frequency of contentious actions (cliometric); but he is also interested in interpreting the

intentions and meanings associated with those actions (hermeneutic).

Consolidated quantitative history

Saturday, November 20, 2010

It is fascinating to browse through the sessions on the program at the Social Science History Association this month (link). SSHA is distinguished by its deep embrace of disciplinary and methodological diversity, and there are panels deriving from qualitative, comparative, and theoretical perspectives. But particularly interesting for me this year are the more quantitative subjects -- reflecting the cliometric impulse that led to the formation of the SSHA several decades ago. (Here are a few comments by Julia Adams, Elisabeth Stephanie Clemens, and Anne Shola Orloff, past and current presidents of SSHA, on this history.) There are panels on historical measures of the standard of living in different parts of Eurasia; on fertility, mobility, and population size in small and large regions; on longterm climate and atmospheric fluctuation over time (the year without a summer in mid-nineteenth century); levels of agricultural productivity over several centuries in several regions; the degree of inequality in landholding in Scania and North China; and many other fascinating studies of measurable social properties. And, of course, the papers offer time graphs of the variables that are the subject of the study.

So what if we had a goal of providing a unified and public measurement of factors like these over a large expanse of time and space? What if we set out to synthesize many studies currently underway and arrive at a common set of measures over time for these regions?

To an extent this is the goal of the Eurasian Population and Family History Project: to assemble a large set of research groups across Eurasia, measuring demographic data using comparable methods in the several locations (link). Though the project hasn't yet produced a synthetic volume summarizing all the results, we can hope that this kind of product will eventually be forthcoming. The researchers describe the project in these terms: “New data and new methods … have begun to illuminate the complexities of demographic responses to exogenous stress, economic and otherwise…. Combined time-series and event-history analyses of longitudinal, nominative, microlevel data now allow for the finely grained differentiation of mortality, fertility, and other demographic responses by social class, household context, and other dimensions at the individual level” (Tommy Bengtsson, Cameron Campbell, James Z. Lee, et al, Life under Pressure: Mortality and Living Standards in Europe and Asia, 1700-1900 (Eurasian Population and Family History), 2004, pp. viii-ix). Their goal is an ambitious one; it is to provide detailed, analytically sophisticated multi-generational studies of a number of populations across Eurasia. The studies are intended to permit the researchers to probe issues of causation as well as to identify important dimensions of similarity and difference across regions and communities. The most recent volume in the series appeared earlier this fall (Noriko Tsuya, Wang Feng, George Alter, James Z. Lee, et al, Prudence and Pressure: Reproduction and Human Agency in Europe and Asia, 1700-1900 (Eurasian Population and Family History)).

Suppose we wanted to go further and create an interactive Wiki site that permitted researchers to upload their findings for a specified set of variables; and suppose the underlying software created a dynamic set of time graphs and maps representing these data over time. And suppose that the data displays can be broken out at different levels

of scale -- North China, China, Eurasia. Finally, of course, we would want to specify that the data summaries are tagged with meta-data indicating the studies and methodologies leading to the graph. Could we say that this hypothetical site would then represent the meta-knowledge of the community of economic historians, climate scientists, and historical demographers? And could we speculate that this product would be an enormous benefit for historical researchers in a broad range of disciplines?

We can immediately predict some limitations to such a collective project. Most important is the unavoidable incompleteness of the data. We may have studies on farm productivity that document output for portions of North China and portions of the Yangzi Delta. But, of course, this doesn't tell us much about western China. So we can't realistically aspire to a full and complete representation of the variables full regions and periods.

Second, there is the problem of methodological inconsistencies across studies. Robert Allen is a leader in attempting to document standard of living across Europe and Asia (Robert Allen, ed., Living Standards in the Past: New Perspectives on Well-Being in Asia and Europe). And a central problem he faces is that multiple studies estimate consumption and wellbeing in different ways. So forming a composite representation requires an additional set of assumptions and models by the meta-study researcher.

Third, there is the question of defining the role for verbal analysis and reasoning in such a knowledge system. Are we to imagine this collective data set as a universal data appendix to a huge range of verbal historical narratives and analyses? Or might we come to think that the graphs speak for themselves, with no need for verbal analysis and inference?

All that said, I think the hypothetical Wiki site would be enormously valuable. It would provide us with birds-eye view of the large structural and material features that defined and constrained Eurasian history. And it has the potential of suggesting new avenues of research and new causal hypotheses about documented processes of change. For example, we may compare the time series of life expectancy and average temperature, and we may hypothesize that mortality and fertility were affected by abnormal climate conditions (through the medium of agricultural performance). But we may also be able to observe suggestive correlations between material variables and behavior -- for example, between ecological crises and the frequency of peasant uprisings. Or, conceivably, our eye might be led to a graph of sex ratios in a region and another of the incidence of banditry, and we might be led to a "bare sticks" hypothesis about social unrest: when there is an excess of unmarried young men, we can expect an upsurge of banditry and crime.

There are increasingly powerful tools available that permit scholars and the interested public to explore large public datasets such as the US Census or Bureau of Labor Statistics (link). It is perhaps not wholly unrealistic to imagine a platform that permits multiple researchers to contribute to a meta-dataset for economic and social history of the world.

Hobbes in context

Tuesday, November 23, 2010

We often think of Hobbes as being an originator in English philosophy, a strikingly innovative thinker who burst on the scene with the first formulation of a social contract theory of government. And we sometimes think of his justification of absolute sovereignty as a fairly direct reaction to the disorders Britain experienced during its Civil War and Glorious Revolution. Richard Tuck's Hobbes: A Very Short Introduction puts Hobbes into a much more nuanced position.

Fundamental to Tuck's approach as a historian of philosophy is to problematize the idea of "philosophy". Rather than assuming that the subject matter and methodology of philosophy were fixed once and for all by some traditional authority -- perhaps Aristotle and Plato -- Tuck takes the position that thinkers have defined themselves in ways that have eventually come to be described as "philosophy," but that nonetheless cover a very wide range of intellectual approaches and concerns. Here is a particularly striking set of ideas from Tuck's contextualization of Hobbes:

It is sometimes tempting to think that the heroes of the various histories of philosophy or ethics -- men as different as St Thomas Aquinas, Machiavelli, Luther, Hobbes, Kant, or Hegel -- were all in some sense engaged in a common enterprise, and would have recognized one another as fellow workers. But a moment's reflection reminds us that it is we who have made a unity of their task: from their own point of view, they belonged to very different ways of living and had very different tasks to perform. They would have seen themselves as intellectually kin to men who do not figure in these lists -- priests or scholars who had on the face of it no great philosophical interest. (1)

I think his point here is an important and insightful one: ***philosophy*** was reinvented in the Europe of the 16th and 17th centuries, and swerved dramatically away from ancient and medieval philosophy. It was a new project, motivated by different problems, assumptions, and goals.

Tuck gives a good deal of attention to Hobbes's biography, with the implication that these historical, social, and familial circumstances contributed to shaping the philosophical imagination of the maturing thinker. The situation of service as tutor and secretary to the household of William Lord Cavendish that occupied Hobbes for most of his life plays an important role in his intellectual development. It also provided him with direct access to some of the great intellectuals and scientists of France and Venice, including eventually Mersenne, Descartes, and Galileo.

A central intellectual theme in the air during Hobbes's early development was that of humanist skepticism about empirical and ethical knowledge.

The central feature of this literature was a pervasive scepticism about the validity of the moral principles by which an earlier generation had lived. (7)

The response of many of Lipsius's generation (he was born in 1547) was to give up strongly held and publicly defended beliefs of all kinds, and to retreat to a dispassionate and skeptical stance. (9)

Tuck argues that Hobbes defined his thought in terms of an effort to create a new, though

more modest, basis for knowledge in both empirical and ethical matters. In fact, Tuck leaves the impression that the philosophy of science is as important in Hobbes's work as the philosophy of politics. He was greatly influenced by the example and thinking of Galileo. Galileo's *Dialogue Concerning the Two Chief Systems of the World* appeared in 1632, and during 1634 Hobbes purchased a copy of the book for Newcastle. One of the key issues in the philosophical world was whether the senses deceive us; and Hobbes followed Descartes in holding that the observable features of the world (color, smell) should not be understood to directly correspond to real characteristics of the invisible reality of the object. Hobbes was interested in optics and mathematics -- the areas of science that appeared to be most relevant to the question of the real features of the world. And he sought to articulate a conception of knowledge according to which real properties in the world create phenomenal properties in the observer through "motions" (or causal processes).

Another core theme in Hobbes's itinerary is a visceral opposition to government religion -- religious requirements embodied in the state. Tuck shows with repeated examples why this issue was so important during the Civil War; the struggle between contending sides had very much to do with the scope of religious discipline to be imposed by the state. Hobbes was opposed to religious law and mandates of belief, and therefore found himself in roughly the camp of the Tolerationists.

The ecclesiastical regime put into place by the new republic after 1649 was very close to what Hobbes seems to have wanted on general grounds, and which he may well have enthusiastically preferred to traditional episcopacy. This is because, like almost all the most interesting 17th-century political theorists (including Grotius and Locke), he seems to have feared the moral and intellectual disciplines of Presbyterian Calvinism far more than anything else. (39)

Hobbes's primary object in arguing like this was to elevate the power of the sovereign over the churches -- bands of fanatics (in his eyes) who wished to enforce absurd opinions upon their fellow citizens, and whose activities were primarily responsible for the civil wars of Europe. They could only be controlled if the soverign was empowered to determine public doctrine and silence disputes. (85)

Tuck argues that Hobbes's earliest and most important influence on Hobbes in the area of moral and political philosophy was Hugo Grotius and his book, *The Laws of War and Peace*. Tuck describes this influence in these terms:

[Grotius] could play the same role for him as Galileo's *Dialogues* did for all members of the Mersenne circle, as a represntation for them of the kind of science which was to be put on their new, post-sceptical foundations. (25)

Tuck summarizes Grotius's core theory in two fundamental principles: "All men would agree that everyone has a fundamental right to preserve themselves, and wanton or unnecessary injury to another person is unjustifiable" (26). Tuck finds that these principles have counterparts in Hobbes's arguments in *Leviathan*.

So Tuck seems to be putting forward several important strands of interpretation that run against the grain of the customary telling of Hobbes's philosophy: first, that his philosophy of science and sensation plays a larger role than we might have thought; and second, that his most famous theory, the theory of unlimited sovereignty, has rather specific roots in Hobbes's immediate intellectual context (Grotius) and political environment (struggles over the extent of religious legislation). It is not the result of a purely abstract reflection on the situation of rational persons in a state of nature, but rather a complex argument that intertwines with England's own political tensions in mid-seventeenth century.

Steven Pincus's 1688: The First Modern Revolution is a nice complement to this line of thought, in that it offers a fundamentally new reading of the Glorious Revolution of 1688-89. Here is how Pincus describes his project:

England's Glorious Revolution of 1688-89 holds a special place in our understanding of the modern world and the revolutions that had a hand in shaping it. For the better part of three centuries scholars and public intellectuals identified England's Revolution of 1688-89 as a defining moment in England's exceptional history. Political philosophers have associated it with the origins of liberalism. Sociologists have contrasted it with the French, Russian, and Chinese revolutions. Historians have pointed to the Revolution as confirming the unusual nature of the English state. Scholars of literature and culture highlight the Revolution of 1688-89 as an important moment in defining English common sense and moderation. All of these interpretations derive their power from a deeply held and widely repeated narrative of England's Revolution of 1688-89. Unfortunately, that narrative is wrong. (Introduction)

Urban and metropolitan problem solving

Thursday, November 25, 2010

The issues that almost all large American metropolitan regions and cities are facing are important and messy. Here is a short list: racial segregation, concentration of poverty, poor health and nutrition, poor schools, crime and violence, and disaffection of young people. These problems are important because they hold back the personal lives of millions of Americans living in poverty and degraded urban neighborhoods. And they are messy because they are multi-causal and interconnected. Each problem feeds into another, and it is generally difficult to say what kinds of policy changes and plans would lead to eventual improvement. These are "wicked" problems (link) that require planners to work with complex and unpredictable processes in an effort to improve Cleveland, Chicago, Oakland, Miami, Houston, Kansas City, and Detroit.

There is another reason why urban and metropolitan problems are hard to solve -- the lack of political will to seriously address the problems in a long-term and sustained way. State legislatures often have an anti-urban bias. Regions often embody conflicts of interest between suburbs and city. Jurisdictions are often more concerned about their own narrow interests than in finding workable regional solutions. And the Federal government often fails for decades to mount serious and realistic urban strategies. So the result is often stasis -- nothing happens.

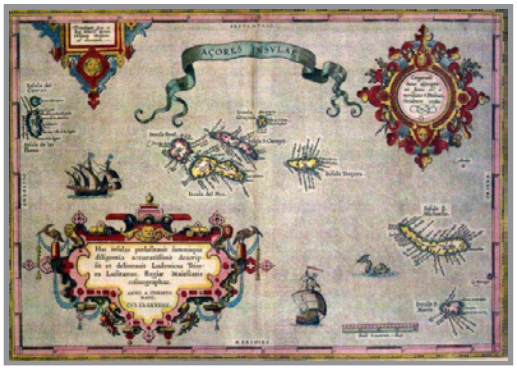
One aspect of the challenge is the availability of timely, reliable data about a region's health and performance. City governments collect a lot of data about health status, land use, and crime; but they are often reluctant to make their information available to researchers and the public. Foundations and individual researchers undertake studies focused on one problem or another; but often the reports are difficult to find and difficult to compare.

So we might hypothesize that the situation would be improved if there were an active, well-resourced clearinghouse for regional data from a wide range of sources: census, municipal departments, academic studies, land use surveys, and environmental surveys. Ideally these data sets would be managed by a professional staff who are able to integrate the various sources into a query-based GIS system, and ideally the data sets themselves would be publicly available (subject to appropriate privacy conditions). this kind of regional data warehouse would not directly solve the problems the region faces; but it would give a clear understanding of the scope and distribution of the problems that need to be addressed; it would provide an empirical base for proposed policy solutions; and it would provide a baseline for eventually evaluating the policies that are adopted.

Fortunately, there are good examples of exactly this kind of effort underway in various regions around the country. One such effort is underway at the Community Research Institute, part of the Johnson Center for Philanthropy at Grand Valley State University in Michigan (link). The Institute focuses primarily on several counties surrounding Grand Rapids, but it is also preparing to expand its coverage to other parts of Michigan. With a foundational database linking US Census data geographically, the Institute attempts to provide geographically linked data down to the neighborhood level. Here is an example of a map of the teen birth rate in neighborhoods of Grand Rapids (link). The Center has developed a general tool, MAPAS, that can serve as a platform for integrating and presenting a wide range of social data sources (link).

A similar effort is underway in the Detroit metropolitan region, under the rubric of Data Driven Detroit (link). D3 is attempting to create this kind of publicly accessible, spatially presented data warehouse for the city and the region, and the early results are promising. Here is a report on a recent study conducted by D3 on housing stock in Detroit (link).

So how can data sources like these be folded into good planning efforts for urban and metropolitan progress? The city of Detroit under the leadership of Mayor Dave Bing is just beginning an important planning effort that ties into the need to adjust the cityscape to the dramatically smaller population it now contains. This effort is called the Detroit Works Project (link), and it is explicitly committed to data-driven decision making and planning.



Another effort that is underway is the Integration Initiative within Living Cities (link, link). Detroit is one of the cities that has been funded within the program. Here is how Living Cities describes the national project of the Integration Initiative:
The Integration Initiative builds upon Living Cities' 20-year history of investing in cities. It acknowledges both the power and limitations of the neighborhood as a lever for change and seeks to drive a broader perspective that recognizes the role systems and regions must play in securing economic opportunity for low-income people.

The Integration Initiative will provide at least $80 million in grants, loans and Program-Related Investments (PRIs) to five regions to help them tackle the greatest barriers to opportunity for low-income residents, including education, housing, health care, transit and jobs. Living Cities and its members are making a total investment of $15 million in grants, $15 million in PRIs and $50 million in commercial debt. PRIs are flexible, low-cost loans provided at below-market rates to support charitable activity.
In order for a project like this to succeed, it needs to be based on solid empirical data. It is crucial for the progress of metropolitan Detroit, and other cities around the country, that the region succeed in creating a unified regional data source.

DYNAMICS OF COMMERCIAL DEVELOPMENT

TABLE 1.1

London Cloth Exports: Denizens, 1488–1614

SOURCES: Compiled from E. M. Carus-Wilson and O. Coleman, *England's Export Trade, 1275–1547* (Oxford, 1963), tables; Gould, *Great Debasement*, app. C; Fischer, "English Trade to Asia," pp. 23–35; Fisher, "Commercial Trends and Policy," p. 96; Supple, *Commercial Crisis*, tables 1–3; PRO, Enrolled Customs Accounts 28, 29 (1559–1581, 1582–1593, 1598–1603); PRO, Customs Accounts 213/19, 90/45, 213/19 (1594, 1595, 1596).

Karl Marx was very interested in ***capital*** -- an abstract concept referring to society's wealth. And he was interested in the persons who owned and controlled capital -- the capitalists. But the primary focus of his lifelong analysis was upon one particular species of capital, what he referred to as "industrial capital." This is the form of wealth involved in the production process -- factories, mines, railroads. He had less to say about the aspect of capital that designated the exchange process -- what he referred to as "merchant capital" and finance capital. This selective focus reflected one of Marx's main historical opinions -- the idea that history moves forward through the development of the "productive forces," and that industrial capitalists (as well as the industrial proletariat) are the agents of this kind of economic change. Here is a brief description from *Capital* of the role of merchant's capital in his analysis.

The reason is now therefore plain why, in analysing the standard form of capital, the form under which it determines the economic organisation of modern society, we entirely left out of consideration its most popular, and, so to say, antediluvian forms, merchants' capital and money-lenders' capital. The circuit M-C-M, buying in order to sell dearer, is seen most clearly in genuine merchants' capital. But the movement takes place entirely within the sphere of circulation. Since, however, it is impossible, by circulation alone, to account for the conversion of money into capital, for the formation of surplus-value, it would appear, that merchants' capital is an impossibility, so long as equivalents are exchanged; that, therefore, it can only have its origin in the two-fold advantage gained, over both the selling and the buying producers, by the merchant who parasitically shoves himself in between them. It is in this sense that Franklin says, "war is robbery, commerce is generally cheating." If the transformation of merchants' money into capital is to be explained otherwise than by the producers being simply cheated, a long series of intermediate steps would be necessary, which, at present, when the simple circulation of commodities forms our only assumption, are entirely wanting. (*Capital I,* Chapter 5)

According to the labor theory of value, only the expenditure of living labor into the production process of a commodity can create new value; so only industrial capital includes a process that creates new wealth. Merchant capital plays no role in the production process, and it is therefore historically unimportant -- or so is Marx's view in *Capital*.

If we now look back on European history from the sixteenth century to the twentieth century, this assessment seems badly wrong as an historical observation. Merchants and their companies played key roles in the establishment of a world trading system; they actively facilitated the race for colonies by the European powers; and often they played a quasi-military role in suppressing resistance by locals in distant parts of the world. So "merchant capital" and companies established for the purpose of international trade seem to have played a key role in the creation of the modern world system.

Robert Brenner undertook to provide a detailed historical account of the role of merchants and their organizations in the sixteenth and seventeenth centuries in Merchants and Revolution: Commercial Change, Political Conflict, and London's Overseas Traders, 1550-1653 (1993). This is a departure from Brenner's important contributions to the agrarian changes associated with England's agricultural revolution in the sixteenth century (link), and it is also a much more detailed historical study than his previous works. Brenner is interested primarily in two topics: first, how did commerce evolve in the sixteenth century in England, both nationally and internationally; what were the institutions, organizations, and individuals that emerged as vehicles for pursuing individual and corporate interests by large merchants? And second, how did the emergence of large merchant fortunes and companies interact with the politics of the English state during this early modern period?

To offer a historical analysis of commerce, it is necessary to have extensive commercial data. Appropriately, Brenner's research depends heavily on good information about imports and exports throughout the period. Here is his compilation of London cloth exports 1488-1614:

So aggregation of voluminous historical economic data represents one important portion of Brenner's historical research here. The other important part, however, is at the other end of the scale -- detailed information about many of the individuals who played leadership roles in the commercial and political developments of the period.

Fundamentally the book is about the political power of the merchant class. Brenner makes the point that English commercial interests were deeply dependent upon English political and military strength in the competition for import and export markets.

English merchants found it feasible to establish the new trades in large part because of the weakening hold of Portugal and Spain over their commercial empires, as well as certain other favorable political shifts in the new areas of commercial penetration. Even so, they could successfully capitalize on the openings presented to them only because of the growing political, as well as economic, strength of English commerce and shipping in this period. (5)

The development of England's colonies was particularly important for English merchants:

During the first quarter of the seventeenth century, English traders, for the first time, sought systematically to establish commerce with the Americas. Important City merchants had opened up the new trades with Russia, Turkey, Venice, the Levant, and the East Indies that highlighted the Elizabethan expansion, and in each case, had had recourse to their favorite commercial instrument, the Crown-chartered monopoly company. (92)

This meant, in turn, that great merchants had great political interests, both in terms of military policies of the Crown and in terms of the privileges and monopolies upon which their profits depended. And much of Brenner's narrative is a careful parsing-out of the deliberate and purposive political alignments sought out by the great merchants and their companies.

The Levant Company's privileges were indispensable for its elaborate system of trade

regulation and, in turn, for the reservation of the profits of the trade to a restricted circle of merchants. As members of a regulated company, the individual Levant Company merchants traded for themselves with their own capital, but were required to adhere to rules and policies set by the corporation's general court. (66)
Political alignments were especially important during the century of conflict leading to civil war and revolution.

The political activities and alignments of London's merchant community both expressed and helped determine the character of City and national conflict in the period leading up to the outbreak of the Civil War. From November 1640, London politics and national politics became ever more inextricably intertwined, and ovesears merchants played key roles at both levels.... Civil war became inevitable when City and parliamentary conflicts became fully merged through the consolidation of alliances between the City radical movement and the opposition in Parliament, on the one hand, and the City conservative movement and the Crown, on the other. (316)

An overwhelming majority of company merchants ultimately fell into one of these two allied political categories [of royalist supporters]. But it is difficult to be sure how they were distributed between them ... because surviving evidence on the political orientation of large numbers of citizens is available only for the period beginning in July 1641. (317)
But on the other side:
The traders of the colonial-interloping leadership stood at the head of the City popular movement and played a critical role in connecting that movement to the national parliamentary opposition. The new merchants' continuing intimate ties with London's domestic trading community (from which many of them had come) put them closely in touch with a City parliamentary movement that was overwhelmingly composed of nonmerchants. Meanwhile, their activities in the colonial field gave them pivotal links with those Puritan colonizing aristocrates who constituted a key component of the national parliamentary leadership. (317)
If we wanted a single phrase to summarize Brenner's task in this work, it is the idea that much of England's politics in the early modern period were influenced or determined by the demands of the commercial sector. The great merchants wielded great political power. And so we need to have a fine-grained understanding of these companies and their networks if we are to understand the coalitions and policies of the period. Contrary to the view put forward by Marx above, merchant capital and its associated actors and organizations were indeed a potent historical factor in modern history.
A recent book by Stephen Bown, Merchant Kings: When Companies Ruled the World, 1600--1900, picks up the story of merchant capital from a different angle and with a very different level of resolution. Bown is particularly interested in demonstrating the active (and often violent) role that large merchant companies played in the development of the world trading system and the colonial relationships that emerged from the seventeenth century forward. Bown's central focus is on the individuals and the companies that created the colonial world: Jan Pieterszoon Coen and the Dutch East India Company, Pieter Stuyvesant and the Dutch West India Company, Sir Robert Clive and the English East India Company, Aleksandr Baranov and the Russian American Company, Sir George Simpson and the Hudson's Bay Company, and Cecil John Rhodes and the British South Africa Company.

Bown opens his book with the story of the Dutch efforts in the early seventeenth century to push English and Portuguese traders out of the East Indies (Indonesia). The central actor of this story is an employee of the Dutch East India Company and an experienced naval admiral, Pieter Verhoeven. The narrative of Verhoeven's assault on the Moluccas is

a good place for Bown to begin, because it brings together the themes of armed violence and commercial interest that are the core of his book. Verhoeven's instructions from the board of directors of the Dutch East India Company were explicit:

We draw your special attention to the islands in which grow the cloves and nutmeg, and we instruct you to strive after winning them for the company either by treaty or by force. (10-11)

Bown draws out a story of global competition between nations and trading companies that illustrates the brutality and self-interestedness of colonialism throughout the three-century period he traces. And the chief victims of this violence are non-European peoples from Indonesia to Alaska to South Africa. What the book doesn't provide is what is so evident in Brenner's book -- a detailed understanding of the political and organizational relationships that underlay these military and commercial adventures.

Both books have something to add to our own efforts to understand big business in the twenty-first century. On the evidence offered here, business organizations -- corporations and companies -- have their own interests and agendas, and states have a great deal of difficulty in constraining them to the public good. This is obvious in the failures of large financial institutions to safeguard the interests of the public in 2008 -- the harmful conduct of finance capital, but it was equally evident in the behavior of the Dutch East India Company or Brenner's opening example, the Company of Merchant Adventurers. The hidden hand does not assure us that markets, commerce, and private interest will bring about the common good.

Marx on a global wage

Wednesday, December 01, 2010

What is the longterm tendency in the wage for relatively unskilled labor? In the United States we've been thinking about this problem in the past three decades in the context of "outsourcing" and the flight of manufacturing jobs to low-wage countries. Moderate- and high-wage industrial jobs have left the country in large numbers. In the 1970s and 1980s apparel manufacture largely left the US for Latin America and Asia, and in the 1990s and 2000s heavy manufacturing jobs (in the auto industry in particular) were widely perceived to have fled to Asia.

What are the effects of these global shifts in manufacturing for the wage in all countries? It turns out that Karl Marx had some remarkably prescient ideas about this question in the 1860s that still seem important today. Here are some markedly current observations from Marx's *Capital* (link) on the wage in a competitive international context:

A writer of the 18th century, often quoted already, the author of the "Essay on Trade and Commerce," only betrays the innermost secret soul of English capitalism, when he declares the historic mission of England to be ***the forcing down of English wages to the***

level of the French and the Dutch. [37] With other things he says naively: "But if our poor" (technical term for labourers) "will live luxuriously ... then labour must, of course, be dear.... When it is considered what luxuries the manufacturing populace consume, such as brandy, gin, tea, sugar, foreign fruit, strong beer, printed linens, snuff, tobacco, etc." [38] He quotes the work of a Northamptonshire manufacturer, who, with eyes squinting heavenward moans: "Labour is one-third cheaper in France than in England; for their poor work hard, and fare hard, as to their food and clothing. Their chief diet is bread, fruit, herbs, roots, and dried fish; for they very seldom eat flesh; and when wheat is dear, they eat very little bread." [39] "To which may be added," our essayist goes on, "that their drink is either water or other small liquors, so that they spend very little money.... These things are very difficult to be brought about; but they are not impracticable, since they have been effected both in France and in Holland." [40] (*Capital I*, chap. 24)
And the footnote amplifies:

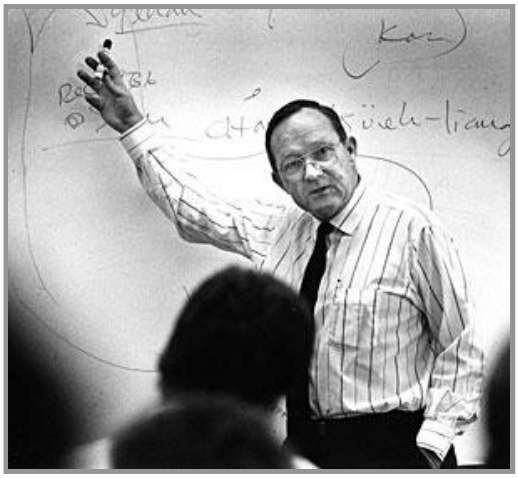
[40] Today, thanks to the competition on the world-market, established since then, we have advanced much further. "If China," says Mr. Stapleton, M.P., to his constituents, "should become a great manufacturing country, I do not see how the manufacturing population of Europe could sustain the contest without descending to the level of their competitors." (Times, Sept. 3, 1873, p. 8.) The wished-for goal of English capital is no longer Continental wages but Chinese.
In other words, Marx's view in 1867 was that there is an inevitable competitive pressure on British firms (high wages) to seek out manufacturing locations in other countries where labor costs are lower; and, of course, this movement brings competitive downward pressures on the domestic manufacturing wage. So the British manufacturing wage falls as low-wage European competitors (eventually Chinese competitors) are able to produce commodities at lower unit cost. This has a long-term global result: the unskilled manufacturing labor market becomes global, and the wage approaches a global equilibrium that is significantly lower than the present.

One thing is striking about this observation in 1867 is the reference to China. Mr. Stapleton's observations in 1873 were highly speculative; China was a century from becoming a great manufacturing country. But Marx's eye was focused on the long-term patterns; and he (and Mr. Stapleton) correctly noted the inherent logic of global competition for low-wage labor. The long-term result, apparently unavoidably, is that production processes that involve low-skill labor will be involved in a rapid race to the bottom, leading to an equilibrium wage across nations that is barely sufficient for subsistence.
Another major force operating on the level of the wage for unskilled labor that Marx emphasizes is the rapid introduction of technology and innovations enhancing labor productivity -- leading to a reduction in the demand for labor and putting more downward pressure on the wage. Writing after the American Civil War about English cotton manufacture, he writes:
The instrument of labour strikes down the labourer. This direct antagonism between the two comes out most strongly, whenever newly introduced machinery competes with handicrafts or manufactures, handed down from former times. But even in Modern Industry the continual improvement of machinery, and the development of the automatic system, has an analogous effect. "The object of improved machinery is to diminish manual labour, to provide for the performance of a process or the completion of a link in a manufacture by the aid of an iron instead of the human apparatus." [119] "The adaptation of power to machinery heretofore moved by hand, is almost of daily occurrence ... the minor improvements in machinery having for their object economy of power, the production of better work, the turning off more work in the same time, or in supplying the

place of a child, a female, or a man, are constant, and although sometimes apparently of no great moment, have somewhat important results." [120] "Whenever a process requires peculiar dexterity and steadiness of hand, it is withdrawn, as soon as possible, from the cunning workman, who is prone to irregularities of many kinds, and it is t)laced in charge of a peculiar mechanism, so self-regulating that a child can superintend it." [121] "On the automatic plan skilled labour gets progressively superseded." [122] "The effect of improvements in machinery, not merely in superseding the necessity for the employment of the same quantity of adult labour as before, in order to produce a given result, but in substituting one description of human labour for another, the less skilled for the more skilled, juvenile for adult, female for male, causes a fresh disturbance in the rate of wages." [123] "The effect of substituting the self-acting mule for the common mule, is to discharge the greater part of the men spinners, and to retain adolescents and children." [124] The extraordinary power of expansion of the factory system owing to accumulated practical experience, to the mechanical means at hand, and to constant technical progress, was proved to us by the giant strides of that system under the pressure of a shortened working-day. But who, in 1860, the Zenith year of the English cotton industry, would have dreamt of the galloping improvements in machinery, and the corresponding displacement of working people, called into being during the following 3 years, under the stimulus of the American Civil War? A couple of examples from the Reports of the Inspectors of Factories will suffice on this point. A Manchester manufacturer states: "We formerly had 75 carding engines, now we have 12, doing the same quantity of w***ork.... We are doing with fewer hands by 14, at a saving in wages of £10 a-week. Our estimated saving in waste is about 10% in the quantity of cotton consumed."*** "In another fine-spinning mill in Manchester, I was informed that through increased speed and the adoption of some self-acting processes, a reduction had been made, in number, of a fourth in one department, and of above half in another, and that the introduction of the combing machine in place of the second carding, had considerably reduced, the number of hands formerly employed in the carding-room." Another spinning-mill is estimated to effect a saving of labour of 10%. The Messrs. Gilmour, spinners at Manchester, state: "In our blowing-room department we consider our expense with new machinery is fully one-third less in wages and hands ... in the jack-frame and drawing-frame room, about one-third less in expense, and likewise one-third less in hands; in the spinningroom about one-third less in expenses. But this is not all; when our yarn goes to the manufacturers, it is so much better by the application of our new machinery, that they will produce a greater quantity of cloth, and cheaper than from the yarn produced by old machinery." [125] Mr. Redgrave further remarks in the same Report: "The reduction of hands against increased production is, in fact, constantly taking place, in woollen mills the reduction commenced some time since, and is continuing; a few days since, the master of a school in the neighbourhood of Rochdale said to me, that the great falling off in the girls' school is not only caused by the distress, but by the changes of machinery in the woollen mills, in consequence of which a reduction of 70 short-timers had taken place." [126]
(*Capital I*, Chapter 15)
The note is important as well:

[126] l. c., p. 109. The rapid improvement of machinery, during the crisis, allowed the English manufacturers, immediately after the termination of the American Civil War, and almost in no time, to glut the markets of the world again. Cloth,' during the last six months of 1866, was almost unsaleable. Thereupon began the consignment of goods to India and China, thus naturally making the glut more intense. At the beginning of 1867 the manufacturers resorted to their usual way out of the difficulty, viz., reducing wages 5 per cent. The workpeople resisted, and said that the only remedy was to work short time, 4 days a week; and their theory was the correct one. After holding out for some time, the

self-elected captains of industry had to make up their minds to short time, with reduced wages in some places, and in others without.



So is there any way out for the worker? Is there any scenario where ordinary working people can earn a moderate to high wage and corresponding standard of living? There is, through education and skill. The only way of maintaining a high wage for workers is on the basis of a given workforce possessing the ability to accomplish production tasks on the basis of non-generalized knowledge and skill. When labor is a commodity that is interchangeable in Karnataka, Guangdong, and Detroit, the wage will approach something like a low-level equilibrium. But when workers are able to add exceptional value to the process through their skills, talents, and knowledge, they will share in that productivity in the form of higher wages and a higher standard of living.

This observation converges with several themes already discussed in earlier postings: the attractiveness of the "high-skill" alternative to mass manufacturing that is highlighted by Chuck Sabel (link), and the current urgency that we should all feel about making sure that all young people have the opportunity to complete a tertiary degree (link).

Re-reading Chalmers Johnson

Thursday, December 02, 2010

Chalmers Johnson, one of the key contributors to Asian studies since the early 1960s, died on November 20, 2010. (Here are several notices -- link, link, link.) Johnson has been an important contributor to Asian studies since the appearance of his first book in 1962, Peasant Nationalism and Communist Power: The Emergence of Revolutionary China, 1937-1945, based on his doctoral dissertation at Berkeley. The book created a long debate about the causes of the Chinese revolution -- patriotism or class? -- which shed new light on the nature of Communist mobilization.

Johnson was a brilliant thinker who was exceptionally attuned to language -- both in his own writing and in the importance of making nuanced use of Chinese and Japanese sources in studying Asian history. And he was a figure who seemed to relish controversy, from this early debate about the Revolution to his focus on American empire in the past half dozen years (Dismantling the Empire: America's Last Best Hope).

Here is a posting on the debate about

Johnson's theory of peasant nationalism and current thinking about the Chinese Revolution that I provided for ChinaBeat.

Chalmers Johnson, co-founder and president of the Japan Policy Research Institute at the University of San Francisco and long-time professor of political science at the University of California, Berkeley and University of California, San Diego, died on November 20, 2010. (Here are several notices -- link, link, link.) In the past ten years or so Johnson has become widely known for his critical books about American empire (Blowback: The Costs and Consequences of American Empire (2004), The Sorrows of Empire: Militarism, Secrecy, and the End of the Republic (2005), Nemesis: The Last Days of the American Republic(2008), and Dismantling the Empire: America's Last Best Hope (2010)). The bulk of his career, however, was devoted to the study of China and Japan, and this posting examines one of his most notable contributions to these areas.

His earliest contribution to China studies was his 1962 book, Peasant Nationalism and Communist Power: The Emergence of Revolutionary China, 1937-1945. The core of the book was written as a Ph.D. dissertation at Berkeley, making use of archives of secret Japanese wartime materials collected by Robert Scalapino. (Johnson describes the origins of the book in "Peasant Nationalism Revisited: The Biography of a Book"; link.) The book was one of the early efforts to provide a more systematic explanation of the success of the Chinese Communist Party in mobilizing mass support during the Anti-Japanese War. The book became one of the linchpins of later debates about the Chinese Revolution. As a political scientist, Johnson was mindful of the inherent unlikelihood of a successful revolution anywhere, and this seemed particularly true in China in the 1920s and 1930s. Large-scale mobilization is inherently difficult to sustain, and local discontents rarely escalate to national scale. (Lucien Bianco made this point about China, writing in Peasants Without the Party: Grass-Roots Movements in Twentieth-Century China that "The essential difference between chronic peasant agitation and revolutionary action is that the latter is deliberately offensive in nature, whereas the former resembles the defensive reaction of a beleaguered organism. If peasant agitation was chronic ... , it was because the occasions for such conduct were endemic in rural China" (4).)

Johnson's book is based almost entirely on secret Japanese archives, and Johnson takes special care to attempt to validate these sources as legitimate indications of the nature of events in China during these war years. He believed that the fact that these documents were "secret" gave them an evidentiary status they would lack if they had been produced for the sake of propaganda or political influence by the army or other officials; but rather than representing an effort to spin events in one direction or another, they were intended as "realistic appraisal of military and political developments in China by Japanese leaders" (x). So Johnson is emphatic in arguing that these secret wartime archives provide a valid window of knowledge into both Japanese and Chinese strategies and actions.

So what structural or institutional factor was present in China that permitted mass mobilization by the Communist Party during this period? According to Johnson, it was nationalist identity and a patriotic desire to resist the Japanese invaders on the part of millions of rural Chinese people. The Communist Party was able to offer itself as the most effective force available to achieve the patriotic goals of defeating the Japanese and restoring China's peace and security. The central thesis of the book, then, and the element that generated the greatest controversy, is Johnson's view that the Communists succeeded in the crucial period because they mobilized a mass following around patriotic resistance to the Japanese invaders.

On the basis of a study of wartime resistance in China, the view advanced here is that the Communist rise to power in China should be understood as a species of nationalist movement. (ix)

It is the thesis of this study that the rise to power of the CCP and YCP [Yugoslav Communist Party] in collaboration with the peasantry of the two countries can best be understood as a species of nationalism. (19-20)

Johnson's definition of nationalism is what he labels "functionalist". What he means by this, however, is not a Mertonian "structural-functional" analysis; rather, it is closer to a behavioral-causal analysis. "This study employs a functional definition of nationalism -- in other words, one which identifies specific physical pressures that by acting upon given political environments give rise to nationalist movements" (ix). He draws largely from Karl Deutsch's Nationalism And Social Communication: An Inquiry Into The Foundations of Nationality (1953) in laying out a definition of nationalism and mass mobilization. Johnson identifies social mobilization of the masses around a national myth as the heart of modern nationalism. This is what nationalism is, according to Johnson; and the causes that brought it about in China were Japanese invasion and subsequent harsh treatment of rural people, and skillful mobilization of the countryside by Communist political officers in enhancing a sense of shared cause.

In essence, the Party is seen as the leader of a war-energized, radical nationalist movement.... The Chinese masses, the peasants, were unified and politicized as a concomitant of the drastic restructuring of Chinese life that accompanied the Japanese conquest of north and east China.... This wartime awakening became the basis for a new order in China following Japan's collapse. (ix-x)

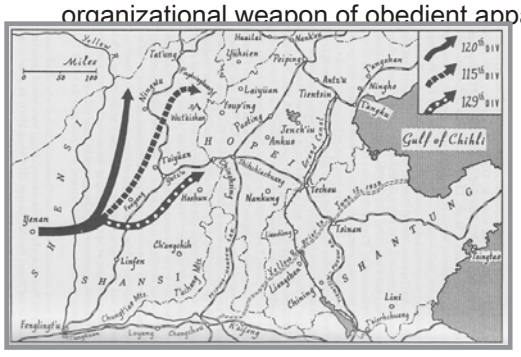
Since patriotic nationalist mobilization is primary, then radical mobilization around peasant interests must be secondary. So Johnson is particularly concerned to refute the idea that it was economic issues and class exploitation that led to peasant support. (Mark Selden's The Yenan Way in Revolutionary China (1971) was a central advocate of this position.) Johnson expressly rejects the idea that the Communist Party's overall strategy depended on a class appeal to poor peasants during these years. One key argument to this conclusion is the markedly different fortunes of the Communist movement in China in the 1920s versus the wartime years. The Communist movement in the 1920s was plainly based on a mobilization strategy around revolution and social change, and, according to Johnson, it failed in achieving mass following. The Japanese invasion and subsequent brutality in attempting to govern the rural areas, however, coincided with a massive increase in the movement's following in the countryside; and, according to Johnson, the mobilization rhetoric of Communist leaders of that period was about patriotic self-defense rather than social upheaval.

Although the Communists were in effective control of various small enclaves in the Chinese countryside from 1927 on, their painful efforts during that period to set up rural "soviets" were incomparably less successful than their activities during the blackest period of the Sino-Japanese War. (1)

During the Anti-Japanese War period the Party abandoned the radical land program altogether and carried out a policy designed to create maximum unity for national defense. All plans for agrarian reform were abrogated during the war while a mild policy of rent reduction and general rationalization of debts was carried out. (19)

Later historians have largely taken a critical view of this central theoretical argument. Some historians -- notably Donald Gillin in a 1964 review in the *Journal of Asian Studies* (link) -- have argued compellingly that Johnson mis-estimates the importance and persistence of class strategies during the period. (Johnson had harsh words for Gillin in his retrospective article in *China Quarterly* (link).)

Probably the most consistent line of response to Johnson's peasant nationalism theory in the intervening years is that it is too comprehensive and couched at too high a level. The concept of nationalism paints too broad a brush when applied to tens of millions of



Chinese rural people in many different settings. Conditions varied across the many base areas where the CCP held power, and subsequent historians have concluded that patriotism and village self-defense played a highly variable role across China. As Odoric Wou writes, "In a recent article, Tony Saich called our attention to the fact that the Chinese Communist revolution was a series of 'local revolutions.' Unless we go deeply into the localities, carefully examining the social structure and networks, patterns of elite dominance, and local politics of these communities, it is not likely that we can obtain a clear picture of the actual process and dynamics of the Communist base building and the reasons behind the success in its revolutionary mobilization" (link).

Subsequent historians such as Chen Yung-fa (Making Revolution: The Communist Movement in Eastern and Central China, 1937-1945), Odoric Wou (Mobilizing the Masses: Building Revolution in Henan), Pauline Keating (Two Revolutions: Village Reconstruction and the Cooperative Movement in Northern Shaanxi, 1934-1945), and others have argued instead for a more differentiated and local approach to the success of Communist mobilization in the 1937-1949 period. Tony Saich summarizes much of this consensus in these terms:

Writing on the Chinese revolution has always attracted proponents of the "Grand Theory." This is not surprising, for the revolution itself was on a grand scale in both time and space. New research has made the field more hesitant to put forward bold ideas to encapsulate the majestic sweep of the revolution and has contented itself with compiling details and hammering away at previously held explanations. The debate between those who argued that the Communist success was primarily a result of its nationalist appeal in the anti-Japanese war and those who stressed the CCP's capacity to mobilize the peasantry through its socio-economic programmes, while stimulating, has been left behind by recent research. There is now an infinitely more complex picture of the Party's policies and its relationship to the different social forces in China than was possible previously. (link)

Joseph Esherick puts some of the current understanding of the Chinese Revolution into a series of theses (link), and several are particularly important in the context of Chalmers Johnson's argument:

1. The triumph of the CCP was the product of a series of contingent events.
2. The revolution was produced by a conjuncture of domestic and global historical processes among which the worldwide depression and Japanese imperialism were particularly important.
3. The larger structures of China's state and society did not make revolution inevitable, but they imposed significant constraints on the agents of revolution and counterrevolution.
4. The CCP was a social construct of considerable internal complexity, not an organizational weapon of obedient apparatchiks commanded by the Party Center.

So the nationalist hypothesis has not prevailed as a comprehensive explanation of Communist success at mobilizing revolution. In fact, even the project of providing a single theoretical framework for explaining this success has largely been abandoned.

What is not often recognized, however, is the fact that *Peasant Nationalism* also contains a substantial empirical historical core that is valuable whether or not we accept the overriding nationalism interpretation.

First, Johnson provides a detailed accounting of Japanese military-political strategies and

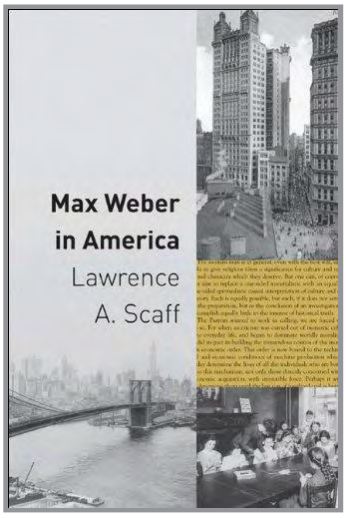
failures that could not have been conceived of without Johnson's deep and extended immersion in the Japanese secret archives. He makes sense of the very complex and confusing story of Japanese invasion and occupation of north and east China, with multiple military commands and a difference of opinion within high leadership about the best way of defeating Communist opposition.

Equally interesting and important is his lengthy narrative of Communist military and political strategies during the period. This narrative takes up almost half the book, and it is still one of the most detailed and clear expositions of this complex story. (There is also some detail on Guomindang strategies as well.) Johnson pieces together the complicated military movements of Communist armies in north and central China in a masterful way.

In short, Johnson's narrative of military and political developments of the Anti-Japanese War is an important permanent contribution.

So we might say that the theoretical framework of the book has run its course; whereas the empirical and historical findings continue to be an important source of knowledge about the period. And in an ironic way, this suits rather well Johnson's later polemics against rational choice theory and his insistence on the primacy of close, factual research in area studies. (These arguments are found in "A Disaster in the Making: Rational Choice and Asian Studies" (with E.B. Keehn) (link) and "Preconception vs. Observation, or the Contributions of Rational Choice Theory and Area Studies to Contemporary Political Science" (link).) Here is how he characterizes these issues in a 2005 interview with Hidenori Ijiri:

What we mean by areas studies, however, it seems to me, is simply empirical, inductive research about other cultures. Not research that is theoretically driven but driven by knowledge of the culture and a proficiency in the language. In that sense, it is mor einthe classical anthropological mode of trying to understand a culture that is alien to you by personally, inductively getting inside of it, reading the main classics in the field, being able to talk with felllow scholars in the area, and in some cases, doing field research in a particular topic for which your research may very well have theoretical implications. But such research was not driven by a theoretical issue at first. (link)



The more serious challenge to area studies -- one that I have been deeply involved in fighting against and that has affected above all my own field of political science -- is the influence of mathematical economics. The charge is that area studies are un-theoretical, that they do not partake of grand systems of theory. Moreover it is argued that the amount of time spent learning a language like Chinese or Japanese is a waste of time. According to this fad, what a good scholar needs is an education in abstract theory. If he understands theory he can study any place.... Today, political science departments have very elaborate models, often mathematical, and formal ones from which you can supposedly deduce outcomes.... A political science Ph.D. today has been increasingly defined in terms of an ability in rational choice theory, game theory, the manipulation of economic models, and the formal creation of models in which the mode of analysis is deductive rather than inductive. (link)

The central point here is that theory can only be a support for concrete historical and social research, not a substitute. But this is no less true in the study of Communist mobilization in China than in Japanese technology policies. And perhaps there is a larger point here as well: Chalmers Johnson did a great job of "area studies" in his Peasant Nationalism and Communist Power: The Emergence of Revolutionary China, 1937-1945, ***in spite of*** his adherence to the single theoretical framework of nationalism.

Weber in America

Saturday, December 04, 2010

Lawrence Scaff offered a fascinating preview of his forthcoming book, Max Weber in America, at a sociology seminar in Ann Arbor this week. Scaff has written extensively on Weber in the past, and this current research is particularly intriguing and stimulating. The book offers a careful reconstruction of Weber's visit to the United States in 1904, and it then goes on to provide a brilliant interpretation of the "discovery" of Weber in the United States in the 1940s and forward.

Let's start with the obvious: it is startling for those of us who are not Weber experts to learn that Weber spent time in the United States at all. It's weirdly dissonant for me to imagine this quintessentially German sociologist, wandering the streets of Chicago and the plains of Oklahoma. What did he make of Chicago 1904? How did it influence his development as a sociological thinker?

It's even more eye-opening to learn that Weber met W. E. B. Dubois during his visit, and may have shifted some of his later thinking in fairly important ways as a result of his exposure to some of Dubois' ideas about race in America. (Dubois' The Souls of Black Folk appeared in 1903.)

Scaff also writes quite a bit about the intellectual connections between Weber and William James during this period. He explores important parallels between The Varieties of Religious Experience: A Study in Human Nature and The Protestant Ethic and the Spirit of Capitalism. This is significant, because the first part of *The Protestant Ethic* was written and presented for publication just before the trip to America, whereas the second part was written after the visit.

Scaff seems to have done a great job of piecing together archival materials to arrive at a new telling of the story of the trip to America with Marianne. So this addition to the biography of Weber is of great value all by itself. (Marianne Weber's biography of Max provides only limited information about the trip; Max Weber.)

But even more important is the effort that Scaff makes to get inside the developing sociological imagination of the thinker. This is what is most intriguing about the book, and what makes me most eager to read it when it appears in early winter.

Scaff makes a point that I find really intriguing about the way in which "Weber" was constructed as the founding sociologist we now summarize in courses on sociological theory. This falls generally into the topic of the sociology of knowledge: how did concrete historical and institutional processes influence the construction of "sociology" or "physics"? Scaff argues that much of our current representation of Weber derives, not from Weber directly, but from the ways in which Weber was appropriated and "re-broadcast" by American sociologists in the 1940s and 1950s, including especially Talcott Parsons. (Ironically, Scaff argues that the "Weber" who became important in German sociology in the 1960s was this American version, not a systematic re-reading and re-thinking of Weber's corpus. Weber was more or less forgotten in German intellectual circles during the Nazi period.) So this standardized version of Weber's sociology reduces the rich sociological thought of the thinker over a long career to a few standard

theses.

One of Scaff's goals, then, is to "blow up" the sociology expressed across Weber's writings and try to see how the parts might be fitted together in other ways. Can the canonical Weber be interpreted in significantly different and more nuanced ways? This is a particularly interesting and fertile question, and it contributes directly to the important project of trying to rethink the making of modern sociological imagination and frameworks.

Several members of the Ann Arbor seminar commented on the fact that there are some parallels between Weber's interpretation of the "American difference" (chiefly a higher level of civic involvement than in Germany) and the main lines of Tocqueville's observations of America in Democracy in America. Scaff shared that two things are known about this question -- first, that Weber never refers to Tocqueville anywhere in his corpus; and second, that he read *Democracy in America* in French at some point, since an edition of the book annotated in his hand is contained in his book collection in Heidelberg. (Klaus Offe comments on this parallel in Reflections on America: Tocqueville, Weber and Adorno in the United States, based on the Adorno Lecture that he presented in Frankfurt in 2003. Here is a limited Google Books view (link).)

This is all really important material for those of us who are interested in the contingent development of modern sociology. So Scaff's book is one that I'm eagerly anticipating when it appears in January.

Here is the table of contents for the book.

MAX WEBER IN AMERICA

Lawrence A. Scaff

Contents
List of Illustrations
Preface
Introduction

Part I. The American Journey

Chapter 1 Thoughts about America
Traveling to Progressive America
The Horizons of Thought
A “Spiritualist” Construction of the Modern Economy?

Chapter 2 The Land of Immigrants
Arriving in New York
Church and Sect, Status and Class
Settlements and Urban Space

Chapter 3 Capitalism
The City as Phantasmagori
Hull House, the Stockyards, and the Working Class
Character as Social Capital

Chapter 4 Science and World Culture
The St. Louis Congress: Unity of the Sciences?
The Last Time for a Free and Great Development: American Exceptionalism?
The Politics of the Arts and Crafts
Gender, Education and Authority

Chapter 5 Remnants of Romanticism
The Lure of the Frontier
The Problems of Indian Territory
Nature, Traditionalism, and the New World
The Significance of the Frontier

Chapter 6 The Color Line
Du Bois and the Study of Race
The Lessons of Tuskegee
Race and Ethnicity, Class and Caste

Chapter 7 Different Ways of Life
Colonial Children
Nothing Remains except Eternal Change
Ecological Interlude
Inner Life and Public World
The Cool Objectivity of Sociation

Chapter 8 The Protestant Ethic
Spirit and World
William James and His Circle
Ideas and Experience

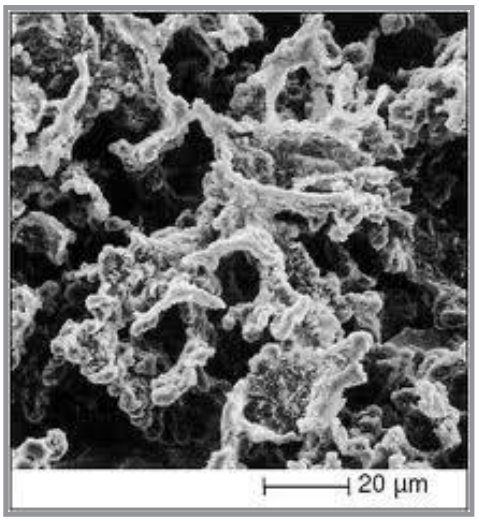
Chapter 9 American Modernity
Strange Contradictions
Becoming American
Cultural Pluralism

Chapter 10 Interpretation of the Experience
The Discourse about America
A Way Out of the Iron Cage?
America in the Work

Part II. The Work in America

Chapter 11 The Discovery of the Author
Author and Audience
Networks of Scholars
Translation History
The Disciplines

Chapter 12 The Creation of the Sacred Text
An American in Heidelberg
Parsons Translates “The Protestant Ethic and the ‘Spirit’ of Capitalism”



Chapter 13 The Invention of the Theory
Gerth and Mills Publish a Weber “Source Book”
Parsons’ “Theory of Social and Economic Organization”
Weber Among the Emigrés
Weberian Sociology and Social Theory
Weber Beyond Weberian Sociology

Appendix I: The Webers’ Itinerary
Appendix II: Selected Correspondence with Americans, 1904-1905
Bibliographic Notes
Index

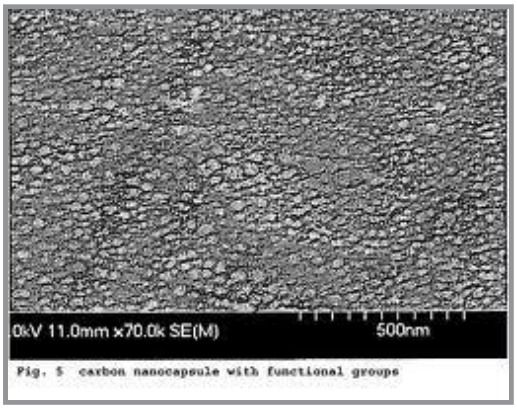
Granularity



Monday, December 06, 2010

If we think back over the history of sociology and political science since 1800, one thing that is striking is the trend away from the most macro-level frameworks of thought in the direction of more situated and proximate social and political arrangements. There was a tendency among the founders -- Montesquieu, Spenser, Comte, for example -- to pose their questions at the civilizational level. The largest social constructs were identified as worthy of study -- religions, kinds of governments, cultures. By the time we get to writers like Tocqueville and John Stuart Mill in mid-nineteenth century, we have thinkers approaching modern social life with a more limited gaze. They are more interested in particular, differentiating social and political arrangements, and they are interested in the particulars of human behavior within those arrangements. And they are much more interested in the empirical details, rather than general philosophical theories of democracy or religion.

Twentieth century thinking in the social sciences has generally continued this trend. What makes social science "scientific" is rigorous attention to empirical characteristics of the social world. There is generally even less patience with large philosophical theories of society and history. A good theory isn't of much interest unless it can be closely tied to particular bodies of empirical observation. It is hard to think of a 20th-century sociologist who took up the Comtean project of comparing the course of civilizations. And there is a growing consensus that the focus of social research needs somehow to capture the behavior of situated actors within socially specific arrangements -- in other words, a refinement of focus towards the more particular arrangements.

Pig. 5 carbon nanocapsule with functional groups

A partial exception to this trend is the field of comparative politics (Lichbach and Zuckerman, eds., Comparative Politics: Rationality, Culture, and Structure). This is a paradigm that undertakes to discover similarities and differences in large political institutions across settings -- with the implication that there is some reason to expect that "developmental states" will have some important similarities whether in Brazil, Nigeria, or Syria. How does "electoral competition" work in the United States, Mexico, and Poland? Hw do anti-corruption regimes work in Indonesia, Singapore, and Hong Kong? Comparative politics specialists have accepted the need for careful empirical investigation, to be sure, and they are mindful of differences as well as similarities. But the field is more macro than many other areas of contemporary social science.

Another exception seems to be "world systems theory", which locates social-historical analysis at the global level. But as argued earlier (link), Wallerstein was in fact sensitive to historically specific "granularities" within the world system. Here's what I concluded there:

But Wallerstein's practice as a sociologist is far more defensible than this language would suggest. He was in fact sensitive to causal heterogeneity, contingency, and variation in the systemic relations he meant to capture -- particularity as well as universality. So he doesn't actually treat the modern world system as if it were analogous to a set of gravitational objects governed by fixed laws of nature.

So we might say that two of the large features of modern social science research paradigms are these: the conviction that a researcher needs to formulate questions that permit careful empirical observation and assessment; and the idea that the scope of research should be tailored to capture social behavior and organization at an intermediate level. We need to formulate research questions that capture enough social behavior to be interesting, while at the same time permitting careful, rigorous empirical investigation and assessment.

This is where the metaphor of granularity comes in. It suggests the idea of a deliberate choice of levels of analysis, a deliberate selection of the zone of focus we choose for the investigation. Go too fine and you lose sight of the structures that will turn out to be interesting. Go too gross and, once again, those structures disappear. Then there is the important idea of heterogeneity -- the idea that stuff is not uniform in structure all the way down (link); so it matters what level we choose to focus on.

The scanning electron microscope image above (center) is illustrative of this fact with regard to the natural world. Carbon appears uniform at a gross level (anthracite), and it is also uniform at an atomic level. But there is an intermediate level of resolution where there are structures that are very important for the physical properties of the stuff; and we won't find these structures unless we look at this intermediate level.

Something very much like this seems to be true about the social realm as well. If we ask questions about "citizens" or "consumers", we have characterized the actor in a highly abstract way, with no indication or recognition of the more specific circumstances in which the actor conducts his/her life. If we provide more institutional, organizational, and

motivational context, however -- that is, if we increase the level of resolution in our depiction of the social actor -- we are likely to find more illuminating features of behavior, and we are likely to find discriminating explanations for differences in behavior.

Perhaps an illustration is found in the kinds of social action that Erving Goffman investigates -- the stylized behaviors and interactions of restaurant workers, for example (link). Go too deeply into the personal stories of the persons involved and you lose what is distinctive about the social context of the restaurant. Aggregate facts about service workers everywhere, and once again, the distinctive behaviors disappear. And, if we abstract too severely from the specifics of the social setting of the restaurant worker -- that is, if we zoom our microscope out to the level of pure rational choice theory -- then we will overlook the differentiating social circumstances that influence behavior in real hotels and restaurants.

We might say that all of this is pointing towards a certain kind of sociological research that focuses on the proximate social settings within which people act and interact. This takes us towards what I call methodological localism (link). But it also conforms to the sociological frameworks of the new institutionalism (link, link) and even with the emerging emphasis on explanations based on social causal mechanisms (link).

In seeking out the concept of granularity here, I've actually invoked several different contrasts: abstract to concrete, apriori to empirical, and macroscopic to microscopic. If we put all these together, we might say that a "granular" approach to a social phenomenon is one that achieves a degree of specificity in conceptual definition, a robust degree of empirical detail, and an intermediate analytical and representational perspective that permits discovery of the mid-sized structures that influence the behavior of the whole.

(This issue has come up previously under the topic of "macro, meso, micro" (link).)

India's Naxalites

Sunday, December 12, 2010

India is the world's largest democracy. It also is home to one of the more persistent and deadly Maoist insurgencies in the world, the Naxalite movement in eastern India (Communist Party of India (Maoist) (CPI/M)). The Naxalites were a splinter group that separated from India's Communist Party in the 1960s, and their hallmarks have been a commitment to violent revolution and a determined effort at mobilizing India's most disadvantaged rural people. Here is a review article about the movement from *The Economist* in 2006 and a review in the *New York Times* in 2009, and here are several updates from *The Economist* (link, link, link). (*The Hindu* provides frequent coverage of the Naxalite insurgency; for example, here.)

The 2006 *Economist* article was occasioned by a deadly attack against a police camp by Naxal guerillas in Chhattisgarh State. The attack signalled the fact that this movement

continued to possess organization, followers, and deadly intent. This map (reproduced from the Wikipedia article on the Naxalites) indicates the regions where the Naxalites currently have organizational presence; it is a large swath of rural India. Estimates of the number of active fighters range from 14,000 to 20,000, with several times these numbers of local supporters and militias.

Naxalite attacks have continued since 2006. Here is a chronology of attacks since 2006 compiled by NDTV (link). Particularly widely noted in the world press was an April 2010 attack against Central Reserve Police Force, killing 75 police personnel, also in the forests of Chhattisgarh (link). And the insurgency appears to be growing; in 2009 just under 1000 people were killed in Naxalite attacks -- almost triple the 2008 figures.

The leadership of CPI(M) has focused its mobilization efforts almost exclusively at the poorest of the poor and the most disadvantaged people within the caste system; and they have had particular success among tribal people living in India's forests. But extending back to the 1960s the movement also has had some appeal to educated elites in cities and universities -- people on the left who believe that India has made no serious efforts to ameliorate poverty or caste.

What is surprising about this 40-year history is the fact that a violent revolutionary movement has managed to survive and conduct operations within the interstices of a democratic India. Atul Kohli provided some context for this question in his 1991 Democracy and Discontent: India's Growing Crisis of Governability. Here is how Kohli summarized his assessment twenty years ago:

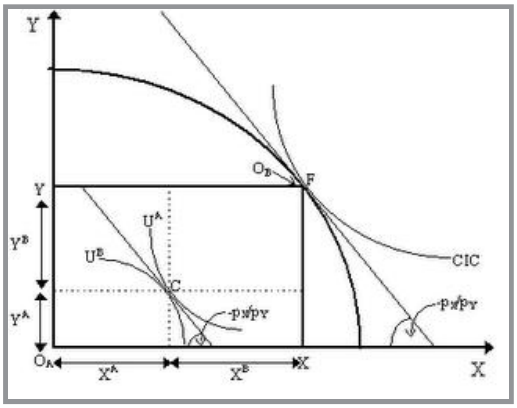
India is still, of course, a functioning democracy, but increasingly it is not well governed. The evidence of eroding political order is everywhere. Personal rule has replaced party rule at all levels -- national, state, and district. Below the rulers, the entrenched civil and police service have been politicized. Various social groups have pressed new and ever more diverse political demands in demonstrations that often have led to violence. The omnipresent but feeble state, in turn, has vacillated; its responses have varied over a wide range: indifference, sporadic concessions, and repression. Such vacillation has fueled further opposition. The ineffectiveness of repression, moreover, has highlighted the breakdown of the civil machinery intended to enforce the law and maintain order. Inorder to protect themselves, citizens in some parts of the country have begun organizing private armies. The growing political violence has periodically brought the

armed forces into India's political arena, whereas the armed forces were considered apolitical. (3)
The main national parties in India, Congress and the Hindu nationalist Bharatiya Janata Party (BJP), have contested for control of the national government. But India's states have consistently demonstrated a wider range of parties and politics. West Bengal has been governed for decades by the Communist Party Marxist (CPM). Kerala has been governed through left-coalitions including the Communist Party of India (Marxist) (CPI(M)). Both these parties have renounced revolutionary violence and pursue a poverty-oriented set of economic and political policies. Other states are governed by right and center-right coalitions, with a rhetoric that is much more focused on Hindu nationalism and pro-market ideology.

Kohli's study of governability focuses on West Bengal, Gujarat, and Bihar, and his goal is to identify some of the political and social processes that have led to a national and regional governability crisis. Kohli finds substantial inter-state variability in governability across the three states he studies.

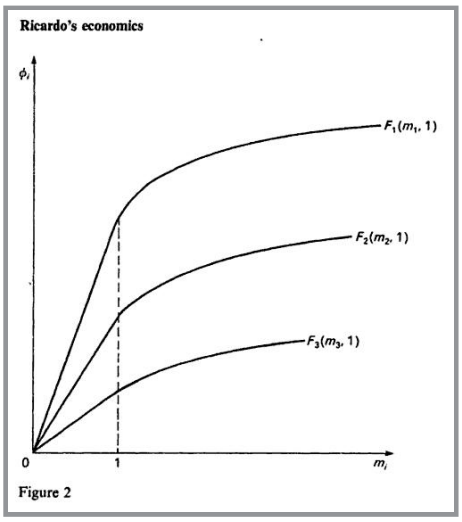
The situation of total breakdown of order in Bihar, for example, has resulted from corrosion of the authority vested in the social structure and absence of cohesion in political structures. Increasing power struggles in the society and a highly factionalized elite have provided a combustible political mixture that ignites periodically, and in Bihar even the forces of repression are ineffective. Political violence in Gujarat has had a more purposive quality than in Bihar. It results not primarily from a breakdown of social order but from the calculated mobilization strategies employed by competing elites.

In contrast to the situations of these two states, the case of West Bengal demonstrates how the presence of a cohesive party can bring stability even in a highly mobilized political environment: Strong leaders and disciplined ruling parties -- forces that can impart a degree of cohesion to state structures -- can help moderate the impact of corrosion of authority in the social structure. The emergence of incoherence in both state and social structures, however, is a sure recipe for a breakdown of order. (15)
So how is it possible for a violent rural insurgency to survive and grow in a modern democracy? There seem to be several primary factors. One is the familiar fact that insurgents establish their bases of operations in remote, lightly-policed regions. The Naxalite movement has managed to secure its "base areas" in forests and other poorly developed rural areas.



(The Hindu) A second factor is the fact that Indian rural society is generally only lightly policed by professional police forces. India is a "weak state" when it comes to local presence in the countryside. The local presence of police is very thin on the ground, and easily overrun by trained guerillas. Third, the Naxalites direct their mobilization efforts to the most disadvantaged and disaffected segments of rural Indian society; so their anti-state message is relatively well received. And, finally, it would appear that the ideology of class and class antagonism has its own resonance in Indian political culture, far beyond the violent extremism of the Naxalite party. This movement was a splinter from the Communist Party of India (Marxist) (CPM), which now governs West Bengal on the basis of its electoral successes (at least up until the present). But CPM rhetoric sounds many of the same themes of anti-capitalism and anti-globalization that the Naxalites advocate. So it is possible for elements of the left to become frustrated with the electoral program of CPM and develop new resonance with the radical program of the Naxalites.

The consensus view seems to be that the national and state governments in India have



failed in efforts to suppress the Naxalite insurgency to date out of a failure of will, a degree of conflict of political interests in several states, and a failure to arrive at a winning strategy of police and military force combined with significantly more successful delivery of rural development successes. Villages that lack roads, clean water, education, and health clinics are certainly more likely to find a radical program of change more appealing, and India's states have had little success in improving the quality of life for India's poorest rural people.

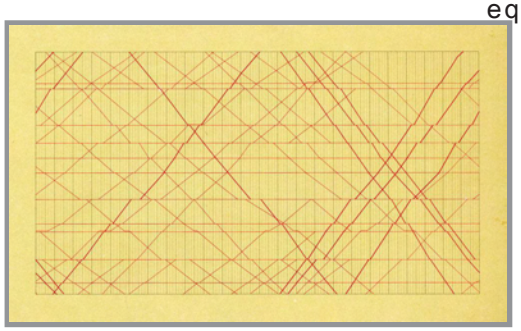
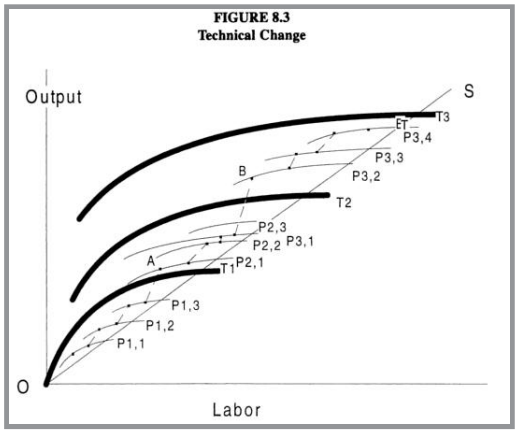
Diagrams and economic thought



Monday, December 13, 2010



source: The Paretian System (link)
The most vivid part of any undergraduate student's study of economics is probably the diagrams. Economists since Walras, Pareto, and Marshall have found it useful to express their theories and hypotheses making use of two-axis diagrams, allowing for very economical formulation of fundamental relationships. Supply-demand curves, production functions, and a graph of diminishing marginal product all provide a way of making geometrical sense of a given economic principle or hypothesis. They allow us to visualize the relationships that are postulated among a set of factors.

Mark Blaug has made a long and fruitful career out of his remarkable ability of placing economic thought into its context (Economic Theory in Retrospect (1962), The Methodology of Economics: Or, How Economists Explain (1992)). Now he has collaborated with Peter Lloyd to produce Famous Figures and Diagrams in Economics (2010), and the book is a marvelous contribution.

The book is organized into several large sections: Demand and supply curve analysis; Welfare economics; Special markets; General equilibrium analysis; Open economies; Macroeconomic analysis; and Growth and income distribution. Experts have been recruited to write short, technical but accessible essays on some 58 topics, including discussion of about 150 diagrams. The figures that the book considers pretty much reproduce the history of modern economic thought. And, indeed, some figures have been repeatedly rediscovered; Blaug attributes the "Marshallian cross" to Cournot (1838), Rau (1841), Dupuit (1844), Mangodt (1863), and Jenkin (1870). Almost

all the examples are drawn from the history of orthodox neo-classical economics; rare exceptions are Joan Robinson's "graph of discrimination" and August Losch's "market areas". The main insights of classical economics are equally amenable to presentation through diagrams, so it is interesting that the classical economists (including Marx) were not particularly inclined to use them. Here is a diagram not included in the book, representing Michio Morishima's effort to express some of Ricardo's central economic intuitions:

source: Michio Morishima, Ricardo's Economics: A General Equilibrium Theory of Distribution and Growth, p. 38

It is worth thinking a bit about what a diagram is, from a cognitive point of view. To start, it is not a data graph; a diagram does not generally provide a summary of actual economic variables over time, such as unemployment. But generally an economic diagram is not simply a graph of a given mathematical function either, plotting the value of a function over part of the domain of the independent variable. We need more than a graphing calculator to create a useful economic diagram.

Rather, an economic diagram is a stylized representation of the behavior and interaction of (often) several variables in a range of interest. Take the most fundamental diagram of neoclassical economics, the supply-demand diagram. We are asked to consider "supply" and "demand" over a range of "price". One curve represents the quantity of the good that will be produced at a low price through high price; the other curve represents the quantity of the good that will be purchased at the range of prices. The intersection of the curves is the point of interest; it is the equilibrium at which quantity demanded equals quantity supplied. The shape of the curve is significant; a straight line represents the view that supply and demand are linear with respect to price, whereas a curved line represents a non-linear relation between quantity and price. (Each increment in price stimulates a smaller change in quantity.)

Here are some of the uses of diagrams in economics that Blaug and Lloyd mention in their introduction:

Figures and diagrams have been used in economic theory in several ways. They have been used as a device to discover economic results; theorems or properties of models; or comparative static propositions and dynamic propositions. They have been used to prove some results. And they have been used as an expository device. (5)

They go on to quote Marshall:

It happens with a few unimportant exceptions all the results which have been obtained by the application of mathematical methods to pure economic theory can be obtained independently by the method of diagrams. Diagrams represent simultaneously to the eye the chief forces which are at work, laid out, as it were, in a map; and thereby suggest results to which attention has not been directed by the use of methods of mathematical analysis. (5)

We might imagine that economic diagrams are purely mathematical constructs, and we might suppose that we have little choice in the way that a diagram is constructed. But Edward Tufte has quite a bit to say on this subject in a series of books beginning with The Visual Display of Quantitative Information. Essentially Tufte's message is that quantitative ideas can be conveyed in better and worse ways, and that much of the communication we do about quantities is misleading. Conveying a quantitative relationship through a diagram can be done more or less insightfully; it is up to the

economist to find a concise way of representing the relationships he/she is interested in exploring.

source: EJ Marey's train schedule, Paris to Lyons, in Edward Tufte, The Visual Display of Quantitative Information

Blaug and Lloyd take some note of the "presentation aesthetics" of economic diagrams when they discuss modern methods of presentation:

In many areas of economic theory, the way in which economists understand economic concepts and propositions is through figures and diagrams. What teacher of economic theory has not seen the dawn of understanding come over students when, failing to understand an exposition of some complex model in algebra or calculus, they are presented with a simple illustration? ...

One can comprehend relationships among a number of variables (as in the box diagrams) or the effects of shifting curves or multiple equilibria more readily than in the corresponding algebra. This advantage has been increased by modern technologies. Textbooks today use multi-coloured diagrams to great effect and the delivery of diagrams in classroom from computer-based programs allow overlays and other graphical techniques that aid the exposition of complex ideas. (8-9)

One of my favorite economic diagrams is the one introduced by Mark Elvin to represent his theory of a high-level equilibrium trap in agricultural development in The Pattern of the Chinese Past.

This diagram represents several different kinds of historical change in one compact figure: gradual technical progress along a production curve, shift of production curves through technical innovation, and the maximum production possibility curve that lies above each of these. The axes represent "total output" and "rural population." The concave shape of each curve has a very specific economic and demographic meaning: as population grows within a given mix of techniques, output grows more slowly; so average output per capita approaches the subsistence line OS. The HLET is graphically and laconically indicated on the upper right quadrant of the graph; there is no further room for technical improvement, and population has increased to the point where there is no surplus to fund radical technological innovation. (Elvin's theory of the high-level equilibrium trap is discussed in my Microfoundations, Methods, and Causation; link.)

Hate as a social demographic

Saturday, December 18, 2010

Every democracy I can think of has a meaningful (though usually small) proportion of citizens who fall on the extreme right by any standard: racist, White supremacist, hateful, anti-immigrant, anti-Semitic, anti-Muslim, nativist, nationalist, or violently anti-government individuals and groups. In the United States we have many, many organizations that are basically racist and potentially violent hate groups. They provide a basis for cultivating, recruiting and mobilizing like-minded followers, and they are sometimes co-opted by opportunistic politicians for their own narrow purposes. The Southern Poverty Law Center (link) and the Anti-Defamation League (link) do a great job and a needed service in tracking many of these organizations. (For example, SPL

monitors 26 hate groups in the state of Michigan; link.) The umbrella term for these organizations and individuals is "hate groups" -- individuals and organizations who organize their views of the social world around intolerance of other groups and a motivation to harm or subordinate those other people.

A recent report by the Institute for Research and Education on Human Rights (link) provides a detailed snapshot of how some of these racist groups have shown up in the Tea Party movement (link). The NAACP made a very careful statement about racist statements and provocations that had occurred at Tea Party protests in 2009 and 2010 (link), including the egregious incident that occurred in Washington in which Representatives Emanuel Cleaver, John Lewis, and Barney Frank were showered with vitriol. And this temperate and careful statement was derided by Tea Party leaders. The IREHR study goes a long way to document the concerns raised in the NAACP statement.

The maps of Tea Party membership are genuinely interesting. Here is an aggregate map including six factions of Tea Party organizations around the country (p. 14):

Here is a summary finding from the IREHR report:

Tea Party organizations have given platforms to anti-Semites, racists, and bigots. Further, hard-core white nationalists have been attracted to these protests, looking for potential recruits and hoping to push these (white) protestors towards a more self-conscious and ideological white supremacy. One temperature gauge of these events is the fact that longtime national socialist David Duke is hoping to find money and support enough in the Tea Party ranks to launch yet another electoral campaign in the 2012 Republican primaries. (7)

What I find really worth considering is the question of the fact of the very existence of these pockets of virulent racists and anti-semites in our society. I'm not thinking here of garden-variety racial stereotyping and prejudice, which is surely much more widespread, but of a kind of racism that extends to overt hostility and sometimes violence against the other group. It is hard to estimate the percentage of our society that falls in this category, though there are some public opinion surveys that help us make a crude estimate (Howard Schuman, Charlotte Steeh, Lawrence Bobo, Racial Attitudes in America: Trends and Interpretations, Revised Edition and Schuman and Bobo, "Survey-Based Experiments on White Racial Attitudes towards Residential Integration" (link); Pew Research Center, "Race, Ethnicity & Campaign '08" (link)).

But here is the important question: why do a certain number of people in modern societies have these attitudes in the first place? Is it just a sort of basic fact about our population that a certain percentage of us fall in this mindset? Are there specific features of our informal system of acculturation that creates this minority of hate-disposed people? Are these the result of a sort of sub-culture of militia encampments, prison gangs, and biker groups who are somehow able to promulgate their hatred to new recruits? Is it ignorance, disaffection, and economic uncertainty that brings out these qualities in otherwise decent people? In short -- is it the organizations that produce the hate in some people, or is it the hateful individuals who create the organizations?

Michael Mann's The Dark Side of Democracy: Explaining Ethnic Cleansing is one kind of empirical study of a related question, the occurrence of murderous ethnic cleansing. Here are a few of his hypotheses.

Murderous cleansing is modern, because it is the dark side of democracy. Let me make clear at the outset that I do not claim that democracies routinely commit murderous cleansing. Very few have done so. Nor do I reject democracy as an ideal – I endorse that ideal.Yet democracy has always carried with it the possibility that the majority might tyrannize minorities, and this possibility carries more ominous consequences in certain types of multiethnic environments. (2)

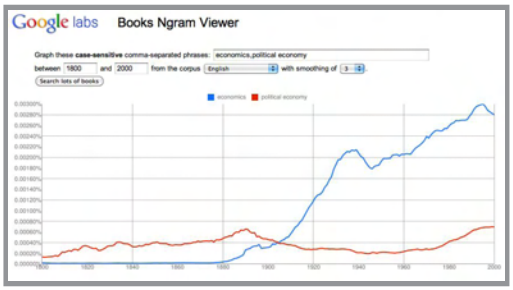
Ethnic hostility rises where ethnicity trumps class as the main form of social stratification, in the process capturing and channeling class-like sentiments toward ethnonationalism.

The danger zone of murderous cleansing is reached when (a) movements claiming to represent two fairly old ethnic groups both lay claim to their own state over all or part of the same territory and (b) this claim seems to them to have substantial legitimacy and some plausible chance of being implemented. (2-9)
These are political-structural theories of the conditions that stimulate outbreaks of hate-based mobilization and murderous ethnic cleansing. But actually, Mann never addresses my question head-on: what accounts for the existence of a certain small percentage of haters in a given society. Mann is interested rather in the behavior and the occurrence of mass mobilization for ethnic violence in certain times and places -- the involvement of thousands of citizens in acts of violence and murder against their fellow citizens. And he doesn't believe that the actors are exceptional; rather, the circumstances elicit the terrible violence from people much like all of us. Here is how he categorizes the perpetrators:

There are three main levels of perpetrator: (a) radical elites running party-states; (b) bands of militants forming violent paramilitaries; and (c) core constituencies providing mass though not majority popular support. (9)
And he doesn't think there is anything distinctive about the third group:

Finally, ordinary people are brought by normal social structures into committing murderous ethnic cleansing, and their motives are much more mundane. To understand ethnic cleansing, we need a sociology of power more than a special psychology of perpetrators as disturbed or psychotic people – though some may be. (9)
This "ordinary people as killers" theory (c) doesn't really seem to do justice to the problem at issue here. And the political opportunists who play the hate card aren't too hard to understand (a). It's really the people Mann includes under (b) that are of concern to me -- the true believers, the extremist White supremacists or virulent anti-Semites who become the local activists and paramilitaries that I'd like to understand better. And this population seems to be defined by the attitudes, motives, and ideologies that they bring with them, rather than the inter-group dynamics and political opportunism that Mann focuses on. So, once again, where does this mentality or psychology of activist hatred come from in our society (or in other contemporary societies)?

The easy answers are ready to hand. We might postulate a strand of political culture and thought in American society that reproduces hate and racism in some of the young people who are exposed to it. (Hate on the Internet falls in this category.) Or we might postulate a recessive "racist personality" type that is a portion of the human psyche (along the lines of the theory of the authoritarian personality). Or we might postulate that lack of opportunity and an enduring situation of defeated expectations pushes some



young people into hate (skinheads in Britain or Germany).
But I don't find any of the theories very convincing by itself. So we seem to have an important theoretical issue here that is unresolved: where does "hate" come from?

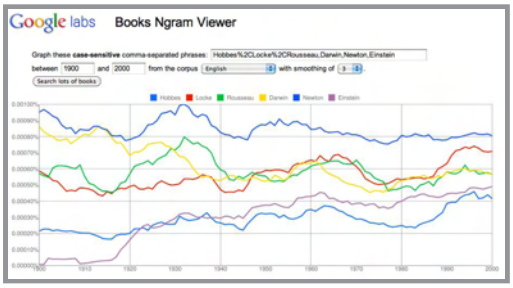
A new tool for intellectual history

Monday, December 20, 2010



Google's NGram Viewer is a really amazing new tool for researchers in literature and the humanities (link, link, link, link). What is perhaps not quite so evident is the power it may have for people interested in the evolution of the social science disciplines.

Basically the concept is a simple one. The Google Book project has now scanned and OCR'd millions of books published over the past several centuries. With the announcement of NGram Viewer, Google has shared a vast indexed database of words and phrases included in this full corpus. And its Viewer tool allows users to provide specific phrases and see a graph of the frequency of that phrase over time (1800-2000 by default). It is important to bear in mind that the project measures the frequency of the phrase, not the absolute number of occurrences; so as the volume of words increases decade by decade, a phrase with a .005% share has an increasing number of occurrences.

Now consider this: to what extent is it possible to track themes, concepts, and theories in the social sciences by making use of the tool and a well-chosen list of terms or phrases? For example, the classical economists (Smith, Ricardo, Marx) referred to their science as "political economy," whereas the economists defining the marginalist revolution (Jevons, Walras, Menger) tended to refer to their work as "economics." Classical economists operated under a fairly distinctive set of assumptions, including the labor theory of value, that differed sharply from the assumptions associated with the marginalist revolution and the creation of neoclassical economics. So is it possible that we can we track the decline of classical economics and

the rise of neoclassical economics by tracking "political economy" and "economics"? Here is what that graph looks like:

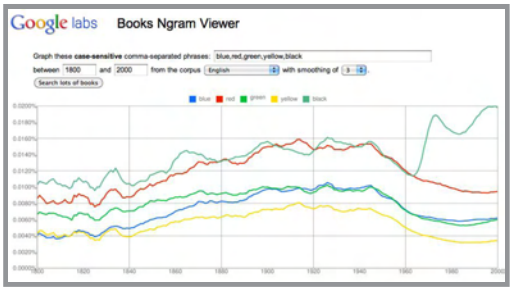
The "political economy" line shows a gradually rising trend from 1800 to 1890, and then declines through about 1950. Only in the 1980s does the term become more popular again -- perhaps corresponding to a resurgence of interest in the classical foundations of economic thought (Smith, Ricardo, Marx, Sraffa). The term "economics" has virtually no use prior to 1880; it then begins to increase in frequency, passing "political economy" in frequency in 1910, and climbing rapidly into the 1980s. The frequency of "economics" appears to be roughly eight times the frequency of "political economy" by 1980.

So how about other areas of the social sciences? We might take a look at the development of anthropology using this approach; for example, how have the terms "anthropology" and "ethnography" changed in frequency in books during the past two centuries? Here's the graph:

Through 1860 both terms are very infrequent. After 1860, however, "anthropology" takes off, and "ethnography" continues at a low level through 1960, roughly at the time when Geertz and other path-breaking anthropologists began redefining the field in the direction of "local knowledge" or ethnography. From that point on both terms increase in frequency (with a large dip for "anthropology in the 1970s), with anthropology remaining a 3:1 favorite.

So now let's try out a somewhat more general question: how did political theory develop during the twentieth century? We might probe this question by picking out a few important political theorists and examine the pattern of frequency that they demonstrate throughout the century; perhaps this will tell us something about them individually, as well as something interesting about the waxing and waning of interest in political theory more generally during the period. Suppose we look at Hobbes, Rousseau, and Locke as the central founders of modern political theory. Here's what that graph looks like:

This is interesting in many ways. First, individually: Rousseau comes on very strongly in the 1930s, whereas Locke is fairly flat during the period. Second, comparatively: Locke and Rousseau are consistently more frequent in the book literature than Hobbes -- in spite of our tendency to think of Hobbes as the ultimate founder of modern political theory. ("Life in the state of nature is nasty, brutish, solitary, and short.") And finally, there is a striking periodicity in the three graphs. There are long waves of rise and fall of frequency over the century, and even more surprisingly, these waves are fairly closely correlated. This implies one of two things: either political theory as a field waxed and waned through the century, with the frequency of references to the founders following along; or else this correlation is a symptom of a large artifact of the method itself. We could test this latter idea by examining a larger set of authorities, including other areas of intellectual work. So let's look at a final graph, including the three political theorists as well as Darwin, Newton, and Einstein:



Naturally enough, Einstein starts slowly in the early twentieth century, but then begins to rise in frequency after 1918 or so. He passes Hobbes for good in 1938 or so. Darwin,

surprisingly enough, shows a falling trend through the century, recovering a bit after 1975. But we were looking for evidence of artifact, and this graph seems to provide it; to the eye, there is a similar periodicity in the frequency of all these authors throughout the century, with a low point in 1945 (the end of World War II), and for all but Newton, another peak around 1965 followed by a trough around 1980. So it isn't "political theory" that is oscillating in the ocean of words included in the universe of books, but intellectuals, philosophers, and scientists generally. And this suggests that there's something going on that may have more to do with the measurements than the reality; more investigation is needed.

In short, it seems promising to think that there are some very interesting patterns to be teased out using this tool, and they are patterns that never could have been identified without the databases that Google has created. A new form of our ability to probe and represent the growth of knowledge is made possible.

Ngram anomalies

Wednesday, December 22, 2010

Now that I've played with the Google Ngrams tool a little, I continue to think it's a powerful window into a lot of interesting questions. But I also see that there are patterns that emerge that are plainly spurious, and surely do not correspond to real changes in language, culture, or collective interest over time. It is easy to find examples of search terms that very plainly indicate that there is some kind of "instrument error", an observation that emerges because of an artifact of the method rather than a real pattern in the underlying behavior.

Fortunately it is possible to probe these areas of anomaly with the goal of figuring out what they mean. So let's see what happens when we pick out a set of common words that are not freighted with a lot of culturally specific significance. This will let us see more clearly how the instrument itself works.

Consider the color words red, green, yellow, blue, black. Let's graph the frequency of these terms in American English from 1800 to 2000. Before looking at the Ngram graph, let's consider what we would expect ex ante. Color words occur in books to designate -- color. Color terms are common words, so we might expect that they would remain fairly constant in frequency over time. So here is the null hypothesis about the frequency of common color terms: without a change in culture about color, we should expect the color words would remain roughly constant in frequency (flat curve). And the usage patterns for each term should be independent from the others. So we should expect a degree of independent random fluctuations in the frequencies of each color word, where "blue" bumps up in frequency in a given year and "red" bumps down.

(Why should we expect a degree of independence in the random fluctuations between "red" and "blue"? Because, fundamentally, there is no common mechanism that would link their behavior.)

Here are some ways in which the actual behavior of color terms might deviate from the null hypothesis. Some colors may be more in style than others at a time -- there may be a cultural preference for red over blue, so the frequency of red may be greater than the frequency of blue. And the frequencies may change as cultural preferences change; so blue may become more frequent than red in a later generation. More generally, literary taste may change by becoming more descriptive overtime -- with more frequent use of color terms -- or more formal, with less use of color terms. So it would be possible to explain persistent differences in frequency of color terms; shifting frequencies across different color words; and even a longterm rise or decline in the whole family of color words.

So ex ante, for this group of common color words we would expect a graph of flat lines for the five terms, with uncorrelated fluctuations in each line.

Now let's look at the actual graph of these word frequencies (link).

Here we can see behavior that flatly contradicts these reasonable ex ante expectations. First, there are stretches of time in which the color words covary extremely closely, to the extent that the graphs look identical in shape. This is true, for example, in the neighborhood of 1820. This is impossible to explain as anything else than an artifact of some sort. It is impossible to believe that the frequencies of several color words would fluctuate up and down with this degree of synchrony.

Here is another aspect of the graph that is also suggestive of artifact: the long wave of rise and fall in the frequency of all the color words between 1810 and 1920. It is not impossible that "color" became more important in literary language and then declined; but that seems improbable. So this long wave coordinated behavior of the color words seems to be more likely the effect of a database anomaly than a manifestation of a real trend.

Is there any reliable information in this graph? Yes. There is one feature of this graph that appears to have real significance, and that is the change in the behavior of "black" after 1960. Prior to that year the term behaves pretty much like all the other color words. After that year it takes off on a very different trajectory. And this abrupt and accelerating increase in the frequency of "black" seems to have everything to do with a real social and cultural change in the 1960s and forward -- the abrupt increase in those decades in the salience of race. There is a similar divergence between the behavior of "black" and all the other color words in 1860; the frequency of the word increases for a few years following the American civil war.

More tantalizingly, it may be significant that "blue" moves up from "yellow" to "green" in frequency over time. This is one element of the graph where the terms are not correlated with each other; instead, "blue" changes its position relative to other color frequencies.

This example shows that we need to be careful about the inferences we draw from the patterns that appear from Ngram searches. We need to always ask: "Does this pattern really correspond to a fact about underlying collective linguistic behavior, or is it the result of an artifact?" More fundamentally, we need to understand the sources of the artifacts we are able to detect -- spurious correlations, inexplicable long-wave changes in frequency, and others still to be discovered. And, finally, we should seek out techniques that can be applied to the results that serve to filter out the artifacts and focus on the real variations the data contain. We need some signal processing here to separate signal from noise. The Ngram tool is powerful, but we need to use it critically and intelligently.

Thinking cities darkly

Tuesday, December 28, 2010

Image: frame from *West of the Tracks*

Cities capture much of what we mean by "modern," and have done so since Walter Benjamin's writings on Paris (link). But unlike the eighteenth or nineteenth centuries, much of our imagining of cities since the early twentieth century has been dark and foreboding. A recent volume edited by Gyan Prakash, Noir Urbanisms: Dystopic Images of the Modern City, offers a collection of recent work in cultural studies that attempts to decode some of this dark imagery.

Several things are particularly interesting about the volume. Most basically, it represents an interesting conjunction of humanities perspectives and sociology. The articles are individually very good. And as a group they pose a series of important questions. How does a film set in Los Angeles or Shanghai serve to depict the city? Is there sociological content in a film that can contribute to a better sociology of the city? But also -- what can we say about the cultural currents that produce a particular vision of the city? Are there post-modern sensibilities and fears that lead filmmakers to turn the ambience dark?

The volume treats cities and their depictions in many parts of the world -- China, South Africa, Mexico, India, Europe, and the United States. What is unusual about the volume is the fact that it is not a collection in "film studies" or in "urban studies", but rather a series of contributions taking seriously representation and the represented. Moreover, there is no effort to force the perspectives taken into a common theory of "noir representation"; there are common themes that emerge, but each contributor brings forward a singular perspective, informed by the specifics of the region and genre that he/she studies. It is a project on the nexus between imaginative representation and existing social realities.

Prakash's excellent introduction begins with these observations:

As the world becomes increasingly urban, dire predictions of an impending crisis have reached a feverish pitch. Alarming statistics on the huge and unsustainable gap between the rates of urbanization and economic growth in the global South is seen to spell disaster. The unprecedented agglomeration of the poor produces the specter of an unremittingly bleak "planet of slums." Monstrous megacities do not promise the pleasures of urbanity but the misery and strife of the Hobbesian jungle. The medieval maxim that the city air makes you free appears quaint in view of the visions of an approaching urban anarchy. Urbanists write about fortified "privatopias" erected by the privileged tow all themselves off from the imagined resentment and violence of the multitude. Instead of freedom, the unprecedented urbanization of poverty seems to promise only division and conflict. The image of the modern city as a distinct and bounded entity lies shattered as market-led globalization and media saturation dissolve boundaries between town and countryside, center and periphery. From the ruins of the old ideal of the city as a space of

urban citizens there emerges, sphinx-like, a "Generic City" of urban consumers.

As important as it is to assess the substance of these readings of contemporary trends in urbanization, it is equally necessary to examine their dark form as a mode of urban representation. This form is not new. Since the turn of the twentieth century, dystopic images have figured prominently in literary, cinematic, and sociological representations of the modern city. In these portrayals, the city often appears as dark, insurgent (or forced into total obedience), dysfunctional (or forced into machine-like functioning), engulfed by ecological and social crises, seduced by capitalist consumption, paralyzed by crime, wars, class, gender, and racial conflicts, and subjected to excessive technological and technocratic control What characterizes such representations is not just their bleak mood but also their mode of interpretation, which ratchets up a critical reading of specific historical conditions to diagnose crisis and catastrophe. (1)
All the essays are interesting and insightful, but I was particularly interested in the Asian contributions -- India, China, and Japan.

First is Li Zhang's treatment of some current treatments of the dark side of Chinese cities (Shanghai and Shenyang) in "Postsocialist Urban Dystopia?". She treats the Sixth Generation and New Documentaries movements in contemporary Chinese filmmaking, focusing on two recent works (Wang Bing's *West of the Tracks*, about the decline of a rust-belt city in the Northeast, and Lou Ye's *Suzhou River*, about the lives of poor and disaffected people in Shanghai).

Both works serve as powerful examples of "noir urbanism" in a Chinese context. *West of the Tracks* is a nine-hour documentary capturing the lives and declining prospects of working class people in Shenyang following the reform of Chinese industry in the 1990s. (C. K. Lee describes this process in Against the Law: Labor Protests in China's Rustbelt and Sunbelt.) Here is a link to *West of the Tracks*, well worth viewing. And *Suzhou River* captures some of the gritty, squalid aspects of life in contemporary Shanghai, but also dwells on the moral shift that China is undergoing, towards a consumerist, wealth-oriented corrupt society. Here is a clip from *Suzhou River*:

Zhang combines her own anthropological fieldwork in Chinese cities with her reading of these films, giving her essay a multiple sense of authority. Here is a brief description of *West of the Tracks* that illustrates the intersection of criticism and fieldwork:

While capturing the "raw and the real" experiences of workers, *West of the Tracks* offers a subtle yet powerful critique of the postsocialist state and its neoliberal turn. What is so striking in the story told here is the lack of government help and the indifference of society toward workers' dilemmas. (137)
She refers to the bleak setting of the break room at the factory:

In their daily conversations in the break room, smelting workers frequently talk about how the managers and cadres of the factories steal public money to line their own pockets by taking kickbacks at the expense of the enterprise. The management and bosses rarely appear in the film. The longest presence is a banquet gathering at a local restaurant where factory managers and cadres talked about the imminent total privatization. They are well dressed in leather and wool coats with fur collars. (137)
So there are several key themes here: First, there is a critical perspective on the rising inequalities and dispossession of ordinary people that have followed from China's growth

policies; this is the documentary aspect of the films she discusses, and plainly reflects the filmmakers' interest in capturing an important and disturbing contemporary social reality in China. And second, there is a critical vision of the moral dislocations that China has undergone, from Maoist egalitarianism to capitalist and consumerist pursuit of wealth. Zhang captures this element of contemporary China in her discussion of both films, but especially in *Suzhou River*. There is squalor and poverty, to be sure, but more pervasive is the sense of moral ungroundedness.

Moneymaking, market exchange, and pleasure-seeking are the dominant forces of everyday life. For example, the power of money erodes Mardar's blossoming love for Mudan and eventually destroys her, the symbol of innocent, unpolluted love. Human greediness corrupts souls and drives violent acts such as kidnaping and murder. (139)
Zhang's summary is explicit:

During market liberalization, Chinese society has irrevocably changed into a mass consumer society in which money increasingly controls people's lives and determines their lifestyles. (139)
Another fine contribution to the volume shifts focus to India's cities. Ranjani Mazumdar's "Friction, Collision, and the Grotesque: The Dystopic Fragments of Bombay Cinema" focuses on the mental urban landscape -- the way in which an Indian city is perceived by its residents, and the ways in which the residents are impaired by the city. Mazumdar discusses three "urban fringe" films, *Dombivli Fast*, *Being Cyrus*, and *No Smoking*. Here is a clip from *Dombivli Fast*:

Dombivli Fast is quite different from the films discussed by Zhang. It is reflective of the current social realities of Mumbai -- meaningless work, endless commuting on super-crowded trains. But it is more personal and introspective than the Chinese works, in that it focuses on one man and his family; it attempts to reveal his inner anxieties and thoughts. The dystopia here is not crushing poverty -- Madhav Apte and his family live a middle-class life in Mumbai. Here the dystopia is the pressure, stress, and callous injustice of society that drives Madhav to the breaking point.

Madhav Apte does not go back home for three days after he explodes. Armed with a cricket bat, Apte acquires a menacing persona as he moves through a city that is almost fated to collapse because of corruption, inequality, and indifference. In his journey across Bombay's deadly streets, Madhav becomes an active figure whose rage makes him see the city with a heightened perception. (159)
(There are clips from *Being Cyrus* and *No Smoking* on Youtube as well. This is one of the fascinating realities of reading the volume: it is possible for us non-specialists to view segments from most of the films that are discussed.)

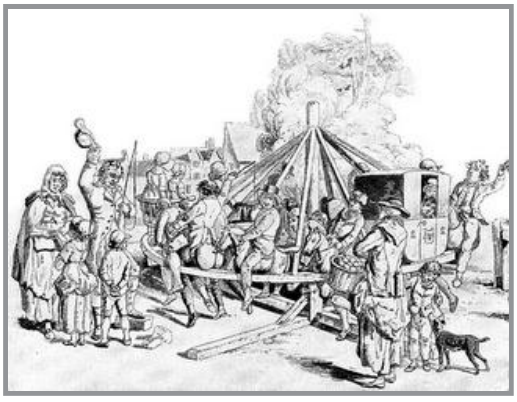
David Ambaras takes up Tokyo in its cultural representations in "Topographies of Distress: Tokyo, c. 1930." He too highlights the discrepancy between official, ideological expressions of the city, and the underlying grinding reality that modern cities often represent.

Yet despite this ebullience, to many contemporaries, urban modernity signaled the destruction of Japanese social values by Western materialism and individualistic hedonism, of which the modern girl served as the prime example. (188)
Ambaras doesn't work through cinema, but rather what he calls "slum discourse" and

graphic pictorial representations of urban life. He highlights the popular and journalistic literature of the 1870s through the early 1900s as a barometer of the anxieties Tokyo residents experienced about their changing city. Stories of disease, child murder, beggars, and abject poverty permeate this literature.

These various forms of representation, ... had combined to produce in the Iwanosaka case a set of images that both shocked the sensibilities of readers and investigators and were necessary to their understanding of themselves as part of a modern metropolitan social formation. They reinforced the sense, common to many interpretations of the modern condition, that modernity was best apprehended through contrasts -- between, for example, utopian promise and dystopian reality -- or in terms of dark mysteries concealed beneath the surface of social relationships, and that the modern (urban) subject was compelled to navigate anxiously between these two positions, ever unsure as to which was the "truth" or in which direction he/she was being led. (210-11)

It is worth sorting out the different perspectives on social knowledge represented in this volume. First, there is the question of knowledge of the object, the contemporary city. Does cinema shed light on the current social realities of Shanghai or Mumbai? Can cinema contribute to urban sociology? Second is the question of the mentality of a place and time; the way that contemporary Mumbai-ers or Shanghai-ers think of themselves and their society. Can cinema accurately capture some strands of social consciousness and anxiety that are real threads in the social landscape? Is cinema a legitimate form of ethnography? And third is the mentality and intentions of the creative class itself -- the filmmakers. Can the critic discover threads in the filmmaker's work that sheds important light on the preoccupations of this slice of contemporary society?



Finally, we can ask the question of perspectivalism: how many Shanghai's are there? Zhang refers to the Maoist preference for social realism or socialist romanticism; there are the entertainment-oriented Shanghai thrillers; there is the global Shanghai as an exotic backdrop to drama; and there is the noir representation of the social problems of the city. Can we say that one depiction is more veridical than the other? Or perhaps, can we say that several of these perspectives are compatible with the truth of Shanghai; and that optimism and pessimism are equally distorting frames for social perception?

(I note that several of the essays refer to Mike Davis's Planet of Slums; this is worth reading.)

The standard of living across time and space

Thursday, December 30, 2010

A very basic question for historians is how to measure and compare the standard of living experienced by people in different historical settings. Is it possible to arrive at credible estimates of the standard of living in the Roman Empire, medieval Burgundy, nineteenth-century Britain, and twentieth-century Illinois? Can we say with any confidence that Romans had a higher (or lower) standard of living than a twelfth-century Burgundian?

Figure 5.5. Labourers' Real Wage, 1727-1913
England and Japan

One part of the problem is conceptual. What do we mean by the standard of living? Is there a specific set of characteristics that are constitutive of the standard of living -- say, nutrition, income, access to health remedies and education, quality of housing, personal security? And how should we take account of the unequal distribution of these characteristics across a given population? Should we be content with an estimate of an average level of nutrition -- even though this may reflect a misleading impression of the circumstances of the poorest segment of society? Should we hope to be able to arrive at an estimate of the standard of living of certain typical social actors -- landless workers, skilled laborers, merchants?

The second major problem we must confront is the availability and quality of historical data about wages, prices, and consumption. The series of wages and prices that are available in different countries are, of course, incomplete. And, more importantly, the commodities that satisfy basic nutritional needs are different in different countries and regions. So it is necessary to make assumptions about the nutritional equivalents in different cultures before we can begin to arrive at estimates of relative standard of living.

Different approaches to these problems have been offered in the past fifty years. One logical approach is to consider a list of "necessities of life" and to estimate the degree to which these necessities are available to people of various stations in various times and places. Nutrition, housing, and clothing are close to the core for much of the history of humanity, and for much of that time, these goods have been available largely through the market at a price. So a standard approach has been to define a wage basket; measure the prices of the goods in the basket; and measure the typical earnings of people in historical settings of interest. This allows us to calculate the subsistence rate -- the percentage of the population whose income is more than sufficient to purchase the items in the wage basket. What this leaves out is "self production" (for peasant farmers, for example) and state provision. Another logical approach is to look at the human results -- the overall health status of people at various times and places. This can be estimated by contemporary data -- height, longevity, and age information collected by the military, for example -- or by analysis of skeletal evidence centuries later. (Amartya Sen's The Standard of Livingreviews many of the complexities of defining the standard of living and offers his own rationale in terms of capabilities and functionings.)

An important step forward is now possible in our ability to estimate and compare historical living standards, thanks to the research by an international group of scholars in Living Standards in the Past: New Perspectives on Well-Being in Asia and Europe, edited by Robert Allen, Tommy Bengtsson and Martin Dribe. The introduction to the volume by Allen, Bengtsson, and Dribe does a great job of providing an overview of the issues. All the essays are first-rate, and particularly noteworthy are contributions by Kenneth Pomeranz, Li Bozhong, and Robert Allen. (Here is a link to the table of contents of the

volume, which gives an idea of the breadth and rigor of the research.)

This group has concentrated their efforts around the current controversy about European and Asian growth patterns in the early modern period. This has several parts: first, careful comparison to determine whether there was a significant difference in the standard of living between Europe and Asia (as held by Smith, Malthus, and Marx); and second, to attempt to determine the timing and causes of differences as they emerged. The editors describe the group's purposes in the introduction in these terms:

How did the standard of living in Europe and Asia compare in the seventeenth and eighteenth centuries? (Kindle loc 230)

The main concern of this book is to assess when the gap between the East and the West emerged and to not only take economic perspectives into consideration but social and demographic ones as well. (Kindle loc 159)

The researchers bring three methodologies to bear on these questions: economic analysis of prices and wages to estimate the real wage; demographic analysis of biometric features such as height, longevity, and fertility to estimate relative standard of living; and historical population analysis to observe the severity of adaptation (mortality, fertility, migration) created in a population by shortterm economic stress, including especially food prices. Here the reasoning is that a population that is close to the edge of subsistence in normal times may be expected to have higher mortality, lower fertility, and greater out-migration than a population with a more comfortable standard of living. So demographic change can be used as an indirect measurement of a population's standard of living. Using these three reasonably independent instruments of observation, it is reasonable to expect that we will gain a fairly accurate idea of the standard of living in a region and how it compares to other regions. The last approach is probably the most innovative:

There were demographic responses ... to high food prices. In the worst case, high prices caused death for those unable to buy enough to eat. In less extreme situations, people resorted to demographic strategies in response to high food prices. These included postponed marriages, migration, and delayed births. Studies of the correlation of death, migration, marriage, and childbearing with food prices, therefore, provide a new approach to the measurement of the standard of living. When aggregate data show that high food prices raised mortality or reduced fertility, one can conclude that the bulk of the population had a low standard of living. (Kindle loc 288)

Cameron Campbell and James Lee make use of this approach in their contribution, "Living standards in Liaoing, 1749-1909: Evidence from demographic outcomes," to assess the standard of living of the bulk of the population in Liaoning in northeast China. They find that the mortality and fertility responses to changes in rice prices essentially disappeared in the north and south of Liaoning in 1780-1850 -- which leads them to infer that the standard of living and nutrition had risen over the past century. (James Lee and others return to this kind of reasoning in Prudence and Pressure: Reproduction and Human Agency in Europe and Asia, 1700-1900, by Noriko Tsuya, Wang Feng, George Alter, and James Lee.)

Robert Allen attempts to establish something like an empirical baseline for the real wage in different parts of Europe and Asia in his contribution, "Real wages in Europe and Asia: A first look at the long-term patterns". He compiles a large dataset of wage data for a number of European cities, and he makes careful inferences about comparable data for India, Japan, and China.

Wages reveal the standard of living if they are compared to the price of consumer goods. This is the interpretation that matters in assessing the prosperity of Asia vis-a-vis Europe. Provided low Asian wages were matched by low consumer goods prices, the standard of living of workers could have been the same at both ends of Eurasia even though Asian manufacturers had a competitive advantage in the textile industry. (Introduction to "Real Wages")

Allen notes that it is necessary to make a number of adjustments in order to estimate the cost of a wage basket in Asia, because of large differences in diet. Allen stipulates 143 kgs/year of rice for the Asian basket versus 208 kgs/year of bread in the European basket. And he converts prices and wages into silver to permit comparison of prices across Europe and Asia. Here is one of Allen's summary graphs comparing laborers' real wages in Japan (farm), Kyoto, England (farm), Oxford, and London.

The graph indicates a significant premium for laborers' wages in London, whereas Japanese and English farm wages are fairly similar throughout most of the period. And it indicates a "take-off" for London laborers' wage beginning in the mid-nineteenth century -- not paralleled by a similar take-off in Kyoto.

Here are Allen's conclusions:

The wage comparisons undertaken in this paper support several important conclusions about living standards in pre-industrial Europe and Asia.

First, wages expressed in grams of silver were lower in China and India than in Europe. The views of the eighteenth century observers cited by Parthasarathi are confirmed. This is important since it was the proximate cause of Asia's competitive advantage in textiles and luxury manufactures and was, thus, the basis for Asian-European trade in the early modern period. Why these differentials persisted for hundreds of years is an important question in international and monetary economics that must be addressed to explain the dynamics of the world economy in this period.

Second, low Asian silver wages were matched by low Asian prices with the result that living standards in Asia were similar to those in many parts of Europe. Farm workers in Europe and urban workers in central and southern Europe did not enjoy higher living standards than their counterparts in Asia.

Third, some parts of Europe did generate higher real wages than we find in Asia. When real wages were at their peak following the Black Death, most Europeans had a higher standard of living. But this was a transitory condition for most of the continent. High wages persisted only in the commercial centres of the northwest – London and the Low Countries generally. During the eighteenth century, the provincial towns of England were drawn into the same high wage orbit, but agriculture was left behind. This dynamic, urban economy was the engine of growth in early modern Europe, and Asia appears to have had no counterpart. It is possible, of course, that a more extensive Asian database would reveal a parallel: the absence of information on urban Chinese wages is particularly troubling in this regard. However, neither the Japanese cities nor the capital of the Moghul Empire had particularly high wages. The evidence at hand suggests that Asia lacked Europe's engine of growth. (Conclusion of "Real Wages")

Contributions by Kenneth Pomeranz and Li Bozhong take up the issue of the supposed backwardness and stagnation of the Chinese rural economy at the beginning of the eighteenth century. In The Great Divergence: China, Europe, and the Making of the

Modern World Economy Pomeranz argued that England and the Yangzi Delta region had roughly comparable levels of productivity and similar levels of standard of living for poor people (laborers and peasants). In his contribution to this volume he pushes this argument forward with more empirical analysis of the standard of living in China. He attempts to handle the "commensurability" problem mentioned above by converting subsistence food commodities to calorie equivalents. He finds that Chinese data for seventeenth century laborers indicate a daily diet of 2,800 calories for adults in the eighteenth century (Kindle loc 532).

Overall, then, the food component of the standard of living seems generally comparable in eighteenth-century China and Europe, and in the most advanced regions of both. (Kindle loc 626)
So Pomeranz's research here broadly confirms the view he advanced in *The Great Divergence*, that the standards of living in comparable regions of Europe and China were roughly the same; and he also confirms a significant decline in the standard of living for the bulk of the Chinese population in the nineteenth century.

Li Bozhong takes up the stagnation issue from a different point of view, a careful consideration of farm labor productivity in the Lower Yangzi region. This extends his important work in Agricultural Development in Jiangnan, 1620-1850. And his central finding is an important one as refutation of the standard involution interpretation of China's economic history; he finds that agricultural productivity rose from 1620 to 1850.

The central theme of this chapter is that labour productivity on farms did improve in Jiangnan between 1620 and 1850. The region of Jiangnan, located in east China and consisting of eight late Imperial Chinese prefectures in the Yangzi Delta, has been the most economically and culturally advanced area in China for centuries. ... In some sense, this region is the best 'window' through which we can clearly see economic changes in China before the arrival of the modern west. (Kindle loc 1038)
The issue of productivity is key to an assessment of the standard of living, because flat or declining productivity in a region with a rising population implies a falling standard of living -- the general "theorem" of Malthus. So Pomeranz's finding would be difficult to support if we were forced to conclude that agricultural productivity was constant or falling. But Li's careful and data-rich analysis indicates, to the contrary, that there was substantial gain in productivity from the Ming to the mid-Qing.

The 'trinity pattern' is the optimal pattern in the Jiangnan peasant economy because under this pattern higher yields per mu can be achieved with lower inputs. As I point out above, in the early seventeenth century, a farm ran, on average, 15 mu of cultivated land with a multi-cropping index of 140%, the second crop being wheat. The yield per mu was 1.7 shi for rice and 1 shi for wheat. If all the 15 mu of land were planted in rice, this farm would harvest 26 shi of rice and 6 shi of wheat, together equivalent to 30 shi of rice. In contrast, in the mid-nineteenth century, the average farm size was 9 mu with a multi-cropping index of 170&. Per mu yield was 2.5 shi of rice and 1 shi of wheat. Farm output was 23 shi of rice and 6 shi of wheat, totalling 27 she of rice, 10% below the early seventeenth-century figures. However, if we calculate labor productivity according to the number of workers, output per worker would be 15 shi of rice in the early seventeenth century and 27 shi of rice in the mid-nineteenth century respectively. That is, the figure for the late Ming period is only 55% of the mid-Qing figure. (Kindle loc 1160)
So labor productivity had risen significantly from 1650 to 1850. Li's conclusion is clear:

Since labour productivity and the standard of living are inseparably linked, the rise in farm

labour productivity in Jiangnan implies an increase in the peasants' standard of living. ... There is little doubt, therefore, that real incomes of peasants did improve considerably in Jiangnan at this time. Second, the quality of the peasants' diet also improvied in Jiangnan during the period. Fang Xing suggested that ordinary Jiangnan peasants ate more fish, meat, and tofu, drank more tea and wine, and consumed more sugar than ever before. ... The improved standard of living can also be seen in the increase in consumption, not only of 'ordinary goods' like cotton cloth, but also of 'luxury goods' such as silk, wine, tobacco, and opium. (Kindle loc 1221)

What is most valuable about this project is the empirical grip it provides on these important questions: What have been the dynamics of the standard of living across Eurasia from the middle ages to the twentieth century? And, eventually, what economic and demographic forces account for the inflection points and persistent differences in different regions that are documented? And, as all the contributors agree, one of the key discoveries is the fact of variation at every level, from regions of England to regions of Europe to the ends of Eurasia.

The contributions of this book show the highly complex and diverse pattern of the standard of living in the pre-industrial period. The general picture emerging from these studies is not one of a great divergence between East and West during this period, but instead one of considerable similarities. These similarities not only pertain to economic aspects of standard of living but also to demography and the sensitivity to economic fluctuations. In addition to these similarities, there were also pronounced differences within the East and within the West -- differences that in many cases were larger than the differences between Europe and Asia. This clearly highlights the importance of analysing several dimensions of the standard of living, as well as the danger of neglecting regional, social, and household specific differences when assessing the level of well-being in the past. (Kindle loc 455)

CPM in West Bengal

Saturday, January 01, 2011

One thing that is interesting about Indian politics is the fact that states have a great deal of autonomy, and there are parties based in various states that are distinct from both Congress and BJP. One of those parties is the Communist Party of India, which has evolved into a pro-poor, anti-capitalist electoral party that has renounced violent revolution, following a split in CPI in the 1960s. The Communist Party of India (Marxist) (CPM or CPI(M)) emerged in the 1960s as a serious electoral party, and it has governed directly or through left coalitions in West Bengal and Kerala since the late 1970s. CPM gains between 5% and 6% of the national vote, and currently there are 46 CPM MPs in Parliament (out of 790). (The Wikipedia entry on CPI(M) provides a detailed timeline of the party's role in India since the 1960s. Here is a link to the *People's Daily*, one of CPM's key publications.)

Here is a table of seats won in elections between 1952 and 1987 in West Bengal:

Table 10.1. *Seats won by major political parties in West Bengal assembly elections, 1952–87*

Party[a]	1952	1957	1962	1967	1969	1971	1972	1977[b]	1982	1987[c]
Congress	150	152	157	127	55	105	216	20	49	40
CPM	28	46	50	43	80	113	14	177	174	187
CPI	—	—	—	16	30	13	35	2	7	11
Forward Bloc	14	8	13	13	21	3	0	25	28	26

[a]The other significant parties that have come and gone and are not listed here include the Bangla Congress, the Praja Socialist Party, and the Revolutionary Socialist Party. The latter continues to be significant; it won 20, 19, and 18 seats in the 1977, 1982, and 1987 assembly elections, respectively.
[b]The newly formed Janata party won 29 seats in 1977, only to vanish completely in the 1982 elections.
[c]Data from *India Today*, April 15, 1987.
Source: Computed from the reports of the Election Commission.

(source: Atul Kohli, *Democracy and Discontent*, p. 274)
Many progressive Bengalis looked at the party as a pro-poor, progressive force in West Bengal during the 1980s. But substantial and rising criticism has developed in the past five years. So where is CPM today?

First, consider the positive view. Distinguished American political scientist Atul Kohli treated West Bengal in detail in his The State and Poverty in India (1989), and he credits CPM for much of the improvement of the status of the poor over a 20-year period in West Bengal.

It is argued that the capacity of the CPM to initiate a systematic attack on rural poverty

stems from its political and class characteristics. The type of leadership, ideology, and organization the CPM regime brings to bear on the operation of political power enables it to perform two essential tasks: first, penetration of the countryside without being captured byt he landed classes; and second, controlled mobilization and incorporation of the lower classes to buttress state power as a tool of social reform. ... To gain an understanding of the CPM regime in West Bengal, one must begin by analyzing the nature of its leadership, ideology, and organization. The important thing to note about the leadership is that is neither concentrated in the hands of an individual nor, as one might expect, in the party alone. While the party wields great influence, leadership is shared by the three "wings" of the CPM, namely, the party organization proper, the Kisan Sabha (the peasant wing) and the parliamentary wing. (96-97)

Kohli gives an overview of CPM in West Bengal in his 1991 Democracy and Discontent: India's Growing Crisis of Governability:

The Communist Party of India, Marxist (CPM), has repeatedly been elected to office in West Bengal since 1977. The party is communist in name only and is essentially social-democratic in its ideology, social program, and policies. The party's disciplined, effective organization has minimized the debilitating elite factionalism and the related elite-led mobilization and countermobilization so common in some other states. The CPM has also consolidated a coalition of the middle and lower strata by implementing some modest redistributive programs. That systematic incorporation of the poor has reduced the attractiveness of populism and its emphasis on deinstitutionalization. And finally, the CPM has adopted a nonthreatening approach toward property-owning groups, whose roles in production and economic growth remain essential for the long-term welfare of the state. (267)

Here is Kohli's summary assessment in 1991:

After having been one of India's most chaotic states in the late 1960s, West Bengal has emerged in the 1980s as one of India's better-governed states. Surely there are lessons in this turnaround for any study of India's growing crisis of governability. For purposes of this concluding discussion, these lessons can be broadly divided into prescriptive and analytical.

The prescriptive lessons are limited. What has worked in West Bengal may not work in other states in India -- and is even less likely to provide an all-India model. The emergence of the CPM as a disciplined ruling party in West Bengal is a product of an unusual sociopolitical configuration -- its long regional traditions of elite radicalism and centralized organization, the weakness of caste as a principle for political organization, and the historical weakness of the Congress party....

In spite of the limited utility of the West Bengal case for generating any direct prescriptions, the analytical implications ... are very important. The West Bengal case highlights the significance of a well-organized reformist party for generating political order. The roots of the political chaos between 1967 and 1977, though complex, were mainly two related political conditions: the fragmentation of the state itself, and virulent elite-led mobilization.

The emergence of the CPM as a ruling party tamed many of the conflicts within West Bengal. As a well-organized party with a clear electoral majority, the CPM was able to create a cohesive government and fill the existing power vacuum. Organizational discipline also enabled the CPM to limit elite factionalism and the debilitating elite-initiated political conflicts that often follow. Thus, organizational cohesion at the heart of

the state was crucial for taming political chaos.

The CPM's reformist orientation has enabled it to pursue some redistributive programs without fundamentally alienating property-owning productive groups. The CPM's performance in West Bengal has by no means been spectacular; it has left quite a few problems unresolved, and it has created some new problems. At the same time, however, it is undeniable that a reform-oriented, disciplined party has generated moderately effective government in West Bengal. (295-96)

So Kohli's assessment of CPM is quite favorable, at least through the early 1990s. Land reform and policies favorable to landless workers had a significant impact on poverty in West Bengal. Now move forward to the early 2000's up to the present. Indian journalism suggests a high degree of discontent with CPM today. There are three large areas of criticism: cronyism and corruption; the use of political violence to silence opponents; and an economic development strategy that is too friendly to international business. And, for the first time in decades, the party is losing electoral support in West Bengal. Here is a fairly representative current critique of CPM in West Bengal (link). Here are a few key criticisms by Pratap Bhanu Mehta:

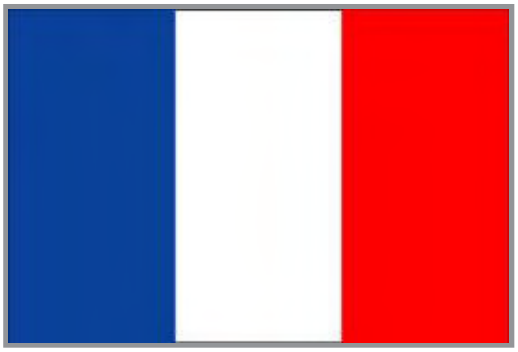
The governance failures of West Bengal, on virtually every indicator that matters -- roads, health, education, nutrition, poverty, infant mortality -- have recently been well documented in searing report by my colleague Bibek Debroy and his co-author Laveesh Bhandari. Even the much touted success in growth in agricultural productivity and decline in rural poverty has been tapering off for years. There is no question that West Bengal is ripe for a paradigm shift in its development model.

There is also no question that the local CPM has become a huge obstacle to the progress of the state. No matter how much Bengali intellectuals, out of a sense of misplaced nationalism, sanitise the issue, the CPM’s implication in violence, intimidation and coercion is extensive. It is now deeply implicated in the political economy of petty corruption in the state. It has virtually destroyed intellectual life in main institutions of the state.

One particular point of controversy has to do with the attempt to establish Special Economic Zones in West Bengal (link). Here is a searing criticism of CPM's use of political violence against peasants from *Mainstream* in an effort to push forward with its plans to create a Special Economic Zone in Nandigram, involving largescale land confiscations:

The irony is that even though the CPI-M has become pro-capitalist, it has little respect for democratic norms or rule of law. So, even before the State Government machinery, centred in Kolkata, actually made any formal requests to peasants for taking over of their lands, a local party bigwig and a Member of Parliament from adjoining Haldia (it is a port town and is apparently booming) deemed fit to send out a circular stating that lands of villagers in quite a few villages will be taken over for the purpose of creating an SEZ. That created a furore among the villagers and a resistance started; they vowed that they will not part with their land which they have tilled for generations. The State Police tried to break the peaceful resistance of the villagers on March 14, and the deaths of innocent peasants led to a plethora of protests from the Opposition political parties and groups and also from independent intellectuals of Kolkata and beyond. Even Gopal Gandhi, Mahatma Gandhi’s grandson and the present Governor of West Bengal, found the killings to be a horrific incident and himself tried to visit the place where the deaths happened but was stopped mid-way by the CPI-M cadres.

The criticism is two-fold: that CPM's current economic policies are too favorable to



international businesses; and that the government has been reckless in its use of force against peasants and critics.

Here is a rebuttal to these criticisms from *LeftVoice*. The document is interesting because it provides a defense of CPM's current policies and actions (link).

The primary political and developmental strategy of the Left Front had two inter-related components – land reform and decentralisation of political power from the state bureaucracy to institutions of local government (i.e. to panchayats and municipalities in rural and urban areas respectively). Right from the start, it was the contention of the Left Front, that refoming the way land was owned in the rural areas, where the bulk of the poor lived, was crucial to tackling the problems of poverty and under-development in the state. In this article we shall see what kind of property relations existed in the state before the Left Front came to power in 1977, how these relations created conditions of massive rural poverty, how the Left Front attempted to undertake land reforms to alter these property relations, how it realised that decentralisation of political power to local government institutions was the best way to undertake such reforms and how this whole strategy reduced rural poverty and also politically empowered the poor in the state to a degree not seen in other states of India.
So the hard question today is this: has CPM maintained the political commitments and integrity it evidently possessed in the 1970s and 1980s, so that it remains a positive force for social reform in West Bengal? Or has it devolved into "party politics", leading to behaviors that have more to do with personal gain and party electoral success than social progress?

France as Theodore Zeldin saw it

Wednesday, January 05, 2011

Histories of France have been written from many points of view. Emmanuel Todd's The Making of Modern France: Ideology, Politics and Culture (1988), Eugen Weber's Peasants into Frenchmen: The Modernization of Rural France, 1870-1914 (1976), and Robert Darnton's Mesmerism and the End of the Enlightenment in France (1968) have all brought a distinctive perspective to their interpretations of France. Each provides an approach that minimizes the goals of traditional narrative and instead focuses on the problematics of identity and culture.

Theodore Zeldin's writings on France are equally original and provocative (A History of French Passions 1848-1945: Volume I: Ambition, Love, and Politics, France, 1848-1945: Politics and Anger). Like these other scholars, he is not an historian who focuses on a

chronicle of events. Instead, he wants to capture some threads of emotion, personality, and ordinary social life that begin to add up to something "French". Here is how he frames the project in the preface to the first volume, *Ambition and Love* (the second volume is titled *Politics and Anger*):

France 1848-1945 may be read in the same way as one would a series of novels, each of which tells the story of a family or a community from a different point of view. Each chapter and each volume may be read independently. Each has its own surprises, for I aim to show that France was not what it seemed to be; each has its own constellation of heroes or anti-heroes, because I do not see France as dominated by one man, one class or one set of principles. Taken as a whole, however, these portrayals of the many faces of the French are designed to make it possible to judge anew, and less partially, the idiosyncracies, the poses and the torments of a nation that has always irritated its neighbours, even when it has won their admiration and sometimes indeed their affection. (vii)

Since I believe that behaviour is muddled and obscure, and cannot be presented truthfully as simply a search for some ideal, like glory, justice or liberty, and since I do not presume to be able to prove anything when it comes to discussing human motivation, I have not written a general national narrative, held together by a more or less plausible string of causes. Instead, I have made the individual my starting-point, and have tried to show him beset by a multitude of pressures, internal as well as external. I have grouped his struggles around six passions: ambition, love, anger, price, taste, and anxiety. (vii)

My method is to hold up a multitude of mirrors around the French, so that they may be seen simultaneously from different angles; and my other volumes pursue these themes into other recesses of their personalities. To adapt to the kaleidoscopic vision I offer, the reader must, of course, be willing to put aside temporarily the expectations that he has of history, in the same way as he must put aside his traditional expectations when looking at the paintings of the Impressionists or the Cubists. I hope the experience will modify his attitude to the French, and to the past, but also that it will tell him something he did not know about himself. (viii)

So it is the ordinary individual rather than the iconic powerful leader; and it is the emotional setting rather than the deliberative process, that most interest Zeldin. But Zeldin also thinks that this study leads to the discovery of important commonalities across the French -- "the common beliefs, attitudes and values of Frenchmen, which often cut across ideological and class lines" (2). So there is an historical point to writing about "the French" which will lead to different findings than "the British" or "the Germans." Careful study and interpretation permits the historian to tease out a "style" or "persona" that distinguishes various national groups.

Zeldin clarifies this goal in these words:

I do not mean by this that I am seeking to define the immutable French soul, mind, or character. But this is something many people talked about and I have tried to investigate why they came to believe that there was such a thing. (3)

This goal runs squarely up against the historiography of difference that Emmanuel Todd advocates in considering the French; Todd's view is that France was constituted through a very specific and intentional process of identity shaping (post), and that there was great diversity of thought and institution across the territory that became France. But the two perspectives are not flatly contradictory; instead, Zeldin's approach can be understood as a kind of historical ethnography, while Todd's approach emphasizes processes and

structures of nation formation.

Is this goal of discovering characteristic ways of thinking and feeling for a national population a credible one? I think it is, once we take a material and institutional view of the formation of personality. The human being is socially constructed; this means that his/her psychology and mental and emotional frameworks are inflected by specific institutions and experiences. And it is entirely believable that there might be enduring differences in the traditions and institutions through which English school boys and girls and French children absorb formative ideas about -- family, morality, anger, comportment, and nation.

How does Zeldin turn this historiographic goal into a workable program of research? One key strategy that he pursues is to identify a handful of central categories of actors in French society -- doctors, notaries, the rich, bankers, industrialists, bureaucrats, peasants, workers -- and to trace out the specifics of how these categories functioned in France. How were doctors educated? How were they compensated? How did they compete for clients? What level of prestige did they enjoy? Zeldin believes that each of these social categories represents a distinctive matrix of characteristics, relative to the analogous social groups in other countries. So by taking the measure of these great social groups, Zeldin believes that he is also able to delineate some of the distinctive elements of French attitudes and social relations.

And what about the most numerous group -- the peasants? How were they regarded in the nineteenth century? Zeldin argues that peasants were essentially invisible to cultivated French society:

The peasants are not studied in Balzac's universal portrait of French society. Though he called one of his novels *Les Paysans* and devoted several volumes ostensibly to painting scenes of rural life, Balzac could not describe the peasants, because he was full of contempt for them. They were savages, like Fenimore Cooper's Red Indians, and he was concerned with them only as subjects for his schemes to improve them. (131-32)

So contempt is one French attitude towards the peasant; another is the romanticized view that seems to trace back to Rousseau:

The romantics, the Catholic revivalists, the believers in a conservative and hierarchic order, all held him up as a model of a human unspoilt by progress. George Sand wrote books about him or rather books about how she would have liked him to be, inaugurating a whole genre of rustic novels. ... Napoleon III inaugurated his reign with an inquiry into popular poetry forgotten 'because of a thoughtless contempt by our rather too worldly literature'. Folklore societies were formed. (133)

After surveying these elite attitudes towards peasants, Zeldin turns to an extended effort to decipher some of the social reality of the peasant in the nineteenth century. And he finds that the stereotypes that French society applied to the peasant, from left to right, were unfounded.

These generalisations about the innate conservatism of the pesant need to be interpreted carefully in the context of French history. The observance of traditional routines, agricultural and social, should not obscure the fact that conflict was part of those routines, and that the pressures involved in preserving them add up to a situation which is far from being one of stagnation. The peasants were neither satisfied nor contented. They were constantly trying to improve their lot, to enlarge their farms, to raise their status. Their world was torn by deep divisions, and by animosities both of interest and of pride. (135)

The sense of community depended also on the way the land was worked. The common generalization that the peasants were innately individualistic and independent is another bourgeois myth. It is important to remember that though individual peasant property had developed before the Revolution, ownership did not imply complete liberty to work the land as one pleased. When the strips and plots were tiny, it was essential to co-operate in sowing and reaping. No man could reach his plot without going through those of his neighbours. (139)
Much of this material on the professions and the major social groups falls under the heading of "ambition" -- competition and striving for one's betterment. This first volume ends with an extended discussion of "love" -- the family and children.

The family, as organised in France in these years, had an effect on people's lives as profound as any political regime or any economic force. It was a powerful institution which resisted change with remarkable vitality. (285)
But here again, Zeldin finds that the realities of nineteenth-century France contradicted the common stereotypes of marriage, family, and children.

Zeldin's writing makes one think of a gifted interpreter of literature or art, more than of a traditional historian. He is very sensitive to telltale nuances, and very creative in building an interpretation of the French based on a series of such insights. In this regard it is "humanities-inspired history" rather than "social-science history." Zeldin appears to affirm this point in saying that his historical writing does not aspire to the "objectivity" and neutrality of the sciences:
Historical study is a personal experience, and the subjective elements in it deserve to be valued, when so many other branches of knowledge are becoming largely technical. To admit that historians solve their problems of colour and light, that they create their compositions for reasons which are ultimately subjective, because these seem to them to be coherent and true, is not to admit a fault, but to assert that each individual historian can express himself in his work. (7)
So Zeldin's project is a broad one: to attempt to discern some of the important strands of mental and emotional framework through which historical French men and women thought and experienced their history. It is a kind of personality psychology for a whole historical population. And Zeldin affirms, as a literary critic would do as well, that there alternative tellings of this story.

Historical GDP estimates for early modern China

Thursday, January 06, 2011

Li Bozhong is one of China's most influential economic historians, and he is undoubtedly the most internationally connected. Much of his work in the past several decades has been devoted to constructing a detailed economic history of the lower Yangzi Delta (for example, Agricultural Development in Jiangnan, 1620-1850). His findings have been crucial empirical contributions to the "involution" debate (link, link, link) about whether the Chinese economy was stagnant and significantly less productive than the European economy. Thanks to his research we now have a much more informed understanding of the economic dynamics of the Lower Yangzi region in the early modern period (1620-1850). And his research largely supports the "no involution, significant productivity growth" interpretation. (Ken Pomeranz has a nice review of *Agricultural Development in Jiangnan, 1620-1850* here.)

Li's most recent book has now appeared in Chinese, and it takes an important step forward in terms of methodology. (The cover and title are included above. The book includes an extended summary in English, which allows non-Chinese speakers to get the highlights of method and findings.) The important step that Li introduces here is a first effort to apply the methodology of historical national accounts to China. Essentially this method allows the researcher to use the discipline of GDP accounting to arrive at systemic and internally validated estimates of economic activity in a region over a period of time. (Jan-Pieter Smits, Edwin Horlings, and Jan Luiten van Zanden provide an extensive and detailed description of the method in "Dutch GNP and its Components, 1800-19193" (link). Olle Kranz describes the method in application to Sweden here.)

Li's current book is a massive effort (over 600 pages), but it is itself only a pilot project for a more ambitious study to come in future years. Li has selected one limited district within his previous area of study in the lower Yangzi Delta (Huating-Lou), and attempts to apply the method of historical GDP to this limited region for a single period of time (1823-29). His goal is to determine whether the discipline and method of historical GDP can shed new light on the scattered economic statistics and materials that more traditional economic histories have assembled. The results are highly interesting, and they challenge several key assumptions that have been made about the early Qing economy.

Li hopes for two advantages from this approach. The first is that it provides a unified framework within which to organize and validate existing economic data. "Because the methods of the GDP study are quite elaborate and standardized, they can provide a

coherent macroeconomic framework covering the whole economy" (603). And the second is to provide a consistent basis for comparison with other historical regions where the same methods have been utilized. This means that the kinds of comparisons suggested by recent work in Eurasian economic and demographic history will be enhanced as other scholars apply the methodology to European regions.

Huating-Lou is roughly a single county, Songjiang County, with an area of 870 square kilometers and a population in 1816 of 563,052. (From the maps it appears that the county falls squarely within the current city of Shanghai.) So the area covered by Li's study is a microcosm of the larger economic region in which it is lodged; Jiangnan had a population of roughly 36 million in the mid nineteenth century. Li makes use of the same kinds of data sources he has used in earlier works: gazetteers, agricultural handbooks, and modern field investigations of the region (in particular, the Japanese South Manchurian Railway Company studies from 1937-41). Essentially Li proceeds by transforming the variety of data provided by these sources into a uniformly formatted table of national accounts.

今日上海市行政区图

The method involves attempting to estimate the magnitude of economic activity in several sectors by assessing production, expenditure, and income. The idea is that the data for these three aspects of the economy are fairly independent; but they should be expected to lead to similar estimates of overall economic activity. (If production estimates indicate a region is producing 10 million yuan of goods, but income estimates indicate only 2 million yuan of income, we can be assured that there is an important data inconsistency.) The method involves making use of the System of Historical National Accounts to provide a unified framework for collecting and presenting the economic data. (See also a paper by Frits Bos describing the use of national accounts as a tool for economic history (link).)

Here is a description of this method as implemented by Luiten van Zanden and colleagues for the Netherlands (link):

Our main method is to gather specific information on annual output and added value in each of the most important economic branches, following the System of National Accounts (SNA) used in contemporary economic-statistical research. The starting point is the production approach; the branches that are being reconstructed include agriculture, herring fisheries, peat extraction, production of textiles, sugar and paper, to name but a

few. Weights will be derived from a reconstruction of the structure of the labour force in three moments in time: 1510/14, 1670/80 and around 1800. Combined, the chronological series and the data on the structure of the labour force will serve as a basis for estimating developments in the level and structure of national income.

Li's results are fascinating. First, he finds that production, income, and expenditure estimates for Huating-Lou in 1823-29 all converge on an estimate of about 13.5 million taels of silver. The production estimate is 13.5 million taels, the income estimate is 13.3 million taels, and the expenditure estimate is 13.9 million taels. So the three systems of accounting all point to approximately the same level of economic activity. This amounts to an estimate of GDP per capita of about 24 taels of silver.

Table 1: Value Added, the Huating-Lou area, 1823-29

	Value Added (1,000 taels of silver)	%
Primary Sector		
Agriculture	4,002	30
Fisheries	166	2
Total primary	4,168	31
Secondary Sector		
"ordinary"	546	4
Textile	1,270	9
"manufacture"	2,666	20
Total secondary	4,482	33
Tertiary Sector		
Commerce	1,727	13
Service	277	2
Finance	486	4
External trade	907	7
Water transportation	251	2
Education	358	3
Government	856	6
Total tertiary	4,862	36
GDP	13,501	100

Second, the sectoral composition of the Huating-Lou economy is genuinely surprising (as indicated in table 1). We commonly think of China's Ming-Qing economy as largely rural and agricultural. But the primary sector, including agriculture and fisheries, amounts to only 31% of the local economy, while the secondary sector (manufactures and textiles) contribute 33% and the tertiary sector (commerce, service, government, etc.) contributes 36%. The prior expectation we might have had of the early modern Chinese economy as largely agricultural is flatly refuted for this region by the 1820s. This finding is corroborated by Li's analysis of the structure of employment in the region; only 27% of employment was in the primary sector, with 56% in the secondary and 16% in the tertiary sectors.

Third, Li points out that the composition of income is also somewhat surprising. Wages represented 61% of the Huating-Lou economy; rent 11%; interest 3%; profit 20%; and depreciation 6%. What is surprising about this estimate is the unexpectedly low percentage of all income that derived from rent -- contradicting the idea that the Chinese economy was a rent-dominated one. (Earlier work by Victor Lippit (Land Reform and Economic Development in China: A Study of Institutional Change and Development Finance) sought to estimate the total surplus created by the Chinese rural economy; he estimates 10.7% of income from rent, 3.4% of income from farm business profits, and 2.8% from rural interest payments. See Understanding Peasant China: Case Studies in the Philosophy of Social Science, pp. 121-22, for more discussion. Li's estimates of rent and interest are about the same as Lippit's, whereas Li's estimate of profits is substantially higher than Lippit's.)

All of this is highly interesting, though (as Li emphasizes throughout), it is based on only one small region during one limited time period. So it will be very interesting to see whether it is possible to perform this kind of analysis for larger parts of the historical Chinese economy.

Estimating economic activity was one of the goals of this research. The other was to establish a consistent basis for comparison across different parts of Eurasia. Li takes up the comparison with the Netherlands that is made possible by the work mentioned above by Jan-Pieter Smits, Edwin Horlings, and Jan Luiten van Zanden (link). And indeed, the comparisons are very interesting. Here is the comparison of the sectoral composition of Huating-Lou and the Netherlands:

Table 9: Comparison of the structure of GDP (%)

	Huating-Lou 1823-39	The Netherlands 1807
Primary sector	30.8	24.6
Secondary sector	33.2	29.1
Tertiary Sector	36.0	46.3
Total	100	100

And here is the comparison for the structure of employment:

Table 10: Comparison of the Structure of Employment (%)

	Huating-Lou 1823-39	The Netherlands 1807
Primary sector	27	43
Secondary sector	56	26
Tertiary Sector	16	31
Total	100	100

The one comparison that Li does not highlight (in the English summary, anyway) is the GDP per capita comparison between Huating-Lou and the Netherlands. This comparison raises some of the issues involved in a recent discussion here of the standard of living (post), since the Dutch analysis is denominated in guilders and the Chinese work is denominated in taels of silver. Smits, Horlings and van Zanden estimate a Dutch population size of 2,163,092, implying a GNP per capita of 227 guilders per capita. Recall that Li estimated a per capita GNP of 24 taels.

So what is the conversion of tael to guilder? Here I have to go beyond my own specialized knowledge and speculate a bit, so this calculation shouldn't be taken uncritically. The guilder was defined in 1840 as equivalent to 9.45 grams of fine silver (link). A tael was equivalent to 37.3 grams of silver, according to Li. So in silver equivalents, the Dutch GDP per capita was 227*9.45 grams of silver, and the Chinese GDP per capita was 24*37.3 grams of silver -- 2,145 grams versus 895.2 grams. By this estimate, the early nineteenth-century Dutch economy produced a silver equivalent per capita over two times that of the Chinese economy. However, the purchasing power of silver was significantly greater in China than Europe; so this estimate overstates the disparity in real wage between the two regions. In "Real Wages in Europe and Asia: A First Look at the Longterm Patterns" Robert Allen estimates the wage basket for China at 247.3 grams of silver, versus 579.7 grams of silver in England (link, pp. 180, 182). If we took the wage basket as the basis of a cost-of-living deflator, then the disparity between the Netherlands and China essentially disappears. The Dutch GDP per capita PPP-

adjusted product is 3.7 against a 3.6 per capita PPP-adjusted product for China, using the wage basket as deflator. This would indicate that the Dutch economy was marginally richer than the Chinese economy in the lower Yangzi region -- but not by much.

Li finishes this comparison by raising the question of traditional versus modern economies. Both economies considered here contradict the assumptions of a "traditional" economy -- largely rural, largely agricultural, and largely stagnant. Instead, these comparisons indicate a surprisingly urban, manufacturing- and service-based economy in the second decade of the nineteenth century, and Li argues that we can appropriately describe each of them as a "modern" economy.

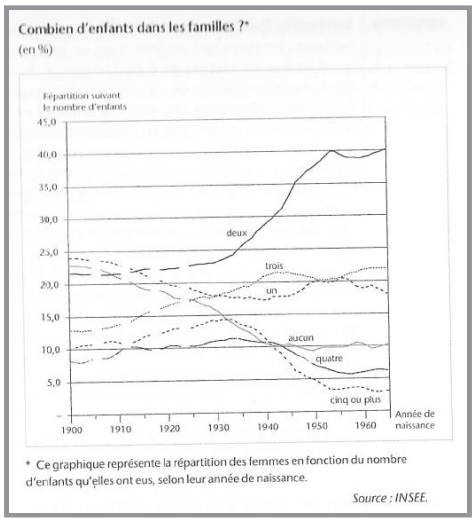
Li's book is an important new contribution to Chinese economic history, and the historical GDP method seems to be a highly fruitful innovation. It is a really valuable new analytical perspective on the Chinese economy. I hope the book will be translated into English as quickly as possible.

Deciphering French society

Sunday, January 09, 2011

Louis Maurin recently published a valuable book on contemporary French society, Déchiffrer la société française, which is intended to shed light on the social realities of France in a way that is genuinely accessible to the public. There are chapters on population, the family, schooling, immigration, unemployment, consumption, and social values, among other important topics (link). The book is intended to capture and encapsulate some of the data that is available through French sources that will make the basic outlines of France more transparent to the public. (There is a companion website for the book as well.) Denis Clerc provides the preface for the book -- another voice in French society calling for greater transparency about inequalities.

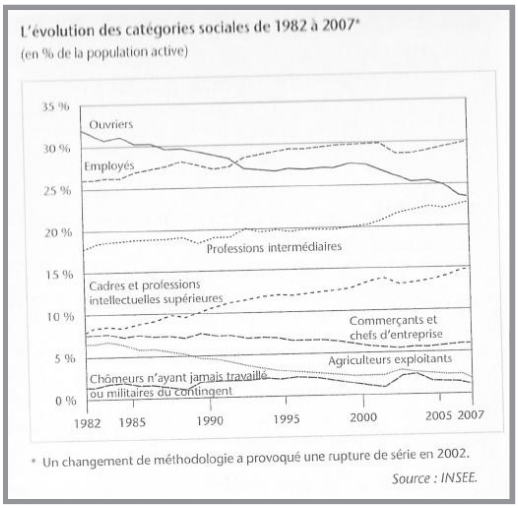
Maurin believes that there is a wide gap between the rhetoric that French elites and journalists use to characterize contemporary French society, and the social realities. In order for France to successfully address the social problems it faces, it is important for the public to have a better understanding of the background and the current realities. So the goal of this project is straightforward:



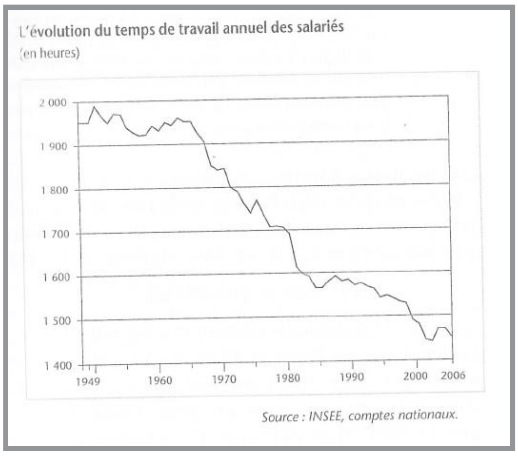
À l'encontre de ce mouvement, ce livre vise à dresser un état de lieux et à expliquer certains mécanismes du fonctionnement de la société française. Il s'agit bien d'abord de «déchiffrer», car l'objectif est, autant que faire se peut, de mesurer et d'analyser des évolutions. Sans fétichisme du chiffre, il devient indispensable de mettre sur la table des

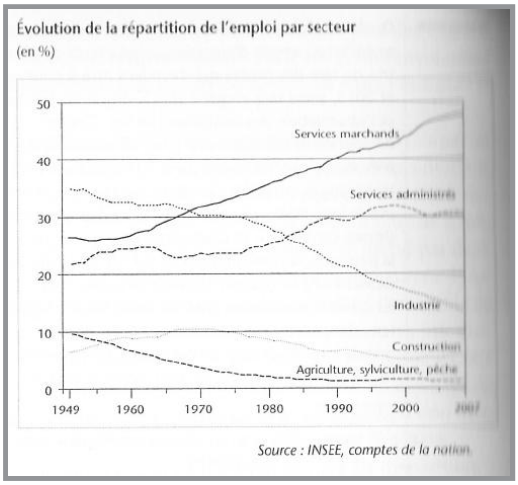
données pour sortir de la rhétorique française où chacun se paie de bons mots. Ce qui permet à tout le monde d'avoir raison en même temps, faute de pouvoir être départagé par les faits. Dans la mesure du possible, nous essaierons de présenter des séries sur longue période, pour élargir les perspectives. L'objectif est aussi de « déchiffrer » des phénomènes qui ne sont pas tous immédiatement perceptibles. De dégager des tendances pour mieux comprendre l'évolution de la société dans un monde où l'avenir semble, pour beaucoup, très incertain. Sur la plupart des phénomènes présentés, vécus au quotidien, chacun a sa petite idée, qu'il s'agisse de famille, d'école, d'immigration, de chômage… Toute la difficulté de la démarche et son intérêt consistent à échapper aux expériences personnelles pour analyser le comportement d'un ensemble. (Avant-propos)

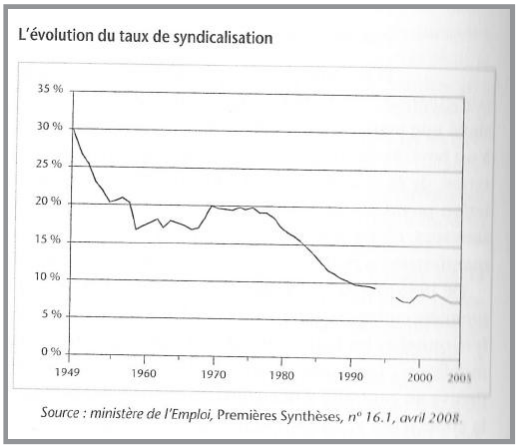
[To counter this trend, this book aims to develop a baseline description and to explain some mechanisms of how French society functions. It is indeed a first effort, because the goal is, as far as possible, to measure and analyze trends. Without making a fetish of data, it is necessary to provide tables of facts in order to escape the rhetoric to which everyone pays lip service. Without facts, everyone can claim to be right at the same time. Wherever possible, we attempt to present a series of data over a long period, to broaden the perspective. The goal is also to "decipher" phenomena that are not immediately obvious. We seek to identify trends in order to better understand society in a world where the future for many is very uncertain. For most of the phenomena presented, each individual has his/her own perspective, whether it concerns the family, schooling, immigration, unemployment, ... The challenge is to separate out one's personal experiences in order to analyze the behavior of the larger group.]
Each topic is a fundamental one -- population, nuptiality, family, schooling, immigration, employment, consumption. And the data that Maurin summarizes are often striking and unexpected.



Here is a striking graph of the absolute number of marriages and divorces since 1960, and a graph of family size changes between 1900 and 1970. The marriage rate increased sharply in the 1960s into the early 70s; it then went into a steep decline.

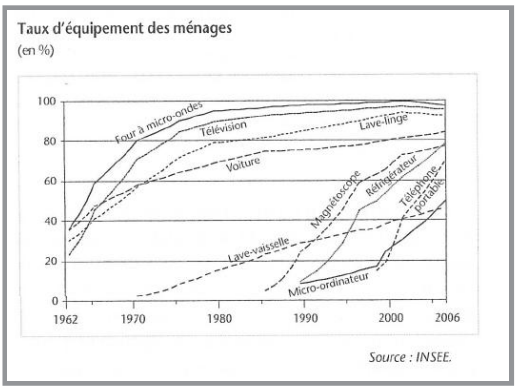


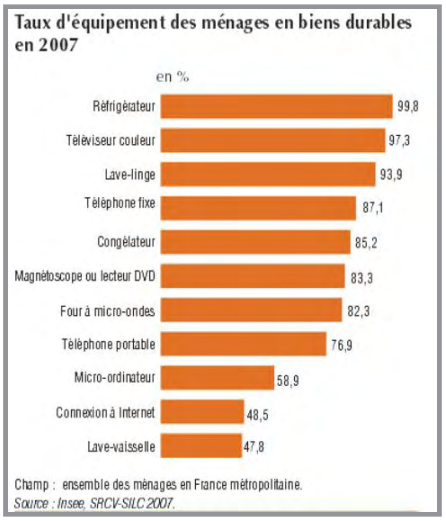


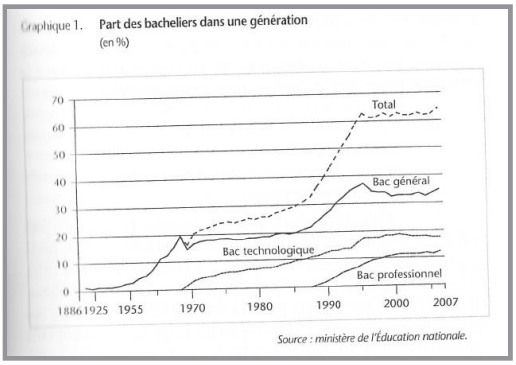


Here are several graphs representing economic and social changes in the past thirty years. The first tracks the percentage of adults in different socio-economic groups: workers, managers, professionals, executives, farmers, and permanently unemployed. The second tracks the fairly steep decline in the number of hours worked annually by a worker, from under 2000 to under 1500. The third tracks the shifting composition of the

workforce, documenting a dramatic decline in industrial labor from 35% to 15%. And the fourth graph tracks union membership, from a high of 30% in 1949 to a low of 8% in 2005. This is surprising for Americans who think of the French workforce as being highly unionized.







Here is an indication of how French consumption has evolved over the past sixty years. Television and washing machines started early; home computers and mobile phones came in the decade of 1990-2000. (It appears that several labels may be switched on this graph; it's hard to believe that microwave ovens became common well before refrigerators. And in fact the 2007 snapshot from INSEE suggests that these two labels have been switched.)

Here is a snapshot from INSEE for household items for 2007:

And what about education? Maurin draws attention to the progress of the *bac* over the past 60 years. The creation of the *bac technologique* and the *bac professionnel* in 1968 and 1988 respectively conjoined with growth in the *bac general* to produce rapid increase from the mid 1980s through 1990s; and the total has remained flat since the 1990s.

Maurin expresses a certain amount of disappointment with the discipline of academic sociology in France for its failure to provide a "public" sociology -- an empirical and theoretical research program aimed at shedding light on the most pervasive patterns in French society today. ("Malgré des progrès récents, le monde scientifique — la sociologie, en particulier — ne semble plus vraiment chercher à dresser ce portrait social de la France;" avant-propos.) And here again in the conclusion:

La statistique n'est pas seule en cause : la recherche laisse de côté de très nombreux domaines, pourtant indispensables à la compréhension du monde contemporain, quand bien même les données existent. Les sociologues qui travaillent sur des sujets aussi essentiels que les revenus, la mobilité sociale ou la consommation ne sont qu'une poignée. Dans certains domaines, comme l'exclusion ou l'immigration, ils se comptent par dizaines… Personne ne conteste la nécessité de ces travaux. Il n'en demeure pas moins que, pour partie, la sociologie française s'attache aux «dominés », oubliant que, pour analyser les processus de domination, il faut aussi regarder vers le haut. (Conclusion)

[The data are not the only cause. Researchers leave to the side many domains that are indispensable to comprehending the contemporary world, even when the data exist. Sociologists who work on such essential subjects as income, social mobility, or consumption are only a handful. In some domains, such as exclusion or immigration, they are fewer than dozens. No one can disagree about the necessity of this work. Instead, the French sociologists prefer to focus on the "dominated", forgetting that it is necessary to look at the top in order to understand the processes of domination. (Conclusion)]
In short -- French society is as complicated as any other, with its own history and current social forces. And many of the social realities the French currently face are obscure in their causes and their distribution across regions and classes. So it is particularly important for authors like Maurin to help pull back the curtain from some of these basic social facts.

(Each chapter offers a short list of key internet sources that allow the reader to pursue the data questions of the chapter directly. A few key resources on population, labor, poverty, family, immigration, and education include --

- Eurostat (Service statistique de l'Union européenne link)

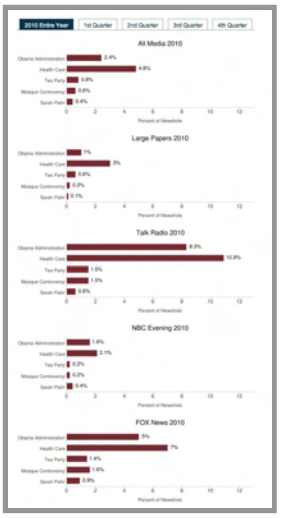
There is a volume of valuable data available from these sources.)

Media and political culture

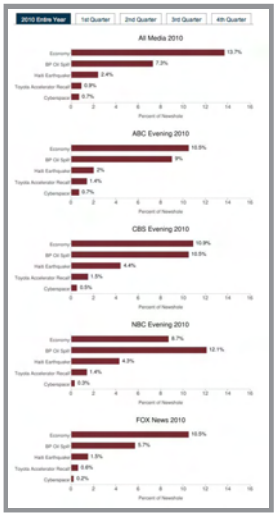


Tuesday, January 11, 2011

How are people's political beliefs, concerns, and passions influenced within a modern mass society? There are many mechanisms, certainly: family, school, place of worship, place of work, and military service, to name several. But certainly the various channels of the media play an important role. Newspapers, television and radio, social media, and blogs have a manifest ability to focus some parts of the electorate on one issue or another.

So it seems worthwhile to ask whether it is possible to perform some empirical study of the content and value systems associated with various media channels. (Here is a textbook by Klaus Krippendorff on the use of content analysis in journalism and the media; Content Analysis: An Introduction to Its Methodology.) This question falls into several parts: first, are there important differences in content and tone across various media channels? And second, what effects do these configurations of content and tone have on the users of the media?

The Pew Research Center's Project for Excellent Journalism offers a window into the first of these questions with a fascinating new tool (link). The "*Year in the News Interactive*" tool is the front end of a valuable database that codes various media streams according to content. The database is then searchable so that the user can produce reports on the percentage of the "newshole" devoted to a particular issue or person in a particular medium. Here is a sample of what the tool produces:



This chart repays close examination. It picks out five segments of media -- "All Media," "Large Papers," Talk Radio," "NBC Evening News," and "Fox News," and it compares these outlets with respect to five issues: Obama Administration, Health Care, Tea Party, Mosque Controversy, and Sarah Palin. These are highly politicized issues, so it is

interesting to see how the patterns of treatment differ across different segments of the media.

If we consider "All Media" as a benchmark -- representing the average amount of attention given by the media as a whole to various issues -- we see that Talk Radio and Fox News show a few remarkable patterns. Both sources give the mosque controversy more than twice the percentage of the newshole; likewise the Tea Party gets twice as much attention with Talk Radio and Fox News as with All Media. Fox News gives Sarah Palin over twice the exposure she gets from All Media -- and nine times the exposure she gets from Large Papers. Both Talk Radio and Fox News give an inordinate amount of air time to Health Care and the Obama Administration.

Now take a different cut: the network news programs and Fox News with respect to a much less political list of topics -- BP Oil Spill, Haiti Earthquake, Toyota Accelerator Recall, and Cyberspace.

Here the main contrast that seems evident is that Fox News devotes significantly less time to the non-political issues. Fox devoted about half the percentage of its newshole to the BP Oil Spill compared to NBC news; Haiti got roughly a third the amount attention on Fox; and the Toyota Accelerator Recall got less than half the exposure as it received on NBC news.

At a minimum, this shows something pretty interesting: the regular viewer or listener to Fox News and Talk Radio will get a very different view of the world from the person exposed to All Media or Large Papers. These media channels give an inordinate amount of airtime to "hot button" issues that have the potential of inflaming their viewers. And these channels spend much less time that the other media on non-political issues -- Haiti, Toyota recall, or Cyberspace.

What would be particularly interesting in today's environment is an additional dimension of content analysis, reflecting antagonism, intolerance, and hostility. It would be very useful to have a few years of data on the percentage of the newshole devoted to incendiary reporting about issues, individuals, and the government. Many observers have the definite impression that this kind of language has increased dramatically; it would be very useful to have quantifiable data on this topic.

(As we think about the tenor and extremism of some of the voices in political media today, it is sobering to remember the role that "hate radio" played in the Rwandan genocide; link.)

Rawls on political liberalism

Friday, January 14, 2011

Long after the transformative impact Rawls brought to social and political philosophy with A Theory of Justice: Original Edition (1971), Rawls continued to wrestle with the question of how a just society ought to work. One major part of this question is how a just society ought to encompass major disagreements among its citizens about values and "conceptions of the good;" and much of his thinking is reflected in his 1993 collection of essays, Political Liberalism. Here is how he formulates the central problem:

A modern democratic society is characterized not simply by a pluralism of comprehensive religious, philosophical, and moral doctrines but by a pluralism of incompatible yet reasonable comprehensive doctrines. No one of these doctrines is affirmed by citizens generally. Nor should one expect that in the foreseeable future one of them, or some other reasonable doctrine, will ever be affirmed by all, or nearly all, citizens. Political liberalism assumes that, for political purposes, a plurality of reasonable yet incompatible comprehensive doctrines is the normal result of the exercise of human reason within the framework of the free institutions of a constitutional democratic regime. Political liberalism also supposes that a reasonable comprehensive doctrine does not reject the essentials of a democratic regime. (xvi)

So, to start, Rawls recognizes that modern society is not based on consensus around the major values or issues; rather, individuals differ in their commitments about rights, justice, and the good human life. How in the context of this pluralism of important value systems, is it possible for a modern society to nonetheless possess the features of civility and stability that we would desire?

Here, then, is what Rawls calls the problem of political liberalism:

How is it possible that there may exist over time a stable and just society of free and equal citizens profoundly divided by reasonable though incompatible religious, philosophical, and moral doctrines? Put another way: How is it possible that deeply opposed though reasonable comprehensive doctrines may live together and all affirm the political conception of a constitutional regime? What is the structure and content of a political conception that can gain the support of such an overlapping consensus? (xviii)

One prior thought we may have had about a liberal society is that the state establishes no more than a neutral system of law, within the context of which individuals can pursue their own separate and incompatible conceptions of the right and the good. So the liberal state is a neutral state -- one that gives no privilege to one conception of the good over another.

Neutrality is certainly part of the ideal of a liberal state; but it isn't quite enough. The reason is that some conceptions of the good and the right require the intervention of the state for enforcement. If the Alpha group believe that fetal stem cells are nascent human beings and therefore should never be used for the purpose of scientific research, while the Beta group believe that fetal stem cells are no more than useful compounds of organic molecules that can relieve human misery; then both sides of the debate want to

prevail through legislation -- either to prohibit stem cell research or to permit stem cell research. Each side sees its position as being driven by a moral imperative -- and therefore not to be compromised without an unacceptable loss of moral integrity on the part of the losing group.

To overcome this contradiction, neutrality is not enough. We need to add a commitment to democratic, constitutional procedures as being the moral trump card when it comes to legislation about areas of conflict based on fundamental disagreements about the right and the good. Essentially this comes down to a second-order commitment that every citizen needs to share: When policy issues arise that lead to profound disagreement among blocs of citizens, the right solution is the procedurally correct solution arrived at through legitimate democratic processes. In other words, all citizens need to put their commitment to legitimate democratic procedures ahead of their commitment to a particular conception of the good and the right. Democratic values supersede religious, political, and moral convictions when there is no choice but to legislate an issue. Citizens are entitled to argue their case for or against proposed legislation; but they are then morally obligated to accept the democratically chosen outcome as a legitimate resolution of the issue.

Rawls captures this conundrum with the idea of ***toleration***: the idea that citizens must tolerate and respect the strongly-held convictions of their fellow citizens, even while participating in a political process that leads to legislation that is inconsistent with those convictions. This means that if the Alphas prevail through the political process, the Betas need to accept the outcome as morally legitimate -- even though it contradicts their own firmly held moral convictions. But why would one accept the moral necessity of toleration? Doesn't this mean sacrificing one's own moral convictions to the will of a contrary majority? And doesn't this imply that one's own convictions are tentative and conditional?

The answer seems to go along something like these lines. When one is a member of a society, one recognizes the inevitable fact of the kind of fundamental pluralism Rawls has described here. This means that society will sometimes legislate about issues concerning which reasonable citizens disagree, based on fundamental moral convictions on both sides. So the citizen is asked to bracket his/her particular moral convictions when considering outcomes, even as he/she is free to vigorously argue on the basis of those convictions during the process leading up to legislation. The citizen is asked to take a double perspective on his/her own moral convictions: first-person, that these are my convictions and they seem binding and justified from my point of view; and third-person, that there is disagreement about these matters, and the only defensible process for resolving the issue is the democratic process in which each person's reasons count as much as every other person's. This is something like Thomas Nagel's understanding of altruism in The Possibility of Altruism; the individual is asked to recognize the moral reality of other persons and not to assign a privileged role to his/her own perspective.

A key part of Rawls's own solution to this problem of democratic pluralism is the idea of an "overlapping consensus" among citizens. Here is how he defines that idea:

Such a consensus consists of all the reasonable opposing religious, philosophical, and moral doctrines likely to persist over generations and to gain a sizable body of adherents in a more or less just constitutional regime, a regime in which the criterion of justice is that political conception itself. (15)

In such a consensus, the reasonable doctrines endorse the political conception, each from its own point of view. Social unity is based on a consensus on the political conception; and stability is possible when the doctrines making up the consensus are affirmed by society's politically active citizens and the requirements of justice are not too much in conflict with citizens' essential interests as formed and encouraged by their social arrangements. (134)

So the ideal here is the notion that some set of constitutional arrangements may be acceptable from all points of view -- from Christian to libertarian to Muslim to socialist. This hope seems to rest on the idea that a neutral, democratic set of political institutions give the best opportunity for the adherents of any particular theory of the good to pursue their interests; so each of the "reasonable opposing religious doctrines" may have good reason to endorse the neutral democratic constitution. (This is a kind of "original position" argument, applied to opposing comprehensive doctrines.)

What makes this a consensus of any kind is ***not*** the notion that there is an overlapping set of values that persist across all the comprehensive doctrines; rather, it is the hope that there will be at least one political arrangement that can serve as the consensus choice of all the incompatible comprehensive doctrines.

The preceding account says that the consensus goes down to the fundamental ideas within which justice as fairness is worked out. It supposes agreement deep enough to reach such ideas as those of society as a fair system of cooperation and of citizens as reasonable and rational, and free and equal. As for its breadth, it covers the principles and values of a political conception ... and it applies to the basic structure as a whole. (149)

So -- what is a political liberal, according to Rawls? It seems to boil down to this. It is a moral individual who has his/her own conception of the good and set of fundamental doctrines; who recognizes nonetheless that he/she is a member of a polity that is fundamentally plural when it comes to conceptions of the good; who recognizes that there is no basis for insisting on privilege for one's own conception of the good; and who recognizes the moral legitimacy of constitutional democratic procedures when it is necessary to decide among policies that involve conflicting conceptions of the good. It is a person who puts civic commitment to constitutional democratic processes ahead of one's one fundamental convictions when necessary. And it is a person who is fully committed to ensuring the neutrality of the state across fundamental convictions. Neutrality of law across persons and conceptions of the good, full recognition of fundamental pluralism within a modern society, respect for the equal worth of all other citizens, and a recognition that one's own beliefs have no basis for being privileged over those of other citizens -- these are the fundamental commitments of a political liberal.

We can now give a fairly simple explication of illiberal thinking as well. It is moral, religious, or political fundamentalism -- the idea that one's own moral convictions are so compelling that no democratic process could legitimately override them. It is the idea that the individual has a persistent right to oppose the state when the state's actions are inconsistent with one's own moral convictions. It is authoritarian -- it endorses the idea that one's own group or party has the right to override the majority's will when the state contradicts one's fundamental convictions. And it is, of course, a position that is fundamentally disrespectful of democracy and of the equal dignity and worth of one's fellow citizens.

National values on racial equality

Monday, January 17, 2011

Today the country celebrates the birthday of Dr. Martin Luther King, Jr. Most of us think of Dr. King as a genuinely important American thinker, and one whose life and actions permanently changed some important values and thought processes in this country when it came to racial equality and affirming communities in the United States. His death by assassination at the age of 39 cut short a life of influence from which our country could have benefited greatly in the intervening decades.

How much have we changed in our thinking about race since 1968? Is it possible to assess the degree of influence that Dr. King has had on current American attitudes about race and about what needs to be done? How would we assess the nature and depth of changes that have occurred in American attitudes towards race, equality, and community since 1968? What were some of the mechanisms of value transmission through which those changes took place? And how would we attempt to sort out the elements of those changes that can be traced back to Dr. King?

One part of the mechanism of influence is pretty obvious. Dr. King was a visible and influential leader from the Montgomery bus boycott in 1955 to the month of his assassination in Memphis in 1968. He gave hundreds of speeches, he had a meaningful and visible footprint on television and radio, and he reached a mass audience during those years. White and black Americans probably heard his messages differently, but there is no doubt that King influenced millions of Americans during his lifetime. So this is a very direct form of influence -- people who were exposed to the struggles of the Civil Rights era and to the speeches and actions of Dr. King, and who absorbed a new set of attitudes about racial equality and social progress from those experiences.

It is an interesting and difficult question to assess how much of that direct first-person influence persisted into the next generation of children and adults. But here again, mechanisms of transmission are easy enough to identify. Many of those persons who were directly influenced during the Civil Rights generation had children of their own, whom they influenced through their example and their speech, and a certain number of them became teachers and broadcasters and health care providers -- each creating his/her own avenue of influence on others. So the primary contemporary effects of Dr. King's teachings and actions had a second- and third-generation echo.

Another form of influence during his lifetime was more focused. Dr. King was an elite civil rights leader and strategist, and he stood in a central position within networks of activists and leaders, both black and white. He was successful in positioning his own rhetoric and strategies in nodes of influence within these networks and organizations. His own views didn't always prevail -- but they did often enough to permanently influence debates about racial justice and strategy within the next generation of influencers. So King's philosophy and vision found vivid expression by the next generation of leaders and influencers both nationally and regionally. And these leaders in turn influenced future debates and many millions of people through their own political actions and leadership.

A third mechanism of influence stems from historical tragedy -- the assassination itself. The traumatic impact on American consciousness of King's assassination surely had an impact on the degree to which his philosophy and vision penetrated the American psyche. It was a visceral warning for all of America about the virulence and violence of racial hatred. It served as an unforgettable signal that these conflicts must be resolved and that we must find ways of ending American racism. And Dr. King's message was a promising one: we can be better than this, we can move beyond slavery and discrimination to a world of equal love and respect.

All these pathways of influence contributed to other large changes as well, including especially the effort to broaden school curricula to include issues of race and racial equality. Those curricular innovations were certainly influenced by Dr. King's example; and millions of American children from the 1970s through the present were exposed to positive ideas about equality and the value of diversity in language that had very much in common with Dr. King's vision of the future. So it is reasonable to expect that young people's attitudes towards race in the 1970s through 1990s were very different from those of children educated in the 1940s and 1950s.

So how much change has there been in fundamental attitudes since 1954 (the year of the Supreme Court school desegregation decision, Brown v. Board of Education)? And how much of MLK's stamp do current American attitudes bear? Howard Schuman and other scholars have attempted to investigate this question empirically (Racial Attitudes in America: Trends and Interpretations, Revised Edition, Black Racial Attitudes: Trends and Complexities). Schuman and his colleagues work carefully through the main political events of the 1940s through 1960s, and attempt to synthesize public opinion data to assess the changes that occurred within the population over a fifty-year period.

It certainly appears that American attitudes towards race, and towards a racially just society, have changed dramatically since the 1950s. The Civil Rights struggle itself -- the struggle by African-American men and women to overcome systematic discrimination and racism -- is surely the largest part of this change. And there certainly were other visions and voices among civil rights leaders who helped to shape the debate. But Dr. Martin Luther King, Jr.'s voice seems to have had the most pervasive and enduring impact on mainstream America when it comes to racial justice and an inclusive community. Dr. King offered a unique combination of realism and optimism that seems to have worked very well with other deep American values. Here is some realism, from "A Testament of Hope" included in A Testament of Hope: The Essential Writings and Speeches of Martin Luther King, Jr..

Whenever I am asked my opinion of the current state of the civil rights movement, I am forced to pause; it is not easy to describe a crisis so profound that it has caused the most powerful nation in the world to stagger in confusion and bewilderment. Today's problems are so acute because the tragic evasions and defaults of several centuries have accumulated to disaster proportions. (313)

And here is some of his finest optimism, concluding the same essay:

A voice out of Bethlehem two thousand years ago said that all men are equal. It said right would triumph. Jesus of Nazareth wrote no books; he owned no property to endow him with influence. He had no friends in the courts of the powerful. But he changed the course of mankind with only the poor and the despised. Naive and unsophisticated though we may be, the poor and despised of the twentieth century will revolutionize this era. In our "arrogance, lawlessness and ingratitude," we will fight for human justice, brotherhood, secure peace and abundance for all. When we have won these -- in a spirit of unshakable nonviolence -- then, in luminous splendor, the Christian era will truly begin. (328)

Violent rhetoric and violent behavior

Thursday, January 20, 2011

Is there a possible causal relationship between an increasing occurrence of violent political rhetoric in broadly available media channels and the occurrence of violent political behavior? How would a social scientist investigate this hypothetical relationship? (Here is a pretty worrisome timeline of events, statements, and actions over the past several years involving violent rhetoric against the government and violent actions.)

Much of the debate since the Tucson shootings has focused on what seems like the wrong question: was there a direct influence from the extremist rhetoric of the past two years to the violent actions of this particular assailant? Sometimes the answer to this kind of question is "yes" -- Timothy McVeigh was directly inspired by the violent ideas and passions associated with the right-wing militia movement. But the harder question is that of ***indirect*** and diffused influence: is it possible for a pattern of virulent media communications to create a ***culture*** of violent attitudes that leads through indirect mechanisms to political violence directed against individuals and institutions?

In order to think carefully about this set of issues, we need to think through the ways in which individuals are led to commit violent actions. We might model the potentially violent person along these lines: Anger and hatred are **emotional states** that motivate violent attacks. **Social inhibitions and processes of self-control** work in most people to inhibit acting on hateful, violent impulses. Some social and physiological influences have the effect of **weakening inhibitions**. Individuals are most likely to engage in violence when hateful emotions are strongest and inhibitions are weakest. They are most likely to direct violence against symbols or representatives of the object of their anger and hatred.

Media and public discourse can affect each of these three factors. Angry speech can increase feelings of anger in the listener. This is very much the purpose of the speech; it is aimed at whipping up the passions of the viewer. Second, it can focus angry impulses towards a specific group. Again, this is the goal; it is to focus anger on government, or government officials, or other groups. And it can lower inhibitions by positively valorizing violent action. "Your peers will admire you for taking action; other people have done so too. You are justified."

We might model the media ranters as involved in a game of escalation, competing against each other for greater shock value and virulent language. They have an interest in generating a committed audience, and they are competing with other voices for that audience. They have an interest in escalation. "Shock radio" is intended to shock.

It doesn't appear that direct psychological research has yet been done on this question. But there is a related question that has been very extensively studied, and that is the effect of dramatized television violence on children's propensity for aggression. It appears that there is fairly strong evidence in the social psychology and developmental psychology literatures for a causal link between exposure to television violence in children and increased aggression. Here is a paper in *Developmental Psychology* by L.

Rowell Huesmann, Jessica Moise-Titus, Cheryl-Lynn Podolski, and Leonard Eron (link), where the authors find a significant link between childhood exposure to TV violence and adult aggression.

Over the past 40 years, a body of literature has emerged that strongly supports the notion that media-violence viewing is one factor contributing to the development of aggression. The majority of empirical studies have focused on the effects of watching dramatic violence on TV and film. Numerous experimental studies, many static observational studies, and a few longitudinal studies all indicate that exposure to dramatic violence on TV and in the movies is related to violent behavior (Huesmann & Miller, 1994; Huesmann, Moise, & Podolski, 1997). Furthermore, a substantial body of psychological theory has developed explaining the processes through which exposure to violence in the mass media could cause both short- and long-term increases in a child's aggressive and violent behavior (Bandura, 1977; Berkowitz, 1993; Eron, 1963; Huesmann, 1988, 1998; Zillmann, 1979). Long-term effects with children are now generally believed to be primarily due to long-term observational learning of cognitions (schemas, beliefs, and biases) supporting aggression (Berkowitz, 1993; Huesmann, 1988, 1998), whereas short-term effects with adults and children are recognized as also due to priming (Huesmann, 1998), excitation transfer (Zillmann, 1983), or imitation of specific behaviors. Most researchers of aggression agree that severe aggressive and violent behavior seldom occurs unless there is a convergence of multiple predisposing and precipitating factors such as neurophysiological abnormalities, poor child rearing, socioeconomic deprivation, poor peer relations, attitudes and beliefs supporting aggression, drug and alcohol abuse, frustration and provocation, and other factors. The evidence is already substantial that exposure to media violence is one such long-term predisposing and short-term precipitating factor. The current longitudinal study adds important additional empirical evidence that the effects of childhood exposure to media violence last into young adulthood and increase aggressive behavior at that time for both males and females. (201)

And here is a 2003 article from *Psychological Science in the Public Interest* by Anderson, Berkowitz, Donnerstein, Huesmann, Johnson, Linz, Malamuth and Wartella summarizing research leading to similar conclusions (link). Here is their abstract:

Summary—Research on violent television and films, video games, and music reveals unequivocal evidence that media violence increases the likelihood of aggressive and violent behavior in both immediate and long-term contexts. The effects appear larger for milder than for more severe forms of aggression, but the effects on severe forms of violence are also substantial (r = .13 to .32) when compared with effects of other violence risk factors or medical effects deemed important by the medical community (e.g., effect of aspirin on heart attacks). The research base is large; diverse in methods, samples, and media genres; and consistent in overall findings. The evidence is clearest within the most extensively researched domain, television and film violence. The growing body of video-game research yields essentially the same conclusions.

Short-term exposure increases the likelihood of physically and verbally aggressive behavior, aggressive thoughts, and aggressive emotions. Recent large-scale longitudinal studies provide converging evidence linking frequent exposure to violent media in childhood with aggression later in life, including physical assaults and spouse abuse. Because extremely violent criminal behaviors (e.g., forcible rape, aggravated assault, homicide) are rare, new longitudinal studies with larger samples are needed to estimate accurately how much habitual childhood exposure to media violence increases the risk for extreme violence.

Well-supported theory delineates why and when exposure to media violence increases

aggression and violence. Media violence produces short-term increases by priming existing aggressive scripts and cognitions, increasing physiological arousal, and triggering an automatic tendency to imitate observed behaviors. Media violence produces long-term effects via several types of learning processes leading to the acquisition of lasting (and automatically accessible) aggressive scripts, interpretational schemas, and aggression-supporting beliefs about social behavior, and by reducing individuals' normal negative emotional responses to violence (i.e., desensitization).

Certain characteristics of viewers (e.g., identification with aggressive characters), social environments (e.g., parental influences), and media content (e.g., attractiveness of the perpetrator) can influence the degree to which media violence affects aggression, but there are some inconsistencies in research results. This research also suggests some avenues for preventive intervention (e.g., parental supervision, interpretation, and control of children's media use). However, extant research on moderators suggests that no one is wholly immune to the effects of media violence.

Recent surveys reveal an extensive presence of violence in modern media. Furthermore, many children and youth spend an inordinate amount of time consuming violent media. Although it is clear that reducing exposure to media violence will reduce aggression and violence, it is less clear what sorts of interventions will produce a reduction in exposure. The sparse research literature suggests that counter-attitudinal and parental-mediation interventions are likely to yield beneficial effects, but that media literacy interventions by themselves are unsuccessful.

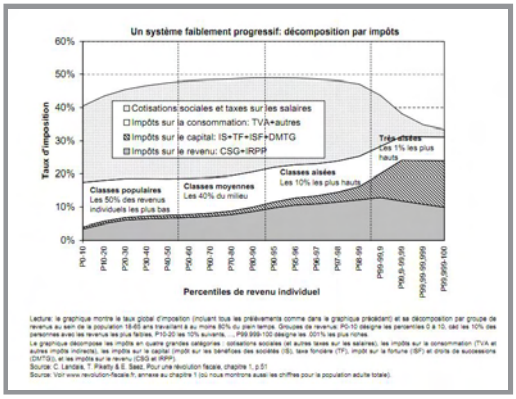
Though the scientific debate over whether media violence increases aggression and violence is essentially over, several critical tasks remain. Additional laboratory and field studies are needed for a better understanding of underlying psychological processes, which eventually should lead to more effective interventions. Large-scale longitudinal studies would help specify the magnitude of media-violence effects on the most severe types of violence. Meeting the larger societal challenge of providing children and youth with a much healthier media diet may prove to be more difficult and costly, especially if the scientific, news, public policy, and entertainment communities fail to educate the general public about the real risks of media-violence exposure to children and youth. (81)
Significantly, both reviews single out mechanisms that appear relevant to hateful and violent language by widely disseminated media commentators. Here are some of the important psychological mechanisms cited in these two survey articles:

- long-term observational learning of cognitions (schemas, beliefs, and biases) supporting aggression
- imitation of specific behaviors
- priming existing aggressive scripts and cognitions
- increasing physiological arousal
- triggering an automatic tendency to imitate observed behaviors
- reducing individuals' normal negative emotional responses to violence (i.e., desensitization)

These articles seem to go some ways towards framing an answer to the question posed above: can exposure to violent speech in the media create indirect causal influences leading to more violent behavior by individuals? The psychological literature appears to support the plausible prior belief that exposure to extreme and violent language in the political media can make individuals somewhat more disposed to aggressive behavior. And this effect doesn't need to proceed through the direct "true believer" mechanism; virtually everyone who has a television or a computer is exposed to this kind of speech, and the literature suggests broad and diffused effects on behavior as a result.

Here are a few possible mechanisms that seem relevant today when we consider the possible causal connections from over-the-top political rhetoric to the occurrence of acts of political violence:

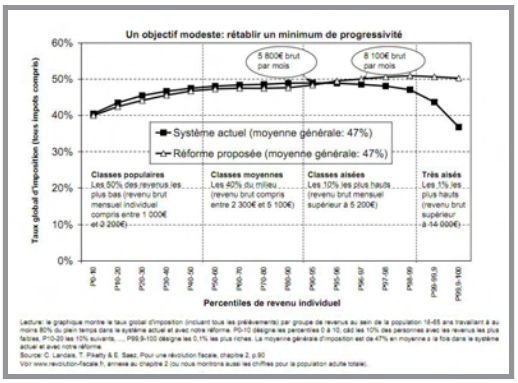
- Exposure to violent language directly motivates some individuals to become "***true believer***" violent actors.
- Exposure to violent language causes some unstable individuals to ***focus their aggression*** against a specific range of targets.
- Exposure to violent language gradually ***reduces inhibitions*** against violence, leading to more readiness to commit violent acts.
- Exposure to violent language influences groups and networks of individuals to be ***more favorable*** to the use of violence.



So these seem to be fairly strong empirical reasons for being very concerned about the inflammatory language that has become increasingly common in political discourse and media rants. The issue isn't simply the value of political civility; it is the very real possibility that extremist rants can influence a small number of listeners to be more prone to engage in acts of political violence, and even people who aren't listeners can be influenced by those who are.

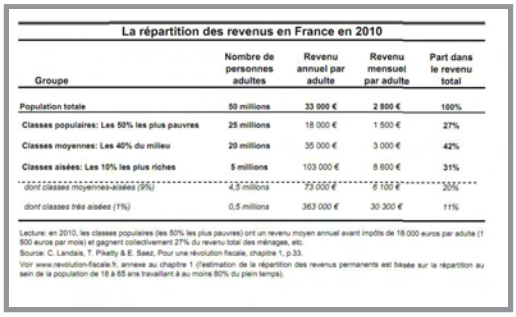
New ideas about taxes in France

Saturday, January 22, 2011



The structure of the tax code in France is getting new attention these days. President Sarkozy has made fiscal reform a key issue in the run-up to the presidential elections in 2012. The Nouvel Obs has a very good section this week on a recent book by Camille Landais, Thomas Piketty, and Emmanuel Saez, economists with long expert knowledge of the French fiscal system. The book is Pour une révolution fiscale: Un impôt sur le revenu pour le XXIe siècle, and it offers a stringent critique of the existing system and a set of proposals for a reformed system. The book has a companion website here.

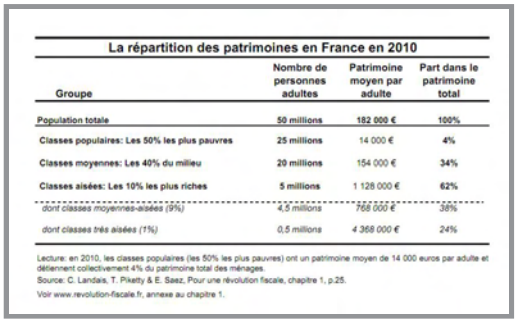
In a word, these experts conclude that the existing tax structure in France is seriously unjust because it is anti-progressive at the very high end of the income distribution -- the top 1 percent decline steeply in the percentage of their income that is collected in the form of the several tax vehicles. Only 20% of the state' revenues derive from taxes that are truly progressive (*Nouvel Obs*, 2411, p. 18).



As we can see from the graph, the total tax burden of the top 1 percent of income earners declines sharply from 48% to about 32%. And the reason for this is the portion of the French tax system devoted to funding social services (*Cotisations sociales et taxes sur*

les salaires). This assessment is roughly flat from the 30th percentile to the 99th percentile, and then it declines rapidly. (The other components of taxes represented here include the income tax, a tax on returns on capital, and taxes on consumption including the TVA.)
Here is what the distribution of tax burdens would look like on the basis of their proposals:

So what is their proposal? It is to significantly revamp the income tax and the *cotisation*. The *cotisation* needs to be progressive rather than regressive; and the income tax needs to be higher. Their proposal is revenue-neutral in this particular sense: the median tax payer today bears a 47% tax burden, and this remains the same under the reform.



Ce livre plaide pour une revolution fiscale précise et opérationnelle, dont tous les détails sont chiffrés au grand jour. Nous proposons en particulier la création d'un nouvel impôt sur le revenue, remplaçant un grand nombre de taxes existantes, notamment la contribution social généralisée (CSG), l'actuel impôt sur le revenu (qui, sou sa forme actuelle, serait purement et simplement supprimé), le prélèvement libératoire, la prime pour l'emploi et le bouclier fiscal. Ce nouvel impôt sur le revenu, payé par tous les Français et socialement adapté a la France du XXIe siecle, sera entièrement individualisé, prélevé directement a la source sur les revenus du travail et du capital. (18)
Also of interest are the summary graphs that the authors provide of the distribution of income and wealth in France:

La répartition des revenus en France en 2010

Groupe	Nombre de personnes adultes	Revenu annuel par adulte	Revenu mensuel par adulte	Part dans le revenu total
Population totale	50 millions	33 000 €	2 800 €	100%
Classes populaires: Les 50% les plus pauvres	25 millions	18 000 €	1 500 €	27%
Classes moyennes: Les 40% du milieu	20 millions	35 000 €	3 000 €	42%
Classes aisées: Les 10% les plus riches	5 millions	103 000 €	8 600 €	31%
dont classes moyennes-aisées (9%)	*4,5 millions*	*73 000 €*	*6 100 €*	*20%*
dont classes très aisées (1%)	*0,5 millions*	*363 000 €*	*30 300 €*	*11%*

Lecture: en 2010, les classes populaires (les 50% les plus pauvres) ont un revenu moyen annuel avant impôts de 18 000 euros par adulte (1 500 euros par mois) et gagnent collectivement 27% du revenu total des ménages, etc.

Voir www.revolution-fiscale.fr, annexe au chapitre 1 (l'estimation de la répartition des revenus permanents est biaisée sur la répartition au sein de la population de 18 à 65 ans travaillant à au moins 80% du plein temps).

La répartition des patrimoines en France en 2010

Groupe	Nombre de personnes adultes	Patrimoine moyen par adulte	Part dans le patrimoine total
Population totale	50 millions	182 000 €	100%
Classes populaires: Les 50% les plus pauvres	25 millions	14 000 €	4%
Classes moyennes: Les 40% du milieu	20 millions	154 000 €	34%
Classes aisées: Les 10% les plus riches	5 millions	1 128 000 €	62%
dont classes moyennes-aisées (9%)	*4,5 millions*	*768 000 €*	*38%*
dont classes très aisées (1%)	*0,5 millions*	*4 368 000 €*	*24%*

Lecture: en 2010, les classes populaires (les 50% les plus pauvres) ont un patrimoine moyen de 14 000 euros par adulte et détiennent collectivement 4% du patrimoine total des ménages.
Source: C. Landais, T. Piketty & E. Saez, Pour une révolution fiscale, chapitre 1, p.25.
Voir www.revolution-fiscale.fr, annexe au chapitre 1.

Two things are particularly striking in this discussion. One is how significantly different the French fiscal system is from the U.S. system. Income tax is less than 10% of income for all income levels. And the *cotisation* is a substantially larger share of total taxes than the Social Security tax in the U.S.

But the other striking thing is the significantly different perspective that these authors take on taxes, compared to almost all discussions of taxes in the U.S. They are fundamentally

concerned about the fairness of the tax burden; they care about progressivity; and they are concerned to prevent the ability of "les tres aisées" to exercise political influence in order to reduce their share. "Fiscal rigor" doesn't mean severe budget reductions and elimination of the social security net for French citizens; it means creating a tax system that is adequate to the spending commitments of the French state, and that is fair in its distribution of tax obligations across the whole of society.

I think most observers of French politics doubt that this kind of progressive and sweeping fiscal reform is in the cards in the coming decade. But it is at least encouraging that the issues are being raised.

The politics of cultural despair

Friday, January 28, 2011

The last century gave us far too many examples of the rise of extremism in mass societies -- both democratic and authoritarian. Some of the political mechanisms of extremist seizure of power are well known -- paramilitary force, extremist organizations, demogogic leaders, hyper-heated rhetoric, appeals to nationalism and racism, and inflammatory mass media. But it's also worth asking -- what is the cultural basis for the rise of various extremisms? What factors in the ideas, thoughts, and emotions of a population have sometimes led to the rise of extremist states -- fascism, ethnic cleansing, murderous nationalism, or deranged communism such as the killing fields of Cambodia? Does philosophy play a role in the rise of extremism?

For observers born since 1930 a natural place to raise this question is the rise of National Socialism in Germany. How could a party dedicated to an explicit programme of racism, repression, and murder have gained mass support and control of the state in Germany?

A particularly important early effort to answer this question was Fritz Stern's pathbreaking The Politics of Cultural Despair: A Study in the Rise of the Germanic Ideology (1961), now fifty years old. The book is a careful intellectual history; but it is more than that. It is an effort to link a set of philosophical ideas to a series of political developments that involved increasingly wide circles of German citizens. So it serves as one example of how we might think about the relationship between large cultural ideas and currents, and more specific developments in politics.

Stern opens the book with these words:

This is a study in the pathology of cultural criticism. By analyzing the thought and influence of three leading critics of modern Germany, this study will demonstrate the dangers and dilemmas of a particular type of cultural despair. Lagarde, Langbehn, and Moeller van den Bruck--their active lives spanning the years from the middle of the past century to the threshold of Hitler's Third Reich--attacked, often incisively and justly, the deficiencies of German culture and the German spirit. But they were more than critics of Germany's cultural crisis; they were its symptoms and victims as well. Unable to endure the ills which they diagnosed and which they had experienced in their own lives, they sought to become prophets who would point the way to a national rebirth. Hence, they propounded all manner of reforms, ruthless and idealistic, nationalistic and utopian. It was this leap from despair to utopia across all existing reality that gave their thought its fantastic quality. (1)
These three figures were important cultural voices in Germany, even though they were undistinguished within the academic world. Paul de Lagarde (1827-1891), Julius Langbehn (1851-1907), and Arthur Moeller van den Bruck (1876-1925) were intellectual and cultural precursors for the ideology of National Socialism. They were harsh, vitriolic critics of modern German social life; they were anti-Semites; and they were wedded to a discourse of passion and hatred as devices for influencing their readers.

The central focus of this cultural criticism was the fact of ***modernity*** -- liberalism, secularism, Manchesterism, consumptionism, and individualism. These were conservative critics; they favored an earlier time that was more traditional, moral, hierarchical, and religious. They preferred villages and towns to cities; they preferred cultivated thinkers to merchants and professionals, and they feared the rise of the proletariat.

By liberalism they meant to encompass several ideas: individualism, self-interest, parliamentary government, and glorification of commerce and the market. And their criticisms were unswerving: they hoped to turn back all of the liberal democratic and industrial transformations that modern Europe was undergoing.

The movement did embody a paradox: its followers sought to destroy the despised present in order to recapture an idealized past in an imaginary future. They were disinherited conservatives, who had nothing to conserve, because the spiritual values of the past had largely been buried and the material remnants of conservative power did not interest them. They sought a breakthrough to the past, and they longed for a new community in which old ideas and institutions would once again command universal allegiance. (7)

The conservative revolutionaries denounced every aspect of the capitalistic society and its putative materialism. They railed against the spiritual emptiness of life in an urban, commercial civilization, and lamented the decline of intellect and virtue in a mass society. They attacked the press as corrupt, the political parties as the agents of national dissension, and the new rulers as ineffectual mediocrities. The bleaker their picture of the present, the more attractive seemed the past, and they indulged in nostalgic recollections of the uncorrupted life of earlier rural communities, when men were peasants and kings true rulers. (9-10)
In addition to their critique of a rising liberalism in Germany (and Europe more generally), these critics were also united in a virulent anti-Semitism. Their denunciations of the Jews became a common thread in Nazi propaganda in the 1920s and 1930s.

Stern makes the important point that these three writers depended on the emotions and

the passions rather than reason and argument to express themselves. "All three wrote with great fervor and passion. They condemned or prophesied, rather than exposited or argued, and all their writings showed that they despised the discourse of intellectuals, denied reason, and exalted intuition" (4). Here is a particularly important observation of the nature of this cultural criticism that appears to be relevant in our own time as well. Julien Benda, a liberal thinker, noted that political discourse "began to play the game of political passions.... Our age is indeed the age of the intellectual organization of political hatreds" (6).

Stern has two fundamental aims in this study. First, he hopes that the study of these three cultural critics will illuminate an important current of history: Germany's drift towards extremism and anti-Semitism.

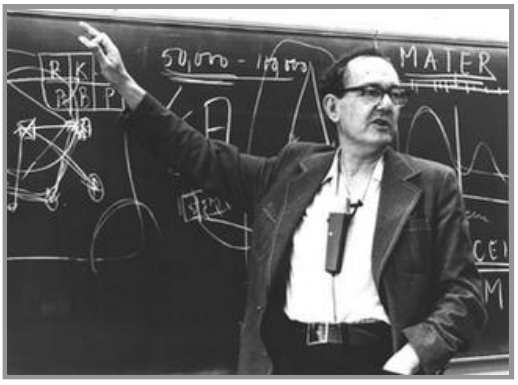
This study, then, takes up the origins, content, and impact of an ideology which not only resembles national socialism, but which the National Socialists themselves acknowledged as an essential part of their legacy. But it will also point to another link, admittedly less tangible--to wit, that the Germanic critics in the peculiar tension between their lives and their ideological aspirations anticipate the type of malcontent who, in the 1920's, found a haven in the idealism of the Hitler movement. ... We may not have sufficiently reckoned with the politically exploitable discontent which for so long has been embedded in German culture. (5)

But second, the book is interested in popular culture as well. How did ordinary Germans fall prey to mobilization and propaganda based on nationalism, violence, and anti-Semitism? Stern tries to show through a detailed study of the cultural framework expressed by these thinkers, that we can also attempt to reconstruct the modes of popular consciousness that percolated through German society in these decades. These ultra-conservative currents helped to make even ordinary people susceptible to the efforts at mobilization that were directed towards them by the National Socialists.

Are there parallels in twentieth-century America? Stern thought there were, in 1961.

Cultural pessimism has a strong appeal in America today. As political conditions appear stable at home or irremediable abroad, American intellectuals have become concerned with the cultural problems of our society, and have substituted sociological or cultural analyses for political criticism. ... There is a discontent in the Western world that does not stem from economic want or from the threat of war; rather it springs from dissatisfaction with life in an urban and industrialized culture -- a dissatisfaction that the three critics discussed in this book felt and fostered. (13, 14-15)

Two elements seem especially relevant in today's political culture: the willingness of some voices in the political sphere to engage in the emotional hyperbole and hatred that were the stock-in-trade of these German critics; and the extremist language surrounding the rejection of "liberalism" that is to be found in the airwaves today. Today too we are confronted with a virulent rejection of many aspects of a "liberal" world, and an apparent yearning for an earlier (mythical) time when there was one defining moral-religious framework to which all of society subscribed.



One of the greatest failures of German liberals and academics in the 1920s and 1930s was their inability -- perhaps even their unwillingness -- to make the positive case for a modern, liberal society. The values of justice, equality, citizenship, and mutual respect embodied through decent economic and political institutions need to be defended; and German thinkers fell short in this historical task in the early twentieth century. It is certainly important for Americans in the early twenty-first century to be more successful in

making this case.

Herbert Simon's satisficing life

Sunday, January 30, 2011

Herbert Simon was a remarkably fertile thinker in the social and "artificial" sciences (The Sciences of the Artificial - 3rd Edition (1969, first edition)). His most celebrated idea was the notion of "satisficing" rather than "optimizing" or "maximizing" in decision-making; he put forward a theory of ordinary decision-making that conformed more closely to the ways that actual people reason rather than the heroic abstractions of expected utility theory.

Essentially the concept of satisficing takes the cost of collecting additional information into account as a decision maker searches for a solution to a problem -- where to eat for dinner, which university to attend, which product to emphasize in a company's short-term strategy. And the theory commends the idea that we are best served overall by accepting the "good-enough" solution rather than searching indefinitely for the best solution. Rather than attempting to inventory all possible choices available at a given point in time and assigning them utilities and probabilities, the satisficing theory recommends setting parameters for a problem of choice, and then selecting the first solution that comes along that satisfies these parameters. It means searching for a solution that is "good enough" rather than optimal.

And why not go for the optimal solution? Because the cost of collecting the additional information associated with a broader choice set may well exceed the total benefit of the current decision. This is obvious in the case of the decision of which restaurant to go to; slightly less obvious in the case of the decision of which university to attend; and perhaps flatly unpersuasive in the case of decisions where the outcome can influence life and death.

I've described the theory of satisficing in a little detail here for an unexpected reason: Simon took some interest in the art of autobiography, and it turns out that he interprets his own life as a series of satisficing decisions. His autobiography Models of My Life appeared in 1996, and it's an interesting narrative of the intellectual and personal choices that led Simon from Milwaukee to Pittsburgh and beyond.

The idea is particularly apt for Simon's view about how a life unfolds. He rejects the idea

that one's life has an overriding theme. He discusses the fact that the title of the book is a plural noun -- "*Models* of My Life".

There is a further reason for using the plural [models]. It is a denial -- a denial that a life, at least my life, has a central theme, a unifying thread running through it. True, there are themes (again the plural), some of the threads brighter or thicker or stronger than others. Perhaps clearest is the theme of the scientist and teacher, carrying on his persistent heuristic search, seeking the Holy Grail of truth about human decision making. In my case, even that thread is woven of finer strands: the political scientist, the organization theorist, the economist, the management scientist, the computer scientist, the psychologist, the philosopher of science. (xviii)

Rather than one underlying theme that underlies a person's biography and career, there are multiple choices, directions, and emphases -- that add up to a woven lifetime of contribution when the choices work out well.

Simon accepts the implication that this vision of a life presents: that there is no single "self" underlying all these changes and choices:

Which of the wanderers through these different mazes will step forward at the call for the real Herbert Simon? All of them; for the "real" self is an illusion. We live each hour in context, different contexts for different hours.... We act out our lives within the mazes in which Nature and society place us. (xviii-xix)

The analogy between daily decision-making and living a life is a direct one: instead of setting upon a course with very specific goals and objectives, and then taking the steps necessary to bring about the achievement of that system of goals, Simon is recommending a more local form of life decision-making. Build capacities, recognize opportunities, take risks, and build a life as a result of a series of local choices. It is a form of bounded rationality for living rather than an expression of a fully developed life plan. So we might say that Simon's "philosophy of living" is entirely consistent with his theory of bounded rationality.

There are a few real surprises in the book -- for example, a conversation between Simon and Jorge Luis Borges in Argentina in 1970. Simon was fascinated by Borges' use of the idea of a labyrinth in his novels, and wanted to find out from Borges how he was led to this family of metaphors. Simon himself was drawn to the idea of a series of choices as a maze -- incorporating the insight that there are always unexplored outcomes behind the avenues not taken. So a labyrinth is a good metaphor for choice within uncertainty and risk.

I have encountered many branches in the maze of my life's path, where I have followed now the left fork, now the right. The metaphor of the maze is irresistible to someone who has devoted his scientific career to understanding human choice. (xvii)

Here is a snippet of the conversation between Simon and Borges as quoted in the book:

SIMON: I want to know how it was that the labyrinth entered into your field of vision, into your concepts, so that you incorporated in your stories.

BORGES: I remember having seen an engraving of the labyrinth in a French book -- when I was a boy. It was a circular building without doors but with many windows. I used to gaze at this engraving and think that if I brought a loupe close to it, it would reveal the Minotaur.

SIMON: Did you see it?

BORGES: Actually my eyesight was never good enough. Soon I discovered something of the complexity of life, as if it were a game. In this I am not referring to chess.

...

SIMON: What is the connection between the labyrinth of the Minotaur and your labyrinth, which calls for continual choice? Does the analogy go beyond the general concept?

BORGES: When I write, I don't think in terms of teaching. I think that my stories, in some way, are given to me, and my task is to narrate them. I neither search for implicit connotations nor start out with abstract ideas; I am not one who plays with symbols. But if there is some transcendental explanation of one of my stories, it is not for me to discover it, that is the task of the critics and the readers.

And a final surprise -- it emerges from the conversation that Borges had read "a very interesting book" early in his life, Bertrand Russell's Introduction to Mathematical Philosophy -- not exactly the most predictable influence on the creator of magical realism. And Russell's mathematical logic was likewise a formative influence for Simon, at a comparably early age.

There is an interesting short section where Simon discusses one of the directions he did ***not*** take in his own personal career maze -- the step of trying to become a college president at Carnegie Mellon or elsewhere (262 ff.). Simon writes briefly about the reasons why this might have been a realistic aspiration for him -- a history of administrative competence at the department level and a stellar academic record. But he decided not to pursue the presidency at CMU:

However that may be, I did not seriously consider taking on the context. ... I have never regretted the decision, especially in view of Dick's stellar performance on the job, a performance made possible by a "deviousness" that our colleague Leland Hazard admiringly attributed to him, and that I surely did not possess. (263)

He adds that he didn't have the personality needed to cultivate the community of wealthy businessmen whose support would be essential to Carnegie: "In fact, the close association with the business community that is essential for effective performance as president of a university such as Carnegie Mellon would have been uncomfortable for me" (263).

But here is the way this discussion strikes me (as a person whose career ***did*** take him in that direction). Simon gives no evidence here of understanding even the most basic facts about this domain of choice: what the job of president actually is; what the qualities of personality and leadership are that would lead to success; and what the intellectual satisfactions might be in the event that he became a university president. He seems to be working from a very shallow stereotyped view of the job of university president. In other words, Simon had ***none*** of the information that would be needed to make an informed career choice about this option. And this suggests that his decision-making on this issue was narrowly bounded indeed -- driven by a few stereotyped assumptions that were probably a poor guide to the reality.

(Here is a lecture by Herbert Simon on organizations, public administration, and markets:)

Decision-making in complex systems

Tuesday, February 01, 2011

source: The Financial Ninja (link)

How should we make intelligent decisions in contexts in which the object of choice involves the actions of other agents whose choices jointly determine the outcome and where the outcome is unpredictable? Robert Axelrod and Michael Cohen address these issues in Harnessing Complexity: Organizational Implications of a Scientific Frontier. They define a complex adaptive system in something like these terms: a body of causal processes and agents whose interactions lead to outcomes that are unpredictable. So the interactions among agents often have unpredictable consequences; and the agents themselves adapt their behavior based on past experiences: "They interact in intricate ways that continually reshape their collective future." Here is how Axelrod and Cohen put their question:

In a world where many players are all adapting to each other and where the emerging future is extremely hard to predict, what actions should you take? (xi)

This book is about designing organizations and strategies in complex settings, where the full consequences of actions may be hard -- even impossible -- to predict. (2)

Complexity and chaos are often used interchangeably; but Axelrod and Cohen distinguish sharply between them in these terms:

Chaos deals with situations such as turbulence that rapidly become highly disordered and unmanageable. On the other hand, complexity deals with systems composed of many interacting agents. While complex systems may be hard to predict, they may also have a good deal of structure and permit improvement by thoughtful intervention. (xv)

Here is a simple current example -- an assembly of 1000 Egyptian citizens in January 2011, interested in figuring out what to do in light of their longstanding grievances and the example of Tunisia. Will the group erupt into defiant demonstration or dissolve into private strategies of self-preservation? The dynamics of the situation are fundamentally undetermined; the outcome depends on things like who speaks first, how later speakers are influenced by earlier speakers, whether the PA system is working adequately, which positions happen to have a critical mass of supporters, the degree to which the government can make credible threats of retaliation, the presence of experienced organizers, and a dozen other factors. So we cannot predict whether this group will move towards resistance or accommodation, even when we assume that all present have serious grievances against the Egyptian state.

The fact of path dependence comes into this understanding of complexity, in that the

order of actions by the agents can influence the outcome. So we could run the Egypt scenario forward multiple times and arrive at different outcomes repeatedly. We might imagine a tool along the lines of a Monte Carlo simulation that models the range of possible outcomes; and in the sorts of systems Axelrod and Cohen are interested in, the range of outcomes is very wide with no "modal" and most probable outcomes at the core.

The difficulty of prediction in the future development of a complex system derives in part from the adaptiveness of the agents who make it up; but it also derives from the fact of non-linearity of causation in complex systems. Small influences can have large effects; there is often a discontinuity between the magnitude and direction of a cause and its effect.

What makes prediction especially difficult in these settings is that the forces shaping the future do not add up in a simple, systemwide manner. Instead, their effects include nonlinear interactions among the components of the system. The conjunction of a few small events can produce a big effect if their impacts multiply rather than add. (14)

Decision theorists distinguish between situations of parametric rationality and strategic rationality. In the former the decision maker is playing against nature, with a fixed set of probabilities and causal properties; in the latter the decision maker is playing against and with other rational agents, and the outcome for each depends upon the choices made by all. Game theory offers a mathematical framework for analyzing strategic rationality, while expected utility theory is advanced as a framework for analyzing the problem of choice under risk and uncertainty. The fundamental finding of game theory is that there are equilibria for multi-person games, both zero-sum and non-zero-sum, for any game that can be formulated in the canonical game matrix of agents' strategies and joint outcomes. Whether those equilibria are discoverable for ordinary strategic reasoners is a separate question, so the behavioral relevance of the availability of an equilibrium set of strategies is limited. And here is the key point: neither parametric rationality nor equilibrium-based strategic rationality helps much in the problem of decision-making within a complex adaptive system.

The situation that Axelrod and Cohen describe here is an instance of strategic rationality, but it doesn't yield to the framework of mathematical game theory. This is because we can't attach payoffs to combinations of strategies for the separate agents; this follows from the unpredictability assumption built into the idea of complexity. And, second, complex adaptive systems are usually in a dynamic process of change, so that the system never attains an equilibrium state.

Axelrod and Cohen are hoping to provide counsel for how decision makers can "harness" complexity -- that is, how they can design policies and strategies that perhaps push a complex situation in a favorable direction, or that insulate an organization from the worst outcomes that the complex system may produce.

Harnessing complexity ... means deliberately changing the structure of a system in order to increase some measure of performance, and to do so by exploiting an understanding that the system itself is complex. (9)

Axelrod and Cohen make use of three high-level concepts to describe the development of complex adaptive systems: variation, interaction, and selection. Variation is critical here, as it is in evolutionary biology, because it provides a source of potentially successful innovation -- in strategies, in organizations, in rules of action. The idea of adaptation is central to their analysis -- in this case, adaptation and modification of strategies by agents in light of current and past success. Interaction occurs when agents

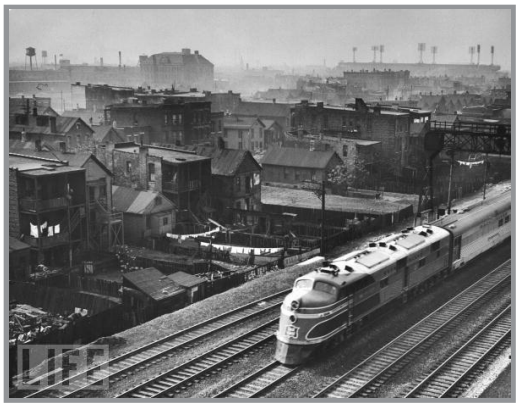
and organizations intersect in the application of their strategies -- often producing unforeseen consequences. (The strategy of open-source software development is one example that they look at, and the interactions that occurred as open-source innovations encountered closed-source innovations.) An organization or a population is best served, they argue, when there is a regular source of innovations (variations); when these innovations are implemented in the form of variant strategies; and when it is possible to cultivate more successful variations and to damp out less successful (selection). Here is how they summarize their view:

Agents, of a **variety of types**, use their **strategies**, in **patterned interaction**, with **each other** and with **artifacts**. **Performance measures** on the resulting events drive the **selection of agents** and/or **strategies** through processes of error-prone **copying** and **recombination**, thus changing the **frequencies** of the **types** within the **system**.

And they arrive at eight rules of thumb for "harnessing complexity" when it comes to organizations and social policies:

- Arrange organizational routines to generate a good balance between exploration and exploitation.
- Link processes that generate extreme variation to processes that select with few mistakes in the attribution of credit.
- Build networks of reciprocal interaction that foster trust and cooperation.
- Assess strategies in light of how their consequences can spread.
- Promote effective neighborhoods.
- Do not sow large failures when reaping small efficiencies.
- Use social activity to support the growth and spread of valued criteria.
- Look for shorter-term, finer-grained measures of success that can usefully stand in for longer-run, broader aims. (156-158)

So how should we understand these heuristics as a conclusion to this analysis? They function as an "operating manual" for leaders and policy makers attempting to bring about good effects within a population of agents demonstrating adaptive complexity. And perhaps these are plausible meta-strategies for intervening within a complex social system.



What is worrisome, though, is the implicit functionalism that seems to underlie the book: the idea that agents of good will and having the longterm best interests of the population in mind are making the rules. But what happened to the predators -- the organized crime figures, the drug lords, the conspirators, the predatorial businesses, the anti-democrats? Won't they too be looking to exploit (harness) the workings of complexity? Axelrod's earlier work on repeated prisoners' dilemmas explicitly took into account the availability of strategies designed to exploit the cooperators; and his work on cooperation emphatically makes the point that cooperation is often deployed for anti-social and predatory purposes (cartels, extortion rackets, ...) (The Evolution of Cooperation: Revised Edition). Shouldn't this counter-social agency be incorporated into this analysis of complex adaptive systems as well? As Charles Tilly points out, crime and piracy also depend upon "trust networks" and innovative forms of predation (Trust and Rule).

During the 1980s the Reagan administration wanted to create a "Star Wars" anti-missile shield, and some of their policy makers argued that we could solve the technical challenges because the U.S. had succeeded in putting a man on the moon. But critics of this military space strategy rejoined, "But the moon didn't fight back;" whereas Soviet scientists and engineers were fully capable of adapting their ICBM technologies to evade the defensive characteristics of a missile shield. There seems to be something of the same blind spot in this analysis of social complexity; predation and the common good are

in competition with each other, and neither has a decisive advantage.

Persistent racial inequalities in America

Thursday, February 03, 2011

Historian Thomas Sugrue is a national expert on the state of persistent racial inequalities in our nation today. His The Origins of the Urban Crisis: Race and Inequality in Postwar Detroit set the standard for the field of recent urban history when it appeared in 1996. His most recent book, Not Even Past: Barack Obama and the Burden of Race, provides a vivid statement of his current views. The title refers to William Faulkner's line in *Requiem for a Nun*, "The past is not dead. In fact it's not even past." It is a particularly apt metaphor for the status of race in America today.

The book addresses the often-heard view that President Obama's election demonstrates that we live in a post-racial society. The argument is that if the United States is able to elect an African-American president, then surely issues of racial prejudice are in the past. However, Sugrue provided current data on disparities of income, employment, education, residence, health, and wealth that demonstrate that structures in our country continue to reproduce grave racial disparities. By any measure, we are not post-racial.

Here are a few factual findings from the book:

The most persistent manifestation of racial inequality in the modern United States has been racial segregation in housing and education. From 1920 through 1990, patterns of black white segregation hardened in most of the United States, despite shifts in white attitudes about black neighbors, and despite the passage of local and state antidiscrimination laws and the enactment of Title VIII of the Civil Rights Act (1968) which prohibited housing discrimination nationwide. (101)

Persistent residential segregation compounded educational disparities. Beginning in the late 1970s, when courts began a thirty-year process of abandoning the mandate of *Brown v. Board of Education*, school districts around the country resegregated by race, especially by black and white. (103)

African Americans are far more likely than whites to be economically insecure. The statistics are grim. In 2006, the median household income of blacks was only 62 percent of that of whites. Blacks were much more likely than whites to be unemployed (black unemployment rates have remained one and a half to two times those of whites since the

1950s). (104-5)

Social scientists have documented employers discriminating against job applicants with comparable credentials when one has a "black" name or has a place of residence in a known "black" neighborhood. (105)

The starkest racial disparities in the United States are in wealth (a category that includes such assets as savings accounts, stocks, bonds, and especially real estate). In 2003, the U.S. Census Bureau calculated that white households had a median net worth of $74,900, whereas black households had a median net worth of only $7,500. (105)

Another important indicator of quality of life is health. ... The racial and ethnic gaps in health and life expectancy are stark. The life expectancy of whites in 2004 was 78.3; for blacks, it was 73.1. ... In 2003, infant mortality rates were nearly 2.5 times as high for blacks as for whites. (107)

A couple of empirical sources are particularly central to Sugrue's argument. One is the 2007 book by William Julius Wilson and Richard Taub, There Goes the Neighborhood: Racial, Ethnic, and Class Tensions in Four Chicago Neighborhoods and Their Meaning for America, which provides quite a bit of empirical data about neighborhood racial attitudes in Chicago. Another crucial piece of empirical evidence that plays a large role in Sugrue's findings is a major ongoing social-science research project coordinated by the Russell Sage Foundation, the *Multi-City Study of Urban Inequality* (link). There are separate volumes on Detroit, Boston, Atlanta, and Los Angeles, and there is a synthesis volume that tries to draw conclusions from all the studies (Urban Inequality: Evidence from Four Cities (Multi City Study of Urban Inequality.)). The introductory chapter by Alice O'Connor is available on the website; link. Here are a few passages from the introduction:

Nowhere are these intertwined problems more vividly captured than in the complex economic, gender-based, and racial and ethnic divisions of contemporary urban America. In major cities nationwide, overall economic growth is accompanied by higher than average rates of unemployment and poverty, concentrated especially in low-income, working-class minority neighborhoods that have only recently begun to show signs of recovery following decades of steady decline (U.S. Department of Housing and Urban Development 1999). Still, the low-skilled urban workforce, greatly expanded by the “end of welfare,” has little access to local jobs that provide living wages, employment security, and adequate benefits. (1)

Explaining these economic, spatial, and racial divisions is the central purpose of the Multi-City Study of Urban Inequality, a unique inquiry launched in the early 1990s by an interdisciplinary team of social scientists with sponsorship from the Russell Sage and Ford foundations. Based on surveys of households and employers in the metropolitan areas of Atlanta, Boston, Detroit, and Los Angeles, the study affords a comprehensive and systematic look at the roots of inequality in labor markets, residential segregation, and racial attitudes. (2)

The significance of race in urban inequality is to be found not in any single place but in various aspects, and at multiple levels, of social experience: in discriminatory behavior, policies, and institutional practices; in the structural segmentation of labor markets and residential space; and in the attitudes, stereotypes, and ideological belief systems through which people make sense of broader social conditions and determine their own policy preferences. Race has a deep and enduring historical significance as well, still visible in residential color lines constructed by years of racial exclusion, violence, and

overtly discriminatory policies; in the persistent racial gaps in education, skills, and capital that stem from opportunity denied; and in the mistrust between minorities and local law-enforcement agencies that has once again erupted around the issue of racial profiling. And race has significance as the basis of a color-coded sense of social hierarchy that affects individual attitudes and behavior, and that is embedded in social structure as well as in shared cultural norms. (5)

The essays in this volume do not tell a simple story. They point to intergroup attitudes, residential and industrial location, discriminatory practices, and the declining prospects for low-skilled workers as important, interlocking sources of inequality across metropolitan America. But they also point to several conclusions about race, both as a shaping force in the distribution of opportunity and as a variable in social scientific analysis. While not offered as a statement of consensus, they do advance the ongoing debate about race and inequality in important ways. (27)
This is careful social scientific research, and it contributes to a much better understanding of the mechanisms that produce and reproduce urban poverty and persistent racial gaps. These mechanisms are both structural and ideational; the processes that lead to discrimination in employment, for example, include both structural factors like urban transportation, and ideational factors such as racial stereotyping by recruiters.

So race continues to be a determining fact of life for many millions of Americans. But here is the other part of Sugrue's story: our public discourses, and our political process, are virtually silent about these facts. We simply do not honestly confront the realities of race, whether in electoral competition, in the media, or in other forms of public debate. And we need to.

Bourdieu's "field"

Saturday, February 05, 2011

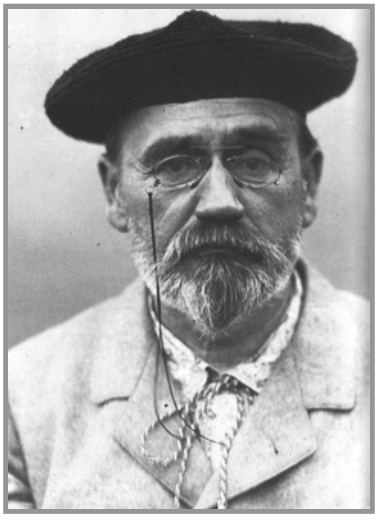


image: Emile Zola, 1902
How can sociology treat "culture" as an object of study and as an influence on other sociological processes? This is, of course, two separate questions. First, internally, is it possible to treat philosophy or literature as an embedded sociological process (a point raised by Jean-Louis Fabiani in his treatment of French philosophy (link))? Can we use

the apparatus to pull apart the sociology of the fashion industry?

And second, externally, can we give a rigorous and meaningful interpretation of "bringing culture back in" -- conceptualizing the ways that thought, experience, and the institutions and mental realities of culture impact other large social processes -- e.g. the rise of fascism (link)?

The problem here is to find ways of getting inside "culture" and decomposing it as a set of social, material, and semiotic practices. We need an account of some of the culture mechanisms through which voices develop, acquire validation, and are retransmitted. And we need concrete accounts of how this culture activity influences other socially important processes. Culture cannot be thought of as a monolith if we are to explain its development and trace out its historical influences; rather, we need something like an account of the microfoundations of culture.

One of the fertile voices on this question is that of Pierre Bourdieu. His core contribution is the idea of cultural life and production being situated in a "**field**." So what does Bourdieu mean by a field? Is this concept genuinely useful when we aim at providing a sociology of a literary tradition or a body of ideas like "cultural despair"?

One place where Bourdieu provides extensive analysis and application of this construct is in a collection published in 1993, The Field of Cultural Production, and especially in the title chapter, originally published in 1983. Here Bourdieu is primarily interested in literature and art, but it seems that the approach can be applied fruitfully to a wide range of cultural phenomena, including American conservativism and early twentieth century German colonialism. (George Steinmetz makes extensive use of this concept of the field in his analysis of the causes of specific features of German colonial regimes; The Devil's Handwriting: Precoloniality and the German Colonial State in Qingdao, Samoa, and Southwest Africa.)

The heart of Bourdieu's approach is "**relationality**" -- the idea that cultural production and its products are situated and constituted in terms of a number of processes and social realities. Cultural products and producers are located within "a space of positions and position-takings" (30) that constitute a set of objective relations.

> The space of literary or artistic position-takings, i.e. the structured set of the manifestations of the social agents involved in' the field -- literary or artistic works, of course, but also political acts or pronouncements, manifestos or polemics, etc. -- is inseparable from the space of literary or artistic positions defined by possession of a determinate quantity of specific capital (recognition) and, at the same time, by occupation of a determinate position in the structure of the distribution of this specific capital. The literary or artistic field is a field of forces, but it is also a field of struggles tending to transform or conserve this field of forces. (30)

This description highlights another characteristic feature of Bourdieu's approach to social life -- an intimate intermixture of objective and subjective factors, or of structure and agency. (This intermixture is also fundamental to Bourdieu's theory of practice in Outline of a Theory of Practice.) Bourdieu typically wants to help us understand a sociological whole as a set of "doings" within "structures and powers." This is captured in the final sentence of the passage: a "field of forces" but also a "field of struggles". The field of the French novel in the 1890s established a set of objective circumstances to which the novelist was forced to adapt; but it also created opportunities for strategy and struggle for aspiring novelists. And in fact, Emile Zola, pictured above, did much to redefine aspects

of that field, both in ideas and in material institutions.

Fundamental to Bourdieu's view is that we can't understand the work of art or literature (or philosophy or science, by implication) purely in reference to itself. Rather, it is necessary to situate the work in terms of other points of reference in meaning and practice. So he writes that we can't understand the history of philosophy as a grand summit conference among the great philosophers (32); instead, it is necessary to situate Descartes within his specific intellectual and practical context, and likewise Leibniz. And the meaning of the work changes as its points of reference shift. "It follows from this, for example, that a position-taking changes, even when the position remains identical, whenever there is change in the universe of options that are simultaneously offered for producers and consumers to choose from. The meaning of a work (artistic, literary, philosophical, etc.) changes automatically with each change in the field within which it is situated for the spectator or reader" (30).

This fact of relationality and embeddedness raises serious issues of interpretation for later readers:

One of the major difficulties of the social history of philosophy, art or literature is that it has to reconstruct these spaces of original possibles which, because they were part of the self-evident givens of the situation, remained unremarked and are therefore unlikely to be mentioned in contemporary accounts, chronicles or memoirs. (31)

Here is how Bourdieu describes the intellectual field within which philosophy proceeds in a time and place:

In fact, what circulates between contemporary philosophers, or those of different epochs, are not only canonical texts, but a whole philosophical doxa carried along by intellectual rumour -- labels of schools, truncated quotations, functioning as slogans in celebration or polemics -- by academic routine and perhaps above all by school manuals (an unmentionable reference), which perhaps do more than anything else to constitute the 'common sense' of an intellectual generation. (32)

This background information is not merely semiotic; it is institutional and material as well. It includes "information about institutions -- e.g. academies, journals, magazines, galleries, publishers, etc. -- and about persons, their relationships, liaisons and quarrels, information about the ideas and problems which are 'in the air' and circulate orally in gossip and rumour" (32). So the literary product is created by the author; but also by the field of knowledge and institutions into which it is offered.

Another duality that Bourdieu rejects is that of internal versus external readings of a work of literature or art. We can approach the work of art from both perspectives -- the qualities of the work, and the social embeddedness that its production and reception reveal.

In defining the literary and artistic field as, inseparably, a field of positions and a field of position-takings we also escape from the usual dilemma of internal ('tautegorical') reading of the work (taken in isolation or within the system of works to which it belongs) and external (or 'allegorical') analysis, i.e. analysis of the social conditions of production of the producers and consumers which is based on the -- generally tacit -- hypothesis of the spontaneous correspondence or deliberate matching of production to demand or commissions. (34)

A key aspect of Bourdieu's conception of a field of cultural production is the material facts of power and capital. Capital here refers to the variety of resources, tangible and intangible, through which a writer or artist can further his/her artistic aspirations and achieve "success" in the field ("book sales, number of theatrical performances, etc. or honours, appointments, etc." (38)). And power in the cultural field is "heteronomous" -- it is both internal to the institutions of the culture field and external, through the influence of the surrounding field of power within which the culture field is located. Here is an intriguing diagram that Bourdieu introduces to represent the complex location of art

activity within the broader field of social power and the market.

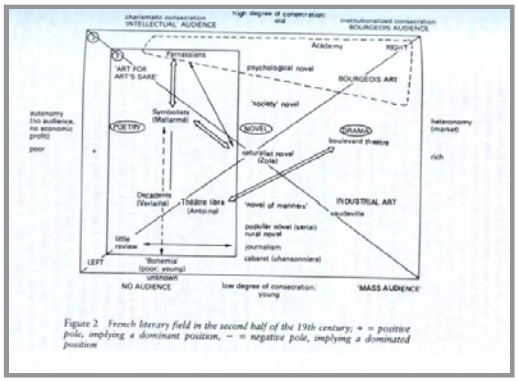

Figure 2 French literary field in the second half of the 19th century; + = positive pole, implying a dominant position, – = negative pole, implying a dominated position

These comments give us a better idea of what a "field" encompasses. It is a zone of social activity in which there are "creators" who are intent on creating a certain kind of cultural product. The product is defined, in part, by the expectations and values of the audience -- not simply the creator. The audience is multiple, from specialist connoisseurs to the mass public. And the product is supported and filtered by a range of overlapping social institutions -- galleries, academies, journals, reviews, newspapers, universities, patrons, sources of funding, and the market for works of "culture." It is also important to observe that we could have begun this inventory of components at any point; the creator does not define the field any more than the critic, the audience, or the marketplace.

I see some similarities between Bourdieu's conception of a field and the broad ideas of paradigm and research tradition in the history and sociology of science. Both ideas encompass a range of different kinds of things -- laboratories, journals, audiences, critics, and writers and scientists. Here Lakatos and Kuhn are relevant, but so are Bruno Latour and Wiebe Bijker. In each case there is some notion of rules of assessment -- explicit or tacit. And in each case we are given breadth enough to consider the social "determinants" of the cultural product at one end -- economy, institutions of training and criticism -- and some notion of the relative autonomy of the text or object at the other (truth and warrant, beauty and impact).

The point mentioned above about the validity and compatibility of both internal and external analysis of a work of art is equally important in the sociology of science: to identify some of the social conditions surrounding the process of scientific research does not mean that we cannot arrive at judgments of truth and warrant for the products of scientific research. (This point has come up previously in a discussion of Robert Merton's sociology of science (link).)

This is a very incomplete analysis of Bourdieu's concept of the field; but it should give an idea of the leverage that Bourdieu provides in framing a scheme of analysis for culture and ideas as concrete sociological factors and objects of study. Certainly Bourdieu's writings on these subjects -- especially in The Field of Cultural Production -- repay close reading by sociologists interested in broadening their frameworks for thinking about culture. (Jeremy Lane's Pierre Bourdieu: A Critical Introduction is a good introduction to Bourdieu's sociology, though it doesn't give much attention to this particular topic.)

Social Science History Association call for papers

Sunday, February 06, 2011

SSHA CALL FOR PAPERS Macrohistorical Dynamics Network

36th Annual Meeting of the Social Science History Association
Boston, Massachusetts 17-20 November 2011
Submission Deadline: 15 February 2011

"Generation to Generation"

We invite you to take part in Macrohistorical Dynamics (MHD) panels of the 36th annual meeting of the Social Science History Association, November 17-20, 2011 in Boston. For more information on the meeting as well as the call for proposals, please refer to the SSHA website:
www.ssha.org
The deadline for paper and/or panel submissions is **February 15, 2011**.
The members of the Social Science History Association share a common interest in interdisciplinary and systematic approaches to historical research.
The thematic topic of the 2011 annual meeting is “Generation to Generation” – a theme that works very well with the research interests of many of the scholars involved in the Macrohistorical Dynamics network.
Macrohistorical Dynamics (MHD) is an interdisciplinary social science research field that focuses on problems of large-scale, comparative historical inquiry. Contributors to the field have brought perspective on a wide variety of problem areas, including Eurasian comparisons; macro- and historical sociology; comparative histories; world history; world-system analysis; comparative study of civilizations; philosophy of history; and studies of long-term socio-ecological, technological, demographic, cultural, and political trends and transformations. The Macrohistorical Dynamics network brings a rigorous perspective to bear on questions having to do with “large” history.
Possible topics that illustrate some of the general themes of Macrohistorical Dynamics

include …

- Comparative Methods in Macrohistory
- Eurasian comparisons
- Large-scale historical causes: climate, population, geography
- Cultural and National Identities in Large-scale Historical Change
- Theory in Macro-history: Are There Successful Macrosociological Theories?
- Macro-, Meso-, Micro- in Historical Explanations
- Empires and Peoples
- Globalization and World Cities
- Social Evolution and Systemic Transformations in World History

The list of MHD panel themes for 2011 is open, and we encourage you to submit proposals for paper topics or panel themes.

SSHA requests that submissions be made by means of its web conference management system. Paper title, brief abstract, and contact information should be submitted on the site www.ssha.org, where the general SSHA 2011 call for papers is also available. (If you haven't used the system previously you will need to create an account, which is a very simple process.) Here is the direct link for submissions:

http://conference.ssha.org/

The online system is now accepting submissions. If you have any questions, please contact either of the MHD co-chairs (Peter Perdue, James Lee, Dan Little).

NOTE: There is an SSHA rule concerning book sessions. For a book session to proceed, the author (or at least one of multiple authors) MUST be present. Proposals for book sessions should only be submitted if there is high confidence that the author will be able to travel to Boston November 17-20, 2011.

Visit the SSHA Facebook site at http://www.facebook.com/pages/Social-Science-History-Association/146259262094506?ref=ts&v=wall.

Feel free to contact the MHD network organizers for further information.

History of economic thought and the present

Monday, February 07, 2011

What is the relationship between the history of economic thought and contemporary economics? There are polar views on this issue. At one extreme, it is sometimes held that the history of economics, like the history of physics, is irrelevant to contemporary theory and analysis. Alfred North Whitehead is quoted with approval: "A science which hesitates to forget its founders is lost" ('The Organization of Thought'. *Science*, 1916(22) : 409–19). Where useful analytical or theoretical insights were put forward in the past, they have been incorporated into more general theories; and the fine grain of how Marshall or Pareto constructed his economics is simply not pertinent to contemporary economics. This position does not necessarily dismiss the value of the discipline of the history of economic thought (though it is interesting to note how uncommon it is for research departments of economics to include faculty lines in the history of economic thought). It simply says that this discipline is irrelevant to contemporary knowledge of how an economy works. Put brutally: there is nothing to learn from the history of economic thought for improving our understanding of contemporary economic realities.

A position at the other end of the spectrum holds that the history of economic thought is indeed relevant to contemporary economic theory and analysis. In particular, we can gain new insights into the contemporary global economy by reconsidering and developing theories that fall in the category of "alternative economics" -- e.g. Marx, Polanyi, Georgescu-Roegen, or even Malthus. The rationale here is that economics is an open-textured field of thought today, with some threads of analysis deeply and fully developed, others left fallow, and yet others still undiscovered. If the scientific challenge of economics is to provide hypotheses, theories, and modes of analysis that permit us to understand the behavior of a modern economy – then modesty and recent experience should convince us that there are major gaps in our knowledge.

This in turn suggests that it is likely enough that there are large perspectives within the history of economic thought that have not been adequately developed and assessed. There is a great deal of path dependence in the development of economics as a discipline and profession (link); and there are identifiable turning points where we can judge with confidence that themes that were eliminated at a certain time would have led to a substantially different intellectual system had they persisted. So careful work in the history of economic thought is indeed relevant to improving our current understanding of a complex economy. (See several earlier posts that illustrate these points; link, link.)

A limited way of taking this latter position to heart is to return to some of the early economists in order to reformulate their basic insights in more adequate theoretical and mathematical ways. Pierro Sraffa did some of this work with regard to Ricardo in Production of Commodities by Means of Commodities : Prelude to a Critique of Economic Theory. Michio Morishima illustrates this approach in his books on Ricardo (Ricardo's Economics: A General Equilibrium Theory of Distribution and Growth) and Marx (Marx's Economics: A dual theory of value and growth). And John Roemer does similar work by returning to Marx's theory of exploitation and finding alternative analytics leading to essentially the same conclusions that Marx reached in A General Theory of Exploitation and Class. In each case, modern economic analytical tools are used to reformulate the theories and insights of the earlier economist.

The harder question, though, is whether a reconsideration of the history of economic thought can lead to fundamentally ***different*** frameworks of thought for economics. Is there a place for "political economy" in our contemporary discipline of economics? What about a Polanyian economics? Should we reconsider the relevance of ethnography for economic theorizing? And, of course, are there parts of Marx's economics which are once again relevant to our understanding of contemporary economic institutions?

This issue comes up in other areas of the social sciences as well, of course. Paul Adler addresses the issue of the relevance of the history of the social sciences for contemporary research in his introduction to The Oxford Handbook of Sociology and Organization Studies: Classical Foundations (link). Adler makes a strong case for why the classics of sociology remain relevant for the discipline and, indeed, provide a powerful resource for trying to understand the most current social processes. Here is a description which works equally well for the history of economics:

This trend bodes badly for the intellectual development of organization studies. As Jeffrey Alexander (1987), Art Stinchcombe (1982), and others have argued, social sciences—as distinct from natural sciences—are considerably enriched by rereadings of their classics. (5)
An important point that Adler makes is that the social sciences have historically defined their research topics in close relationship to important contemporary social problems; whereas there is a tendency for contemporary social science research to define research agendas around a more "academic" set of priorities. Attention to the history of the social sciences can lead us back to a better set of research priorities.

The contributors to this volume share a concern that organization studies reconnect with broader social issues. Since ours is a society of organizations, many of these big issues are directly organizational, as evidenced by the headlines of the daily news: globalization, outsourcing, the pressure of financial markets on industrial firms, new technologies that obsolete old organizations, the fate of the individual, and the possibility of collective agency in the face of massive systemic forces of change, and so on.

The discrepancy between this list and the list of topics in recent organization studies research is both saddening and troubling. Saddening, because it represents a narrowing of scope, ambition, and concern compared to the founders of the field. Troubling, because this narrowing saps the vitality of the field. A field that hides its head in the sand when its ostensible subject matter is undergoing such massive turbulence is a field that risks losing any credibility. Moreover, it risks losing its ‘franchise’, its legitimacy as a key discipline in the broader public’s effort to make sense of these changes. (6)
These comments seem equally relevant to contemporary economic research as well.

Persistent high unemployment, for example, is both a huge social problem and an unresolved theoretical issue -- whether in Milan in the 1950s or in Detroit in 2011.

So -- given the richness of debates and theories that have taken place in the past two centuries of economic reasoning; given the variety of approaches to economic institutions and mechanisms that have been put forward during that history; and given the unresolved challenges we face in understanding and guiding a complex modern economy -- surely the careful study of the history of economic thought will repay the effort we give it.

Is there a revolution underway in Egypt?

Wednesday, February 09, 2011

source: *Guardian*, February 8, 2011

Is what is going on in Egypt today a "revolution"? What about Tunisia? And how about the Georgian "Rose" Revolution (2003) or the Philippine Yellow Revolution of 1986? Do these social and political conflicts and outcomes add up to a "revolution" in those societies? Are they analogous in any way to other revolutions in the post-World War II period -- e.g. Cuba, Nicaragua, Zimbabwe?

In the case of Tunisia, the world witnessed several things: large, sustained street demonstrations by tens of thousands of people demanding the resignation of Tunisia's president; tactics of repression and intimidation by the state intended to quiet the protests; an unexpected ability of the population to sustain its demonstrations; and the eventual flight of the president from the country. We also witnessed the establishment of an interim government that was nominally committed to free elections within a reasonable timeframe -- though we don't yet know how that process will unfold. So we saw a popular movement aiming to topple a dictator and demanding institutional changes in government; we saw the downfall of the dictator; and we saw an apparent commitment to establish the institutional reforms that had been demanded. Does all of this add up to a "revolution"?

This is as much a conceptual question as it is an empirical one. What do we mean by "revolution"? Is there a reasonably clear and uncontroversial definition that would allow us to classify various uprisings and changes as governments as "revolution" or not? Let's look at the way that a number of recent theorists have dealt with the concept of revolution. Here are three, with rather different approaches: Samuel Huntington, Theda Skocpol, and Jack Goldstone. Each of them seems to capture something important about the way we think about the idea of revolution.

Samuel Huntington offers a very clear definition of revolution in "Revolution and Political Order", collected in Jack Goldstone's Revolutions: Theoretical, Comparative, and Historical Studies:

A revolution is a rapid, fundamental, and violent domestic change in the dominant values and myths of a society, in its political institutions, social structure, leadership, and government activity and policies. Revolutions are thus to be distinguished from insurrections, rebellions, revolts, coups, and wars of independence. (39)

A full-scale revolution thus involves the rapid and violent destruction of existing political institutions, the mobilization of new groups into politics, and the creation of new political institutions. The sequence and the relations among these three aspects may vary from one revolution to another. (40)
In Huntington's view, revolution usually unfolds from collapse of the state to the emergence of a new political group or elite capable of seizing and institutionalizing power.

If no group is ready and able to establish effective rule following the collapse of the old regime, many cliques and social forces struggle for power. The struggle gives rise to the competitive mobilization of new groups into politics and makes the revolution revolutionary. Each group of political leaders attempts to establish its authority and in the process either develops a broader base of popular support than its competitors or falls victims to them. (41)

The two prerequisites for revolution are, first, political institutions incapable of providing channels for the participation of new social forces in politics and of new elites in government, and secondly, the desire of social forces, currently excluded from politics, to participate therein, this desire normally arising frlom the group's feeling that it needs certain symbolic or material gains which it can achieve only by pressing its demands in the political sphere. (45)
Huntington's approach to revolution, then, emphasizes the grievances and demands of the population and the rigidity or flexibility of political institutions, and it highlights the sweeping character of the changes, political, social, and ideological, that resulted.

Next, consider Theda Skocpol conception of a "social revolution" in States and Social Revolutions: A Comparative Analysis of France, Russia and China:
Social revolutions are rapid, basic transformations of a society's state and class structures; and they are accompanied and in part carried through by class-based revolts from below. Social revolutions are set apart from other sorts of conflicts and transformative processes above all by the combination of two coincidences: the coincidence of societal structural change with class upheaval; and the coincidence of political with social transformation. In contrast, rebellions, even when successful, may involve the revolt of subordinate classes -- but they do not eventuate in structure change. Political revolutions transform state structures but not social structures, and they are not necessarily accomplished through class conflict. And processes such as industrialization can transform social structures without necessarily bringing about, or resulting from, sudden political upheavals or basic political-structural changes. What is unique to social revolution is that basic changes in social structure and in political structure occur together in a mutually reinforcing fashion. And these changes occur through intense sociopolitical conflicts in which class struggles play a key role. (4-5)
Several things are evident in this paragraph. First, Skocpol is not offering a general

definition of revolution here, but rather a sub-category, the "social revolution." A ***social*** revolution involves both significant transformation of political structure and major change of social structure. It is both political (having to do with the institutions of the state) and social (having to do with the basic relations of property and class that exist in society). She does presuppose that there is such a thing as a purely political revolution; but she indicates that she is not particularly interested in this category of change. Second, she postulates that social revolutions derive from a duality of types of grievances as well: grievances about the economic structure (property, class, and inequality) and the political structure (the institutions through which a dominant group exercises power and coercion over the rest). So a social revolution derives from demands for social as well as political change, and it results in largescale structural changes in both social and political institutions.

Jack Goldstone is a historical sociologist who has written very extensively on revolution in the past decade or so. His Revolution and Rebellion in the Early Modern World (1991) offers an innovative interpretation of several modern revolutions -- the English Revolution, the French Revolution, and state breakdowns in the Ottoman Empire and Ming-Qing China. So let's look at Goldstone's way of conceiving of revolutions.

It turns out that Goldstone doesn't really place much weight on "revolution." Instead, he gives conceptual priority to the idea of "state breakdown" over the more complex concept of revolution.

I shall refer to the revolutions and rebellions examined in this book as cases of state breakdown. By state breakdown I mean a particular combination of events, but not quite a revolution. (7-8)
He frames his intellectual task as that of explaining why there were waves of periods of state breakdown in modern European and Asian history. Revolution is a consequence of state breakdown rather than an event having its own historical dynamic. So what is state breakdown? Goldstone doesn't give a developed analytical discussion of this concept; but it presumably encompasses fiscal breakdown (inability to collect sufficient taxes to maintain the state's actions); military and police breakdown (inability to marshall sufficient manpower to quell foreign and domestic enemies); and ideological breakdown (inability to maintain the loyalty and adherence of the subject population).

Here is Goldstone's definition of the state:

By "the state" I mean the institutions of centralized national-level rule-making and rule-enforcing power, including the individuals who controlled those institutions when acting in their official capacities. (4)
And "breakdown":

State breakdown generally involved the collapse of the central authority's ability to dominate in a confrontation with other politically powerful actors, rather than the breakdown of all political institutions. (4-5)
So -- what about Tunisia and Egypt? It seems that none of these three conceptual frameworks for revolution would classify Tunisia and Egypt as revolutions. Neither is a "social revolution" by Skocpol's definition. There is no indication of major change in the system of property and class, either demanded or forthcoming -- even if there are economic reforms that make life a little better for poor people. And the anti-government popular movement does not seem to have been largely driven by under-class interests; rather, the demands seem largely to be centered on grievances about the misuse of

government power and corruption of the state that are of interest across almost all segments of society.

Second, neither appears to represent the situation of "state breakdown" in Goldstone's sense. Up until the street demonstrations began to grow and to represent a credible and sustainable social movement of opposition, no expert observer would have said that Tunisia or Egypt was suddenly losing its ability to control society, collect taxes, or run the government's operations. So the dramatic political events in Tunisia and Egypt did not result from "state breakdown."

Finally, Tunisia and Egypt do not appear to fit Huntington's definition either. These movements have not been particularly violent -- instead, they depend on "people's power" for their political force. And they don't seem to have resulted in the kinds of sweeping changes of social, political, and ideological structures that Huntington postulates either. We don't know precisely where things will end up in either Tunisia or Egypt; but the case of the Philippines is well known, and only fairly superficial political institutional changes have persisted, with virtually no change in the basic social-property relations that govern ordinary people's lives. What is more congruent to Tunisia and Egypt is Huntington's observation about the rigidity of certain political systems: in neither Tunisia nor Egypt was there an avenue for effective political expression and change for non-elites, over a three-decade period. So these regimes were neither inclusive nor accountable; as a result, they had no way of containing the growing discontent in the population.

Perhaps the most we can say about Tunisia and Egypt is fairly descriptive: these were instances of governmental change forced by a largely spontaneous social movement that erupted into the streets, with very little organization or leadership. Promises of political reform were made in response to the demonstrations, and if these promises are kept, then the movement will have produced some degree of political reform in addition to the successful ouster of the dictator. So popular movements can push the governments of Tunisia and Egypt in the direction of more inclusive democratic political institutions. But this process, and these limited outcomes of political change, seem to fall far short of the idea of "revolution." And, along with the realism that Huntington often expresses about this sort of process, it is entirely possible that these transformations will be hijacked by other groups as events unfold, so that their progressive political goals will be frustrated.

Unfortunately, though, we don't have a convenient umbrella term for this kind of political transition. The closest I can come is something like this: these are people-powered processes of forced political reform, intended to lead to institutions that are more inclusive and more accountable than the dictatorships they replace. They are "people-power" political transformations, not revolutions.

Democracy in a polarized society

Sunday, February 13, 2011

What are some of the institutional arrangements that can work to preserve a functioning democracy in a society with extensive inequalities of wealth and power?

This is a key question in part because we can easily see the factors that work against the democratic outcome. A Berlusconi in Italy is capable of dominating the political institutions in his country through his wealth and control of a media empire. An Abhisit in Thailand is able to maintain his political power through his reliance on the support of the armed forces and their willingness to use force against popular movements like the Redshirts (link). And the sham democracy resulting from elections rigged by Burma's junta last fall demonstrates how the generals can exert their rule through and behind ostensibly "electoral" legislative institutions.

These questions are most relevant today because of the people's movements in Tunisia and Egypt. But they are also relevant in many of the "semi-democracies" in the world today -- for example, Putin's Russia, Georgia, and Uzbekistan. In each case a strongman and his political organization are able to intimidate opponents and govern through a charade of elections. There are some of the trappings of democracy -- elections, parties, legislatures -- but there is the reality of authoritarian rule backed ultimately by the threat of violence -- against journalists, against the opposition, and against the people if they bring their politics into the street. And behind all is the reality of the plutocrats -- the wealth holders whose property originates in privileged access to the state and depends on the state for its continuation.

An idealized conception of democracy might go along these lines. The population as a whole is entitled to decide the basic issues confronting the nation. Individuals have an unencumbered right to form and express their opinions about the issues of the day. Individuals have the right to join and support political organizations (parties) whose program they wish to support. Individuals and organizations have the right to compete for political office, legislative and executive. An elected legislative body has the authority to enact legislation. All parties in society are fundamentally committed to supporting the constitutionally defined democratic processes, whether or not their preferences prevail. No party has the ability to overturn the outcomes of democratic competition. And no group has such a concentration of resources that it is able to dominate political outcomes.

These assumptions are idealized in a variety of ways, but I think they capture our general intuitions about a functioning democracy.

These are simple assumptions. But they are incredibly demanding in the context of many historical circumstances. It is almost always true that there are groups that have very

strong material interests in one set of outcomes over another and have access to resources that would permit them to go extra-constitutional. They may use money to corrupt the process; they may support paramilitary organizations and militias to protect their interests; and they may form alliances with the military and police to gain their will. (El Salvador in the 1980s is a terrible but apt example.)

So given these class-based factors that threaten to destabilize and undermine an emerging democracy, what countervailing factors exist that can help to secure an emerging democracy? There seem to be several.

First, an independent press (and Internet news and communications world) can serve as a check on anti-democratic and corrupt usurpation of the democratic process.

Second, a broadly shared public commitment to constitutional procedures can help to reduce the likelihood of anti-democratic seizure of power, whether by leaders or the military.

Third, a strong ethical conviction within the officer corps of the need for constitutionality in the conduct of the military can reduce the likelihood of intervention in politics by the army.

Fourth, a tradition of a neutral and independent judiciary can constrain the emergence of anti-democratic leaders.

Fifth, and most important, the citizenry can remain vigilant and courageous in the face of corruption and anti-democratic actions by government, legislators, and power-holders. Citizens can return to the streets when their government deviates from constitutionality and democracy.

None of this makes it seem as though the creation of a functioning democracy is easy work or a process that inevitably leads to success. In fact, it suggests the contrary: that polarization, severe inequalities of wealth and power, and the existence of a military with entrenched economic interests in an authoritarian society make the attainment of a genuinely citizen-centered democracy inordinately difficult.

The best hope for a democratic Egypt, it seems, is the existence of far-sighted groups of democratic activists who can help create the institutions of individual participation and governance that democracy requires; and who can use the tools available to them (including the publicity of the Internet and political organizations of the masses of Egyptians) to create a working constitution and the institutions and loyalties that will support it.

These questions fall within what might be called "applied theory of democracy" rather than ideal theory. Adam Przeworski is a political scientist who has made particularly incisive contributions to this aspect of the study of political institutions, especially in the context of emerging democracies. Particularly useful are Democracy and the Limits of Self-Government (2010) and Capitalism and Social Democracy (1986).

Thinking about disaster

Tuesday, February 15, 2011

Charles Perrow is a very talented sociologist who has put his finger on some of the central weaknesses of the American social-economic-political system. He has written about corporations (Organizing America: Wealth, Power, and the Origins of Corporate Capitalism), technology failure (Normal Accidents: Living with High-Risk Technologies), and organizations (Complex Organizations: A Critical Essay). (Here is an earlier post on his historical account of the corporation in America; link.) These sound like very different topics -- but they're not, really. Organizations, power, the conflict between private interests and the public good, and the social and technical causes of great public harms have been the organizing themes of his research for a very long time.

His current book is truly scary. In The Next Catastrophe: Reducing Our Vulnerabilities to Natural, Industrial, and Terrorist Disasters he carefully surveys the conjunction of factors that make 21st-century America almost uniquely vulnerable to major disasters -- actual and possible. Hurricane Katrina is one place to start -- a concentration of habitation, dangerous infrastructure, vulnerable toxic storage, and wholly inadequate policies of water and land use led to a horrific loss of life and a permanent crippling of a great American city. The disaster was foreseeable and foreseen, and yet few effective steps were taken to protect the city and river system from catastrophic flooding. And even more alarming -- government and the private sector have taken almost none of the prudent steps after the disaster that would mitigate future flooding.

Perrow's analysis includes natural disasters (floods, hurricanes, earthquakes), nuclear power plants, chemical plants, the electric power transmission infrastructure, and the Internet -- as well as the threat of deliberate attacks by terrorists against high-risk targets. In each case he documents the extreme risks that our society faces from a combination of factors: concentration of industry and population, lax regulation, ineffective organizations of management and oversight, and an inability on the part of Congress to enact legislation that seriously interferes with the business interests of major corporations even for the purpose of protecting the public.

His point is a simple one: we can't change the weather, the physics of nuclear power, or the destructive energy contained in an LNG farm; but we can take precautions today that significantly reduce the possible effects of accidents caused by these factors in the future. His general conclusion is a very worrisome one: our society is essentially unprotected from major natural disasters and industrial accidents, and we have only very slightly increased our safety when it comes to preventing deliberate terrorist attacks.

This book has been about the inevitable inadequacy of our efforts to protect us from major disasters. It locates the inevitable inadequacy in the limitations of formal

organizations. We cannot expect them to do an adequate job in protecting us from mounting natural, industrial, and terrorist disasters. It locates the avoidable inadequacy of our efforts in our failure to reduce the size of the targets, and thus minimize the extent of harm these disasters can do. (chapter 9)

A specific failure in our current political system is the failure to construct an adequate and safety-enhancing system of regulation:

Stepping outside of the organization itself, we come to a third source of organizational failure, that of *regulation*. Every chapter on disasters in this book has ended with a call for better regulation and re-regulation, since we need both new regulations in the face of new technologies and threats and the restoration of past regulations that had disappeared or been weakened since the 1960s and 1970s. (chapter 9)

The central vulnerabilities that Perrow points to are systemic and virtually ubiquitous across the United States -- ***concentration*** and ***centralization***. He is very concerned about the concentration of people in high-risk areas (flood and earthquake zones, for example); he is concerned about the centralized power wielded by mega-organizations and corporations in our society; and he is concerned about the concentration of highly dangerous infrastructure in places where it puts large populations at risk. He refers repeatedly to the risk posed by the transport by rail of huge quantities of chlorine gas through densely populated areas -- 90 tons at a time; the risk presented by LNG and propane storage farms in areas vulnerable to flooding and consequent release or explosion; the lethal consequences that would ensue from a winter-time massive failure of the electric power grid.

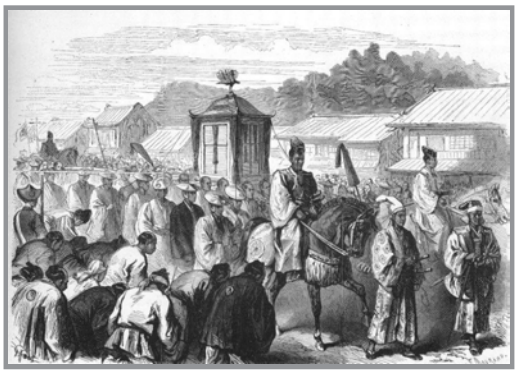
Perrow is an organizational expert; and he recognizes the deep implications that follow from the inherent obstacles that confront large organizations, both public or private. Co-optation by powerful private interests, failure of coordination among agencies, lack of effective communication in the preparation of policies and emergency responses -- these organizational tendencies can reduce organizations like FEMA or the NRC to almost complete inability to perform their public functions.

Organizations, as I have often noted, are tools that can be used by those within and without them for purposes that have little to do with their announced goals. (Kindle loc, 1686)

Throughout the book Perrow offers careful, detailed reviews of the effectiveness and consistency of the government agencies and the regulatory legislation that have been deployed to contain these risks. Why was FEMA such an organizational failure? What's wrong with the Department of Homeland Security? Why are chronic issues of system safety in nuclear power plants and chemical plants not adequately addressed by the corresponding regulatory agencies? Perrow goes through these examples in great detail and demonstrates the very ordinary social mechanisms through which organizations lose effectiveness. The book serves as a case-study review of organizational failures.

Perrow's central point is stark: the American political system lacks the strength to take the long-term steps it needs to in order to mitigate the worst effects of natural (or intentional) disasters that are inevitable in our future. We need consistent investment for long-term benefits; we need effective regulation of powerful actors; and we need long-term policies that mitigate future disasters. But so far we have failed in each of these areas. Private interests are too strong, an ideology of free choice and virtually unrestrained use of property leads to dangerous residential and business development, and Federal and state agencies lack the political will to enact the effective regulations that would be necessary to raise the safety threshold in dangerous industries and developments. And,

of course, the determined attack on "government regulations" that has been underway from the right since the Reagan years just further worsens the ability of agencies to regulate these powerful businesses -- the nuclear power industry, the chemical industry, the oil and gas industry, ...



One might think that the risks that Perrow describes are fairly universal across modern societies. But Perrow notes that these problems seem more difficult and fundamental in the United States than in Europe. The Netherlands has centuries of experience in investing in and regulating developments having to do with the control of water; European countries have managed to cooperate on the management of rivers and flood plains; and most have much stronger regulatory regimes for the high risk technologies and infrastructure sectors.

The book is scary, and we need to pay attention to the social and natural risks that Perrow documents so vividly. And we need collectively to take steps to realistically address these risks. We need to improve the organizations we create, both public and private, aimed at mitigating large risks. And we need to substantially improve upon the reach and effectiveness of the regulatory systems that govern these activities. But Perrow insists that improving organizations and leadership, and creating better regulations, can only take us so far. So we also need to reduce the scope of damage that will occur when disaster strikes. We need to design our social system for "soft landings" when disasters occur. Fundamentally, his advice is to decentralize dangerous infrastructure and to be much more cautious about development in high-risk zones.

Given the limited success we can expect from organizational, executive, and regulatory reform, we should attend to reducing the damage that organizations can do by reducing their size. Smaller organizations have a smaller potential for harm, just as smaller concentrations of populations in areas vulnerable to natural, industrial, and terrorist disasters present smaller targets. (chapter 9)
If owners assume more responsibility for decisions about design and location -- for example, by being required to purchase realistically priced flood or earthquake insurance -- then there would be less new construction in hurricane alleyways or high-risk earthquake areas. Rather than integrated mega-organizations and corporations providing goods and services, Perrow argues for the effectiveness of networks of small firms. And he argues that regulations and law can be designed that give the right incentives to developers and home buyers about where to locate their businesses and homes, reflecting the true costs associated with risky locations. Realistically priced mandatory flood insurance would significantly alter the population density in hurricane alleys. And our policies and regulations should make a systematic effort to disperse dangerous concentrations of industrial and nuclear materials wherever possible.

Steve Pincus on revolution

Saturday, February 19, 2011

Steve Pincus offers a sweeping and compelling reinterpretation of the English Revolution in 1688: The First Modern Revolution. Along the way he provides a review of existing theories of revolution -- Skocpol, Huntington, Barrington Moore, and Goldstone, in particular (chapter 2). Pincus's definition of revolution goes along these lines:

Revolutions thus constitute a structural and ideological break from the previous regime. They entail changes to both the political and socioeconomic structures of a polity. They involve an often violent popular movement to overturn the previous regime. Revolutions change the political leadership and the policy orientations of the state. And revolutionary regimes bring with them a new conception of time, a notion that they are beginning a new epoch in the history of the state and its society. (kindle loc 549)

Pincus criticizes each of the prevailing theories of revolution. Fundamentally Pincus's criticism is that these theories share a common error of conceptualization: they work on the assumption that revolutions are the outcome of a conflict between a rigid, conservative, and exhausted state, on the one hand, and a movement of modernizers, on the other. Tocqueville embodies this assumption in his own history of the French Revolution -- the defenders of the *Ancien regime* are defeated by economic and social reformers (Ancien Regime and the French Revolution). But Pincus argues that the historical reality was quite different, in France, Russia, China, the Ottoman Empire, and England.

In all cases the old regime had ceased to exist before the revolution. Revolutions, then, do not pit modernizing elements against defenders of the traditional order. Instead revolutions occur only after the regime in power has set itself on a modernizing course. State modernization itself cannot occur without prior socioeconomic modernization. But that socioeconomic modernization is a necessary though not a sufficient cause of state modernization. It is for that reason that revolutions are the often-violent working out of competing state modernization programs. (kindle loc 613)

So it is fissures and catalysts created by the state's own processes of modernization that create the impetus towards revolution, according to Pincus. But what is modernization? Here is Pincus's brief account:

By state modernization I mean a self-conscious effort by the regime to transform itself in fundamental ways. State modernization will usually include an effort to centralize and bureaucratize political authority, an initiative to transform the military using the most up-to-date techniques, a program to accelerate economic growth and shape the contours of society using the tools of the state, and the deployment of techniques allowing the state to gather information about and potentially supporess social and political activities taking place in a wide range of social levels and geographical locales within the polity. (kindle loc 613)

But not all modernizing states result in revolution; so what factors make revolution more likely? Pincus mentions Sweden, Denmark, and Meiji Japan as historical examples of

societies with modernizing states and no revolution. Pincus thinks the answer lies in the degree to which the modernizing state is able to keep credible control of the apparatus of social order.

Revolutions are more likely in situations in which the modernizing regime is not clearly perceived to have a monopoly of the forces of violence.... When the modernizing state quickly demonstrates its control of resources and disarms the opposition, as in seventeenth-century Denmark and Sweden or late-nineteenth-century Japan, revolutions do not occur. (kindle loc 699)

So the causal narrative the Pincus offers goes along something like these lines:

- The state initiates a process of reform and modernization.
- There are multiple visions of what "modernization" ought to look like for the polity, both within the state and outside the state.
- These multiple visions have the capacity to create advocates and processes of collective mobilization outside the state within civil society.
- One or more parties in civil society gain the intention and the resources to challenge the state.
- The state marshalls its forces to repress opposition.
- If it lacks sufficient capacity to intimidate or repress opposition, revolution occurs.

What this narrative discounts is quite a bit of what other theories of revolution place in the foreground -- under-class revolt, state breakdown, demographic change, ideological conflict, the disruptive social effects of war, and fiscal crisis, to name several. Pincus is too good a historian to truly overlook these factors, and they all come into his narrative of the English Revolution. But when it comes to offering a "theory" of revolution, Pincus is led down the same rhetorical path as the authors he criticizes: he wants to identify a single factor that "explains" the occurrence of revolution. Within the viewpoint of that single factor, he is willing to interweave the "secondary" factors mentioned here; but there is an intellectual desire to identify a single, most-important factor. And this seems misguided.

Better is the approach taken by McAdam, Tarrow, and Tilly in Dynamics of Contention. Fundamentally, they reject the impulse towards any kind of single-factor theory of revolution or any other kind of contentious politics. They argue that these large social outcomes are the result of the concatenation of a diverse range of social mechanisms and processes, none of which is paramount.

To call the events of 1789 "contentious politics" may seem to demean a great revolution. This book aims to demonstrate that the label "contentious politics" not only makes sense but also helps explain what happened in Paris and the rest of France during that turbulent summer. ... Further [the book] shows how different forms of contention -- social movements, revolutions, strike waves, nationalism, democratization, and more -- result from similar mechanisms and processes. It wagers that we can learn more about all of them by comparing their dynamics than by looking at each on its own. Finally, it explores several combinations of mechanisms and processes with the aim of discovering recurring causal sequences of contentious politics. (4)

Revolution is an instance of what McAdam, Tarrow, and Tilly call "transgressive contention" (7), but there are important examples of transgressive contention that are not revolutionary -- for example, the American civil rights struggle, cycles of protest in Italian cities, the Mau Mau rebellion, and other examples.

So *Dynamics of Contention* offer a serious methodological alternative to all of the theories of revolution mentioned here: rather than looking for a small number of structural

characteristics that "cause" or "inhibit" revolution, we are better served by moving down to the meso- and micro-levels of mobilization, claim-making, repression, state building, tax collecting, and ideological competition that constitute the real causal stuff of revolution and contention.

It is worth observing, further, that the *Dynamics of Contention* approach -- identifying discrete mechanisms and processes of contentious politics -- offers vastly better resources for investigating and explaining the wave of revolts, uprisings, and popular movements that are taking place today across the Middle East than any single theory of revolution would provide. The processes of grievance-making, group mobilization, communication, escalation, brokerage, and state tactics of repression that MTT describe are of obvious relevance in trying to understand the last few months of unrest in Tunisia, Egypt, Bahrain, Libya, and other countries. In particular, none of the macro-theories -- class conflict, state breakdown, or crises of the modernizing state -- seem to shed much light on these events. What is occurring seems to be much more akin to the path-dependent, multi-causal kind of process that McAdam, Tarrow, and Tilly describe.

(McAdam, Tarrow, and Tilly have been discussed several times here, including link, link.)

New thinking about the Red Guards

Tuesday, February 22, 2011

Andrew Walder has spent almost all of his academic life, on and off, studying the Chinese Cultural Revolution. In Fractured Rebellion: The Beijing Red Guard Movement (2009) he offers some genuinely new insights into this crucial and chaotic period of China's revolutionary history. Some historians have focused on the political motivations of Mao and other top leaders in the party; others have examined the economic and social cleavages that existed in China only a decade and a half into its Communist Revolution. Walder is interested in a much more grass-roots question: what were the motivations, calculations, and states of mind of the "foot soldiers" of the CR, the Red Guards in the earliest years of the upheavals? And why did the political activism of the CR devolve almost inevitably into intense ***factionalism*** between groups whose ideologies seemed virtually indistinguishable -- loyalty to Mao, defense of the revolution, attacks on treacherous leaders? Walder is a political sociologist, and he wants to understand the dynamics of mobilization and affiliation that led to the group violence and inter-group factionalism in the early years of this period.

Here is an example of the kind of factionalism that most interests Walder:

Chapter 8 examines the puzzling disintegration of the rebel movement in January 1967, soon after the decisive victory over its opponents. Why did the victorious rebel coalition rapidly split into two opposing camps? In their earlier attacks on ministries and commissions, rebels stayed within separate bureaucratic hierarchies. Work teams were dispatched down these hierarchies to the schools under them, and the pursuit of work teams led rebels directly back up this hierarchy to the ministry or commission that sent them. When these rebels moved to seize power in national and municipal agencies, however, they crossed into different bureaucratic hierarchies. Rebel groups from different schools who went to the same organs of power turned quickly from allies into competitors. These competitive rivalries were exacerbated by deep splits that had earlier developed among rebel forces in the two largest and most important campuses, Beijing and Quinghua universities. The splits at Beida and Qinghua served as a wedge to divide

rebel forces citywide, as factions of different schools aligned themselves with one or another faction at these two large campuses. The resulting split between "Heaven" and "Earth" factions crippled the student movement and frustrated the CCRG until the very end. (26-27)

Walder suggests that earlier scholars have sought to understand the motivations and factions of China's young people in terms of the class position of the participants and the pervasive political indoctrination of youth that had been ubiquitous in the 1950s and 1960s. Factions existed, according to this line of thought, either because different groups had different interests, or they had different political theories and ideologies ("conservative" and "radical"). Walder finds these explanations unsatisfactory, since they apply equally to both sides in all the factions -- and so he wants to identify some other feature of the political landscape that would explain the behavior and the factionalization. And, unlike the scholars of the 1970s and 1980s who had to largely speculate about these issues, Walder takes advantage of primary sources that allow the researcher to get a great deal of information about the participants in their own words, and in their relationships to other activists.

Walder also questions the relevance of the core assumptions of social mobilization theory for the Cultural Revolution -- the idea that social movements need to be understood in terms of grievances, resources, and the state's ability to resist group demands. Fundamentally his objection is that this theory doesn't help to explain the early months of the Cultural Revolution because all the postulated conditions were present in 1966, and mobilization did in fact occur (14). But it occurred in a very distinctive way that resource mobilization theory seems not to prove a basis for explaining -- the constant fissioning of a group of activists into two or more factions, bitterly opposed to each other. It appears, then, that resource mobilization theory lacks the tools necessary to explain this specific pattern of mobilization -- radicalization followed by bitter factionalism.

Walder's explanation is a novel one. He argues that factionalization was a consequence, not of class differences or ideological disagreements between individuals, but simply of the early choices that various individuals made early in the period. A central feature of this period was the fact of denunciation -- denouncing past or current leaders for disloyalty to the revolution or other ideological errors. And these denunciations within the universities were highly consequential: "by mid-July 55 percent of all university party first secretaries and 40 percent of all general branch secretaries had been labeled anti-party reactionaries and placed in category 4" (57). The rapid proliferation of denunciations meant that persons close to the denounced leader needed to decide -- should they join the denunciation or should they refrain? The work teams that were sent into Beijing's elite universities in June 1966 (Peking University, to begin with) were forced to make choices in light of radical students' denunciation of top university officials; lower officials had to make similar choices; and activist student leaders had to decide whether to support or oppose the activities of the work teams. And, Walder argues, this choice was fateful and enduring. It meant that the individual would be shunted into this group or that group, with further decisions cementing the affinity with the group.

Another way of stating the argument is that factional identities and the common interests that define them are the product of political interactions rooted in specific contexts whose properties must be researched, not simply assumed. Individual decisions -- to join factions, to oppose or support a work team -- are not the product of prior socialization or social ties but are actdively shaped by political encounters. The focus is on the interactions that generate choices and outcomes, not the prior statuses of individuals or their preexisting social and political ties. These processes determine when prior social

statuses or network ties are activated in a conflict, and when they are not. (13)
In other words, Walder argues that the fact of pervasive factionalization in the Cultural Revolution does ***not*** reflect fundamental underlying disagreements or contradictions between the factions; it does not reflect prior sociological distinctions among the participants; but rather reflects the emergence of separate networks of political affiliation from which there was no exit.

Chapter 3 describes how the work teams split university power structures into warring factions, with a focus on the issues that bred conflict between work teams and militant students. Only in rare and fleeting circumstances were the issues of contention about attacks on the incumbent power structure -- a question that might distinguish "conservative" from "radical" political orientations. Instead, they were usually about the work team's authority over student actions and the physical control of officials held for interrogation, and about heavy-handed work-team punishment of students who proved hard to control. (24)
This is a fascinating micro-sociology of a crucial span of a few months of violent upheaval in a single city. It helps to explain a particularly pervasive feature of a broad and chaotic period of political unrest in China -- the constant factionalism that occurred at virtually every level of conflict. It introduces an innovative model of political behavior (path-dependent choices by individuals leading to a durable configuration of political affiliations). And it provides a new avenue through which the methods of network analysis can be fruitfully used to explain complex social processes. It is a valuable contribution to the new wave of scholarship that is currently underway about the Cultural Revolution. (Other contributions to this new scholarship are included in Esherick, Pickowitz, and Walder, eds., China's Cultural Revolution As History.)

A side note, not crucial to Walder's argument but interesting nonetheless, is the apparently simple question of when the Cultural Revolution took place. It is conventional by many historians to date the CR to the years 1966-1976. In 1966 the Red Guard movement erupted with wall posters and virulent activism in Beijing, among high school and university students. And in 1976 Mao died, the Gang of Four were arrested, and the disruptions of the decade were decisively put aside. But Walder dates the CR to a much shorter period, 1966-68, beginning with the same Red Guard explosion that occurred in 1966 but ending in 1968 when Mao unleased the military to put down the radical activists: "Not until August 1968 were the flames of China's Cultural revolution extinguished by the imposition of a harsh regime of martial law" (1).

Spartacus, Kitty Genovese, and social explanation

Friday, February 25, 2011

What is most interesting in paying attention to social life is noticing the surprising outcomes that often materialize from a number of uncoordinated choices and actions by independent individuals. We want to understand why and how the aggregate-level social fact came to be: was it a set of features of the individual actors' preferences or decision-making? Was it the unintended result of strategic choices by various actors? Was it simply the path-dependent and contingent outcome of a serial interactive process? Was it brought about by structural conditions -- power, wealth, race -- within the context of which actors made their choices? And what were the ***mechanisms*** of constraint, aggregation, contagion, and escalation through which actions and processes at the more proximate

level came together into the outcome at the distal level?

Consider a pair of examples. Kitty Genovese is attacked by an assailant over an extended period of time in a dense neighborhood in Queens, many people observe the crime, and no one intervenes. The woman is eventually murdered. The question here is, why was there a total absence of intervention by any individual or group in this crime? And a parallel surprise: General Marcus Licinius Crassus, having trapped the rebellious slave army of Spartacus, announces that the slaves will be spared death if they give up Spartacus for crucifiction. Spartacus rises to his feet to say, "I am Spartacus." And in minutes the army of men rise as well, all declaring "I am Spartacus." Here the question is the reverse: why do these men expose themselves to death to stand in solidarity with Spartacus? In each case, there is an occasion for action presented to a group of individuals, in which members of the group can attempt to save the life of another person. The collective behavior is fundamentally different in the two cases. Why so? What are the mechanisms, psychological and social, that led to non-intervention in the first case and fatal solidarity in the second?

We might form a number of hypotheses about both of these cases in order to explain the very different outcomes. In the Kitty Genovese case, we might cite anomy and anonymity as possible causes of the lack of response by bystanders. With a low level of civic bonds, perhaps city dwellers have such a low level of emotional involvement with each other that even the slightest effort is unjustified. Or perhaps it is the fact that each potential responder is anonymous to the others that leads to the result; he/she can make the decision to refrain from offering aid without fear of criticism from others. Or perhaps collective behavior is strongly influenced by the actions of the first few, with later observers mimicking earlier non-aiders. So the outcome might have been highly different if the first or second witness had intervened; others might have followed suit. In the case of Spartacus, we might hypothesize that the bonds of solidarity forged by a history of fighting the Roman army gave the soldiers the moral motivation to support Spartacus; or perhaps it is the publicity of the scene, or the early example of the first few supporters, that spread to the behavior of the others. Or perhaps it is an expression of fundamental mistrust by the soldiers of the good faith of Marcus Crassus; "he will kill us anyway." With nothing to lose, the army makes its symbolic statement of rejection. These are each social psychological hypotheses, concerning the ways that individuals choose to involve themselves in an emergency and a situation of potential sacrifice.

Each of these hypotheses represents a social mechanism that can be incorporated into a narrative explaining the aggregate outcome. In order for such a story to be scientifically compelling, we need to have some way of using empirical evidence to evaluate whether the postulated mechanism actually works in the real world of human behavior. Is there empirical evidence for a social psychology of mimicry? Do we have evidence to suggest that members of a crowd are more likely to do X or Y if a few others have already done so? Is there empirical support for a theory of solidarity as a social motivation: do combat teams, groups of deep-ground miners, or emergency room doctors develop a higher willingness to conform their behavior to the good of the group or of other individuals in the group? These examples of social mechanisms all fall in the category of putative behavioral regularities, and it should be possible to investigate them experimentally and statistically.

The challenge of explanation for any social outcome, we might say, is that of constructing an interpretation of the states of minds of a set of actors; the constraints and opportunities within which they choose a course of action; and the interactions that are

created as they act within a common environment, leading to the outcome in question. This is what we can refer to as an ***aggregative explanation***, and it lies at the heart of Thomas Schelling's methodology in Micromotives and Macrobehavior. As Schelling points out, sometimes the explanation turns on specific features of agency (the actors' preferences or their modes of decision-making), and sometimes it turns on the specifics of the environment of choice (the fact that the outcome of action is a public good). But in general, explanation proceeds by showing how agents with specific features, acting within a social and natural environment with specific characteristics, bring about specific kinds of outcomes.

This, in a nutshell, represents a simple but powerful statement of a philosophy of social explanation. It also represents the rudiments of a social ontology: higher-level social features are composed of the actions and states of agency of a set of actors within the context of locally embodied rules, norms, and expectations. This is what I refer to as "methodological localism":

This theory of social entities affirms that there are large social structures and facts that influence social outcomes. But it insists that these structures are only possible insofar as they are embodied in the actions and states of socially constructed individuals. The “molecule” of all social life is the socially constructed and socially situated individual, who lives, acts, and develops within a set of local social relationships, institutions, norms, and rule. (link)
Social explanations derive their force from empirical research into the nature of the actor, the nature of the locally embodied social environment, and the processes of aggregation through which actions by multiple actors coalesce into social outcomes. The explanation satisfies us when it demonstrates the pathways through which individuals, constituted as they are found to be, located in institutions of the sort described, contribute to collective outcomes of the kinds described.

Searle on social ontology

Sunday, February 27, 2011

Speech Acts: An Essay in the Philosophy of Language made a big impression on the field of the philosophy of language when it appeared in 1969. But its author, John Searle, thinks the theory of speech acts has a much broader scope than simply the philosophy of language; he thinks it provides a foundation for the philosophy of mind, and -- of particular interest here -- for the philosophy of society. Two books in the past decade or so have pushed this programme forward -- The Construction of Social Reality (1995) and Making the Social World: The Structure of Human Civilization (2010). So -- how much

insight into the social world can we get from the ideas underlying speech act theory?

Fundamentally, Searle's interest is in the nature of social ontology:

[The philosophy of society is] the study of the nature of human society itself: What is the mode of existence of social entities such as governments, families, cocktail parties, summer vacations, trade unions, baseball games, and passports? (MSW, kindle loc 161)
His answer is categorical and dogmatic; there is precisely one human intentional activity that underlies all of social reality:

Humans have the capacity to impose functions on objects and people where the objects and the people cannot perform the functions solely in virtue of their physical structure. [E.g. a five-dollar bill can't be physically transformed into a grande latte.] The performance of the function requires that there be a collectively recognized status that the person or object has, and it is only in virtue of that status that the person or object can perform the function in question. (kindle loc 194)
Status functions are fundamental, according to Searle, because they are the bearers of rights, obligations, and norms -- what he refers to as "deontic powers." As a member of the American Philosophical Association, I have a right to attend the annual conference, and this right is embodied in the states of intentionality of other actors who recognize that status and the associated right. "So status functions are the glue that holds society together. They are created by collective intentionality and they function by carrying deontic powers" (kindle loc 225).

Searle thinks that rules, institutions, and collective intentions are the fundamental "atoms" of social phenomena; and -- this is the dogmatic part -- he thinks that these all depend on one mental action, which he refers to as a Status Function Declaration. He holds that we cannot understand the working of a rule, a socially embodied obligation, or a socially embodied right, without postulating a commonly recognized Status Function Declaration that establishes that practice. And, sure enough -- a status function declaration is a form of a speech act.

All institutional facts, and therefore all status functions, are created by speech acts of a type that in 1975 I baptized as "Declarations".... With the important exception of language itself, all of institutional reality, and therefore, in a sense, all of human civilization, is created by speech acts that have the same logical form as Declarations.... Institutional facts are without exception constituted by language, but the functioning of language is especially hard to see. (kindle loc 253, 282, 1683)
So speech acts, and the linguistic intentionality that they express, are the foundation of all social phenomena. "All of institutional reality is created by linguistic representation" (kindle loc 313). Voila.

What this all seems to boil down to, is three points: (1) Social interactions always involve language, both internally in thought and externally in communication. (2) The idea of a norm is an inherently social idea that needs to be embodied in the beliefs and attitudes of the individuals in the group through linguistically framed mental representations. (3) Norms need to be shared and publicly articulated if they are to be socially real. Searle represents these three common ideas in a more technical vocabulary: individuals have individual and collective intentionality; individuals have deontic commitments; and deontic commitments result from status function declarations -- speech acts of a specific kind.

Let's consider each of the points. Is intentionality inherently linguistic? Of course adult

human intentionality is -- we can always paraphrase a state of consciousness as a linguistic declaration of some sort, and it is common to think of "thought" as internal speech. But is it possible to imagine purposiveness and intentionality in a non-linguistic species? Can we find examples of non-human cooperation that appears to presuppose intentionality without language? The answers to these two questions appear to be affirmative. Examples of primate problem-solving, group hunting, and simple cooperation in which the behavior of members of a group are oriented to the behavior of others all appear in the animal behavior literature. (Here is an earlier post on current research on human cooperation that appears to contradict the assumption that intentionality requires language; link. The post draws on the work of Michael Tomasello and colleagues in Why We Cooperate.)

Is it possible for a group of humans to embody a set of norms of behavior that are not explicitly formulated in language? Again, it seems that we have good empirical and theoretical reasons for thinking that "implicit norms", conventions, and practices exist. Searle himself gives some attention to what we would call "norms by convention", but only to argue that these examples are on their way to full-fledged status function declarations ("pre-institutional examples of the same logical form") (kindle loc 404, 449). But David Lewis's extensive work on the topic in Convention: A Philosophical Study (which Searle does not discuss) gives substantial support for the idea that conventions can emerge within a human group without formal linguistic articulation, and they can persist as a basis for organizing group behavior without requiring "codification" through a speech act. Here is a simple example:

In my hometown of Oberlin, Ohio, until recently all local telephone calls were cut off without warning after three minutes. Soon after the practice had begun, a convention grew up among Oberlin residents that when a call was cut off the original caller would call back while the called party waited. Residents usually conformed to this regularity in the expectation of conformity by the other party to the call. In this way calls were easily restored, to the advantage of all caoncerned. New residents were told about the convention [deontic speech act!] or learned it through experience [no deontic speech act required!]. It persisted for a decade or so until the cutoff was abolished. (43)
So, according to Lewis, coordination through tacit or implicit convention is a common feature of social life, and it does not require a deontic speech act for its effectiveness. (In fact, Lewis argues that the arrow points the other direction: language presupposes conventions rather than being a necessary condition to the possibility of a convention.) Lewis's analysis is responsive to condition (3) above as well; Lewis has demonstrated how a practice can become "common knowledge" and effective in regulating coordinative and cooperative behavior, without ever having been expressed through a deontic declaration.

So it seems that Searle's insistence on the inescapable role of language and performative speech acts goes beyond what is justified by the facts. The social is not reducible to a set of logical characteristics of language. That said, it is of course true that human social life -- coordination, planning, strategizing, conspiring, cooperating, and competing -- is enormously dependent on our species' ability to use language to express our thoughts and intentions. But we don't gain very much by paraphrasing social action in the language of speech acts; the real challenge for the social scientist is to explain social outcomes, not to redefine them.

Most fundamentally, we would hope that the philosophy of society or the philosophy of social science will help to formulate better theories and better research questions in the

social sciences. The hard part of the social sciences is not arriving at a logical analysis of how institutions and norms can be defined in terms of something else; it is rather the difficult challenge of sorting out real human behavior within a set of institutions and explaining outcomes on that basis. But because of its single-minded focus on a single logical hypothesis, *Making the Social World* doesn't really do that. It is a formal treatment of the supposed relationship between institutions and speech acts that unfortunately does not provide substantive insight into the workings of real social institutions or human behavior.

England's Glorious Revolution

Tuesday, March 01, 2011

Earlier posts have remarked upon the interesting fact that large historical events are often significantly reconsidered and re-understood through the passage of time. China's Cultural Revolution is one such example (link), as are the revolutions of 1848 (link).

A truly stunning example of this kind of historical recasting of something that we think we've fully understood is Steve Pincus's 1688: The First Modern Revolution. Pincus sets up his argument beautifully: there has been a dominant and eventually unquestioned narrative about the English Revolution of 1688-89, and in detail and in broad outline -- this narrative is incorrect. Here is the thrust of the standard story:

> Men and women all over the English-speaking world once knew what happened in England's Revolution of 1688–89. In 1685, the Catholic King James II inherited the crown of England. In 1689 the English people agreed to replace him with the Protestants King William III and Queen Mary II. In the intervening years, James II gradually and myopically alienated the moderate and sensible English people. He did this in a series of well-known missteps. In late 1685 he overreacted to the romantic but hopeless rebellion of his nephew, the Protestant Duke of Monmouth, by judicially murdering hundreds of humble inhabitants of the English West Country in the Bloody Assizes. Determined to improve the social and political status of his Catholic coreligionists, James then ran roughshod over English law. He insisted on his right to defy parliamentary statute and awarded Roman Catholics military and naval commissions. In 1687 he used his newly formed and illegal ecclesiastical commission to force England's Protestant universities to accept Roman Catholic fellows. When the fellows of Magdalen College Oxford resisted their king's demands, he had the dons stripped of their fellowships, turning the institution into a Catholic seminary.

According to this dominant story,

The revolution was unrevolutionary. Unlike other subsequent revolutions, England's revolution was ***bloodless, consensual, aristocratic, and above all sensible***. The English had no desire to transform their polity, their society, or their culture. Instead they worried that James II had intended to do just that. Second, the revolution was Protestant. James II had tried to reinstitute Catholicism in England. The revolution insured that England would remain a Protestant polity. Third, the revolution demonstrated the fundamentally exceptional nature of English national character.... Fourth, there could have been no social grievances undergirding the Revolution of 1688-89 because English society had changed little in the modern world. (kindle loc 134)

According to Pincus, this account fundamentally misrepresents the nature of the transformation that 1688 represented in English history, and it defines the scope of the historical question incorrectly in profoundly misleading ways. Pincus wants to tell a more accurate and revealing story; and he also wants to provide a political historiography that attempts to explain how these misrepresentations have come to define the dominant view of this revolution -- the political ins and outs of Establishment Whigs, Conservatives, and Opposition Whigs in the ensuing century and a half of debate and historical interpretation.

His own approach to the historical problem is to start over: to reassess the materials and archives that exist today that allow the historian to gain fragmentary glimpses into the complex social reality that 1688 represented. As he points out, there are substantial materials available today that were not available in the eighteenth or nineteenth centuries when the master narrative was pieced together. But he also observes that even materials available to Macaulay and Trevelyan can be read to a very different conclusion from those drawn by the eighteenth and nineteenth century historians.

Pincus's interpretation disagrees with the standard narrative in every major respect. First, he believes that the English Revolution was "the first modern revolution" -- the result of conflicts created by the process of state modernization that James II had undertaken. Second, he believes that the English Revolution was fundamentally located within a European context -- not a purely *sui generis* English affair.

The Revolution of 1688-89 is important not because it reaffirmed the exceptional English national character but because it was a landmark moment in the emergence of the modern state. (kindle loc 184)

Just as in the French and Russian Revolutions, there was extensive and violent crowd activity. And just as in other modern revolutions, the revolutionary events resulted not in consensus and compromise but in deep ideological cleavages. (kindle loc 3450)

Third, fourth, and fifth, Pincus refutes the idea that the revolution was "bloodless, aristocratic, and consensual". He documents that mass mobilization and violence were just as striking in England, Scotland, and Ireland as in the first year of the French Revolution (chapter 9), that segments from all levels of society were actively involved in these conflicts (chapter 8), and that the Revolution and its aftermath involved deep and abiding disagreements about the directions that the English state and society should take (chapter 10). So -- not bloodless, not aristocratic, and not consensual.

Instead Pincus tells a new story:

In this book, then, I retell the story of the Glorious Revolution, but I retell it in significantly new ways. Instead of a story of triumphant English exceptionalism emphasizing the far-seeing actions of a few men, I tell a story about a wide range of actors reacting not only

to developments in English high politics and in the English church but to changes in society, in the economy, and on the broader European scene. (kindle loc 210)

The Revolution of 1688-89, then, like all modern revolutions, was a struggle ultimately waged between two competing groups of modernizers. The revolution did not pit defenders of traditional society against advocates of modernity. Both Whigs and Jacobites were modernizers. It was the Tories who wished to defend a version of the old order. The Tories were placed in the unpalatable position of having to choose between two very imperfect political outcomes. (kindle loc 7542)

So how is it that a great historical event could be so fundamentally mis-construed and mis-remembered? Pincus refers to a number of factors that have distorted the historical understanding of the English Revolution over intervening centuries. One is an English belief in "English exceptionalism." There was a powerful desire on the part of English intellectuals -- for example, Burke and Hume -- to see England as being very different from France -- more civil, more consensual, and more constitutional. Second is the intellectual framework of "revolution as conflict between a decaying traditional state and a challenging modernist opponent" (see an earlier post on this conception of revolution). This led historians to narrow the focus of the events they highlighted, and to give primacy in their accounts to the debates and positions of the great figures inside and outside of government.

Third and most important is a feature of English political ideology, as expressed in the political conflicts between Tory and Whig parties and between establishment and opposition Whigs.

Walpole and his political allies now claimed that the revolution had instantiated parliamentary rather than popular sovereignty and that it had established a constitution rather than a blueprint for further reform. (kindle loc 310)

Opposition Whigs insisted that the revolution's principles should continue to drive a reformist agenda. In short, by the 1720s the establishment Whigs were emphasizing the immediate tyrannical *causes* of the events of 1688-89, whereas the Opposition Whigs were highlighting *long-term* structural causes and the revolutionary *consequences* of 1688-89. (kindle loc 394)

The works of Burke, Macaulay, and Trevelyan reasserted the establishment Whig interpretation of the revolution. ... Their interpretations became hegemonic not because they had uncovered new, irrefutable historical evidence but because in the face of contemporary political events their interpretative opponents had abandoned the field. .... Burke, Macaulay, and Trevelyan did not so much refute the arguments of the Opposition Whigs as assume that in the contemporary political climate their claims were irrelevant. (kindle loc 470)

These passages perhaps represent the key to Pincus's own perspective on the English Revolution -- we might argue that the book contributes to an unfettered "***Opposition Whig***" account of the revolution. And Pincus seems to support this interpretation: "It is now time to find answers to the questions that the Opposition Whigs raised in the eighteenth century" (kindle loc 503).

So we have the makings of a partial answer to the historiographic question -- why did several generations of historians so badly misunderstand the nature of the English Revolution? Ideology played a role; mental frameworks about "being English" played a role; and concrete political conflicts about what the state should do played a role. And, of

course, these sorts of factors are still with us.

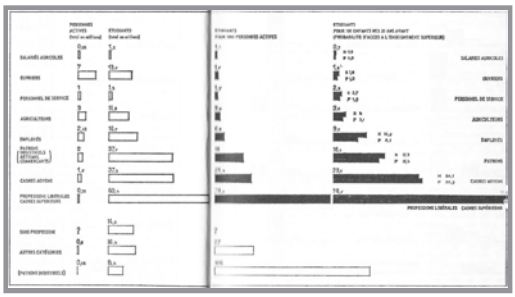
Education a leveler?

Friday, March 04, 2011

The role of education in social inequalities is difficult to assess, because it seems to have contradictory tendencies. On the one hand, improving access to education at all levels -- from elementary school to graduate school -- levels the playing field because it enhances the ability of everyone affected to realize their human talents and to pursue their goals with a greater foundation of cognitive and mental skills. Closing the literacy gap, the numeracy gap, or the technology gap across all of society gives the previously disadvantaged population a better chance to compete for success in seeking employment or creating other economic and social benefits for themselves and their families. Traditional sources of social inequality -- positions of privilege in social hierarchies, privileged access to political benefits, disproportionate ownership of land and other forms of productive property -- are to some extent blunted by a greater degree of equality of access to good schooling and the knowledge and skills it provides. So we might say that improving the quality and reach of a society's educational system should be expected to reduce existing inequalities.

On the other hand, access to education amplifies everyone's talents -- elite and disadvantaged alike. And more importantly, education proceeds through specific, concrete social institutions -- schools and universities -- and the quality and effectiveness of these educational institutions varies enormously across the face of a complex society. It is possible -- perhaps likely -- that these variations in quality will correspond to populations and neighborhoods in ways that align with patterns of prior advantage and disadvantage. So it is likely that we will have high-quality, effective schools providing education to advantaged groups; and low-quality drop-out factories providing education to the disadvantaged institutions. In this case, the education system might actually have the effect of deepening and entrenching the social inequalities that exist across groups.

I've put this point in hypothetical terms. But we know that across much of the United States, this isn't simply a hypothetically possibility. It is largely a fact on the American cityscape that schools vary in quality by race, poverty, and social status at the K-12 level. Affluent people are often served by good public schools, and they have the financial ability to choose good private schools if they are unsatisfied. Poor people are usually served by schools with severe disadvantages -- under-resourced, dilapidated, endemic management crisis, disaffected teachers and principals. So it is hard to make the case that American public education is a powerful force for decreasing social inequalities.



So what about American universities? Here the picture is more favorable. High school graduates who have gained the intellectual abilities required for succeeding at the university level -- admittedly, often a minority of all graduates -- have a range of choices that can genuinely erase most of the disadvantages of birth. A first-generation freshman from a low-income family can nonetheless gain a great engineering education or a great education in art history at an affordable public university; and this undergraduate success in turn positions him or her for future successes in graduate school or employment. So American universities do in fact deliver much of the promise of the theory of democratic education: broad access without regard to status or income, and substantial enhancement of life prospects as a result.

That said, American universities continue to reproduce a more specific form of elite advantage. Here is a January 2011 *Newsweek* review of America's elites and their university degrees. The snapshot it provides is a familiar one; elite positions in our society are disproportionately held by graduates of elite universities. Think of the number of US presidents and members of Congress with Ivy League degrees. Plainly our political elite was disproportionately produced by an elite set of universities (link). But similar results seem to obtain in the business world as well. The same *Newsweek* story reports that elite universities also produced the largest bloc of CEOs of Fortune 500 companies, with Harvard, Columbia, and the University of Pennsylvania leading the list, and Wisconsin, Michigan, and Ohio State providing a significant number of CEOs as well. Put the point this way: entry into an elite university greatly increases an individual's likelihood of becoming a member of the political and business elites in America. It is true, of course, that talented young people attend these universities, and it is predictable that they will be successful. But there seems to be more at work here than simply "elite schools educate the most talented young people of their generation."

Rather, it seems likely that the pathways that lead to career success are themselves facilitated by the social resources created for the graduate by his or her university: networks of alumni, the prestige of the degree, and the classmates and their families whom they come to know. The density of elite social networks seems to be a key part of the story; avenues into elite careers are facilitated by these contacts and social advantages. Contacts in government, politics, journalism, business, and Wall Street are richly available to the rising elite university graduate. An elite university provides a great reserve of social capital for the graduate. and this is unrelated to the actual level of achievement and talent that the graduate possesses.

Here are two empirical studies that complement these suspicions -- one in France in the 1960s and the other in the United States in the 1990s. Both studies are interested in essentially the same question: to what extent do universities (French or American) provide equitable opportunities across social groups? To what extent are the universities in these countries effective agents for bringing about greater social equality?

First, France. One of Pierre Bourdieu's earliest works is a study (with Jean-Claude Passeron) of the social inequalities that are reproduced by the French educational system (Les Héritiers : Les étudiants et la culture, 1964). Essentially Bourdieu and Passeron provide empirical data from 1961-62 that demonstrate that the population of French university students was highly unrepresentative of the social categories of the larger population. The likelihood of attending university was many times higher for some economic classes than others. Here is a graphic that captures the heart of Bourdieu and Passeron's findings:

In spite of the pre-Pixar graphics, I think Edward Tufte would approve; the graph displays very economically the fundamental relationship that the authors want to highlight in the data. The left panel of the graph represents the sizes of the populations associated with various social groups as well as the number of students whose background stems from the group. The right panel aggregates these data by computing the percentage of students from each who enroll in a university. For children from the humble social categories, including workers and farmers, the likelihood of attending university was very small, ranging from .7% to 3.6%. Higher social categories had substantially greater rates of attendance, ranging from 16.4% for the children of the owners of businesses to 29.6% and 58.5% for the children of lesser and higher civil servants and professionals. From top to bottom, then, the disparity of odds for different social groups is staggering. The children of professionals and high civil servants were 85 times more likely to attend university than hired farm workers, and they were 42 times more likely to attend than the children of blue collar workers. They also look carefully at academic success and choice of professions by the social class of the students' parents -- a perspective which continues through the present. Naturally, these findings are specific to a point in time -- 1961-62. No doubt these disparities have narrowed in the fifty years since Bourdieu and Passeron did this research. But they asked the right questions, and they established a perspective on French education that has continued to guide research in France.

And second, the United States. William Bowen, Martin Kurzweil, and Eugene Tobin provide a careful, empirically detailed and historically nuanced treatment of these issues in Equity and Excellence in American Higher Education (2005). One chapter of *Equity and Excellence* is particularly relevant to the question here. In "The Elite Schools: Engines of Opportunity or Bastions of Privilege?" the authors consider a large data set of admissions and outcomes at 19 selective colleges and universities (94). It is a fascinating analysis.

Their conclusion is a nuanced one:

By providing an increasingly straight path to entry and graduation for academically talented students from all socioeconomic strata, these prestigious institutions are fulfilling their historical promise to serve as "engines of opportunity." On the other hand, the disproportionately large number of graduates of these schools who come from the top rungs of American society indicate that they also remain "bastions of privilege." Vigorous recruiting notwithstanding, the applicant pools of these schools contain only a small number of well-prepared students from families of modest circumstances. This is the "controlling reality." (135)

They also find that students from disadvantaged socioeconomic origins are severely underrepresented in the elite institutions included in their study (parallel to the Bourdieu-Passeron findings):

Students whose families are in the bottom quartile of the national income distribution represent roughly 10 to 11 percent of all students at these schools, and first-generation college students represent a little over 6 percent of these student populations.... Both

groups are heavily underrepresented at the institutions in our study. ... When we combine the two measures of SES, and estimate the fraction of the enrollment at these schools that is made up of students who are both first-generation college-goers and from low-income families, we get a figure of about 3 percent. Nationally, the share of the same-age population who fell into this category was around 19 percent in 1992, making this doubly disadvantaged group even more underrepresented than students with just one of the two characteristics. (98)

This looks at the issue from the point of view of "probability of attendance" -- the focus of the Bourdieu-Passeron analysis. What about the outcomes of students from different socioeconomic groups who have successfully graduated from the elite institutions that Bowen et al survey? Does SES status influence career success? Bowen and his colleagues find that it does. First, a very crude measure: "The average income in 1994 or 1995 of a former student from the bottom income quartile was over $67,000; former students from the middle two quartiles had average incomes of between $73,000 and $75,000; and those from the top quartile had average earnings of nearly $86,000" (123). And an even more telling statistic when it comes to the sociology of American elites: "Just under 2% of former students from the bottom income quartile had a very high income 15 years out of college, while almost 6 percent of former students from families in the highest income quartile were themselves already in the top income category" (123). So socioeconomic background makes a difference all the way through; high SES graduates are three times as likely to have very high income than their equally qualified classmates from low SES circumstances. This certainly suggests that elite universities fail in the democratic ideal of leveling the playing field for persons of talent.

So it isn't really possible to answer the simple question with a simple answer: do modern educational systems in democracies level inequalities or increase inequalities? It would seem that they do some of both; they provide access to disadvantaged people who can then leverage success for themselves and their families, and they also create mechanisms of recruitment into elite organizations that are anything but egalitarian.

Democracy and contentious politics

Sunday, March 06, 2011

Democracy and contention are back on the front page, thanks to the uprisings in the Middle East and North Africa (MENA). As always, Chuck Tilly provided some important insights into today's events based on his depth analysis of several hundred years of contentious politics. The relevant work on the intersection between democratization and

contention is Contention and Democracy in Europe, 1650-2000 (2004). As the history of contentious politics demonstrates, nothing in the nature of social contention leads necessarily to a demand for greater democracy; in fact, nineteenth century observers tended to believe that "revolutionary contention" and democracy were antithetical to each other. So democratization and contention are interweaving subjects rather than different aspects of the same process.

As always, Tilly is interested in using historical comparisons to shed light on the processes of contention and democratization, and the history that they focus on in this volume is that of modern France and Britain.

To explain similarities and differences in French and British experience since 1650 constitutes a reasonable start toward more general explanations of variation within Europe as a whole. Since European polities and their immediate transplants originated most of the contemporary institutions we recognize as democratic, furthermore, any explanation that gets right the last few centuries of European involvement in contention and democracy offers some promise of helping to identify likely origins of democracy elsewhere. (7)

So comparison is one key methodological pillar. The other is the framework of mechanisms and processes that he and his colleagues developed in Dynamics of Contention and in other subsequent works. "[This book's] claim to attention resets instead on the identification of mechanisms and processes that promote, inhibit, or reverse democratization" (ix). This places Tilly's approach in direct opposition to several other theories of largescale social change -- theories that look for common structural factors that explain large outcomes such as democracy or revolution, and theories that look primarily to the intentions of the actors.

My inquiry guesses, furthermore, that the social world’s order does not reside in general laws, repeated large-scale sequences, or regular relationships among variables.We should not search for a single set of circumstances or a repeated series of events that everywhere produces democracy. Nor should we look for actors having democratic intentions, seeking to discover how and when they get chances to realize those intentions. We should look instead for robust, recurrent causal mechanisms that combine differently, with different aggregate outcomes, in different settings. (9)

If we are to attempt to understand the factors that are conducive to (or inhibitive of) greater democracy, we need to have a fairly specific idea of what we are thinking of under the concept of democracy. Tilly provides this definition of democratization:

Democratization means increases in the **breadth and equality of relations** between governmental agents and members of the government’s subject population, in **binding consultation of a government’s subject population** with respect to governmental personnel, resources, and policy, and in **protection of that population** (especially minorities within it) **from arbitrary action by governmental agents**. (13-14)

Remarkable in this definition is the fact that Tilly does not chiefly highlight institutions such as representative voting or separation of powers, but rather several more general features of a polity: **equality** between government and the subject population, **binding consultation** of the subject population, and **protection** of the subject population from arbitrary action. Each of these dimensions has a strong theoretical relationship to the concept of democracy; the equal worth of citizens favors the first point, the idea that citizens should contribute to the formation of government's policies finds expression in "binding consultation"; and the idea of the rule of law is expressed in the idea of protection from arbitrary action. Greater democratization means increasing one or more

of these three dimensions in the given society. Tilly refers to this as a "political process" approach to the conceptual problem. And he folds this definition into a substantive historical hypothesis:

Only where positive changes in trust network integration, inequality insulation, and the relevant internal transformations of public politics all intersect does effective, durable democracy emerge. Most changes in public politics, on the contrary, produce undemocratic outcomes. (17)

So what are the high-level factors that work on the state's side to influence the state's ability to crush popular contention? And what external factors might bring about abrupt changes in these factors? Tilly refers to a state's command of "coercion, capital, and commitment" as a measure of its ability to enforce its will -- including the ability to repress popular movements demanding social and political change. Coercion has to do with the apparatus of the military and police, and the administrative infrastructure through which these are controlled. Capital has to do with the amount of wealth the state is able to summon to its purposes. And commitment has to do with the networks of committed partners the state can call upon throughout the population within its scope of control -- what he refers to as the "trust networks" of the state. When the state's ability to marshall these forms of power is great, contentious movements are unlikely to succeed. But specific, concrete social factors can work to undermine each of these aspects of the state's power. Those factors can be internal -- a food crisis that greatly undermines the loyalty of the state's agents, for example -- or external -- the stresses of international efforts by the state. In particular, he singles out revolution, conquest, confrontation, and colonization as large stresses for the state that can significantly change its ability to enforce its will (40). And all of this leads Tilly to a fairly strong hypothesis:

Regional variation in the accumulation and concentration of coercion, capital, and commitment strongly affected the sorts of governmental institutions that formed in different parts of Europe through the centuries, but the presence of certain sorts of regimes in a region shaped what kinds of regimes formed later. (45)

These factors give some insight into how a regime can be more or less capable of resisting contentious challenges; but what factors influence the likelihood of such challenges themselves? Tilly's analysis takes an important step towards greater specificity through his construction of three tables of concrete mechanisms in these areas of political process: "mechanisms segregating categorical inequality from public politics," "mechanisms integrating trust networks into public politics", and "mechanisms increasing breadth, equality, enforcement and security of mutual obligations between citizens and government agents" (18-20). Examples from each group of mechanisms are highly relevant to the processes currently underway in Egypt, Tunisia, and Libya:

- Adoption of devices that insulate public politics from categorical inequalities; for example, secret ballots, payment of officeholders, and free, equal access of candidates to media forward formation of cross-category coalitions (18)
- Disintegration of existing segregated trust networks; for example, decay of patrons' ability to provide their clients with goods and protection promotes withdrawal of clients from patron-client ties (19)
- Central co-optation or elimination of previously autonomous political intermediaries; for example, regional strongmen join governing coalitions, thus becoming committed to governmental programs (20)

These tables amount to a detailed micro-analysis of mechanisms and processes that can occur more or less independently, and that have impact on the democratic issues of categorical inequalities, consultation, and protection. Here is a causal model in which Tilly attempts to capture the meso-level causality that he finds in the comparison of British and

French contentious politics over three centuries:

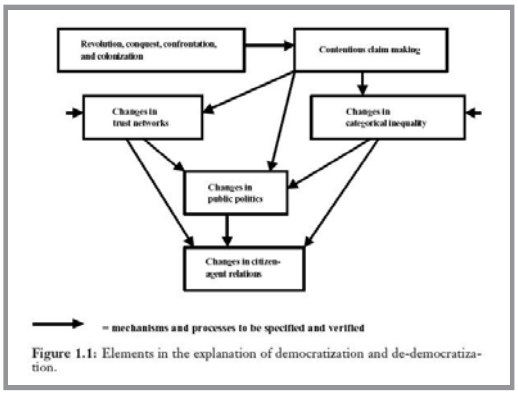


Figure 1.1: Elements in the explanation of democratization and de-democratization.

Tilly encapsulates his key findings in these thirteen hypotheses:

1. *Differing combinations of coercion, capital, and commitment in various regions promote the formation of significantly different kinds of regimes, and different directions of regime change, within those regions.*
2. *Trajectories of regimes within a two-dimensional space defined by (a) degree of governmental capacity and (b) extent of protected consultation significantly affect both their prospects for democracy and the character of their democracy if it arrives.*
3. *In the long run, increases in governmental capacity and protected consultation reinforce each other, as state expansion generates resistance, bargaining, and provisional settlements, on one side, while on the other side protected consultation encourages demands for expansion of state intervention, which in turn promote increases in capacity.*
4. *At the extremes, where capacity develops farther and faster than consultation, the path to democracy (if any) passes through authoritarianism; if protected consultation develops farther and faster than capacity and the regime survives, the path then passes through a risky zone of capacity building.*
5. *Although the organizational forms – elections, terms of office, areal representation, deliberative assemblies, and so on – adopted by democratizing regimes often emulate or adapt institutions that have strong precedents in villages, cities, regional jurisdictions, or adjacent national regimes, they almost never evolve directly from those institutions.*
6. *Creation of citizenship – rights and obligations linking whole categories of a regime's subject population to governmental agents – is a necessary but not sufficient condition of democratization.*
7. *In high-capacity regimes, nondemocratic citizenship sometimes forms, and with extensive integration of citizens into regimes even reduces or inhibits democracy.*
8. *Nevertheless, the prior presence of citizenship, other things equal, generally facilitates democratization.*
9. *Both creation of citizenship and democratization depend on changes in three arenas – categorical inequality, trust networks, and public politics – as well as on interactions among those changes.*
10. *Regularities in democratization consist not of standard general sequences or sufficient conditions but of recurrent causal mechanisms that in varying combinations and sequences produce changes in categorical inequality, networks of trust, and public politics.*
11. *Under specifiable circumstances, revolution, conquest, confrontation, and*

colonization accelerate and concentrate some of those crucial causal mechanisms.

12. *Almost all of the crucial democracy-promoting causal mechanisms involve popular contention – politically constituted actors' making of public, collective claims on other actors, including agents of government – as correlates, causes, and effects.*
13. *In the course of democratization, repertoires of political contention (arrays of widely available claim-making performances) shift from predominantly parochial, particular, and bifurcated interactions based largely on embedded identities to predominantly cosmopolitan, modular, and autonomous interactions based largely on detached identities. (7-8)*

Here is what France's political history looks like, according to Tilly's analysis of its path through the space of "governmental capacity" and "protected consultation":

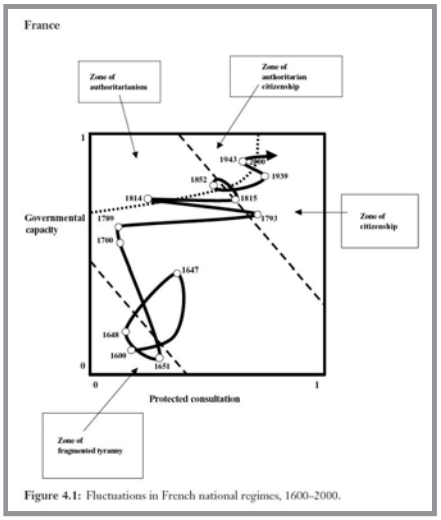

Figure 4.1: Fluctuations in French national regimes, 1600–2000.

Some readers might be disappointed at the complexity of the analysis Tilly offers here. But that is inherent in his foundational assumptions: that there are many relevant mechanisms and processes, that these mechanisms interact in multiple complex ways, and that there are many pathways to democracy and dictatorship. So even the most systematic tracing of possible scenarios will result in a highly complex "phase diagram" of a polity as it moves through its political processes over time.

* * *

In light of the recent post about Steve Pincus's reinterpretation of the Glorious Revolution of 1688-89, it is interesting to pull out a few of Tilly's observations about the same period.

- The Glorious Revolution that brought William and Mary to power wrought enduring effects, but at a price. Considering the British Isles as a whole, the settlement of 1690 produced a higher capacity government than had ever existed before. It did so, for the time being, at the expense of protected consultation. (144)
- The new regime likewise brought the rise of party politics and Dutch inspired fortification of public finances (Braun 1975: 290–94, 't Hart 1991; Kishlansky 1996: 290; Scott 2000: chapter 21). Creation of a Bank of England (1694) coupled with parliamentary control over governmental indebtedness to produce a relatively secure national debt, heavy involvement of London financiers in the funding of that debt, and widespread investment of the wealthy in government securities (Armitage 1994; Muldrew 1998: 328–29). (145)
- As military forces exploded during the 18th century, moreover, Parliament's

> authorization of taxation and expenditure added weight to parliamentary decisions, beginning a decisive shift of power from the royal administration to Parliament (Brewer 1989; Stone 1994; Tilly 1997). (147)

These points converge closely with Pincus's points about the modernizing state, and the role of financial elites in the changes of the period. But it is also interesting that Tilly treats the earlier part of the English seventeenth century as being more crucial for the process of British democratization. The "Glorious Revolution" plays a secondary role in his analysis.

Social justice and democratic stability

Wednesday, March 09, 2011

One thing I find interesting about the sustained demonstrations and protests in Madison, Wisconsin is the fact that people on the streets do not seem to be chiefly motivated by personal material interests. Rather, the passion and the sustainability of the protests against Governor Walker's plans seem to derive from an outrage felt by many people in Wisconsin and throughout the country, that the Governor's effort is really an attempt to reduce people's **rights** -- in this case, the right to come together as a group of workers to bargain together. This is a well established right in the private sector, protected by the National Labor Relations Act, and the rationale is substantially the same in the public sector.

So when the Governor attempts to eliminate the right to collective bargaining for public employees, he offends the sense of justice of many citizens in Wisconsin and elsewhere -- whether or not they are directly affected, whether or not they themselves are members of unions. Restricting established social rights is a very serious thing -- well beyond the specific calculation of interests that people might make. It's morally offensive in the way that state efforts to roll back voting rights would be offensive. And this moral offensiveness can be a powerful motivator of collective resistance.

So this seems to provide an intriguing clue about political mobilization more generally. To what extent is moral outrage, a perception of injustice, an important motivator of individual political engagement and activism?

When we look at the MENA rebellions, even from a great distance, it seems that concerns about social and political justice have as much prominence as more material motivations -- demands for food subsidies, demands for state-sponsored jobs programs, etc. Egyptians, Tunisians, and Libyans interviewed on the BBC talk more frequently

about the outrage of dictatorship and arbitrary state power than they do about material demands. And really, it's hard to see an economic interest in forcing a certain kind of food subsidy program being strong enough to create enough of a political motivation to lead a person to stand up against fighter jets and attack helicopters.

This is an insight that James Scott expressed a generation ago in The Moral Economy of the Peasant: Rebellion and Subsistence in Southeast Asia, and E. P. Thompson a generation before that in Customs in Common, in the theory of the ***moral economy***. In its essence, the theory holds that the fact of sustained violation of a person's moral expectations of the society around him or her is a decisive factor in collective mobilization in many historical circumstances. Later theorists of political activism have downplayed the idea of moral outrage, preferring more material motivations based on self-interest. But the current round of activism and protest around the globe seems to point back in the direction of these more normative motivations -- combined, of course, with material interests. So it is worth reexamining the idea that a society that badly offends the sense of justice of segments of its population is likely to stimulate resistance.

This basic and compelling idea has an important implication for sustainable social and political stability in a political regime. If citizens react collectively to sustained injustice, then a regime that wants to rule sustainably needs to respect the demands of justice. It is important for a social order to arrive at a rough-and-ready shared understanding about the rights and obligations that citizens have, and it is important for the state to conduct itself in ways that honor those expectations.

This sounds like a social contract theory, and it certainly has something in common with that normative theory. But its relevance here is more sociological. It is the basis of a prediction about what social and political circumstances will elicit sustained protest and resistance, and which kinds of arrangements are likely to be accepted indefinitely by the population. And it leads to a policy recommendation for any regime that wants to create a stable, ongoing polity: work hard to make sure that social arrangements and institutions treat citizens fairly, and don't gratuitously violate their deeply held convictions about their rights and about the general features of justice.

So what moral expectations do American citizens have about how society ought to work? Several things seem fairly clear. Americans care about equality of opportunity. We are deeply rankled by the idea that the good opportunities in society are somehow captured by an elite of any sort. Second is the idea of equal treatment of all citizens by the institutions of the state. Teenagers and persons of color rankle at being singled out for special attention by the police. Women rightly seethe at the persistence of institutions in the workplace that continue to treat them differently. Arab Americans rightly resent special scrutiny at airports. We don't accept status inequality easily -- especially in our own cases. And third, we are very sensitive about the inviolability of our rights -- our right to vote, right to go where we want, right to speak our minds and associate with whomever we want to.

What Americans don't yet seem to have is a specific moral sensitivity to extreme inequalities of income and wealth. The fact of the accelerating concentration of income at the top doesn't seem to produce the moral outrage in the US that perhaps it would in France or Germany. And maybe this comes from another element of our moral economy -- the idea that inequalities are all right as long as they are fairly earned. But more information about bonuses on Wall Street and the banking industry may begin to erode that tolerance.

It is intriguing to have widely separated examples of social mobilization going on right now. Surely there are sociologists and political scientists working right now to interview leaders and followers in Egypt, Madison, or Benghazi trying to sort out the motivations and social networks through which these movements arose and solidified. As a theoretically informed prediction, it seems likely that moral motivations like resentment of arbitrary power, violations of strongly held rights, and persistent status inequalities will be found to have played a role.

Social brains

Saturday, March 12, 2011

Here is a foundational question that is worth asking periodically in the philosophy of social science: what is the relationship between the evolutionary history of the human species and our current social and cultural behavior? The sociobiologists had one answer to the question: many of our current social behaviors are an expression, through the medium of the evolved central nervous system, of the compounding of a set of social instincts that were favored by natural selection. E. O. Wilson describes the intellectual agenda of sociobiology in these terms in In Search of Nature:

Much of the new effort falls within a discipline called sociobiology, which is defined as the systematic study of the biological basis of social behavior in every kind of organism, including man, and is being pieced together with contributions from biology, psychology, and anthropology. There is nothing new about analyzing social behavior, and even the word "sociobiology" has been around for years. What is new is the way facts and ideas are being extracted from their traditional matrix of psychology and ethology (the natural history of animal behavior) and reassembled in compliance with the principles of genetics and ecology. ... With genetic evolution always in mind, sociobiologists search for the ways in which the myriad forms of social organization adapt particular species to the special opportunities and dangers encountered in their environment. (76)

This view sometimes takes the form of a very direct connection from hardwired disposition to behavior. And sometimes it takes the form of a more mediated connection, from selection-favored capacity to complex mental state to behavior. The response we have to a smiling baby falls in the first category, and the "good Samaritan" impulse falls in the latter.

The view at the other end of the spectrum holds with the (relative) autonomy of human thought and action. Human beings are natural biological organisms, to be sure, and our mental capacities are embodied in neural circuitry that has a specific evolutionary history. But what evolution provided us was an all-purpose "reasoning, acting, interpreting" machine that is capable of creating and embodying all cultural and behavioral systems. Much as a computer can embody any algorithm (program), a human brain can incorporate any system of cultural rules. Much as a human child can acquire any human language, so too any human child is a voracious "culture-acquisition device," primed to absorb the cultural rules and meanings around him or her. And once absorbed, it is the cultural program rather than the evolutionary instincts that rule behavior.

These are the polar views of the relation between evolution and culture. I think philosophers and anthropologists may prefer the second story over the first -- philosophers because it creates space for an all-purpose reasoning engine and anthropologists because it gives maximum autonomy to the symbolic and normative workings of freely created culture systems. For both there is the idea that humanity has

kicked away its biological origins and limitations. And both are reflexively opposed to the apparent reductionism of the first position.

It seems to me that there is a sturdy intermediate position that incorporates some of both extremes and does a superior job of capturing the truth about human behavior and mind than either. Certainly human cognitive and behavioral capacities have an evolutionary history. But equally, it is plausible that there is a great deal of plasticity and multiple-realizability that has been built into these systems -- with the result that there is no one-to-one relationship between biological origins and current behavioral patterns. Culture is a powerful intervening structure.

Concerning the first point: the evolutionists are surely correct in believing that there is a great deal of brain structure that is responsive to the fundamental situations of human sociality -- family relations, cooperation and competition within small groups, and coordination. These elements of human daily life are too ever-present and too consequential not to have had implications for the evolution of the brain. Moreover, we know that there are highly evolved neural systems for non-social activities and challenges -- finger dexterity, for example, or simple problem solving. And, finally, we have the example of language, which involves both the kinds of latent linguistic structures that Chomsky postulates and the universality of application that results. So it would be surprising if evolution had not shaped the brain around these features of the human condition.

So acknowledging the likelihood of neural structures specific to social life seems pretty compelling. But what specifically? Almost certainly not determinate behavioral routines or dispositions. We surely don't have a gene for "promise-keeping". More credibly, we may have an abstract behavioral disposition for generalized reciprocity; and this may be invoked by a particular cultural system and set of value specifications that give a concrete moral motivation to keep one's commitments and promises.

This is where another important stylized fact about human society comes in: behavior differs widely and persistently across societies, and the best explanation of that fact is the causal efficacy of cultural and value systems that are reproduced within communities of human beings.

We know that those normative and symbolic systems are somehow embodied in persistent human neurophysiology, since all psychological states depend on the brain. But from the variety of human symbolic, cultural, and normative systems we also know that the neurophysiology that underlies culture necessarily possesses a high degree of plasticity. Along with the sociobiologists, we can look with favor on the notion that there may be important and contingent features that all human culture systems possess -- at some level of abstraction -- that are the result of constraints in the brain created by our evolutionary history. But along with the cultural autonomists, we can work on the basis of the hunch that the human brain embodies enough plasticity and capacity for learning to make the role of culture and social norms a credible source of behavioral variation.

(These topics have been considered in earlier posts on human nature (link) and moral psychology (link).)

Basic institutions and democratic equality

Monday, March 14, 2011

Modern societies seem to produce persistent social inequalities that are contradictory to many of the values we espouse when it comes to the idea of democratic equality. We continue to find wealth and income inequalities, inequalities of educational and health outcomes, inequalities of political power and influence, and these disparities seem to increase over time. Is this a residual defect in these specific societies, or is it rather a natural result of the logic of the institutions that define a market economy and an electoral democracy in the circumstances of extensive existing inequalities of wealth and power?

Consider these polar views:

- Modern market democracies work to narrow social and economic inequalities over time.
- The institutions of modern market democracies work to increase economic and political inequalities; the rich and powerful become more so through their privileged positions within existing institutions.

Which of these views is correct?

We would like to think that it is possible for a society to embody basic institutions that work to preserve and enhance the wellbeing of all members of society in a fair way. We want social institutions to be **beneficent** (producing good outcomes for everyone), and we want them to be **fair** (treating all individuals and groups with equal consideration; creating comparable opportunities for everyone).

There is a fundamental component of liberal optimism that holds that the institutions of a market-based democracy accomplish both goals. The economic institutions of the market create efficient allocations of resources across activities, permitting the highest level of average wellbeing. Free public education permits all persons to develop their talents. And the political institutions of electoral democracy permit all groups to express and defend their interests in the arena of government and law.

But social critics cast doubt on all parts of this story, based on the role played by social inequalities within each of these sets of institutions. The market embodies and reproduces a set of economic inequalities that result in grave inequalities of wellbeing for different groups. Economic and social inequalities influence the quality of education available to young people. And electoral democracy permits the grossly disproportionate influence of wealth holders relative to other groups in society. So instead of reducing inequalities among citizens, these basic institutions seem to amplify them.

On this line of thought, market and electoral institutions both create and reproduce social inequalities even when they are working correctly; inequality is built into them at a very basic level. The institutions are tilted in favor of privileged groups, and it is no surprise when corporations wield substantial influence in Washington and Paris and tax policies are enacted that favor the richest percent of American income earners. These aren't abnormal anomalies; they are instead precisely what we should expect when we analyze the basic institutions carefully.

What remedies are available to help move a modern society towards greater democratic equality for ***all*** of society? Several large institutional variations have been tried in the past century -- social democracy, small self-sufficient communities, local economies based on

cooperatives, etc. Jon Elster surveyed some of these alternatives in Alternatives to Capitalism over twenty years ago -- at a time when there was more openness to the idea of fundamental institutional reform. Tamas Bauer opens his essay, "The unclearing market," with these words:

The well-functioning market of textbooks brings about general satisfaction. Under market-clearing prices, goods and factors offered for sale are sold; the demand of each agent is satisfied by supply by others. Wage earners are paid wages that more or less correspond to their marginal contribution. Etc., etc. ... Life is, of course, much different. (71)

The social-democratic solution to these tendencies was developed in the early twentieth century. It was recognized that market institutions create unacceptable inequalities and leave some citizens in circumstances of insecurity, deprivation, and indignity; and it was argued that the institutions of the state needed to correct these tendencies through the establishment of a strong social safety net. The majority of a society would have the electoral strength to create and maintain strong protections of the interests of ordinary working people through a combination of positive economic rights. (Gosta Esping-Andersen reviews this history in The Three Worlds of Welfare Capitalism.)

The triumph of social and economic conservatism -- Thatcher, Reagan, and other conservative European leaders and their political parties -- took this theory of the role of the state off the public agenda, and the past thirty years have witnessed the systematic disassembly of the institutions of social democracy in most countries. And the consequences are predictable: more inequality, more deprivation, more severe disparities of life outcomes for different social groups.

What is truly surprising is that there has been so little continuing exploration of alternatives in the intervening two decades. Democratic theorists have explored alternative institutions in the category of deliberative democracy (link), but there hasn't been much visioning of alternative economic institutions for a modern society. We don't talk much anymore about "economic justice," and the case for social democracy has more or less disappeared from public debate. But surely it's time to reopen that public debate.

New ideas about structure and agency

Saturday, March 19, 2011

The social sciences have chosen up sides around a number of dichotomies -- quantitative versus qualitative research methods, macro versus micro, ethnographic versus causal. A dichotomy that spans many of the social sciences is the opposition of structure versus agency. "Structures" are said to be the objective complexes of social institutions within which people live and act. "Agents" are said to be human deliberators and choosers who navigate their life plans in an environment of constraints. If structure and agent are considered to be ontologically distinct levels, then we have a series of difficult questions to confront. For example: Which has causal priority? Are structures determinative of social outcomes, with agents merely playing their roles within these structures? Or are agents the drivers of social causation, and structures are merely secondary effects of individual-level actions and states of consciousness? Are features of structures reducible or explicable in terms of the actions and characteristics of individuals? Or, possibly, are the behavioral characteristics of individuals merely the consequence of the social structures they inhabit?

The contrast goes back to the founders, including Marx, Durkheim, and Weber. And authors such as Anthony Giddens, Maurice Godelier, and Pierre Bourdieu provided

second-generation refinements. But new ideas have come forward in the past decade that merit reconsideration.

Some of this new thinking is contained in Peter Martin and Alex Dennis, eds., Human Agents and Social Structures. Here is a thumbnail of the approach taken by this group of philosophers and sociologists.

[The current book's] aim is to be an intervention which seeks to make the case that structural, system, or holistic approaches to the understanding of social life and the explanation of human action are fundamentally misconceived -- as, equally, are efforts which rest on individualistic assumptions. In essence, our view is that human social life is conducted in and through patterns of collaborative interaction: sociologically, our interest is thus not in the subjectivity of individuals but in the ways in which intersubjectivity is achieved and maintained. (7)

This group of researchers addresses the contrast between agency and structure; but really their goal is to help to dissolve the distinction. They want to show that "structures" do not exist in any strong sense (including the senses associated with critical realism), and that a proper understanding of "agency" involves both subjective and objective features of the individual's actions, thoughts, and situation. Social relationships are densely intertwined with reasons, emotion, commitments, beliefs, and attitudes -- the aspects of consciousness that make up agency and action.

Here is a representative statement about social structures:

The collective concepts (such as family, state, organisation, class and so on) -- which have often been seen as fundamental to sociological analysis -- have often encouraged 'the temptation to reify collective aspects of human life' (Jenkins 2002a:4); that is, to treat them as if they were real entities, independent of the human beings who constiTute them. (7)

Their affirmative theory of agency -- now stripped of the notion that it is a polar opposite to structure -- has much in common with the traditions of micro-sociology -- Goffman, ethnomethodology, symbolic interactionism, and phenomenological sociology. The idea here is to emphasize the very concrete ways in which each of these traditions succeeds in identifying the agent, the social actor, as both subjective and objective. He/she is a subject, in the sense that the agent possesses thoughts, emotions, desires, aversions, allegiances, and the like, which in turn contribute to the actions and lives they live. But the agent is objective, in the sense that he/she is embedded and developed within a concrete set of social relationships and institutions.

Thus each of these approaches develops in its own way the idea that human social life is carried out through processes of interaction among real people in specific situations, and each seeks to avoid the reification of collective concepts -- there are no such 'things' as social 'structures,' 'classes', or indeed 'societies', yet terms such as these are indispensable, not only for sociologists but for the purposes of everyday communication. (14)

Martin and Dennis quote Anthony King with approval: "human agency is a collective product, germinated with others and dependent upon the social networks in which we al exist. Human agency is better understood as the collective product of social relations ... than as an autonomous individual power" 14).

So is there space within this view of sociology for investigation of "macro" features of society? They argue that there is, but not as an autonomous domain:

There is nothing in the perspective developed here that would prevent the investigation of social phenomena conventionally described in terms of 'macro' structures. But what we are suggesting is that, for example, the 'class structure' must be conceived as the outcome of stratifying processes and practices, many of which -- like the grading of students' work or the awarding of educational credentials -- may appear to be routine and mundane. This interactionist sociologists have investigated the processes through which social class differences in educational attainment are produced. (15)

One reason I'm intrigued by the approaches taken to this aspect of social ontology by the contributors to *Human Agents and Social Structures* is that these approaches seem to converge with the ideas about "***methodological localism***" that I've been drawn to as a bottom-level description of social ontology (link). On this approach, neither "structure" nor "agent" can be specified in its own terms alone; rather, we need to base our social concepts on the socially situated and socially constituted individual, located within a set of locally manifest social relations (link, link). So we cannot separate agency and social location (structure); rather, the fundamental unit of social activity involves both aspects.

Andreas Glaeser on agency

Sunday, March 20, 2011

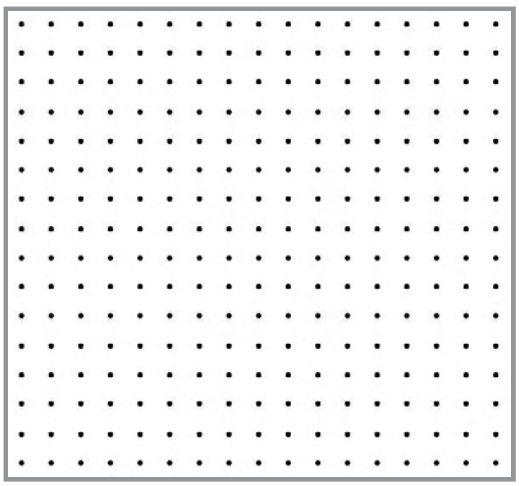
Andreas Glaeser is another gifted contemporary sociologist who takes a different approach to providing a sociological analysis of agency. Glaeser's most recent scholarship is a careful and detailed study of the end of communism in the German Democratic Republic. This research appears in a book that is just now being published, Political Epistemics: The Secret Police, the Opposition, and the End of East German Socialism. (Glaeser provides several chapters and related materials here on his research page at the University of Chicago.) The work is concrete, historically situated, and close to the ground in the sense that it pays close attention to the ideas, emotions, and mental frameworks of the various actors as expressed in Glaeser's interviews with them. But along the way he develops a powerful framework for understanding some of the fundamental concepts and theoretical frameworks that are employed by sociologists when they attempt to understand individual and collective behavior. Here is the publisher's description of the book:

What does the durability of political institutions have to do with how actors form knowledge about them? Andreas Glaeser investigates this question in the context of a fascinating historical case: socialist East Germany's unexpected self-dissolution in 1989. His analysis builds on extensive in-depth interviews with former secret police officers and the dissidents they tried to control as well as research into the documents both groups produced. In particular, Glaeser analyzes how these two opposing factions' understanding of the socialist project came to change in response to countless everyday experiences. These investigations culminate in answers to two questions: why did the officers not defend socialism by force? And how was the formation of dissident understandings possible in a state that monopolized mass communication and group formation? He also explores why the Stasi, although always well informed about dissident activities, never developed a realistic understanding of the phenomenon of dissidence.

Out of this ambitious study, Glaeser extracts two distinct lines of thought. On the one hand he offers an epistemic account of socialism's failure that differs markedly from existing explanations. On the other hand he develops a theory—a sociology of understanding—that shows us how knowledge can appear validated while it is at the

same time completely misleading.
And here is the abstract that Glaeser provides for the first chapter at the link above:

ABSTRACT: On the basis of ethnographic data gathered during 11 months of field study in two east German police precincts, four processes of identity construction are analysed which link selves to space and thereby to one of the main aspects of material culture. These processes are (1) the tropic (as opposed to literal) reading of space, producing a complex web of identifications through a play of metonymy, synecdoche, metaphor, ellipsis and hyperbole; (2) the writing of space as a material inscription of self in small spatial contexts such as neighbourhoods, cities and regions; (3) the placement of self into larger spatial wholes such as neighbourhoods, cities and regions; (4) the anchoring of life-stories and narrated life experiences in significant time-space combinations or chronotopes. The paper argues that identities are not only constructed in interaction with other actors but also in "dialogue" with material culture and spatial practices. It argues also that the spatial dimension of identity brings to the fore the fact that identities are not only knowable, but that they can be experienced. Through space, identities become sensualised.
The topic of "agency" comes out of this research very directly and immediately: why did the various actors choose to live and act as they did? Why were Stasi agents so complex in their behavior -- neither passive puppets of the regime nor hidden activists within the state? What were the "epistemics" on the basis of which they and other social actors acted -- the assumptions about themselves and the world that framed their choices? These questions lead Glaeser to attempt to arrive at a better and more satisfying account of the forms of consciousness, locatedness, and feeling that create the individual's field of choice.



Here is how Glaeser describes his current thoughts about agency and the questions that will guide his next program of research:

I have begun researching and writing a third book with the working title *Agency, Institutions and Understanding: A Sociology of Liberation*. With it I aim to offer a fundamental critique of the schizoid contemporary social imaginary that flip-flops between ontological individualism categorically asserting persons' power to act on the one hand and structural determinism which pays no heed to individual actors in whatever form or shape on the other. Instead I aim to show how agency does not only vary historically and situationally but how it can be cultivated by individuals and collectivities from within a realistic understanding of the operation of institutional arrangements. Thus I aim to rejuvenate and reposition an older normative understanding of the task of the social sciences as a reflexive enterprise in the service of emancipatory politics.
Against the "schizoid" opposition of pure subjectivity of the individual actor and pure objectivity of social structures, Glaeser prefers a stance that allows him to weave together the social situatedness of the actor -- in very concrete spatial and social-relationship terms -- with the thoughts, motives, and impulses that lead them to act as they do. Here is a nicely concrete description of how he proceeds to investigate these states of social consciousness:
The social arenas I have chosen to study identity formation through acts of identification are two police precincts in what used to be East Germany. The first is Precinct 66 (southern Kopenick) in the southeastern corner of Berlin, the second is Potsdam in the state of Brandenburg just outside Berlin . The ethnographic material on which this paper is based was collected during 11 months of ethnographic fieldwork, consisting chiefly in participant observation of all sorts of police practices (patrol car shifts, neighbourhood beat patrols, administrative work, social events , etc.). Another important source of data

was open-ended tape-recorded biographical interviews. The rationale for choosing the Berlin police is that identity is a hotly contested issue between former West Berlin and former East Berlin police officers, who have had to cooperate after the unification of Germany into one unified All-Berlin police corps. The second fieldsite was primarily chosen to establish a backdrop for Berlin, which is in many ways a special case. (link, 8) Like the arguments of Martin and Dennis considered in an earlier post, Glaeser is led to a position that negates the traditional strong distinction between agent and structure. Like them, his work brings him into close relationship to the micro-sociologies of ethnomethodology, phenomenological sociology, and interactionist sociology. Unlike rationalist approaches that exclusively emphasize discursive states of mind -- reasons, beliefs, goals -- Glaeser positions his actors in terms of their discursive, emotional, and kinesthetic representations of their situation.Glaeser refers to his approach as hermeneutic. The work is ethnographic in detail; but the goal is plainly sociological. He wants to provide a detailed analysis of the modes of understanding that constitute the position from which concrete individuals construct their activities and choices. And he wants to understand the complex social world that was East Germany at the end of socialism.

Connecting the dots

Saturday, March 26, 2011

There isn't very much transparency about the deep structure of almost any complex modern society. For most people their primary impressions of the society's functioning comes from the mass media and their own personal experiences. We each see the limited bits to which we are fairly directly exposed through our ordinary lives -- the newsroom if we happen to be a beat reporter, the university if we are professors, the play-and-learn center if we are in the business of preschool education. We gain a pretty good idea of how those networks of institutions and organizations work. But it's very difficult to gain a birds-eye picture of the social system as a whole.

The most basic goal of Marx's economic programme was to demystify the workings of the political economy of capitalism. He wanted to sweep aside the appearances that capitalism presents and to lay bare the underlying social relations of inequality and exploitation that really constituted the causal core of the system. (This is the point of his theory of the fetishism of commodities; link.) And he believed that active systems of

ideology and false consciousness conspired to conceal these workings from ordinary participants. In particular, he wanted to demonstrate the process through which wealth is created within capitalism, and the relations of inequality through which its benefits are distributed. It is a class-based analysis, and Marx proposes to the proletariat (and the rest of us) that we look for the class mechanisms of our ordinary economic experiences.

What is unsatisfying about Marx's theory in the current context is that in the end it isn't really very much of an empirical demonstration. It is an abstract model of how the theorist thinks capitalism works, rather than a detailed empirical exposure based on rigorous and diverse data that demonstrates the flows that he postulates. It offers a schema for connecting the dots of our ordinary experience, but it doesn't actually carry out the effort.

Other researchers have done so, of course; researchers who demonstrate the widening inequalities of income and wealth that market democracies contain, the consequences of these inequalities for people at both ends of the divide, the often degrading conditions of work that the majority of the working population experience, and so forth. So on the dimension of wealth, income, and privilege, it isn't too difficult to gather the information we need to better understand our current economic realities based on information that is readily available; but most Americans don't seem to bother to do so. The ease with which the right has succeeded in setting the terms of popular ideas about organized labor, racial inequalities, and immigration bears that out. Lies and slogans replace honest factual argument.

And what about the other large determinant of outcomes in modern society, the workings of political power? Here too there are founding theorists who sought to lay bare the "real" workings of power in a market democracy. Foucault is one; Domhoff and Mills sought to do so a generation earlier. The goals of C. Wright Mills (The Power Elite; link) and G. William Domhoff (Who Rules America? Challenges to Corporate and Class Dominance; link) were similar to Marx's, but in the sphere of political power within a democracy. They wanted to demonstrate how the language of pluralism and representative democracy works to conceal a system of power and influence that was anything but egalitarian. They wanted to shred the ideologies and obscurantist narratives that conceal these political realities.

But, like Marx to some extent, their writings too remained schematic. They offered a framework for thinking about political power that was radically different from that of the pluralists. But they didn't really provide a detailed empirical exposure of the workings of this system in real time. So here again, we'd like to have an organized way of connecting the dots within the contemporary world. How do corporations use lobbying firms and campaign PACs to shape policy and legislation to their liking? How is it going on today? And, as is the case of the domain of economic inequalities, there are plenty of sources today shedding light on aspects of these processes. But these political realities seem if anything, even more difficult to perceive.

The blog Naked Capitalism approximates the kind of dot-connecting that I'm describing, with specific application to the financial industry. Here a group of very expert observers are taking the trouble to track the complexities and the hidden interests involved in the financial industry, and to try to make sense of what they find in an honest way. I. F. Stone was a one-man dot-connector in the 1960s when it came to the Indochina War (Best of I. F. Stone). The opening chapter of Frances Fox Piven's Challenging Authority: How Ordinary People Change America does a good job of sketching out the influence systems that set the planets in motion in American democracy. And Bob Herbert's last column for

the New York Times does it as well (link). We need exactly these kinds of effort in other areas too -- defense contracting, influence peddling, the pharmaceutical industry, news media, ... We need help connecting the dots of how our society works, who pulls the strings and who benefits.

Blogging, critical journalism, and crusading thinkers like I. F. Stone and Frances Fox Piven can help a lot. And, by the way, it must be done in a way that is committed to high standards of empirical fidelity; it needs to inspire the kind of trust that Stone was able to do fifty years ago. And maybe, with the makings of a more truthful shared understanding of how our society actually works, we will succeed in creating a politics that transforms it.

Why peasant activism?

Sunday, March 27, 2011

I have long been interested in peasant struggles as an historical phenomenon -- for example, the causes and outcomes of the peasant rebellions in China in the eighteenth and nineteenth centuries (Understanding Peasant China: Case Studies in the Philosophy of Social Science). But it is also true that peasant movements are still visible in contemporary politics in a number of countries. For example, mobilization by peasants and landless workers in West Bengal against the state's proposed development of a Tata factory led to the project's relocation to Gujarat (link). In some instances and issues, peasants and other disadvantaged people come together as a mass organization to press their interests and concerns; in other apparently similar instances they do not. How are we to understand this variation?

People are generally careful about their active political investments, especially when their choices can lead to serious personal consequences. Are there good reasons for poor people to form and support organizations that seek strategies for expressing their needs and interests? Should they consider supporting demonstrations, strikes, and protests? What is the likelihood that social mobilization of the poor majorities in India, Egypt, or Brazil might lead to improvement in their daily lives?

A first point is fairly obvious. As a low-income society undertakes policies and strategies for growth, there are choices to be made. These choices have differential effects on different social groups. And poor people and peasants are often at a severe disadvantage in competing over the terms of these choices within the formal institutions of government. China's decision to create the Three Gorges Yangtze River dam system created many winners; but it also created many millions of low-income losers whose homes and livelihoods were destroyed in the process (link). Largescale social and

economic change is a time when the stakes are exceptionally high, and having a voice is crucial.

A second point has more to do with the "normal" workings of power in a developing state. Poor people's interests are almost always overlooked or undervalued by official power-holders in developing societies -- a point made thirty years ago by Michael Lipton in Why Poor People Stay Poor: Urban Bias in World Development (1977). And this is often true even within parties that are ostensibly devoted to the poor, like the Congress Party in India. Corruption by leaders and powerful organizations is endemic, and landlords, business owners, and the military almost always wield disproportionate influence in the corridors of power. So if nothing is done to disturb this "tilt" in the political system, then the outcomes will be unfavorable to poor people.

Third, it is plain that the organized efforts of under-class people can be powerful. Women's organizations advocating for environmental protection or property rights for women can push state and national authorities towards policies they would not otherwise have chosen. (Bina Agarwal has documented these processes in India; for example, here.) Organizations of landless agricultural workers can pressure the state into adopting reforms and programs that provide some relief for their poverty. Mass mobilization is almost the only way to assert the material interests of the people.

Debal Singha Roy considers these issues in detail with regard to rural India in Peasant Movements in Post-Colonial India: Dynamics of Mobilization and Identity. Here is how Roy puts the point:

Social movements have always been an inseparable part of social progression, and through organized protests and resistance against domination and injustice they pave the way for new thoughts and actions that rejuvenate the process of change and transformation in society. They bring forth for public scrutiny the hard and hidden realities of social dynamics. (8)

So, according to Roy, popular movements -- e.g. peasants' movements -- can lead to measurable change in favor of the dispossessed. They do so by making injustice visible to the broader society; pressing effectively for social changes that improve the condition of one's group; giving voice to segments of society who are almost always invisible to the middle classes; and asserting one's own agency as a fundamental aspect of being human. These are all reasons for thinking that social activism and social movements are important.

What about the rest of us? Is activism important in a modern market democracy? Frances Fox Piven argues that these points do indeed apply in modern market democracies as well. In her recent book, Challenging Authority: How Ordinary People Change America, she lays out this case through a new analysis of American policy history.

This book argues that ordinary people exercise power in American politics mainly at those extraordinary moments when they rise up in anger and hope, defy the rules that ordinarily govern their daily lives, and, by doing so, disrupt the workings of the institutions in which they are enmeshed. (kl 23)

Piven's basic view is that the structural inequalities of property and power in market democracies mean that electoral processes are usually tilted against the interests and concerns of poor and middling people. Electoral competitions are generally won by enough candidates reflecting the interests and world views of the powerful, that the perspectives of the poor and disadvantaged in American society rarely prevail in the

statehouse or the Congress. The exceptions occur, she believes, when poor and disadvantaged people find ways of expressing their interests through avenues that threaten to disrupt "business as usual" -- boycotts, strikes, demonstrations, and other activities outside of formal politics. Rights of speech and association underlie many of these strategies, and they express a different aspect of democracy. And these in turn depend upon a combination of mobilization and a moment in time when such collective actions have the potential of creating significant disruption -- when French farmers block roads to protest milk prices, for example.

So it seems that democracy almost requires a dynamic tension between formal representative politics and informal, nonviolent popular politics. What goes on in the state house needs what goes on in the streets of Madison if outcomes fair to ordinary working people are likely to occur.

Pincus re-presented

Wednesday, March 30, 2011

Several earlier posts have discussed aspects of Steve Pincus's 1688: The First Modern Revolution (link, link). The book provides a major rethinking of the events and significance of England's Glorious Revolution, and it has already made a deep impression within English studies (link). Pincus tells a large, complicated story, spread out over a period of several decades and including important actions, persons, and events in England, Scotland, Ireland, France, and the Netherlands.

Much of the interest of his account is how fundamentally it differs from the received narrative, its novel use of familiar and new resources, and the author's strong ability to link to current work in some areas of the historical social sciences. But here I want to raise a different sort of question: how could we propose to make this story more vivid and comprehensible for the reader? The book is organized as a fairly traditional academic argument, with chapters on Catholic modernity, pre-Revolution policy change, and aspects of the Revolution itself. Pincus marshalls his evidence to tell a significantly different story from the received one. And as an academic work, it is highly readable and logical. But it is from beginning to end a complex canvas, and it is difficult for a non-specialist reader to keep it all in mind. How might an author -- or a producer -- more fully engage the reader's historical imagination in these complex events? How might the material be presented in a way that gives the reader a more comprehensive apprehension of this history of the English Revolution?

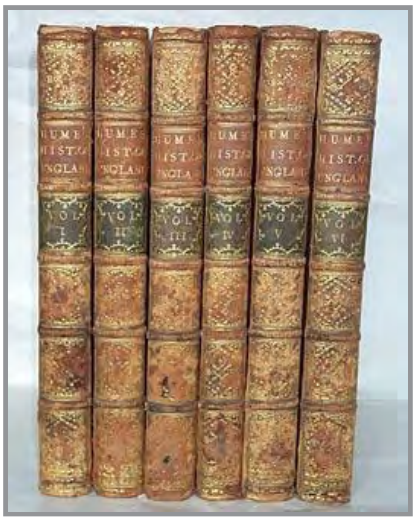
One possibility is a very well produced and very long film. A dramatization could serve to give the viewer a more vivid sense of acquaintance with the central actors -- James, Monmouth, William. Dramatic reconstruction and enactment certainly gives the viewer a more visceral grasp of the historical personnages. But another value of dramatization could be to give the viewer a better grasp of the mass politics of the events -- skirmishes with brigades, vandalism against Catholic churches and property, and a few major battles in Ireland -- and perhaps even a sense of the motives and passions that moved people. Viewers of *Battleship Potemkin* (link) certainly come away with a more intense set of representations of the Russian revolution of 1905 and some of the personalities than they do from reading Trotsky's History of the Russian Revolution.

But the film described here would be very long -- even Sergei Eisenstein's canvas would fall short. (I seem to recall reading a long time ago that Eisenstein once proposed to produce a seven-hour film based on Marx's *Capital*.) And the academic historian has specific cognitive goals -- to present a narrative of the period, to refute common assumptions ("no mass underclass violence in the Glorious Revolution"), and to present some compelling evidence for the interpretation. So a film probably wouldn't be a satisfactory platform for Pincus's academic goals. He wants to present new knowledge, not an abbreviated and highly selective sketch.

Another possibility that appeals to me is a mutimedia production that is integrated with the existing book. A core element might be an interactive map that the reader can manipulate -- "what was happening in Essex at this time?" -- and that is keyed to the text itself so the reader always has a sense of the geography of the events. This hypertext "rich" document might also include significantly more graphics -- reproduction of key pieces of archival evidence, contemporary paintings and engravings of events, graphs of important population and trade statistics, a snippet of Youtube video in which another major historian of the period offers an alternative reading. (Here is Simon Schama on Anne Boleyn (link)).

Here the idea is that the historian needs some new tools of representation for better conveying to the reader a grasp of the complex, multidimensional argument and narrative. This suggests the value for academic historians of taking very seriously the potential of "rich" media as an integrated platform for conveying arguments and knowledge. And here I'm not thinking simply of pedagogy -- how to get these complexities across to the lay reader -- but new ways of presenting the historian's central ideas and arguments. Perhaps this kind of rich document could actually be a better way of making the case based on narrative, multimedia components, interactive maps, graphics, etc.

One difficulty with this notion is the fact that historians are trained as narrative writers. They have learned to organize their thoughts into arguments, narratives, and chapters, and they expect their readers to do the work of putting it together into an integrated historical presentation. The skills possessed by an Eisenstein or a David Simon, executive producer of *The Wire*, are substantially different -- more graphical, more attuned to the audience (viewer/reader), and more able to encapsulate their story into a handful of scenes of drama that permit the viewer to connect the dots and arrive at an interpretation of the full story. These are skills that are entirely foreign to PhD training in history.



I suspect that not many academic historians would be especially receptive to these ideas, and sometimes for good reasons. (Simon Schama may be an exception; his efforts with the BBC to put together a serious multi-episode history of Britain indicates a willingness

to experiment with new forms of presentation of history; link.) A central part of the resistance from traditional historians might reasonably reflect their core views of what a "history" of something needs to accomplish. The academic historian's primary goals are cognitive and epistemic: offering interpretations, drawing inferences, and providing evidence for their views. Part of the task of a narrative is to distill the complex whole into a comprehensible set of events. Another part is to categorize actions and occurrences. It is to provide a more abstract analysis of the events. And sequential narratives may be thought to be a more-or-less ideal form for this kind of logical, cumulative argument.

All this said, it does seem clear that there are tools for the presentation of knowledge that may prove more helpful than the printed page for synthesizing a large complex story, and it would be very interesting to see what happens when a few innovative academic historians begin thinking along these lines.

Hume as historian

Friday, April 01, 2011

David Hume is probably the greatest British philosopher of his century or the next one. He set the framework for empiricist theories of knowledge, causation, and induction, as well as providing trenchant writings about religion, psychology, and the self. And he appears to have been an appealing personality as well, with the courage of his convictions when it came to his atheism and his stocism in the face of impending death.

So he was a truly brilliant and original philosopher. But he was best known during his lifetime for his million-word history of England, The History of England, Volume I (1754-62), in six long volumes. The work covers Britain from the Saxon kings through the Glorious Revolution of 1688. As such, it intersects to some extent with a topic discussed several times before, Steve Pincus's recent 1688: The First Modern Revolution. So it is worth taking a quick look at a bit of the history, in order to get an idea of how Hume thought about historical knowledge and how to present it.

The final section of volume I treats the reign of Charles II. (I'm using the Kindle edition; A Short History of England.) This is a key period in Britain's modern history, following the Civil War, the execution of Charles I, and the brief rule of Cromwell. And, of course, it

leads up to the revolution that led to the flight of James II and succession by William and Mary. So how did Hume synthesize this period of history? What factors did he select for inclusion? How did he structure his narrative? And to what extent did he offer large interpretations or explanatory judgments about the period?

The book went through some 50 editions during the century following Hume's death; it was a stunning success with the British reading public. That said, it reads as a pretty pedestrian piece of historical writing today. The prose is inviting and clear; but there is very little to stimulate the reader's intellect.

Content. Hume opens the volume with extensive description of the personality and character of Charles II himself. The focus on the personalities of the period takes a high proportion of the text. Second, he describes the diplomacy and military affairs of the monarch's court in some detail. (He shows a particular interest in naval battles.) He introduces some of the important turning-points of the period and provides some details about their how's and why's. Third, he goes into some detail about the politics of religion and the jockeying of Catholics and Protestants for power and freedom of political and religious activity. Fourth, he gives substantial attention to the politics and actions of Parliament and the King's relations with Parliament.

What is almost wholly lacking is any detail or attention to the social or economic context of the period. There is no mention of common people, villages, agriculture, hunger, or popular religious beliefs. The resolutions of the new King's finances are discussed, but there is no sustained discussion of the fiscal system or the reforms that were enacted. The "modernizing" efforts of this regime that are so important in the account Pincus offers are invisible in this history.

The one exception to this observation comes in the final dozen pages of volume I, following without break his account of the ascension of William and Mary. There he takes a very different approach. He provides a brief summary of the fiscal realities of the Crown, military and naval affairs, England's state of commerce and manufacture, England's colonies, the advancement of science and technology, and the state of letters and literature. This chapter is wholly exceptional; it is a synthetic summary rather than a linear narrative, it is topically organized rather than chronological, and it looks much more like a multi-threaded history than the succession of actions, wars, plots, and trials that precedes.

Structure. The history takes the form of an entirely linear narrative, down to section breaks for successive years (1660, 1661, 1662, ...). Hume structures his task as one of organizing the facts of each year into a story that incorporates the main details of person, event, and political action. There are no synthetic chapters that attempt to rise to a higher level of historical abstraction. The narrative proceeds from court to parliament to war to plots to trials and executions, with virtually no commentary on the sequence.

Explanations. Hume's explanations in this part of the history, at least, are essentially biographical and interpretive. He explains outcomes as the result of the goals and intentions of the elite actors. But he does not offer anything like the large interpretive schemes offered by his contemporary, Edward Gibbon, in his history of the Roman Empire. Hume does not find systemic causes of change during this dynamic period of British history, and he does not attempt to offer a big-picture schema for the period. The character of the king is relevant, as are the motives and loyalties of dozens of other characters. But there is nothing in the way of reference to historical forces or trends.

So Hume's history is NOT a number of things. It is not a precursor to "history from below"; it is not a history of state or social institutions; it is not an interpretive history with a "big-picture" theme of interpretation. And really, it is not particularly interesting from a historiographic point of view.

This assessment leaves us with something of a puzzle to unravel: how is it that such a brilliant and penetrating philosopher would have devoted so much of his life to such a plodding historical book? Why did he not perceive the need for inclusion of some of the factors mentioned here? And why did he so assiduously avoid anything remotely resembling an explanatory hypothesis about the sources and dynamics of change during the period? Is it simply that the parameters of historical writing in the first half of the eighteenth century were so limited that even a great and original mind could not transcend them?

And the mystery deepens when we arrive at the synthetic section mentioned above. This section demonstrates that Hume was fully aware of these other topics, and had interesting views about them. So he could have written a history that incorporates social, economic, and institutional context. He therefore must have made a conscious decision not to do so. Why not?

I suppose there is a case to be made for the idea that Hume's philosophical beliefs themselves were partially responsible for the limitations of his history. Take causal explanation, for example. Given Hume's skepticism about "real" causes, and given the absence in history of strong regularities, perhaps it is unsurprising that Hume refrained from offering a causal hypothesis about the twists and turns of the period. And given his insistence on the primacy of "facts" that can be observed and documented, perhaps this comes close to implying the necessity of a historical narrative that simply chronicles the facts. If it can't be observed, then it is pure speculation; and it has no place in empirical historical writing. On this line of thought, it is Hume's fundamental empiricism that leads to the fundamental flatness of his historical writing.

This doesn't provide a complete explanation -- it doesn't explain Hume's deliberate exclusion of social questions or ordinary people in history, for example. But maybe it suffices to explain the flatness and linearity of the narrative and the absence of explanatory themes.

(It is interesting to note that Hume sometimes uses the language of cause in a very untroubled way -- for example, in this passage about the Great London Fire:

The causes of this calamity were evident. The narrow streets of London, the houses built entirely of wood, the dry season, and a violent east wind which blew; these were so many concurring circumstances, which rendered it easy to assign the reason of the destruction that ensued. (kl 867)
This is remarkably realist language about causation for the great skeptic on this subject.)

Studying the socially constituted agent

Monday, April 04, 2011

We think we know quite a bit about being an "agent". It is to be an intervener in the world: a being capable of changing things around him or her through physical action; a subjectivity (consciousness, feelings, thoughts, desires); a user of language for thought and for communication. We also think we are well prepared when it comes to recognizing the diversity of the subjectivities on which agents act and live. We are familiar with important cultural differences; we know that people have different sets of values and commitments; we know that people from different backgrounds see and experience the world differently. Perhaps even, like Benjamin Whorf, we may think that different language systems and grammars give their users fundamentally different categories in term of which to analyze the world (link).

So we seem to know a lot. But in fact, this is the part of the social sciences and humanities that is the least developed and the least adequate to the complexity of the facts. What we lack most basically is a useable meta-framework in the context of which to characterize and analyze -- and to study -- the workings of these features of agency. We're not even clear about what to call these personally realized features of subjectivity and vision -- Mentalities? Conceptual frameworks? Value systems? Worldviews? Depth grammars of social cognition?

One reason for this under-development is the intangibility of these sorts of characteristics. They are features of the subjectivity of the individual; they are unobservable; they are difficult or impossible for the agent herself to articulate. So it is easier for the social sciences to proceed on the basis of highly schematic "models" of the agent -- e.g. the rational-choice model of preferences and beliefs, or the traditionalist's model of roles and norms. But these models aren't adequate. Worse, they lead us to paraphrase features of novel agency into the stylized forms of the model. They erase the differences.

The topic is important, because ultimately, all social phenomena are the result of agents acting for their own reasons, and we need to understand the varieties of their thought processes. So the social sciences need detailed understandings of the varieties of human subjectivity -- agency. We need to understand in concrete detail what it means to say that the subject is socially constructed, and through what concrete social mechanisms this construction takes place. We need to know how differences in culture produce systemically different world views or mental frameworks. And we need to be able to investigate these differences in detail and rigorously.

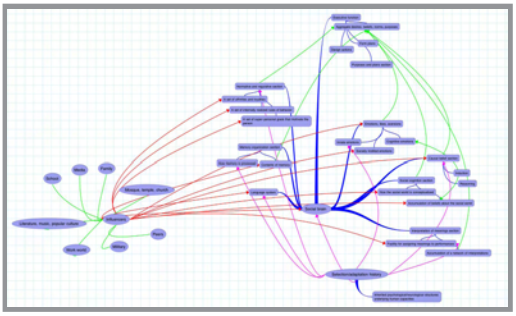
A few concrete examples are helpful:

- How did French and Chinese legal systems think differently about "property"? How did these differences influence differences in judgment between French and Chinese officials?
- How does the idea of an after-life influence worldview, action, and behavior for believing Christians and Muslims?
- In what ways do Balinese people have a non-individualistic conception of the individual person?
- Is it true that Japanese workers have a deeper affinity with team and group than American workers?
- Was the "Greatest Generation" really different in significant ways having to do with

values and social perceptions than the next generation?

There are research vehicles through which to conduct this kind of research -- ethnography, careful study of texts, literary analysis, interviews in depth about political perceptions, the methods of phenomenological sociology, and perhaps the tools of cognitive and personality psychologists. Particularly interesting is Robert Darnton's reconstruction of the specific and surprising mentality of the 18th-century printer's apprentices in the The Great Cat Massacre: And Other Episodes in French Cultural History. And his interpretation is based on rigorous analysis of varied documents and practices (link). It is good social science and good discovery of subjectivity.

But before we are likely to make a lot of progress on framing a research agenda around "mentality", we need a better and more commonly understood vision of the goal of the study. And I would say this means trying to formulate a meta-theory of subjectivity and agency, into which our findings about value systems, cognitive frameworks, moral ideas, and the like can be fitted.



There are some meta-frameworks that might be considered at the outset. The idea of a scientific paradigm or research programme is one; here philosophers of science have tried to get concrete about the specific presuppositions and concepts in terms of which the community of physicists understand theory and the laboratory bench. The idea of a cultural tradition is likewise a fairly concrete idea, where anthropologists try to use the statements, speeches, and artifacts of a community to help decode the subjectivity that underlies.

This topic is important in many areas of the social sciences, but none more so than in comparative research across civilizations. When we consider economic and political institutions in Europe and Asia, as Bin Wong does in China Transformed: Historical Change and the Limits of European Experience, the fact of massive differences in starting points, presuppositions, fixed values, and moral perceptions of the populations involved loom enormous. But without more refined tools for analyzing these differences, it is difficult to treat them in a satisfying way.

This seems like an ideal place for an interdisciplinary research group of social scientists, psychologists, philosophers, and humanists to begin charting new ground.

Picturing social consciousness

Wednesday, April 06, 2011

Here is a schematic effort at capturing some of the main factors involved in the socially constituted agent. There are the "influencers" that impact the development of the person

and his/her "social brain" -- that is, the neurophysiological infrastructure we have evolved through our evolutionary history for gaining knowledge, representing the world, interacting with other people, etc. I've singled out media, family, school, religion, peers, popular culture, work, and the military as primary social and cultural influencers. And the red arrows indicate the schematic notion that these institutions and structured experiences affect the development of multiple aspects of the social agent's mental system. The idea is that each of these institutions creates an environment and a set of experiences that lead the young person into a specific "grammar" of interpretation and action.

Second, there is a marker in the diagram for the evolutionary history of the human "social brain" -- the neurophysiological systems we have evolved to support cognition, language, dexterity, cooperation, ... This part of the diagram represents a whole set of fields of interdisciplinary research, from neurophysiology to animal ethology to the study of morality embodied in human practices.

Third, there are the "sections" of the fully developed actor -- memory, emotion, meaning, purposes, norms, affinities, and social and causal beliefs. And there is an "executive" department that aggregates these action-relevant inputs into actions and plans. Each of these departments is itself the subject of development and influence by the "influencers"; and many interact with each other. In particular, memories and emotions may mutually interact. Adherence to a cause may be amplified by a set of memories and a set of emotions. And so forth.

I don't put this forward as a serious effort in the "science of the mind", but rather as a way of providing an inventory of the various aspects of consciousness and agency that we recognize as going into the social constitution of the actor; and a sketch of some of the various ways in which these aspects are influenced by social experience and culture.

To me the interesting part of the diagram is that it suggests many avenues of empirical and hermeneutic investigation. For example, how exactly are the memory system and its contents influenced by social experience? How does this system in turn influence social perception, choice, and action? Or the emotions: how are the emotions and passions shaped by social and cultural experience? And how do they in turn influence action? It would seem that there is ample room along each of the "arrows" of influence provided here for extensive empirical and interpretive investigation.

Structures and structuration

Friday, April 08, 2011

Several recent posts have focused on new thinking about how to characterize "agency". Much of that thinking is aimed at dissolving the distinction between agency and structure. So what remains to be said about "structure"? Has the structure side of the debate developed much in the past decade or so?

One of the important exponents of a structure-centered approach to social theory is Anthony Giddens. His 1979 book, Central Problems in Social Theory: Action, Structure, and Contradiction in Social Analysis, is one place where his views on structure are expressed. He separates himself from earlier versions of "structuralism," including Saussure and Levi-Strauss; but he advocates for the reality of social structures and the methodological appropriateness of attempting to arrive at empirically based theories of

social structures in sociology and other areas of the social sciences. He emphasizes the fact of process rather than static organization in his theory of structures; to capture the "verbiness" of a process view, he prefers the language of "structuration" rather than "structuralism." This distinction having to do with the location of things in time -- a static snapshot versus a continuous process -- extends to his treatment of action as well:

'Action' or agency, as I use it, thus does not refer to a series of discrete acts combined together, but to a continuous flow of conduct. We may define action... as involving a 'stream of actual or contemplated causal interventions of corporeal beings in the ongoing process of events-in-the-world'. (55)

A recent and unapologetic treatment of the reality of social structures is presented in Dave Elder-Vass's The Causal Power of Social Structures (2010). Elder-Vass accepts the point that agency and structure are inseparable; neither functions as a solely sufficient cause of social outcomes. But he argues strongly for the idea that social structures have causal powers that are not reducible to facts about individuals. He places his analysis generally within the tradition of critical realism (Bhaskar, A Realist Theory of Science). And he relies heavily on the theory of supervenience to solve the riddle of how structures can be composed of individual-level activity and yet possess autonomous causal powers (Kim, Mind in a Physical World: An Essay on the Mind-Body Problem and Mental Causation).

Elder-Vass rejects the ontology of methodological individualism, which he regards as a species of reductionism: social properties need to be reducible to features of individuals. And yet he fully and unambiguously embraces the obvious fact that social structures must be **composed** of individuals in relations to each other. His way out of this apparent contradiction is to argue that social structures possess **emergent** causal powers: causal characteristics that pertain to the whole but not to the parts or their ensembles. Here is how he characterizes emergence:

A thing ... can have properties or capabilities that are not possessed by its parts. Such properties are called emergent properties. (4)

And later:

An emergent property is one that is not possessed by any of the parts individually and that would not be possessed by the full set of parts in the absence of a structuring set of relations between them. (17)

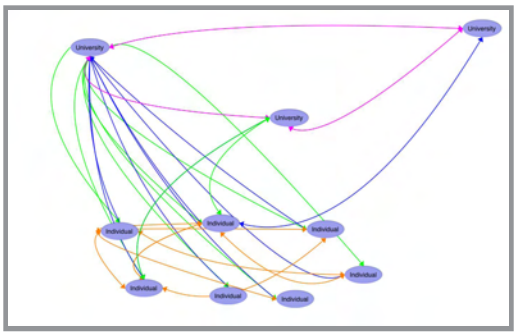
It is obvious and unexceptional that there are "emergent" properties in this limited sense. However, I'm not sure it captures the full concept of emergence. It would appear that holists have another idea in mind as well: the idea that the properties of the whole cannot be derived from knowledge of the properties of the parts and their relations to each other. ((E-V discusses this angle under the topic of "eliminative reductionism"; 24, 54.) A square figure is composed of four lines; the figure possesses area, whereas the lines do not. Sugar is sweet, but its component parts -- carbon, hydrogen, oxygen -- are not. So is "sweetness" an emergent property? Apparently it is not; because the sweetness of the compound can in fact be explained by the knowledge we have of the chemistry of the components, their molecular bonds, and the human sensors that register "sweetness." The property of sweetness can be **derived** from knowledge of the basic chemistry and the workings of the sensory system. So sweetness can be "reduced" to facts about the molecule and the sensor. It is not a novel causal power.

Here is why Elder-Vass thinks the concept of emergence is valuable in the context of social structures:

The value of the concept of emergence lies in its potential to explain how an entity can have a causal impact on the world in its own right: a causal impact that is not just the sum of the impacts its parts would have if they were not organised into this kind of whole. (5)
But really his central insight is that composites may have causal powers that are relatively *autonomous* from the powers of their parts:

Reductionist thinkers have argued that if we can explain how a causal power works in terms of lower-level forces, the original power itself becomes redundant to any explanation of its effects. By contrast, I argue in chapter 3 that when we explain a causal power, we do not explain it *away*. (6)
And here is his central point:

I shall argue that social entities [structures] are causally effective in their own right, with causal powers that are distinct from those of human individuals. But I shall also examine the mechanisms that underpin these causal powers, thus recognizing the contributory role that human individuals make to the functioning of social structures. (6)
(This last point is what I and others refer to as providing "microfoundations" for claims about social causation.)



So this seems to be Elder-Vass's core ontology of structures: structures are composed of individuals in relation to each other; structures have "emergent" causal powers that are not simply the sum of the causal powers of the component individuals; these emergent powers derive from the relations between the components; and for any particular causal power of the structure it must be possible to provide an explanation of the power in terms of mechanisms involving the individuals and their relations.

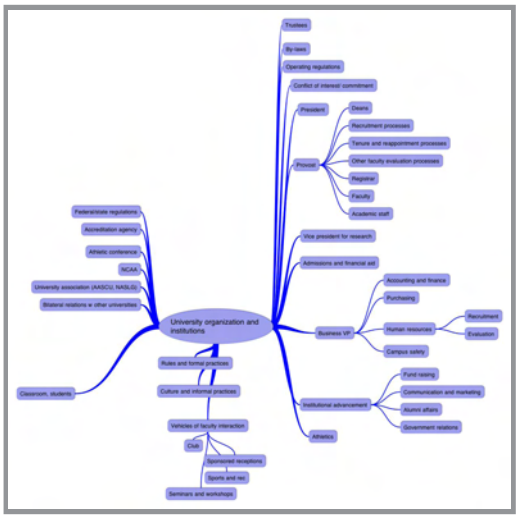
The bulk of the book takes the form of an effort to work out this view in detail with respect to two important types of social structures: organizations and normative circles. A bank is an organization (which in turn fits into a web of other organizations). A normative circle is a set of overlapping sets of individuals who both embody and conform to a normative rule or ideal. (E-V traces the idea here back to Durkheim and Simmel.) More on this later!

I suggested above that the concept of explanatory autonomy might work better than emergence. So what is a good definition of "relative autonomy" of causal powers at one level or another, with respect to the underlying entities? I think there are many areas of the sciences where we identify a set of causal processes that are sufficiently regular and predictable, that we don't feel obliged to drop down to the next level in order to achieve an adequate explanation. A level is "explanatorily autonomous" if entities at that level conform to a regular set of causal relations. Thinking of the brain as a computing system is an example. If we analyze the visual system in terms of a set of receptors, aggregators, detectors, analyzers, etc., and if this model allows us to explain and predict the organism's perceptual capacities (including mistakes), then we don't need to have a full theory of the neurophysiology that underlies. On this example, "perception as computational system" is relatively autonomous with respect to the underlying neurophysiology.

University as a causal structure

Thursday, April 14, 2011

An earlier post laid out a case for a modest social holism, in the form of a set of arguments for the idea that there are social forces and causal powers that are relatively autonomous from the features of the individuals who constitute them (link). These ideas parallel some of those offered by Dave Elder-Vass that were discussed in a recent post. I hold that this modest holism is compatible with the ideas of methodological localism (link) and the requirement that social causes require microfoundations (link, link). At the same time, it helps make sense of the fairly obvious point that social institutions, norms, and linguistic communities exercise powerful influence over the thoughts and behaviors of individuals.



The causal processes linking institution and individuals appear to be fully two-directional, with reinforcing feedback loops. The institution consists of a set of rules, processes, and role-players. The rules are both formal (laws, standard practice guides, by-laws) and informal (long-standing and widely recognized practices and norms governing specific kinds of activity). Some of the role players have the role of enforcing the rules and incentivizing the desired behaviors. These "enforcers" may act on the basis of a range of levels of understanding and commitment; so enforcement itself is variable. Ordinary participants within the institution are subject to the incentives and sanctions created by the rules and the enforcers; so their behavior is to some extent responsive to the rules. And ordinary participants in turn have internalized some understanding of the core processes and regulations of the institution -- and are (in varying degrees of involvement) prepared to encourage or sanction the behavior of their peers based on their understanding of the rules.

This description raises a number of theoretical issues. (1) What social processes establish the relative degree of continuity of the rules and practices of the institution? What prevents "drift" away from the rules of a given moment? (2) What social and agentic processes lead individuals to conform to the rules, and under what circumstances do individuals subvert or evade the rules? (3) What social processes ensure a reasonable degree of commitment by "agents" (officers, managers, directors) of the institution to its foundational rules and practices? How is an alignment between rules, agents, and participants established and maintained?

We might imagine that there are "tipping points" when it comes to adherence to the institution's norms, rules, and practices. When a sufficient number of agents or participants sincerely endorse the rules and adhere to them, this leads other agents to do so as well. When rule evasion is perceived to be common, this probably leads to a precipitous decline in rule adherence. So widespread conformance is itself a causal factor in the persistence of the rules into the next time period.

But how do we go beyond these general statements about structural causation? It may

be helpful to think through a familiar example -- the ways in which a specific institution like a university both shapes and influences the behavior of many individuals, and the ways in which its own internal functions and culture are themselves constituted by the behaviors, beliefs, attitudes, and morés of the individuals who fall within its ambit. Here is a sketch of the functional organization of a fictitious university:

The diagram has place-holders for formal, explicit rules and procedures (by-laws and operating regulations) and informal norms and practices; it has a sketch of some typical processes and transactions within which actors need to make various performances (tenure evaluation processes, research account oversight, purchasing decisions); and it identifies core "enforcer and incentivizer" roles -- CFO, provost, dean, auditors ... The actions that take place within the university generally fall within the scope of one or more of these regulations and norms. Actors (faculty members, front-line staff, administrators) are generally aware of the procedures that regulate their actions, and they either conform or deviate from the procedures. If they conform, generally things go well for them; if they deviate (submit false receipts for travel reimbursement) they are often detected and punished. So behavior of actors within the institution shows a measurable level of conformance with regulations and norms. And there are direct forms of oversight, reward, and punishment that serve to reinforce compliance. Finally, to close the circle -- the enforcers and incentivizers themselves fall within a circle of appraisal and accountability; so if their behavior deviates from what the standards and norms of the institution require, there is a likelihood of discovery and remedial action by others.

Outside the scope of the formal and informal norms of the institution, there are a variety of strands of institutional culture. Faculty, for example, find themselves in specific social settings within the university -- department meetings, faculty clubs, research seminars, etc. -- in which they gain exposure to local attitudes and values. And, as anyone who has spent much time in a university knows, these experiences often lead up to a fairly stable institutional culture among faculty -- in a department or division, or in the university as a whole (link). The faculty in a liberal arts college have a rather different culture from that of the faculty at a large research university. And liberal arts college faculties differ among themselves as well in this respect.

There is another kind of causal influence that is indicated in the first diagram above -- the fact that universities also have relations of influence with other universities. So if University A is looking to refine or modify its employee benefits policies, it is likely to examine the best practices of University B and C as well; and it is likely to adopt a few of those best practices. So the network of learning and emulation that exists across institutions is another form of causal influence at the level of the social structure. Here

again, it is not difficult to disaggregate this causal mechanism into specific individual-level actions -- attendance at an ACE conference, a site visit to University B by several representatives of University A, the drafting of a new policy by those individuals when they return home for consideration by a deliberative body, and the ultimate selection of the new policy by the president of the university.

So it isn't difficult to specify the ways in which the institution and its components exercise "macro" causal impact on the behavior of individuals within a university. An organization develops specific arrangements to solve problems of coordination, incentives, and rule enforcement; and these social arrangements have a strong influence on the behavior of the individuals who live within the institution. But likewise, it is not difficult to specify how these rules, norms, and enforcement mechanisms are embodied in the actions and mental states of a set of individuals. The people who occupy positions of influence within this organization have been "trained" by the organization to do their jobs; the skills learned through this training (and through their experience in the position over time) are embodied in their cognitive systems as "managerial skills"; and their motivations and behaviors themselves are subject to a degree of institutional control. (A dean who refuses to accept the responsibility of maintaining fiscal balance in his or her unit will soon be removed.) This causal system is indeed cyclical: both the organizational components and the participants have history and skills developed by past experience that allow them to function adeptly within the system. The participants have learned their university "habitus" from prior experience of the university; and the university's rules, norms, and procedures are in turn embodied in the present in the habitus of the current members of the university, and the embodied traces of its norms and rules in the form of written regulations.

Academic freedom and faculty email

Friday, April 15, 2011

There have been several efforts recently by partisan groups in Michigan and Wisconsin to gain access to faculty email messages on subjects that fall within the scope of the faculty member's research or personal political opinions. These groups have made use of state Freedom of Information laws, on the basis that faculty members are "state officials" and their communications are therefore "business records" of the university.

This is an alarming intrusion into the zone of academic and personal freedom of the faculty member, and it threatens to create a chilling effect on the faculty member's ability to freely communicate his or her ideas with colleagues without fear of retaliation or punishment, or premature disclosure of ideas not yet fully developed. It is vital that universities think very carefully about these issues before complying.

Once a scholar's ideas are published, they are in the public forum and are readily available to anyone who is interested, including the partisan groups who are now attempting to gain access to private emails. But before the scholar chooses to publish his or her ideas, she needs and deserves to have a zone of private conversation and expression through which she can test and refine her ideas. This is part of being a human being. It is a key reason why academic freedom is so important, to allow the free expression and refinement of ideas through intellectual interaction. And being able to control the publicity or privacy of one's thoughts is essential for this process, and is very close to being a human right.

So accepting the principle that a faculty member at a public university is a state official

and his/her communications about research ideas or social and political opinions are "business records" represents a huge erosion of academic and personal freedom. Academic freedom requires a zone of untrammeled private expression and discussion through which the individual can develop and refine her ideas.

If public universities are to be successful in maintaining their commitment to academic freedom for their faculty, they need to draw a bright line between **business records** and **intellectual, critical, and creative documents.** Freedom of information laws pertain to the former but should not require disclosure of the latter.

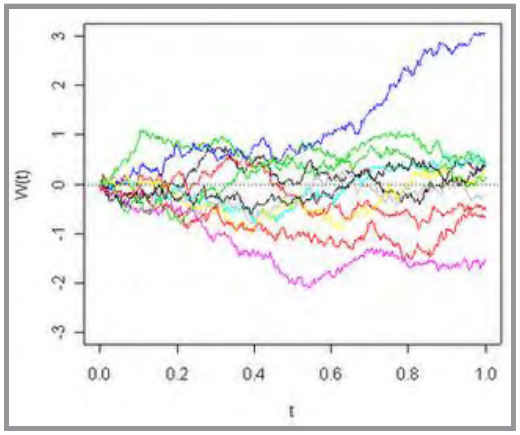
So what is the distinction? Here is one way of drawing the distinction. **Business activities** have to do with decision making about material issues within the organization. They have to do with concrete decisions involving such issues as purchasing, contracting, personnel decisions, hiring, and other material administrative actions. **Intellectual, critical and creative documents** are those that express the faculty member's ideas, thoughts, judgments, and hypotheses about subjects of interest. Transparency about business deliberations and decisions is essential in order to prevent conflict of interest, favoritism, and other improper business activities within any institution. But privacy with regard to "intellectual, critical, and creative documents" falls outside the scope of business activity, and should be protected.

The argument is sometimes made that professors are hired to think and do research; therefore their writings, even in email, are part of their employment work; therefore these writings are business records. But this line of thought is incorrect. The faculty member is hired to teach courses. An expectation of their work is that they will be active intellectuals and scholars. They will exercise their talents, it is expected, in an autonomous and self-directed way, to arrive at their own original results. But the content and product of their intellectual works are not themselves paid work products. Evidence of this, in part, is the fact that the university does not claim ownership of the copyright on faculty writings. Originality, autonomy, independence, and creativity are key to intellectual work, including faculty work. And this in turn underlines the importance of the zone of privacy within the context of which their intellectual and personal thinking and expression take place.

There are extreme and untenable results that ensue if you take this paradigm to its limit. Right now the FOIA requests are for a range of emails delimited by a list of keywords. But if the principle is accepted that the faculty member's intellectual products, in whatever form, are a business record, then preliminary drafts of scholarly work, laboratory notebooks, the jottings of a creative writing professor in preparation of a short story or novel -- all these products ultimately lead to a research result, which is a part of the expectations of the faculty member's work. And therefore, by this paradigm, they would be discoverable. Therefore it would be possible to FOIA a poet working for a public university to make available preliminary drafts of a poem. Likewise, paintings, drawings, and sculptures are the work of faculty in the arts. By this same principle, it is hard to see a basis for denying a FOIA request for drawings, sketches, and clay models.

On the subject of the expression of political and social opinions, observations, and judgments: Clearly this set of ideas and expressions by the faculty member does not fall within the scope of faculty employment under any description. The university does not hire faculty members to have political opinions. Rather, as citizens they may or may not have such opinions, and it is entirely within their rights to hold and express them. Further, neither the state nor the university has a right or an interest to surveilling or observing or criticizing or delimiting their expressions of political opinion. So any emails that are

primarily expressive of political opinions or judgments are not part of their work, do not have business content, and should not be provided under the scope of a FOIA request, even though they are expressed by a faculty member hired by a public university.



These FOIA requests, it should be noted, do not depend on the issue of whether the email account is owned by the university or is a private account. FOIA requires university officials to provide emails that have business content relevant to a particular subject, without regard to the platform on which these messages were transmitted. If the judgment were to stand that the faculty's intellectual products are in fact business records, then it wouldn't matter whether they are expressed in an email owned by the university or a private account.

Background

Here is a story in TPM about the Mackinac Center FOIA request in Michigan (link). Here is a summary of Michigan's FOIA law. Here is a posting from Inside Higher Education that describes the decisions the University of Wisconsin administration made with respect to requests for some of history professor William Cronon's email (link). And here is a thoughtful piece from the Center for Free Speech on Campus on the issues (link).

Scenario-based projections of social processes

Sunday, April 17, 2011

As we have noted in previous posts, social outcomes are highly path-dependent and contingent (link, link, link, link). This implies that it is difficult to predict the consequences of even a single causal intervention within a complex social environment including numerous actors -- say, a new land use policy, a new state tax on services, or a sweeping cap-and-trade policy on CO2 emissions. And yet policy changes are specifically designed and chosen in order to bring about certain kinds of outcomes. We care about the future; we adopt policies to improve this or that feature of the future; and yet we have a hard time providing a justified forecast of the consequences of the policy.

This difficulty doesn't only affect policy choices; it also pertains to large interventions like the democracy uprisings in the Middle East and North Africa. There are too many imponderable factors -- the behavior of the military, the reactions of other governments, the consequent strategies of internal political actors and parties (the Muslim Brotherhood in Egypt) -- so activists and academic experts alike are forced to concede that they don't

really know what the consequences will be.

One part of this imponderability derives from the fact that social changes are conveyed through sets of individual and collective actors. The actors have a variety of motives and modes of reasoning, and the collective actors are forced to somehow aggregate the actions and wants of subordinate actors. And it isn't possible to anticipate with confidence the choices that the actors will make in response to changing circumstances. At a very high level of abstraction, it is the task of game theory to model strategic decision-making over a sequence of choices (problems of strategic rationality); but the tools of game theory are too abstract to allow modeling of specific complex social interactions.

A second feature of unpredictability in extended social processes derives from the fact that the agents themselves are not fixed and constant throughout the process. The experience of democracy activism potentially changes the agent profoundly -- so the expectations we would have had of his/her choices at the beginning may be very poorly grounded by the middle and end. Some possible changes may make a very large difference in outcomes -- actors may become more committed, more open to violence, more ready to compromise, more understanding of the grievances of other groups, ... This is sometimes described as endogeneity -- the causal components themselves change their characteristics as a consequence of the process.

So the actors change through the social process; but the same is often true of the social organizations and institutions that are involved in the process. Take contentious politics -- it may be that a round of protests begins around a couple of loose pre-existing organizations. As actors seek to achieve their political goals through collective action, they make use of the organizations for their communications and mobilization resources. But some actors may then also attempt to transform the organization itself -- to make it more effective or to make it more accommodating to the political objectives of this particular group of activists. (Think of Lenin as a revolutionary organization innovator.) And through their struggles, they may elicit changes in the organizations of the "forces of order" -- the police may create new tactics (kettling) and new sub-organizations (specialized intelligence units). So the process of change is likely enough to transform all the causal components as well -- the agents and their motivations as well as the surrounding institutions of mobilization and control. Rather than a set of billiard balls and iron rods with fixed properties and predictable aggregate consequences, we find a fluid situation in which the causal properties of each of the components of the process are themselves changing.

One way of trying to handle the indeterminacy and causal complexity of these sorts of causal processes is to give up on the goal of arriving at specific "point" predictions about outcomes and instead concentrate on tracing out a large number of possible scenarios, beginning with the circumstances, actors, and structures on the ground. In some circumstances we may find that there is a very wide range of possible outcomes; but we may find that a large percentage of the feasible scenarios or pathways fall within a much narrower range. This kind of reasoning is familiar to economists and financial analysts in the form of Monte Carlo simulations. And it is possible that the approach can be used for modeling likely outcomes in more complex social processes as well -- war and peace, ethnic conflict, climate change, or democracy movements.

Agent-based modeling is one component of approaches like these (link). This means taking into account a wide range of social factors -- agents, groups, organizations, institutions, states, popular movements, and then modeling the consequences of these

initial assumptions. Robert Axelrod and colleagues have applied a variety of modeling techniques to these efforts (link).

Another interesting effort to carry out such an effort is underway at the RAND Pardee Center, summarized in a white paper called Shaping the Next One Hundred Years: New Methods for Quantitative, Long-Term Policy Analysis. Here is how the lead investigators describe the overall strategy of the effort:

This report describes and demonstrates a new, quantitative approach to long-term policy analysis (LTPA). These robust decisionmaking methods aim to greatly enhance and support humans' innate decisionmaking capabilities with powerful quantitative analytic tools similar to those that have demonstrated unparalleled effectiveness when applied to more circumscribed decision problems. By reframing the question "What will the long-term future bring?" as "How can we choose actions today that will be consistent with our long-term interests?" robust decisionmaking can harness the heretofore unavailable capabilities of modern computers to grapple directly with the inherent difficulty of accurate long-term prediction that has bedeviled previous approaches to LTPA. (iii)

LTPA is an important example of a class of problems requiring decisionmaking under conditions of deep uncertainty—that is, where analysts do not know, or the parties to a decision cannot agree on, (1) the appropriate conceptual models that describe the relationships among the key driving forces that will shape the long-term future, (2) the probability distributions used to represent uncertainty about key variables and parameters in the mathematical representations of these conceptual models, and/or (3) how to value the desirability of alternative outcomes. (iii)
And here, in a nutshell, is how the approach is supposed to work:

This study proposes four key elements of successful LTPA:

- *Consider large ensembles (hundreds to millions) of scenarios.*
- *Seek robust, not optimal, strategies.*
- *Achieve robustness with adaptivity.*
- *Design analysis for interactive exploration of the multiplicity of plausible futures.*

These elements are implemented through an iterative process in which the computer helps humans create a large ensemble of plausible scenarios, where each scenario represents one guess about how the world works (a future state of the world) and one choice of many alternative strategies that might be adopted to influence outcomes. Ideally, such ensembles will contain a sufficiently wide range of plausible futures that one will match whatever future, surprising or not, does occur—at least close enough for the purposes of crafting policies robust against it. (xiii)

Thus, computer-guided exploration of scenario and decision spaces can provide a prosthesis for the imagination, helping humans, working individually or in groups, to discover adaptive near-term strategies that are robust over large ensembles of plausible futures. (xiv)
The hard work of this approach is to identify the characteristics of policy levers, exogenous uncertainties, measures, and relationship (XLRM). Then the analysis turns to identifying a very large number of possible scenarios, depending on the initial conditions and the properties of the actors and organizations. (This aspect of the analysis is analogous to multiple plays of a simulation game like SimCity.) Finally, the approach requires aggregating the large number of scenarios to allow the analysis to reach some

conclusions about the distribution of futures entailed by the starting position and the characteristics of the actors and institutions. And the method attempts to assign a measure of "regret" to outcomes, in order to assess the policy steps that might be taken today that lead to the least regrettable outcomes in the distant future.

It appears, then, that there are computational tools and methods that may prove useful for social explanation and social prediction -- not of single outcomes, but of the range of outcomes that may be associated with a set of interventions, actors, and institutions.

Social networks as aggregators

Thursday, April 21, 2011

We think of social phenomena as "relational" in some important respect. Individuals contribute to social outcomes through structured and dynamic relationships with other individuals. So outcomes are not just heaps of aggregated individual behavior; rather, they are the filigreed result of interlinked, coordinated, competitive and sometimes unintended actions of people who have intentional and structural relationships to each other. And we think of these relationships, often, in terms of the metaphors and analytics of social "networks." So it is worthwhile giving some thought to how the machinery of social network theory can help us in better understanding the ways that social processes unfold. Here is a nice passage from Mario Diani's introduction to Social Movements and Networks: Relational Approaches to Collective Action.

It is difficult to grasp the nature of social movements. They cannot be reduced to specific insurrections or revolts, but rather resemble strings of more or less connected events, scattered across time and space; they cannot be identified with any specific organization either, rather they consist of groups of organizations, with various levels of formalization, linked in patterns of interaction which run from the fairly centralized to the totally decentralized, from the cooperative to the explicitly hostile. Persons promoting and/or supporting their actions do so not as atomized individuals, possibly with similar values or social traits, but as actors linked to each other through complex webs of exchanges, either direct or mediated. Social movements are in other words, complex and highly heterogeneous network structures. (1)

This passage emphasizes quite a few themes that have been important throughout *UnderstandingSociety* -- the heterogeneity of social phenomena, the difficulty of formulating a clear understanding of social ontology, and the challenge of representing the processes of aggregation through which individual social actions contribute to mid- and large-scale social outcomes.

So how do the analytical resources of network theory contribute to a better understanding of the ways that actions aggregate into outcomes? Diani emphasizes several ways in which network analysis has contributed to the study of contentious politics.

Network analysis as it is best known developed with reference to a 'realist' view of social structure as networks which linked together concrete actors through specific ties, identifiable and measureable through reliable empirical instruments. This view represented an alternative to both views of social structures as macro forces largely independent from the control of the specific actors associated with them ...., and views of structure as aggregates of the individual actors sharing determinate specific traits (5).

So if we take it as a plain fact about the social world that individuals have a range of meaningful and material relationships with other individuals, both proximate and distant, then it is plainly important to understand the effects that those relationships have on their consciousness and behavior. These causal relationships are likely to extend in both directions -- from the network to the actor, and from the actor back into the network.

What kinds of social relationships are most relevant to understanding social processes like contentious movements? Particularly important are "personal ties linking prospective participants to current activists or dense counter-cultural networks affecting rates of mobilization in specific areas" (3). Diani mentions "personal friends, relatives, colleagues, and neighbours; ... people who share with prospective participants in some kind of collective engagement, such as previous or current participation in other movement activities, political or social organizations, and public bodies" (7). To this list we might add membership and interaction within the kinds of civic and communal organizations that Robert Putnam emphasizes in Bowling Alone: The Collapse and Revival of American Community.

Here is the key point: different people find themselves in very different networks of social connections, and these relationships contribute to their social and political consciousness in diverse ways. If we are interested in the spread of militant civil rights activism, as Doug McAdam is in Political Process and the Development of Black Insurgency, 1930-1970, or in the spread of fascist activism and mobilization in Europe in the 1920s and 1930s, as Michael Mann is in Fascists, it is highly relevant to discover the relationships and organizations through which individuals come into contact with each other and with the ideas of the nascent movements. Likewise, if we are interested in the proliferation of support for the Deacons of Defense in the American South in the 1950s and 1960s, as Lance Hill is in The Deacons for Defense: Armed Resistance and the Civil Rights Movement, then it is important to identify the personal and organizational linkages through which ordinary people became aware of this response to white supremacy and violence. Communication of ideas and political emotions requires a mechanism connecting the "signallers" and those to whom the messages eventually percolate, and this is not a depersonalized, homogeneous process.

Recruitment and mobilization is one aspect of contentious politics where social networks are plainly important. Relationships in the workplace, the neighborhood, or the church or mosque are a likely location for the diffusion of a range of socially relevant material -- news, gossip, indignation, shared views about politics. And these relationships are a potential vector for the recruitment of followers and activists for a range of new political ideas -- from civil rights to Tea Party to fascism.

Identifying coalitions of collective actors is another area of current research. Once a topic has gained some degree of visibility and salience, it is likely enough that multiple groups will begin to focus on it. Anti-tax activism is a good example -- dozens of "citizen-based" organizations emerged in California in the 1950s and 1960s with the overall goal of

limiting property and income taxes in the state, and it is useful to track the emerging relationships that developed among these organizations and their activists.

Diani also highlights the role that concrete social networks play in "framing and tactical adaptation of action repertoires" (4). Framing has to do with the ways that issues are understood by the participants; so this topic unavoidably has to do with culture and social interpretation. But the ways in which cultural frames are conveyed to people through a population are material processes that can be studied empirically. And social networks play a key role in these processes. As people interact with their friends and associates, they develop their political and social representations of the society around them. These interactions are the direct embodiment of their social networks. Diani singles out "communitarian and subculture networks" for particular attention: "communitarian ties operate at a minimum to strengthen the identity and solidarity among movement activists and sympathizers. At the same time, though, they provide the specific locus of social conflict in those cases where the challenge is eminently on the symbolic side and where, in other words, the definition of identities and the preservation of opportunities for the enactment of alternative lifestyles are mainly at stake" (9). These features of identity-based mobilization, through networks of like-minded individuals, are important in Michael Mann's analysis of the rise of fascism in Fascists as well:

The fascist core consisted everywhere of two successive generations of young men, coming of age between WorldWar I and the late 1930s. Their youth and idealism meant that fascist values were proclaimed as being distinctively “modern” and “moral.” They were especially transmitted through two institutions socializing young men: secondary and higher education, encouraging notions of moral progress, and the armed forces, encouraging militarism. Since the appeal was mainly to young men, it was also distinctly macho, encouraging an ethos of braggart, semi-disciplined violence, in peacetime encouraging militarism to mutate into paramilitarism. The character of fascism was set by young men socialized in institutions favorable to moralizing violence and eventually to murder. Yet the similarity of values between paramilitarism and militarism always gave fascism a capacity to appeal to armed forces themselves, not to the extent of inducing military rebellions but to the extent of generating sympathy there that at its most extreme could immobilize the army. (26)

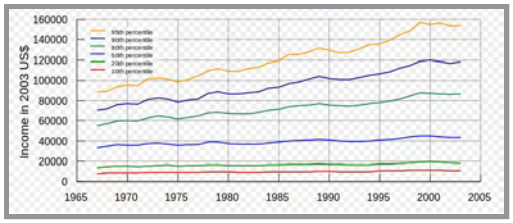
“Fascists” were not fully formed at the moment they entered the movement. People may formally sign up for a movement and yet possess only a rudimentary knowledge of it – sympathy for a few slogans, respect for a charismatic F¨uhrer or Duce, or simply following friends who have joined. Most recruits joined the movement young, unmarried, unformed, with little adult civilian experience. On them, fascist parties and paramilitaries were especially powerful socialization agencies. These movements were proudly elitist and authoritarian, enshrining a pronounced hierarchy of rank and an extreme cult of the leader. Orders were to be obeyed, discipline to be imposed. Above all, they imposed a requirement of activism. Thus militants experienced intense emotional comradeship. Where the movement was proscribed, clandestinity tightened it. Many activists lost their jobs or went into prison or exile. Though this deterred many of the more fainthearted, among those remaining active such constraints further tightened the movement. (28)

The social processes that Mann describes here have to do with all three aspects -- recruitment, mobilization, and framing; and they depend on the networks of relationships through which the core fascist values and worldviews were transmitted to new recruits. Institutions were key in this transmission -- the military, the workplace, the youth organization -- and a large part of their influence was their ability to create a significant cohort of young men with a specific set of set of social relationships.

The lens of social networks, in short, seems to be a very powerful tool for understanding

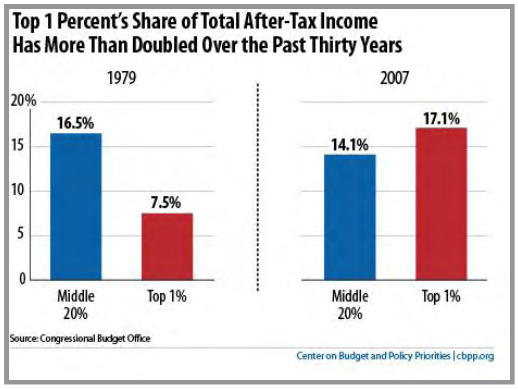
the processes of aggregation -- upward, downward, and lateral -- through which ideas, grievances, and actors come together into major social upheavals and movements.

What is perhaps more difficult to see, though, is how to engage in empirical research on the concrete networks of social relationships that have important effects on outcomes we care about. As the United States moved towards civil war in 1860 and 1861, there were hundreds or thousands of individuals in the U.S. Army officer corps who had antecedently mixed loyalties -- Southern birth, family still residing in the South, but a tradition of education and service within the U.S. Army. So what accounts for the choices that were made by various officers when they had to decide -- North or South? It is intuitively plausible that each officer's concrete social network played an important role in his decision -- appeals from family and friends, business relationships in Virginia, long-standing relationships with senior Northern officers, an education and cohort at West Point. But it is not entirely clear how to turn this plausible view into a feasible research plan.



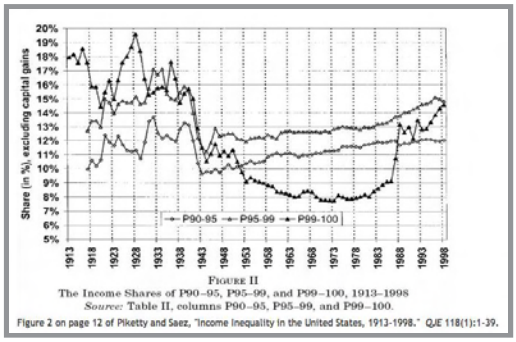
This is one reason why the Diani volume is such a worthwhile contribution. Most of the contributors focus their work on specific empirical problems in the field of social contention. Maryjane Osa looks at activist networks in the Polish People's Republic; Christopher Ansell looks at community activism in the San Francisco Bay environmental movement; Jeff Broadbent looks at social networks in the Japanese environmental movement; and Chuck Tilly and Lesley Wood look at networks in contentious episodes in British history around 1828. These are concrete, empirical-historical efforts to take the guiding ideas of network analysis and discover some substantive insights into the specific ways that a variety of protest movements unfolded. And they give a better understanding of the contribution that social network analysis can offer to concrete historical research.

Inequalities and the ascendant right



Saturday, April 23, 2011

The playing field seems to keep tilting further against ordinary people in this country -- poor people, hourly workers, low-paid service workers, middle-class people with family incomes in the $60-80K range, uninsured people, ... 75% of American households have household incomes below $80,000; the national median was $44,389 in 2005. Meanwhile the top one percent of Americans receive 17% of total after-tax income. And the rationale offered by the right to justify these increasing inequalities keeps shifting over time: free enterprise ideology, trickle-down economics, divisive racial politics, and irrelevant social issues, for example.



Here is the trajectory of US income by quintile since 1965 (link); essentially no change in the bottom three quintiles over that 40-year period. Plainly the benefits of growth and productivity change in the national economy have benefited the top 40% of the population, and disproportionately have flowed to the top 5%.

Just consider what has happened to income to the "middle" class versus the top 1% in the US economy. The 40-60% segment of earners have declined from 16.5% to 14.1% of after-tax income, while the top 1% has more than doubled its share, to 17.1%.

And here's a very graphic demonstration of the rapid increase in the percent of income flowing to the top percent of US income earners since the Reagan revolution (thanks to benmuse):

Meanwhile, the power of extreme wealth in the country seems more or less unlimited and unchallenged. Corporations can spend as much as they want to further candidates -- as "persons" with freedom of speech rights following Citizens' United v. Federal Election Commission (link). Billionaires like the Koch brothers fund the anti-labor agendas of conservative governors. Right-wing media empires dominate the airwaves. Well-financed conservative politicians use the language of "budget crisis" as a pretext for harshly reducing programs that benefit ordinary people (like Pell grants). Lobbyists for corporations and major economic interests can influence agencies and regulations in the interest of their clients, more or less invisibly. And billionaire lightweights like Donald Trump continue to make ridiculous statements about President Obama's birth status.

The political voice of the right, and the economic elite they serve, has never been louder. And it is becoming more reckless in its attacks on the rest of society. Immigrants come in for repressive legislation in Arizona and other states. Racist voices that would never have been tolerated a generation ago are edging towards mainstream acceptability on the right. Self-righteous attempts to reverse health care reform are being trumpeted -- threatening one of the few gains that poor and uninsured people have made in decades. And the now-systematic attack on public sector unions is visibly aimed at silencing one of the very few powerful voices that stand in the political sphere on behalf of ordinary working people.

The big mystery is -- why do the majority of Americans accept this shifting equation without protest? And how can progressive political organizations and movements do a better job of communicating the basic social realities of our economy and our democracy to a mass audience? Social justice isn't a "special interest" -- it is a commitment to the fundamental interests and dignity of the majority of Americans.

Quiet politics

Tuesday, April 26, 2011

image: *Conspiracy*, Edward Biberman (cover illustration, *Quiet Politics*)

Pepper Culpepper's Quiet Politics and Business Power: Corporate Control in Europe and Japan sheds some very interesting light on one key question in contemporary western democracies: how do corporations and business organizations so often succeed in creating a legislative and regulatory environment that largely serves their interests? And, for that matter, why do they sometimes fail spectacularly in doing so, even while spending oceans of money in the effort to influence public policy?

The book is a careful comparative study of the development of corporate governance laws and institutions in France, Germany, the Netherlands, and Japan. It offers special focus on the institutions governing hostile corporate takeovers (very different across the four examples), but also takes on other issues of current interest, including executive pay. But though the cases and issues considered in the book are fairly esoteric and specialized, Culpepper's analysis is intended to provide a broadly useful tool for understanding how corporate influence is exercised in a democracy.

Culpepper wants to know what political and situational factors explain the divergent course that corporate governance has taken in these four contemporary democracies, from more permissive to more restrictive. Do elected officials determine the broad outlines of the governance regime? Are differences across states the result of differences in the platforms of large political parties in these states? Or are the outcomes driven by something else? Culpepper thinks that it is usually something else:

In this book, I argue that the outcomes observed in these four countries result not from variations in government partisanship or from different interest coalitions, but from differences in the political preferences of managerial organizations. In all four countries, the rules favored by the managers of large firms are those that triumphed, often against substantial political opposition. (3)

Or in other words, the outcomes are those favored by the business elites rather than

elected officials or mass-based political parties. And differences in outcomes are explained by differences in the business environment in the four countries. This is the "business power" part of the question, and Culpepper's fundamental empirical finding is that businesses elites generally have proven successful in creating the institutional and regulatory regimes in their polities that they prefer. But how do they succeed?

Here Culpepper's central finding is encapsulated in the other half of his title: these corporate governance issues usually fall in the domain of what he refers to as "quiet politics." Noisy politics arise around the issues that generate significant and sustained interest by large numbers of voters; these issues have "***high salience***" to the electorate, and parties and elected officials find it in their interest to adjust their positions around voter preferences on these salient issues. Quiet politics arise in the context of issues with "***low salience***" -- issues to which the mass of voters are largely indifferent. "The political salience of an issue refers to its importance to the average voter, relative to other political issues" (4). In the context of "low salience" issues that matter to the interests of high-level business managers and elites, it is possible for these elites to deploy an arsenal of influential tools that succeed very well in bringing about the legislative and regulatory outcomes that the managerial elites prefer. Most fundamental is an information asymmetry between managers and policy makers:

> The managerial weapons of choice in quiet politics are a strong lobbying capacity and the deference of legislators and reporters toward managerial expertise. The political competitors of managers, be they liberalizing politicians or crusading institutional investors, lack access to equivalent political armaments, so long as voters evince little sustained interest in and knowledge about an issue. (4)

Culpepper unpacks the political advantage residing with business elites and managers in terms of acknowledged expertise about the intricacies of corporate organization, an ability to frame the issues for policy makers and journalists, and ready access to rule-writing committees and task forces. These factors give elite business managers positional advantage, from which they can exert a great deal of influence on how an issue is formulated when it comes into the forum of public policy formation. Culpepper refers to British Cadbury Committee, tasked to develop "best practices" in corporate governance (9), as an important example of an occasion where high-level managers had a very powerful ability to write the rules that would govern their behavior. Vice President Cheney's energy committee during the Bush administration is another great example (link). Informal working groups, containing a significant representation of managerial elites, have an ability to set the agenda for a regulatory regime that allows them to privilege positions they prefer and to protect their organizations from worst-case outcomes.

> As in the case of direct lobbying, the power of managers in this context is the power to set the terms of the debate in an environment that is established with an explicit eye to protecting their interests. (9)

Here is one of many detailed examples that Culpepper studies in the book: the Peters Committee in the Netherlands in 1997, tasked to "establish a voluntary code of best practice in corporate governance" (100). He notes that the Peters Committee was very similar in structure to the Cadbury Committee. It was chaired by a former CEO, and had representation from the VEUO (Dutch Association of Securities-Issuing Companies), pension funds, and the Amsterdam Stock Exchange. Unions were not represented. And, Culpepper reports, the forty recommendations of the Committee were essentially ignored by the Dutch corporate actors.

Scholars of corporate finance point to the Peters Committee as a textbook example of the failures of self-regulation of business without any legal enforcement. Yet from the viewpoint of the managerial interests that dominated the committee, its results were consistent with their highest political priority: to defend protection mechanisms [against hostile takeovers]. (101)
In other words: from the point of view of Dutch corporate elites, the committee was not a failure, but rather a demonstration of their ability to shape the agenda and secure a near-term environment that enabled their freedom of action.

So essentially Culpepper's empirical-institutional argument is that top business managers (CEOs and their teams) have a very powerful set of tools on the basis of which they are able to influence legislation and regulation. This tool set leads to an impressive win percentage when it comes to legislation and regulation affecting the business environment.

But he also finds that these tools are really only decisive in the context of "low salience" issues -- issues that have not engaged the voting public with any intensity. When a hitherto boring and technical issue of corporate governance suddenly jumps into high salience -- for example, the conflicts of interest faced by accounting firms involved in the Enron debacle -- these weapons of quiet influence essentially lose their ability to shape the outcomes.

The more the public cares about an issue, the less managerial organizations will be able to exercise disproportionate influence over the rules governing that issue. (177)
Parties, political entrepreneurs, legislative committees, and elected officials become interested in the issue; it becomes worthwhile for business journalists to learn the technical details; and the public demands solutions that may be contrary to the preferences of the business elite. And Culpepper works through one of these examples in detail as well: the public and public policy debates that have flared up concerning executive pay (chapter 6).

In addition to its substantive political-institutional findings, the book is interesting for its methodology. Culpepper explicitly favors the "causal mechanism" approach to social research and investigation. He treats cases comparatively; and he attempts to "process-trace" the paths through which outcomes came about. He depends extensively on interviews with pivotal actors in some of the cases studied. He does a very good job of aligning his analysis against its main competitors -- median voter theories and coalition politics analysis. Finally, the book is explicitly comparativist; he want to understand in some detail the situations and factors that lead to different outcomes with respect to corporate governance, and the rules governing hostile takeovers, in the four countries he studies. So the book does an admirable job of sketching out some of the microfoundations of corporate influence in existing democracies. As such, it is a very useful contribution -- it helps to connect the dots (link).

The math of social networks

Saturday, April 30, 2011

A social network is constituted by a number of units (nodes) that are connected to each other by a defined relationship -- for example, "x cites y", "x sends 5 email messages a week to y", "x and y belong to an organization in common." There are a few wrinkles -- the units may be persons, organizations, cities, journal articles, or other types of entities;

the relationships may be uni-directional or bi-directional; and the linking relationships may represent categorical relationships or intensity relationships. "x and y are friends" is a bi-directional relationship; "x and y are close friends" is a bi-directional relationship recording intensity.

Some of the basic questions about a social network are easy to formulate but difficult to assess. Basically, we would like to know what groups of individuals are unusually closely interconnected with each other, relative to the average for the population as a whole. Here are a few basic questions that we may have about networks of people.

- Who is connected to whom?
- Are there a subset of persons who are unusually well connected?
- Are there sub-groupings of individuals who are more closely connected to each other than they are to others in the network?

This last point may be put into the language of "communities": are there communities of individuals that can be identified on the basis of mathematical features of their positions within the graph of relationships defined by the data recording pairwise connections?

This question is especially important for sociologists because it goes to the heart of the reason why network maps are of sociological interest in the first place: we think that the social relationships among individuals explain important features of social action -- readiness to mobilize for a political cause, for example; this intuition derives from the idea that individuals influence each other through the exchange of information and the observation of each other's behavior; and so subgroups of persons with especially dense social connections with each other may have distinctive social characteristics as a group. So identifying the "communities" within a social network is an important sociological discovery.

This is where the mathematics of network graphs comes in. We need to have justifiable procedures for partitioning a network into sub-networks. These procedures need to make sense in terms of the intuition that there are often subgroups of nodes more closely related to each other. The procedures need to be non-arbitrary. They should be robust with respect to where we begin -- it shouldn't matter whether we begin analysis with this node or that node. And they need to be consistent with the fact that all the nodes are related to everyone else at some degree of separation. Neighborhoods that are entirely detached from the rest of the population are a trivial case; normally network ties extend transitively throughout a whole society.

Greek mathematician and social scientist Moses Boudourides is focused on this problem in his current work. (Follow him on Twitter at link.) Boudourides is deeply sensitive to the sociological importance of the questions, so his work does a great job of bridging the two fields of thought. Some of his current work is available online, and it is very useful for people who want to understand more about the mathematics of social networks. It falls into the field of graph theory in mathematics, and it serves as a good tutorial to current thinking about the mathematics of social networks.

Worth reading first is "An Introduction to Community Detection in Graphs" (link). Here Boudourides offers a clear exposition of the mathematical problem of identifying a set of neighborhoods within a complex graph and lays out three approaches that have been taken.

Our aim here is to present an introductory and brief discussion of the formal concept of community in the context of the theory of complex networks (and social network analysis)

and to describe (mostly by examples) a few of the many computational techniques which are commonly used for the detection of communities in a graph-theoretic background. (1) Here is his definition of a community in the context of a network graph:

By a community structure of such a graph, we mean a partition of the set of nodes into a number of groups, called communities, such that all nodes belonging to any one of these groups satisfy a certain property of relative cohesiveness. Note that one may consider partitions, which are not necessarily strict, i.e., one may allow the case of overlapping communities, when there exist graph nodes belonging to more than one groups (communities) of the partition. (1)

The three iterative techniques he describes for analyzing a complex network into sub-communities are --

1. Betweenness -- Centrality-based community detection
2. k-Clique percolation
3. Modularity maximization

In each case the analysis proceeds by working through the graph iteratively, identifying notes and links with certain characteristics, and arriving at a series of stages of community definition. This process can proceed from above (divisive) or from below (agglomerative).

The "betweenness" approach derives from an application of the idea of "betweenness centrality" of edges: "the number of shortest paths between pairs of nodes that run through that edge" (3). On this approach, edges are ranked by their betweenness measure; the highest ranked edge is removed; and the process is repeated for the reduced graph. This is a divisive method.

The k-clique model is an agglomerative approach, or what Boudourides refers to as a "local community-finding approach" (6). And modularity maximization approach begins with the graph as a whole and looks for regions that are locally higher in density than the graph as a whole. Boudourides' explanation of each of these methods is technical and clear. He indicates that the MM approach is most widely used; but that it falls in a class of particularly intractable optimization problems like the traveling salesman problem (NP-complete). Consequently it is necessary to design heuristic algorithms on the basis of which to arrive at approximate solutions. (As I understand the point, however, there is no guarantee that the approximate solution will be close to the ideal solution.)

With these tools at hand, he offers a detailed example: analysis of a data set of individuals who participated in peace demonstrations against the war in Iraq and the organizations and issues with which they were associated. Data on these activists are included in the International Peace Protest Survey (IPPS). And the resulting neighborhood maps are fascinating. These results are described in detail in a detailed research report on "Communities in the IPPS Survey Data" [link] and a theoretical paper on "Why and How Culture Matters in Community Interorganizational Structure" [link]. These presentations show the real power of mathematical network theory, in that they bring out social relationships among individuals within this population of activists that couldn't be discovered otherwise. Here are a pair of network graphs for 972 activists in Italy presented in "Culture Matters":

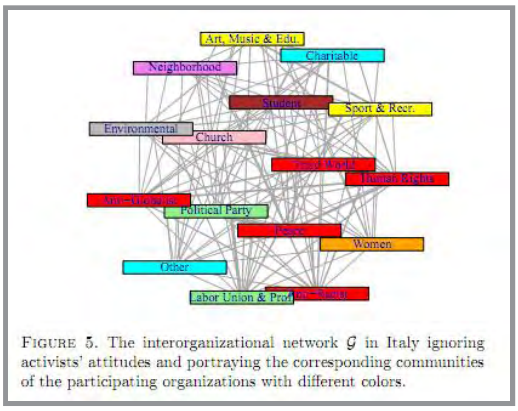


FIGURE 5. The interorganizational network $\mathcal{G}$ in Italy ignoring activists' attitudes and portraying the corresponding communities of the participating organizations with different colors.

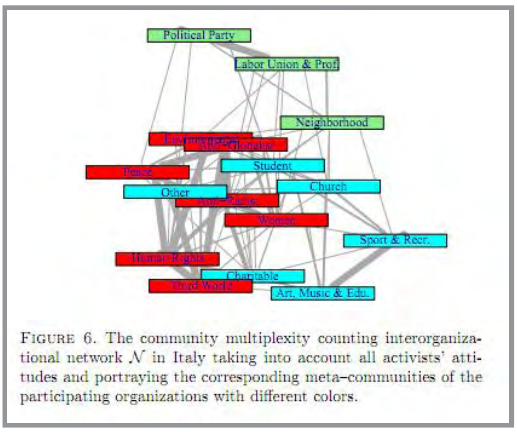

FIGURE 6. The community multiplexity counting interorganizational network $\mathcal{N}$ in Italy taking into account all activists' attitudes and portraying the corresponding meta–communities of the participating organizations with different colors.

Boudourides' particular goal here is to demonstrate the difference it makes to incorporate "cultural" affiliations into the structural analysis of the first figure. Incorporating attitudes permits simplification of the community structure of this network, from nine communities in figure 5 to four communities in figure 6. But more generally, the analysis demonstrates the analytical gain that is possible through this analysis, allowing us to discover important patterns of affiliation among these 900+ activists. And this, in turn, appears very relevant when we come to trying to understand their behavior within a complex process of collective action. It allows us to give some rigorous detail to the idea that a social movement has a refined micro-structure underlying its macro-level actions and demands.

What is especially useful about these papers is the help they offer us non-specialists in understanding the mathematical techniques on the basis of which we can extract sociologically meaningful information from a network graph. This is a bit analogous to the gain we get from using statistical techniques to analyze and summarize a large data set. The statistical techniques allow us to winnow the data into a few statistical measures. And the techniques of graph theory that Moses Boudourides demonstrates allow a similar analytical power for the task of making sociological sense of a large network of connected individuals. In both cases it is necessary for us to understand the basics of the mathematical techniques if we are to use the tool appropriately.

Social media and social cohesion

Sunday, May 01, 2011

The current topic on the UnderstandingSociety blog poll is a proposition about social cohesion:

THE INTERNET IS HELPING TO CREATE NEW PATHWAYS OF SOCIAL COHESION IN CONTEMPORARY SOCIETY.

The poll is still open, but as of today 70% of respondents somewhat or strongly agree that the Internet creates a basis for new forms of social cohesion, while only 16% somewhat or strongly disagree. On its face, a large majority of readers are optimistic about the ability of the Internet to contribute to a stronger national community. What the poll question doesn't reveal is the respondents' underlying thinking as the basis of their judgment. So let's see what some of the considerations might be.

First, what do we mean by "social cohesion"? Along with Durkheim, we can approach the concept by relating it to the bonds of morality and loyalty that lead members of a society to adapt their behavior to the perceived needs of society. A willingness to sacrifice in times of crisis, a willingness to defer to the common good, a willingness to conform to widespread social norms -- these are the sorts of things that go into the concept of social cohesion. A society that lacks all bonds of social cohesion is one in which individuals care only about their own interests; who pay attention only to their own individual ideas about morality; and who find the idea of sacrifice for the greater good to be for the gullible. (Interestingly, this is a state of affairs that Durkheim describes as "anomie", and it is the factor that he believes conduces to a heightened rate of suicide in a population; Suicide.) (Here is a nice contemporary survey of the sociological literature on social cohesion by Noah Friedkin; link.)

Where would the social basis of this kind of cohesion come from? Ferdinand Tönnies characterizes a traditional society with a strong basis for social cohesion in terms of the idea of "*gemeinschaft*"; whereas he describes a modern liberal-market society in terms of the idea of *gesellschaft* (Community and Society: (GEMEINSCHAFT AND GESELLSCHAFT)). According to Tönnies, traditional societies maintain social cohesion through traditional social mechanisms: face-to-face relations in a village, common religious institutions, and other institutions representing and inculcating collective values. And as these traditional mechanisms have lost traction in modern civil society, the intuitive idea is that modern societies are generally declining in the level of social cohesion that they reflect.

So how might the mechanisms of social connection provided by the Internet potentially influence the facts about social cohesion in a twenty-first century society? How might Facebook, Twitter, YouTube, blogs, and webpages have effects that are either favorable or unfavorable for social cohesion? It seems that these capabilities of the Internet have the potential for working in both directions -- both undermining cohesion and enhancing cohesion. So overall, it is very difficult to assess the net impact of these capabilities.

First, consider a few tendencies in the negative direction. Much as Internet-based news sources have fragmented the audience for the network news -- and thereby have reduced the degree of commonality citizens have through their regular interactions with Walter Cronkite -- we might speculate that the Internet facilitates a fragmentation of social groups into smaller and smaller segments. So instead of a set of attitudes that bind citizens together as part of American society, we get micro-sets of attitudes that bind individuals together into micro-constituencies. This would seem to be a force working against social cohesion at the level of the population as a whole.

A related point stems from the evident ability of Internet tools to create ever-more strident groups of people around very specific issues and concerns. If each issue has its own website, Facebook page, Twitter feed, social media management strategies, and the like, individuals are drawn into greater engagement with ever-smaller groups of like-minded individuals. So it is increasingly difficult for politicians to create mass-based constituencies around a core set of values; there is a declining basis for a social consensus in a world in which individuals gravitate towards divisive social and political advocates.

These points suggest that the Internet has effects that are corrosive of social cohesion. What are the tendencies of the Internet that point in the other direction? The example of the use of Facebook during the democracy demonstrations in Egypt provides one positive indication. It would appear that activists were able to gain strong support from thousands of interested Egyptians through the real-time communication and social expression that Facebook pages enabled. This was a process of agglomeration rather than fragmentation for some period of time -- a process through which a broader and broader group of individuals became actively engaged with the values and current happenings associated with the pro-democracy movement.

Second, a little more generally, it is possible that social media like Facebook or YouTube may facilitate the development of more other-oriented interest on the part of the people who use them. If the United Way of Chicago or San Francisco can begin to attract tens of thousands of followers to a Facebook page with powerful, current information about the social needs of other Chicagoans or San Franciscans, we can imagine that there might be a rising level of willingness to get engaged in United Way fundraising and community efforts throughout the community. So YouTube and Facebook can become a contemporary alternative to the face-to-face relationships that Durkheim and Tönnies highlighted.

Third, several recent national elections have demonstrated that millions of people are willing to get involved in presidential and congressional campaigns through social media -- including the act of making online political contributions. The success of these efforts since 2006 suggests the faint possibility that online communities may begin to regain some of the pervasiveness that a fragmented television audience has lost. Perhaps this capability for aggregating large numbers of citizens around online communities of political interests suggests that the Internet can begin to help citizens build a broader consensus.

These considerations suggest that social media and the Internet have tendencies in both directions -- fragmentation and agglomeration -- with the result that its overall influence on cohesion may be neutral. In fact, we might speculate that social media enhance small group cohesion while undermining national cohesion.

In short, I'm inclined now to change my vote in the poll. I had supported the idea that the Internet is mildly favorable to increasing social cohesion. I now think that it's a wash, with negative as well as positive tendencies at work at the same time.

Causality and Explanation Conference Call for proposals

Monday, May 02, 2011

CALL FOR ABSTRACTS:CaEitS2011: CAUSALITY AND EXPLANATION IN THE SCIENCES www.caeits2011.ugent.be 19-21 September Faculty of Arts and Philosophy, Ghent University Blandijnberg 2, Ghent, Belgium

This is the sixth conference in the Causality in the Sciences series of conferences. **Organizers**: Phyllis McKay Illari, Federica Russo, Jon Williamson, Erik Weber, Julian Reiss

KEYNOTE SPEAKERS
Henk de Regt, Daniel Little, Michael Strevens, Mauricio Suarez and James Woodward.

INTRODUCTION

Causality and causal inference play a central role in the sciences. Explanation is one of the central goals of scientific research. And scientific explanation requires causal knowledge. At least, these are well-known tenets in present-day philosophy of science.

In this conference, we aim to bring philosophers and scientists together to discuss the relation between causality and explanation.

Even though the view that explanation requires causal knowledge is widespread, some accounts of explanation present themselves as a-causal or even as non-causal. Kitcher's unificationism had it that causal relations are epistemically dependent on explanatory relations, not vice versa. In the mechanistic framework, interlevel explanation is said to be constitutive, not causal. Other accounts of explanation are primarily functional. What is the precise relation between causal and a- or non-causal accounts of explanation?

Relatedly, one of the close relatives of explanation is understanding. But what is the precise relation between explanation and understanding? And what is the role of causation herein?

But wait a minute. There is no consensus as to what causation is. Probabilistic, mechanistic, interventionist, and other accounts are available on the market and it is still an interesting and open question how precisely they relate to each other and how this bears upon the problem of scientific explanation.

Are causality and explanation the same across scientific disciplines? Is causality in physics the same as in psychology? Is causal discovery in biology the same as in economics? And is explanation in geology the same as in chemistry? Mathematics seems to be devoid of causation. Does that mean that it is also devoid of explanation? And is there a place for causation in technological explanation?

Our explanatory practices are partly determined by pragmatic considerations. What precisely do we want to explain, and what do we want to use our explanatory knowledge for? Do these pragmatic considerations influence our search for causal relations? Do they play a role, either implicitly or explicitly, in our algorithms for automated causal discovery (such as algorithms based on causal Bayes nets)?

We welcome contributions addressing these and other questions.

EXAMPLE QUESTIONS

- How is causality related to explanation? Is all explanation causal?
- Which accounts of causality best fit which accounts of explanation?
- Do different sciences demand different notions of causality and explanation?
- Which case studies shed most light on the uses of causality and explanation in the sciences?

TIMETABLE

15 May: deadline for submission of titles and abstracts of papers for presentation

- 500 words
- To be emailed to CaEitS2011@UGent.be
- Please write "ABSTRACT SUBMISSION" in the Subject header of your mail
- A notification of receipt will be sent shortly after 15th May
- All abstracts will be carefully refereed

15 June: notification of acceptance of papers for presentation. 1 July: deadline for registration to attend the conference

- Instructions for registration will be listed on www.caeits2011.ugent.be in due course
- Please also send an email to CaEitS2011@UGent.be to say that you will be attending
  (with "REGISTRATION" in its Subject header)

19-21 September: conference

The drop-out crisis (II)

Thursday, May 05, 2011

We've talked about "wicked problems" before -- problems that involve complex social processes, multiple actors, and murky causal pathways (link, link). A particularly important example of such a problem currently confronting the United States is the high school dropout crisis. The crisis is particularly intense in high-poverty areas, but it is found in all states and all parts of urban, suburban, and rural America. (Here is an earlier discussion of these issues; link.)

The consequences of this crisis are severe. More than a million high school students a year drop out of high school. Over 50% of these dropouts come from fewer than 20% of high schools. These young people have virtually no feasible pathways to a middle class life or a job in the 21st-century economy. And this in turn means a permanent underclass of unemployed or underemployed young people. This in turn has consequences for crime rates, social service budgets, incarceration rates, and a serious productivity gap for our economy as a whole. So the problem is an enormously important one. (The Alliance for Excellent Education is a national organization devoted to tracking this issue; link. Another important resource is Building a Grad Nation ((link) from the America's Promise Alliance.)

Changing this current situation requires change of behavior on the parts of many independent parties -- teenagers, parents, teachers, principals, elected officials, and foundation officers, to name only some of the most obvious participants.

There are many social actors who have an interest in this problem and a commitment to trying to resolve it. Teachers, principals, school boards; mayors and governors; non-profit organizations; foundations; universities and schools of education; citizens' groups -- there are committed and concerned actors throughout the country that are highly motivated to attempt to solve the problem.

But it is very, very hard to marshal these actors into effective attacks on the causes of this crisis. One part of the problem is strategic -- what are the interventions that can work on a large scale? How can a school system introduce changes in behavior and organization that really change the outcomes in a measurable way?

Another part of the problem is a coordination problem. How can we succeed in gaining commitment and cooperation across this range of actors, even if we have some credible strategies at hand? It often seems that every actor has a different theory of the problem, and often it is difficult to gain concerted action across diverse actors. A foundation has one strategy; a school board has a different theory; and the teachers themselves work on the basis of a different understanding of the problem as well. All are well motivated; but there is a clash of efforts.

In this context the Diplomas Now initiative is particularly encouraging. It is focused on a national initiative to target the "drop out factories" through a clear theory of how to create turn-around schools. It is referred to as a civic Marshall Plan. It is based on careful empirical research. It has developed a clear theory about how interventions with children through the schools can impact persistence through graduation. It has mobilized a strategic group of partners -- CityYear, Communities in Schools, and Talent Development at Johns Hopkins. And it has an ambitious and effective national strategy that is already being implemented.

And the most impressive fact is that Diplomas Now is beginning to work. There are DN schools in some of the toughest urban contexts in America; these schools are showing real measurable progress; and the example is spreading to other cities and systems. Concrete evidence of these successes is highlighted by a wide range of committed leaders, academics, and corps members at the CityYear National Leadership Conference in Washington (link).

So maybe we can have some cautious optimism that our wicked problems can be solved, with sufficient commitment and persistence from a range of actors.

Taxes on business

Saturday, May 07, 2011

What is a fair level of taxation for businesses in a state? How much should businesses pay relative to individuals in supporting the services provided by government? How should we even begin to answer this question?

The question is easier for individual taxation, since there are only a few possible alternatives: a flat rate income tax or a graduated income tax; more reliance on income taxes or consumption taxes; a tax system that attempts to shelter the most vulnerable in society or a tax system aimed at stimulating profitability and economic growth, ... For individuals, the fundamental principle is clear: each individual should pay a share of the costs of government based on income, perhaps moderated by a graduated rate.

But with businesses the issues don't seem as clear. Businesses in a state have a clear economic interest in the services provided by government, from fire and police protection, to preservation of the environment, to provision of a skilled and well-educated workforce. Business should pay its fair share in supporting the necessary costs of the state; but what is a fair share? And what is "necessary" when it comes to state services?

The situation is even more complicated when we bear in mind that business activity is itself an important source of good for citizens. More business activity means more employment and income. More jobs and wages mean more demand for services and products of all kinds -- and more income for people employed in those goods and service industries. Business disinvestment leads to significant hardship for citizens. A tax system that discourages business activity is harmful to the economic wellbeing of the state and its citizens. So business tax rates ought to be high enough to support a fair share of the costs of government, but not so high as to discourage business investment.

And the latter point in turn requires comparison with other feasible locations for business activity. If Michigan and Ohio assess business income at significantly different rates, we should expect some flow of investment from one to the other.

The state of Michigan is an interesting current example. Michigan's governor, Rick Snyder, has proposed a major change in the structure of business taxes in the state. He proposes abolishing the Michigan Business Tax, enacted only a few years ago, and replacing it with a 6% corporate income tax that applies only to the largest businesses and corporations in the state. This reform is promoted as one that is needed to simplify the tax obligations of businesses and to improve the business attractiveness of the state for future investment, and it has been welcomed with enthusiasm by the business community. (According the the Tax Foundation's State Business Tax Climate Index, Michigan ranked 17th in 2010 and 2011 in the Tax Climate Index overall and ranked 48th on the corporate tax index, based on the existing Michigan Business Tax; link.)

Often tax reforms are put forward under the banner of "revenue neutrality" -- the rules are changed and simplified, but the "before" and "after" rules collect the same amount of revenue. This reform in Michigan is distinctly **not** revenue-neutral. In 2009 businesses in Michigan paid $2.6 billion under the Michigan Business Tax. Sales taxes collected $8.8 billion, and personal income taxes collected $6.0 billion. (These data are presented in a 2011 report of the Citizen's Research Council in Michigan; link.) In 2013 it is projected that the flat corporate income tax, when fully implemented, will collect only $749 million -- a decline of over 1.2 billion dollars in tax revenues for the state compared to the $2.0 billion estimated under the Michigan Business Tax if applied in that year. (These estimates are provided in a February 17, 2011 report issued by the Michigan government; link.) This amounts to a greater than **60% reduction in the taxes** paid by businesses in support of the general fund. And this shortfall is being addressed in the state's fiscal plan through adjustments in the structure of individual taxes: pensions would be taxed for the first time and Michigan's Earned Income Tax Credit would be abolished. In other words, a billion dollars of tax reductions for business are being paid for by sacrifices by pensioners and poor people.

So here is a question worthy of discussion: are Michigan businesses being asked to pay their fair share under the revised business tax policies? Is 6% enough? Were businesses significantly over-taxed under the Michigan Business Tax? Should the corporate income tax be applied only to the small subset of businesses in the state that qualify, or should it be applied more broadly? And is a 6% corporate tax rate competitive with other states?

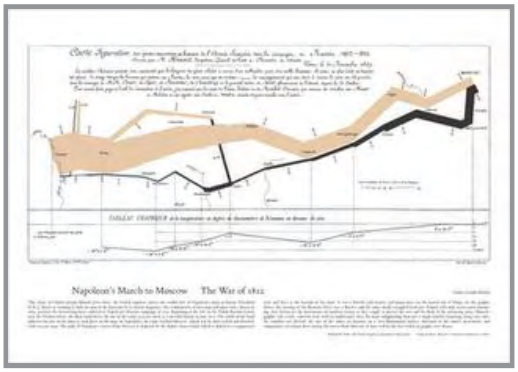
Let's look at the competitiveness question. It is broadly asserted by leading business organizations in Michigan that businesses pay too much taxes for the state to be competitive, and that 6% is about as high as the rate can go without losing investment to other states. But the facts appear to be otherwise. The Tax Foundation provides annual

data on corporate income rates by state (link). Here is the Tax Foundation data, ranked by the highest bracket. (A number of states have a graduated rate, so small businesses pay lower rates.)

State corporate income tax rates (ranked by hightest bracket) source: Tax Foundation http://www.taxfoundation.org/taxdata/show/230.html **StateRatesBrackets(a)Rank** Iowa 12.00% $250K 1 Pa. 9.99% $0 2 D.C. 9.98% 0 3 Minn. 9.80% $0 4 Ill. (c) 9.50% $0 5 Alaska 9.40% $90K 6 N.J. (b) 9.00% $100K 7 R.I. 9.00% 0 8 Maine 8.93% $250K 9 Calif. 8.84% $0 10 Del. (a) 8.70% $0 11 Ind. 8.50% $0 12 N.H. (a) 8.50% $0 13 Vt. 6% 8.50% $25K 14 W.Va. 8.50% $0 15 Md. 8.25% $0 16 Mass. 8.25% $0 17 La. 8.00% $200K 18 Wis. 7.90% 0 19 Nebr. 7.81% $100K 20 Idaho 7.60% $0 21 N.M. 7.60% $1M 22 Ore. 7.60% $250K 23 Conn. 7.50% $0 24 N.Y. 7.10% $0 25 Kans. 7.00% $50K 26 Ariz. 6.97% $0 27 N.C. 6.90% $0 28 Mont. 6.75% $0 29 Ala. 6.50% $0 30 Ark. 6.50% $100K 31 Tenn. 6.50% $0 32 Hawaii 6.40% $100K 33 N.D. 6.40% $50K 34 Mo. 6.25% $0 35 Ga. 6.00% $0 36 Ky. 6.00% $100K 37 Okla. 6.00% $0 38 Va. (a) 6.00% $0 39 Fla. 5.50% $0 40 Miss. 5.00% $10K 41 S.C. 5.00% $0 42 Utah 5.00% $0 43 Colo. 4.63% $0 44 Nev. 0.00% 45 S.D. 0.00% 46 Wash. (a) 0.00% 47 Wyo. 0.00% 48 Mich. (a) Ohio (a) Tex. (a) Note: In addition to regular income taxes, many states impose other taxes on corporations such as gross receipts taxes and franchise taxes. Some states also impose an alternative minimum tax. (a) Michigan, Ohio, Texas, and Washington do not have a corporate income tax but do have a gross receipts tax with rates not strictly comparable to corporate income tax rates. (c) On January 12, 2011, Illinois increased its corporate income tax from 7.3% to 9.5%, retroactive to January 1, 2011. Illinois's rate includes two separate corporate income taxes, one at a 7% rate and one at a 2.5% rate. Source: Tax Foundation; state tax forms and instructions.

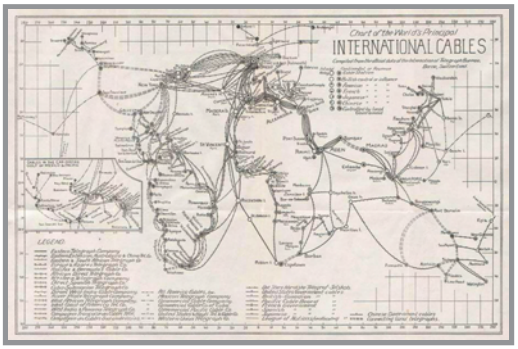
The 6% rate proposed for Michigan falls at the bottom end of this ranking; 35 states have higher rates, extending to 12% in Iowa; four states have a 6% rate; and nine states have a lower rate. It would appear that a 7% or 7.5% rate would still leave Michigan in a competitive position when it comes to the corporate income tax. This would result in an additional $200 million in revenue -- and would permit significant dollars for the Earned Income Tax Credit. So a larger share from business would permit a better outcome for poor and working people.

But the really difficult question is the "fair share" question: how should the costs of government be allocated across individuals and businesses? What principles of equitable contribution are helpful in addressing these issues? And how would we try to judge whether Michigan's corporate tax reform plan results in a fair allocation of the costs of government across individuals and business?

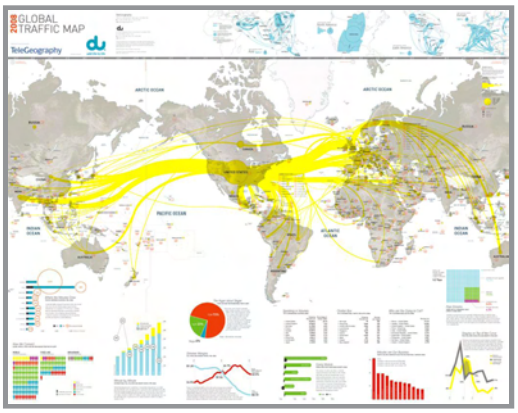


(Here is an interesting post by Donald Barrett and James Steele on "Are Corporations Paying Their Fair Share of Taxes?". In a word -- no!)

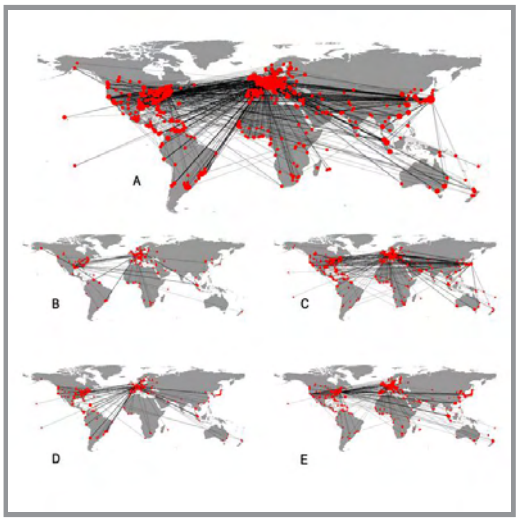
Flood courses of the Mississippi River



Sunday, May 08, 2011



This fantastic map of the historical twists and turns of the Mississippi River near Cairo, Illinois, was drawn in 1944. It is reproduced in the *New York Times* today (link). In an age of digitally produced information displays, it is fascinating to see the density of historical information represented in this hand-drafted map. It is reminiscent of the maps Edward Tufte highlights in The Visual Display of Quantitative Information. Here is Charles Joseph Minard's 1869 map of Napoleon's invasion of Russia that Tufte made famous:



While on the subject of great maps, here is one by George Abel Schreiner in 1924, representing the structure of the world's telegraph cable system (link).

Here is a contemporary graphic representing global Internet flow:

And here is a graph of global cities connections, produced by R. Wall and B. v.d. Knaap in "Sustainability within a World City Network" (link).

What these images have in common is a very simple point: the power of graphical representation to capture complex sets of inter-related data.

Aggregation dynamics

Saturday, May 14, 2011

The social world starts with social individuals. So how do we get more complex social outcomes out of the actions and thoughts of independent individuals? How do the actions and thoughts of individuals aggregate into larger social happenings? How did the various religious, political, and relational attitudes of rural Kenyans aggregate to widespread ethnic violence a few years ago? What sorts of conditions lead to interactions that bring about unexpected outcomes? And, of course, how do larger social happenings impinge upon individuals, leading to characteristic kinds of socialized behavior?

These are questions I've usually addressed from the other angle -- the "dis-aggregation" angle. I've asked how large social entities and processes can be disaggregated into actions and relationships pertaining to socially situated individuals. This is what we're aiming at when we ask for **microfoundations** for things like state power or the changing impact of Islam. Here, though, let's look at the upward-facing processes.

Here are some examples of the kinds of happenings and situations that we might be interested in:

- **collective social behaviors**: riots, uprisings, boycotts, protests, panics, runs on the bank
- **coordinated actions by differentiated but organized groups**: design of a new model vehicle at General Motors, movement of a tank squadron through a battle zone, actions by squads of fire fighters in a large forest fire
- **shifts of valuations and attitudes:** styles, slang, inter-ethnic attitudes, diffusion of religious beliefs, dissemination of rumors through a population
- **preservation of stable organizations and structures:** maintenance of the rules governing shop-floor behavior in a factory, sustaining command authority within a military organization, keeping a sustainable level of parent involvement in a cooperative childcare center, keeping a reasonably high level of taxpayer compliance within a mass society

How do the reasonings, thoughts, and choices of socially situated individuals aggregate and link together in ways that constitute these higher-level phenomena?

Some social outcomes are essentially **agglomerative**. A riot sometimes occurs when a small group of people have a grievance and a provocation; a larger group share sympathy with the original rioters; others see the behavior and join for their own reasons; and in a few hours thousands of people are breaking windows, setting cars on fire, and blocking the streets.

Second, some outcomes are the result of **strategic behavior** by a number of individuals. Competition leads agents to tailor their actions in such a way as to take advantage of the expected behavior of others; cooperation leads individuals to attempt to coordinate their behavior so as to bring about an outcome that the group prefers. These are the kinds of aggregative processes that Thomas Schelling describes in Micromotives and Macrobehavior; and, of course, some of the outcomes of both competitive and cooperative behavior are paradoxical with respect to the interests and intentions of the individuals who take part in them.

Third, some outcomes come about because individuals have constituted themselves as **collective agents**; they have come to identify themselves as members of a group and they behave deliberately out of consideration for what other members in the group will do. Their behavior is oriented to the behavior and intentions of the others in the group. They specifically strive to coordinate their actions with others through a shared set of social goals, identities, and attitudes. Raimo Tuomela explores this perspective in The Philosophy of Sociality: The Shared Point of View.

Other outcomes are largely structured by **imperatives** (rules or commands) conveyed through delineated social relationships from a group of decision makers to a group of agents. This is the key subject matter of the study of organizations and institutions. The Midwest account manager for a national bank issues instructions to loan officers throughout the region to do this or that; communications are sent out, supervisors are instructed to observe compliance, and loan officers change their behavior. This process too works through the incentives and purposes of a set of dispersed agents; but in this case there is a substantial degree of top-down coordination that is secured through communication channels and a supervisory structure.

The dynamics of competition and cooperation are well understood; the ideas of a

prisoners' dilemma, tragedy of the commons, and race to the bottom capture some of the logic of independent individuals each seeking to maximize their own interests (Mancur Olson, The Logic of Collective Action: Public Goods and the Theory of Groups, Thomas Schelling, Micromotives and Macrobehavior). But cooperation too has its logic; even when a group of individuals are seeking to find a common strategy to further their group interests, it is easy to spot the organizational obstacles that stand in the way: lack of consensus, imperfect communication, etc. These are aggregation dynamics that derive from the logic of individual agency.

And the dynamics of organizations and systems of rules likewise have some obvious characteristics. Costs of enforcement mean that an institution's rules are only imperfectly enforced. Conflicts of interests among powerful actors lead to inefficient behavior within the organization (e.g. ministry of steel and ministry of railroads). Well known organizational shortfalls like the principal-agent problem, imperfect and costly communications transmission, and costly information all lead organizations to fail in somewhat predictable ways. Robert Bates (Markets and States in Tropical Africa: The Political Basis of Agricultural Policies) and Charles Perrow (Normal Accidents: Living with High-Risk Technologies, The Next Catastrophe: Reducing Our Vulnerabilities to Natural, Industrial, and Terrorist Disasters) each capture some of the imperfections of organizations in their works. These are aggregation dynamics that derive from more structural features of systems of rules, roles, and actors.

Let's look at an example of an aggregate-level phenomenon a bit more closely. Take style change over space and time. There are several different types of actors: street-level people who wear clothes with some degree of intentionality (want to look cool); street-level innovators (the first person to wear droopy jeans); clothing designers who want to influence the market for clothes through innovations that will be adopted by the public; "cool" finders who are looking for emerging innovations in hot places; marketers who specifically design strategies for proliferating new designs at Banana Republic or Abercrombie and Fitch. In this space of actors, consumers, and creators it sometimes happens that a new fashion emerges and quickly spreads to a larger population; how does this occur? What are the mechanisms of diffusion and adoption that lead to the success of a new look in denim jackets deriving ultimately from Seattle skateboarder culture? Stan Lieberson looks at some of these surprising dynamics in A Matter of Taste: How Names, Fashions, and Culture Change.

I won't try to catalogue here all the pathways through which individual actors aggregate into larger social happenings. But it seems clear that several factors are key to any such discussion: communication channels, organizations, and social networks.

France 1848

Tuesday, May 17, 2011

The revolutions of 1848 have gotten renewed attention in light of this year's "Arab Spring" uprisings. (The amazing photo above depicts the barricades in Paris, 1848.) The parallels are obvious -- uprisings in a number of countries, similar grievances across countries, and a degree of cross-communication among the movements and leaders. And, of course, widespread optimism among progressives and activists about the prospects for fundamental social and political reform. The outcomes of 1848 were discouraging to progressives -- repression and authoritarian governments were usually successful in turning back the progressive tide. So one hopes that the prospects for democracy and equality are better in the MENA uprisings.

Particularly interesting, of course, is the example of France. So it is intriguing to look back at the causes and processes of demonstrations and resistance in May and June, 1848, in Paris and in other parts of the country. Roger Price's Documents on the French Revolution of 1848 (Documents in History Series) is worth reading for a number of reasons. First, it provides an astute analysis of the economic, social, and political situation of France in the first half of the nineteenth century, and the events that unfolded into the revolution of 1848. But second, it is a genuinely interesting book from an historiographical point of view. The analytical text takes up roughly 50 pages of an introductory essay. The remainder of the book consists of short extracts from primary documents of the period. The extracts are selected and ordered according to the author's conception of the factors and turning points that were historically central to the moment; so they constitute a narrative of an unusual kind. Price presents his analysis and framing of the events entirely through the extracts he provides; the participants tell the story.

Price's framing essay begins with the point that France was a backward country in the first part of the nineteenth century, compared to Britain. The population was overwhelmingly rural, the economy was primarily agricultural, and the infrastructure of roads and railroads was underdeveloped. Industry was in the most embryonic state of development, and markets were primarily local because of the weakness of the transport system.

The great weakness of the system, however, lay in its transport infrastructure. Communications by water and, particularly, road were slow and costly. Only the first unconnected lines of the future railway network had been constructed before the 1850s. (12)

And, unlike Britain, there were few signs of an emerging proletariat in large factories and industrial cities, along the lines of the Manchester documented decades earlier by Engels:

The typical French worker would be the artisan working in a small workshop rather than the factory worker. This was true in Paris, for example, where the majority found work in industries catering for the material needs of the population -- food, clothing, furniture and housing -- or in the typically Parisian luxury industries, all traditionally operating on a small scale. (18)

These factors had social consequences. Hunger in the countryside was a recurring possibility. Landlords and gentry had great power over the rural population. Social inequalities in both town and countryside were visible and extreme. And neither peasant nor urban worker had a strong social basis for resistance.

The contrast in the living standards of rich and poor that daily greeted the eyes of the urban populations, especially in the larger towns, was often extreme. For as long as such a contrast was felt to be inevitable, it could be accepted only with resignation, or with a resentment that might burst out in violence. But new ideas and the diffusion of a more critical outlook were bound to erode this attitude. (20)

At the same time as economic inequalities were increasing the power of a small sector of elites was increasing as well.

The grand notables -- landowners, financiers, major industrialists, but also politicians and administrators -- collaborated in extending their economic power and safeguarding their social and political authority. This was a group given unity not simply by shared material interests, but by an entire style of life. (23)

Of course it is clear that this is one particular framing of the historical episode, and another historian would have highlighted other issues and other turning points. So the book doesn't serve as a broad repository of documents, potentially relevant to many different interpretations; instead, the documents have been specifically selected to serve as waypoints on a particular path through Price's interpretation. That said, the documents are fascinating to read, from observations by elite participants, to government announcements, to confessions by activist leaders and followers.

Was this a social revolution? Some of the goals of the activists involved radical social transformation; but these goals were entirely unsuccessful. The balance between the propertied and the property-less did not change in any meaningful way. Was it more successful as a political revolution? Again, not really. Universal suffrage was established before the June repression; but what followed was autocratic rule and eventually the election of yet another dictator, Napoleon III. So it is hard to see that the revolution of 1848 in France had much effect on the conditions of freedom and well-being of the majority of the poor in France.

It would be very interesting to have a similar compilation of documents and framing social descriptions for Egypt, 2011. I'm sure that researchers and observers in Cairo have been collecting interviews, posters, and other kinds of documents that will shed more light on the social and political grievances offered by ordinary Egyptians as they participated in the demonstrations and collective resistance that led to the fall of Mubarak. And, likewise,

it will be valuable to document the timeline of reaction by the state during these crucial several weeks, including repression, accommodation, and eventually capitulation by the ruling circles in favor of -- the army.

Garfinkel on social competence

Thursday, May 19, 2011

Harold Garfinkel made highly original contributions to the field of micro-sociology in the form of his program of ethnomethodology, and the fruits of these contributions have not been fully developed. His death a few weeks ago (link) has led quite a few people to look back and re-assess the importance of his contributions. This renewed attention is very much warranted. Studies in Ethnomethodology (1967) is the primary place where his ideas reached a broad public, so let's take a look at some of the ideas advanced there.

The interest that I take in his work flows from the idea of agent-centered sociology that I've found so appealing -- the idea of the situated actor, the idea that we need to have a substantially richer set of concepts in terms of which to characterize the actor's thought processes, and the idea that current conceptions of the rational actor or the cultural actor are inadequate (link). In order to provide a basis for explanations of social outcomes deriving from the interactions of purposive agents, we need a developed and nuanced set of ideas about how agents tick. And theorists like Garfinkel and Goffman provide substantial resources in this area. (Here are discussions of Goffman; link, link.)

Here is a key statement of Garfinkel's research goals in *Studies in Ethnomethodology*:

The following studies seek to treat practical activities, practical circumstances, and practical sociological reasoning as topics of empirical study, and by paying to the most commonplace activities of daily life the attention usually accorded extraordinary events, seek to learn about them as phenomena in their own right. (1)
A central empirical interest of Garfinkel's is the nuance of the ordinary knowledge -- commonsense knowledge -- that people use to navigate their daily lives and tasks. What presuppositions about actions and motives do jurors rely on as they reach judgments about truth and falsity of testimony? What ellipses occur in ordinary conversations that are nonetheless intelligible to the participants because of unspoken background knowledge? What implicit beliefs and standards do coders for the Los Angeles Suicide Prevention Center use to classify unexpected deaths (11 ff.)?

Here is Garfinkel's explication of a conversation between husband and wife about their son's putting a penny in the parking meter:

An examination of the colloquy reveals the following. (a) There were many matters that the partners understood they were talking about that they did not mention. (b) Many matters that the partners understood were understood on the basis not only of what was actually said but what was left unspoken. (c) Many matters were understood through a process of attending to the temporal series of utterances as documentary evidences of a developing conversation rather than as a string of terms. (d) Matters that the two understood in common were understood only in and through a course of understanding work that consisted of treating an actual linguistic event as "the document of," as "pointing to," as standing on behalf of an underlying pattern of matters that each already supposed to be the matters that the person, by his speaking, could be telling the other about. (39-40)

Garfinkel devised an experimental method for probing presuppositions that he referred to as "breaching" experiments: interactions with subjects that deliberately challenged their conversational or practical expectations. For example, a subject was invited to play the game of tic-tac-toe; and the researcher erased the subject's first move and placed the subject's mark in another location. The subject was incensed. Another example:

My friend said to me, "Hurry or we will be late." I asked him what did he mean by late and from what point of view did it have reference. There was a look of perplexity and cynicism on his face. "Why are you asking me such silly questions? Surely I don't have to explain such a statement. What is wrong with you today? Why should I have to stop to analyze such a statement? Everyone understands my statements and you should be no exception!"

Garfinkel takes the discomfort and irritation expressed by the subjects in these experiments to be an indicator of their expectations about normal social interaction. Here is one of his reflections about this dynamic:

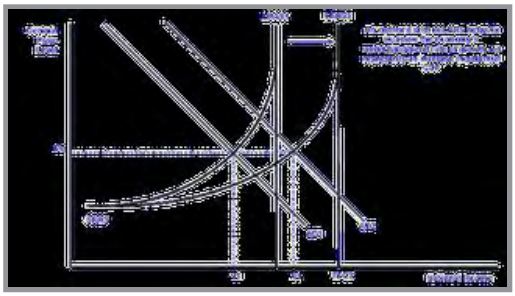
Despite the interest in social affects that prevails in the social sciences, and despite the extensive concern that clinical psychiatry pays them, surprisingly little has been written on the socially structured conditions for their production. The role that a background of common understandings plays in their production, control, and recognition is, however, almost *terra incognita*. (49)

Here is a summary statement of Garfinkel's goals:

I have been arguing that a concern for the nature, production, and recognition of reasonable, realistic, and analyzable actions is not the monopoly of philosophers and professional sociologists. Members of a society are concerned as a matter of course and necessarily with these matters both as features and for the socially managed production of their everyday affairs. The study of common sense knowledge and common sense activities consists of treating as problematic phenomena the actual methods whereby members of a society, doing sociology, lay or professional, make the social structures of everyday activities observable. (75)

The way that I would like to paraphrase Garfinkel's work is that he is offering an empirical research program designed to fill in a rich theory of the human actor's "competence" in engaging in ordinary social interactions. What does the actor need to know about immediate social relationships and practices in order to get along in ordinary social life? And how can we study this question in empirically rigorous ways? The program of ethnomethodology is intended to focus attention on the knowledge of rules and practices

that ordinary people employ to make sense of their social surroundings.



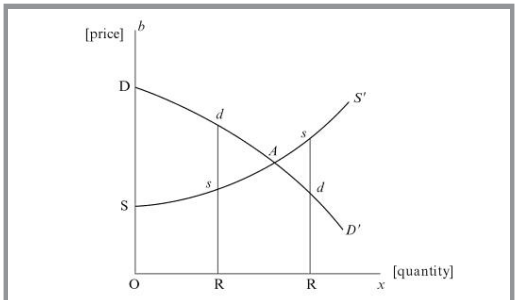
One objection that some purists might offer of this formulation is that it puts the object of investigation "inside the head," rather than in the behavioral performances -- primarily conversations and classificatory tasks -- that Garfinkel primarily studies. It is thought that Garfinkel's method is formal rather than mentalistic. It is true that he says repeatedly that he is not interested in getting inside the head of the individuals he studies. But the logic of his findings still has important implications for the cognitive systems of the individuals, and this is in fact the only reason we would be interested in the research. So I want to understand his research along the lines of a Chomskian linguist: making inferences about psychologically real "competences and capacities" on the basis of analysis of non-mental performances (utterances).

On this approach, Garfinkel did not pretend to offer a full theory of agency or actor consciousness; instead, his work functioned as a sort of specialized investigation of one aspect of social cognition -- the competences, rules, and practices we can attribute to specific actors on the basis of careful analysis of their observable performances.

(John Heritage's Garfinkel and Ethnomethodology is generally recommended as a highly insightful survey and discussion of Garfinkel's work.)

More on figures and diagrams in economics

Sunday, May 22, 2011



Mark Blaug and Peter Lloyd's Famous Figures and Diagrams in Economics is a genuinely interesting perspective on the development of modern economics. Each diagram illustrates a single analytical point; but there is a cumulative logic to the exposition of the various diagrams that reproduces the main turns in the development of modern economic theory. So reading the book cover-to-cover is an excellent way of working through the logic of the discipline. (Here is an earlier post on the book.)

A core question that needs to be addressed in this book is the question of proof: does a good diagram prove a principle or truth of economics? Blaug and Lloyd address this question directly. “The use of figures and diagrams as a vehicle of proof has a chequered history. Mathematicians have always warned of the danger of proving propositions by geometry” (6). The problem, they observe, is that a diagram consists of curves of a particular shape; and there is always the possibility that the result obtains as a consequence of particular and non-generalizable features of the specific curves that are chosen. The authors illustrate this possibility with the law of diminishing returns. “One statement of the Law, the textbook by Stonier and Hague [London: Longmans, 1957] – which was widely used in the UK and elsewhere at that time – contended that the Law of

(everywhere) Diminishing (marginal) Returns holds if the production function is linearly homogeneous. The proof is geometric. But it is false. They had drawn their isoquants as strictly concave from above … and with positive marginal products, without realizing that linear homogeneity plus these assumptions suffice but linear homogeneity alone does not" (6). The authors' suggestion, then, is that the geometrical features of economics diagrams are an unreliable foundation for proving an economics proposition; rather, a formal mathematical derivation with clearly specified axioms and principles is preferable. The diagram serves to illustrate the point; the mathematical proof establishes the point. "Thus algebra has advantages of being more general and more precise" (8).

The authors draw attention to the interesting fact that many of these foundational diagrams were "discovered" multiple times by independent researchers. Following the sociologist of science Robert Merton (The Sociology of Science: Theoretical and Empirical Investigations), they argue that multiple discovery is a very common feature in the history of the sciences (14). They note a number of diagrams in the current volume that have appeared multiple times in the development of economics: "the Slutsky equation, the kinked oligopoly demand curve and monopolistic and imperfect competition" (14). The fact of multiple discovery suggests that some ideas are floating around within the community of researchers before they find expression in writing -- much as natural selection was in the air for scientists like Darwin and Wallace to incorporate into their pathbreaking books on evolution in the mid-nineteenth century.

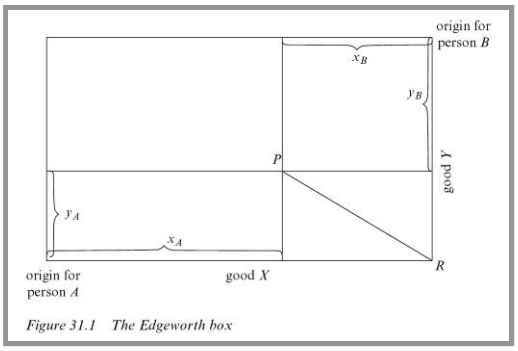
It is worth considering several diagrams in particular here. In his article on "Marshallian cross diagrams" Thomas M. Humphrey describes the history and logic of what is arguably the most fundamental of economic diagrams in neoclassical economics, the intersecting curves of supply and demand by price. "The diagram achieves much with little. It illustrates how parametric shifts in its two curves caused by changes in tastes, incomes, technology, factor prices and prices of related goods operate to alter a good's equilibrium price and quantity…. For all its simplicity, it is a powerful and flexible tool" (29). Humphrey notes that the diagram did not originate with Marshall. Instead, Cournot was the first to represent a supply-price diagram for a single good in 1838. Humphrey notes further that a German economist, Hans von Mangoldt, introduced formally similar diagrams into his economics work in 1863, evidently without influence from Cournot. All told, he finds five figures in the history of economic thought who made use of this schema, almost always without influence from one to the other. "Had [Marshall] never published, later economists probably would have discovered the work of his predecessors or invented the diagram themselves" (36).

Source: Marshall, *The Pure Theory of Foreign Trade*, p.16, fig. 22a, http://socserv2.mcmaster.ca/~econ/ugcm/3113/marshall/foreigntrade.pdf

Figure 1.1 Marshall's diagram

A second fundamental diagram is the Edgeworth box (1881), with an entry by John

Creedy to explain the logic and history of this influential contribution to welfare economics (233). The Edgeworth box models the behavior of price-taking utility maximizers who barter two goods with each other, and allows discovery of the contract curve defined by the shape of the indifference curves of the two traders. The points within the box represent the quantities of each of two goods that the two actors hold. Each individual has a set of indifference curves through the space of quantities of the two goods: individual A is indifferent between one allocation with more of X and less of Y, and another allocation with less of X and more of Y. The box diagram is provided as a way of analyzing the conditions of barter between two persons and two goods. “The contract curve is the locus of points of tangency between traders’ indifference curves” (233). Creedy situates the importance of the Edgeworth box in terms of this important result: “a price-taking equilibrium is Pareto-efficient” (237). In other words, at this point it is not possible to make one person better off without making the other person worse off. This is referred to as the “First Fundamental Theorem” of welfare economics. “Edgeworth was thus able to clarify the sense in which a competitive equilibrium is ‘optimal’, fully recognizing that it is just one of many (Pareto) optimal points” (233). Creedy explicates the idea of equilibrium in these terms: “Equilibrium is a situation in which no individual’s plans are frustrated, that is where there are no excess demands or supplies. In the present context this must imply that both individuals plan to consume at precisely the same point in the Edgeworth box” (236). (Here is a Youtube video explaining the Edgeworth box.)



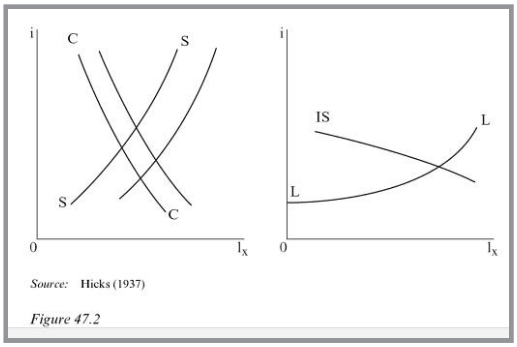


Figure 31.1 The Edgeworth box

Now consider a fundamental diagram in macroeconomics, the IS-LM diagram deriving from John Hicks’ work in 1936 and 1937. The diagram (or series of diagrams) serves as an important step in the effort to make rigorous economic sense of Keynes’s theory of money and capital. Warren Young provides an article on this topic (348). This diagram is often regarded as a crucial contribution to the assessment and interpretation of Keynesian economics. The diagram is designed to analyze the relationship between capital investment, savings, liquidity, and the interest rate. Young’s article is more developmental than most contributions to the volume, in that he attempts to track the development of Hicks’ concept through several important stages in 1936 and 1937. Alvin Hansen built on Hicks’ 1937 IS-LL diagram by introducing the IS-LM diagram in 1949. Hansen also introduced consumption into the representation. Young concludes that “the plasticity of the approach and its extension into augmented forms has enabled the diagram to become the basis for more sophisticated diagrammatic approaches such as AS-AD, which even include endogenous (rational) expectations, thus making the approach more acceptable to those of non-Keynesian predilection” (354).

Source: Hicks (1937)

Figure 47.2

One persistent impression that emerges from the discussion of most of the figures and diagrams in the book is that economic theory is often an area of pure mathematics, not an empirical investigation of human behavior. It is a precise, rigorous and mathematical exploration of the mathematical implications of a set of assumptions about rational consumer and producer behavior. There is no empirical content in many of these theories whatsoever. This part of modern economics, anyway, looks more like Euclidean geometry than natural history. This feature raises the important question of the empirical status of economics: is it an empirically-based science describing and explaining human behavior, or is it largely a formal exploration of certain mathematical premises about "rationality"? (Or, perhaps most plausibly, it is both, with more empirical studies being located in specific sub-disciplines such as development economics and consumer economics.)

It is also interesting to consider whether the use of diagrams and figures is as intellectually and theoretically important in other areas of the sciences. There are iconic diagrams in physics, biology, and psychology; but it does not appear that these devices played as important a role in those areas of the sciences as they have done in economics. And it is plain that diagrams and figures do not play anything like this role in other areas of the social sciences, including political science and sociology.

Practical mentality

Friday, May 27, 2011

How should we try to characterize the mental processes of the real human actor as he or she proceeds through life activity? One individual decides to stop by a retirement home to visit an elderly friend; another individual breaks into a car to steal a briefcase; another has an argument with her boss and decides to quit her job. What sorts of thinking go into these choices and innumerable others?

These are all actions that are to some extent deliberate and considered; and yet they are also complicated responses to shifting circumstances and events that have prudential and emotional meanings to the actors in question. Here I'm not asking the question, "What sorts of factors motivate people, and how do they process their motivations?", though these are interesting and important questions. Rather, I'm asking a more basic question: what categories and concepts should we use in attempting to analyze deliberate action in the first place? What features of mental experience need to be highlighted? Should we expect there to be a best framework of analysis of the components of practical mentality? Or is this fated always to be an open question?

Think of the range of vocabulary that is relevant to our discourse about the kinds of

examples mentioned above: decision, belief, desire, emotion, fear, habit, norm, obligation, reason, impulse, weakness of will .... These terms and others constitute something like a mental ontology, a set of concepts that we attribute to the agent as he/she acts. And some of them bring presuppositions that are debatable. Take "decision," for example. Did the thief "decide" to break into the car? Or was the action an impulse, prior to thought and deliberation?

Here is one way of approaching the issue. What are the questions we would like to answer about the human actor?

- What motivated the action?
- What was the actor thinking?
- What was the actor feeling?
- What beliefs were highlighted in the actor's conscious thoughts?
- What memories played a role in the actor's decision?
- What rules of thumb did the actor make use of?
- What emotional stream occurred?
- How did the actor process emotions?
- What scripts were salient?
- What unconscious biases and impulses were operative?

Our ordinary "folk psychology" provides a range of simple theories available of the agent's mentality.

- Desire-belief-opportunity
- Emotion-dynamics of psychology-action
- Habit/practice-context-performance
- Environment scan-rules of thumb-action

And we might incorporate all these factors into a large composite model: desires, beliefs, habits, emotions, past experience, and moral conviction all play a role. But the key point is this: we need to have richer modes of representation of consciousness and agency than we currently have. Further, it seems that novelists like James Joyce or Henry James do as good a job of conceptualizing these processes as any philosopher has done.

One influential set of ideas on this question of practical agency is that offered by Pierre Bourdieu in his theory of "habitus". Here is how he describes action and habitus in Outline of a Theory of Practice (1972):

The habitus, the durably installed generative principle of regulated improvisations, produces practices which tend to reproduce the regularities immanent in the objective conditions of the production of their generative principle, while adjusting to the demands inscribed as objective potentialities in the situation, as defined by the cognitive and motivating structures making up the habitus. (78)

In practice, it is the habitus, history turned into nature, i.e. denied as such, which accomplishes practically the relating of these two systems of relations, in and through the production of practice. (78)

What I understand by this concept is a more fluid conception of thinking-experiencing-doing on Bourdieu's part than is characteristic of a more Aristotelian conception. There is a suggestion of a sort of tacit knowledge underlying activity, with action looking as much like the smooth, intelligent motions of a soccer player as a deliberative chess master. It is a less epistemic view of the human condition -- less a concoction of explicit beliefs and reasonings than a smooth coordination of tacit understandings and movements in the situation. It is less about deliberation and decision and more about intelligent doing.

This interpretation is born out in a cryptic passage a page or so later:

If witticisms surprise their author no less than their audience, and impress as much by their retrospective necessity as by their novelty, the reason is that the *trouvaille* appears as the simple unearthing, at once accidental and irresistible, of a buried possibility. It is because subjects do not, strictly speaking, know what they are doing that what they do has more meaning than they know. (79)

There are many uncertainties about how to think about this most intimate of human facts -- the ways our thoughts process our needs and movements. And it seems to me that the choice of ontology surrounding action -- the concepts and entities we use -- is important and difficult, and worthy of careful attention.

Philosophy of social science today

Monday, May 30, 2011

A sign of arrival for a sub-discipline is the appearance of a handbook for the field. By that criterion, the philosophy of social science has passed an important threshold with the appearance of Ian Jarvie and Jesus Zamora-Bonilla's SAGE Handbook of the Philosophy of Social Sciences. The 750-page volume offers 37 main articles, as well as an extensive reflective introduction by Ian Jarvie and an epilogue by Jesus Zamora-Bonilla. A majority of the contributors are European, confirming an impression that the most active research networks in this field are currently in Western Europe. Germany and the Scandinavian countries are particularly well represented.

Ian Jarvie's extensive introduction does a good job of setting the stage for the volume. He is in a unique position to offer this perspective, having served as editor of the key journal *Philosophy of the Social Sciences* for many years. He begins by noting the heterogeneity of the field:

As a set of problems, the philosophy of the social sciences is wide-ranging, untidy, inter-disciplinary and constantly being reconfigured in response to new problems thrown up by developments in the social sciences; in short, disorderly. (1)

The orientation to the philosophy of social science represented in this volume is largely grounded in the analytic philosophy tradition. By this I mean an emphasis on rationality,

an interest in generalizations and laws, a commitment to empirical methods of inquiry, and an over-arching preference for conceptual clarity. (Paul Roth describes the analytic approach in his contribution to the volume; 103ff.) But David Teira also offers an interesting contribution on "Continental Philosophies of the Social Sciences." He begins the article by writing,

In my view, there is no such thing as a continental philosophy of the social sciences. There is, at least, no consensual definition of what is precisely *continental* in any philosophical approach. (81)

Among these approaches he highlights Marxist, phenomenological and Foucauldian philosophies and theories of the social sciences. His finding is one that I agree with -- that one of the particularly valuable aspects of the continental traditions is the fact that thinkers in this tradition have offered large, insightful conceptual schemes for thinking about social life -- whether historical materialism, ethnomethodology, or the rhetoric of power. He writes, "I guess that if continental philosophies seem attractive to many social scientists, it is because they offer the prospect of a somewhat radical reconstruction of current research practices" (96).

Particularly interesting for me were contributions by Alban Bouvier ("Individualism, Collective Agency and The "Micro-Macro Relation"), Daniel Steel ("Causality, Causal Models, and Social Mechanisms"), Joan de Marti and Yves Zenou ("Social Networks"), Peter Hedstrom and Petri Ylikoski ("Analytical Sociology"), Chris Mantzavinos ("Institutions"), and Jeroen Van Bouwel and Erik Weber ("Explanation in the Social Sciences").

What is particularly valuable in this collection is the fact that most of the essays are not dogmatic in their adherence to a "school" of philosophical thought. Instead, they get down to the serious business of understanding the social world, and understanding what is involved in achieving a scientific understanding of that world. Chris Mantzavinos's essay, "Institutions," is a good example of this intellectual pragmatism. His contribution is a careful study of the new institutionalism and the variety of theoretical challenges that the concept of an institution raises. The essay is very well grounded in the current sociology and political science literatures on institutions, and it goes on to make substantively interesting points about these debates. "Only a theory of institutions that increases our information about the structure of social reality can provide us with the means of reorienting this reality in a direction that we find desirable" (408-9).

Many of the contributors -- probably the majority -- have taken seriously what I think is a particularly fundamental requirement for productive work in the philosophy of an area of science. This is the need for the philosopher to take up the particular theories and controversies of some current research in the social sciences as a framework and stimulus to their philosophical analysis. The philosopher needs to gain a significant level of expertise in a particular field of social science if his or her work is likely to find traction with conceptual issues that really matter. The topics for the philosophy of social science should not derive from apriori speculation about society; instead, they should be selected on the basis of careful engagement with serious empirical and theoretical attempts to explain the social world.

This is the kind of book that would benefit from a simultaneous digital edition. An affordable Kindle edition would help; but more radically, an online, hypertexted and cross-linked version would be fantastic. It would be fascinating to see a concept map linking the articles by theme or keyword; it would be illuminating to see some analysis of the patterns of citation across the articles in the volume; and it would be great for the reader to be able to click to some of the references directly. (Jarvie provides something like a map of themes in his tables representing "Principal Problems in Philosophy of the Social Sciences" and "Problematics in 14 Selected Anthologies"; 7-8.)

Making structures

Wednesday, June 01, 2011

John Levi Martin's Social Structures (2009) takes an innovative approach to the question, "where do structures come from?" His approach is aggregative: he wants to see how institutions and structures accrete from features of individual relationships. (Here is an earlier post on Aggregation Dynamics.) He writes in the Preface:

More generally, the structures we see around us -- up to and including the state organizations that first inspired analogies to organismic structures -- in most cases also developed from smaller components. These components in turn may be residues of a shattered former large-scale structure, or, more interestingly, they may have been generated from even smaller units, namely interpersonal relationships. Could we reconstruct the process, at least analytically, whereby individual relationships combine to form structural units, and these structural units then aggregate to form large-scale structures? (kindle loc 71)

This book is thus an attempt to begin an analysis of the structural tendencies inherent in certain forms of relationships, and their eventual consequences up to and including some of the structures that first impressed Spencer and the other organismic thinkers. (kindle loc 113)

There is a cumulative logic to L-M's account of structures, from local (cliques, pecking orders) to meso (patron-client systems, serfdom) to macro (command army, political party). In this way L-M attempts to deliver on the promise of giving an aggregative account of social structures at every level, stemming from patterns of individual interaction. Like Thomas Schelling, he wants to show how important features of macro social structures emerge from features of individual agency and interaction; and further, he wants to derive some of the dynamic properties of these higher-level configurations.

Here is how Levi Martin characterizes an institution:

An institution exists when interactants subjectively understand the formal pattern in terms of the *content* of the relationships. (kl 167)

In other words, an institution (in this sense, anyway), codifies and formalizes individual relationships, with a recursive effect backwards onto the participants. He illustrates this concept through a brief discussion of "marriage" as an institution. "This content my be seen as the translation of the formal characteristics of marriage as a set of dyads into a subjective sense of what marriage 'is all about': trust, commitment, exclusivity, and so on" (kl 167).

This is a somewhat atypical conception of institutions. His conception of social structure is also somewhat unique:

To preserve such a distinct sense of "structure," I propose that we begin by considering social structure simply as regular patterns of interaction, and leave to the side the question of why these patterns exist. (kl 248)

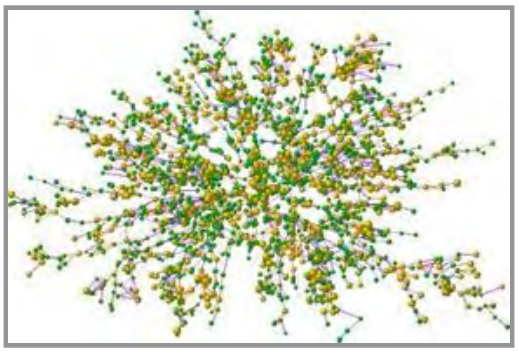
Here the operative words are *patterns* and *interactions*: interactions invoke particular human relationships, and patterns invoke the idea of a level of intra-social similarity among some kinds of interactions and relationships.

Levi Martin's approach takes inspiration from Simmel's idea that social structures are the

"crystallization" of individual social interactions (kl 127). In its most abstract version, Levi Martin wants to discover the topologies of relationships that are implied by certain kinds of social interactions -- friendship, marriage, fealty, dominance. These relationships have formal properties such as symmetry, equality, and transitivity and their opposites that have topological implications for the aggregates of individuals bearing these relationships. L-M demonstrates that the agglomerates begin to look like identifiable social arrangements -- cliques, patron-client systems, and mass political parties.

This part of the theory is formal and mathematical. What is particularly original here is L-M's ability to conjoin this style of analysis with detailed historical examples exemplifying the emergence of the type of social structure hypothesized by the formal analysis. The abstract logic of a command army is exemplified by a careful analysis of the organization of the Roman and American armies and the imperatives of coordination and effectiveness in conflict that led to these organizational features.

In short, both empirically and methodologically, this is a pathbreaking book that repays close attention.



Aggregation dynamics of conditional psychological dispositions

Sunday, June 05, 2011

We can use computational modeling techniques to aggregate individual behavior into collective patterns. A simple version of this is Thomas Schelling's segregation model (Micromotives and Macrobehavior).

Most commonly these tools have been used to model the results of rational choices by the actors involved, often using the tools of game theory. But the approach is more general; any common behavioral feature at the individual level can be aggregated through similar modeling techniques as well if we can specify our assumptions about conditionality plausibly.

Here is a hypothetical example illustrating the feasibility of modeling non-rational social dynamics. Suppose individuals have a social behavior disposition that is variable depending on the behaviors of other individuals in their acquaintance spaces. Examples might include: cooperative behavior, racist behavior and intolerance, abuse against women, or philanthropy. Assume individuals exist in an extended social graph of "acquaintance", so each has a specific list of immediate acquaintances (for example along the lines of the Framingham Heart Study graph below). And assume a contagion rate: the probability of switching when one acquaintance switches is p, the probability of switching when two acquaintances switch is p', and so forth.

Now we are in a position to do some interesting modeling based on recursive calculation of each individual's state based on the states of individuals within his/her acquaintance space. (This is analogous to Schelling's segregation model.) Calculate each individual's state based on the states of his/her acquaintances in the previous iteration. And run this recalculation through the whole population as many iterations as you like. The series of full iterations will represent moments in time as this dynamic system moves to a new equilibrium. Each represents a frame in an animation of the spread of intolerance through the population. (It should be possible to embody this simulation in a spreadsheet. Models like these are sometimes referred to as cellular automata.)

Now we can do a number of interesting things. We can observe the spread of racist attitudes and behavior. We can introduce disturbances in various parts of the graph and observe the transmission process. We may be able to document path dependency: perhaps it matters where the disturbance occurs.

After performing a large number of iterations, four large possibilities exist: everyone intolerant, everyone tolerant, stable neighborhoods within the graph of tolerance and intolerance, and no equilibrium at all.

(Actually, based on the assumptions outlined so far, it is inevitable that the graph will eventually go 100% "infected" with intolerance, since there is no recovery mechanism at the individual level. So we would probably want to incorporate some influence that turns individuals from intolerant to tolerant once in a while. We could also introduce more complexity into the model by postulating multiple states for the actor -- perhaps high, moderate, low intolerance. Individuals moving up or down the scale could infect their neighbors in the same direction. And we might attribute different infection rates to different individuals, to see how this affects the outcome.)

This example also creates the possibility of strategic intervention by outsiders: knowing how these dynamics work affords both the state and activist organizations to undertake actions designed to alter the outcome by strategically "seeding" the graph with intolerant individuals. Racist anti-immigrant organizations in western Europe appear to be doing exactly this at present.

If actors are wired this way (i.e. their social dispositions are a function of those of the individuals in their acquaintance space), then racism, philanthropy, and violence against women will behave like a communicable disease and the tools of social epidemiology will be applicable. And the consequences are great: some societies will have a stable anti-racist population and others the opposite, depending on contingent events, the nature of the network, and deliberate actions and policies.

This example is framed in terms of behavioral dispositions of social psychology. But it is equally pertinent to any individual characteristic that is variable in response to social contacts: slang, manners, social perception, ... Any psychological, cognitive, or emotional state with behavioral consequences that is responsive to context in this way is amenable to the same kind of modeling.

This is an example of social aggregation dynamics that is not grounded in strategic rationality but rather in features of conditionalized social psychology. The example is fully compatible with the requirement that macro-outcomes need to be explained on the basis of mechanisms with microfoundations. And it does not depend on the assumptions of rational actor theory or game theory.

Abbott on mechanisms

Monday, June 06, 2011

Peter Hedstrom and Richard Swedberg's Social Mechanisms: An Analytical Approach to Social Theory (1998) announced to the world the power of social mechanisms as a foundation for social explanations. It was based on a conference on this approach in Stockholm in 1996, and the volume includes contributions by outstanding authorities such as Thomas Schelling, Jon Elster, Aage Sorensen, and Arthur Stinchcombe (among others).

One person whom it does not include is Andrew Abbott. Abbott did indeed participate in the conference, but his contribution was not included in the volume when it appeared in 1998. The article did appear subsequently, however, in a special volume of *Sociologica* in 2007, with discussions by Delia Baldassarri, Gianluca Manzo, and Tommaso Vitale. (Here is a link to Abbott's essay and to his reply to discussants.) And the whole debate is worth reading. Abbott's piece is a serious challenge to the ontology of mechanisms. And each of the discussants in the *Sociologica* volume bring important criticisms and perspectives to the table.

Essentially Abbott takes issue with the mechanisms approach because it attempts to analyze the social world into fixed "atoms" of causal events (mechanisms and actors) rather than a more contextual ontology of relations and actions.

I shall consider the mechanisms movement from the viewpoint of a different theoretical tradition, one that focuses on the processual and relational character of social life and that traces its roots to pragmatism. (2)

By the relational view I mean the notion that the meaning of an action is comprehensible only when it is situated in social time and place. A fundamental assumption of the mechanism view as set out here is that the meaning of a certain activity is given in itself. By contrast, the relational view assumes that the meaning of an action arises from its relations to other actions – both temporally, as a successor and a forerunner in coherent sequences of social events, and structurally, as a vertex in a synchronic ensemble of actions. Beneath this lies a more profound assumption that actions, not actors, are the primitives of the social process. The substratum of social life is interaction, not biological individuals who act. (7)
Abbott agrees with the CM approach in its rejection of a positivist search for statistical regularities among social characteristics -- what he refers to as the variables paradigm --

but he isn't persuaded by the ontology of mechanisms. He prefers actions to actors, and he prefers relationships linked to their contexts in time and place to portable mechanisms.

The most important part of Abbott's article is his positive argument for the primacy of a relational approach and actions-in-context instead of unitary actors. Much of this line of thought comes down to Abbott's view that actors and agency are deeply socially constructed; so it doesn't make sense to take the actor as a given who then deliberates about options.

Making interaction primitive makes it possible to give an account of the self. By making the self be continuously recreated in the flow of interaction we bring it out of the realm of assumptions and into that of investigation. At the same time, by making interaction primitive we allow for the endless interplay of cross-individual structural definitions of the flow of action, an interplay that is an evident fact in social life. (8)

For the relational account defines an act as a making of relations within a scene.... Social actors are cobbled together by actions that turn existing potential boundaries into actual ones. (9)

I am arguing the stronger point that the acting self is continuously remade in interaction and that the environment of possible endowments and contrasts--the environment of others and past experiences--provides the ground whence comes this remaking. (12)
Another central thrust of Abbott's critique of the mechanism approach is that it is "reductionist" and depends on a rational-choice model of the actor. Essentially his line of argument is this: the mechanism approach requires microfoundations for macro-causal mechanisms; microfoundations presuppose rational actors; and therefore macro-facts are being reduced to facts about rational individuals. Each of these links is debatable, however, and in fact several of the discussants in the *Sociologica* volume question each of them. Essentially, many advocates of microfoundations (including me) insist on a richer theory of the actor than narrow economic rationality. And others -- for example, Dave Elder-Vass -- maintain that microfoundations don't imply reductionism either. (He prefers the idea of supervenience; I prefer explanatory autonomy; link.)

Delia Baldassarri highlights this issue in her comment, when she talks about the strengths and weaknesses of methodological individualism:

This approach has been quite successful in explaining "macro-phenomena that are emergent effects of the interdependent but uncoordinated actions of many individuals" [Mayntz 2004, 250]. The same approach has been less effective, however, in accounting for dynamics of identity construction, interest formation, boundary definition and institutional change, and in general, for social processes where macro-level states cannot be considered as given. (2)
Gianluca Manzo's comment is the most extensive of the three in the *Sociologica* volume. His careful assessment leads him to conclude that Abbott overstates the incompatibility between "mechanisms" and "relations," and overstates as well the degree to which the analytical sociology perspective is "reductionist". Manzo advocates for what he calls "complex methodological individualism", and concludes that:

The "relational sociology" that Abbott defends is inconceivable without the "mechanismal sociology" (AS) he critiques.
One feature of Abbott's article gives it its own particular relationality: he illustrates his

meaning by describing a prolonged disagreement he had as a dean with the president of the University of Chicago over admissions recruitment strategies. His point, seemingly, is that the strategy chosen by the president presumes a rational-actor theory of college choice, and it further misunderstands the true priorities and considerations that motivate prospective UC students.

More important, we might phrase the difference by saying that the relational model is interested in how a student becomes a person who matriculates at the University of Chicago. (15)
The inference: if UC is to continue to recruit the edgy, intellectual and quirky undergraduates it has been famous for, it will need to have a more nuanced understanding of the whole process. Or in the context of mechanisms versus relations: it won't do to think a marketing can pull the lever on a strategy (mechanism) and expect to get the desired result. Rather, we need a more contextualized and relational approach. There is no recipe of mechanisms -- grounded, moreover, in a rational expectations theory -- that will do the job. Instead, Abbott advises a relational, processual approach to college marketing: figure out the kinds of identities the desired segment of high school students are trying to make for themselves, and construct a series of experiences around that.

In many ways I find Abbott's essay more original than several in the original Hedstrom-Swedberg volume. So it's unfortunate that it wasn't included. It could have influenced the subsequent discussions very fruitfully.

Readers will also be interested in a recent collection edited by Pierre Demeulenaere that serves as a valuable follow-on to the original Hedstrom-Swedberg volume, Analytical Sociology and Social Mechanisms. It includes a piece by a German philosopher and sociologist whose work on this subject I admire, Michael Schmid, as well as contributions from Dan Sperber, Raymond Bouton, Jon Elster, Robert Sampson, and others. Schmid's *Die Logik mechanismischer Erklarungen* (2006) isn't available in English, which is unfortunate. The causal mechanisms approach has been picked up internationally, including an interesting book on the subject by the Italian sociologist Filippo Barbera (*Meccanismi Sociali; Elementi di sociologia analitica*; 2004).

Dissecting the social

Thursday, June 09, 2011

The past dozen years or so have witnessed the emergence of a distinctive approach to

the social sciences that its practitioners refer to as "analytical sociology." Peter Hedström's Dissecting the Social: On the Principles of Analytical Sociology (2005) serves as a manifesto for the approach, and Pierre Demeulenaere, ed., Analytical Sociology and Social Mechanisms, and Peter Hedström and Peter Bearman, eds., The Oxford Handbook of Analytical Sociology provide substantive foundations for several areas of research within this approach. And the European Network of Analytical Sociologists provides an institutional framework within which research approaches and findings can be shared (link).

Hedström describes the analytical sociology approach in these terms:

Although the term analytical sociology is not commonly used, the type of sociology designated by the term has an important history that can be traced back to the works of late nineteenth- and early twentieth-century sociologists such as Max Weber and Alexis de Tocqueville, and to prominent mid-twentieth-century sociologists such as the early Talcott Parsons and Robert K. Merton. Among contemporary social scientists, four in particular have profoundly influenced the analytical approach. They are Jon Elster, Raymond Boudon, Thomas Schelling and James Coleman. (kl 113)

One important characteristic of the analytical approach is that it aims to gain understanding by dissecting the social phenomena to be explained. To dissect, as the term is used here, is to decompose a complex totality into its constituent entities and activities and then to bring into focus what is believed to be its most essential elements. (kl 65)
And here is how Hedström and Bearman describe the approach in the *Handbook*:

Analytical sociology is concerned first and foremost with explaining important social facts such as network structures, patterns of residential segregation, typical beliefs, cultural tastes, common ways of acting, and so forth. It explains such facts not merely by relating them to other social facts -- an exercise that does not provide an explanation -- but by detailing in clear and precise ways the mechanisms through which the social facts under consideration are brought about. In short, analytical sociology is a strategy for understanding the social world. (3-4)

Two interrelated aspects are of particular importance: the explanatory principles guiding the approach and the type of explanatory factors being evoked. Analytical sociology explains by detailing mechanisms through which social facts are brought about, and these mechanisms invariably refer to individuals' actions and the relations that link actors to one another. (4)
In my assessment, AS rests on three central ideas.

First, there is the idea that social outcomes need to be explained on the basis of the actions of individuals. This position is referred to variously as methodological individualism, methodological localism, or microfoundationalism. It is often illustrated by reference to "Coleman's Boat" in James Coleman, Foundations of Social Theory (1994:8) describing the relationship that ought to exist between macro and micro social phenomena:

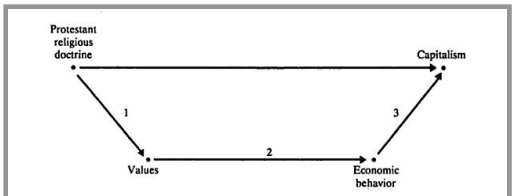


Figure 1.2 Macro- and micro-level propositions: effects of religious doctrine on economic organization.

The diagram indicates the relationship between macro-factors (Protestant religious doctrine, capitalism) and the micro factors that underlie their causal relation (values, economic behavior). Here are a few of Hedström's formulations of this ontological position:

In sociological inquiries, however, the core entity always tends to be the actors in the social system being analyzed, and the core activity tends to be the actions of these actors. (kl 106)

To be explanatory a theory must specify the set of causal mechanisms that are likely to have brought about the change, and this requires one to demonstrate how macro states at one point in time influence individuals' actions, and how these actions bring about new macro states at a later point in time. (kl 143)
Further, Hedström is drawn to a broad version of rational-choice theory -- what he calls the "Desire-Belief-Opportunity theory".

Desires (D), beliefs (B) and opportunities (O) are the primary theoretical terms upon which the analysis of action and interaction will be based. ... The desires, beliefs and opportunities of an actor are here seen as the proximate causes of the actor's action. (kl 507)
This is a variant of rational choice theory, because the actor's choice is interpreted along these lines: given the desires the actor possesses, given the beliefs he/she has about the environment of choice, and given the opportunities he/she confronts, action A is a sensible way of satisfying the desires. It is worth pointing out that it is possible to be microfoundationalist about macro outcomes while not assuming that individual actions are driven by rational calculations. Microfoundationalism is distinct from the assumption of individual rationality.

Second is the idea that social actors are socially situated and socially constructed; the values, perceptions, emotions, and modes of reasoning of the actor are influenced by social institutions, and their current behavior is constrained and incented by existing institutions. (This position has a lot in common with the methodological localism that I've defended.) Practitioners of analytical sociology are not reductionist about social behavior, at least in the way that economists tend to be; they want to leave room conceptually for the observation that social structures and norms influence individual behavior and that individuals are not unadorned utility maximizers. (Gary Becker's effort to explain much of social life on the basis of the premise of maximizing utility is an example of the reductionist tendency of purist rational choice theory; Uncommon Sense: Economic Insights, from Marriage to Terrorism.) In the Hedström-Bearman introduction to the *Handbook* they put the point this way:
Structural individualism is a methodological doctrine according to which social facts should be explained as the intended or unintended outcomes of individuals' actions. Structural individualism differs from traditional methodological individualism in attributing

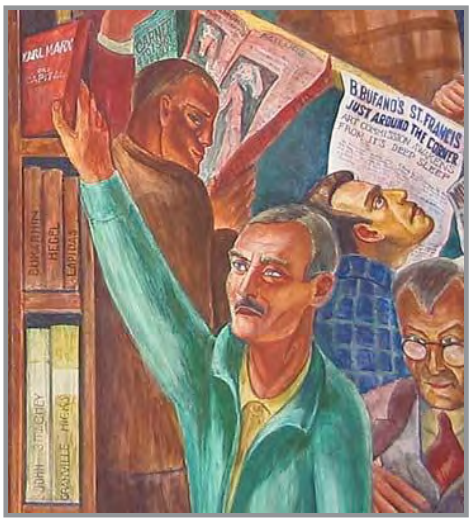
substantial explanatory importance to the social structures in which individuals are embedded. (4)

This is a direction of thought that is not well advanced within analytical sociology, but would repay further research. There is no reason why a microfoundational approach should not take seriously the causal dynamics of identity formation and the formation of the individual's cognitive, practical, and emotional frameworks. These are relevant to behavior, and they are plainly driven by concrete social processes and institutions.

Third, and most distinctive, is the idea that social explanations need to be grounded in a hypothesis about the concrete social causal mechanisms that constitute the causal connection between one event and another. Mechanisms rather than regularities or necessary/sufficient conditions provide the fundamental grounding of causal relations and need to be at the center of causal research. (This is a position developed and discussed many times in this blog; thread.) This approach has several intellectual foundations, but one is the tradition of critical realism and some of the ideas developed by Roy Bhaskar (A Realist Theory of Science). Hedström advocates for a theory of causal explanation that is grounded in the idea of a causal mechanism:

The position taken here, rather, is that mechanism-based explanations are the most appropriate type of explanations for the social sciences. The core idea behind the mechanism approach is that we explain a social phenomenon by referring to a constellation of entities and activities, typically actors and their actions, that are linked to one another in such a way that they regularly bring about the type of phenomenon we seek to explain. (kl 65)

A social mechanism, as defined here, is a constellation of entities and activities that are linked to one another in such a way that they regularly bring about a particular type of outcome. (kl 181)



In addition to these three orienting frameworks for analytical sociology, there is a fourth characteristic that should be mentioned. This is the idea that the tools of computer-based simulation of the aggregate consequences of individual behavior can be a very powerful tool for sociological research and explanation. So the tools of agent-based modeling and other simulations of complex systems have a very natural place within the *armoire* of analytical sociology.

In short, analytical sociology is a compact, clear approach to the problem of understanding social outcomes. It lays the ground for the productive body of research questions associated with the "aggregation dynamics" research program (link). There is active, innovative research being done within this framework of ideas, especially in Germany, Sweden, and Great Britain. And its clarity permits, in turn, the formulation of rather specific critiques from researchers in other sociological traditions who reject one or another of the key components. (This is the thrust of Andrew Abbott's article on mechanisms, discussed previously.)

(An earlier post described John Levi Martin's effort to show how social structures come to be as the result of the accretion of patterns of individual social interaction. Where Levi Martin proceeds from micro to macro through aggregation, Hedström proceeds from macro to micro through disaggregation (or dissection, in his words). But both are fundamentally interested in analyzing the micro-macro link.)

Marx an analytical sociologist?

Saturday, June 11, 2011

In an earlier post I gave a brief sketch of the emerging field of analytical sociology, and summarized its foundations around three premises: microfoundations, rational social actors, and causal mechanisms.

Marx is often thought to be a "structuralist" thinker, highlighting large social processes and entities such as the mode of production, the economic structure, and social class (for example, by Althusser and
Balibar in Reading Capital). However, I argued in The Scientific Marx (1986) that a careful examination of Marx's economic writings reveals something quite different. I argued, first, that Marx embraced the idea that social explanations require **microfoundations**.

Marxist social science commonly has advanced macro explanations of social phenomena in which the object of investigation is a large-scale feature of society and the explanans is a description of some other set of macro phenomena. Some Marxist social scientists have recently argued, however, that macro explanations stand in need of microfoundations: detailed accounts of the pathways by which macrolevel social patterns come about. These theorists have held that it is necessary to describe the circumstances of individual choice and action that give rise to aggregate patterns if macroexplanations are to be adequate. Thus to explain the policies of the capitalist state it is not sufficient to observe that this state tends to serve capitalist interests; we need an account of the processes through which state policies are shaped and controlled so as to produce the outcome. (127-28)

Consider now a second issue underlying the call for "microfoundations" for Marxian explanations: the gap between the interests of a group as a collective and the interests of the individuals who comprise the group. (John Roemer refers to this as the "aggregation gap.") "Rational-action" explanations depend on identifying an individual's interests and then explaining the person's behavior as the rational attempt to best serve those interests. The model is often extended to account for collective behavior of groups as well.... However, Mancur Olson and others have made it plain ... that it is not sufficient to

refer to collective interests in order to explain individual behavior. (129-30)

In both cases the objection being advanced to macro-Marxism is grounded in a recognition that there are no supraindividual actors in a society. (131)

After examining several examples of Marx's most important explanations, I conclude that his arguments conform to the requirements of the microfoundations principle. His most characteristic explanations proceed from reasoning about the actions of typical individuals within capitalist institutions to an effort to aggregate these individual choices up to the level of larger collective patterns.

Second, I argued that Marx's explanations were almost always grounded in an analysis that highlighted **rational individual decision-making**. But Marx differed from the perspective we would now call "public choice theory" in that he gave much greater attention to the historically specific motives and values of the actor. Marx highlighted what we might now call "political psychology" of the actor -- the socially specific ideas, motivations, and ideologies that the actor acquired through ordinary experience of capitalism. So there is a developed "action theory" present in Marx's writings. It is a theory that gives prominence to means-end rationality. And it gives attention to the social specificity of the actor as well.

Here is how I described Marx's assumptions about the actors within capitalism in TSM:

Marx's accounts depend on an examination of the circumstances of choice of rational individuals. Marx identifies a set of motivational factors and constraints on action for a hypothetical capitalist and then tries to determine the most rational strategies available to the capitalist in these circumstances of choice.... A second part of this model of explanation involves an attempt to determine the consequences for the system as a whole of the forms of activity attributed to the typical capitalist at the preceding stage of analysis. (141-42)

But Marx has a nuanced and socially specific conception of the actor:

Against both these positions -- the nonsocial individualism of political economy and the uncritical holism of speculative philosophy -- Marx puts forward an alternative position. On this account the socialized individual is the ultimate unit of analysis in social explanation. "Individuals producing in society -- hence socially determined production -- is of course the point of departure" (*Grundrisse* 83).... On this account society is not a freestanding entity, and social relations exist only through the individuals who stand within them. At the same time, however, individuals exist only within particular sets of historically given social relations. Consequently, social explanations must begin with a concrete conception of the individual within specific social relations." (150)

These assumptions about social actors conform fairly well to the assumptions incorporated into analytical sociology.

And third, I argued that Marx offered **causal mechanism explanations** based on an analysis of what I termed the "institutional logic" of a particular social setting. So various features of capitalism are explained as resulting from rational actors situated within a particular set of institutions. These accounts serve as descriptions of the social mechanisms through which capitalist dynamics take place.

Marx attempts to work out the institutional logic of these capitalist institutions. What distinctive features of organization and development are imposed on the capitalist economy by its defining structural and functional characteristics? What are the "laws of motion" of the mode of production defined by these conditions? We may call this an institutional-logic analysis of social regularities, and it is significantly different from the construction of theoretical explanations in natural science. Such an analysis is concerned with determining the results for social organization and development of an entrenched set of incentives and constraints on individual action. (34)

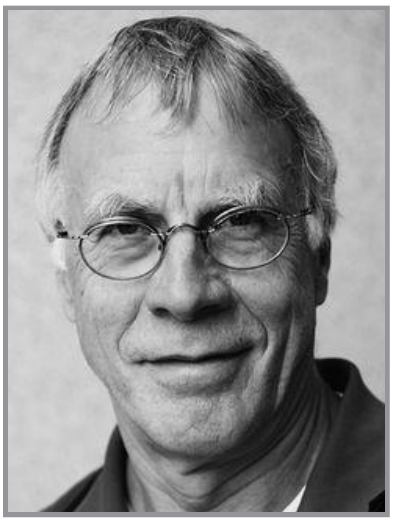
Marx's interest in discovering and elaborating the social mechanisms that drive social processes is found within his theory of historical materialism as well. In TSM I argue that Marx's claims about causation between levels of the social and economic structures of various modes of production are best understood as "mechanisms" explanations.

In order to understand fully this view of the relation between the economic structure and noneconomic phenomena, it is necessary to describe the mechanisms through which the lower-level structures constrain or filter superstructural elements. The filtering may occur through a variety of mechanisms, both intended and unintended. (56)

This account of Marx's implicit theory of social explanation -- microfoundations, rationality, and mechanisms -- reproduces Coleman's boat (Foundations of Social Theory). The institutions and structures of capitalism create a local environment of choice for individual capitalists and workers, and their behavior aggregates to a macro-outcome of interest (for example, the falling tendency in the rate of profit). This is a "logic of institutions" argument in a specific sense. The institutions (property relations) create an environment of choice in which actors pursue specific strategies, and these strategies aggregate to a certain kind of macro-level outcome. These are the "laws of motion" of the capitalist mode of production, in Marx's terms. And it is a mechanisms-based explanation in a specific sense as well. Marx is deliberately seeking out the social mechanisms through which the institutional setting produces a set of macro-outcomes, through their influence on the behaviors of the actors. *The Scientific Marx* offers a handful examples of these aggregative explanations. The point here is that this logic conforms very well to the framework of thought associated with analytical sociology.

There is one additional point of convergence between the methods I identified in Marx's writings in 1986 and the current doctrines of analytical sociology. I argued that the covering law model of explanation and the deductive-nomological model of justification did not work at all well in application to Marx's reasoning. The reason? Because the covering law model assumes that explanatory warrant proceeds from laws and regularities, whereas the heart of Marx's explanations rests upon the discovery of particular social processes and mechanisms.

Do Marx's explanations conform to the subsumption theory? ... There are statements of lawlike regularities in Marx's explanations, but these statements are somewhat trivial.... The real weight of the argument lies elsewhere: in the particular details of the circumstances of choice in which capitalists find themselves, and in Marx's reasoning from these circumstances to patterns of collective behavior. (152) [Or in other words, he seeks to uncover the social mechanisms of capitalism and their aggregative dynamics.]



The process of discovering an institutional logic is not merely one of working out the deductive consequences of the theory; it is rather discovering new aspects of the social process. These aspects are perhaps "implicit" in the original theory, but their discovery is a substantive one, not a mere deductive exercise. (153)

Here too there is a strong affinity between Marx's theory of science (as I interpreted it in 1986, anyway) and the philosophy of social explanation developed within analytical sociology.

So it looks as though Marx's analysis of capitalist society -- at least as it is reconstructed in The Scientific Marx -- falls squarely within what we would now call "analytical sociology" with a commitment to microfoundations, mechanisms, and socially constituted purposive actors. What a surprise!

Esser's sociology

Saturday, June 18, 2011

Sociology in Germany seems to be particularly prolific today, and this extends to the contributions that German sociologists are making to the sub-discipline of ***analytic sociology***. One of the leaders who has played a key role in this active field is Hartmut Esser. Esser's Soziologie. Spezielle Grundlagen 3. Soziales Handeln (2002) is particularly important, but it hasn't been translated into English yet. (Here is a link to the second volume of this work on Google Books, and here is a link to *Soziologie Allgemeine Grundlagen* (1993).) So Esser's contributions are not yet as widely known in the US sociology world as they ought to be. (Here is a short Wikipedia entry on Esser in German (link).)

One of Esser's primary areas of empirical research is on the general topic of immigration and ethnicity. Here are a couple of relevant articles in English: "Assimilation, Ethnic Stratification, or Selective Acculturation? Recent Theories of the Integration of Immigrants and the Model of Intergenerational Integration" (link) and "How Far Reaches the “Middle Range” of a Theory? A Reply to the Comments" link). His goal generally is to consider the theories of ethnicity and assimilation that have been developed since the Chicago School and Robert Parks, and to attempt to reconcile the empirical experience of assimilation with a synthetic theory.

Several things seem fairly clear. First, Esser was an early and influential contributor to analytical sociology in two important ways. He advocates for social mechanisms as a foundation for social explanation. And he highlights rational individual actions as the heart of most (all?) social mechanisms. His work appears to be comparable in importance and impact to that of Raymond Boudon, James Coleman, and Jon Elster: rationality, microfoundations, mechanisms. (Here is a contribution by Esser on the topic of "Theories of the Middle Range" in a very interesting volume by Renate Mayntz available online; link.)

Second, Esser is especially interested in topics within the philosophy of science in connection to sociology. He is interested in the logic of explanation, the development of theory, and the role of models in scientific explanation. He is influenced by Karl Popper

and Carl Hempel, and there are occasional references to other philosophers of science from the 1950s and 1960s. There are no references to Thomas Kuhn, W. V. O. Quine, or Hilary Putnam in *Soziologie Allgemeine Grundlagen.*

Another thing seems evident: that Esser is a sociologist in the tradition of Max Weber and interpretive sociology, with particular affinity to the "rational actor" Weber. Along with other German sociologists today, Esser appears to be helping to constitute a "Weber 2.0", more attuned to issues of contemporary interest such as immigration and assimilation, but with a strong sense of the importance of appropriate use of social theory in arriving at explanations of complicated contemporary social processes. (Here is a link to a book chapter by Esser on "The Rationality of Value".)

Here is an example of his use of rational choice theory in his theory of ethnic assimilation ("Assimilation, Ethnic Stratification, or Selective Acculturation? Recent Theories of the Integration of Immigrants and the Model of Intergenerational Integration"):

At the heart of the model are the options for those immigrants who are currently present within a receiving context. Options include activities which are related to the receiving country (receiving context option, in short: rc-option) and those which are related to the ethnic context (ethnic context option, in short: ec-option). Examples are changing or maintaining habits, relationships, or orientations. In order to explain when and why a certain activity occurs, we need a general rule for the selection between options that can be applied to, in principle, all empirical constellations. The model uses the rule of the expected utility theory as such a general selection rule. For each of the possible options a so-called EU weight is computed. The EU weight is the sum of both the negative and positive returns that can be achieved with the selection of a particular option, weighted with the corresponding expectation that the return actually occur with the selected option. Individuals would then select the option with the highest expected value [cfr. Esser 2004, 1135 ff.; Esser 2006, 39 ff. on details of the expected utility theory and also with reference to the model.
Esser has also attempted to find affinities between rationality theory and micro-sociology, including especially the phenomenological sociology of Alfred Schütz. Here is the abstract of "The Rationality of Everyday Behavior: A Rational Choice Reconstruction of the Theory of Action by Alfred Schütz" (link):

This article argues that Alfred Schütz, one of the founders of the interpretative paradigm in sociology, developed a theory of action whose basic structure is compatible with subjective expected utility theory (i.e., a specific variant of rational choice theory). Alfred Schütz's view with respect to the characteristics of everyday action—the individual orientation toward routines and structures of relevance—is modeled in terms of subjective expected utility theory. In this perspective, these characteristics appear as the result of an action-preceding rational choice in the process of the cognition of situations, under the conditions of bounded rationality.
Esser is the object of quite a bit of discussion and reflection by other German sociologists. One whose name shows up frequently in these discussions is Rainer Greshoff (Die Transintentionalität des Sozialen. and *Integrative Sozialtheorie: Esser, Luhmann, Weber* (Rainer Greshoff and Uwe Schinank, eds.)).

(For those of us whose German reading knowledge is limited, I'm finding Google Translate to be a helpful source of assistance as I struggle with some of these texts; it helps with vocabulary even though the translations of complete sentences are not ready for prime time.)

Alternatives to analytical sociology

Monday, June 20, 2011

I've now spent a fair amount of time in the past month on the micro-macro link and the foundations of analytical sociology (AS). It is worth taking stock to consider how this approach relates to other important methodologies in sociology and the social sciences more generally.

To start: I've generally found the strictures of "microfoundations" and "agent-based explanations" as representing ontological constraints on sociological explanations rather than guides for empirical research. The constraints require, essentially, that all our explanations of social processes and causal connections need to be **compatible** with providing plausible micro-level accounts of how they work. This is somewhat analogous to the philosophy of atomism in pre-Socratic natural philosophy; atomism postulated that there was a most fundamental level of physical phenomena; that these "atoms" were discrete and indivisible; and that all natural phenomena are composed of atoms and their aggregations. But this philosophy doesn't prescribe how to pursue the science of chemistry.

So these constraints don't necessarily provide guidance about what social phenomena to study or how to study it. In particular, they don't imply that sociological research needs to flow from bottom up, and they don't imply that the content of sociology should derive from features of individual agency and psychology.

But it seems that advocates of AS believe that the framework goes beyond this; that it leads to research strategies and areas of empirical inquiry that are distinctive from those adopted by other approaches to sociology. Research needs to fit into one of the struts of Coleman's boat. It needs to provide an empirical understanding of some of the micro-micro linkages or the micro-macro linkages; and it needs to offer rigorous techniques for establishing causal connections from micro to macro. Hedstrom puts the point this way early in Dissecting the Social: On the Principles of Analytical Sociology:

To be explanatory a theory must specify the set of causal mechanisms that are likely to have brought about the change, and this requires one to demonstrate how macro states at one point in time influence individuals' actions, and how these actions bring about new macro states at a later point in time. (kindle location 139)

This brief summary of the central dogmas of AS provides one reason why AS theorists are so concerned to have adequate and tractable models of the actor -- often rational actor models. Thomas Schelling's work provides a particularly key example for the AS research community (Micromotives and Macrobehavior, Choice and Consequence, Strategies of Commitment and Other Essays); in field after field he demonstrates how micro motives aggregate onto macro outcomes. And Elster's work is also key, in that he provides some theoretical machinery for analyzing the actor at a "thicker" level -- imperfect rationality, self-deception, emotion, commitment, and impulse (Explaining Social Behavior: More Nuts and Bolts for the Social Sciences, Sour Grapes: Studies in the Subversion of Rationality, Ulysses Unbound: Studies in Rationality, Precommitment, and Constraints, Alchemies of the Mind: Rationality and the Emotions).

This summary also shows why agent-based modeling and simulations are so attractive to AS researchers: these techniques offer tractable methods for aggregating the effects of lower-level features of social life onto higher-level outcomes. If we represent actors as

possessing characteristics of action X, Y, Z, and we represent their relations as U, V, W -- how do these actors in social settings aggregate to mid- and higher-level social patterns? This is the key methodological challenge that drives the Santa Fe Institute, and it produces very interesting results (link). (Here is an interesting recent paper on agent-based simulations for the social sciences by Dirk Helbing and Stefano Balietti called "How to Do Agent-Based Simulations in the Future: From Modeling Social Mechanisms to Emergent Phenomena and Interactive Systems Design" (link).)

There certainly is intellectual power in this approach -- actors in social relations and the aggregation of their actions; but it isn't the whole of sociology. So let's quickly consider a few examples of sociological research that seem fairly distant from AS and consider how they might relate.

We might consider such fertile social scientists as Jack Goldstone, Theda Skocpol, Charles Tilly, Andrew Abbott, Emmanuel Wallerstein, Pierre Bourdieu, Stanley Lieberson, George Steinmetz, Douglas Massey, and Erving Goffman, with respect to these questions:

- To what extent do their theories rely on "mechanisms" as a foundation for social explanations?
- Are their theories compatible with the requirement of microfoundations at a local actor level?
- Do they have a theory of the actor?
- And do they make use of social ontologies that presuppose large social causes and macro causal relationships?

In many instances some but not all answers to these questions will be affirmative. Goffman and Bourdieu have a theory of the actor; Tilly and Lieberson appeal to social mechanisms; and in different ways I would say that each of them offer theories that are compatible with the requirement of microfoundations. At the same time, the explanatory logic that these authors provide is rarely "aggregative"; they are not interested in showing how a macro phenomenon is the aggregate result of local actors' choices. Moreover, several of them make specific and deliberate use of macro factors as central explanatory constructs: Goldstone, Skocpol, Wallerstein, and Massey. And Tilly explicitly criticizes the individualism that is characteristic of rational-actor theories, preferring a relational understanding of social phenomena. So there isn't an easy translational relationship between AS and a number of other important and productive research traditions in sociology today.

One interesting data point on this question of the relationship between AS and other approaches to social explanation can be examined in Kathleen Thelen's contribution to Renate Mayntz, *Akteure – Mechanismen – Zur Theoriefähigkeit makro-sozialer Analysen*. (The book is very interesting and is available as a PDF download; link.)

Thelen is a brilliant scholar within the new historical institutionalism perspective (How Institutions Evolve: The Political Economy of Skills in Germany, Britain, the United States, and Japan), and her contribution to the Mayntz volume ("The Explanatory Power of Historical Institutionalism") implicitly aims at tracing out some of the points of contrast between AS and historical institutionalism. She highlights several key methodological and theoretical assumptions underlying current research in historical institutionalism: attention to the formation of collective interests (92), attention to context (93), attention to meso- and macro-causal analysis (95), and sensitivity to the temporal dimension of social processes (96). Here are some representative passages:

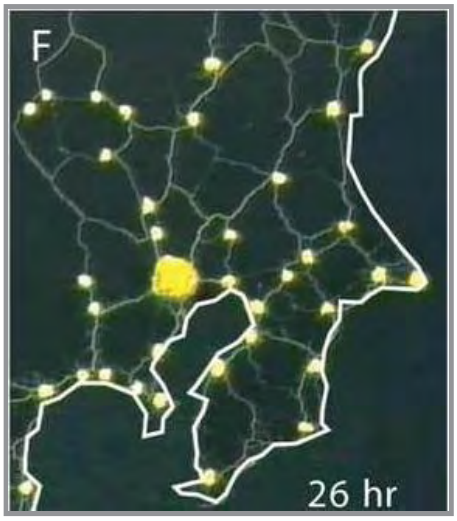
Thus, historical institutionalists have consistently drawn attention to the way in which institutional configurations »foster the emergence of particular definitions of mutual interest« (Immergut 1998: 339), and how they also often shape political outcomes by facilitating the organization of certain groups while actively disarticulating others (e.g., Skocpol 1992). (92)

A good deal of historical-institutional scholarship shows that the impact of institutions is often heavily mediated by features of the overarching political or historical context, a point that Charles Ragin's work has repeatedly emphasized and underscored (Ragin 1987; also Katznelson 1997). (93)

However, beyond that, the emphasis on timing and sequencing in historical institutional research is also motivated by the insight, borne out in a number of studies, that when things happen, or the order in which different processes unfold, can itself be an extremely important part of the causal story (Pierson 2000c). (97)

Thus, for example, a number of authors have suggested that rational choice institutionalism applies best to understanding the strategic interaction of in- dividuals in the context of specific, well established and well known rules and parameters (e.g., Bates 1997; Geddes 1995). By contrast to this, the strength of historical-institutional approaches is precisely in the leverage it provides on understanding configurations of institutions (Katznelson 1997) and over much longer stretches of time (Pierson 2001). Historical institutionalism is concerned not just with how a particular set of rules affects the strategic orientation of individual actors and their interactions, but also with the broader issue of the ways in which institutional configurations define what Theda Skocpol has termed »fields of action« that have a very broad influence not just on the strategies of individual players but on the identities of actors and the networks that define their relations to each other. (103-4)

My takeaway from Thelen's thinking here and elsewhere is that there is a pretty significant methodological divide between her way of thinking about social processes and that of AS. She highlights a handful of characteristics of HI research. Historical institutionalists are inclined to focus on the meso level -- the settings of rules, norms, and processes through which social life is mediated; and they are sensitive to the crucial variations across time and place that these arrangements illustrate. Nothing in this construction is antithetical to the requirement of microfoundations and the recognition that socially situated actors constitute the social world; but the emphasis of the research is not on the discovery of the aggregation dynamics from the level of the individual actor.



So I'm inclined to judge two things: first, that the methodological requirement of microfoundations is indeed a universal requirement on valid sociological research; but second, that the program of aggregation from micro to macro is only one way of conducting sociological research and explanation. So we shouldn't expect other areas of sociological thinking and research to simply fold into the framework of analytical sociology -- any more than a common commitment to natural selection as the causal mechanism underlying species change dictates the content and methods of the various areas of biology.

This is a place where the ontological framework of social structures that Dave Elder-Vass provides in The Causal Power of Social Structures: Emergence, Structure and Agency seems methodologically useful. It provides a rigorous basis for conceding the point that context, institutions, moral ideas, and value systems have a causal role to play in social explanation. In E-V's view, these social structures supervene upon facts about individual

actors; but their causal properties do not need to be reduced to features of the actors.

Mental illness, big pharma and agent-based simulation

Saturday, June 25, 2011

The *New York Review of Books* has an absorbing two-part piece by Marcia Angell on mental illness, psychiatry, and big pharma (link, link). (The NYRB Facebook page provides a good way of following the NYRB.) Angell provides an in-depth discussion of books by Irving Kirsch, Robert Whitaker, and Daniel Carlat. There has been an explosion in the numbers of patients diagnosed with a list of mental disorders, and there has been an explosion in the profits associated with the drugs prescribed in treatment of these disorders as well.

It seems that Americans are in the midst of a raging epidemic of mental illness, at least as judged by the increase in the numbers treated for it. The tally of those who are so disabled by mental disorders that they qualify for Supplemental Security Income (SSI) or Social Security Disability Insurance (SSDI) increased nearly two and a half times between 1987 and 2007—from one in 184 Americans to one in seventy-six. For children, the rise is even more startling—a thirty-five-fold increase in the same two decades. Mental illness is now the leading cause of disability in children, well ahead of physical disabilities like cerebral palsy or Down syndrome, for which the federal programs were created. (Angell, part 1)

What is going on here? Is the prevalence of mental illness really that high and still climbing? Particularly if these disorders are biologically determined and not a result of environmental influences, is it plausible to suppose that such an increase is real? Or are we learning to recognize and diagnose mental disorders that were always there? On the other hand, are we simply expanding the criteria for mental illness so that nearly everyone has one? And what about the drugs that are now the mainstay of treatment? Do they work? If they do, shouldn't we expect the prevalence of mental illness to be declining, not rising? (Angell, part 1)

To oversimplify, the thrust of several of these books is that the psychoactive drugs *created* the mental illnesses through the profit incentives and strategies of big pharma,

rather than the diseases creating the drugs (through research and development aimed at treating the diseases). This is over-simple, of course, since no one would question that mental illnesses exist prior to drugs. But the explosion of treated disorders like depression, anxiety, sleep disorders, and attention deficit disorder in children -- the "epidemic" to which Angell refers -- seems to conform to the reverse order. Deliberate strategies of marketing, influence on physicians, and influence on guiding medical documents such as the DSM seem to have produced a much larger patient base in specific mental disorders, with large profits accruing to pharma as a consequence. (Ian Hacking looks at the degree to which mental illnesses are socially constructed in The Social Construction of What?.)

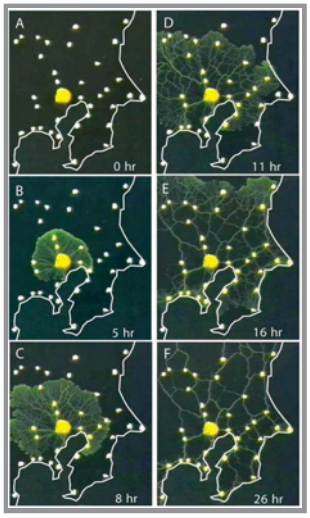
Here is the main thrust of the interpretation offered by the books that Angell reviews:

First, [the authors] agree on the disturbing extent to which the companies that sell psychoactive drugs—through various forms of marketing, both legal and illegal, and what many people would describe as bribery—have come to determine what constitutes a mental illness and how the disorders should be diagnosed and treated. (Angell, part 1)
A couple of pieces of evidence are especially pertinent in support of this telling of the story. One is the observation that psychiatrists as a profession are the largest beneficiaries of funding by pharma, by a large margin.

As psychiatry became a drug-intensive specialty, the pharmaceutical industry was quick to see the advantages of forming an alliance with the psychiatric profession. Drug companies began to lavish attention and largesse on psychiatrists, both individually and collectively, directly and indirectly. They showered gifts and free samples on practicing psychiatrists, hired them as consultants and speakers, bought them meals, helped pay for them to attend conferences, and supplied them with “educational” materials. When Minnesota and Vermont implemented “sunshine laws” that require drug companies to report all payments to doctors, psychiatrists were found to receive more money than physicians in any other specialty. The pharmaceutical industry also subsidizes meetings of the APA and other psychiatric conferences. About a fifth of APA funding now comes from drug companies.

Drug companies are particularly eager to win over faculty psychiatrists at prestigious academic medical centers. Called “key opinion leaders” (KOLs) by the industry, these are the people who through their writing and teaching influence how mental illness will be diagnosed and treated. They also publish much of the clinical research on drugs and, most importantly, largely determine the content of the DSM. In a sense, they are the best sales force the industry could have, and are worth every cent spent on them. Of the 170 contributors to the current version of the DSM (the DSM-IV-TR), almost all of whom would be described as KOLs, ninety-five had financial ties to drug companies, including all of the contributors to the sections on mood disorders and schizophrenia. (Angell, part 2)
A second piece of evidence is a recounting of the drafting of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM) through five editions, especially the third edition. In each case there is a strong suggestion of swaying of medical and scientific opinion through financial incentives.

These efforts to enhance the status of psychiatry were undertaken deliberately. The APA was then working on the third edition of the DSM, which provides diagnostic criteria for all mental disorders. The president of the APA had appointed Robert Spitzer, a much-admired professor of psychiatry at Columbia University, to head the task force overseeing



the project. The first two editions, published in 1952 and 1968, reflected the Freudian view of mental illness and were little known outside the profession. Spitzer set out to make the DSM-III something quite different. He promised that it would be “a defense of the medical model as applied to psychiatric problems,” and the president of the APA in 1977, Jack Weinberg, said it would “clarify to anyone who may be in doubt that we regard psychiatry as a specialty of medicine.”

When Spitzer’s DSM-III was published in 1980, it contained 265 diagnoses (up from 182 in the previous edition), and it came into nearly universal use, not only by psychiatrists, but by insurance companies, hospitals, courts, prisons, schools, researchers, government agencies, and the rest of the medical profession. Its main goal was to bring consistency (usually referred to as “reliability”) to psychiatric diagnosis, that is, to ensure that psychiatrists who saw the same patient would agree on the diagnosis. To do that, each diagnosis was defined by a list of symptoms, with numerical thresholds. For example, having at least five of nine particular symptoms got you a full-fledged diagnosis of a major depressive episode within the broad category of “mood disorders.” But there was another goal—to justify the use of psychoactive drugs. The president of the APA last year, Carol Bernstein, in effect acknowledged that. “It became necessary in the 1970s,” she wrote, “to facilitate diagnostic agreement among clinicians, scientists, and regulatory authorities given the need to match patients with newly emerging pharmacologic treatments.” (Angell, part 2)

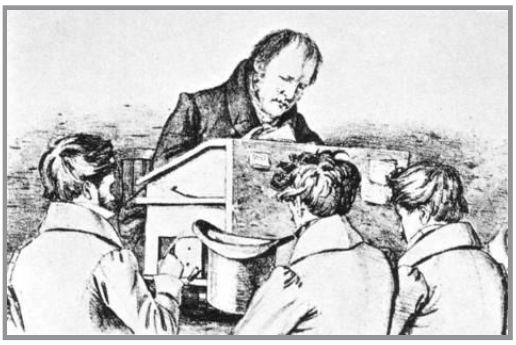
Another element of the strategy used by the drug companies to promote their products, according to these authors, is the selective way that clinical studies are used in order to establish the safety and effectiveness of a given psychoactive drug:

For obvious reasons, drug companies make very sure that their positive studies are published in medical journals and doctors know about them, while the negative ones often languish unseen within the FDA, which regards them as proprietary and therefore confidential. This practice greatly biases the medical literature, medical education, and treatment decisions. (Angell, part 1)

What this story made me think of was ... slime molds. Here's what I mean. Japanese researchers have discovered that certain examples of optimizing processes can be simulated with slime molds and food supplies distributed across space. Here is an example of this research in the context of rail networks: the researchers found that a colony of slime mold essentially reproduces the configuration of existing rail networks when food is distributed in a configuration mirroring major cities (Tero et al 2010; link, link). Here is the experiment based on the configuration of cities around Tokyo:

After about a day of growth, the slime mold has established a network of tunnels connecting the food supplies, and this network looks strikingly similar to the configuration of Japanese railroads in the region.

So here's the question for consideration here: what if we attempted to model the system of population, disease, and the pharmaceutical industry by representing pharma as the slime organism and the disease space as a set of disease populations with different profitability characteristics? Would we see a major concentration of pharma slime around a few high-frequency, high profit disease-drug pairs? Would we see substantial underinvestment in pharma slime on low frequency low profit "orphan" disease populations? And would we see hyper-concentrations around diseases whose incidence is responsive to marketing and diagnostic standards?



I'm just speculating here, but I'm guessing that a Petri dish designed with these characteristics would produce the outcome described in the books included in the Angell reviews: a hyper-concentration of the slime organism around the "plastic" diseases that display positive feedback from marketing to incidence. Essentially the model would suggest that the pharma industry "grows" into the space of emerging diseases, making investments in research and marketing that allow for growth of revenues around the disease segments of the population.

I suppose that this thought experiment simply supports a dismal but familiar finding: that profit-maximizing firms will aggressively seek out new sources of profits; that they will be particularly interested in opportunities where the possibility exists of strategically increasing the demand market; and that they will find creative ways of inducing other actors to behave in ways that enhance their business interests. Unfortunately, in this case the business optimal outcome seems to have very negative consequences for public health. And it seems to cast some doubt on the ability of professional ethics and conflict of interest policies to keep the medical profession as a whole on the track of placing the patient's health as the highest priority.

(I think this thought experiment could be recast as an agent-based simulation, with similar results.)

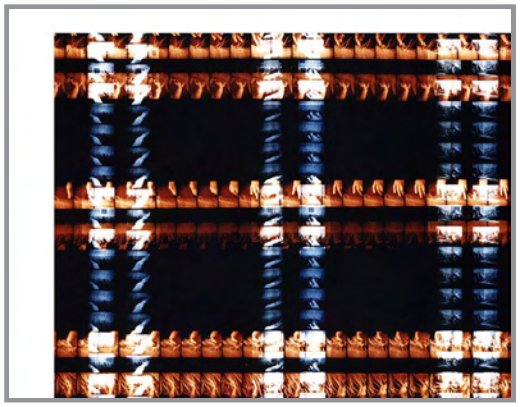
What is the philosophy of history?

Sunday, June 26, 2011

When philosophers have written about “history”, they have often had different and even incompatible goals in mind. One tradition of philosophers, generally pre-twentieth century and generally from continental Europe, have wanted to contribute to answers to large questions about the nature of history as it presented itself over time as a compound of individuals, actions, nations, and civilizations: Does history have a direction? Does history have meaning? Is there a plan to history? Do civilizations rise and fall? Is materialism or idealism the better framework for understanding the movement of history? G. W. F. Hegel, for example, wanted to discover the underlying rationality within history. This approach to the study of history is often referred to as “speculative” or “substantive.”

A second group of philosophers, also largely continental, were inspired by the strong connections that exist between individual human life and expression, and large collective events and processes. The theory of hermeneutics attempts to provide an intellectual framework for analyzing and interpreting meaningful human expressions – poetry, actions, thoughts, and motives. Hermeneutic philosophers in the nineteenth and twentieth centuries extended this approach to efforts to understand large historical events and processes in similar terms. Wilhelm Dilthey was one of the early exponents of the hermeneutic approach to human affairs. Hermeneutic philosophy of history seeks to understand events, movements, and processes in terms of the meanings that they embody and the meaningful relations they bear to other historical events.

Another group of philosophers, often in the twentieth century and often English-speaking, have focused their attention on the nature of historical knowledge rather than the concrete events of history. Analytic philosophers have wanted to clarify the grounds of historical knowledge and explanation. Issues such as the nature of narrative, the role of general laws in historical explanations, and the objectivity or subjectivity of historical judgment have been taken up by Arthur Danto, Patrick Gardner, Carl Hempel, and others. This approach is sometimes referred to as “analytical”; more generally, we might say that it is epistemological and methodological.



New questions have emerged since World War II within the discourse of philosophy about “history” by philosophers, both analytical and continental. These new areas were stimulated, first, by the atrocities of the Holocaust, and the effort to make sense of this horrendous tear in the fabric of modern civilization. How are we to make sense of the Holocaust? How should we remember it? A second source of new thinking about history by contemporary philosophers is the linguistic and semantic turn that many of the human sciences took in the 1970s and 1980s (Rorty, 1967). A cohort of writers in the 1980s and 1990s undertook to approach history from the point of view of narrative and meaning. In some ways this was a return to the hermeneutic approach to human affairs of the nineteenth century; but it was also original in that it brought new thinking from the philosophy of language into the debate.

There is a valid but limited place for metaphysical research in the area of the philosophy of history. Fundamentally, we need to have a clearer specification of the meaning of key concepts that we use in analyzing and describing historical events and structures. Philosophers can help in probing and refining these concepts. These ontological questions are really about our conceptual schemes rather than about substantive historical facts. What presuppositions are we making when we divide history into epochs or regions? Does it make sense to refer to civilizations as a whole? So we need a more explicit theory of historical ontology, and the philosophy of history can help to provide such a theory. What we cannot hope to achieve is an apriori discovery of the reality of history – its meaning, direction, or foundational causes. This is not a limitation of our ability to discover historical truths, but rather a reflection of the fact that there are no general answers to these questions at all. Kant's critique of substantive metaphysics is decisive here.

As this summary suggests, there are many unanswered questions that philosophers can usefully pose to the discipline and facts of history. For this reason it is timely to consider some new approaches to the philosophy of history. The past decade has seen several contributions that are difficult to classify according to the distinctions provided above. They are analytic but not reductionist; they pay attention to narrative but nonetheless attribute rational warrant to historical accounts; and they are respectful towards the actual practices of gifted historians, rather than assuming that the philosophy of history can proceed as a separate philosophical discourse. Significantly, new contributions to this subject come from philosophers, literary critics, anthropologists, and historians. Perhaps this is a clue for how the field might most productively move forward: by incorporating several philosophical perspectives, by raising new questions, and by reaching across the human sciences as well as philosophy to find some innovative new answers.

Microfoundationalism

Tuesday, June 28, 2011

detail: Lynn Cazabon photo

The philosophy of social science encompasses several important tasks, and key among them is to provide theories of social ontology and social explanation. What is the nature of social entities? What is needed in order to substantiate a claim of social causation? What constitutes an acceptable social explanation?

The concept of microfoundations is relevant to each of these domains. A microfoundation is:

a specification of the ways in which the properties and structure of a higher-level entity are produced by the activities and properties of lower-level entities.
In the case of the social sciences, this amounts to:

a specification of the ways that properties, structural features, and causal powers of a social entity are produced and reproduced by the actions and dispositions of socially situated individuals.
This concept is relevant to social ontology in this way. Social entities are understood to be compositional; they are assemblages constituted and maintained by the mentality and actions of individuals. So providing an account of the microfoundations of a structure or causal connection -- say a paramilitary organization or of the causal connection between high interest rates and the incidence of alcohol abuse -- is a specification of the composition of the social-level fact. It is a description of the agent-level relationships and patterns of behavior that cohere in such a way as to bring about the higher-level structure or causal relationship.

The concept of microfoundations is directly relevant to explanation. If we assert a causal or explanatory relation between one social entity or condition and another, we must be prepared to offer a credible sketch of the ways in which this influence is conveyed through the mentalities and actions of individuals.

Much turns, however, on what precisely we mean to require of a satisfactory explanation: a full specification of the microfoundations in every case, or a sketch of the way that a given social-level process might readily be embodied in individual-level activities. If we go with the second version, we are licensing a fair amount of autonomy for the social-level explanation; whereas if we go with the first version, we are tending towards a requirement of reductionism from higher to lower levels in every case. I am inclined to interpret the requirement in the second way; it doesn't seem necessary to disaggregate every claim like "organizational deficiencies at the Bhopal chemical plant caused the devastating chemical spill" onto specific individual-level activities. We understand pretty well, in a generic way, what the microfoundations of organizations are, and it isn't necessary to provide a detailed account in order to have a satisfactory explanation.

The ontological position associated with microfoundationalism falls in the general area of methodological individualism and reductionism, in that it insists on the compositional nature of the social. However, there is a recursive aspect of the theory that distinguishes it from strict reductionism. The individuals to which microfoundations are traced are not a-social; rather, their psychology, beliefs and motives are constituted and shaped by the social forces they and others constitute. So the microfoundational account of the workings of a paramilitary organization may well refer to the locally embodied effects of that organization on the current psychology of the members of the organization; and their behavior in turn reproduces the organization in the next iteration. This is why I prefer the idea of methodological localism over that of methodological individualism (link).

The theory of microfoundations is also very consistent with the idea of social mechanisms. When we ask about the microfoundations of a social process, we are asking about the mechanisms that exist at a lower level that create and maintain the social process.

One way of motivating the theory of microfoundations is to observe that it is a prescription against "magical thinking" in the social realm. There is no "social stuff" that has its own

persistent causal and structural characteristics; rather, all social phenomena are constituted by patterns of behavior and thought of populations of individual human beings. And likewise, social events and structures do not have inherently social causal properties; rather, the causal properties of a social structure or event are constituted by the patterns of behavior and thought of the individuals who constitute them and nothing else.

The theory of supervenience is often invoked to express the idea that social entities and properties are constituted by individuals. (Jaegwon Kim is the primary creator of the theory of supervenience in the philosophy of mind; Supervenience and Mind: Selected Philosophical Essays.) This basic idea is expressed as:

No difference at level N without some difference at lower level K.

The advantage of the theory of supervenience is that it provides a way of recognizing the compositional nature of higher-level entities without presupposing explanatory reductionism from one level to the lower level.

The explicit idea of microfoundations appears to have been first developed in the domain of microeconomics; there it referred to the necessity of deriving macroeconomic phenomena from the premises of rational economic behavior (Weintraub, Microfoundations: The Compatibility of Microeconomics and Macroeconomics). (Here is an interesting article by van den Bergh and Gowdy on recent analysis of the microfoundations debate in economics.) Maarten Jansen describes the theory of microfoundations in economics in his entry in The New Palgrave Dictionary of Economics and the Law:

The quest to understand microfoundations is an effort to understand aggregate economic phenomena in terms of the behavior of individual economic entities and their interactions. These interactions can involve both market and non-market interactions. The quest for microfoundations grew out of the widely felt, but rarely explicitly stated, desire to stick to the position of methodological individualism ..., and also out of the growing uneasiness among economists in the late 1950s and 1960s with the co-existence of two subdisciplines, namely microeconomics and macroeconomics, both aiming at explaining features of the economy as a whole. Methodological individualism, as explained in the entry on the topic, is the view according to which proper explanations in the social sciences are those that are grounded in individual motivations and their behavior.

The idea of microfoundations is now important in many areas of the social sciences, including especially sociology and political science. Particularly important were ideas formulated by James Coleman in Foundations of Social Theory. Coleman doesn't use the term "microfoundations" explicitly in this work, but his analysis of the relationship between the macro and the micro seems to imply a requirement of providing microfoundations as a condition on good explanations in the social sciences. The Coleman boat (link) seems to be a graphical way of representing the microfoundations of a macro-level fact.

A second mode of explanation of the behavior of social systems entails examining processes internal to the system, involving its component parts, or units at a level below that of the system. The prototypical case is that in which the component parts are individuals who are members of the social system. In other cases the component parts may be institutions within the system or subgroups that are part of the system. In all cases the analysis can be seen as moving to a lower level than that of the system, explaining the behavior of the system by recourse to the behavior of its parts. This mode of explanation is not uniquely quantitative or uniquely qualitative, but may be either. ... I call [this] the internal analysis of system behavior. (2)

Coleman's view here is complex, though, and isn't entirely unambiguous. Consider this qualification a few pages later, which refers unexpectedly to "emergent phenomena" and intermediate levels of explanatory mechanisms between the macro and the micro:

Those readers familiar with debates and discussions on methodological holism and methodological individualism will recognize that the position taken above on explanation is a variant of methodological individualism. But it is a special variant. No assumption is made that the explanation of systemic behavior consists of nothing more than individual actions and orientations, taken in aggregate. The interaction among individuals is seen to result in emergent phenomena at the system level, that is, phenomena that were neither intended nor predicted by the individuals. Furthermore, there is no implication that for a given purpose an explanation must be taken all the way to the individual level to be satisfactory. The criterion is instead pragmatic. (5)

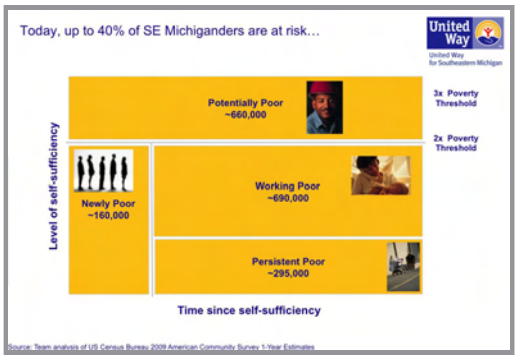
Other more explicit advocates of the microfoundations principle are Jon Elster, John Roemer, Adam Przeworski, and other contributors to the theories of analytical Marxism (Analytical Marxism). Here is how I attempted to synthesize some of this thinking in 1994:

Marxist thinkers have argued that macro-explanations stand in need of microfoundations: detailed accounts of the pathways by which macro-level social patterns come about. These theorists have held that it is necessary to provide an account of the circumstsances of individual choice and action that give rise to aggregate patterns if macro-explanations are to be adequate. Thus in order to explain the policies of the capitalist state it is not sufficient to observe that this state tends to serve capitalist interests; we need to have an account of the processes through which state policies are shaped or controlled so as to produce this outcome. ("Microfoundations of Marxism," reprinted in D. Little, Microfoundations, Methods, and Causation, 4)

As noted in a prior post, the idea of microfoundations is also a core constituent of the methodology of analytical sociology (Peter Hedström, Dissecting the Social: On the Principles of Analytical Sociology).

In short, a fairly wide range of social science research today embraces the general idea of providing microfoundations for macro-level assertions. And this seems to be a very reasonable requirement, given what we know about how social entities, processes, and forces are composed.

The safety net in Michigan



Wednesday, June 29, 2011

Poverty in the United States has increased measurably in the past ten years, and this is particularly visible in the state of Michigan. (Here is a webpage provided by the Michigan Department of Human Services with some basic information on poverty in the state.) State departments of human services and non-profit organizations alike are being stretched by the need for poverty-related services -- food assistance, childcare, heating assistance, job training, and the like. So how good a job are we doing to ensure that poor people in the United States have reasonable access to the necessities of life?

In general, the answer to the question seems mostly to be -- not a very good job. The amount of money available for services to the poor is under pressure in most state legislatures. The processes through which low-income people need to pass in order to apply for assistance are confusing and needlessly lengthy. And the "front doors" for providers are highly decentralized, so the potential recipient of assistance needs to

conduct a lengthy search simply to find a possible source.

The United Way of Southeast Michigan is a highly capable social service agency that is genuinely committed to helping to improve the situation of Michigan's poorest residents (link). Here is a UWSEM report on the status of basic needs of the population in Michigan. The report is worth reviewing in detail. One point stands out very starkly -- a strikingly high percentage of the state's population falls in the status of poor or near-poor. The report provides a very legible description of the composition of the 40% of Michigan's population who are "at-risk":

This is a truly sobering statistic: two out of five residents of Michigan fall within the groups of the persistent poor, working poor, newly poor, and potentially poor.

One of the United Way's current priorities is to do a careful review of the system of assistance as a whole in the state. Generally, their finding is that resources, agencies, and strategies are highly fragmented in the state, so it is easy to guess that the provision of services is somewhat sporadic and inefficient. More importantly, their analysis shows that over a billion dollars of federal assistance to individuals are left unused year after year -- at a time when the need for assistance is greater than it has ever been. (This report should appear on the UWSEM website sometime soon.)

It's worth looking closely at the data compiled by UWSEM. Over $34 billion are expended on assistance to the poor in Michigan, with over 55% of the funds coming from Federal sources ($19.9 billion). The state's own resources represent roughly half that amount ($9.4 billion). Foundations and private resources make up the rest. Second, these $34 billion are expended through a large number of state agencies -- treasury, school aid, public housing, the department of human services, etc. And finally, the funds flowing from these multiple agencies then re-aggregate at the level of the users in a variety of basic categories of need: workforce development, housing, family preservation, food, cash assistance, and healthcare.

There are several key conclusions that emerge from the UWSEM analysis. One is that this is a process that is plainly designed for providers and auditors, not users. The idea that the system of social services should be streamlined in such a way as to allow maximum access for eligible residents is clearly not the guiding design principle.

A second point is that the system is needlessly complex for the user. It should be possible to streamline services and application processes in such a way as to increase the impact of available resources for eligible people.

A third point is that it should be possible to use the Internet to significantly increase the accessibility and transparency of the system. It should be possible for the poor person to enter a single "portal"; enter his/her information into a database; and find out on one screen what programs and benefits for which he/she is eligible.

In short, it would appear that there are significant opportunities for public "safety net" providers in Michigan to increase the efficiency and reach of their services with some intelligent redesign of the delivery systems. And we certainly need to make sure that the billion dollars of unexpended federal benefits find their way to eligible citizens.

(Here is a nice example of how universities and communities can work together to address the issues of poverty that their region faces (link). This collaboration between Western Michigan University and various organizations in Kalamazoo, Michigan is aimed at providing easy access to data about poverty and well-being in Kalamazoo that can help guide programs and resources towards effective reduction of poverty.)

Income inequalities and social ills

Sunday, July 03, 2011

According to Kate Pickett and Richard Wilkinson in The Spirit Level: Why Greater Equality Makes Societies Stronger, income inequalities in a society are a source of a variety of social problems in that society, almost without regard to the absolute level of income in the society.
Their basic measure of inequality across countries and states in the United States is the ratio of income from the top quintile to the bottom quintile. (They also sometimes make use of the Gini coefficient.) The quintile income ratio varies across OECD countries from a low of about 4 (Japan) to a high of just under 10 (Singapore). The United States has the second highest ratio, at about 8.5 (figure 2.1).

In order to empirically evaluate the impact of a society's income inequalities on social well-being, they construct an Index of Health and Social Problems for each country and US state. The index incorporates --

- Level of trust
- Mental illness
- Life expectancy and infant mortality
- Obesity
- Children's educational performance
- Teenage births
- Homicides
- Imprisonment rates
- Social mobility

These ten factors are all weighted equally. Here is their most basic graph plotting the index against income inequality among OECD countries (figure 2.2):

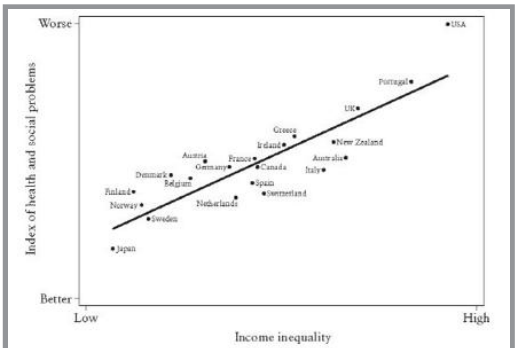


Figure 2.2 *Health and social problems are closely related to inequality among rich countries.*

A similar but looser relationship obtains between these variables for US states; figure 2.4. And they find similar relationships between the UNICEF index of child wellbeing and income inequality; figure 2.7. So their most basic claim is well substantiated: there is a strong negative relationship between social inequalities and social well-being. Most importantly, they maintain that this relationship is causal.

This is indeed a striking hypothesis. Their argument is not that material deprivation causes social harms and high inequality societies have more material deprivation; it is rather that the degree of inequality is itself an important cause of social harms. Further, they maintain that these relationships persist in affluent societies. And they are explicit in accepting that this implies a causal relationship between a structural feature of society and individual outcomes (chap 3).

Some of the most interesting content in the book comes in the form of specific empirical analysis of some of the kinds of social malaise that are rising in society, and some of the mechanisms through which inequalities contribute to this rise. Chapter 3 takes on stress and anxiety. Figure 3.1 documents a generally rising level of anxiety among men and women college students from the 1950s to the 1990s. The authors relate this rise to an increase in social anxieties: feelings of inadequacy, friendlessness, and separation from community (kl 745). And these features of social relationship, they believe, derive from rising hierarchy and inequality.

Another important mechanism of social harm is the erosion of trust that modern societies have experienced. This too the authors attribute to rising hierarchy and inequality and the pronounced separation this creates among members of society. Figure 4.1 illustrates this relationship.

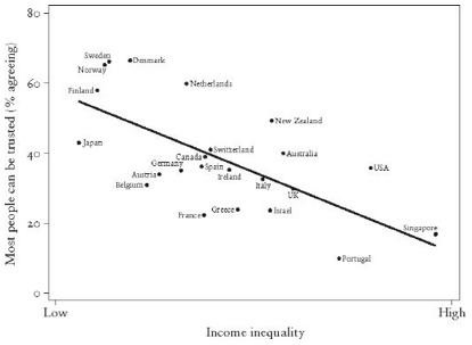

Figure 4.1 *The percentage of people agreeing that 'most people can be trusted' is higher in more equal countries.*

Similar analysis and findings are presented for mental illness (chapter 5), health and life expectancy (chapter 6), obesity (chapter 7), educational performance (chapter 8), teen births (chapter 9), violence (chapter 10), rates of incarceration (chapter 11), and social mobility (chapter 12).

The data presented here are very striking: a standard set of scatter plots demonstrating a positive relationship between inequality and a variety of social harms. In each case the authors attempt to provide an account of a mechanism that plausibly leads from inequality to the higher incidence of the social harm.

It strikes me, though, that all the mechanisms amount to the same sociological idea: that extreme inequality leads to a set of psychological conditions that in turn produce the harm in question. They emphasize status differences on the one hand (inequality) and friendship on the other (equality) as powerful determinants of social well-being and harm (kl loc 2927).

Much of this argument seems to come down to some familiar hypotheses in sociology: that anomie is a social feature that produces social and individual harms (Durkheim) and that the strands of community are favorable to human wellbeing (Tonnies, Putnam). Inequalities are toxic, according to this line of argument, because they undermine the strands of social relationships and community among individuals; they produce a situation of rising anomie and separation among individuals in society. Societies with lower inequalities allow higher levels of trust and community to persist and this gives rise to fewer social problems.

It is an appealing argument, but in the end I find it monocausal and therefore less convincing than the authors would wish. I'm finding it to be "Durkheim on epidemiological steroids". Even if we accept the point that reciprocity and mutual respect are key components of a society's health, there are other factors that undermine these besides economic inequality -- racism, ethnic hatred, sexism, and other kinds of "othering" besides income inequality. I appreciate the book. But I'd like a more multicausal analysis of the findings.

It is also interesting to ask whether the authors think there is a tipping point when it comes to inequalities. Is there a level of income inequality where inequalities are a non-factor when it comes to the social ills that they highlight? Is the level of inequality current

in Sweden just fine as a foundation for social cohesion and reciprocity? Or is the situation more analogous to exposure to second-hand smoke: every level creates a risk? In other words, is it only high inequality societies that create these harms, or does every society north of Babeuf do so to some extent?

More on The Spirit Level

Wednesday, July 06, 2011

There are quite a few interesting comments on my earlier post on *The Spirit Level* on Economist's View. I can't respond in detail to all of them, but here are a few additional thoughts.

A few commentators seem to think I'm unsympathetic to the book, which isn't accurate. So let me be more direct in my assessment of The Spirit Level: Why Greater Equality Makes Societies Stronger. I find the empirical data presented to be highly suggestive and interesting. Pickett and Wilkinson demonstrate simple trend relationships between the income inequality score of a set of countries and states and a series of social problems. I myself do not have reason to doubt their statistical methods, though other critics have done so, including Lane Kenworthy in a balanced and reasonable critique in 2010. What troubles me about the central argument of the book is what I find to be a flatly unconvincing hypothesis, that the psychological states created in a country's population by status conflict and income inequality suffice to explain the variation in health outcomes for individuals in these societies. There are many determinants of a person's satisfaction with his/her life besides income inequality; and there are many social factors that influence health outcomes for individuals besides their perception of income inequalities and the level of stress that those inequalities create in them.

In my view, a good causal explanation requires an analysis of the mechanisms that bring about the relation between cause and effect. I find only one mechanism underlying their accounts of this relationship – essentially a psychological mechanism linking the individual's perception of income inequalities to health and behavioral outcomes. They flesh this out with a description of the physiology of stress induced by rising income inequalities leading to rising mental illness; perceived status differences leading to decline in trust; stress based on perceived inequalities leading to increased "comfort eating" and obesity; status competition leads to increased violence; etc. This is what I mean by monocausal; there is just one causal process at the heart of their analysis.

The variety of causal mechanisms that seem pertinent to me in consideration of their data include several different kinds. First, as I mentioned in my post, there are serious and systemic sources of separation between individuals within societies that have nothing to do with income inequalities and that might be expected to have the same kinds of psychological and physiological effects on individuals: racism, ethnic hatred, sexism, economic conflicts that do not have to do with inequalities, and so on. For example, in the United States there are credible efforts to explain racial disparities in health outcomes on the basis of the effects on individuals living in circumstances of endemic racial discrimination and prejudice. (See, for example, Arline T. Geronimus, ScD, Margaret Hicken, MPH, Danya Keene, MAT, and John Bound, PhD, ""Weathering" and Age Patterns of Allostatic Load Scores Among Blacks and Whites in the United States"; link.) These effects are unrelated to income inequalities and derive instead from another aspect of social separation. So race rather than income appears to explain this set of health disparities. So perhaps this implies that if we had a way of measuring a "composite

index of non-economic social separation" we might have a similar set of graphs, with societies with a lot of racism and ethnic hatred at the upper right quadrant of the graph. I don't suppose that this index would be highly correlated with the quintile-quintile ratio that the authors use as their proxy for economic inequality.

Second, there are structural influences on a population's health outcomes that do not derive from the degree of income inequalities that exist in a society but are nonetheless highly influential on health status of the population. For example, the quality and accessibility of rural healthcare has a large influence on the health status of rural people; the accessibility of health insurance to inner city residents has a large influence; the targeting of food marketing in favor of "comfort foods" has a large potential influence on the whole population; and differential treatments and discrimination within health systems for different populations of patients have large potential effects. None of these factors derive from the ratio of quintile incomes – the degree of income inequality – in the society; they are independent causes of differential health outcomes across sub-populations.

I'm not an expert on statistical reasoning; but of course every reader knows that evidence of correlation between two variables A and B is not conclusive evidence of a causal relation existing between those variables. There may be a common factor that causes variation in both A and B, or the correlation may be flatly spurious. It is necessary to frame a credible and testable hypothesis about how the putative causal condition leads to the putative effect. On the other hand, finding that a proposed mechanism is not in fact valid does not establish that there is not a causal connection between the variables; it only mandates that we then search further for a mechanism that does in fact obtain. Only if we are ultimately convinced that there is no possible mechanism would we come to the conclusion that the correlation is spurious. So my position in the posting under discussion is simply that the authors have not established a mechanism linking income inequalities to bad health outcomes that satisfies me.

One can be opposed to extreme and rising income inequalities in one's society – as many of the readers of *The Spirit Level* are – without being convinced of the particular causal connections that the authors assert. And this matters quite a bit; if we want to reform society, we need to have well grounded theories of the causal processes that lead to the outcomes we want to reduce or avoid.

Dilthey on the human sciences

Friday, July 08, 2011

Wilhelm Dilthey (1833-1911) maintained that the human sciences were inherently distinct from the natural sciences in that the former depend on the understanding of meaningful human actions, while the latter depend on causal explanation of physical events. Human life is structured and carried out through meaningful action and symbolic expressions. Dilthey maintains that the intellectual tools of hermeneutics—the interpretation of meaningful texts—are suited to the interpretation of human action and history. The Formation of the Historical World in the Human Sciences takes the hermeneutic approach to understanding history a step further by exploring the idea of "objectification" – the specific ways in which persons establish their *persona* in the world through concrete actions and relations.

Here is how he introduces his approach in *TheFormation of the Historical World*:

The human sciences form an epistemic nexus that strives to attain objectively engaged and objectively valid conceptual cognition of the interconnectedness of lived experiences in the human-historical-social world. The history of the human sciences shows a constant struggle with the difficulties encountered here. ... The investigation of the possibility of such objective conceptual cognition forms the foundation of the human sciences. In the following, I present some contributions to such a foundation. (23)

The human-historical world as it confronts us in the human sciences is not a copy, as it were, of a reality existing outside it. The cognitive process cannot produce such a copy. It is and remains bound to its means of intuiting, of understanding, and of conceptual thinking. Nor do the human sciences want to produce such a copy. Rather, they refer what happens and what has happened -- the unique, the contingent, the momentary -- to a system of value and meaning. As it progresses, conceptual cognition seeks to penetrate this system ever more deeply. It becomes ever more objective in its grasp, without ever being able to surpass its own essence, namely, it can experience what is only through re-feeling and re-construing, through connecting and separating, through abstract systems and a nexus of concepts. (23-24)

Such conceptual cognition of the processes themselves in which the human sciences develop is at the same time the condition for the understanding of their *history*. On that basis, one recognizes the relation of the particular human sciences to the coexistence and sequence of lived experiences upon which they are founded. (24)

And one last point becomes intelligible. The development of the human sciences must be accompanied by a logical-epistemological self-reflection, that is, by the philosophical consciousness of the way in which the intuitive-conceptual system of the human-socio-historical world is formed on the basis of the lived experience of what has happened. (24)
These are dense, difficult paragraphs, and they are worth spending time on unravelling. What is Dilthey saying here? What is the philosophy of society, history, and cognition that he is expressing?

The first sentence defines two domains: the knowledge system of the human sciences and the dense reality of the social world. Through the knowledge systems of the human sciences we arrive at representations of the social-historical world. The social-historical world is characterized in terms of the inter-connected lived experience of human beings; this implies communication, interaction, and subjectivity as crucial features of social life. The knowledge systems of the human sciences are characterized as being "objective" and "conceptual". The objectivity in question has to do with the fact that there is a reality associated with social life that serves as the object of knowledge; the conceptuality has to do with the fact that it is necessary to arrive at categories in thought in terms of which to organize and represent that reality.

This interpretation of the first sentence sounds rather Lockean or Cartesian; knowledge represents the world. The first sentence of the second paragraph, however, unsettles that naive realism, because here Dilthey insists upon the distinctness of representation and reality. Our knowledge of the social world is not a "copy"; it is an abstract representation. This observation seems to be analogous to the obvious point that a verbal description of an apple is not similar to the apple; rather it is a syntactic construction that attributes characteristics to the features of the apple. The next several sentences in the second paragraph seem to change the subject slightly; Dilthey distinguishes between "copying or representing" and "interpreting and locating in terms of a meaning system." This point is understandable in terms of the hermeneutic method: discover the meaningful

relationships among elements of the text (or ensemble of actions). The "re-feeling and re-construing" seems to be an expression of the method of *verstehen*: to reconstruct the meaning of an action by placing oneself as fully in the position of the actor as possible. And the final two sentences seem to suggest a refinement of knowledge through the discovery of finer detail in the interconnections among events and their connections to a system of meaning in the world of lived experience.

There seem to be three high-level features of this conception: first, that human reality is relational and meaningful; second, that the knowledge of human reality involves refined interpretation of actions and interactions in terms of the meanings attributed to them by the actors; and third, that the knowledge enterprise itself is a meaningful activity that requires critical self-reflection. And, finally, there is a respect in which Dilthey's method is empirical rather than idealist. The objectivity that he seeks in these paragraphs seems to have at least in part to do with the idea of evidence-driven discovery.

W. H. Walsh's philosophy of history

Tuesday, July 12, 2011

English-speaking philosophers have often made a hash of the philosophy of history. Either they have had such disdain for continental philosophy that they could not get their minds around the thoughts of a Hegel or a Dilthey, or they became pre-occupied with certain minor linguistic or logical issues and therefore couldn't get to the more serious problems. W. H. Walsh was a surprising exception in the British environment of the 1950s. His Philosophy of History. An Introduction, first published in 1951 and revised in 1960, is an open-minded and very well grounded effort to provide an in-depth presentation of the field.

The book attempts to treat both major aspects of the philosophy of history: the nature of historical knowledge and the possibility of gaining “metaphysical” knowledge about history. An Oxford philosopher evidently trained in modern philosophy, Walsh was strongly influenced by Collingwood and was well aware of the European idealist tradition of philosophical thinking about history, including Rickert, Dilthey, and Croce, and he treats this tradition in a serious way. He draws the distinction between these traditions along the lines of “critical” and “speculative” philosophy of history. Walsh’s goal for the book is ambitious; he hopes to propose a framework within which the main questions about history can be addressed, including both major traditions. I find the book to be an excellent piece of work on the subject, and very enjoyable to work through. Here are a couple of large groups of questions that he poses in the book in order to formulate a structure for thinking about the philosophy of history.

I
Walsh lays out the field of the philosophy of history along the following lines.

First, he offers some ideas about the subject matter and knowledge content of history. He describes the goal of historical inquiry in these terms:

[The historian] aims ... at a reconstruction of the past which is both intelligent and intelligible. (32)

What every historian seeks for is not a bare recital of unconnected facts, but a smooth narrative in which every event falls as it were into its natural place and belongs to an

intelligible whole. (33)
The historian is presented with a number of events, actions, and developments during a period. How do they hang together? The process of cognition through which the historian makes sense of a set of separate historical events Walsh refers to as "***colligation***":

Colligation: to locate a historical event in a larger historical process in terms of which it makes sense (23). This process of reasoning serves to establish the "inner connections between certain historical events" (24).
Walsh fundamentally accepts Collingwood's most basic premise: that history concerns conscious human action. Collingwood's slogan was that "history is the science of the mind," and Walsh appears to accept much of this perspective. So the key intellectual task for the historian, on this approach, is to reconstruct the reasons or motives that actors had at various points in history (and perhaps the conditions that led them to have these reasons and motives). This means that the tools of interpretation of meanings and reasons are crucial for the historian -- much as the hermeneutic philosophers in the German tradition had argued.

II
One of the central questions that Walsh identifies is whether history is a part of "science," or whether it is a *sui generis* kind of knowledge. Here is Walsh's summary definition of the key features of a field of scientific knowledge:

We may sum up the results of this brief attempt to bring out the main features of the common conception of science and scientific knowledge as follows. We apply the term "science" to knowledge which (i) is methodically arrived at and systematically related; (ii) consists of, or at least includes, a body of general truths; (iii) enables us to make successful predictions and so to control the future course of events, in some measure at least; (iv) is objective, in the sense that it is such as every unprejudiced observer ought to accept if the evidence were put before him, whatever his personal predilections or private circumstances. (36)
And he argues that history satisfies (i); probably not (ii); not (iii); and qualified yes to (iv). In other words, according to Walsh, history is not a science in the paradigmatic sense of physics or chemistry.

If history is not "science," then what kind of knowledge is it? The main alternative is what Walsh characterizes as the idealist conception of historical knowledge. Here is what Walsh refers to as the "***standard idealist account of historical knowledge***":

History, because it offers a body of knowledge methodically arrived at, is a science; but it is a science of a peculiar kind. It is not an abstract but a concrete science, and it terminates not in general but in individual truths. 43

Nature we must look at from the outside, but thoughts and experiences are accessible to us from within. We can grasp them in a unique way because we can re-think or re-live them, imaginatively putting ourselves in the place of the persons, past or present, who first thought or experienced them. (44)

The idealist theory of history, we may begin by remarking, consists in essentials of two propositions. **First**, that history is, in a sense which remains to be specified, properly concerned with human thoughts and experiences. And **second** that, just because of this, historical understanding is of a unique and immediate character. (48)
These characteristics recall German historicism and interpretivism. (See this post on the

methodological crisis in German thought around 1900; link.)

III

Walsh suggests that the philosophical content of the philosophy of history falls naturally into two different sorts of inquiry, parallel to the distinction between philosophy of nature and philosophy of science. The first has to do with metaphysical questions about the reality of history as a whole; the latter has to do with the epistemic issues that arise in the pursuit and formulation of knowledge of history. He refers to these approaches as "speculative" and "critical" aspects of the philosophy of history. And he attempts to formulate a view of what the key questions are for each approach.

Speculative philosophy of history asks --

- What is the meaning and purpose of the whole historical process? (25)
- Can we "write such an account of the detailed course of historical events that its 'true' significance and 'essential' rationality are brought out?" (25)
- What is the main driving factor in history? (Marx: economics) (26)
- "We may summarize by saying that if the philosopher can be said to have any specific concern with the course of history, it must be with that course as a whole, i.e., with the significance of the whole historical process." (27)

Walsh take a supportive or or at least agnostic position on these questions; he asserts that they are meaningful questions and can meaningfully be considered. This is in contrast to the position of the verificationist end of the analytic philosophy spectrum, which would deny the meaningfulness of these questions (and proposed answers).

Critical philosophy of history asks these four key sets of questions:

- "What sort of thing is history and how does it relate to other studies?" (16)
- Are there "facts" in history? What makes a historical statement "true"? (18)
- Is historical knowledge "objective"? (19) [historian's bias; rational decidability]
- What is the nature of a historical explanation? (22)

Critical philosophy is what we now refer to as "analytic" philosophy; it is the equivalent for history of what the philosophy of science is for nature.

The book is divided into two large discussions. Chapters II-V treat these four major groups of questions for critical philosophy of history. Chapters VI-VIII focus on the issues and theories offered by Kant, Herder, Hegel, and a few others on "metaphysical" questions about history.

IV

It is interesting to consider the intellectual origins of innovative philosophical insights. So where did this philosophical perspective and methodology come from in Walsh's own development? Walsh is plainly an expert on the history of modern philosophy, including especially German philosophy. This means that he has read, and thought about, the tradition from Kant and Schleiermacher and Herder to Hegel and Dilthey, and is able to make philosophical sense of their theories. He authored a number of articles on Kant, Hegel, and other German philosophers, and was the author of a book on Kant's metaphysics (Kant's Criticism of Metaphysics). What does this imply about his training and his development within British philosophy? He entered Merton College, Oxford, in roughly 1930, and took his first professional post as a philosopher at Merton College in 1947 through 1960. The bulk of his academic career was spent at the University of Edinburgh as a professor of logic and metaphysics. So here is the interesting question for me: to what extent was Walsh an analytic philosopher, in the mold of Russell, Ayer, and Ryle, and to what extent was he an idealist philosopher, in the pattern of Collingwood or

Bradley? (He refers several times to Ryle's The Concept of Mind.) His comments in the first chapter of the book suggest that he positions himself separately from both camps, while understanding the philosophical perspectives and methods of both. The evidence of this book suggests that he had an admirably pluralistic approach to the problems of philosophy.

Here is a bibliography of some of Walsh's published articles and reviews (link), and here is a reconsideration of his philosophy of history with regard to "facts and truth," published in 1977 in *History and Theory* as a review of Leon J. Goldstein, *Historical Knowing* (Austin, Texas and London, University of Texas Press, 1976). In the course of the review he considers how the discipline of analytic philosophy of history has developed since 1951, and he finds that three of his four questions have come in for very extensive discussion.

(I discovered along the way, an amazing bargain as a Kindle book, Marnie Hughes Warrington's Fifty Key Thinkers on History, Second Edition ($14). The book has 3000-word discussions of fifty important historians and philosophers -- Bloch, Collingwood, Dilthey, Hempel, Obsbawm, Oakeshott, Ricoeur, Vico -- and is well worth having on the Kindle. The essays are concise and informative, and they generally raise the big issues that were important to the various thinkers. There is an entry for Walsh as well.)

Idealist philosophy of history

Wednesday, July 13, 2011

In a previous post I commended W.H. Walsh's approach to the philosophy of history for Walsh's sympathetic effort to understand both traditions in the field, including what is called "speculative" philosophy of history (An Introduction to Philosophy of History). And Walsh is to be commended as well for his analytical ability to formulate and explicate these positions. This is in fact what we want from good historians of philosophy -- a detailed, text-based explication of the theories of difficult thinkers such as Hegel and Dilthey.

So the fact that Walsh offers an extended and nuanced interpretation of the efforts by Hegel, Herder, and Dilthey is to his credit as an exegetical scholar. But a key issue remains: do the positions that he explicates stand up to criticism? Is there in fact an intellectually credible place for speculative or idealist philosophy of history?

Walsh's position seems to be ambiguous on this question. On the one hand, he seems sometimes simply to be saying that there is a meaningful and philosophically intelligible program of thought associated with the speculative school -- which is consistent with an ultimate finding that this program fails in execution. And at other times he seems to go further and to assert that Hegel or Herder actually succeed in providing something of a substantive speculative philosophy of history that adds to our knowledge. Here is how he describes the intellectual work Hegel seeks to complete:

To accomplish this task the philosopher must take the results of empirical history as data, but it will not suffice for him merely to reproduce them. He must try to illuminate history by bringing his knowledge of the Idea, the formal articulation of reason, to bear upon it, striving, in a phrase Hegel uses elsewhere, to elevate empirical contents to the rank of necessary truth. (143)
Here is part of Walsh's assessment of the success of Hegel's project:

We must now try to estimate the adequacy of this defence. As regards the first point, it is surely successful. I have tried to stress throughout this chapter and the last the metaphysical and moral context within which speculative philosophy of history arose and was pursued. As we have seen, those engaged in these enquiries were concerned to divine the meaning or point or rationality behind the historical process as a whole, and they took up this question primarily because of its metaphysical relevance. (148)

My own assessment of idealist philosophy of history as presented by Walsh is measured. First, Walsh includes the centrality of action and ideas within history as a central tenet of idealist philosophy of history. This is Collingwood's central idea, and it seems to be Dilthey's as well. And in my opinion, it is a credible and empirically suitable hypothesis. Even if we conclude in the end that there is more to the historical process than deliberation and action, we can agree that action is a highly important component. And therefore an explication of the ways we investigate and interpret meanings and actions is a valid exercise. It falls in the category of epistemology, with a harmless bit of ontology stirred in (the constitutive importance of action).

But it must be emphasized that this perspective doesn't rule out other important insights into the ways that historical change takes place. In particular, we can also adhere to a limited materialism and structuralism in history, following Marx in holding that "men make their own history, but not in circumstance of their own choosing."

Second, I'm willing to be persuaded that there is a valid object of study for philosophers in the logical-semantic systems that thinkers like Hegel have created; and this extends to their philosophies of history. So the philosophical study and explication of metaphysical philosophy of history is a rationally acceptable enterprise as well.

What I have difficulty in accepting is that such a system can actually succeed. When Walsh writes that the goal of the historian and the philosopher is to tell the story of history in such a way that all the events make sense within the context of a master narrative -- when he proposes that the goal of the philosophy of history is to discover the real meaning and rationality of history as a whole -- I believe he is describing an effort that cannot succeed. There is no single unifying meaning or plan in history. And efforts to "colligate" events in such a way as to demonstrate that they contribute to such a plan seem to be unguided acts of creativity.

It is a commonplace that a series of actual events can be interpreted in different and apparently incompatible ways. We can attribute different motives to the actors and interpret their actions in such a way as to tell very different stories. (This is what we refer to as the "Rashomon effect".) In ordinary settings we can sometimes gain more evidence to choose between them. But when the choice is between interpretation frameworks at the highest level -- a materialist theory of history and a theory based on the unfolding of reason, for example -- we can't possibly provide empirical evidence that would choose between these all-encompassing hypotheses.

So I'm putting my bets on several ideas: yes to the validity of the hermeneutic program, yes to the interpretive task of understanding the great metaphysical systems from a philosophical point of view, and no to the idea of rationally justifiable interpretations of the whole of history. In Walsh's terms this means yes to a limited idealism, yes to the task of the history of philosophy, and no to the aspiration towards a substantive metaphysics of history.

And, indeed, Walsh seems eventually to come to a similar conclusion:

Our speculative philosophy of history must accordingly be a mixed one. In a way, we are forced to characterize it as utterly wrong-headed, since its programme amounts to an attempt to comprehend history from the outside; an attempt which, as Croce made clear long ago, cannot have any appeal for working historians. On the other hand, its most celebrated exponents certainly did make an important indirect contribution to the development of historical studies, as we have just tried to show. Whether there is any future in this type of philosophizing is another question, dependent, it would seem, on what chance there is of anyone's producing a tenable moral justification of the course history has taken. (153-54)

Food and water

Friday, July 15, 2011

It seems likely enough that one of the largest global security issues in the next fifty years will be food and water. There is a brewing food crisis underway already, with prices for staple grains rising world wide, and poor countries are beginning to experience the consequences. But a crisis in fresh water seems not too far in the future as well. Both these necessities depend on inherently scarce resources: arable land and large sources of fresh water. Along with energy, these goods are crucial to every person and every country in the world; and this in turn suggest the possibility of serious conflict over these resources in the future.

So what makes food and water a global security crisis? How does the possibility of dearth at the family level get transformed into the possibility of international conflict? Rising food prices create social unrest at the national level long before they lead to famine or malnutrition. International grain markets have been unstable over the past decade, with periodic upward spikes in prices. And grain riots have occurred as a consequence in a number of developing countries. This piece from DemocracyNow from 2008 documents demonstrations and riots across a range of African countries (link), with an interview with Raj Patel, author of Stuffed and Starved: The Hidden Battle for the World Food System. Here are some updates from the Christian Science Monitor (link) and Energy Bulletin (link), including riots in Algeria in 2011.

The bottom line of several of these reports is fairly simple: the international trade system for grains, including especially rice and wheat, periodically undergoes abrupt and prolonged price rises, and these price increases have dire consequences for urban poor and middle class people in the developing world. When a large population mobilizes in protest against rising food prices, national governments are at risk. And this is where the

security risk comes in: when countries like Algeria or Morocco suffer serious instability, this has the potential of leading to international instability in the region as well.

Here is another, more distant cause of international tension that comes from the food crisis. Governments are interested in taking steps to provide greater food security for their own populations. And this sometimes involves taking actions that are harmful for other countries or for other populations. One symptom of the pressures mounting on the world food system is a widespread land grab of agricultural land around the developing world. Here is a report by the United Nations Food and Agricultural Organization (FAO) on this issue (link) and a piece from the *Guardian* that describes the situation a few years ago (link), and here is a FastCompany story about China's land purchases (link). The FAO report documents a significant transfer of land ownership from developing countries to middle and upper income countries; this implies serious future constraints on the development possibilities available to those countries. And it suggests a new form of colonialism -- not direct governance, but substantial absentee ownership. This too has the potential for stimulating international conflict.

So what about water? Here is a recent report by the Council for Foreign Relations on the interconnected consequences of fresh water shortages in different parts of the world (link). In this piece the effects of China's water crisis are traced internationally. Here is an inventory of resources by GlobalPolicy on international conflicts over water (link); it is a long list of potential conflicts. Here is the introduction the editors offer:

As demand for water hits the limits of finite supply, potential conflicts are brewing between nations that share transboundary freshwater reserves. More than 50 countries on five continents might soon be caught up in water disputes unless they move quickly to establish agreements on how to share reservoirs, rivers, and underground water aquifers. The articles and analysis below examine international water disputes, civil disturbances caused by water shortages, and potential regulatory solutions to diffuse water conflict.
Chinese-financed dam projects in Burma and other parts of Southeast Asia indicate how high the stakes are. The great rivers of Southeast Asia now face a major of challenges as a result of plans for hydroelectric dams regulating flow to downriver users. Here is a piece from the *Irrawaddy* on the controversies surrounding the Myitsone Dam in northern Burma; link. Similar issues arise on the Mekong River and other great rivers in the region; link. The problems that have arisen with regard to dams in Southeast Asia include displacement of villages and towns, serious environmental damage, and significant lowering of water levels in many of the great rivers of the region. Here is a background piece in *Global Policy Forum* on China's massive expansion of hydropower; link.

These sources of conflict over the most basic necessities of life suggest the need for serious international planning today to arrive at equitable and sustainable regimes for resolving conflicts over resources in the future.

Academic freedom from Hofstadter to Dworkin

Wednesday, July 20, 2011

Academic freedom is a core value in American higher education. At certain times in our history it is a value that has been severely challenged, including especially during the McCarthy period of the 1950s. But what, precisely, does it entail?

One way of starting on this topic is to consider Richard Hofstadter's writings on the subject. Hofstadter was an historian who did an excellent job of tracking some deep currents in American political culture, including the powerful currents of progressivism, conservatism and paranoia that American politics have embodied over the past two centuries (The Progressive Movement: 1900-1915, Anti-Intellectualism in American Life, The Paranoid Style in American Politics). (Here is an informative review of Hofstadter's biography in the *New York Times*.)

One of those currents on the progressive side is the idea of academic freedom. Hofstadter was a champion of the value of intellectual discourse in a democracy, and Development of Academic Freedom in United States (with Walter Metzger, 1955) was a direct response to the attack on the academic freedoms of professors of the McCarthy period beginning in 1953. (The first part of this book was later published as Academic Freedom in the Age of the College (1961), which covers the history of the freedoms assigned to colleges and universities from the European middle ages to American colleges at the time of the Civil War.) The project as a whole is an interesting one. It was funded by the American Academic Freedom Project at Columbia as a response to Joseph McCarthy's attack on universities and professors. Hofstadter's part of the project was to write a history of the evolving idea of academic freedom from the European middle ages through the American colleges of the 1860s. Walter Metzger's contribution analyzed the development of universities and academic freedom in America after the 1860s. Robert MacIver wrote a companion volume, Academic Freedom in Our Time.

What is lacking in *Development of Academic Freedom* is an analytical definition of the idea of academic freedom. Hofstadter is clearest in his defense of the idea of the independent intellectual, whether in the medieval Italian university of the nineteenth century American university. But neither he nor Metzger give a succinct definition of the concept of academic freedom itself.

So what is academic freedom? And how is it distinct from the other kinds of freedoms we have as either constitutional protections or fundamental human rights -- freedom of

association, freedom of speech and thought, freedom of expression? Fundamentally the idea is that the faculty of a university have a more extensive and specialized version of each of these fundamental freedoms, and that their exercise of their academic freedom cannot be used as a basis for dismissing them from their positions within the university. (This is the fundamental justification of the system of faculty tenure.) The employees of a corporation have a right of freedom of expression; but their conditions of employment may set limits on their exercise of that freedom. For example, there are numerous examples of people dismissed from their jobs in the private sector as a result of their comments about the company they work for. The idea of academic freedom is that professors have a special right to think, reason, and express their ideas about subjects relevant to their teaching and research responsibilities without fear of sanction by the universities (or legislatures) that employ them.

A second dimension of the idea of academic freedom is institutional. The university ought to be significantly autonomous from the power centers of society in its internal organization and decision-making. The curriculum, the subjects that are taught and researched, and the processes of appointment and review of faculty should be governed by the processes of the university rather than external powers in society. And most fundamentally, this aspect of the idea depends on the notion that the pursuit of truth should depend on the rational procedures of the disciplines of the sciences and humanities, not on the particular interests of powerful segments of society.

The classical justification for the idea of a form of academic freedom more extensive than the general freedoms that citizens enjoy qua citizens derives essentially from arguments expressed in the nineteenth century in John Stuart Mill's On Liberty: the pursuit of truth requires the untrammeled exploration of and expression of conflicting ideas, so that rational citizens can arrive at a better understanding of the issues. Here is how the 1940 AAUP statement puts the point (link):

Academic freedom is essential to these purposes and applies to both teaching and research. Freedom in research is fundamental to the advancement of truth. Academic freedom in its teaching aspect is fundamental for the protection of the rights of the teacher in teaching and of the student to freedom in learning. It carries with it duties correlative with rights.[1]
The argument is fundamentally utilitarian: Society is best served when it embodies a university system that is fundamentally committed to the the principles of academic freedom.

Here is the classic statement of academic freedom from the AAUP *Red Book*, drafted in 1940 (link).

Academic Freedom

1. *Teachers are entitled to full freedom in research and in the publication of the results, subject to the adequate performance of their other academic duties; but research for pecuniary return should be based upon an understanding with the authorities of the institution.*
2. *Teachers are entitled to freedom in the classroom in discussing their subject, but they should be careful not to introduce into their teaching controversial matter which has no relation to their subject.[2] Limitations of academic freedom because of religious or other aims of the institution should be clearly stated in writing at the time of the appointment.[3]*
3. *College and university teachers are citizens, members of a learned profession, and*

officers of an educational institution. When they speak or write as citizens, they should be free from institutional censorship or discipline, but their special position in the community imposes special obligations. As scholars and educational officers, they should remember that the public may judge their profession and their institution by their utterances. Hence they should at all times be accurate, should exercise appropriate restraint, should show respect for the opinions of others, and should make every effort to indicate that they are not speaking for the institution.[4]

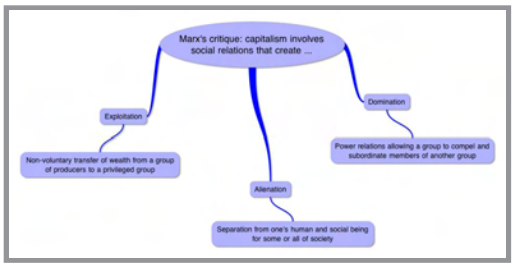
This statement refers to three zones of academic freedom: in research and publication, in the classroom, and in "extramural expressions" by faculty members in the exercise of their ordinary citizens' rights of expression. Essentially this final point comes down to the idea that a faculty member has an ordinary citizen's right to express ideas that are unpopular to the public without punishment, "censorship or discipline" from the university for this expression. Noam Chomsky's opinions about the Vietnam War or the Gulf War were often unpopular with officials and the public; but his academic freedom assured that he would not be censored by his university employer. An employee of Northrup or Krogers would not have had the same protections. (Note that principle 3 is the most qualified of the three, and sets somewhat vague limits on the content and form of extra-mural utterances by the faculty member.)

The AAUP statement does not separately justify its inclusion of the extramural principle; but presumably it goes along these lines. Determining public policy in a democracy requires open debate among well informed citizens. Faculty members are well positioned to develop their knowledge and arguments about important public issues -- welfare reform, desegregation, war and peace. The public and the common good are well served by a set of arrangements that enable faculty members to speak their minds without fear of retaliation from their university employers. So it is felicitous to extend the protections of academic freedom to expressions by faculty members in the public sphere as well as within the university.

The philosopher of jurisprudence Ronald Dworkin provided a pivotal contribution to Louis Menand's The Future of Academic Freedom (1998). Dworkin argues that the issues surrounding academic freedom have shifted since the 1970s, and that they have as much to do with criticisms of faculty speech from the left as from the right. Here is how Dworkin describes the essentials of academic freedom:

We begin reinterpreting academic freedom by reminding ourselves of what, historically, it has been understood to require and not to require. It imposes two levels of insulation. First, it insulates universities, colleges, and other institutions of higher education from political institutions like legislatures and courts and from economic powers like large corporations. A state legislature has, of course, the right to decide which state universities to establish -- whether, for example, to add an agricultural or a liberal arts college to the existing university structure. But once political officials have established such an institution, fixed its academic character and its budget, and appointed its officials, they may not dictate how those they have appointed should interpret that character or who should teach what is to be taught, or how. Second, academic freedom insulates scholars from the administrators of their universities: university officials can appoint faculty, allocate budgets to departments, and in that way decide, within limits, what curriculum will be offered. But they cannot dictate how those who have been appointed will teach what has been decided will be taught. (183)

In addition to the utilitarian reasons for defending academic freedom mentioned above, Dworkin argues that there is also a principled ethical basis for these institutional protections based on his theory of "ethical individualism".



It seems relatively clear that academic freedom is a fragile value that depends substantially on the willingness of the public to recognize its crucial role in securing democratic progress, and legislatures and elected officials who are prepared to resist the inclination to narrow its scope. And it also seems right that Hofstadter's central intuitions about universities are still the strongest justification for the defense of academic freedom: the integrity of intellectuals and scholars seeking and debating the truth and the contribution they can make to a civil democracy. Here is how Robert MacIver puts this point in *Academic Freedom in Our Time*:

The search for knowledge, honestly undertaken, is a moral discipline. With the pursuit of this discipline goes the liberation from intolerance. . . Thus the intellectual mission of the university becomes also a moral one. Men sensitive to experience may learn the lesson in other ways, but the institution of learning is a major training ground. . . . Not knowledge itself but the free search for and the free communication of knowledge distinguishes the open mind from the closed mind, and the open society from the closed society.... The attack on academic freedom is an attack on all these values. (261-262.)

Here is a review of Hofstadter and Metzger, Development of Academic Freedom in United States as well as MacIver, Academic Freedom in Our Time. Here is an article in the *Journal of Philosophy* on MacIver's book, including a fascinating letter by John Dewey to the New York Times in 1949 on the subject of academic freedom. And here is an AAUP piece in *Academe* on what it regards as a different kind of threat to academic freedom -- from commercial and corporate interests.

Marx's critique

Friday, July 22, 2011

Marx was a critic above all else. His most comfortable intellectual stance was criticism -- most of the subtitles of his works involve the word "critique". He was, of course, a critic of other thinkers --Proudhon, Smith, Bakunin, for example. And here, the key to criticism is the unearthing of indefensible intellectual presuppositions. But even more importantly, he was a critic of the society he observed around him. The key here is to uncover systemic features of a given society that are fundamentally inconsistent with important human values. His earliest social criticism took its aim at the German society he inhabited in the 1830s and 1840s. But it is his critique of modern capitalist society that is the most enduring, and this critique took shape through his observations of the society and economy of Great Britain in the 1850s and 1860s.

I think that Marx's critique of 19th-century capitalist society can be summarized in three words: **exploitation**, **domination**, and **alienation**. These are simple ideas, but they invoke large and somewhat separate theories. The first has to do with economic relations in capitalism, in which one group extracts wealth from the work of another group. The

second has to do with political relations in which one group has the power to compel subordination on the part of another group. And the third has to do with consciousness and the social psychology of the members of capitalist society.

You might say that it is the work of Capital: A Critique of Political Economy, Vol. 1 to address the first set of questions. Capitalism depends on free labor and freedom of property; it depends on a system of free exchange; so how can exploitation take place? The exploitation inherent in slavery or feudalism is apparent in the formal legal and political relations of those regimes: slaves and serfs are compelled to transfer part of the product of their labor to the masters through a juridical regime enforcing inequality. But how does this work in the system of free exchange in capitalism? Marx's answer, briefly, is that the privilege of ownership of the means of production allows owners to set the wage at a level that permits the creation of a profit; this profit is a form of surplus value.

Marx's political writings, and his writings about power within capitalism, are less systematic. But in his writings about French politics and the revolution of 1848 he expresses some of his ideas about how domination works through a political system (Eighteenth Brumaire of Louis Bonaparte, The Civil War in France: The Paris Commune). And in *Capital* he offers a vivid description of the social power wielded by the capitalist (link).

On leaving this sphere of simple circulation or of exchange of commodities, which furnishes the “Free-trader Vulgaris” with his views and ideas, and with the standard by which he judges a society based on capital and wages, we think we can perceive a change in the physiognomy of our dramatis personae. He, who before was the money-owner, now strides in front as capitalist; the possessor of labour-power follows as his labourer. The one with an air of importance, smirking, intent on business; the other, timid and holding back, like one who is bringing his own hide to market and has nothing to expect but — a hiding.

Marx's writings about alienation are among his earliest writings. The most systematic exposition occurs in The Economic and Philosophic Manuscripts of 1844, where he describes the social consciousness associated with the "modern" factory system. The worker is separated from the product; he is separated from the process; and he is separated from his own essence, his creative capacity for invention and creative labor. Here are a few representative passages (link).

We proceed from an actual economic fact.

The worker becomes all the poorer the more wealth he produces, the more his production increases in power and size. The worker becomes an ever cheaper commodity the more commodities he creates. The devaluation of the world of men is in direct proportion to the increasing value of the world of things. Labor produces not only commodities; it produces itself and the worker as a commodity – and this at the same rate at which it produces commodities in general.

This fact expresses merely that the object which labor produces – labor’s product – confronts it as something alien, as a power independent of the producer. The product of labor is labor which has been embodied in an object, which has become material: it is the objectification of labor. Labor’s realization is its objectification. Under these economic conditions this realization of labor appears as loss of realization for the workers[18]; objectification as loss of the object and bondage to it; appropriation as estrangement, as

alienation.[19]

...

All these consequences are implied in the statement that the worker is related to the product of labor as to an alien object. For on this premise it is clear that the more the worker spends himself, the more powerful becomes the alien world of objects which he creates over and against himself, the poorer he himself – his inner world – becomes, the less belongs to him as his own. It is the same in religion. The more man puts into God, the less he retains in himself. The worker puts his life into the object; but now his life no longer belongs to him but to the object. Hence, the greater this activity, the more the worker lacks objects. Whatever the product of his labor is, he is not. Therefore, the greater this product, the less is he himself. The alienation of the worker in his product means not only that his labor becomes an object, an external existence, but that it exists outside him, independently, as something alien to him, and that it becomes a power on its own confronting him. It means that the life which he has conferred on the object confronts him as something hostile and alien.

...

Estranged labor turns thus:

(3) Man's species-being, both nature and his spiritual species-property, into a being alien to him, into a means of his individual existence. It estranges from man his own body, as well as external nature and his spiritual aspect, his human aspect.

(4) An immediate consequence of the fact that man is estranged from the product of his labor, from his life activity, from his species-being, is the estrangement of man from man. When man confronts himself, he confronts the other man. What applies to a man's relation to his work, to the product of his labor and to himself, also holds of a man's relation to the other man, and to the other man's labor and object of labor.

In fact, the proposition that man's species-nature is estranged from him means that one man is estranged from the other, as each of them is from man's essential nature.

The estrangement of man, and in fact every relationship in which man [stands] to himself, is realized and expressed only in the relationship in which a man stands to other men.

Each of these theories highlights a different dimension of the social reality of modern society, in Marx's worldview. Each implies a positive theory of a good society; it is one that emphasizes a kind of human equality, and a positive view of society as an environment that enables the full development of each as a condition of the full development of all. So equality and the fullness of human flourishing are the underlying values.

Finally, there are systemic connections among the three areas. It takes power to sustain an exploitative system; so exploitation and domination are interlinked. A specific group of individuals are privileged by both systems; and Marx has a subtle view of the ways in which the propertied classes wield power through a group of power specialists. Alienation, finally, is a predictable consequence of the circumstances of life created by the social relations of exploitation and domination. There is the alienation of the worker; but there is also the alienation of the consumer and the voter, each carried along by a system of activity that frustrates real human engagement and satisfaction.

Does any of this seem relevant in the contemporary world? The inequalities we see in the current economy certainly suggests the idea of exploitation of someone; wealth is being

created and a large proportion of it is flowing to a small privileged group. Power is visibly concentrated in contemporary society -- whether it comes to legislation, regulation, or the influence of the media. This implies a degree of domination on the part of a small segment of society -- a "ruling elite". And few would doubt that there seems to be a growing sense of value-less-ness in contemporary society -- a condition strikingly like what Marx described as alienation. So it certainly seems timely for all of us to sharpen our critical skills and help figure out what we need to do to create the foundations of a more just and more humanly satisfying social order.

This is a short posting about a large subject. Is it possible to argue that these few paragraphs capture the heart of the view? Could Marx have formulated his key ideas in a posting in the *New York Herald Tribune*? Essentially, I'd like to argue yes. Much of Marx's work takes the form of detailed discovery of the facts that make this case and an unconvincing effort to formulate a mathematical economic theory, the labor theory of value. But what is probably of the greatest value today are the dimensions of social criticism outlined here, not the economic theory.

Social explanation and causal mechanisms

Monday, July 25, 2011

To explain a social outcome or regularity, we need to provide an account of why and how it came about; and this means providing a causal analysis in terms of which the explanandum appears as a result.

Having a causal theory of a realm requires having an ontology: what kinds of things exist in this realm, and how do they work? Along with others, I offer a social ontology grounded in the actions and relations of socially constituted actors, which I refer to as methodological localism (link). (This is also the ontology asserted by the programme of "analytical sociology"; link.)

This entails, basically, that we need to understand all higher-level social entities and processes as being composed of the activities and thoughts of individual agents at a local level of social interaction; we need to be attentive to the pathways of aggregation through which these local-level activities aggregate to higher-level structures; and we need to pay attention to the iterative ways in which higher-level structures shape and influence individual agents. Social outcomes are invariably constituted by and brought into being by socially constituted, socially situated individual actors (methodological localism). Both aspects of the view are important. By referring to "social constitution" we are invoking the fact that past social arrangements have created the social actor. By referring to "social situatedness" we invoke the idea that existing social practices and rules constrain and motivate the individual actor. So this view is not reductionist, in the sense of aiming to reduce social outcomes to pre-social individual activity.

We also want to refer to supra-individual actors -- firms, agencies, organizations, social movements, states. The social sciences are radically incomplete without such constructs. But all such references are bound by a requirement of microfoundations: if we attribute intentionality to a firm, we need to be able to sketch out an account of how the individuals of the firm are led to act in ways that lead to the postulated decision-making and action (link).

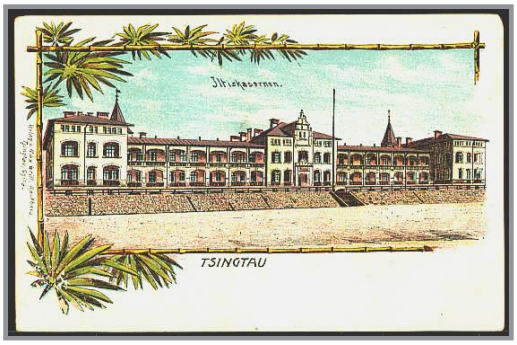
So, then: what is involved in asserting that social circumstance A causally produces social circumstance B? There are, of course, numerous well developed answers to this question: statistical inference based on correlations of occurrences, conditional probabilities, and necessary-sufficient condition analysis. My view, however, is that there is a more basic meaning of causation: A caused B ***iff*** there is a sequence of causal mechanisms leading from A to B. This approach is especially suitable for the social realm because, on the one hand, there are few strong statistical regularities among social outcomes, and on the other, it is feasible to identify social mechanisms through a variety of social research methods -- comparative analysis, process tracing, case studies, and the like.

The social mechanisms approach (and the scientific realism that lies behind it) goes back at least as early as the late 1980s. An early statement of the view was presented in my Varieties Of Social Explanation: An Introduction To The Philosophy Of Social Science in 1991. Mario Bunge and Jon Elster took similar positions. The view took a large step forward, on the theory side, with the publication of Hedstrom and Swedberg's Social Mechanisms: An Analytical Approach to Social Theory (1998), and on the empirical research side with the publication of McAdam, Tarrow, and Tilly's Dynamics of

Contention (2001). There are important differences; theorists within analytical sociology largely favor methodological individualism and mechanisms grounded in rational individuals, whereas Tilly and his colleagues favor "relational" mechanisms. But in each case the model of agent-centered explanations that either require microfoundations or are plainly compatible with such a requirement. (Here is a recent post on causal mechanisms.)

Several social scientists have anticipated this approach through their own concrete analysis of aggregation phenomena. A good illustration is Thomas Schelling. His work presents a large number of examples of mundane social outcomes that he explains on the basis of simple individual-level choices and an aggregation mechanism (Micromotives and Macrobehavior, Choice and Consequence). Features of organized crime, traffic patterns, segregation, and dying seminars all come in for treatment. Schelling demonstrates in concrete terms what sorts of things we can identify as "social mechanisms" and traces them back to the circumstances of action of individuals in social situations.

The framework of social mechanisms as a basis for social explanation raises an important question about the role and scope of generalizability that we expect from a social explanation. Briefly, the mechanisms identified here show a degree of generalizability; as McAdam, Tarrow and Tilly assert, social mechanisms can be expected to recur in other circumstances and times. But the event itself is one-of-a-kind. This is a familiar feature of Tilly's way of thinking about contentious events as well: the American Civil War was a singular historical event. But a good explanation will invoke mechanisms that recur elsewhere. We shouldn't expect to find general theories of civil wars; but our explanations of particular civil wars can invoke quasi-general theories of mid-level mechanisms of conflict and escalation. (Here is a recent posting on general and specific causal claims.)



Another important methodological question for this approach to social explanation is the issue of explaining general statistical patterns in social life. What if we want to explain something more quantitative -- say a gradually rising divorce rate or the finding that co-habitants before marriage have higher divorce rates than non-co-habitants? On the social mechanisms approach, we would want two things. First, we would like an agent-level mechanism that explains the statistic; and second, we would like to find a common cause if the phenomenon is similar in several countries.

Finally, the actor-based mechanisms approach invites an area of study which is now being referred to as "aggregation dynamics" (link, link). We need to have theories and tools that permit us to aggregate different micro-level processes over time into meso- and macro-outcomes, taking into account the complexity of causal interactions in a dynamic process. The tools of agent-based modeling are relevant here (link).

Steinmetz on colonialism

Wednesday, July 27, 2011

George Steinmetz offers a comparative sociology of colonialism in The Devil's Handwriting: Precoloniality and the German Colonial State in Qingdao, Samoa, and Southwest Africa. More specifically, he wants to explain differences in the implementation of "native policy" within German colonial regimes around the turn of the twentieth century. He finds that there are significant differences across three major instances of German colonialism (Samoa, Qingdao, Southwest Africa), and he wants to know why. (For example, the Namibia regime was much more violent than the Samoa or Qingdao

examples.) This is a causal question, and Steinmetz is one of the most talented sociologists of his cohort in American sociology. So it is worth looking at his reasoning in detail.

One reason this is interesting to me is that it seems to represent a hard case for the perspective of analytical sociology (link, link), with its goal of providing an overarching model of all valid sociological explanations. On its face, Steinmetz's analysis doesn't look much like Coleman's boat -- identify a macro pattern of interest, look for the actors whose behavior gives rise to the pattern, and try to identify individual-level circumstances that cause the pattern through the individuals' actions. So let's look in a little bit of detail at the explanations that Steinmetz offers.

Here are the guiding research goals for Steinmetz's study.

Social theorists have often treated colonialism as a monolithic object, a uniform condition. Yet even a cursory overview of the historical literature indicates that colonialism is actually an extremely capacious category, encompassing everything from pillage and massacre in the Spanish conquest of the New World to the peaceful coexistence between British rulers and Chinese subjects in late colonial Hong Kong. The colonies that made up the German overseas empire, which lasted from 1884 until the end of World War I, exemplify the enormous variability even within the more delimited category of modern colonialism. This specifically modern variant of European colonialism, as opposed to the early modern (or earlier) forms, is my focus in this book. I have selected three colonies to illustrate the wide spectrum of colonial native policy, which I will argue below, was the core activity of the modern colonial state. These colonies are German Southwest Africa, forerunner of modern-day Namibia; German Samoa, precursor of the contemporary nation-state of Samoa; and Kiaochow, a colony that consisted of the city of Qingdao and its surrounding hinterland in China's Shandong Province. (1)

What I try to account for in this book -- my "explanandum" -- is colonial native policy. Four determining structures or causal mechanisms were especially important in each of these colonies: (1) precolonial ethnographic discourses or representations, (2) symbolic competition among colonial officials for recognition of their superior ethnographic acuity, (3) colonizers' cross-identification with imagos of the colonized, and (4) responses by the colonized, including resistance, collaboration, and everything in between. Two other mechanisms influenced colonial native policy to varying degrees: [5] "economic" dynamics related to capitalist profit seeking (plantation agriculture, mining, trade, and smaller-scale forms of business) and [6] the "political pressures generated by the international system of states. (2)

This book does not attempt to identify any singular, general model of colonial rule. Indeed, general theory and general laws are widely recognized as implausible goals in the social sciences. Historians have always preferred complex, overdetermined, conjunctural accounts, but sociologists and some other social scientists have been reluctant to abandon the chimerical goals of parsimony and "general theory." Rather than attempt to use colonial comparisons to fabricate a uniform model of the colonial state, I will seek instead to identify a limited set of generative social structures or mechanisms and to track the ways they interacted to provide ongoing policies. Even though each

instance of colonial native policy was shaped by a different constellation of influences, the four primary mechanisms named above were always present and efficacious to varying degrees. (3)

Note that Steinmetz proceeds here in a clearly comparativist fashion (three cases with salient similarities and differences); and he proceeds with the language of causal mechanism in view. The comparativist orientation implies a desire to identify causal differences across the cases that would account for the differences in outcomes in the cases. He suggests later in the analysis that all six factors mentioned here are causally relevant; but that the general structural causes (5 and 6) do not account for the variation in the cases. These structural factors perhaps account for the similarities rather than the differences across the cases. But Steinmetz emphasizes repeatedly that general theories of colonialism cannot account for the wide variation that is found across these three cases. "The patterns of variation among these three colonies are as puzzling as is the sheer degree of heterogeneity" (19).

So what kind of account does Steinmetz offer for the four key mechanisms he cites? Consider first factor (2) above, the idea that the specifics of colonial rule depended a great deal on the circumstances of the professional and ideological "field" within which colonial administrators were recruited and served. (Here is a posting on Bourdieu's concept of "field"; link.) "Social fields are organized around differences -- differences of perception and practice. It is difficult to imagine what sorts of materials actors could use in their efforts to carve out hierarchies of cultural distinction if they were faced with cultural formations as flat and uniform as Saidian 'Orientalism'" (45-46). The idea here is that the particular intellectual and professional environment established certain points of difference around which participants competed. These dividing lines set the terms of professional competition, and prospective colonial administrators as well as functioning administrators needed to establish their program for governance around a distinctive package of these assumptions.

Was the colonial state characterized by common perceptions of distinction and stakes of conflict? German colonial administrators did in fact compete for a specific form of cultural distinction within the ambit of the colonial state, and this struggle guided each individual toward particular kinds of native policy. ... The colonial stage thus became an exaggerated version of imperial Germany's three-way intraelite class struggle. (48, 49)

This mechanism is a fairly clear one; and it provides a promising basis for explaining some of the otherwise puzzling aspects of colonial rule and native policy. It derives, fundamentally, from Bourdieu's theories of social capital. Consider an analogy with current military policies in Iraq and Afghanistan. Suppose there are two large ideas of strategy in the air, counter-insurgency and state-building. Suppose that each of these frameworks of thought has resonance with different groups of powerful political leaders within the government. And suppose that senior military commanders are interested in establishing their credentials as effective strategists. It makes sense to imagine that there may be a competition for choosing on-the-ground strategies and tactics that align with the grand strategy the theater commander thinks will further his long-range career success the best.

This mechanism is consistent with an agent-centered theory of explanation: actors (administrators or generals) are immersed in a policy environment in which conflicting ideas about success are debated; the actors seek to align their actions to the framework they judge to be most likely to prevail (and preserve their careers). No one wants to be the last Curtis LeMay in Vietnam when the prevailing view back home is "winning hearts and minds." The explanation postulates a social fact -- the prevalence of several

intellectual frameworks about the other, several ethnographic discourses; and the individual's immersion in these discourses permits him or her to act strategically in pursuing advantageous goals.

We can often begin to understand why one strand of precolonial discourse rather than another guided colonial practice once we know who was put in charge of a given colony. (54)

So this illustrates the way that factors (1) and (2) work in Steinmetz's explanation. What about (3)? This falls in the category of what Steinmetz calls "symbolic and imaginary identifications" (55). Here Steinmetz turns away from conscious calculation and jockeying on the part of the colonial administrator in the direction of a non-rational psychology. Steinmetz draws on psychoanalytic theory and the theories of Lacan here. But it remains an agent-centered analysis. Steinmetz refers to elements of mentality as an explanation of the administrators' behavior, and their possession of this mentality needs its own explanation. But what proceeds from the assumption of this mentality is straightforward; it is a projection of behavior based on a theory of the mental framework of the actor.

The fourth factor in Steinmetz's analysis turns to the states of agency of the colonized. Here he refers to strategies of response by the subject people to the facts of colonial rule, ranging from cooperation to resistance.

Resistance is located on the opposite side from cooperation. Colonized peoples were able to modulate and revise native policies. By signing up as a native policeman one might be able to temper colonial abuses of power. More frontal forms of resistance could bring a regime of native policy to an abrupt halt and force the colonial state to seek a new approach. (66)

This aspect of the story too is highly compatible with a microfoundations approach; it is straightforward to see how social mobilization theory can be fleshed out in ways that make it an agent-centered approach.

Here is how Steinmetz sums up his account:

The colonial state, I have argued here, can best be understood as a kind of field, one that is structured around opposing principles and interests and around conflict over specific stakes. Actors in the field of the colonial state competed to accumulate ethnographic capital. This field's internal heterogeneity and the fact that a field is "a space of possibilities" with an "immense elasticity" meant that colonial policy was never a smooth, continuous process but was prone to sudden shifts in direction. The relative autonomy of the colonial government from the metropolitan state and its independence from other fields in terms of its definition of symbolic capital meant that it was, in fact, a kind of state, even if political theorists have paid little attention to it. Just as it is impossible to generalize about the contents of ethnographic discourse or the policies of the colonial state,neither can one characaterize the "mind of the colonizer" in general terms, except to say that it was as complex and internally contradictory as the subjectivity of the colonized. (517-518)

It should also be noted that a great deal of Steinmetz's account is not explanatory, but rather descriptive and narrative. He provides detailed accounts of the history and behavior of the colonial regimes in these three settings, and much of the value of the book indeed derives from the research underlying these descriptive accounts.

So Steinmetz's account seems to have several important characteristics. First, it is interested in providing a contextualized explanation of differences in nominally similar

outcomes (different instances of German colonial rule). Second, it is interested in providing an account of the causal mechanisms that shaped each of the instances, in such a way as to account for their differences. Third, the mechanisms that he highlights are largely agent-centered mechanisms. Fourth, the account deliberately highlights the contingency of the developments it describes. Individuals and particular institutions play a role, as well as historical occurrences that were themselves highly contingent. And finally, there is a pervasive use of collective concepts like field, ideology, worldview, and ethnography that play a crucial causal role in the story. These concepts identify a supra-individual factor. But each of them can be provided with a microfoundational account. So Steinmetz's analysis here seems to be largely consistent with microfoundationalism. It diverges from analytical sociology in one important respect, however: Steinmetz does not couch his explanatory goals in terms of the idea of deriving social outcomes from individual-level actions and relations. Rather, it is for the reader to confirm that the mechanisms cited do in fact have appropriate microfoundations.

(Steinmetz discusses his theoretical approach to colonialism in his interview included in the "interviews" page. Here is an appreciative review of The Devil's Handwriting; link.)

Civil society in a globalizing world

Thursday, July 28, 2011

An important component of western political theory since Locke and Rousseau is the notion of civil society—the idea of a society in which members have a variety of cross-cutting activities and associations, and where the state is not the sole source of social power. On this conception, a civil society is one that is characterized by multiple associations, free activities and choices by individuals, and a framework of law that assures rights and liberties for all citizens. It is a society with multiple forms of power and influence, minimizing the potential for exploitation and domination by powerful elites or the state. And it is a society in which citizens have developed a sense of mutual respect and consideration for each other. The fact of civil association serves to enhance the strength of collective identities among citizens, by building new loyalties and affiliations. Citizenship and unity are built through association with other citizens and the knowledge that they can pursue their interests and values through their associations (Robert Putnam, Better Together: Restoring the American Community, Bowling Alone: The Collapse and Revival of American Community). But we can emphasize as well the importance of civil associations as a counterweight to the power of the state. Citizens have greater security when they can be confident that the state cannot act against their interests with impunity.

What is involved in sustaining a civil society? What are the conditions that enhance civility within a community? There are several factors that are particularly important. There is **solidarity**—some degree of shared identity among the individuals who make up the society as groups with interests in common. There is a **sense of justice**—confidence that the basic institutions are fair to all. There is **confidence in the future**, that one's children will have reasonable (and improved) life prospects. There is a **sense of dignity**—of being treated with human dignity, of being assigned equal human worth. And

there is a need for **stable, fair, and predictable institutions** that give citizens the confidence that they can pursue activities, form associations, and engage in civil discourse without fear. When these conditions are satisfied we can have the greatest confidence in the stability and flourishing of a civil society.

Several of these features fall within the concept of what John Rawls calls a well-ordered society. Rawls introduced the concept of a well-ordered society in A Theory of Justice. It is the conception of society "as a fair system of cooperation over time from one generation to the next, where those engaged in cooperation are viewed as free and equal citizens and normal cooperating members of society over a complete life" (Justice as Fairness: A Restatement : 4). Citizens within a well-ordered society respect one another; they have confidence that their most basic interests are fairly treated; and they have confidence that the basic institutions of society permit them fair access and permit them to pursue their conceptions of the good. A well-ordered society is thus a powerful and pervasive foundation for a stable society, and justice is an important causal factor in sustaining and reproducing a society. The underlying hypothesis is that shared moral values, including particularly the values, that determine the terms of social interaction, create the grounds of stability in a society. And profound disagreement about these values creates the possibility of serious conflict. (Here are a few earlier postings on Rawls's views in this area; link, link).

These ideas find their most common application in the context of local or national communities. How does this concept pertain to the idea of a world society? Is there any meaning we can assign to the notion of a ***global civil society***? Or does this concept apply only to connected populations engaged in face-to-face interactions with each other? Is a global civil society feasible? This would be a world in which all persons recognize and respect the human reality and worth of all others—near and far. It is a world in which people are tied together through cross-cutting civil associations—local, national, and international. These may include labor organizations, women's organizations, environmental organizations, or religious groups. It is a world in which persons share a sense of justice—they share a basic agreement on the essential fairness of the institutions that govern their lives. And it is a world in which all people have grounds for hope for the future—that there are opportunities for them to improve their lives, that they will have fair access to these opportunities, and that their children will have better lives than they themselves have had. Such a world has every prospect of sustaining stable, peaceful, and civil social life—both local and international.

How does a theory of global justice relate to this vision (The Paradox Of Wealth And Poverty: Mapping The Ethical Dilemmas Of Global Development)? The connections are profound. Justice requires an urgent commitment to ending poverty throughout the world. It requires a commitment to democracy and human rights—and the effective legal institutions that can secure both. It entails adherence to the values of fairness and human equality, and the importance of reshaping international institutions with these values in mind. And these are precisely the values that are needed to establish the basis of peaceful civil society. If these values are genuinely and deeply embedded in our planning for the future—and if the people of the developing world become convinced that these are real, guiding priorities for the people and governments of the wealthy world—then the potential bonds of international civility will be established. And at the country level the positive institutions of law, democracy, and economic opportunity will reinforce the values of civility and mutual respect.

So the important values that pertain to just global development are arguably critical to a decent future for humanity. A world order that is not grounded in a permanent commitment to human dignity and justice is not only disqualified from the perspective of morality. It is likely to be an increasingly unstable and violent arena for deep and desperate conflict. So for our own sakes and for the sake of future generations we need

to commit ourselves in practical and enduring ways to the establishment of global justice, an end to poverty, and the extension of effective democratic and human rights to all persons in all countries.

Three specific points are particularly central. First, poverty is not simply a problem for the poor or for poor countries. Rather, it is a problem for the world, and one that we must confront with determination and resources. This means that we need to develop plans that have a likelihood of success for poverty alleviation; we need to work toward the political consensus that will be needed in order to carry these plans out; and we need to exercise our democratic rights and voices so as to bring about the large commitment of resources that will be needed. The Millenium Development Goals place this as the first priority (link).

Second, the equality of worth of all persons is an essential moral fact. All persons are equally deserving of attention. And much follows from this fact. The extreme inequalities of life prospects between citizens of the north and the south are inconsistent with this principle. The persistence of anti-democratic and authoritarian regimes throughout the developing world is inconsistent with the equal rights and worth of the citizens who suffer under those regimes. And the inequalities of voice that are present in current international institutions represent an affront to the moral equality of all persons who are affected by those institutions.

Finally, democracy and human rights are critical. It is only through effective democratic institutions for government and decision-making that the interests and concerns of citizens will be aggregated into just policies and progressive social institutions. Democratic institutions permit all citizens to influence the policies that affect the terms of their lives, and they represent a meaningful obstacle to the emergence of exploitation and domination of the powerless by elites.

Are there examples of international settings that embody some of the features of a global civil society? The European Union, and the pan-European institutions and identities that the EU is in the process of forging, offer a promising example of a system that can bring about a just international order. Here we find fledgling experiments in the creation of solidarities that transcend language, religion, nation, or place. And we find an emerging discourse of solidarity that may provide the political basis that will be needed to bring about global justice (and the international transfer of resources and knowledge that this will require). There is a measure of “global thinking” among European citizens that offers a basis for optimism about the feasibility of an engaged world citizenry. OECD institutions have already gone a long way in the direction of giving meaningful priority to the needs of developing countries. The OECD and the Development Assistance Committee represent effective and broadly supported institutional agents of change within the processes of economic development. And surveys of European public opinion suggest an emerging and strengthening public support for global justice (link, link).

Finally, what does the concept of a global civil society imply for the durability of national or cultural identities? Can the Brazilian, Sikh, or Muslim at the same time be a member of a global civil society? This question can be posed at virtually every level of scale—village, region, nation, or global system. And the answer is everywhere the same. One can be both cosmopolitan and Muslim, both Brazilian Catholic and citizen of the world (Martha Nussbaum and Josh Cohen, For Love of Country?), (Charles Taylor, The Ethics of Authenticity). In other words, this conception of a just global civil society does not presuppose a process of homogenization of world cultures. Instead, it presumes the development of a cross-cultural consensus about the importance of civility as a necessary context for the many cultural, religious, or national differences that will persist and that constitute one of the positive engines of creativity that are available to the world’s people.

Peter Demeulenaere on analytical sociology

Monday, August 01, 2011

Here is another take on the core features of analytical sociology, this time from Peter Demeulenaere in the introduction to his very interesting recent collection on the subject, Analytical Sociology and Social Mechanisms. The volume includes thirteen essays by leading experts grouped around "Actions and Mechanisms," "Mechanisms and Causality," and "Approaches to Mechanisms," and it is an important further contribution to the framework of analytical sociology. (The volume is also available in an affordable Kindle edition; Analytical Sociology and Social Mechanisms.)

Demeulenaere makes several basic points. First, he holds that AS is not just another new paradigm for sociology. Instead, it is a reconstruction of what valid explanations on sociology **must** look like, once we properly understand the logic of the social world. He believes that much existing sociology conforms to this set of standards -- but not all. And the non-conformers are evidently condemned to being judged non-explanatory. So this sets a claim of a very high level of authority over the whole field -- what Ronald Jepperson and John Meyer refer to as micro-chauvinism (link, 57). Here are several of Demeulenaere's statements of the intended scope of AS:

Analytical sociology should not therefore be seen as a manifesto for one particular way of doing sociology as compared with others, but as an effort to clarify (“analytically”) theoretical and epistemological principles which underlie any satisfactory way of doing sociology (and, in fact, any social science). The social sciences already command a considerable stock of substantive descriptions and explanations; and some of the alternatives to these are either redundant, or resistant to proof, even false or imprecise, quite regardless of their status with respect to one or other established paradigm. Analytical sociology should seek to define a set of sound epistemological and methodological principles underlying all previously established and reliable sociological findings. The aim of analytical sociology is to clarify the basic epistemological, theoretical and methodological principles fundamental to the development of sound description and explanation. (Kindle loc 121)

The most important aspect of the analytical approach should be to clarify the strategy by which we endeavour to separate and conceptualize different elements entering into descriptions and explanations of the social world, so that we might understand their mutual relationships, and in particular the causal links existing among them. (Kindle loc 139)

Second, Demeulenaere provides a long, detailed, and helpful analysis of the doctrine of methodological individualism and its current status. He believes that criticisms of MI have usually rested on a small number of misunderstandings, which he attempts to resolve. For example, MI is not "atomistic", "egoistic", "non-social", or exclusively tied to rational choice theory. He prefers a refinement that he describes as structural individualism, but essentially he argues that MI is a universal requirement on social science.

The two core ideas behind MI, first expressed by John Stuart Mill and Carl Menger, and subsequently by Weber, can be expressed very simply:

-- Social life exists only by virtue of actors who live it;
-- Consequently a social fact of any kind must be explained by direct reference to the actions of its constituents.

These two simple propositions remain central to the analytical approach; we therefore have to address the problem of the relationship between MI and AS. This section is directed to a brief exposition of the problem. (Kindle loc 183)
This is important, because it involves two separate assertions: social things are **composed** of individual actions and nothing else; and "therefore" social outcomes must be **explained** on the basis of facts about individual actions. But the inference doesn't hold -- more in an upcoming post on explanatory autonomy.

Demeulenaere specifically disputes the idea that MI implies a separation between society and non-social individuals. He believes that even the originators -- Watkins and Mill, for example -- recognized that individuals are social organisms. But he believes this recognition can be folded into a consistent elaboration of MI that he describes as structural individualism:

The combination of these two approaches can be called “structural individualism” (Wippler 1978; Udehn 2001). Any serious attempt to reflect on a social situation should deploy both in turn. Their combination is in some respect illustrated by Coleman‘s famous “boat” (1986, 1990). It remains a central aspect of analytical sociology. (kl 246)
That said, Demeulenaere fully endorses the idea that AS depends upon and presupposes MI:

Does analytical sociology differ significantly from the initial project of MI? I do not really think so. But by introducing the notion of analytical sociology we are able to make a fresh start and avoid the various misunderstandings now commonly attached to MI. (kl 318)
Third, Demeulenaere holds that AS depends closely on the methodology of social causal mechanisms. The "analytical" part of the phrase involves identifying separate things, and the social mechanisms idea says how these things are related. Demeulenaere gives a compressed history of the development of this framework over the past decade or so.

Analytical sociology incorporates an affirmation that “social facts” are generated, triggered, produced, brought about, or “caused” by individual actions which themselves are in some sense “caused”, or at least partly determined by, the constraints presented by the social environments and situations in which such actions take place.

Therefore the focus has to be on the causal “process” occurring at the action level. The idea that there are laws directly implemented at a macro level can be easily rebutted, since the effectiveness of the outcome necessarily leads to the “active” level, the level of action. One general implication of the notion of “mechanism” is to move analysis away from an “inactive” level to an “active” level, where effective actions occur. A strong correlation between variables should not therefore be interpreted in causal terms unless a mechanism linking the two dimensions is identified, mechanisms involving effective actions. (kl 378)
So causal mechanisms are expected to be the components of the linkages between events or processes hypothesized to bear a causal relation to each other. And, more specifically to the AS approach, the mechanisms are supposed to occur solely at the level of the actors--not at the meso or macro levels. So this means that AS would not countenance a meso-level mechanism like this: "the organizational form of the supervision structure at the Bopal chemical plant caused a high rate of maintenance lapses that caused the accidental release of chemicals." Both features are meso-level factors or conditions, and it would appear that AS would require that their causal properties be unpacked onto individual actors' behavior.

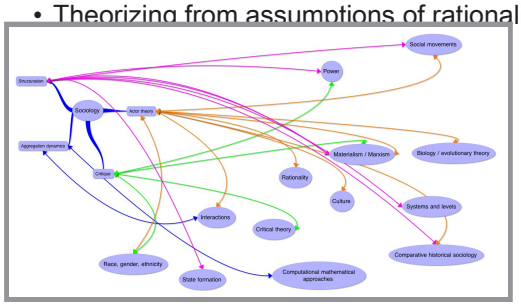
I, on the other hand, would maintain that this is a perfectly legitimate social mechanism because we can readily supply its microfoundations at the behavioral level. So this suggests that we can legitimately refer to meso-level mechanisms as long as we are mindful of the microfoundations requirement. And this corresponds as well to the tangible fact that institutions have causal force with respect to individuals -- a point Demeulenaere acknowledges here:

Hence we commonly encounter the fact that, one set of actors having at a certain point adopted a norm, or built up an institution, it then become more difficult for actors subsequently coming onto the scene to adopt another norm, or replace the institution. But this is never impossible. (kl 372)

There is quite a bit of the framework of AS that I find appealing and constructive. Moreover, several of the core premises line up well with assumptions I've argued for in my own philosophy of social science -- microfoundations, causal mechanisms, and agent-centered ontology, for example. Where there appear to be a few inches of separation between the views is on the subject of reductionism and explanatory autonomy. I will return to these differences in an upcoming post.

Mapping sociology

Friday, August 05, 2011



Sociology is now composed of a wide expanse of approaches, theories, methodologies, and paradigms. The American Sociological Association has 49 sections, and even this variation doesn't capture the full diversity of the field (link). In fact, Jonathan Turner refers to the current situation as one of "hyper-differentiation of theories" (1). It is therefore useful to try to map out some of the main dimensions of activity, aspiration, and method that currently define the discipline. One way of doing this is to look closely at some of the handbooks that leaders in the field have compiled over the past fifteen years or so. Several are particularly useful in my opinion, including Craig Calhoun's Sociology in America: A History (2007), Jonathan Turner's Handbook of Sociological Theory (2001), and Julia Adams et al's Remaking Modernity: Politics, History, and Sociology(2005). What can we learn by examining the structure and signposts that these editors and teams of scholars have chosen to frame their collections?

It is interesting to notice that each volume limits its perspective in significant and different ways. They represent very different intellectual efforts at synthesis. Jonathan Turner's volume references the intellectual diversity of sociology from the point of view of theory. But not all sociological research is theoretical; so the dimensions of variation that we can find among ***theoretical*** orientations to understanding society is unavoidably more limited than the full range of the discipline. There are groups of sociologists who are primarily interested in careful ***descriptive*** work -- either at the macro level or the micro level. And there are sociologists whose primary concern is for providing an empirical basis for policymaking -- again, an exercise that has little to do with theory. Calhoun's volume focuses primarily on the intellectual history of the discipline. And Adams and her

colleagues have tried to work out a narrative of the development and brachiation of the frameworks of comparative sociology over time.

Turner groups the contributions to his collection around these meta-topics:

- Theoretical methodologies and strategies
- The cultural turn in sociological theorizing
- Theorizing interaction processes
- Theorizing from the systemic and macrolevel
- New directions in evolutionary theorizing
- Theorizing on power, conflict, and change
- Theorizing from assumptions of rationality

In other words, Turner's analytical strategy is to identify key topics that have inspired important recent work in the development of sociological theory over the past two decades.

Calhoun's volume takes a different approach. He wants to provide insights into the historical origins of contemporary American sociology -- both situational and intellectual. On the situational side, several essays in the Calhoun volume focus on the effects that large historical developments such as the Cold War, the Great Depression, and World War II had on the intellectual, theoretical, and institutional development of sociology. And on the intellectual side, essays in the volume consider the influence of large currents of thought on the development of American sociology -- for example, Spencer, Comte, positivism, pragmatism, feminism, and critical race theory.

In Remaking Modernity: Politics, History, and Sociology Julia Adams, Elisabeth Clemens, and Ann Shola Orloff present a collection of essays that attempt to provide a similar kind of complex unity to one specific sub-discipline within sociology, the field of comparative historical sociology. Their primary locational metaphor is time rather than space; they analyze the history of comparative historical sociology into a sequence of three waves of theory and method from the mid-nineteenth century to the present. Their core definition of the subject matter of this discipline es expressed in these terms:

How did societies come to be recognizably "modern"? How did selves come to be understood as individuated, coherently centered, and rationally acting human subjects.... Various lines of theory developed as an effort to understand the processes by which social structures and social actors were created and transformed over the course of the transition from "traditional" or feudal societies to some distinctively modern social life. (3) And a key inspiration for the discipline of comparative historical sociology is that paying attention to history permits us to tease out the causes and processes that have led to specific kinds of social outcomes.

Adams, Clemens, and Orloff also offer some useful thoughts about the nature of the disciplines of the social sciences:

Disciplines -- like any structure -- provide both distinctive constraints and capacities embedded in theoretical and methodological orientations, transmitted through graduate education, hiring, the tenure process, and the gatekeeping of fellowship, research proposal, and manuscript review. (11)

They make the point, however, that these constraints still leave a wide degree of indeterminacy in the development of a disciplines: which topics are foregrounded, which methods of inference are favored, and which implications are pursued are all issues that are underdetermined by the constraints of the discipline.

One of the tasks of philosophy has traditionally been to provide a degree of organization to the fields of knowledge. As this quick review of the diversity of knowledge-products involved in contemporary sociology indicates, it is challenging to provide an ordering of topics, methods, and ontological presuppositions that might permit us to bring the complexity of the trees and undergrowth down to a map of the forest. But perhaps the sketch below begins to suggest some of the ways in which we might try to analyze sociological research into a smaller number of clusters of topics, methods, and assumptions.

The upper left quarter of the diagram represents sociology as a compound of four large meta-topics: structuration, actor theory, aggregation dynamics, and critique. The links in many colors bring this formation into relationship with a large number of topics and approaches within sociology, indicating roughly where topics such as "state formation" or "social power" fit within the framing topics. It would seem possible to work iteratively with a graph along these lines along with a careful reading of the three handbooks mentioned here, and fill out a set of meta-topics that would capture the great majority of the approaches described in the handbooks. Further, it might be illuminating to begin to map the links that exist between first-order topics in the graph -- for example, between "social movements," "materialism," and "culture."

Relative explanatory autonomy

Sunday, August 07, 2011

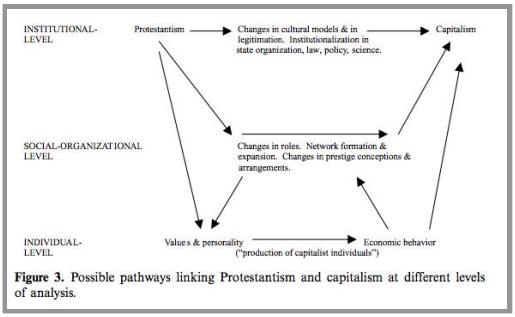


Figure 3. Possible pathways linking Protestantism and capitalism at different levels of analysis.

In an earlier post I indicated a degree of disagreement with the premises of analytical sociology concerning the validity of methodological individualism (link). This disagreement comes down to three things.

First, for reasons I've referred to several times here and elsewhere (link), I prefer to refer to methodological localism rather than methodological individualism.

This theory of social entities affirms that there are large social structures and facts that influence social outcomes. But it insists that these structures are only possible insofar as they are embodied in the actions and states of socially constructed individuals. The "molecule" of all social life is the socially constructed and socially situated individual, who lives, acts, and develops within a set of local social relationships, institutions, norms, and rules. (link)

I believe that the ideas of localism and socially constructed, socially situated actors do a better job of capturing the social molecule that underlies larger social processes than the simple idea of an "individual". Structural individualism seems to come to a similar idea, but less intuitively.

Second, the requirement of providing ***microfoundations*** for social assertions is preferable

to methodological individualism because it is not inherently reductionist (link). A microfoundation is:

a specification of the ways that properties, structural features, and causal powers of a social entity are produced and reproduced by the actions and dispositions of socially situated individuals. (link)

We need to be confident that our theories and concepts about social structures, entities, and forces appropriately supervene upon facts about individuals; but we don't need to rehearse those links in every theory or explanation. In other words, we can make careful statements about macro-macro and macro-meso links without proceeding according to the logic of Coleman's boat -- up and down the struts. Jepperson and Meyer make this point in "Multiple Levels of Analysis and the Limitations of Methodological Individualisms" (link), and they offer an alternative to Coleman's macro-micro boat that incorporates explanations referring to meso-level causes (66).

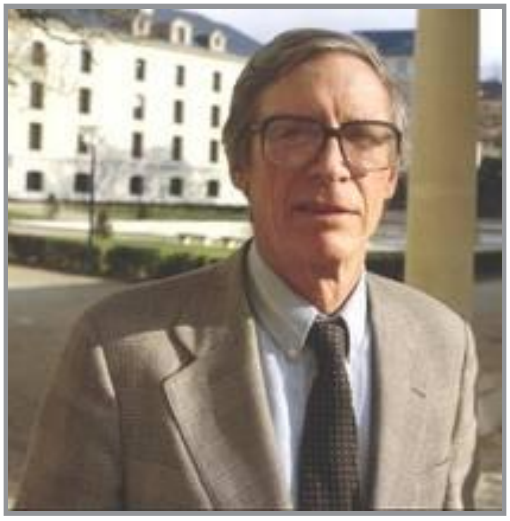
Third, these points leave room for a meta-theory of *relative explanatory autonomy* for social explanations. The key insight here is that there are good epistemic and pragmatic reasons to countenance explanations at a meso-level of organization, without needing to reduce these explanations to the level of individual actors. Here is a statement of the idea of relative explanatory autonomy, provided by a distinguished philosopher of science, Lawrence Sklar, with respect to areas of the physical sciences:

Everybody agrees that there are a multitude of scientific theories that are conceptually and explanatorily autonomous with respect to the fundamental concepts and fundamental explanations of foundational physical theories. Conceptual autonomy means that there is no plausible way to define the concepts of the autonomous theories in terms of the concepts that we use in our foundational physics. This is so even if we allow a rather liberal notion of “definition” so that concepts defined as limit cases of the applicability of the concepts of foundational physics are still considered definable. Explanatory autonomy means that there is no way of deriving the explanatory general principles, the laws, of the autonomous theory from the laws of foundational physics. Once again this is agreed to be the case even if we use a liberal notion of “derivability” for the laws so that derivations that invoke limiting procedures are still counted as derivations. (link)

The idea of relative explanatory autonomy has been invoked by cognitive scientists against the reductionist claims of neuro-scientists. Of course cognitive mechanisms must be grounded in neurophysiological processes. But this doesn't entail that cognitive theories need to be reduced to neurophysiological statements. Sacha Bem reviews these arguments in "The Explanatory Autonomy of Psychology: Why a Mind is Not a Brain" (link). Michael Strevens summarizes some of these issues in "Explanatory Autonomy and Explanatory Irreducibility" (link). And here Geoffrey Hellman addresses the issues of reductionism and emergence in the special sciences in "Reductionism, Determination, Explanation".

These arguments are directly relevant to the social sciences, subject to several important caveats. First is the requirement of microfoundations: we need always to be able to plausibly connect the social constructs we hypothesize to the actions and mentalities of situated agents. And second is the requirement of ontological and causal stability: if we want to explain a meso-level phenomenon on the basis of the causal properties of other meso-level structures, we need to have confidence that the latter properties are reasonably stable over different instantiations. For example, if we believe that a certain organizational structure for tax collection is prone to corruption of the ground-level tax agents and want to use that feature as a cause of something else -- we need to have

empirical evidence supporting the assertion of the corruption tendencies of this organizational form.



Explanatory autonomy is consistent with our principle requiring microfoundations at a lower ontological level. Here we have the sanction of the theory of supervenience to allow us to say that composition and explanation can be separated. We can settle on a level of meso or macro explanation without dropping down to the level of the actor. We need to be confident there are microfoundations, and the meso properties need to be causally robust. But if this is satisfied, we don't need to extend the explanation down to the actors.

Woven throughout this discussion are the ideas of reduction and emergence. An area of knowledge is **reducible** to a lower level if it is possible to derive the statements of the higher-level science from the properties of the lower level. A level of organization is **emergent** if it has properties that cannot be derived from features of its components. The strong sense of emergence holds that a composite entity sometimes possesses properties that are wholly independent from the properties of the units that compose it. Vitalism and mind-body dualism were strong forms of emergentism: life and mind were thought to possess characteristics that do not derive from the properties of inanimate molecules. Physicalism maintains that all phenomena -- including living systems -- depend ultimately upon physical entities and structures, so strong emergentism is rejected. But physicalism does not entail reductionism, so it is scientifically acceptable to provide explanations that presuppose relative explanatory autonomy.

Once we have reason to accept something like the idea of relative explanatory autonomy in the social sciences, we also have a strong basis for rejecting the exclusive validity of one particular approach to social explanation, the reductionist approach associated with methodological individualism and Coleman's boat. Rather, social scientists can legitimately aggregate explanations that call upon meso-level causal linkages without needing to reduce these to derivations from facts about individuals. And this implies the legitimacy of a fairly broad conception of methodological pluralism in the social science, constrained always by the requirement of microfoundations.

Economic thinking in Rawls's thought

Wednesday, August 10, 2011

John Rawls's (1971) A Theory of Justice: Original Edition (TJ) had a sizable impact on a number of disciplines, including economics and economic policy thought. (His ideas in this original version of the theory are clarified and further developed in his 2005 Justice as Fairness: A Restatement (JF).) Rawls's influence on economics largely derived from one aspect of his theory of justice, the theory of justice in distribution, which has implications for economic inequalities, taxation, and social welfare benefits. Did Rawls actually think about these issues in the ways that an economist would have done?

One of the primary goals of Rawls's theory of justice is directly relevant to economic policy. He specifically wanted to work out the implications of the theory of justice for the justice of fundamental economic institutions:

My aim in this chapter is to see how the two principles work out as a conception of political economy, that is, as standards by which to assess economic arrangements and policies, and their background institutions. (Welfare economics is often defined in the same way. I do not use this name because the term "welfare" suggests that the implicit moral conception is utilitarian; the phrase "social choice" is far better although I believe its connotations are still too narrow.) (TJ, 259)

What is the purpose of this aspect of the theory of justice?

A doctrine of political economy must include an interpretation of the public good which is based on a conception of justice. It is to guide the reflections of the citizen when he considers questions of economic and social policy. (259)

Rawls is explicit in addressing the issue of the relationship between his own theorizing and the theories of the economists:

It is essential to keep in mind that our topic is the theory of justice and not economics, however elementary. We are only concerned with some moral problems of political economy. For example, I shall ask: what is the proper rate of saving over time, how should the background institutions of taxation and property be arranged, or at what level is the social minimum to be set? In asking these questions my intention is not to explain, much less to add anything to, what economic theory says about the working of these institutions. ... Certain elementary parts of economic theory are brought in solely to illustrate the content of the principles of justice. (265)

So what use does Rawls in fact make of current economic theories? Does he think like an economist? Key to thinking like an economist is thinking in terms of incentives, markets, and institutions. Let's start with incentives. Rawls pays attention to the incentives that citizens have within various sets of institutions:

Moreover, the theory of justice assumes a definite limit on the strength of social and altruistic motivation. It supposes that individuals and groups put forward competing claims, and while they are willing to act justly, they are not prepared to abandon their interests. (281)

He also does a good job of articulating and motivating the central insights of public choice theory -- essentially, reasoning about public goods within a democratic public (TJ, 265 ff.). He analyzes the two key features of a public good -- indivisibility and non-excludability. He explains the free rider problem and the prisoners' dilemma clearly and accurately, and reproduces the conclusion that a public of independent citizens will not achieve public goods at an appropriate level without legislation. The discussion is compact, but it is solidly linked to the best available literature on public goods (Baumol, Sen, Buchanan, Olson). Rawls thinks this is a good place to start, because the institutions of the state have a very substantial role to play in establishing conditions in which public goods are achieved. He also addresses a series of reasons for favoring, and limiting, the institutions of the market as determinants of investments and incomes. He refers to allocative efficiency and personal liberty as positive features, while noting the possibility or likelihood that markets by themselves will create economic inequalities in excess of the requirements of the difference principle. "There is with reason strong objection to the competitive determination of total income, since this ignores the claims of need and an appropriate standard of life" (277).

When discussing the role of government in economic activity Rawls refers to four "branches" of fiscal and resource management activity (TJ 275 ff.). The allocation branch keeps the price system competitive and "prevents the formation of unreasonable market power" (276), and actively monitors market imperfections and externalities. The stabilization branch "strives to bring about reasonably full employment". The transfer branch is responsible for managing the transfer of incomes necessary to establish the social minimum. And the distribution branch "is to preserve an approximate justice in distributive shares by means of taxation and the necessary adjustments in the rights of property" (277).

The primary implications of the theory of justice for economics cross several topics: distribution, taxation, and the idea of a social minimum. Rawls thinks about taxation in several places. The topic arises in TJ under "Institutions for Distributive Justice" (277-280):

The taxes and enactments of the distribution branch are to prevent this limit [in the range of wealth inequalities] from being exceeded. (278)

The second part of the distribution branch is a scheme of taxation to raise the revenues that justice requires. Social resources must be released to the government so that it can provide for the public goods and make the transfer payments necessary to satisfy the difference principle. (278)

A parallel discussion of taxation occurs under the topic of "Economic Institutions" in JF (160-162). There Rawls makes several comments on wealth and inheritance taxes:

First, consider bequest and inheritance: we borrow from Mill (and others) the idea of regulating bequest and restricting inheritance. ... The principle of progressive taxation is applied at the receiver's end. Those inheriting and receiving gifts and endowments pay a tax according to the value received and the nature of the receiver.... The aim is to encourage a wide and far more equal dispersion of real property and productive assets.

Second, the progressive principle of taxation might not be applied to wealth and income for the purposes of raising funds (releasing resources to government), but solely to prevent accumulations of wealth that are judged to be inimical to background justice....

Third, income taxation might be avoided altogether and a proportional expenditure tax adopted instead, that is, a tax on consumption at a constant marginal rate. People would be taxed according to how much they use of the goods and services produced and not according to how much they contribute. (JF, 161)

Another important economic idea that emerges from Rawls's theory is the notion of a social minimum -- essentially an income guarantee for low-income people, established through an income supplement system if needed. This principle derives from the difference principle, Rawls's view that inequalities need to be the least system of inequalities consistent with the maximum result for the least-well-off segment of society.

Once the difference principle is accepted, however, it follows that the minimum is to be set at that point which, taking wages into account, maximizes the expectations of the least advantaged group. By adjusting the amount of transfers (for example, the size of supplementary income payments), it is possible to increase or decrease the prospects of the more disadvantaged, their index of primary goods (as measured by wages plus transfers), so as to achieve the desired result. (285)

Here is what seems to come out of Rawls's discussion of economic institutions and

justice. It is a theory of political economy that holds that government has substantial obligations based on distributive justice. It has the obligation of maintaining and correcting the system of economic institutions so as to prevent "unacceptable" levels of inequalities of income and wealth. It has the obligation of providing the resources for securing public goods at an appropriate level. and it has an obligation of collecting taxes sufficient to fund the social minimum for all citizens. It is an account that is well informed about then-current thinking about institutions and public choice. It rests on realistic assumptions about motivation and incentives. And it appears to set the stage for a set of institutions that appear to be economically feasible, along the lines of Scandinavian forms of social democracy.
(Some readers may wonder, as I do, whether the concept of a "proportional expenditure tax" has been seriously explored by economic experts. Here is a review by Michael Graetz in the Harvard Law Review in 1979, arguing that the system is politically infeasible.)

Ethical thinking for global public health

Friday, August 12, 2011

Here is a fine recent book that brings together recent thinking about development ethics with some of the specific issues faced in the field of global public health. Madison Powers and Ruth Faden published Social Justice: The Moral Foundations of Public Health and Health Policy in 2008, and it represents a genuinely interesting extended essay on the topic of justice in global health policy. Here is an early statement of their governing perspective:

Our central focus, only vividly appreciated in hindsight, was in a notion of social justice that went beyond issues of distributive justice, micro-allocational questions of priority setting in medical care, or any number of questions centered on how one individual fares relative to some other individual. Beginning, as we did, with moral questions in public health and health policy, it is perhaps not surprising that our focus in social justice is largely directed at the well-being of people in social communities or groups. (ix)
What is evident here is that Powers and Faden are bringing the perspective of public health into the discussion of issues that have been raised in other contexts (development ethics, bio-medical ethics) without the population-based starting point.

A second important difference in approach taken by Powers and Faden is to take seriously the finding within public health studies that inequalities come into populations' health outcomes in ways other than inequalities of access.

We contend that it is impossible to make progress in our understanding of the demands of justice within medical care without looking outside of medical care to public health and to the other determinants of inequalities in health and indeed without situating an analysis of justice and health policy in the wider social and political context. (x)
This perspective brings Powers and Faden into a degree of connection to Kate Pickett and Richard Wilkinson in The Spirit Level: Why Greater Equality Makes Societies Stronger (link).

A third distinctive feature of the project is the authors' rejection of the goal of arriving at a simple, unified theory of health justice.

In place of some single theory of justice drawn from one of the leading contenders for being the "right" account of justice, we argue instead that most of these other contenders have it wrong. Indeed, we use the term 'theory' somewhat cautiously. ... We choose to steer a middle course on the question, and we agree with Thomas Nagel's conclusion that whatever we are likely to attach the label of 'theory' to in the realm of normative inquiry will reflect an aspiration to develop some systematic but noncomprehensive account of some part of the moral landscape. (x)

The job of justice, as we see it, is to specify those background social and economic conditions that determine whether certain inequalities, that may themselves result from the promotion of other indispensable moral aims, should be seen as unfair. Ours is an account of justice that denies that there are separate spheres of justice, within health policy or within social policy more generally. (x)

Ours is a nonideal theory of justice, intended to offer practical guidance on questions of which inequalities matter most when just background conditions are *not* in place. (30)
Their central concern is with justice in health; and this comes down to a theory about inequalities.

The central question we pose in this book is, Which inequalities matter most? The aim of this book is to develop a theory of social justice suitable for answering questions of this kind in a variety of concrete circumstances. (3)
But they insist on the point that theirs is not an "ideal" theory of justice; rather, it is intended to provide the basis for reasoned decisions about the practical, real problems we face in a world of substantial inequalities in life prospects. Moreover, their account does not begin with a principle of distributive justice, but rather with a conception of the human good. They offer Amartya Sen and Martha Nussbaum as exemplars rather than John Rawls (4).

As Sen correctly notes, a theory of justice of this sort begins with some underlying account of what persons "can do and be" (Sen 1993). Theories in this tradition start with ideals, to be sure, but they are ideals of a very different kind from those that form the starting points of Rawlsian ideal theory. (4)
So their theory is one that begins with a rich conception of human well-being and flourishing, not with a contractual deliberation between hypothetical individuals behind a veil of ignorance. Here is a general statement of their view:

Social justice is concerned with human well-being. In our view, well-being is best understood as involving plural, irreducible dimensions, each of which represents something of independent moral significance. Although an exhaustive, mutually exclusive list of the discrete elements of well-being is not our aim (and may not be possible), we build our account around six distinct dimensions of well-being, each of which merits separate attention within a theory of justice. These different dimensions offer different lenses through which the justice of political structures, social practices, and institutions can be assessed. Without attention to each dimension, something of salience goes unnoticed. (15)
The six dimensions of well-being that they identify include health, personal security, reasoning, respect, attachment, and self-determination (16).

This approach has a lot in common with Amartya Sen's most recent thinking in The Idea of Justice (as well as Sen's earlier work and that of Martha Nussbaum). Here is Sen's description of his work in *The Idea of Justice*:

What is presented here is a theory of justice in a very broad sense. Its aim is to clarify how we can proceed to address questions of enhancing justice and removing injustice, rather than to offer resolutions of questions about the nature of perfect justice. (kl 183)
Here the emphasis is on "enhancing" justice rather than providing a conception of ideal justice. Sen's work here is intended to be practical: it should assist policy makers in their deliberations as reforms are considered. Sen refers to this approach as "comparative justice".

We are engaged in making comparisons in terms of the advancement of justice whether we fight oppression (like slavery, or the subjugation of women), or protest against systematic medical neglect (through the absence of medical facilities in parts of Africa or Asia, or a lack of universal health coverage in most countries in the world, including the United States), or repudiate the permissibility of torture ..., or reject the quiet tolerance of chronic hunger. (kl 225)
In terms of the analysis offered by Powers and Faden, we improve justice by moving a population forward in any one of the six (or more) dimensions of human well-being that were noted.

Inherent in the idea of comparing the justice of several different scenarios, is the idea of reasoning across different perspectives on justice. Sen is committed to the notion that it is possible to engage in reasoned dialogue with people with whom you have deep disagreements about starting points. And this theory of comparative justice is intended to help facilitate those reasoned discussions.

Sen contrasts his approach to justice with that of John Rawls in these terms:

In the approach to justice presented in this work, it is argued that there are some crucial inadequacies in [Rawls's] overpowering concentration on institutions (where behaviour is assumed to be appropriately compliant), rather than on the lives that people are able to lead. (kl 203)
Several things seem important to me in both books mentioned here. First, each is an innovative contribution to issues that are core to what we might refer to as "global justice" -- hunger, health, abusive states, educational deprivation. Second, each is aiming to create a philosophical framework within which practical, real-world issues can be handled in a reasoned way. Third, each seeks to broaden the moral perspective of contractualism that has set the terms for discussions of justice for the past forty years. And, finally, each shuns the goal of formulating a general system or a unified theory on the basis of which to judge all possible social arrangements in terms of justice.

These features make the moral ideas of Powers, Faden, and Sen particularly helpful when we turn our attention to trying to influence international practices and institutions in the direction of greater justice for the people of the world. The arguments are pragmatic, modest in scope, and potentially less bound to a particular tradition of moral thinking. (Sen makes this latter point quite explicitly: "Some of the reasoning of, for example, Gautama Buddha (the agnostic champion of the 'path of knowledge'), or of the writers in the Lokayata school (committed to relentless scrutiny of every traditional belief) in India in sixth-century BC, may sound closely aligned, rather than adversarial, to many of the

critical writings o the leading authors of the European Enlightenment" (kl 268).)

Global justice

Monday, August 15, 2011

There is a clear and reasonably uncontroversial basis for a simple theory of justice that all nations/cultures can accept. This is grounded a few core values about human development and is expressed in the Universal Declaration of Human Rights, the Millenium Development Goals, and other founding documents of the United Nations. This conception emphasizes several key values:

- equal worth of all persons
- value of freedom
- value of democracy and self-determination
- the injustice of hunger, lack of education, lack of healthcare
- the injustice of capricious arrest and state violence (illegality)

These values provide a basis for steering our core institutions and practices in the direction of greater justice: whenever it is possible to reform institutions and practices in ways that enhance one or more of these factors, we should do so. Policy makers and legislators can ask the question, how will this or that change to a set of institutions affect the well-being of individuals and populations affected; how will the change affect the freedoms and opportunities for self-determination of the people affected; how will it work to increase the effective scope of law within various societies?

John Rawls drew a strong distinction between ideal justice and imperfect justice, and noted that his contributions were directed to the formulation of a theory of ideal justice (Justice as Fairness: A Restatement, 13). He did not believe that the ideal theory of justice would suffice to provide a road map for creating a more just society. When we consider the complexity and difficulty of improving the justice of fundamental international institutions and relations, the program of arriving at an ideal theory seems unappealing. Instead, we need to have some plausible and action-supporting principles that allow for practical improvement in the overall justice of the global system. We need to have some concrete ideas about how to get from here to there.

This approach -- the idea that we can improve justice in a piecemeal way -- spares us the heroic pretense of offering a general, universal theory of justice that we hope or expect all people can be persuaded to accept. It works from the point of view that **in**justice is more specific and more widely agreed upon. We don't need to engage in irresolvable debates about whether there are universal human rights in order to agree that the world will be more just if fewer people are forced into famine conditions.

This is the approach taken by Madison Powers and Ruth Faden in their study of the ethics of global public health in Social Justice: The Moral Foundations of Public Health and Health Policy (link), and it has the clear advantage of pragmatism. It is pragmatic on the side of moral agreement, in the sense that it makes no strong claims about abstract moral theories that may be controversial across perspectives. And it is pragmatic on the side of policy, in the sense that it provides an incremental strategy for improving the conditions of justice in the world. And in fact, the premises mentioned above conform fairly closely to the six dimensions of personal well-being that Powers and Faden highlight: ***health, personal security, reasoning, respect, attachment, and self-determination***.

One of the greatest advocates for justice in global development is Amartya Sen (Development as Freedom). Sen's major contribution is the idea of the importance of creating conditions in which people can fulfill and actualize their human capabilities. Sen's most recent work on global justice topics is his The Idea of Justice, in which he offers an alternative to Rawls's approach to the problem. Here he gives primacy to the value of full human development as a benchmark for global justice.

I turn now to the second part of the departure, to wit the need for a theory that is not confined to the choice of institutions, nor to the identification of ideal social arrangements. The need for an accomplishment-based understanding of justice is linked with the argument that justice cannot be indifferent to the lives that people can actually live. The importance of human lives, experiences and realizations cannot be supplanted by information about institutions that exist and the rules that operate. (17)

Tom Pogge's work on global justice provides a good bridge between abstract moral theory and practical, real-world issues of justice in a developing world. Pogge has sought to engage these issues in ways that have real, substantive engagement with the issues of poverty, hunger, and maltreatment that continue to set the stage for the majority of the earth's population today. In an important recent volume, World Poverty and Human Rights: Cosmopolitan Responsibilities and Reforms, Andreas Follesdal and Thomas Pogge have pulled together an extended working group of scholars and activists concerned with global justice. The volume took its origin at a conference in Oslo in 2003. (Here is an article by Pogge on global justice and poverty (link), and here is a video interview with Pogge on the consequences of the global economic crisis on poverty; link.) Pogge and his colleagues focus closely on the actual workings of international institutions to attempt to measure the degree to which they disadvantage the people of the less-developed world.

Consider for example a long-term contract concerning the exportation of natural resources which the government of some African country concludes with a rich Western state or one of its corporations. Within the traditional philosophical framework, it is self-evident that such an agreement must be honored: "People are to observe treaties and undertakings" says Rawls's second principle of state conduct, and the third one adds: "Peoples are equal and are parties to the agreements that bind them" (Rawls 1999). But here is the reality. The African government is corrupt and oppressive, and its continuation in power depends largely on the military. The sales it conducts impose environmental harms and hazards on the indigenous population. Yet, most of these people do not benefit, because the revenues are partly siphoned off by the small political elite and partly spent on arms needed for military repression. (These arms are suppled by other rich Western states in accordance with other contracts executed, without coercion, between them and the African government.) (5)

Why should gimlet-eyed policy makers take these arguments about global justice seriously? What does justice have to do with the nuts and bolts of international economic policy reform? Why should self-interested nations and their leaders adjust their policies to the demands of justice? The humanitarian and moral reasons are self-evident. But it is also true that there is a powerful reason to care about justice that is based in self-interest. This is because systemic injustice is itself a threat to national security. Governments are destabilized, insurgencies are supported, cities experience riots, and anti-liberal violent movements flourish in conditions where masses of people are enmeshed in circumstances of injustice. Barrington Moore, Jr. made these arguments in Injustice: The Social Bases of Obedience and Revolt (1978), and his conclusions seem even more compelling in the world today.

Possessive individualism

Wednesday, August 17, 2011

C. B. Macpherson was a political philosopher who placed a genuinely novel interpretation on the history of political thought in The Political Theory of Possessive Individualism: Hobbes to Locke when the book appeared in 1962. Macpherson was a Canadian philosopher who influenced quite a few young scholars in the 1970s in North America and Great Britain. Macpherson offered the basis of a strong critique of a certain kind of liberalism -- the liberalism that places essentially the whole normative weight on the value of the individual and his/her liberties, and essentially no emphasis on the social obligations we all have towards each other. A first wave of criticism of narrow liberalism took this form:

The repair that was needed [to liberal theory] was one that would bring back a sense of the moral worth of the individual, and combine it again with a sense of the moral value of community, which had been present in some measure in the Puritan and Lockean theory. (2)

But Macpherson feels the need to go further:

The present study … suggests that the difficulties of modern liberal-democratic theory lie deeper than had been thought, that the original seventeenth-century individualism contained the central difficulty, which lay in its possessive quality. Its possessive quality is found in its conception of the individual as essentially the proprietor of his own person or capacities, owing nothing to society for them. The individual was seen neither as a moral whole, nor as part of larger social whole, but as an owner of himself. The relation of ownership, having become for more and more men the critically important relation determining their actual freedom and actual prospect of realizing their full potentialities, was read back into the nature of the individual. the individual, it was thought, is free inasmuch as he is proprietor of his person and capacities. The human essence is freedom from dependence on the wills of others, and freedom is a function of possession. Society becomes a lot of free equal individuals related to each other as proprietors of their own capacities and of what they have acquired by their exercise. Society consists of exchange between proprietors. (3)

The individualism that Macpherson identifies is of a specific sort; it is "possessive" individualism. What does Macpherson mean by this? Here we have the heart of the theory of possessive individualism: the individual as solely an owner of himself. Here is his formulation late in the book:

1. What makes a man human is freedom from dependence on the wills of others.
2. Freedom from dependence on others means freedom from any relations with others except those relations which the individual enters voluntarily with a view to his own interest.
3. The individual is essentially the proprietor of his own person and capacities, for which he owes nothing to society.
4. Although the individual cannot alienate the whole o fhis property in his own person, he may alienate his capacity to labour.
5. Human society consists of a series of market relations.
6. Since freedom from the wills of others is what makes a man human, each individual's freedom can rightfully be limited only by such obligations and rules as

are necessary to secure the same freedoms for others.
7. Political society is a human contrivance for the protection of the individual's property in his person and goods, and (therefore) for the maintenance of orderly relations of exchange between individuals regarded as proprietors of themselves. (263-4)

The core of the book is a set of interpretive chapters on Hobbes, Locke, the Levellers, and Harrington. These chapters are careful, detailed, and closely textual and contextual. The book puts forward a fairly simple theory: the British tradition of political philosophy expresses a rather particular ideology that is pre-philosophical. The ideology (possessive individualism) is a very specific conception of the individual and his/her roles in the social world. The philosophical theories that are built on that ideology give shape to that set of assumptions, but they are ill suited to recognizing or critiquing those assumptions. Macpherson highlights the interpretive challenge of discovering these underlying assumptions: "Where a writer can take it for granted that his readers will share some of his assumptions, he will see no need to set these out at the points in his argument where we, who do not share those assumptions automatically, think they should have been stated to make the argument complete" (5).

What is the social context of this ideology? It is the reality of market society:

These assumptions do correspond substantially to the actual relations of a market society. (4)

One of Macpherson's more indirect goals in his philosophy is to provide an intellectually sound foundation for the liberal democratic state -- a state that recognizes the worth of the individual while also recognizing the social obligations that we all have towards each other and that need to be expressed through the social programs of the state. Fundamentally, Macpherson is interested in helping formulate a political theory that lays a powerful normative base for social democracy.

Macpherson's interpretation of Hobbes's philosophy provides an interesting discussion of "models of society" that is worth drawing attention to. He suggests that Hobbes formulates three models of society: customary or status society; simple market society; and possessive market society (47-48).

The concept of possessive market society is neither a novel nor an arbitrary construction. It is clearly similar to the concepts of bourgeois or capitalist society used by Marx, Weber, Sombart, and others, who have made the existence of a market in labour a criterion of capitalism, and like their concepts it is intended to be a model or ideal type to which modern (i.e. post-feudal) European societies have approximated. (48)

What Macpherson means by a model here needs some careful interpretation. He refers to it as an "ideal type" in this passage. More specifically, a model is a specification of several key structural features of a social order. Here is the model of a customary or status society:

1. The productive and regulative work of the society is authoritatively allocated to groups, ranks, classes, or persons.
2. Each group, rank, class, or person is confined to a way of working, and is given and permitted only to have a scale of reward...
3. There is no unconditional individual property in land.
4. The whole labour force is tied to the land, or to the performance of allotted functions, or (in the case of slaves) to masters. (49)

Macpherson thinks that these four characteristics create a specific form of system behavior for societies that embody them: "From these properties of a status society certain characteristics follow" (49).

The most complex model is the possessive market society, with postulates defining allocation of work, rewards for work, enforcement of contract, individual rational maximizing, individual's property in his labour, individual ownership of land, individuals want more utility or power, individuals have differential energy, skill, or possessions. With these postulates (including institutions and actors), we get a certain kind of social functioning. This is an "aggregation dynamics" argument. In other terms, it is a micro-to-macro argument up the struts of Coleman's boat.

It is worthwhile drawing out the connections between possessive individualism and conservative libertarian political groups in the present. The Tea Party seems to be a contemporary descendant of this ideology. Taxation is theft; the state has no legitimate role beyond protecting individual security and property; government regulation of private business activity is an immoral intrusion on liberty and property; individuals possess liberties and property that the state cannot limit; individuals **deserve** what they own and owe nothing to society or other citizens. Justice is served by simply protecting the possessions of individual citizens. Robert Nozick seems to have represented many of these values in Anarchy, State, and Utopia.

Those who favor a more expansive vision of a democratic society have several core values that conflict with these: Individuals have obligations to other members of society; government has the responsibility of protecting the wellbeing of the least advantaged in society; government has the responsibility of protecting the public good against harmful effects of private activities; decisions about public policies can and should be made through effective institutions of democratic self-determination; inequalities of wealth and power need to be restrained to ensure the political voice of the whole of society. Taxation is legitimate for at least three different reasons: it is a legitimate policy tool for limiting wealth inequalities to levels consistent with democratic equality; it is a legitimate vehicle for redistributing income to satisfy the requirement of providing a social minimum; and it is legitimate as a source of revenue needed to accomplish the public functions of the state, including provision of public goods and regulation of environment, labor, air safety, food safety, and the like. Justice is served by creating a system of legislation and policy that ensures the dignity and democratic rights of all members of society. John Rawls expresses most of these value in Justice as Fairness: A Restatement.

Our political sphere could still use a powerful and unifying theory providing a justification for these social democratic ideas. So Macpherson's voice is still relevant, almost fifty years later.

Here is a review of the book by the great English Marxist historian, Christopher Hill.

The suburbs

Friday, August 19, 2011

There has been lots of work on urban history, and rural life has come in for its own specialized study for almost two centuries as well. But what about the suburbs? Is there anything distinctive about suburban life in the United States that suggests that it needs its own sociology and history? Kevin Kruse and Tom Sugrue think so, and their volume, The

New Suburban History (Historical Studies of Urban America), makes the case. Kruse and Sugrue think that this history is actually crucial to understanding many things about the United States since the 1950s.

In the still-developing history of the postwar United States, suburbs belong at center stage. The rise and dominance of suburbia in America after the Second World War is inescapable. In 1950, a quarter of all Americans lived in suburbs; in 1960, a full third; and by 1990, a solid majority. (1)

This question divides naturally into two tracks. First, has there been a distinctive sociology of suburban life that needs to be tracked? And second, does this social-demographic fact about post-war America have important consequences for larger issues -- electoral politics, race, education, cultural homogenization, and economic competitiveness? Kruse and Sugrue think that suburbanization has implications for each of these topics, and the volume makes the case.

The subject of suburban history isn't a new one. But what is new about the approach taken by the contributors is the fact that they treat the suburbs as part of a system. They treat regions as metropolitan systems including inner cities and multiple suburban places.

[The contributors] take a broader metropolitan perspective, paying attention to the place of suburbs in political and economic relationship with central cities, competing suburbs, and their regions as a whole. (6)
Another distinctive part of their approach is that they look at suburbanization as chiefly a long-running political process. It was the result of many layers of federal, state, and local public policies. Here is how David Freund puts it in his essay:

The modern American suburb is heavily indebted to the federal government. For decades writers have chronicled this debt, documenting how state policy fueled the rapid suburban growth that has so decisively shaped U.S. politics and culture since World War II. ... Meanwhile the nation's cities, and especially the minority populations concentrated within them, were left behind. (11-12)
And it led to a powerful new set of political dynamics of competition.

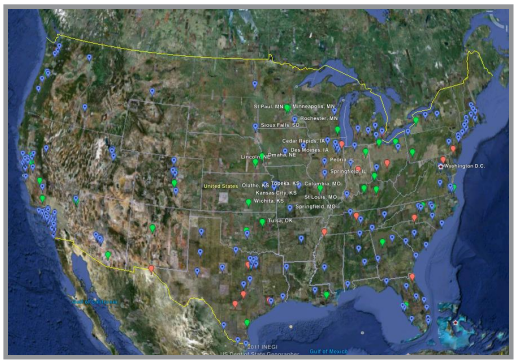
The history of suburbanization and its consequences is, in large part, a question of power. (6)
In fact, the editors point out that a number of key electoral issues in the past half century have emerged out of the conflicts of interest that arose out of the shift of population to the suburbs and competition between suburban communities -- for example, the anti-tax movement that originated in California. (Robert Self analyzes this dynamic in his contribution, "Prelude to the Tax Revolt.")

Arnold Hirsch picks up the issue of segregation in his essay.

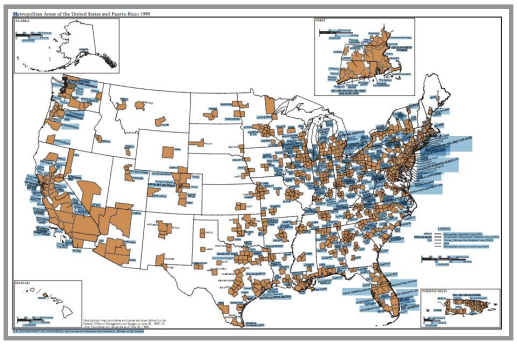
The cumulative effect of federal housing policies ... was to produce a federally sponsored social centrifuge that not only separated black from white but increasingly linked the latter to placement on the economically dynamic fringe as opposed to the crumbling core. (35-36)
It is also interesting to understand in hindsight that these implications of federal housing policy were fairly clearly understood on both sides -- by advocates of a radicalized housing policy and by advocates for the civil rights of African Americans. Hirsch summarizes the prescient views of George Nesbitt:

In 1952, Racial Relations Service officer George B. Nesbitt addressed the meeting of the National Association of Intergroup Relations Officials and warned that the programs then being implemented under the rubric of urban redevelopment would establish the spatial and psychological framework within which the civil rights struggle would take place in "decades to come". The racial implications of the program were awesome and could not be avoided. (52)
(Hirsch's own urban history of Chicago is well worth reading; Making the Second Ghetto: Race and Housing in Chicago 1940-1960 (Historical Studies of Urban America).)

Kruse and Sugrue and most of the contributors to the volume emphasize the range of variation that has existed in American suburbs. The racial and class homogeneity that earlier historians have highlighted has a realistic core -- Federal housing policies certainly contributed to de facto segregation across metropolitan regions -- but the editors note that there were a fair number of embedded clusters of minority residents and low-income workers as suburbs developed. And these facts of race and class diversity -- and sometimes conflict -- have had large consequences.



Detroit and its suburbs provide an almost pure case for the processes described in the volume. White flight beginning in the 1950s, the provision of county and municipal governments, and a very strong separation between Oakland County, Wayne County, and the city of Detroit illustrate many of the social and economic dynamics that are described in the volume. This has left a legacy of fragmented governance where it is very difficult to achieve anything like a shared regional perspective on problems that cross over the whole region. The fate of unified mass transit (which still doesn't exist in the region) and the bitter arguments among governments over the fate of Cobo Hall point to the failure of regionalism to date and the sub-par outcomes that are the result for almost all the 4.5 million people who live in the metropolitan region. Tom Sugrue's The Origins of the Urban Crisis: Race and Inequality in Postwar Detroit (Princeton Studies in American Politics)does a masterful job of telling the story of how we got here.



Kruse and Sugrue and the contributors to the volume succeed in establishing the importance of suburban history within American social development and public policy change, and they do a good job of drilling down into the policy choices that were made at all levels leading to this course of development in the U. S. They also demonstrate how the politics and sociology of race relations played an essential role in this history. What the volume doesn't even try to do is to get at the sociological dynamics that this form of residence, work, and socialization created. So plainly there is still a lot to do in the field by sociologists and ethnographers to capture the suburban experience.

(It is interesting to consider that there is a significant slice of the American population who live in places that are neither urban, suburban, nor rural. These are people who live in towns and small cities -- population 50,000 to 250,000. This is small-city America -- Peoria, Youngstown, Grand Rapids, Indianapolis, Orlando. These places often have many of the same challenges as major cities, without the dynamism and opportunity that are part of the scene in Chicago, Miami, Seattle, or New York. It would be very interesting to see data on things like social and geographical mobility, innovative business ideas, and average educational levels for places like these. Richard Florida has made the case for large cities and their inherent dynamism; do any of these effects extend down the scale to Peoria or Syracuse? Take Peoria, Rockford, and Chicago -- what does a detailed history of Illinois electoral politics and public policy tell us about the relations of competition, cooperation, and dominance that these three cities demonstrate over time?)

Small cities

Wednesday, August 24, 2011

A recent post on the suburbs closed with the observation that there is an important "other" social space in the United States beyond the categories of urban, rural, and suburban. These are the small cities throughout the United States where a significant number of people come to maturity and develop their families and careers. I speculated that perhaps there is a distinctive sociology associated with these lesser urban places. Here I will look into this question a bit more fully.

There are about 275 cities in the US with populations 100,000 or larger (Wikipedia link). 201 of these cities are small, with populations between 100,000 and 250,000. There are 30.3 million people living in these cities -- about 10% of the US population. A certain number of these cities fall within the metropolitan areas of larger cities, but a significant number are at least 50 miles from a major city.

Here is a map of 200 cities with populations between 100,000 and 250,000:

View Small Cities in a larger map

And here is a map of 25 cities with population greater than 500,000 (red) and 48 cities with population between 250,000 and 500,000 (green):

View Small Cities in a larger map

Google Maps limits the number of objects that can be placed on a map to 200 items, so it isn't possible to overlay these maps using Google Maps. Google Earth does not have this limitation, and all these points are included on the Google Earth version of the map. Here is what the overlay looks like:

And here is a map of the Metropolitan Statistical Areas in the US in 1999. Wikipedia provides an up-to-date list of the MSAs in the US (link). (Many of the small cities actually constitute an MSA of their own; so determining whether a small city is "metropolitan" really involves the question of whether the place falls within one of the top 25-50 MSAs by population.)

The group of cities I'm interested in here is a subset of the cities on the first map: those that are more than 50 miles from one of the top 25 cities on the second map. This still

leaves well over 100 cities in the United States with a couple of interesting characteristics: they are relatively small, so they can be expected to lack a number of higher-level functions and industries; and they are relatively isolated from other larger cities, so their populations are extensively dependent on the resources of the city itself for employment, social services, entertainment, consumption, education, etc.

So the takeaway question here is this: what is life like in Billings MT, Topeka KS, Norman OK, Pueblo CO, Springfield IL, Knoxville TN, Cary NC, Green Bay WI, Grand Rapids MI, Allentown PA, Shreveport LA, and Killeen TX? What is it like to grow up in these places? Where do young people go for post-secondary education? What percentage of young people leave these places permanently in the course of their careers? Where do the elected officials in these places come from? How are these cities doing, from the perspective of unemployment, neighborhood and business district decline, and social problems?

Further, we can ask whether there are any structural features in common that imply that these places are more similar to each other than they are to larger cities or smaller towns. Are issues of immigration, race relations, drug use, teen pregnancy, or high school dropout rates different in these places?

Finally, we can ask whether growing up in these places gives rise to a specific mentality. Do those of us who grew up in small cities like these -- Peoria, Rock Island, Springfield -- have a different set of values, a different way of looking at the world, or perhaps different ways of relating to people in ordinary social life? Or are regional differences (south, midwest, Pacific Coast) more of a determinant of one's mentality?

(I've placed the lists of cities and MSAs I've used here as spreadsheets at Google Docs; link, link. Both lists come from Wikipedia entries on US Cities and Metropolitan Statistical Areas.)

Causal narratives about historical actors

Friday, August 26, 2011

A common kind of causal narrative employed by historians is to identify a set of key actors, key circumstances, and key resources; and then to treat a period of time as a flow of actions by the actors in response to each other and changing circumstances. We might describe this as "explanation of an outcome as cumulative result of actions by differently situated actors, within a specified set of institutions, resources, and environmental factors."

Individual actions make sense in the context, so we have explained their behavior at the micro level. But we can also "calculate" aggregate structural consequences of these actions, and we can thereby reach conclusions about how change in one set of structural conditions led to another set of structural changes through the flow of situated actors choosing their strategies. The powers and resources available to different groups of actors are different and must be carefully assessed by the historian.

This explanatory logic is illustrated in Emmanuel Wallerstein's account of the development of the so-called absolute monarchy in France (The Modern World-System I: Capitalist Agriculture and the Origins of the European World-Economy in the Sixteenth Century, With a New Prologue). Actors choose strategies based on the circumstances,

alliances, and opponents that confront them. Actors include: king, lord, peasant, merchant, civil servant, bandit, clergy. Most of these actors also have collective organizations that function as actors at a group level. Economic crisis in the fourteenth and fifteenth centuries led officials of medieval states to broaden and extend their bureaucracies (134). Kings profited from disorder to extend their wealth at the expense of the nobles (135). Kings set more ambitious objectives for their states (135). Kings needed support from nobles and created parliaments. Kings used a variety of strategies to centralize power.

How did kings, who were the managers of the state machinery in the sixteenth century, strengthen themselves? They used four mechanisms: bureaucratization, monopoly of force, creation of legitimacy, and homogenization of the subject population. (136)
These actions aggregate into a new set of circumstances, a more effective set of centralized state powers, for the next period of play.

Institutions come into this kind of narrative in two ways. First, they are objective constraints and facts on the ground for the actors, leading actors to adjust their strategies. But second, institutions are built and modified through strategic actions and oppositions of the actors during a period of time. The king wants to strengthen the institutions of tax collection in the provinces; local lords oppose this effort. Each party deploys powers and opportunities to protect its interests. The resultant institutions are different from what either party would have designed.

Where do "causes" come into this kind of narrative? Climate change is a good example. Wallerstein considers the idea that climate change caused the emergence of a new set of institutions of land use (33 ff.). The mechanism is through the actions of the various stakeholders, competing and cooperating to adjust institutions to fit their current needs. Let us say the king is in a situation of greater power than the peasant or the lord. The king largely prevails in institutionalizing a new set of land use practices. One of the causes of the new institution is climate change, working through the strategic actions of the several groups of players. Or: Medieval landowners suffer income loss during a period of economic crisis; they recognize an income opportunity in enclosing public lands for private cultivation; peasants resist using traditional forms of protest; landowners generally have a power advantage and are supported by the state; landowners prevail. In this story, economic crisis causes change of land property relations, mediated by the strategic actions of key actors and groups. (Marx and Brenner tell different versions of this story; link, link.)

A different kind of example comes in at the level of the state. Wallerstein holds that the absolutist state caused the extension of the world trading system. What does he mean by this? He means that new state institutions created new powers and opportunities for several groups of actors, and the net result of these actor's strategies was to bring about a rapid increase in trade and associated military strategies. Again -- a macro cause of a macro outcome, flowing through an analysis of the strategies, interests, and powers of the historically situated actors.

This model of agent-based causal narratives seems to fit well into the methodology of agent-based simulations, with adjustments of the conditions of play from one iteration to the next. We would specify the goals and knowledge possessed by the actors. We would stipulate the institutional "geography" of the playing field. The institutions would define the powers possessed by each actor and the resources available for competition. We would represent alliances, competitions, and outcomes as they develop, noting that there is a

stochastic and path-dependent nature to the unfolding of these scenarios.

Essentially the model for explaining social change and stability goes along these lines: actors act according to their interests and psychology. To explain a new outcome we need to identify either:

a structural circumstance or resource that significantly changed the situation of action for one or more groups;
Or:

a change in the conditions of agency in the actors themselves -- ideology, religion, new factual theories and beliefs.
Either of these changes can then account for a persistent pattern of behavior leading to a new social outcome. This framework of explanation fits well into the ontology of methodological localism and also leaves room for meso-level causal factors.

The moral basis for an extensive state

Monday, August 29, 2011

A recent post focused on the conception of society involved in seventeenth and eighteenth English political thinking, the theory of possessive individualism. The post suggested that this conception has a lot of resonance with the ideas and rhetoric of the Tea Party today. I've also posted a number of discussions of the social ideals of John Rawls (link, link), expressing a liberal democratic view of the good society. These posts remind me how important it is to have some fairly specific ideas about how we would want society to be organized in the future, so we can also have some ideas about current reforms that might take us in that direction. And today we don't seem to have a lot of clarity about this kind of vision, especially on the progressive side of the political spectrum.

The ideal that seems to lie behind the conservative Tea Party political philosophy is simple but alarming:

1. Citizens should have maximum possible liberties of activity and use of property.
2. Citizens have no positive obligations to other citizens, beyond those associated with respecting liberties and property rights.
3. The state exists only to secure the liberties and security of citizens; this means the state needs to have funds to provide for national defense, enforcement of property rights, and maintenance of public order.
4. The state has no legitimate basis for creating more extensive regulations on the exercise of liberty and property (FDA, EPA, regulation of banks, …). Such regulations represent an unjustified interference with the exercise of private property rights.
5. The state has no legitimate basis for using tax moneys to provide a social safety net (unemployment payments, welfare payments, food and housing subsidies, …). Such transfer programs represent an unjustified system of redistribution of wealth and income that violates the property rights of anyone who is taxed more extensively than a fair share of the costs of providing for national defense and maintenance of public order.

This political philosophy is familiar from Robert Nozick's Anarchy, State, and Utopia (1974). At the time Nozick's vision was considered extreme from a philosophical point of view; it took to a logical limit the very limited assumptions about individual rights that were

a part of the Lockean tradition of political philosophy, and arrived at what was then a very startling set of conclusions about the limits on legitimate state action. Nozick referred to this conception as the "minimal state". Nozick's philosophy expressed a form of libertarian conservativism, with no inclination towards the "social values" of more recent conservatism.

If this political philosophy were to be enacted through legislation, it would imply a number of things: abolition of mandatory social security, abolition of regulatory agencies like EPA and FDA, abolition of unemployment benefits and poverty-based welfare programs, and dramatic reduction of taxes on the affluent. This is a vision of the minimal state with a vengeance; and it seems rather familiar from much of the rhetoric offered by Tea Party activists and Republican presidential candidates alike.

We could spend time thinking about the deficiencies of this political philosophy from a number of points of view. Here my interest is different; I'd like to consider what components might go into a political philosophy that expresses a moral justification for the more extensive state that a great many Americans would want to have. First, what are the institutional arrangements that might be considered?

A strong alternative to the minimal state is the *Nordic model* -- essentially the political and economic system associated with Scandinavian democracies in the 1960s through the 1980s. Here is an interesting monograph on the economic and social characteristics of the Nordic model: *The Nordic Model: Embracing globalization and sharing risks* (Torben M. Andersen, Bengt Holmström, Seppo Honkapohja, Sixten Korkman, Hans Tson Söderström, Juhana Vartiainen; published by the Research Institute of the Finnish Economy); link. The authors describe the key economic and social commitments of the Nordic model in these terms:

- *a comprehensive welfare state with an emphasis on transfers to households and publicly provided social services financed by taxes, which are high notably for wage income and consumption;*
- *a lot of public and/or private spending on investment in human capital, including child care and education as well as research and development (R&D);*
- *and a set of labour market institutions that include strong labour unions and employer associations, significant elements of wage coordination, relatively generous unemployment benefits and a prominent role for active labour market policies. (13)*

A key goal of the study is to assess the economic performance of the Nordic model over the past fifty years. The study's summary conclusion is very favorable: contrary to anti-tax, anti-government ideology, the Nordic economies have performed very well.

The Nordic countries have, according to many indicators, succeeded relatively well in fulfilling their social ambitions. Recently, this has been combined with a satisfactory economic performance in terms of employment and productivity levels as well as growth of GDP per capita. Also, the macroeconomic balance is good and public finances are strong. There is indeed a Nordic success story in the sense of a favourable combination of economic efficiency and social equality.

True, the Nordics went through a period of low productivity growth in the 1970s (like most other OECD countries) as well as a major financial and macroeconomic crisis with very high unemployment rates and large fiscal imbalances in the early 1990s (somewhat earlier and less dramatically in the case of Denmark). But even so, the Nordics have more or less managed to keep up with the US in terms of PPP-adjusted GDP over the

last 25–30 years, which is more than can be said of most other EU15 countries. The longterm performance is mainly recorded as a high rate of total factor productivity growth. This indicates that technical progress, notably in the area of information and communication technology (IT), has played in important role in growth. More importantly, it also shows that the Nordics – contrary to popular belief – demonstrate a high degree of economic flexibility and capacity of structural change. The macroeconomic crises have helped the process by inducing growth-enhancing changes in structural policies (and, for a while, through the improvements of competitiveness caused by large depreciations in the early 1990s). (15)

These are social and economic arrangements that establish an active state, a state with broad responsibilities to the welfare of its citizens, and a state that calls upon a significant fraction of the wealth of society to do its work. What are the moral principles that might underly such a conception of a good society? Here are a few axioms that seem to be worth considering within such a political philosophy.

1. Society is a system of interdependency and mutual benefit for all citizens. Everyone benefits from being part of a just society.
    1. The moral situation of individuals in society includes several important components: Individuals within society have rights, liberties, and needs for personal security.
    2. Individuals have obligations to each other to help prevent hardship and to facilitate full human development. These obligations derive from at least two sources: (a) the benefits we all enjoy as a result of social cooperation in a functioning society; and (b) the moral recognition we have of the equal human worth and dignity of fellow citizens.
    3. Individuals within society have universal needs to facilitate their full human development and functioning, including education, health care, housing, and adequate nutrition.
    1. Certain core functions for the state follow from these moral ideas: The state is obligated to create a system of law that protects the rights, liberties, and security needs of all citizens.
        1. The state is obligated to serve as one of the important vehicles through which our positive obligations to other citizens are honored. The state needs to ensure that all citizens have access to education, healthcare, and the essentials of life.
        2. The state needs to provide a safety net for citizens whose earnings within the market economy leave them unable to provide for a decent standard of living.
    2. The state is obligated to protect the public from the harmful effects of private activities, including regulations concerning health and safety, conditions of labor, and environmental harms.
    1. A handful of moral constraints surround the policies and laws the state may adopt: The state is authorized to collect taxes to efficiently perform its functions of protecting rights, securing welfare, and regulating harmful activities.
    2. The state is obligated to be procedurally just and economically efficient in its administration of public programs.
    3. The policies and laws of the state need to be adopted through a democratic process in which all citizens have equal voice.

This formulation highlights a cluster of values that can potentially gain wide support within a democracy: the equal worth of all individuals, the importance of liberty, the importance of a range of social obligations all citizens have to each other, and the idea that the state needs to be articulated in such a way as to embody these moral ideas.

If the theory of the minimal state owes much of its content to John Locke, the more extensive state described here owes much of its moral rationale to Jean-Jacques Rousseau. Rousseau brought the moral perspective of the "individual within community" into the foundations of political philosophy. Josh Cohen's Rousseau: A Free Community of Equals provides an excellent discussion of Rousseau's political theory; link.

(Gosta Esping-Andersen has studied the politics and policies of social democracies through a lifetime of writing. Especially important are The Three Worlds of Welfare Capitalism and Politics Against Markets: The Social Democratic Road to Power.)

Do organizations have causal powers?

Thursday, September 01, 2011

An organization is a meso-level social structure. It is a structured group of individuals, often hierarchically organized, pursuing a relatively clearly defined set of tasks. In the abstract, it is a set of rules and procedures that regulate and motive the behavior of the individuals who function within the organization. There are also a set of informal practices within an organization that are not codified that have significant effects on the functioning of the organization (for example, the coffee room as a medium of informal communication). Some of those individuals have responsibilities of oversight, which is a primary way in which the abstract rules of the organization are transformed into concrete patterns of activity by other individuals. Another behavioral characteristic of an organization is the set of incentives and rewards that it creates for participants in the organization. Often the incentives that exist were planned and designed to have specific effects on behavior of participants; by offering rewards for behaviors X, Y, Z, the organization is expected to produce a lot of X, Y, and Z. Sometimes, though, the incentives are unintended, created perhaps by the intersection of two rules of operation that lead to a perverse incentive leading to W. For example: a farm supervisor may ask peach pickers to discard the bruised peaches rather than placing them in the basket to be weighed. But if the laborers' salaries are determined solely by the weight of the baskets they present for weighing, they will have an incentive to include the bruised peaches (at the bottom!).

Examples of organizations include things like these:

- the Atlanta police department
- a collective farm in Sichuan in 1965
- the maintenance and operations staff of a nuclear power plant
- a large investment bank on Wall Street
- Certus Corporation (discoverer of the PCR process)
- the land value assessment process in late Imperial China

The organization consists of a number of things:

- a set of procedures for how to handle specific kinds of tasks
- a set of people with skills and specific roles
- a set of incentives and rewards to induce participants to carry out their roles effectively and diligently
- a set of accountability processes permitting supervision and assessment of performance by individuals within the organization
- an "executive" function with the power to refine / revise / improve the rules so as to bring about overall better performance

Let's take the nuclear power plant staff as an example. The tasks of the organization are to control the complex technology and its instruments over an extended time; to conduct inspections of the physical infrastructure of the plant to discover failures before they occur; to conduct routine maintenance of machines and other physical systems; to respond quickly to failures, both large and small; and to sometimes conduct major upgrades on the hardware of the system. We may imagine that there are detailed, written procedures for each of these activities, as well as procedures for action during times of malfunction or breakdown. The people of the plant represent a range of specialized skills and specialized tasks. Wainwrights maintain and repair machinery; computer technicians maintain computer systems; nuclear technicians oversee the measured functioning of the system (pressures, temperatures, power production); safety workers inspect various system; and supervisors assign tasks and monitor performance.

Failures of the system arise for several different kinds of reasons: technical failure (a device fails for unexpected technical reasons, such as a faulty weld); operator failure (an operator disregards or misinterprets a pressure warning, and a pipe explodes before corrective action is taken); training failure (staff are technically or operationally unprepared for performing their tasks routinely or in exceptional circumstances); system failure (two or more sub-systems function as designed, but in an unusual circumstance may interact in such a way as to bring about an explosion, a computer crash, or a release of energy or heat); supervisory failure (procedures were good but supervisors permitted deviation from the procedures); venality failure (individuals in a position to control purchasing decisions authorize bad contracts for faulty materials for their personal profit).

The idea of a principal-agent problem is highly relevant within organizations, at every level. The executive expects the supervisor to faithfully perform his/her tasks of supervision. But since the executive does not directly monitor the performance of the supervisor, it is possible for the supervisor to shirk his/her duties and permit faulty performance by those he supervises. Likewise, the supervisor expects that the operator will continue to monitor and control the machine throughout the day; but it is possible for the operator to keep a solitaire window open on the screen. Each level of accountability, then, requires both formal expectations and a basis for trust in the good faith of the participants in the organization.

Now we are in a position to address the central question here: do organizations have causal powers? It seems to me that the answer is yes, in fairly specific ways. First, the rules and procedures of the organization may themselves have behavioral consequences that lead consistently to a certain kind of outcome.

Second, different organizational forms may be more or less efficient at performing their tasks, leading to consequences for the people and higher-level organizations that are depending on them. For example, two tax-collection systems may be designed for the same goal -- to collect 10% of the grain produced everywhere in the kingdom. If one system is 75% successful in this task and the other is 50% successful, the state depending on the second system will be starved for resources.

Third, the discrepancy between what the rules require of participants and what the participants actually do may have consequences for the outputs of the organization. Police department regulations may require that each piece of physical evidence is separately bagged and catalogued with appropriate information about its collection. If police operatives are careless in the cataloguing of evidence it may be more difficult to convict the accused; this may lead to a rising disregard for the likelihood of conviction

and a rise in the crime rate. Corruption (venal failure to perform one's tasks faithfully) may lead to large consequences: the company is less profitable, the city is discredited to its citizens, the Church is delegitimated by the self-interested behavior of its clergy.

Fourth, the specific ways in which incentives, sanctions, and supervision are implemented differentiate across organizations. We may find that organizations with supervision system X are on average more productive or more effective than those with system Y.

Fifth, the organization has causal powers with respect to the behavior of the individuals involved in the organization. By presenting its rules, sanctions, and rewards to its participants, it changes their behavior in specific ways. Google and Apple have organized their internal procedures and rewards in such a way as to encourage creativeness, teamwork, and confidentiality. These organizations look quite different in their functioning and their products from a steel company or a shoe company.

This means two things. First, we can say with some confidence that the way an organization is structured makes a difference to its performance; this is a causal power all by itself. And second, we may be able to discover that there are broad characteristics that differentiate organizational types, and it may turn out that these distinct types also have different performance characteristics. We might discover, for example, that one system of oversight and employee motivation is significantly more likely to permit theft and corrupt behavior by its agents than another. In that case, we might say that these two systems differ in their propensities for generating corrupt behavior. (This is an argument that Robert Klitgaard makes in Controlling Corruption.)

So far we haven't mentioned the familiar subject of "microfoundations" at all; we have considered an organization as a complex social entity. It is easy to specify the microfoundations of the causal powers we have identified. The organization's performance is determined by the behaviors of the individuals who fall within it, and the aggregate individual behaviors are explained by the rules and procedures embodied in the organization. So the causal powers having to do with efficiency, effectiveness, and corruptibility can be disaggregated into the incentives and behaviors of typical individuals. But here is the key point: we don't need to carry out this disaggregation when we want to invoke statements about the causal characteristics of organizations in explanations of more complex social processes. This is a case illustrating the point of relative explanatory autonomy developed in a prior post, and it also illustrates the point that David Elder-Vass makes in The Causal Power of Social Structures: Emergence, Structure and Agency.

These observations lay a basis for concluding that meso-level social entities have causal powers that can legitimately be invoked in social explanations. Significantly, there are clear and convincing examples of sociological explanations that take the causal powers of organizations as fundamental to their explanations of important social outcomes -- for example, technology failure (Charles Perrow, Normal Accidents: Living with High-Risk Technologies; link), corruption (Robert Klitgaard, Controlling Corruption), and the use of common property resources (Elinor Ostrom, Governing the Commons: The Evolution of Institutions for Collective Action).

Rawls on the EU

Saturday, September 03, 2011

During the final preparation of The Law of Peoples: with "The Idea of Public Reason Revisited" John Rawls had extensive interaction with Philippe van Parijs. Van Parijs was particularly interested in the political and legal circumstances surrounding the establishment of the legal structure of the European Union and the obligations states and their citizens would have to each other within the EU. A key question is whether a political body -- a state or confederation -- needs to encompass a single unified "people" (whether by language, traditions, or culture); or if, on the contrary, such a body can consist of multiple peoples who nonetheless have duties of justice to each other.

What turns on this from a moral point of view is the level of moral concern that members of this kind of union owe each other. Are their obligations limited to the domain of "concern" that gives rise to some obligations of charity? Or are they closely enough interconnected that they are subject to the demands of justice towards each other? If the latter then the difference principle applies to them when inequalities of life circumstances are apparent. If the former then only weaker principles of assistance apply.

For van Parijs this question is particularly acute in the case of Belgium, which was even then subject to fissional pressures along linguistic-cultural lines between Flemings and Walloons.

Van Parijs and Rawls exchanged several careful and thoughtful letters on these issues in 1998, and these letters were published in their entirety in Revue de philosophie économique in 2003 (link).

The disagreements between van Parijs and Rawls are very interesting to follow in detail. There is one aspect of the exchange that is particularly intriguing on the subject of Rawls's own assessment of modern capitalism. The passage is worth quoting. Here is an excerpt from Rawls's letter:

One question the Europeans should ask themselves, if I may hazard a suggestion, is how far–reaching they want their union to be. It seems to me that much would be lost if the European union became a federal union like the United States. Here there is a common language of political discourse and a ready willingness to move from one state to another. Isn't there a conflict between a large free and open market comprising all of Europe and the individual nation-states, each with its separate political and social institutions, historical memories, and forms and traditions of social policy. Surely these are great value to the citizens of these countries and give meaning to their life. The large open market including all of Europe is aim of the large banks and the capitalist business class whose main goal is simply larger profit. The idea of economic growth, onwards and upwards, with no specific end in sight, fits this class perfectly. If they speak about distribution, it is [al]most always in terms of trickle down. The long–term result of this — which we already have in the United States — is a civil society awash in a meaningless consumerism of some kind. I can't believe that that is what you want.

So you see that I am not happy about globalization as the banks and business class are pushing it. I accept Mill's idea of the stationary state as described by him in Bk. IV, Ch. 6 of his Principles of Political Economy (1848). (I am adding a footnote in §15 to say this, in case the reader hadn't noticed it). I am under no illusion that its time will ever come –

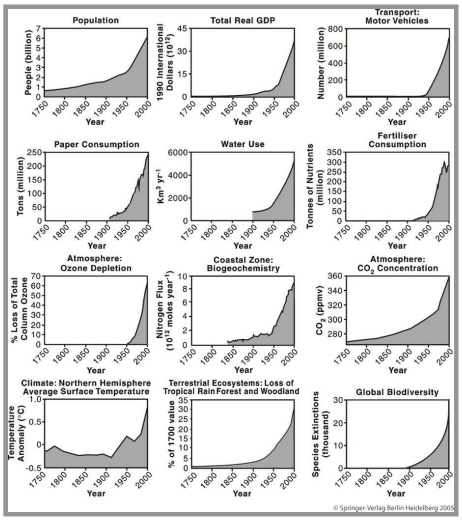
certainly not soon – but it is possible, and hence it has a place in what I call the idea of realistic utopia.

Several aspects of this passage are noteworthy. The first is a tentative skepticism about the goal of creating a European *community* in a strong sense -- a polity in which individuals have strong obligations to all other citizens within the full scope of the expanded boundaries. Rawls seems to equate this goal with the idea of creating a somewhat homogeneous and pervasive European culture, replacing German, French, or Italian national cultures. And he offers the idea that the traditions, affinities, and loyalties associated with national identities are important aspects of an individual's pride and satisfaction with his/her life.

What is surprising about these views is that Rawls seems to overlook the polyglot, poly-cultural character of the United States and Canada themselves. Both North American countries seem to have created some remarkable solutions to the problem of "unity with difference." It is possible to be a committed United States citizen but also a Chicago Polish patriot, a Los Angeles Muslim, or a Mississippi African American. Each of these is a separate community with its own traditions and values. But each can also embody an overlay of civic culture that makes them all Americans. It certainly doesn't seem impossible to imagine that Spaniards will develop a more complex identity, as both Spaniard and European. So Rawls's apparent concerns about homogenization and loss of collective meaning seem ill founded.

Even more interesting, though, are his several comments about globalization and capitalism. As we observed in a post about the property-owning democracy (link), Rawls has already expressed the idea that capitalism has a hard time living up to the principles of justice. Here he goes a step further and reveals a significant mistrust of the value system created by capitalism. He refers to the world the "bankers and capitalists" want to create -- one based on acquisitiveness and the pursuit of profit -- and he clearly expresses his opinion that this is incompatible with a truly human life.

The goal of perpetual growth expresses this ideology, and Rawls reveals his skepticism about this idea as well. He offers the opinion that the pursuit of growth by this class is no more than the pursuit of greater wealth and more meaningless consumption. And he clearly believes this is a dead-end. Instead, he endorses J. S. Mill's idea of a steady-state (link). (Interestingly, this position lines up well with current thinking of environmentalists; for example, James Gustave Speth and The Bridge at the Edge of the World: Capitalism, the Environment, and Crossing from Crisis to Sustainability (link).)



Here Rawls seems to express a cultural critique of capitalism: the idea that the driving values of a market society induce a social psychology of consumerism that overrides the individual's ability to construct a thoughtful life plan of his/her own.

Finally, Rawls criticizes the neo-liberal dogmas about distribution of income that had dominated public discourse in the U.S. almost since the publication of *A Theory of Justice*: the theory of trickle-down economics. That theory holds that everyone will gain when businesses make more profits. And, of course, the data on income distribution in the U.S. since 1980 has flatly refuted that theory (link).

(Van Parijs' most recent book, Linguistic Justice for Europe and for the World (Oxford Political Theory), will be published in October. It is highly relevant to this debate with Rawls.)

Low income and wellbeing

Monday, September 05, 2011

source: J. G. Speth, *The Bridge at the End of the World*

A recent post on Rawls's critique of capitalism closed with an intriguing mention of a contrast Rawls draws between economic growth and human wellbeing. He is particularly critical of the consumerism that is enmeshed in the social psychology of a growth-oriented market system. This point is worth focusing on more closely.

We seem to work on the basis of a couple of basic assumptions about income, lifestyle, and community in this country that need to be questioned. One group of these clusters around the idea that a high quality of life requires high and rising income. High income is needed for high consumption, and high consumption produces happiness and life satisfaction. Neighborhoods of families with high income are better able to sustain community and civic values. And symmetrically, we assume that it is more or less inevitable that poor communities have low levels of community values and low levels of the experience of life satisfaction.

All these assumptions need to be questioned. As any social service agency can document, there are ample signs of social pathology in the affluent suburbs of American cities. These suburban places aren't paragons of successful, happy human communities in any of the ways Robert Bellah talks about (Habits of the Heart: Individualism and Commitment in American Life, Good Society). And there is little reason to believe that the consumption-based lifestyles that define an American ideal of affluence really contribute consistently to life satisfaction and successful community.

But here I want to focus on the other end of this set of assumptions: the idea that non-affluent people and communities are necessarily less happy, less satisfied, and less integrated around a set of civic and spiritual values. So here is the central point: people can build lives within the context of low income that are deeply satisfying and rewarding. And communities of low-income people can be highly successful in achieving a substantial degree of civic and spiritual interconnection and mutual support. It doesn't require "affluence" to have a deeply satisfying human life and a thriving community.

There are many reasons for thinking these observations are likely to be true. One is the example of other societies. Consider village life in Spain or Italy, for example, where many families still live on incomes that are a fraction of American affluence, who incorporate gardens into their regular lifestyle and household economy, and who enjoy admirable levels of personal and social satisfaction. Or think of stable farming communities in India or Africa that have successfully achieved a balance of farm productivity, a degree of social equality, and a strong sense of community. Or consider examples of communities in the United States that have deliberately put together lives and communities that reject "affluence" as a social and personal ideal.

Of course it's true that extreme poverty is pretty much incompatible with satisfaction and

community. Malnutrition, illiteracy, and untreated disease are counterparts of extrme poverty and destroy happiness and community. But "non-affluence" isn't the same as extreme poverty.

What everyone needs, at every level of income, is decent access to the components of a happy life: healthcare, nutrition, shelter, education, dignity, and security. These are what an earlier generation of development thinkers called basic needs. And it is self-evident how these fit into the possibility of a decent and satisfying life. But access to these goods isn't equivalent to the American dream of affluence.

So here is a fairly profound question: what steps can be taken to promote the features of personal wellbeing and robust community relations that can make "non-affluence" a sustainable social ideal? And how can we help poor communities to strengthen their ability to nurture these positive values according to their own best instincts?

This line of thought converges closely with the striking arguments made by James Gustave Speth in The Bridge at the Edge of the World: Capitalism, the Environment, and Crossing from Crisis to Sustainability. The graphs at the top represent Speth's summary of the environmental catastrophe associated with the idea of permanent economic growth. Much of Speth's critique of consumerism and growth is summarized in this account of a talk he gave at McGill in 2008. Speth argues that a radical rethinking of well-being is necessary if we are to achieve a society that is environmentally sustainable.

More on meso causation

Saturday, September 10, 2011

A recent post considered the question, do organizations have causal powers? There I argued that they do, in a number of ways. Here I'd like to return to these claims and see how they disaggregate onto subvening circumstances, including especially patterns of individual and group activity. The italicized phrases are extracted from the earlier post.

- *First, the rules and procedures of the organization may themselves have behavioral consequences that lead consistently to a certain kind of outcome.*

How do rules and procedures causally affect the behavior of the actors who participate in them? (a) Through training and inculcation. The new participant is exposed to training processes designed to lead him/her to internalize the procedures and norms governing his/her function. (b) Through formal enforcement. Supervisors are institutionally charged to enforce the rules through direct observation and feedback. (c) Through the normative example of other participants, including informal sanctions by non-supervisors for "wrong" behavior. (d) Through positive incentives administered by supervisors and mid-level functionaries. Each of these avenues for influencing the behavior of an actor within an organization depends on the actions and motivations of other actors within the organization. So we have the recursive question, what factors influence the behavior of **those** actors? And the answer seems to be: all actors find themselves within a dynamic system of behavior by other actors, frequently maintaining an equilibrium of reproduction of the rules and roles.

- *Second, different organizational forms may be more or less efficient at performing their tasks, leading to consequences for the people and higher-level organizations that are depending on them.*

Institutions designed to do similar work may differ in their functioning because of specific differences in the implementation of roles and processes within the organization. This is a system characteristic of the particular features and interactions of the rules and

processes of the organization, along with the expected behaviors of the participants. It is also a causal characteristic: implementing system A results in greater efficiency at X than implementing B. The underlying causal reality that needs explanation is how it comes to pass that participants carry out their roles as prescribed--which takes us back to the first thesis.

- *Third, the discrepancy between what the rules require of participants and what the participants actually do may have consequences for the outputs of the organization.*

This causal claim highlights the difference between formal and informal procedures and practices within an organization. Informal practices can be highly regular and reproducible. In order to incorporate their implications into our analysis of the workings of the organization we need to accurately understand them; so we need to do some organizational ethnography to identify the practices of the organization. But in principle, the logic of explanation we provide on the basis of informal practices is exactly the same as those offered on the basis of the formal rules of the organization.

- *Fourth, the specific ways in which incentives, sanctions, and supervision are implemented differentiate across organizations.*

This is one of the key insights of the "new institutionalism." The specific design of the institution in terms of opportunities and incentives presented to participants makes a large difference in actors' behavior, and consequently a large difference to the system-level performance of the institution. Tweaking the variable of the level in the organization's hierarchy that needs to sign off on expenditures at a given level has significant effects on behavior and system properties. On the one hand, higher-level sign-off may serve to restrain spending. On the other hand, it may make the organization more unwieldy in responding to opportunities and threats.

- *Fifth, the organization has causal powers with respect to the behavior of the individuals involved in the organization.*

This factor parallels thesis 1 but is meant to refer to longterm effects on behavior and personality. The idea here is that immersion in a particular organization and its culture creates a distinctive social psychology in the people who experience it. They may acquire habits of thought, ways of responding to new circumstances, higher or lower levels of trust of others, and so forth, in ways that influence their behavior in the broader society. The idea of an "organization man" falls in this category of influence. The organization influences the individual's behavior, not just through the immediate system of rewards and punishments, but through its ability to shape his/her more permanent social psychology.

There are only two fundamental causal paths identified here. The causal properties of the organization are embodied in the patterns of coordinated actions undertaken by the actors who are involved; and these orderly patterns create system effects for the organization as a whole that can be analyzed in abstraction from the individuals whose actions constitute the micro-level of the social entity.

The most obvious causal property of an organization is bound up in the function of the organization. An organization is developed in order to bring about certain social effects: reduce pollution or crime, distribute goods throughout a population, provide services to individuals, seize and hold territory, disseminate information. These effects occur as a result of the coordinated activities of people within the organization. When organizations work correctly they bring about one set of effects; when they break down they bring about another set of effects. Here we can think about organizations in analogy with technology components like amplifiers, thermostats, stabilizers, or surge protectors. This analogy suggests we think about the causal powers of an organization at two levels: **what** they do (their meso-level effects) and **how** they do it (their micro-level sub-mechanisms).

A jobless future?

Saturday, September 10, 2011

Stanley Aronowitz and William DiFazio wrote a pretty gloomy book in 1994 with the striking title, The Jobless Future. Here is a *Harvard Educational Review* discussion of the book (link). What is most discomforting in reading the book today is the degree to which the factors they identify seem to be today's headlines. What does jobless mean here? In a word, it means that the US and other OECD countries will never recover the number and quality of jobs they need in order to regain the middle class affluence they had in the 1950s and 1960s. The future will involve work -- but not enough jobs to ensure a low unemployment rate. Here is their assessment in 1994:

For there is no doubt that we have yet to feel the long-term effects on American living standards that will result from the elimination of well-paid professional, technical, and production jobs. At the same time, nearly everyone admits that many of these jobs are gone forever. (xi)

The central structural factors they identified in 1994 are still key parts of our economic environment today: technology innovation replacing labor, rising productivity producing persistently flat labor demand, shifts in the structure of the economy towards finance and service sectors, and internationalization of production.

Technological progress and capital accumulation seem to disrupt the social fabric in the United States. A weakened position in the international economy demands that American industry increase its productivity and cut its unit labor cost. As Carl G. Thor, president of the American Productivity Center in Houston, says, "The trick is to get more output without a surge in employment." Technological change and competition in the world market guarantee that increasing numbers of workers will be displaced and that these workers will tend to be rehired in jobs that do not pay comparable wages and salaries. Women and minorities will suffer the most as the result of these changes; the increased participation in an occupational sector by women and minorities is often an indicator of falling wages in that occupation. (3)

The second explanation, more sobering, emphasized the role of huge federal and consumer debt accumulated beween the late 1970s and the early 1990s that has drained public and private investment, inhibiting recovery and growth. (5)

This, in brief, is the context within which a severely reduced job "market" began to take shape, not only for U.S. workers, but potentially for all workers. In this book we argue that the progressive destruction of high-quality, well-paid, permanent jobs is produced by three closely related developments. (8)

The implication they draw is stark: new jobs will never be created at a rate to satisfy rising demand for jobs.

Our first argument—that the Western dream of upward mobility has died and it is time to give it a respectful funeral—may have at long last seeped into the bones of most Americans, even the most optimistic economist. The dream has died because the scientific-technological revolution of our time, which is not confined to new electronic processes but also affects organizational changes in the structure of corporations, has fundamentally altered the forms of work, skill, and occupation. The whole notion of tradition and identity of persons with their work has been radically changed. (15)

They've also got a vision of what the future could look like: satisfying lives with a decent

standard of living, based on a combination of paid work and guaranteed social income.

The aim of this work is to suggest political and social solutions that take us in a direction in which it is clear that jobs are no longer the solution, that we must find another way to ensure a just standard of living for all. (xii)

Accordingly, if unwork is fated to be no longer the exception to the rule of nearly full employment, we need an entirely new approach to the social wage and, more generally, "welfare" policy. If there is work to be done, everyone should do some of it; additional remuneration would depend on the kind of work an individual performs. (353)
They are as interested in the "satisfying" part of the question as the "standard of living" part. They want to know what sources of meaning, worth, and value are possible for a whole civilization in which work and career are no longer the primary focus? It is an existential question as much as it is an economic one -- which takes us back to an earlier post on income and wellbeing.

But here is someone else who has a vision of a jobless future: William Gibson. His pictures of the Sprawl (an urban agglomeration extending from Atlanta to Boston) and the Bridge (the improvised "off the grid" community living on the earthquake-damaged Oakland Bridge) offer a grim picture of life for people scraping by in a cyberpunk world. There is talent, technology innovation, wealth, economic competition in Gibson's world -- but there's nothing that looks like a middle class life for ordinary people. (Here are a couple of the novels: Neuromancer, All Tomorrow's Parties.)

It seems inescapable that the rising inequalities of income and wealth we have experienced for thirty years are strongly linked to the jobless state of 15% to 20% of us (counting discouraged workers and underemployed workers) and the fairly stagnant living standards of another 50%. By tolerating this acceleration of inequality, our society is also silently sanctioning the end of social solidarity and the compact that we've had according to which everyone benefits from economic activity. Our graph seems to be pointing more in the direction of Gibson than Aronowitz. But maybe this is the fundamental goal of right wing rhetoric after all: to decisively break the bonds of social solidarity and mutual obligation altogether and to allow privilege to have its way unconstrained by social obligations. Surely we owe each other more than this.

So far the strategies on the table about employment are either about job creation (Democrats) or providing even more tax relief for business and the wealthy (Republican). None of these voices consider the more radical implication: we may need to consider a dramatically new way of thinking about income, work, social distribution, and lifestyle in the future. And that's what Aronowitz and DiFazio proposed almost 20 years ago.

(Philippe Van Parijs' recent contribution to *Boston Review* on a universal basic income is a really interesting start on some serious alternative thinking (link).)

Social things, kinds and meso causes

Thursday, September 15, 2011

Consider a social entity -- say the IBM corporation -- and consider the group of individuals who currently make up the entity. What is the relation between the social entity and the individuals? There are several things that are plainly true: the entity is composed of the individuals. The behavior of the entity supervenes upon the individuals.

But other issues are less clear. Does the corporation have causal properties of its own? Is this corporation an instance of a broader class of social entities with similar properties? Do we need to explain the corporation by deriving its properties from the properties of its constituents?

There are analogous issues in other areas of the "special" sciences. Take weather, for example. We have a fairly complex vocabulary of weather ontology and causation: El Nino, warm front, high pressure cell, hurricane, windshear, etc. Two things seem evident. First, weather phenomena are composed of lower-level physical components: bodies of water at a range of temperatures, non-homogeneous gases (atmosphere), inputs of energy (sunlight), and the like. Weather phenomena are "nothing but" ensembles of micro-cells of gases, water, land masses, and energy. Weather states might be exhaustively described as a set of micro-states with no reference to weather vocabulary; we could, if we wanted, reduce weather statements to micro physical statements. At the same time, we can legitimately describe weather phenomena at the meso or macro levels -- storms, etc. There is no compelling scientific reason to insist on reduction or elimination. And we can explain weather outcomes in terms of causal statements that invoke other meso factors. The fact that there are no autonomous weather phenomena does not mean there are no autonomous weather explanations.

There isn't much of a problem in defining or identifying **entities** at the level of social aggregates. The IBM corporation is no more ontologically suspect than Hurricane Irene. Both are high-level entities composed of lower level things and processes. What is more problematic is when we consider whether there are "kinds" of social entities; whether there are law-like generalizations that are true of those kinds of things; and whether kinds of social things have distinctive causal properties and processes.

Candidate social kinds might include armies, bureaucracies, and religions. I take the view, however, that none of these concepts identifies a set of social entities that have enough in common to call them a kind. They are heterogeneous in all the ways that have made them intriguing to historical sociologists. Caesar's army, Rommel's army, and Ho Chi Minh's army had some things in common; but they also had enormously important differences at the level of organization, technology, and leadership structure. So it isn't plausible to look at them as constituting a kind of social entity.

This high degree of heterogeneity among the items classified under social concepts also provides the basis for a negative answer to the question about laws as well. Armies are not like metals; they don't have a common set of generating processes, and they don't give rise to significant regularities. We can't say things like "all armies fight to exhaustion within 12 months."

We can, however, identify common processes and challenges that confront all armies, and we can consequently tease out some causal mechanisms and processes that recur across armies in a wide range of contexts. This is the thrust of McAdam, Tarrow and Tilly's analysis of mechanisms underlying contention.

This discussion illustrates three rather different points. First, there is the level of descriptive concepts we choose to use. Second is the issue of whether explanations need to proceed from more fundamental to more complex. And third is the issue of the ontological status of composite entities.

These topics have been addressed under the rubric of inter-theoretic reduction for almost

forty years. Jerry Fodor's "Special Sciences (Or: The Disunity of Science as a Working Hypothesis" (1974) (link) and "Special Sciences: Still Autonomous After all These Years" (1997) (link) present core arguments for the autonomy of the special sciences. He distinguishes between token-token identity and type-type identity, pointing out that it might be the case that the first kind of identity obtains while the second does not. His central argument is that the possibility of multiple functional realizability demonstrates that it will not be possible to reduce higher-level laws to lower-level laws.

Jaegwon Kim has addressed the issue of physicalism throughout his career, most recently in Physicalism, or Something Near Enough. He holds that the concept of supervenience provides a basis for finessing the demand for reduction from higher kevel to lower level. Julie Zahle raises some of these problems in her contribution to Philosophy of Anthropology and Sociology: A Volume in the Handbook of the Philosophy of Science Series, "Holism and Supervenience."

My general intuition is that the issue of inter-theoretic reduction and an insistence on a strong version of methodological individualism are much less important to the philosophy of social science than they have appeared to be. Once we have sufficiently understood the ways that individuals, institutions, networks, and values work at the local level, we are in a good position to characterize meso-level social entities like organizations and value systems. And we are intellectually empowered to try to discover the dynamic properties of these systems of actors and social arrangements. So meso level causal properties seem entirely legitimate in the social sciences.

Advertising and making consumers

Friday, September 23, 2011

There is a pervasive feature of modern economic life that never entered into the theories of the economists in the first century of the discipline: marketing, advertising, and the shaping of consumer desires. And yet this activity is itself a trillion-dollar industry, and arguably has greater effect on social values and consciousness than religion, politics, or the workplace. Our culture is flooded by marketing messages that surely have a vast cumulative effect on the ways we think about life and the things we value. And this feature of modern social life is radically different from pre-20th century -- village life in France in the 1880s, city life in 17th-century London, or even life in Chicago in 1920. So it's worth thinking about.

The images above come from of a google image search for "advertising 1900". They are all print ads for products around the turn of the twentieth century. There are several brands represented here that are still with us. Plainly advertising in newspapers and magazines was well entrenched by then.

So what factors made advertising a feature of mass society but not the medieval market town? Capitalism is about selling things. Companies need to generate demand for their products. So capitalism needs effective ways of stimulating new desires for products in consumers.

And this suggests one social factor that led to a dramatic increase in advertising and marketing in the late nineteenth century, the sharp increase in urbanization and modern transportation. These factors implied a strong increase in the density of demand and the circulation of consumers using modern transportation. When you have trolleys and railroads you have large numbers of people moving around, and they can be turned into consumers. This made it worthwhile to invest in marketing and advertising.

These observations take me in two directions. One is historical. I'm pretty sure that cities were much less visibly marketed and advertised in 1861 or 1911 than they are today. There must be some interesting work on the history of advertising, but the bottom line is this -- advertising was a product of an intensive consumer product society, and consumerism didn't really become dominant until the twentieth century. So living in Ghent, San Francisco, Grand Rapids, Stockholm, or New Orleans in 1880 would have involved a dramatically quieter environment when it came to product advertising and posters in public spaces. Here are a few street scenes to give an idea of the limited scope of street advertising at roughly the turn of the 20th century from Brussels, New York, and Manchester.

The other line of thought is more systemic. Why did we invent advertising at all in some fairly recent point in our past? Here a number of points seem salient.

Begin by considering the overall purpose of advertising. One aspect is informational. A goal of advertising is to bring information about products to the purchasing public. If everyone knows about your product, then there isn't a need to advertise it. Second, it is to bring about a positive attitude towards this product in that set of consumers. And third, it is to make the sale -- to give the consumer the emotional push needed to go ahead with the purchase.

Being systematic about advertising means being very specific about the targets of the campaign. What segments of the public does the business want to reach?

First, there are already people who would like to purchase something like product X but are not currently doing so. Here the challenge for the company is to get information about

the product in front of these would-be buyers and induce them to make a purchase.

A second group of potential buyers are people who already consume a related product Y but might be persuaded to switch to X. Here the challenge is to create dissatisfaction with Y, or a new conviction that X is better. Cigarette marketing fell partially in this category when it was legal. The goal was to persuade smokers to switch from one brand to another, by implying the experience was better or the smoker would have greater social status. One brand sells "cool," another sells "masculine," another sells "sexy."

There is a third group that sellers would like to reach: people who currently don't want X at all, but might be induced to do so through appropriate messaging. This means changing preferences and creating new desires in the potential consumer. Tobacco advertising and children's cereals seem to fall in this category. Both have aimed to create new consumers -- children who "want" Captain Crunch and adolescents who want cigarettes.

And how about the golden grail -- whole societies that haven't yet acquired the desire for a category of product? Maybe it's luxury skin products in Nigeria, baby nursing formula in Kenya, Weber barbecue grills in Argentina, or Volkswagens in Indonesia. Here the goal is to quickly grow the consumer public interested in acquiring this product -- and positioning the brand so future competitors will have a hard time breaking into the market.

So advertising is about shaping the information people have, the desires and preferences they experience, and the attitudes and emotions they have towards products and the act of consumption. And it is fundamentally aimed at changing both consciousness and behavior. Seen from this point of view, advertising is deliberately a fundamental cause of the shaping of modern social consciousness.

There is a body of thought which focused on this aspect of capitalism and mass society, and that is the critical philosophy of the Frankfurt School. In Dialectic of Enlightenment (1944) Adorno and Horkheimer laid out an extensive critique of the culture industry and the role it played in modern capitalist society. Here are a few lines particularly relevant to advertising (link). Their interest here is the culture industry more generally, but much of their thinking sheds bright light on the role of advertising in mass consumer society.

Interested parties explain the culture industry in technological terms. It is alleged that because millions participate in it, certain reproduction processes are necessary that inevitably require identical needs in innumerable places to be satisfied with identical goods. The technical contrast between the few production centers and the large number of widely dispersed consumption points is said to demand organisation and planning by management. Furthermore, it is claimed that standards were based in the first place on consumers' needs, and for that reason were accepted with so little resistance. The result is the circle of manipulation and retroactive need in which the unity of the system grows ever stronger. No mention is made of the fact that the basis on which technology acquires power over society is the power of those whose economic hold over society is greatest. A technological rationale is the rationale of domination itself. It is the coercive nature of society alienated from itself. Automobiles, bombs, and movies keep the whole thing together until their leveling element shows its strength in the very wrong which it furthered. It has made the technology of the culture industry no more than the achievement of standardisation and mass production, sacrificing whatever involved a distinction between the logic of the work and that of the social system.

...

The whole world is made to pass through the filter of the culture industry. The old experience of the movie-goer, who sees the world outside as an extension of the film he has just left (because the latter is intent upon reproducing the world of everyday perceptions), is now the producer's guideline. The more intensely and flawlessly his techniques duplicate empirical objects, the easier it is today for the illusion to prevail that the outside world is the straightforward continuation of that presented on the screen. This purpose has been furthered by mechanical reproduction since the lightning takeover by the sound film.

...

The might of industrial society is lodged in men's minds. The entertainments

manufacturers know that their products will be consumed with alertness even when the customer is distraught, for each of them is a model of the huge economic machinery which has always sustained the masses, whether at work or at leisure – which is akin to work. From every sound film and every broadcast program the social effect can be inferred which is exclusive to none but is shared by all alike. The culture industry as a whole has moulded men as a type unfailingly reproduced in every product. All the agents of this process, from the producer to the women's clubs, take good care that the simple reproduction of this mental state is not nuanced or extended in any way.

...

The most intimate reactions of human beings have been so thoroughly reified that the idea of anything specific to themselves now persists only as an utterly abstract notion: personality scarcely signifies anything more than shining white teeth and freedom from body odour and emotions. The triumph of advertising in the culture industry is that consumers feel compelled to buy and use its products even though they see through them.

Here is the first chapter of James Gordon Finlayson's Habermas: A Very Short Introduction, which offers some very helpful explication of the perspectives of the Frankfurt School on this set of issues.

Woodward on mechanisms

Friday, September 23, 2011

Jim Woodward has extended a lot of his philosophical effort towards the task of understanding causation in the sciences (Making Things Happen: A Theory of Causal Explanation). Woodward is a primary exponent of the "manipulationist" theory of causation. He brings a counterfactual orientation to the problem of defining causal relations. If we assert that X caused Y, there is an implication that, if X had not occurred, Y would not have occurred. This implication isn't universally valid, since some events or outcomes are causally overdetermined. (Both X and X' may be a sufficient cause for Y -- in which case removing X still allows for Y through the X' pathway.) Notwithstanding this problem, the counterfactual nature of causal assertions is widely recognized. And this implies the association between causation and intervention or manipulation: if X causes Y, then we should be able to influence the occurrence of Y by manipulating X. This fact in turn underlies the logic of experimental design.

Woodward's treatment of causation deserves fuller treatment than I'll give it here. In this post I will focus on his application of these ideas to the notion of a causal mechanism. He lays this treatment out in a short but influential article, "What is a Mechanism? A Counterfactual Account" (link).

Here is the core idea. He focuses on the Machamer-Darden-Craver (MDC) definition of a causal mechanism (link):

Mechanisms are entities and activities organized such that they are productive of regular changes from start or set-up to finish or termination conditions. (3)

Woodward's contribution is to give greater clarity to the idea of regularity or law by adding the idea of a relationship that is "invariant under intervention". This idea models the notion of experimental testing of a causal hypothesis. We are interested in "X causes Y". We look for interventions that change the state of Y. If we find that the only interventions that change Y, do so through their ability to change X, then the X-Y relation is said to be invariant under intervention, and X is said to cause Y. Here is how he expresses the idea in the article:

I understand this in terms of the notion of invariance under interventions. Suppose that X and Y are variables that can take at least two values. The notion of an intervention attempts to capture, in non-anthropomorphic language that makes no reference to notions like human agency, the conditions that would need to be met in an ideal experimental manipulation of X performed for the purpose of determining whether X causes Y. The intuitive idea is that an intervention on X with respect to Y is a change in the value of X that changes Y, if at all, only via a route that goes through X and not in some other way. This requires, among other things, that the intervention not be correlated with other causes of Y except for those causes of Y (if any) that are causally between X and Y and that the intervention not affect Y independently of X. Thus if A is a common cause of B and S as in the example above, manipulating B by manipulating A will not count as an intervention on B with respect to S since in this case the manipulation affects S via a route (the route that connects A to S) that does not go through B. (369-70)
Here is how he applies this idea to causal mechanisms. A mechanism consists of separate components that have intervention-invariant relations to separate sets of outcomes. These components are modular: they exercise their influence independently. And, like keys on an accordion, they can be separately activated with discrete results.

So far I have been arguing that components of mechanisms should behave in accord with regularities that are invariant under interventions and support counterfactuals about what would happen in hypothetical experiments. (374)
Here is the proposal all of this leads up to:

(MECH) a necessary condition for a representation to be an acceptable model of a mechanism is that the representation (i) describe an organized or structured set of parts or components, where (ii) the behavior of each component is described by a generalization that is invariant under interventions, and where (iii) the generalizations governing each component are also independently changeable, and where (iv) the representation allows us to see how, in virtue of (i), (ii) and (iii), the overall output of the mechanism will vary under manipulation of the input to each compo- nent and changes in the components themselves. (375)
Woodward illustrates his theory of mechanisms with simple physical and biological examples. How does this theory work when we consider social mechanisms?

What seems most evident is that social mechanisms are not commonly as complex as Woodward's examples would suggest. The sorts of mechanisms that crop up in sociology seem largely to be "simple" mechanisms: they don't consist of multiple independent components leading to an outcome.

Here is the way that McAdam, Tarrow and Tilly (MTT) characterize mechanisms and processes in Dynamics of Contention:

- *Mechanisms are a delimited class of events that alter relations among specified sets of elements in identical or closely similar ways over a variety of situations.*
- *Processes are regular sequences of such mechanisms that produce similar*

(generally more complex and contingent) transformations of those elements. (24)

These definitions imply that *processes* are compound, whereas typical mechanisms are simple.

Here are examples that MTT offer of mechanisms:

- *resource depletion or enhancement affects people's capacity to engage in contentious politics (25)*
- *commitment is a widely recurrent individual mechanism in which persons who individually would prefer not to take the risks of collective action find themselves unable to withdraw without hurting others whose solidarity they value (26)*
- *Brokerage ... as the linking of two or more previously unconnected social sites by a unit that mediates their relations with one another and/or with yet other sites (26)*
- *Identity shift ... alteration during contentious claim making of public answers to the question: "Who are you?" (27)*

In each case we seem to have a simple relationship between one social or environmental fact and a typical outcome -- not a complex concatenation of "cogs and wheels" of social interaction.

So when we consider typical examples of social mechanisms -- free-riding (Olson), escalation (McAdam-Tarrow-Tilly), identity competition (Horowitz) -- we commonly find that they are all basically one-step mechanisms. So the assumption that a mechanism consists of modular components doesn't fit the social sciences well. There are complex social processes, to be sure, but it seems best to understand these as concatenations of distinct mechanisms rather than as a single complex mechanism. (Why? Because they are all too often unrepeatable.)

This doesn't mean that we can't understand social mechanisms along the lines Woodward suggests, if we are content to acknowledge that it is hard to find *complex* social mechanisms. But in order for even this to be the case, we would have to confirm that these simple mechanisms produce intervention-invariant regularities.

This requirement runs up against a different problem, however. The regularities that correspond to typical social mechanisms are soft regularities, not hard-and-fast laws. Social causation is probabilistic, not deterministic. The regularities corresponding to social causes derive from features of human agency and behavior, and they are deeply exception-laden. The free-rider mechanism tends to give rise to under-investment in the public good -- except when people self-organize, semi-coercive organizations appear, or altruistic religious attitudes take hold. Social mechanisms are productive, in the sense that they "bring about" the associated outcomes. But they are not invariant across all or most cases.

This implies that there are no intervention-invariant relations to be had in the social world. And therefore we need some other analytical foundation if we are to persist in thinking there are social causal mechanisms.

Woodward addresses something very much like this possibility in conjunction with psychological mechanisms. And he draws a prescriptive conclusion: if the "mechanisms" cited in psychology do not have these characteristics of modularity and invariance, then they aren't really mechanisms:

the standard boxological diagrams allegedly describing the operation of psychological mechanisms drawn by psychologists are rarely accompanied by convincing evidence that

the parts corresponding to the boxes satisfy the modularity condition described above. If the argument of this paper is correct, this is a reason for being skeptical that these diagrams describe genuine mechanisms. (377)
It seems likely enough that he would reach a similar conclusion about the kinds of mechanisms offered by MTT.

(Here is an excellent review by Michael Strevens of Woodward, *Making Things Happen*.)

Current issues in causation research

Friday, September 23, 2011

This week's conference on Causality and Explanation in the Sciences in Ghent was an unusually good academic meeting (link). Participants gathered from all over Europe, as well as a few from North America, Australia, and South Africa, to debate the logic and substance of causal interpretations of the world. Among other things, it provided all participants with a very good sense of the ideas about causation that are generating the most discussion today.

A general perception that emerges from the gestalt of papers at the conference is that there are three large focus areas in current research on scientific causation. First, there is interest in specifying what causal assertions and concepts **mean** in scientific explanations. What are the logical, conceptual, and pragmatic issues associated with causal assertions and explanations?

Second, there is a large body of work focusing on the methods we can use to support causal inference in the sciences. Every field of science produces volumes of data about variables and events over time. What methods exist to permit inferences about causal relationships among the observed variables and entities? This includes causal modeling statistical methods, but also comparative methods deriving from Mill's methods of difference and similarity.

Third, there is a group of philosophers and scientists who are primarily interested in the ontology of causation in various parts of the sciences. How do various factors exercise causal powers in ecology, the social sciences, or complex systems? Researchers in these areas need provisional answers to questions raised by the first two groups, but their focus is on substantive causal processes rather than the logic of causal statements.

It is useful to inventory half a dozen approaches that were repeatedly cited. This survey is impressionistic but gives an idea of the current landscape.

The mechanisms approach. The idea that we can explicate causation through the idea of a mechanism has been rising in importance over the past twenty years. The idea here is that the fundamental causal concept is that of a mechanism through which X brings about or produces Y. This is argued to be key to causation from single-case studies to large statistical studies suggesting a causal relationship between two or more variables. Peter Hedstrom and other exponents of analytical sociology are recent voices for this approach for the social sciences, though expositions of this approach don't usually go into the level of detail expected by philosophers like Woodward and Cartwright. An important paper by Peter Machamer, Lindley Darden and Carl Craver, "Thinking about Mechanisms", sets the terms of current technical discussions; their view is referred to as the MDC theory. A common concern is that the approach hasn't been as clear as it should be about what

precisely a mechanism is. James Mahoney made this criticism in 2001 in "Beyond Correlational Analysis" reviewing Charles Ragin, Fuzzy-Set Social Science and Peter Hedstrom and Richard Swedberg, Social Mechanisms: An Analytical Approach to Social Theory (link), and we still need a more generally recognized specification of the idea. (See an earlier post on this approach; link.)

The manipulability account. Jim Woodward is perhaps the leading exponent of the manipulability (or interventionist) account. He develops his views in detail in his recent book, Making Things Happen: A Theory of Causal Explanation. The view is an intuitively plausible one: causal claims have to do with judgments about how the world would be if we altered certain circumstances. If we observe that the concentration of sulphuric acid is increasing in the atmosphere, we might consider the increasing volume of H2SO4 released by coal power plants from 1960 to 1990. And we might speculate that there is a causal connection between these facts. A counterfactual causal statement holds that: If X (increasing emissions) had not occurred, then Y (increasing acid rain) would not have occurred. The manipulability theory adds this point: if we could remove X from the sequence, then we would alter the value of Y. And this in turn makes good sense of the ways in which we design controlled experiments.

Difference-making. Another strand of thinking about causation focuses on the explanations we are looking for when we ask about the cause of some outcome. Here philosophers note that there are vastly many conditions that are causally necessary for an event but do not count as being explanatory. Lee Harvey Oswald was alive when he fired his rifle in Dallas; but this doesn't play an explanatory role in the assassination of Kennedy. Crudely speaking, we want to know which causal factors were **salient**; which factors made a difference in the outcome. Michael Strevens provides a detailed and innovative explication of this set of intuitions in his recent book Depth: An Account of Scientific Explanation, where he introduces his theory of "Kairetic" explanation.

Contrastive analysis as a theory of explanation. When we seek an explanation of something, we generally have something specific in mind: why X rather than X'? And an explanation that keys off the wrong contrast will fail, even though its premises are correct. Bas van Fraassen (1980), The Scientific Image, is often cited in this context. A conference participant, Petri Ylikoski, develops a contrastive counterfactual theory in his dissertation (link). This body of work seeks to clarify pragmatic issues concerning explanation, including understanding and explanatory relevance. If we ask for an explanation for why X occurred, we are usually presupposing a question like this:

Why did X occur [rather than Y]?

- Why is John carrying his umbrella [rather than not]?
- Why is John carrying his umbrella [rather than his raincoat]?
- Why is John carrying his umbrella [rather than his assistant Harry]?

These all demand different answers:

- Because he expects rain;
- Because it is too warm for a raincoat;
- Because Harry is carrying three heavy suitcases.

Here is a much-cited review article by Nancy Cartwright on van Fraasen's work (link), and here is a discussion of contrastive explanation by Jonathan Schaffer (link).

Causal modeling theory. This topic refers to the large body of statistical theory devoted to identifying potential causal relationships among observable variables in a large data set. Hubert Blalock is a founder of this approach (Causal Inferences in Nonexperimental Research; 1964) with his statistical models for causal path analysis. (Here is a short account of the history of path analysis in genetics.) Judea Pearl has contributed a great deal to the method of structural equation modeling (SEM) in Causality: Models,

Reasoning and Inference and elsewhere. Here is a handbook article in which he explains the method and its causal relevance (link). Pearl maintains a research blog on causality here. **Granger causality** is a specific technique for assessing causal relationships within time series data: X Granger-causes Y if variations in X and Y together do a better job of predicting Y than variations in Y by itself.

Prior foundations of philosophical theories of causation. Two older discussions of causality also received some notice in these papers: J. L. Mackie on INUS conditions and causal fields (The Cement of the Universe: A Study of Causation) and Wesley Salmon on the causal structure of the world (Scientific Explanation and the Causal Structure of the World).

Nancy Cartwright's "Causation: One Word, Many Things" provides a very good contemporary review of the varieties of approaches that are currently being taken to the idea of causation (link).

Much of the intellectual vitality of this group of philosophers is captured in the major work recently edited by Phyllis McKay Illari, Federica Russo, and John Williamson, Causality in the Sciences. The book contains a very wide range of disciplines and approaches in its treatment of the topic.

Is justice a security issue?

Monday, September 26, 2011

Most people would probably say they would prefer to live in a more just world to a less just one. There is a strong **moral** basis for preferring justice. But is this a consideration that states and large international organizations need to take into account as they design their strategies and plans for serving their present and future interests? Do national governments have good practical reasons to think about the consequences their policies and actions may have on the circumstances of justice in the world? What about policies and actions through which states attempt to secure their future economic wellbeing -- do policy makers need to pay attention to the social justice consequences of these actions?

There is a strong empirical and historical case for thinking that the answer to this question is "yes." Injustice is a source of resentment, indignation, and conflict. In the long run, the victims of injustice will not be ignored. Justice is a security issue for states and supra-national organizations, and simple prudence demands that policy makers take it into account. To put a simple label on this idea, justice is a security issue.

Here is a European Union statement about its longterm interests that makes this point fairly explicitly (link):

In the context of ever-increasing globalisation, the internal and external aspects of security are inextricably linked. Flows of trade and investment, the development of technology and the spread of democracy have brought prosperity and freedom to many people, while others have perceived globalisation as a cause of frustration and injustice. In much of the developing world, poverty and diseases such as AIDS give rise to security concerns, and in many cases economic failure is linked to political problems and violent conflict. Security is a precondition for development. Competition for natural resources is likely to create further turbulence. Energy dependence is a special concern for Europe.

What are the theoretical and historical arguments for this conclusion? Here are several.

On the side of theory, several points are well established. Chronic and unrelieved poverty

leaves people with low attachment to their own societies and less for the global community. The frustration of very basic human needs is bound to fuel indignation and resistance. So poverty and deprivation are causes of resistance. But there is also evidence that inequality itself has negative consequences for a society's health; this is the central finding of The Spirit Level: Why Greater Equality Makes Societies Stronger (link). Finally, the social psychology created by a system that is perceived to be unfair and exploitative is likely to breed resistance and lawless action. Barrington Moore, Jr. was right when in Injustice he wrote:
Without strong moral feelings and indignation human beings will not act against the social order. In this sense moral convictions become an equally necessary element for changing the social order, along with alterations in the economic structure. 469
Gareth Stedman-Jones summarizes Barrington Moore's conclusion in these terms: "His argument is that human beings in stratified societies accept hierarchies of authority, so long as these hierarchies are not merely imposed by force, but based upon an 'unwritten' social contract, which binds together dominant and subordinate groups in a set of mutual obligations" (link).

So there are good empirical reasons, based in social psychology and the study of contentious politics, for expecting that injustice breeds conflict.

Are there historical demonstrations of the consequences of injustice for disorder? There are. We have the examples of slave revolts throughout the Americas in the 18th and 19th centuries; anti-colonial movements in Africa and Asia following World War II; the sustained resistance of the Burmese and East Timor peoples to dictatorship; and the sustained struggle for equal rights in the United States by African Americans, sometimes punctuated by major urban riots. In each case a set of social institutions had been created that were profoundly unjust for a sizable population, and this population gathered resolve and courage in opposing those arrangements.

So the conclusion seems clear. If we want to have a world in which there is a sustainable level of the rule of law and a low level of social conflict, we need to invest in justice. We need to work to create a system in which all peoples can satisfy their most basic human needs; where everyone can feel that he/she is respected in her humanity; and where no one judges that the basic structure of social life is exploitative.

In other words, states are well advised to actively include the basic requirements of justice in their plans for the future. Otherwise they are simply creating the tinder for future conflict.

Causal-mechanisms theory in Europe

Wednesday, September 28, 2011

The causal-mechanisms theory of social explanation has been influential throughout an extensive network of European philosophers and social scientists, often with a pretty direct connection to the analytical sociology research programme. Peter Hedstrom and his research network are particularly influential in this spread of ideas. It is worth mentioning a couple of books in the past ten years that have brought this approach to non-English speakers.

Philosopher Michael Schmid published Die Logik mechanismischer Erklärungen (*The Logic of Mechanistic Explanation*) in 2006. This appears to be the first full-length

consideration of the "social mechanisms" theory of social explanation in German, and it is an impressive volume. Schmid also has an extensive chapter in English in Peter Demeulenaere's fine collection, Analytical Sociology and Social Mechanisms.

Schmid's book consists of careful analytical expositions of the theories of a dozen social scientists and philosophers who have advocated for this approach to social explanation, including both current and past proponents. Here is the table of contents, in my own non-expert translation, which gives an idea of the topics and authors Schmid concentrates on.

Michael Schmid, *Die Logik Mechanismischer Erklärungen*

1. The logic of sociological explanation

2. Philosophical foundations for an explanatory sociology

2.1 Mechanisms and the "Theory of complex phenomena" (Friedrich A. von Hayek)
2.2 Causality, social system, and mechanistic explanation (Mario Bunge)
2.3 Microfoundations and causal mechanisms (Daniel Little)

3. Mechanisms in sociological theory

3.1 Individual decisions and structural selection (Robert Merton)
3.2 Individual rationality and the interdependence of action (James S. Coleman)
3.3 Bridge principles and the transformation problem (Siegwart Lindenberg and Reinhard Wippler)
3.4 Macro-social phenomena and "rationality située" (Raymond Boudon)
3.5 Generative structuralism and generative mechanisms (Thomas J.Fararo)
3.6 Social mechanisms and the theory of rational decision-making (Peter Hedstrom and Richard Swedberg)
3.7 Process mechanisms and causal reconstruction (Renate Mayntz)
3.8 "Generative mechanisms" and "structural models" (Hartmut Esser)

4.0 The research heuristic of mechanismic explanation

Many of these authors considered here are core to the analytical sociology framework, including especially Merton, Coleman, Boudon, Hedstrom, Swedberg, Mayntz, and Esser.

A second relevant book appeared in 2004 in Italian. This is Filippo Barbera's Meccanismi sociali: Elementi di sociologia analitica. As the title indicates, the book provides a programatic introduction to the social mechanisms approach as expressed within the analytical sociology framework. The contents are descriptive of the focus of the book (again, in my non-expert translation).

Filippo Barbera, *Meccanismi sociali*

Introduction

I. Social mechanisms: history, authors, and objectives

I.1 Introduction
I.2 The Columbia School
I.3 Social mechanisms, theory of action and the crisis of the deterministic paradigm
Summary

II. Analytical sociology in the contemporary scene

II.1 Introduction
II.2 The relation between social theory and empirical research
II.3 Three principles for analytical sociology: causal processes, multi-level schemata, and formal theory
Summary

III. From macro to micro: the logic of the situation

III.1 Introduction
III.2 Interdependence between states: Sour Grapes and Ulysses and the Sirens
III.4 Institutional environments, exchange, and preferences
III.5 Training opportunities
III.6 Effect of social interaction
III.7 Structural effect
Summary

IV. The micro-micro axis: the principle of social action and rationality

IV.1 Introduction
IV.2 The forward-looking model
IV.3 The backward-looking model
IV.4 The cognitive model and framing
Summary

V. From micro to macro: aggregation and emergent effects

V.1 Introduction
V.2 Microfoundations of emergent effects
V.3 Strategic interdependency
V.4 Processual interdependence
V.5 Relational and spatial interdependence
V.6 Dynamic analysis of micro and macro
Summary

VI. Mechanisms in empirical research
VI.1 Introduction
VI.2 The diffusion of pharmacological innovation
VI.3 Individual educational choices
VI.4 Collective violence
Summary

VII. The integration of theory and social research

VII.1 Introduction
VII.2 Building the phenomena to be explained
VII.3 Postulating the generative mechanism
VII.4 Testing the mechanism
Summary

Here is a translation of a few lines from the introduction:

This book presents a theoretical perspective and empirical research that have gained growing acceptance in contemporary sociology. Many terms have been used to identify this perspective: "explanation by social or generative mechanisms", "sociological analysis", "sociology of causal processes", and "analytical sociology". Here we will use each of these expressions interchangeably. The book aims to rebuild from within the core of analytical sociology by isolating the principles and objectives shared, without carrying out a systematic comparison with other trends in contemporary sociology. This systematization had to first try to reduce the heterogeneity that characterizes the internal perspective of the social mechanisms approach, but not completely undo the specificities of the individual authors and the different proposals they put forward. The priority attention given to the objectives of clarification and synthesis of a complex and heterogeneous field has had to overshadow the critical evaluation of analytical sociology. This critical evaluation, incidentally, is not entirely absent, and in any case is made more simple after we have specified the conditions and objectives of the approach. (7)
German philosopher Renate Mayntz also takes up issues on mechanistic explanation in the social sciences. Her 2009 book, Sozialwissenschaftliches Erklären, is a volume of essays on the philosophy of social science and social science methodology that address issues about mechanisms as well as the macro-micro link. Here is a rough translation of the table of contents:

Renate Mayntz, *Sozialwissenschaftliches Erklären*

1. Social science knowledge interests and cognitive capabilities: An Introduction
2. Research methods and cognitive potential: natural and social sciences in comparison
3. Invitation to shadow boxing: sociology and modern biology
4. Rationality in Social Science Perspective
5. Causal reconstruction: theoretical statements in actor-centered institutionalism
6. Social mechanisms in the analysis of social macro-phenomena
7. Individual action and social events: The micro-macro problem in social science
8. Emergence in Philosophy and Social Theory (in English)
9. Embedded Theorizing: Perspectives on Globalization and Global Governance (in English)

Mayntz's critical review article on the mechanisms literature appeared in 2004 in the *Philosophy of the Social Sciences*, and is available online here.

Also worth mentioning is recent work by Petri Ylikoski, including his excellent University of Helsinki 2001 dissertation, *Understanding Interests and Causal Explanation* (link). The dissertation is available online and provides an excellent basis for understanding many of the issues concerning causal explanation as they arise within the analytical sociology framework.

Each of these theorists relates directly or indirectly to the framework of analytical sociology and usually to Peter Hedstrom's group directly. Barbera was a visiting fellow at Nuffield College, Oxford, where he worked closely with Hedstrom. Schmid demonstrates a close knowledge of Hedstrom's work and of the analytical sociology perspective more generally, and Hedstrom is one of the philosophers he focuses on in his book (3.6). Schmid also has sections on Mayntz, Boudon, and Esser, key figures in the literature of analytical sociology. Ylikoski has published co-authored papers with Hedstrom following the completion of his dissertation.

Sen on well-being

Saturday, October 01, 2011

In 1985 Amartya Sen published a very short book entitled Commodities and Capabilities. The book was reissued by Oxford after Sen received his Nobel Prize in Economic Sciences.

The topic is at the core of Sen's economic and philosophical work. Most basically, he is asking Aristotle's question -- what is happiness? -- and is putting forward an answer that combines analysis of economic behavior with philosophical analysis of action and purpose in human life. Economists from Mill to Samuelson sought to understand economic choices in terms of subjective utilities and unanalyzed sets of preferences. A consistent theme was that economics can't be concerned with the content or validity of the individual's utility function or preference ordering. Rather, economics is about the rules by which rational agents design their actions to maximize utility or preference satisfaction. Economic rationality has to do with the choice of means, not ends.

This approach to action also unfolded into the formal theory of social choice. Given that citizens have a set of preferences about social outcomes, what rational procedures can be designed to aggregate these preferences into a single coherent social choice preference ordering. Essentially the underlying idea is that the social good is secured when we succeed in aggregating citizens' preferences onto a single social preference ranking. And this is where Kenneth Arrow's famous impossibility theorem comes in: given a small set of reasonable constraints on social choice, there is no social choice procedure that is both complete and transitive (Social Choice and Individual Values, Second edition). Sen's first major book (1970) gave a different formal exposition to this set of arguments (Collective choice and social welfare).

One of Sen's most fundamental contributions in economics is to question the theory of subjective utility and revealed preference. He thinks that we can give a substantive, not formal, account of wellbeing that permits us to analyze the individual's behavior and choices in a more meaningful way. He writes here:

It is fair to say that formal economics has not been very interested in the plurality of focus in judging a person's states and interests. In fact, often enough the very richness of the subject matter has been seen as an embarrassment. There is a powerful tradition in

economic analysis that tries to eschew the distinctions and make do with one simple measure of a person's interest and its fulfilment. That measure is often called 'utility'. (1)
He wants to complicate the issue by drawing distinctions -- that is, by breaking down the austere abstractions about choice that are most comfortable to the economists:

I would distinguish broadly between two ways of seeing a person's interests and their fulfilment, and I shall call them respectively 'well-being' and 'advantage'. 'Well-being' is concerned with a person's achievement: how 'well' is his or her 'being'? 'Advantage' refers to the real opportunities that the person has, especially compared with others. The opportunities are not judged only by the results achieved, and therefore not just by the level of well-being achieved. It is possible for a person to have genuine advantage and still to 'muff' them. Or to sacrifice one's own well-being for other goals, and not to make full use of one's freedom to achieve a high level of well-being. The notion of advantage deals with a person's real opportunities compared with others. The freedom to achieve well-being is closer to the notion of advantage than well-being itself. (3)
This discussion announces his important distinction between capabilities and functionings; functionings are the realized form that capabilities take when they are fully cultivated. "A functioning is an achievement of a person: what he or she manages to do or to be" (7). It is worth noticing that the idea of freedom comes into this formulation in a fundamental way -- fifteen years before freedom becomes central to his thinking about the good of economic development in Development as Freedom.

Sen's argument next moves into another topic that has been characteristic of his thinking throughout his career, the relationship between two or three central components of "satisfaction" or "well-being". There is subjective satisfaction -- the degree to which the individual has accomplished a large portion of his/her preferences. There is the role of commodities and material things in the composition of individual satisfaction -- the bundle of stuff that the individual can call upon in attempting to satisfy basic needs and desires, from grain and clean water to iPads and access to the Internet. And there is the "fit" between the individual's material circumstances and his/her ability to fulfill capabilities and complete an autonomous plan of life.

The key idea expressed in this monograph and subsequently in Sen's work is that well-being is the aggregation of the individual's collection of functionings. "It is possible to argue that the well-being of a person is best seen as an index of the person's functionings" (17).

On what does the claim of functionings to reflect well-being rest? Basically, the claim builds on the straightforward fact that how well a person is must be a matter of what kind of life he or she is living, and what the person is succeeding in 'doing' or 'being'. (19)
And Sen thinks about this formulation in formal terms: the person's functionings are represented as a vector of qualitatively distinct characteristics, and one of the central problems is to assign relative values to the components of the package.

The primary specification of a person's well-being is in terms of a functioning vector *bi*. It can be converted into a scalar measure of well-being only through a real-valued 'valuation function' *vi(.)*, mapping functioning vectors into numerical representations of well-being. (33)
Sen's approach is appealing largely because it replaces "utility" with a more granular conception of "functionings". This permits more concrete discussion of the individual's life activities and, as Sen argues here, a better way of assessing his/her overall well-being.

What has turned out to be enormously important in Sen's framework of capabilities and functionings is its relevance to the topic of economic development. We want economic development to lead to an overall improvement in human happiness. But how should such a goal be assessed and measured? By offering a concrete theory of functionings, Sen lays a basis for attempting to empirically measure changes in functionings over time. Literacy, for example, is an important functioning for the human being. Extremely poor societies invest very little in formal education, and literacy in the population is low. We can make a very concrete argument that a given strategy of development is improving human well-being if we can demonstrate that it is leading to a higher level of attainment of literacy. Health itself is a complex functioning for the human being; here too, it is possible to measure progress in health achievements in different societies. So the functionings approach provides a concrete way of trying to assess progress in economic development processes. The approach is a great improvement over the "average GDP" approach, since Sen demonstrates in numerous places that average income implies something about access to commodities, but it has only a weak connection to the functionings that the population is able to realize.

The Human Development Index championed by the United Nations Development Programme takes advantage of this insight. HDI includes three measures: life expectancy, literacy, and per capita GDP (link). And a very powerful argument can be made that societies that make the most progress in improving their HDI levels have made more progress in improving human well-being than those that increase GDP but fail to improve factors like literacy and health. It will not surprise the reader to learn that Sen's writings and advocacy played a crucial role in the design of the HDI.

What is "history"?

Monday, October 03, 2011

What is "history"? And what is involved in historical research and knowledge creation?

We might begin by attempting to specify the meaning of the word. Consider this: History is the sum total of human actions, thoughts, and institutions, arranged in temporal order. Call this "substantive history." History is social action in time, performed by a specific population at a time. Individuals act, contribute to social institutions, and contribute to change. People had beliefs and modes of behavior in the past. They did various things. Their activities were embedded within, and in turn constituted, social institutions at a variety of levels. Social institutions, structures, and ideologies supervene upon the historical individuals of a time. Institutions may have great depth, breadth, and complexity. Institutions, structures, and ideologies display dynamics of change that derive ultimately from the mentalities and actions of the individuals who inhabit them during a period of time. And both behavior and institutions change over time. "History" is the temporally ordered sum of all these facts.

We are interested in understanding history for a couple of reasons.

We are interested in knowing **how people lived and thought** in times and settings very

distant from our own. What was it like to be a medieval baker or beadle or wife?

We are interested in the concrete **social arrangements and institutions** that existed at various points in time. We would like to know how marriage or tax collecting worked in rural Ming China.

We are interested in the **dynamics of change** -- the reasons for the rise and fall of the Roman Empire, the reasons for a rash of peasant rebellions in 18th-century China, the reasons for the occurrence and characteristics of the Industrial Revolution.

We are interested in **quantitative assembly of historical data** -- population, economic activity, other kinds of social data.
Understanding the first kind of thing has a lot in common with ethnography or interpretive research; we uncover what we can of the circumstances, actions, and symbols of a group of people, and we try to reconstruct their mentality and their reasons for acting as they did.

Understanding the second kind of thing requires careful study of existing records that permit inferences about how basic institutions worked. Examples include bodies of law, charters, manorial records, and the like.

Understanding the third kind of thing has to do with identifying dynamic causal processes of the sort that the social sciences study -- why legislatures tend towards certain kinds of institutions and behaviors, why bureaucracies tend towards rigidity, why people are susceptible to extremism. This second kind of question pays attention to both internal reasons for change and external reasons -- an internal dynamic towards dynastic instability and an external shock imposed by sudden climate change, for example.

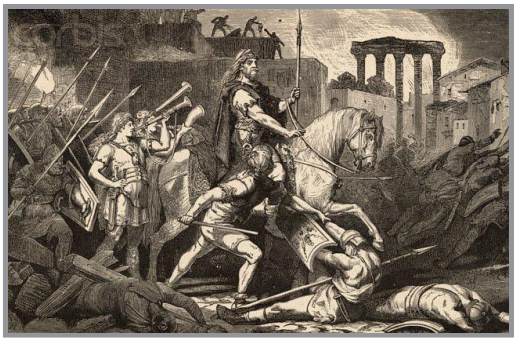
Understanding the fourth kind of thing requires discovering data sources in the historical records and archives that permit estimation of things like marriage rates, grain prices, or church membership totals, and then analyzing and presenting these data in convincing ways using established methods in social science quantitative methodologies.

So historians can ask a relatively limited series of questions about time and change:

- Why did actors choose to act as they did during period P?
- How were actors shaped in agency and identity during period P?
- What institutions, structures, and mentalities existed during period P?
- What dynamics of change were inherent in institutions, structures, and mentalities of these sorts during period P?
- What contingent events and actions took place in period P that influenced the mentality, actions, and structures of the successor period P'?

This suggests a fairly simple logic of historical representation:

- Historians discover factual circumstances about conditions of life, action, and thought (mentality) during specific periods.
- Historians identify changes in these conditions from one period to another.
- Historians identify the features of social relationships, institutions, structures, and ideologies during specific periods.
- Historians use a "path-tracing" methodology to discern how circumstances and actions in one period led to specific outcomes in a later period.
- Historians make use of the findings of the social sciences to identify social dynamics associated with specific kinds of social institutions, structures, and ways of thinking.



The historian who is primarily interested in the specifics of a particular time and place is

more distant from the social sciences. This work is more particularistic and "idiographic". The historian who is primarily interested in the dynamics of transition and transformation is more closely related to the social sciences, since he/she needs to borrow good theories about how institutions work. This work is more interested in causes and generalizations (usually at a meso level).

This description leaves out a great deal of what historians spend a lot of time on: formulating narratives that make sense, discovering unexpected causes or outcomes of historical circumstances, finding new perspectives on old historical questions, or just figuring out what is going on in an archival source (like the photo above), for example. I've tried to strip away those elements of the historian's work, in order to highlight the logic of the varieties of factual and explanatory claims that historians make. What I've described is abstract, of course, but it seems to capture the main elements of historical cognition. In an upcoming post I will ask how philosophy is relevant to this body of intellectual activity -- why, that is, we might want to have a philosophy of history.

Re-mapping the philosophy of history

Wednesday, October 05, 2011

The prior post offered a schematic description of the tasks involved in arriving at historical knowledge. Here I want to ask a related question: what is the work that we can hope to do with a **philosophy** of history? We don't have a philosophy of office furniture; we do have a philosophy of technology. So what is it about history that supports philosophical inquiry? Why is the enterprise of investigating, documenting, and explaining facts about the past amenable to philosophical study? What makes the effort to arrive at knowledge of facts about the past an area of philosophical concern?

There are a couple of matters that are relatively clear. First, the domain of historical knowledge is a familiar subject for philosophical inquiry. Epistemology is the philosophy of knowledge generally. Philosophy of science is the careful analysis of the methods and justification of scientific knowledge. And philosophy of historical knowledge is likewise an epistemic and methodological domain: How do we know about the past? Are there limits to our possible knowledge about the past? What is involved in explaining a historical fact? Answers to these questions and others in the same vein may be difficult and controversial; but it is clear how they fit into existing conceptions of philosophical inquiry.

If the philosophy of history were limited to these sorts of questions, then it would be a variant of epistemology or the philosophy of science. However, some philosophers have felt that substantive history itself raises questions that do not reduce to questions about knowledge of this domain.

Here is one possibility: perhaps we need a **metaphysics** of history -- an account of the kinds of things, forces, and structures that exist in the realm of history. Perhaps the metaphysics of history can shed light on what kinds of structures and entities travel through history, and what kinds of causal processes and dynamical systems propel change in the structures and entities.

For example: Marx wrote that "history is the history of class conflict." This implies that classes are historical objects -- they exist in the flow of historical events. Other historians have said things like this: classical slavery gave way to feudalism, which was followed by capitalism. This formulation presupposes that large social-economic systems -- for example, social property systems -- exist in history and conform to some set of dynamics. And yet others have tried to analyze world history into a set of more or less distinct civilizations -- bodies of values, ideas, identities, and institutions that differ significantly one from the other.

We might say, however, that none of these questions pertains to a metaphysics of **history**, but rather a metaphysics of the **social world**. History is about change and transformation; but the subject of change is social structures, cultures, and agents that exist within the social world at a period of time. So classes, social-property systems, ideologies, and religions are all **social** arrangements that change over time. If there is such a thing as a "civilization", this is a fact about society at a certain time, not a fact about the structure of history. History has to do with events and dynamic properties; the social world encompasses everything that is happening at a moment in time. We might consider an analogy with fluids -- "history" is the waves, society is the water.

We might be more inclined to recognize a metaphysics of history if we thought there were temporal structures that could be discovered in substantive history -- perhaps the business cycle, the Kondratiev long-wave economic cycle, or the rise and fall of civilizations. In other words, if we thought that events and changes conformed to a higher-level pattern of temporal change, we might want to say that the meta-temporal pattern is a metaphysical characteristic of history. But it would also be tempting to say: these patterns of change too represent nothing more than empirical characteristics of social phenomena over time. They need to be explained using the tools of the social sciences and are not properly the subject of *apriori* investigation.
This suggests two important conclusions: There is no such thing as an historical ontology as such but only a social ontology; and there is no such thing as an historical theory of change as such but only social theories of change. The ontologies and theories that historians employ are strictly speaking features of social science knowledge rather than historical knowledge. So, properly understood, there is no legitimate place for an investigation of the "metaphysics" of history; that space is filled entirely by an understanding of the metaphysics of the social world. tIn this case, the philosophy of history is no more than a component of the philosophy of social science, with no distinctive questions or answers of its own other than the epistemological issues mentioned above.

This discussion suggests a few rather deflationary conclusions about the possible scope of research in the philosophy of history:

- Philosophical work directed towards elucidating the epistemology and methodology of historical knowledge is straightforward but limited.
- Philosophical work directed towards elucidating the metaphysical underpinnings of "history" will be disappointing; those foundations exist within the domain of the philosophy of the social sciences rather than the philosophy of history.
- The dynamics of historical change are properly the subject matter of the social sciences rather than the philosopher of history.
- It is true that some historical investigation requires "hermeneutic" interpretation of meanings; but these efforts always fall at the level of interpreting the meaning of historical actions and cultural settings.

This analysis suggests there isn't a lot of scope for the philosophy of history beyond the function of serving as a counterpart to the philosophy of science. We might say that there are basically three relevant activities in the realm of historical thinking. There is first-order research into facts about the past based on currently available evidence. There is analysis and explanation of those facts, including methods ranging from ethnography to process-tracing to application of findings from the social sciences. These two parts of historical research are guided by ensembles of historical methods and practices (historiography). And there is philosophical reflection on the logic and limitations of these processes of inquiry and inference, the narrowly epistemic version of the philosophy of history. This aspect of the discussion includes as well the conceptual work that philosophers are well qualified for -- posing and answering questions like "What is history?", "What is a cause?", or "What is involved in expressing a meaningful action?". On this scenario there is no room at all for substantive or metaphysical philosophy of history.

The title of Ian Hacking's book, Historical Ontology, suggests that he thinks otherwise, and that there is such a thing as an ontology of history. However, the sense of the title is different: he is interested in the history of ontologies -- the ways that our conceptual systems have changed over time -- rather than the ontology of history.

(I should say that this is a pretty limited view of the scope of the philosophy of history, so it should be taken as provisional.)

Adapting to change

Friday, October 07, 2011

Organizations always have a set of fundamental needs. The organization does something -- it provides a commodity to consumers, it provides services that individuals pay for, it provides charitable services based on foundation funding, it employs specialists to steal credit card information on the Internet. All of these activities consume resources.

For the sake of clarity, let's have two organizations in mind: a mid-size company that produces cigarette lighters and a non-profit organization that provides adult literacy education in a high-poverty environment.

Key to an organization's "metabolism" is its regular access to resources, including especially revenue and people. Generally an organization has an existing model for satisfying these needs. It generates revenues through sale of goods and services or through gifts from foundations, corporations, and individuals who have a commitment to the organization's purposes. It acquires a talent base by hiring talented individuals and by attracting motivated volunteers. Call this a business plan--keeping in mind that profit-based and non-profit organizations alike need a business plan. If the business plan is a good one, the revenues match the expenditure needs of the organization, the talented members of the organization use their time and budgets to produce the organization's "deliverables", and the cycle begins again. The organization is sustainable.

A particularly bad scenario for a non-profit service provider is to begin its work on the basis of a large initial grant which is spent down until the organization expires. The profit-based equivalent is the new business that starts up with a large infusion of venture capital but never develops a revenue stream to support its activities.

What happens when the organization's business environment changes abruptly? Significant changes might include --

- Abrupt change in demand for the organization's product
- Abrupt change in the consumer's ability or willingness to pay for the product at the current price
- Change in the willingness of donors to provide support for this kind of activity
- Change in the costs of inputs necessary for producing the deliverables
- Appearance of a strong competitor who draws off demand and donors

We can easily think of examples of each of these changes. Gasoline prices spiked in summer 2010 and demand for large vehicles plummeted. Rapid increase in unemployment results in a massive decline to demand for mid-range restaurants. Foundations get frustrated about the slow rate of progress in education reform and cut back on funding for education reform NGOs. Digital photography rapidly undermines film companies. The iPod swamps the market for digital music players and other suppliers fail in the marketplace.

The question I'm raising here is a difficult one: what does an organization need to do in order to perceive and adapt to persistent changes like these? If we were asking this question in the field of ecology, the answer would be simple: many local species facing this kind of change simply will not be able to adapt in time and will go locally extinct. Natural selection is not a rapid-adaptation process, in general. Random variation and selection take time and large populations.

But this doesn't need to be the case for organizations. Organizations are led by intelligent and forward-looking people, after all, so in theory it should be possible for organizations to perceive impending change in their business environments and adjust accordingly. However, we also know that many organizations fail to do so. Think of the newspaper industry, the music publishing industry, the film-based photography industry, and some sectors of charitable providers.

So what are some positive heuristics that support effective adaptation? And what are some common sources of failure?

On the positive side:

- Be fact-driven and honest in assessing current conditions in the operating environment. Don't permit wishful thinking to cloud the assessment.
- Be rigorous in analyzing the consequences of these changes. If you are the leader of a non-profit with a great mission in an environment where funders have decisively turned away from this issue, consider the alternatives: downsize the delivery plan, reduce the cost of delivery, change the priorities of the organization, find new revenue partners, or find new sources of funding.
- Be innovative; search carefully for new ways of accomplishing the organization's goals at lower overall cost. A labor union might consider whether its army of organizers might be made more efficient (lower resource cost) by making use of social media.

On the negative side, we can think of a number of psychological and institutional factors that impede successful adaptation. Wishful thinking is at the top of the list. It is very easy

for decision makers to persuade themselves that observed trends will quickly reverse -- "the foundations will soon return to a focus on poverty," "digital photography will never achieve the resolution and color fidelity of film," "the state's support for poverty programs will return after the next election."

Second, decision makers may reason that careful but painful adaptation in the near term may be more painful for them individually than the consequences of eventual failure of the organization in the long term. This may be worsened by CEO compensation packages that create perverse incentives for them. The CEO of our fictional cigarette lighter manufacturer may reason that another 10 years of gradually declining sales, leading to bankruptcy, may be preferable to the turbulence and conflict associated with downsizing, shifting to another product, or introducing a lot of new technology.

Third, institutions have an enormous amount of inertia when it comes to change. Consolidating services within an organization, for example, is almost always met with a great deal of resistance from the various divisions that will need to "share" their IT person, their budget specialist, or their web designer. And rethinking the "deliverable" of the organization, or the way that it is provided, is also often met with a lot of internal resistance. A poverty-focused organization like the United Way may decide that its old model of distributing charitable funds needs to be more focused on a few central priorities; and this shift of delivery is likely to be met with resistance both internally (from existing staff) and externally (from powerful beneficiaries of the earlier system).

Fourth, there are very real limits on our ability to project current information onto future realities. What was called wishful thinking above might well be accurate in some situations: the current dire circumstances do sometimes get better and the existing business plan turns out to be sustainable after all. So there is always a degree of uncertainty associated with efforts to assess the current and future business environment.

No organization wants to be classified as a "dinosaur" -- the perfect embodiment of an "organization" (species) trapped in a period of change that moves more rapidly than its ability to adapt. But many do in fact find themselves in the contemporary equivalent of the tarpits when they run into unfamiliar and rapid periods of change. I have to hope that universities don't allow themselves to slip into that kind of endgame as they face the difficult and changing environment that currently confronts them.

The Racial Equity dividend

Wednesday, October 12, 2011

Racial justice organizations around the United States are struggling to find the resources from the corporate and foundation worlds needed to support their continuing work. One part of the problem seems to be that business leaders simply aren't convinced that racial inequalities are a fundamental and debilitating problem in the United States that presents a concrete threat to their own business activities. The issue has fallen off the first page of the priority list. This suggest that we need to revisit some of the costs that the structures of racial inequity are imposing on regions and cities.

The social costs of persistent racial inequity come in many dimensions. But particularly persuasive is the issue of the actual economic costs that these inequities impose on a region. We might put the point this way: racial inequities are an economic drag on a

region, blocking the production of wealth and income and slowing down economic growth. Is it possible to estimate the magnitude of these hidden economic costs of continuing racial inequity?

Let's think about this problem in the context of southeast Michigan and its major city, Detroit. What would southeast Michigan look like if the racial gaps of the region were erased? The gaps that exist between white and black citizens in the region are well documented. Residential segregation is extreme. Unemployment levels are dramatically higher for African-American youth and adults. Health disparities are large and debilitating. Educational outcomes are significantly worse for African-American young people, including high school graduation rates and college attendance. And, of course, family and individual incomes and wealth levels are substantially different.

So imagine a different scenario: a region in which residential segregation has ended. Schooling outcomes are equal for white and black students. Health disparities have disappeared. Employment rates have equalized. And average incomes, wealth holdings, and employment rates have converged across races. Plainly this would be socially desirable outcome; it would be a great improvement in social justice. But what would the economic effects be? How much new income and wealth would this scenario represent over the present situation?

We might approach this question directly, by estimating the aggregate income created by bringing 40% of the population up to the per capita income of the majority population. Likewise we could estimate the aggregate wealth that would be needed in order to equalize the wealth gap. Nationally black households in 2010 earned only 58% of the income of white households (link). I don't have full data for Wayne County at hand, but if the ratio is roughly similar, this implies roughly a $20,000 gap in Wayne County household income between white and black households, which aggregates to almost $6 billion in lost income as a result of racial inequity. If the social factors leading to this inequity were eliminated, this would add $6 billion to the county's income, consumption, and savings. (These are back-of-the envelope estimates, of course, and should be taken only as illustrative of the magnitude of the problem. Here are some basic demographic and income data for Wayne County based on census results; link.)

This scenario presupposes economic growth and jobs growth, but this assumption is supported by the large increase in the talent and education level of the population. We would also need to estimate the economic benefits associated with improved health status for the African-American population -- likewise a large number that public health researchers have probably already estimated. It is well understood in the field of global public health that improving a population's health status also improves its productivity. (Here is a study sponsored by the Kellogg Foundation that tries to estimate these costs and benefits. Nationally the costs associated with racial disparities in health are estimated in the trillions.)

Another approach to this issue would be to follow the lead of CEOs for Cities in attempting to estimate the "talent dividend" (link): do an econometric study of cities measuring degree of racial difference and per capita income. This would be the "racial equity dividend." I don't know if there is a recognized metric that already exists for measuring racial gaps in metropolitan regions, but it shouldn't be hard to construct. It should include components reflecting segregation, income, schooling, and health -- kind of a Human Development Index for Regional Racial Equity. We could then plot racial inequity against per capita income to see whether there is a relationship between these

variables. I don't know the answer, but I'd bet there is such a relationship. This would be a genuinely interesting piece of social research. And it might help communities realize the core importance of attacking their regional issues when it comes to racial equity. (I would love to know from Richard Florida whether there is any work available on this question in his research on cities.)

This whole line of thought depends on a hidden premise: that the racial gaps that exist in the metro regions of our country derive ultimately from racialized social and economic institutions that systematically produce and reproduce these racialized outcomes. This is what we once referred to as "institutionalized racism", though the term now sounds dated. It represents the systemic ways in which African-American people are tracked into lower social outcomes in health, education, employment, and income and wealth. Justice requires that we at long last dissolve those institutional tracks. But the economic health of the country demands no less as well. And it is in the best interest of corporations and foundations to support these efforts in their home cities and regions.

(Here is a series in the Detroit News on the costs of segregation; link.)

Rawls's framework for global justice

Saturday, October 15, 2011

Rawls's A Theory of Justice was immediately received as a major and progressive contribution to the theory of justice within existing societies. His Law of Peoples (1999) was intended to carry his basic ideas about justice to the international realm. (Here is a PDF of a preliminary version of the title essay of the book as published in *Critical Inquiry* in 1993.) Here is how he defined the goal of a law of peoples in 1993:

The law of peoples ... is a family of political concepts along with principles of right justice, and the common good that specify the content of a liberal conception of justice worked up to extend to and apply to international law. It provides the concepts and principles by reference to which that law is to be judged. (43)

In contrast to the reception *A Theory of Justice* received, his work on the international part of the theory has not had much influence, and was roundly criticized for being too accepting of international inequalities. Philip Pettit put the point this way in his contribution to Rex Martin and David Reidy's Rawls's Law of Peoples: A Realistic Utopia:

John Rawls's work on the law of peoples is notorious for its anti-cosmopolitan stance: roughly, its insistence that those of us in well-ordered societies do not owe to the members of other societies the sort of justice we owe to one another. (38)

This is exactly the critique that Philippe van Parijs offered to Rawls prior to publication of the book (link).

Given that Rawls's intuitions seem to have been solidly progressive in other spheres, it is worth considering why he took this very limited view of the obligations of justice in the global context. Why did he begin with the perspective of peoples rather than persons? (Here I'll make use of the 1993 statements of the view.)

A number of the critics put their cases in terms of Rawls's anti-cosmopolitanism. "Cosmopolitanism" is the view that we are all citizens of the world, and we have positive moral relationships with each other no matter what nation issues our passports. No one would deny that everyone has some kinds of moral relationships to everyone else -- for

example, the obligation not to impose harm on innocent people. But cosmopolitanism extends to the idea of positive obligations -- the obligation to render assistance as well as the obligation to refrain from gratuitous harm. The contrary to cosmopolitanism might be called "nationalism", but this implies assumptions that Rawls would presumably not have accepted. So let's call it "bounded people-ism": the claims of justice that a person has against other persons extend only to other members of his/her people and government.

One deep reason for the direction that Rawls took was the assumption he made about how to make use of the original position and the veil of ignorance in arriving at principles of international justice. If this framework involved all human beings, then the results would have been very similar to the argument made in the case of a well-ordered society: inequalities need to be the least system possible consistent with maximizing the position of the least-well-off stratum of society. However, Rawls chose instead to include "peoples" rather than "persons" in the argument from the original position in the case of international justice. What is a people?

By peoples I mean persons and their dependents seen as a corporate body and as organized by their political institutions, which establish the powers of government. In democratic societies persons will be citizens; in hierarchical and other societies they will be members. (41)
And he directly addresses the question of why it should be peoples rather than persons whose perspectives are represented in the original position for international justice:

Wouldn't it be better to start with the world as a whole, with a global original position, so to speak, and discuss the question whether, and in what form, there should be states, or peoples, at all? ... I think there is no clear initial answer to this question. We should try various alternatives and weigh their pluses and minuses. Since in working out justice as fairness I begin with domestic society, I shall continue from there as if what has been done so far is more or less sound. So I simply build on the steps taken until now, as this seems to provide a suitable starting point for the extension to the law of peoples. A further reason for proceeding thus is that peoples as corporate bodies organized by their governments now exist in some form all over the world. (42-43)
So his reasons for beginning with this premise are, first, we have to start somewhere and there isn't a philosophically compelling reason to favor persons over peoples in this setting; and second, peoples (and states) exist as actors in the world, so it is feasible to begin the analysis at this level. This way of formulating the original position is designed to establish fair terms of interaction between societies -- or in other words,

... fair conditions under which the parties, this time as representatives of societies well ordered by liberal conceptions of justice, are to specify the laws of peoples and the fair terms of their cooperation. (45)
This formulation, of course, immediately precludes certain questions, including all questions of difference in outcomes for the least-well-off in the various societies. The fact that the LWO in country X are worse off than the LWO in country Y cannot be a factor in this deliberation, and therefore there cannot emerge a positive obligation to transfer resources from society Y to X to ameliorate this difference.

Here are the principles that Rawls arrives at through this construction:

1. *Peoples (as organized by their governments) are free and independent, and their freedom and independence is to be respected by other peoples.*
2. *Peoples are equal and parties to their own agreements.*
3. *Peoples have the right of self-defense but no right to war.*

4. *Peoples are to observe a duty of nonintervention.*
5. *Peoples are to observe treaties and undertakings.*
6. *Peoples are to observe certain specified restrictions on the conduct of war (assumed to be in self-defense).*
7. *Peoples are to honor human rights. (46)*

In the final version of the argument in 1997 he adds a final principle:

8. *Peoples have a duty to assist other peoples living under unfavorable conditions that prevent their having a just or decent political and social regime.*

Later in 1993 he comments on the idea of a human right:

Human rights have, then, these three roles:
1. Their being fulfilled is a necessary condition of a regime's legitimacy and of the decency of its legal order.
2. Their fulfillment is also sufficient to exclude justified and forceful intervention by other peoples, say by economic sanctions or, in grave cases, by military force.
3. "They set a moral limit to pluralism" among peoples. (59)

Several things are evident from these lists. First, the obligations represented here are indeed minimalist; basically, they are limitations on the use of coercive means by peoples (states) to achieve their ends. Even the 8th principle added in the 1997 version creates an obligation only to assist other peoples in achieving a just political regime. Second, there are no requirements of distributive justice in this list of principles. Each society has internal requirements of distributive justice; but there is no inter-society requirement of distributive justice. The fact that there are large inequalities of resources between countries is not a basis for a claim of injustice, according to these principles.

This framework has been strongly criticized by philosophers and others who found that it was far too accepting of global inequalities. Alan Buchanan focuses on the global inequality part of the story in his 2000 contribution in *Ethics*. Buchanan holds that even representatives of peoples would not have overlooked the significant inequalities imposed on peoples by the global economic system. He maintains that the original position concerned with international justice would have to take into account two important facts:

There is a global basic structure, which, like the domestic basic structure, is an important subject of justice because it has profound and enduring effects on the prospects of individuals and groups, including peoples in Rawls's sense.

The populations of states are not "peoples" in Rawls's sense and are not likely to become so without massive, unjustifiable coercion, but rather are often conflicting collections of "peoples" and other groups. (700-1)

The first fact, if recognized, would ensure that the international original position would necessarily take into account the inequalities created by this system for different peoples. He also believes that the second fact raises salient issues for the international original position. Essentially the issue here is this: what happens when the multiple peoples of a single state come into conflict? By making the assumptions that "peoples within unified states" are the agents within the international original position, Rawls makes it impossible to arrive at principles of international justice that would specify just behavior in the face of civil war or secessionist movements. This approach makes it impossible to address intrastate conflict.

Tom Pogge extends his own critique of Rawls's position on international distributive

justice in a *Fordham Law Review* article (link) (also included in Martin and Reidy's Rawls's Law of Peoples: A Realistic Utopia). Fundamentally, Pogge is highly critical of Rawls's failure to arrive at an international theory of justice that provides a basis for critique of global inequalities. In this piece he argues that Rawls's two theories are in fact inconsistent with each other.

As indicated above, much of this body of criticism has to do with the view that Rawls's *Law of Peoples* creates only the most limited obligations across peoples. His view is not "cosmopolitan". But a more fundamental criticism, which Buchanan hints at, is that there is a major strand of injustice embedded within the world system that is wholly invisible within Rawls's formulation of the law of peoples. This is the fact that global institutions may create systematically imbalanced economic relations among states, with the result that some states are in a position to take unfair advantage of other states. This is a form of injustice that would not be accepted within the terms of a domestic society. But there is no basis within the framework of the law of peoples to identify and criticize these types of injustices.

These criticisms are surely correct. As a theory of global justice, the *Law of Peoples* doesn't begin to provide enough of a normative basis to arrive at sound judgments about international arrangements. I began by asking how it came to pass that Rawls presented such a limited theory of international justice. The best answer I can offer is that he was focusing on the wrong issues. He focused on issues of war and interstate violence, and he did not sufficiently bring into his view the empirical realities associated with a highly unequal world economic structure. And this is puzzling, since questions of global inequalities -- of resources, of power, and of self-determination -- were certainly widely debated at Harvard in the 1970s and 1980s while Rawls's thinking on this subject was developing.

(In addition to critics, Rawls has some defenders in this area. Samuel Freeman provides an extensive and reasoned response to many of these criticisms of Rawls's theory of international justice here (link).)

Historiography and the philosophy of history

Sunday, October 16, 2011

The topic of the philosophy of history comes up frequently here. The related domain of

"historiography" has not come up yet, however. What is the relation between these bodies of study about the writing of history?

Let's begin by asking the basic question: what is historiography? In its most general sense, the term refers to the study of historians' methods and practices. Any intellectual or creative practice is guided by a set of standards and heuristics about how to proceed, and "experts" evaluate the performances of practitioners based on their judgments of how well the practitioner meets the standards. So one task we always have is to attempt to identify these standards and criteria of good performance. This is true for theatre and literature, and it is true for writing history. Historiography is at least in part the effort to do this work for a particular body of historical writing.

Historians normally make truth claims, and they ask us to accept those claims based on the reasoning they present. So a major aspect of the study of historiography has to do with defining the ideas of evidence, rigor, and standards of reasoning for historical inquiry. We presume that historians want to discover empirically supported truths about the past, and we presume that they want to offer inferences and interpretations that are somehow regulated by standards of scientific rationality. (Simon Schama challenges some of these ideas in Dead Certainties: Unwarranted Speculations.) So the apprentice practitioner wants to gain knowledge of the practices of his/her elders in the profession: what counts as a compelling argument, how to assess a body of archival evidence, how to offer or criticize an interpretation of complex events that necessarily exceeds the available evidence. The historiographer has a related task: he/she would like to be able to codify the main methods and standards of one historical school or another.

There are other desiderata governing a good historical work, and these criteria may change from culture to culture and epoch to epoch. Discerning the historian's goals is crucial to deciding how well he or she succeeds. So discovering these stylistic and aesthetic standards that guide the historian's work is itself an important task for historiography. This means that the student of historiography will naturally be interested in the conventions of historical writing and rhetoric that are characteristic of a given period or school.

A full historiographic "scan" of a given historian might include:

- What methods of discovery does he/she use?
- What models of explanation?
- What paradigm of presentation?
- What standards of style and rhetoric?
- What interpretive assumptions?

A historical "school" might be defined as a group of interrelated historians who share a significant number of specific assumptions about evidence, explanation, and narrative.

Historiography becomes itself historical when we recognize that these frameworks of assumptions about historical knowledge and reasoning change over time. On this assumption, the history of historical thinking and writing is itself an interesting subject. How did historians of various periods in human history conduct their study and presentation of history? Under this rubric we find books on the historiography of the ancient Greeks; Renaissance historiography; or the historiography of German romanticism. This kind of reflection has a lot in common with literary history or art history; the historiographer is seeking to identify "styles" of historical thinking in various times, as well as recognizing the distinctive contributions of particular historians. Arnaldo

Momigliano's writings on the ancient historians fall in this category (The Classical Foundations of Modern Historiography). Here is a tantalizing set of questions that Momigliano raises with respect to ancient history-writing:

If these preliminary considerations are valid there is some justification for asking the following six questions: (1) What have Greek and Jewish historiographies in common and why and to what extent did Greek historiography ultimately prevail? (2) Why did Thucydides rather than Herodotus become the most authoritative historian of Antiquity? (3) What part did the antiquarians play in historical research? (4) How was Greek historiography imported into Rome and what did the romanisation of Greek historiography entail? (5) What is the place of Tacitus in historical thought? (6) Why and in what way has ecclesiastical historiography a tradition of its own? (2)

These six questions become the focus of the six chapters of the book. In a nutshell, Momigliano is looking at the several traditions of ancient history-writing as a set of normative practices that can be dissected and understood in their specificity and their cultural contexts. Here is a description that illustrates some of Momigliano's orienting assumptions:

What I think is typically Greek is the critical attitude towards the recording of events, that is, the development of critical methods enabling us to distinguish between facts and fancies. To the best of my knowledge no historiography eralier than the Greek or independent of it developed these critical methods; and we have inherited the Greek methods. (30)

A second primary use of the concept of historiography is more present-oriented and more methodological. It involves the study and analysis of historical methods of research, inquiry, inference, and presentation used by more-or-less contemporary historians. How do contemporary historians go about their tasks of understanding the past? Here we can talk about the historiographical challenges that confronted Philip Huang as he investigated the Chinese peasant economy in the 1920s and 1930s (The Peasant Economy and Social Change in North China), or the historiographical issues raised in Robert Darnton's telling of the Great Cat Massacre (The Great Cat Massacre: And Other Episodes in French Cultural History). Sometimes these issues have to do with the scarcity or bias in the available bodies of historical records (for example, the fact that much of what Huang refers to about the village economy of North China was gathered by the research teams of the occupying Japanese army). Sometimes they have to do with the difficulty of interpreting historical sources (for example, the unavoidable necessity Darnton faced of providing meaningful interpretation of a range of documented events that did not bear their meanings on their sleeves). And sometimes the historiographic question has to do with the mode of presentation chosen by the historian (for example, Darnton's choice of presenting the notebooks of Joseph d'Hemery, the police inspector of the book trade in Montpelier, as a sociological source).

For example, there has been substantial disagreement among historians of China about the status of the Chinese rural economy in the 1920s and 1930s. Historians who give credence to travelers' reports conclude that conditions were awful (R. H. Tawney, Land and labour in China). Historians who maintain that only validated quantitative data constitute a relevant way of answering the question come to a diametrically opposed judgment (Loren Brandt, Commercialization and Agricultural Development: Central and Eastern China, 1870-1937). This is a historiographic disagreement, centered on the issue of what counts as credible evidence.

We might ask, finally, what is the relationship between historiography and the philosophy of history. There is a degree of overlap between the two fields in the fact that both are concerned with identifying and evaluating the standards of reasoning that are used in various historical traditions. That said, historiography is generally more descriptive and less evaluative than the philosophy of history. And it is more concerned with the specifics of research and writing than is the philosophy of history.

Levels of politics

Sunday, October 23, 2011

I've focused occasionally on the idea of "levels" of social arrangements, from the local to the intermediate to the higher levels, with the idea that higher levels are composed of structures and activities at lower levels. Generally I've had in mind examples from one specific area of the social sciences to illustrate these points -- sociology. How do these claims look, however, when we consider them in light of political science?

If we wanted to provide a brief definition of "politics", it might go along these lines: the institutions and patterns of behavior through which decisions about public policies and the expenditure of public resources are determined and implemented. This includes study of the personnel of governing institutions; the nature of governing institutions; and the strategies and behavior of all those affected by those institutions.

There is one clear sense in which politics and government contain "levels". This derives from the fact that governance systems have a hierarchical, semi-nested structure of ascending scope of control and authority. In the United States we have Federal laws, state laws, and county and municipal laws. And this differentiation also imposes a criterion of level: higher level means broader jurisdiction over territory and population. Each possesses a set of legislative institutions and officials, along with a bureaucracy focused on implementation and enforcement. These zones of governance authority differ in terms of scope and scale, with units of governance ranging from national to state to county and city.

However, these zones of political governance are not hierarchical in another important sense: the Federal level is not composed of the state or municipal governance systems. Rather, each is independent from the other. Higher-level units have the authority to enact rules and laws (in some instances) that constrain the actions of the lower-level jurisdictions. But the personnel, officials, and systems of the two jurisdictions are distinct and independent. And it is entirely possible, even predictable, that there will be policy disagreements between them.

A second clear interpretation of "levels" of governance corresponds to the formal hierarchy of a large administrative system. The President exercises authority at the highest level within the executive branch. Cabinet secretaries report to the president and manage and direct complex and extensive organizations (Departments) dedicated to specific functions: Justice, Environmental Protection, Education, ... Each department of the executive branch in turn consists of a descending proliferation of bureaus, regional offices, field offices, and the like. The Chicago field office of the XYZ department reports to a regional director, who takes direction from the Secretary. The layers of the organization of government can be referred to as "levels," differentiated by position within a hierarchical system.

It is also evident that the networks of power and influence that operate at the Federal level are distinct from those at the state or local level. The powerful individuals are different, the organizations through which they exercise their influence are different, and the sources of their power are different. The Daley machine in Chicago in the 1960s exercised great power in city politics, middling power in the corridors of Illinois government, and less influence at the Congressional level. So the different "levels" of government correspond to different loci of influence and activism, and the study of Congressional politics may lead to rather different findings from the study of state or municipal politics.

This means that scholars who are primarily interested in the political mechanisms through which various policies get chosen will select carefully the networks of individuals and organizations they study, in order to shed light on the operative level of governance. But it would be misleading to describe these as different "levels" of politics; rather, different people and organizations are at work in similar policy areas with uncoordinated results in Chicago, Cook County, Springfield, and Washington.

So the idea of "levels" of politics doesn't seem to be a particularly valuable conceptual scheme when it comes to analyzing political behavior and organization. It misleads us into thinking that politics has a fundamental structure from low to high. Instead, we are perhaps better served by a view that picks out various arenas of conflict over resources -- politics -- without the orienting language of higher and lower levels.

Wherever we start our examination of the social world, from the situation of particular individuals, to labor unions, firms, and faith organizations, to federal agencies and multinational trading regimes, the logic of the social world seems to be the same: there are groups of actors planning and acting in that locus, there are structures and rules that surround them, and there are organizations and structures that are broader in scope and jurisdiction and there are such at lesser levels of scope and jurisdiction. There is an up, down, and sideways everywhere in social action. And this is equally true in the zone of political action and institution.

Social complexity

Monday, October 24, 2011

Social ensembles are often said to be "complex". What does this mean?

Herbert Simon is one of the seminal thinkers in the study of complexity. His 1962 article, "The Architecture of Complexity" (link), put forward several ideas that have become core to the conceptual frameworks of people who now study social complexity. So it is worthwhile highlighting a few of the key ideas that were put forward in that article. Here is Simon's definition of complexity:

Roughly, by a complex system I mean one made up of a large number of parts that

interact in a nonsimple way. In such systems, the whole is more than the sum of the parts, not in an ultimate, metaphysical sense, but in the important pragmatic sense that, given the properties of the parts and the laws of their interaction, it is not a trivial matter to infer the properties of the whole. In the face of complexity, an in-principle reductionist may be at the same time a pragmatic holist. (468)

Notice several key ideas contained here, as well as several things that are not said. First, the complexity of a system derives from the "nonsimple" nature of the interaction of its parts (subsystems). A watch is a simple system, because it has many parts but the behavior of the whole is the simple sum of the direct mechanical interactions of the parts. The watchspring provides an (approximately) constant impulse to the gearwheel, producing a temporally regular motion in the gears. This motion pushes forward the time registers (second, minute, hour) in a fully predictable way. If the spring's tension influenced not only the gearwheel, but also the size of the step taken by the minute hand; or if the impulse provided by the spring varied significantly according to the alignment of the hour and second hands and the orientation of the spring -- then the behavior of the watch would be "complex". It would be difficult or impossible to predict the state of the time registers by counting the ticks in the watch gearwheel. So this is a first statement of the idea of complexity: the fact of multiple causal interactions among the many parts (subsystems) that make up the whole system.

A second main idea here is that the behavior of the system is difficult to predict as a result of the nonsimple interactions among the parts. In a complex system we cannot provide a simple aggregation model of the system that adds up the independent behaviors of the parts; rather, the parts are influenced in their behaviors by the behaviors of other components. The state of the system is fixed by interdependent subsystems; which implies that the system's behavior can oscillate wildly with apparently similar initial conditions. (This is one explanation of the Chernobyl nuclear meltdown: engineers attempted to "steer" the system to a safe shutdown by manipulating several control systems at once; but these control systems had complex effects on each other, with the result that the engineers catastrophically lost control of the system.)

A third important point here is Simon's distinction between "metaphysical reducibility" and "pragmatic holism." He accepts what we would today call the principle of supervenience: the state of the system supervenes upon the states of the parts. But he rejects the feasibility of performing a reduction of the behavior of the system to an account of the properties of the parts. He does not use the concept of "emergence" here, but this would be another way of putting his point: a metaphysically emergent property of a system is one that cannot in principle be derived from the characteristics of the parts. A pragmatically emergent property is one that supervenes upon the properties of the parts, but where it is computationally difficult or impossible to map the function from the state of the parts to the state of the system. This point has some relevance to the idea of "relative explanatory autonomy" mentioned in an earlier posting (link). The latter idea postulates that we can sometimes discover system properties (causal powers) of a complex system that are in principle fixed by the underlying parts, but where it is either impossible or unnecessary to discover the specific causal sequences through which the system's properties come to be as they are.

Another key idea in this article is Simon's idea of a hierarchic system.

By a hierarchic system, or hierarchy, I mean a system that is composed of interrelated subsystems, each of the latter being, in turn, hierarchic in structure until we reach some lowest level of elementary subsystem. (468)

I have already given an example of one kind of hierarchy that is frequently encountered in the social sciences: a formal organization. Business firins, governments, universities all have a clearly visible parts-within-parts structure. (469)
Here the idea is also an important one. It is a formal specification of a particular kind of ensemble in which structures at one level of aggregation are found to be composed separately of structures or subsystems at a lower level of aggregation. Simon offers the example of a biological cell that can be analyzed into a set of exhaustive and mutually independent subsystems nested within each other. It is essential that there is a relation of enclosure as we descend the hierarchy of structures: the substructures of level S are entirely contained within it and do not serve as substructures of some other system S'.

It is difficult to think of biological examples that violate the conditions of hierarchy -- though we might ask whether an organism and its symbiote might be best understood as a non-hierarchical system. But examples are readily available in the social world. Labor unions and corporate PACs play significant causal roles in modern democracies. But they are not subsystems of the political process in a hierarchical sense: they are not contained within the state, and they play roles in non-state systems as well. (A business lobby group may influence both the policies chosen by a unit of government and the business strategy of a healthcare system.)

Simon appears to believe that hierarchies reduce the complexity of systems; and they support the feature of what we would now call "modularity", where we can treat the workings of a subsystem as a self-enclosed unit that works roughly the same no matter what changes occur in other subsystems.

Simon puts this point in his own language of "decomposability." A system is decomposable if we can disaggregate its behavior onto the sum of the independent behaviors of its parts. A system is "nearly decomposable" if the parts of the system have some effects on each other, but these effects are small relative to the overall workings of the system.

At least some kinds of hierarchic systems can be approximated successfully as nearly decomposable systems. The main theoretical findings from the approach can be summed up in two propositions:

(a) in a nearly decomposable system, the short-run behavior of each of the component subsystems is approximately independent of the short-run behavior of the other components; (b) in the long run, the behavior of any one of the components depends in only an aggregate way on the behavior of the other components. (474)
He illustrates this point in the case of social systems in these terms:

In the dynamics of social systems, where members of a system communicate with and influence other members, near decomposability is generally very prominent. This is most obvious in formal organizations, where the formal authority relation connects each member of the organization with one immediate superior and with a small number of subordinates. Of course many communications in organizations follow other channels than the lines of formal authoritv. But most of these channels lead from any particular individual to a very limited number of his superiors, subordinates, and associates. Hence, departmental boundaries play very much the same role as the walls in our heat example. (475)
And in summary:

We have seen that hierarchies have the property of near-decomposability. Intra-component linkages are generally stronger than intercomponent linkages. This fact has the effect of separating the high-frequency dynamics of a hierarchy -- involving the internal structure of the components-- from the low frequency dynamics-involving interaction among components. (477)

So why does Simon expect that systems will generally be hierarchical, and hierarchies will generally be near-decomposable? It turns out that this is an expectation that derives from the notion that systems were created by designers (who would certainly favor these features because they make the system predictable and understandable) or evolved through some process of natural selection from simpler to more complex agglomerations. So we might expect that hydroelectric plants and motion detector circuits in frogs' visual systems are hierarchical and near-decomposable.

But here is an important point about social complexity. Neither of these expectations is likely to be satisfied in the case of social systems. Take the causal processes (sub-systems) that make up a city. And consider some aggregate properties we may be interested in -- emigration, resettlement, crime rates, school truancy, real estate values. Some of the processes that influence these properties are designed (zoning boards, school management systems), but many are not. Instead, they are the result of separate and non-teleological processes leading to the present. And there is often a high degree of causal interaction among these separate processes. As a result, it might be more reasonable to expect, contrary to Simon's line of thought here, that social systems are likely to embody greater complexity and less decomposability than the systems he uses as examples.

(A recent visit to the Center for Social Complexity at George Mason University (link) was very instructive for me. There is a great deal of very interesting work underway at the Center using agent-based modeling techniques to understand large, complicated social processes: population movements, housing markets, deforestation, and more. Particularly interesting is a blog by Andrew Crooks at the Center on various aspects of agent-based modeling of spatial processes.)

How can justice be causal?

Wednesday, October 26, 2011

Is social justice an empirical characteristic of a set of social arrangements? And can social justice be a causal factor in processes of social change or social stability?

Before justice could be considered an empirical feature of a set of social arrangements, we would need to have a more specific understanding of what we mean by the term. And we would need to be able to "operationalize" this complex concept in order to be able to apply it to different social arrangements. But neither of these tasks is insurmountable; certainly not more so than defining and applying the ideas of fascism, liberal democracy, or welfare state to specific societies.

So let's begin with a simple, applicable definition of justice. Let's focus on just three

dimensions of a society's functioning: distribution of access to society's wealth; the degree of abuse of power and its contrary, reliable legal protections of the person; and the extent of individual freedoms. Injustice involves --

- exploitation and inequality
- unwarranted coercion by the state or private organizations
- the abuse of people's freedoms.

A society is more just when it involves less of any of these features. And each of these dimensions seems measurable.

But immediately a problem arises. Each of these features requires a key normative judgement. Exploitation is the unfair division of the fruits of productive activity among the participants. The qualifier "unwarranted" requires that we supply a normative theory of the state. And "abuse" of freedom isn't simply restriction on freedom; it is the unjustified or unequal restriction on freedom. So in order to measure any of these characteristics in a particular social context it isn't enough to know who gets what or who does what to whom; we need a background set of normative ideas that allow us to judge which kinds of treatment and inequality count as exploitation, coercion, or the abuse of freedom.

This is where Amartya Sen's ideas about capabilities, realizations, and freedoms are practical and useful. We might substitute "capabilities realization deficit" for exploitation. Here we might argue that a society that leaves a significant portion of its population in material conditions where they cannot fulfill most of their basic human capabilities is for that reason unjust. We might measure the gap in human development between the top quintile and the bottom quintile as an estimate of the degree of exploitation that is prevalent in a given society. We may not know in detail how the system of distribution works, but the severity of the gap gives reason to believe that a portion of the society is being treated unfairly. The Human Development Index provides a basis for beginning to assess different countries along these lines (link).

Second, we might measure coercion and legality by the estimating the degree to which a society has effectively implemented a working system of law that is applied equally. The World Bank has made some efforts in this direction through its Worldwide Governance Indicators (link; working paper here). This gives us an empirical measure of the degree of lawlessness and unchecked state power that exists in various societies.

We might measure freedoms by aggregating observable features of democratic participation in various societies. *The Economist* has constructed a Democracy Index that was first implemented in 2006 (link). This gives us an empirical way of assessing the rough degree of involvement citizens can have in public decision-making; or in other words, it is a measure of the degree to which it is possible for citizens to exercise their freedoms in a public space.

So we might imagine a "justice index" for a society that aggregates measures like these into an overall assessment of the degree of justice the society currently demonstrates. It would then be interesting to see how societies differ in this measure, and how other important social characteristics may be correlated with this measure. I haven't done this experiment, but here's what we might expect: higher injustice ratings correspond to greater likelihood of social conflict, lower productivity, and lower community and civic engagement.

What mechanisms might be hypothesized that would originate in these core aspects of a society's justice profile and its various outcomes? Here we can identify a couple of factors

that would support a causal interpretation. For example, absolute or relative deprivation can cause people to rebel as they struggle to create social changes that protect their interests. Further, as Barrington Moore demonstrated in Injustice, the conviction that basic social arrangements are unfair can also move people to activism and resistance -- as we seem to be seeing in the Occupy Wall Street movement. These factors derive from the distributive arrangements of a society: injustice can provoke resistance. Similar statements can be made about state violence and lawlessness. We have seen in Libya, Syria, and Morocco that state violence against protesters can actually have the effect of strengthening and broadening resistance.

So these aspects of injustice can have effects on mobilization and resistance by a population. Are there other effects that injustice can have? As noted earlier (link), Pickett and Wilkinson argue in The Spirit Level: Why Greater Equality Makes Societies Stronger that inequalities of income have surprisingly strong associations with a variety of social ills. This could be developed into an argument that social justice and injustice lead to behaviors that either promote or undermine social welfare.

Finally, it seems plausible to imagine that the intangibles that accompany a harmonious society -- a population of people who generally feel that they are fairly treated by their basic institutions and their fellow citizens -- will lead to a variety of other social goods, including cooperation, civic engagement, and economic productivity. Conversely, it is plausible to suppose that a dis-harmonious society would give rise to the negatives of these qualities: less cooperation, less civic involvement, and less economic productivity.

So two things seem true. First, it does seem possible to "measure" injustice (supported, of course, by a normative theory of why various kinds of inequality are illegitimate). And second, it does seem plausible that the features of a society that constitute its injustice may also have causal consequences for social unrest, social wellbeing, and social cooperation. And these are certainly significant social consequences.

(Perhaps there is an analogous set of questions at the individual level: Is "virtue" a specific empirical characteristic of a person's character? And can virtue be a causal factor in the individual's life outcomes and level of happiness?)

Theories of the actor

Friday, October 28, 2011

I'm attracted to an approach to sociological thinking that can be described as "actor-centered." The basic idea is that social phenomena are constituted by the actions of individuals, oriented by their own subjectivities and mental frameworks. It is recognized, of course, that the subjectivity of the actor doesn't come full-blown into his or her mind at adulthood; rather, we recognize that individuals are "socialized"; their thought processes and mental frameworks are developed through myriad social relationships and institutions. So the actor is a socially constituted individual.

If we take the approach to social explanation that demands that we understand how complex social processes and assemblages supervene on the actions and thoughts of individuals, then it is logical that we would want to develop a theory of the actor. We would like to have a justifiable set of ideas about how individuals perceive the social world, how they think about their own lives and commitments, and how they move from thought to action. But we have many alternatives available as we attempt to grapple with this task.

We might begin by asking, what work should a theory of the actor do? Here are a set of questions that a theory of the actor ought to consider:

1. How does the actor represent the world of action -- the physical and social environment? Here we need a vocabulary of mental frameworks, representational schemes, stereotypes, and paradigms.
2. How do these schemes become actualized within the actor's mental system? This is the developmental and socialization question.
3. What motivates the actor? What sorts of things does the actor seek to accomplish through action?
4. Here too there is a developmental question: how are these motives instilled in the actor through a social process of learning?
5. What mental forces lead to action? Here we are considering things like deliberative processes, heuristic reasoning, emotional attachments, habits, and internally realized practices.
6. How do the results of action get incorporated into the actor's mental system? Here we are thinking about memory, representation of the meanings of outcomes, regret, satisfaction, or happiness.
7. How do the results of past experiences inform the mental processes leading to subsequent actions? Here we are considering the ways that memory and emotional representations of the past may motivate different patterns of action in the future.

Aristotle guides much philosophical thinking on these questions by offering an orderly theory of the practical agent (The Nicomachean Ethics). His theory is centered on the idea of deliberative rationality, but he leaves a place for the emotions in action as well (to be controlled by the faculty of reason). Deliberation, in Aristotle's view, amounts to reflecting on one's goals and arranging them into a hierarchy; then choosing actions that permit the achievement of one's highest goals.

Formal rational choice theory provides a set of answers to several of these questions. Actors have preferences and beliefs; their preferences are well ordered; they assign probabilities and utilities to outcomes (the results of actions); and they choose a given action to maximize the satisfaction of their preferences.

Ethnographic thinkers such as Clifford Geertz or Erving Goffman take a different tack altogether; they give a lot of attention to questions 1 and 2; they provide "thick" descriptions of the motives and meanings of the actors (3); and they indicate a diverse set of answers to question 5. (Geertz and Goffman are discussed in other posts.)

Other anthropologists have favored a "performative" understanding of agency. The actor is understood as carrying out a culturally prescribed script in response to stereotyped social settings. Victor Turner's anthropology is a leading example of this approach to action (Dramas, Fields, and Metaphors: Symbolic Action in Human Society).

Mayer Zald recommends the work of Karl Weick on the first question (Sensemaking in Organizations (Foundations for Organizational Science)). Here is how Weick explains

sensemaking:

The concept of sensemaking is well named because, literally, it means the making of sense. Active agents construct sensible, sensable events. They "structure the unknown". How they construct what they construct, why, and with what effects are the central questions for people interested in sensemaking. Investigators who sensemaking define it in quite different ways. Many investigators imply what Starbuck and Milliken make explicit, namely, that sensemaking involves placing stimuli into some kind of framework. The well-known phrase "frame of reference" has traditionally meant a generalized point of view that directs interpretations. (4) (references omitted)
It's worthwhile addressing this topic, because it would appear that we don't yet have a particularly good vocabulary for formulating questions about agency. As indicated above, Aristotle's theory of the mind has been dominant in western philosophy; and yet it feels as though his approach is just one among many starting points that could have been chosen. Here is an earlier treatment of this question (link).

I'm reminded by my friends that not all sociologists accept the actor-centered approach. Some (like Andrew Abbott and Peggy Somers) prefer what they refer to as a "relational" understanding of the basis of social activity. It is not so much the actor as the action; it is not the internal state of the individual agent so much as the swirl of interactions with others that determine the course of a social activity. This is part of Abbott's objection to the idea that sociology should aim to uncover social mechanisms (link).

Notes from Xi'an

Tuesday, November 01, 2011

People here in Xi'an say: "The Chinese city of the present is Beijing. The city of the future is Shanghai. The city of China's past is Xi'an." This seems to be more than a slogan. People in Xian seem deeply proud of the history and heritage that Xian represents -- the thirteen dynasties that made Xi'an their capital, the extraordinary excavations that the Shaanxi region hosts, and the "forest of stones" that is a remarkable collection of steles conveying calligraphy from the Tang Dynasty (Xi'an Beilin Museum). (The entire collection of the sayings of Confucius are represented on one massive Tang-era stone monument.)

At the same time, the city is not trapped in the past. Since my previous visit in 2007 the city has undergone many of the same changes that are so striking in other great Chinese cities: new skyscrapers and hotels, more traffic, more smog, and more luxury shopping. One of Xian's major universities, Xi'an Jiaotong University, is developing a major new campus. Particularly striking is a newly developed park in the center of the city that memorializes the Tang Dynasty and its emperors with sculptures, monuments, and light shows. Like the rest of urban China, Xi'an is moving forward rapidly.

Particularly interesting for me, though, is the opportunity that a visit to Xi'an creates for talking to people about how they feel about China's rapid changes. A couple of conversations stand out. I asked a very accomplished young historical guide at the Beilin Museum whether Chinese young people found any resonance with the values of ancient Chinese culture -- whether Confucian ideas about the duties of governments and officials or the aesthetic values represented by calligraphy were formative for young people. His response was a reflective one. He observed that middle-aged Chinese men seem to be very interested in these topics, and very interested in practicing calligraphy. He noted that

all of China's top leaders in modern times, including Chairman Mao, took pride in their calligraphy. Young people, by contrast, do not share these interests, and they prefer to use the click of a mouse rather than pen and ink to produce a character. He disapproved of this change in cultural attitudes and indicated that learning calligraphy is learning to think in a particular way.

Another value slipped into this conversation almost unnoticed. The guide informed me that one pagoda contains a Qing-era stele with a text from the Emperor exhorting the suppression of a minority-based rebellion. This pagoda is sealed, he said, because the government wants to create a feeling of national harmony and the message of the stele is contrary to harmony. Even scholars are not permitted to view the text. His ready acceptance of the legitimacy of the government's suppressing information was very striking to my ears. It made me think of the regime's casual decision to make western blogging platforms unavailable on the Internet in China, making a vast domain of information and opinion unavailable here. The idea that the government has the right to select and filter the information that citizens can access is a harmful one to anyone with liberal values; but it is one that is readily accepted and justified by many thoughtful people in China.

Another snippet of conversation that interested me took place with a university staff person. This young man's wife is expecting the delivery of their first (and only) child in the next month. Because he works for a university, he is interested in education. So I asked him about the current situation of the education of Chinese children. He was very passionate on this subject. He talked about the incredible pressure that children are under from the very earliest age, to compete and excel in school. The competition to gain entry into the "best" kindergarten, middle school, and high school pushes parents and children to unbearable effort. He talked about middle school children pushed by their parents and the sense of deeply important competition, to excel in their grades, their violin and piano lessons, their dance lessons, and their other extra-curricular activities. And he talked about middle- and high-school students working on homework well past midnight in order to gain the best possible grades. He observed that this pressure takes a terrible toll on children, even while it produces students who are very, very good at taking competitive examinations. But he doubted whether the other qualities of a well-educated student are coming through -- an ability to communicate well, and an openness to innovation, for example. What was striking to me in the conversation was not only the content of his observations, but the passion and emotion with which he spoke.

One additional observation seems somewhat telling. This has to do with the flying public in China. As I passed through the first class seating area to my own seat in economy flying from Shanghai to Xi'an, I noticed that the first class section was completely filled with young Chinese professionals, their smartphones, laptops and folios in hand, heading off to a day's worth of appointments in Xi'an. This is a sign, of course, of the familiar fact that China's professional service class has expanded dramatically in the past twenty years. This is part of the change that has brought Prada, Jaguar, and Ferragamo to every large city in China. But I also noticed something else in the economy section of the flight from Detroit to Shanghai – a good number of young Americans who have decided to spend some or all their careers in China. The opportunities created by China's growth are drawing a large number of middle class Americans to work in Shanghai rather than Knoxville, Peoria, or Tampa. This isn't the business elite that has done business in China for decades, but a new wave of young engineers, managers, or skilled workers who are following the global opportunities. The young man sitting next to me in economy defined the situation for me: a Kentuckian with a community college degree in technology,

experience in the US in setting up a factory, and now employed in a two-continent job taking him between Shanghai and Louisville working for a Chinese company that is setting up a major chemical plant in Suzhou. He recently married a young Chinese woman who will be returning to Kentucky with him in a month or so.

A final observation about Xi'an: People here seem to be very accepting of China's system of single-party rule. The comment is often heard that "when the central government has decided what to do, it gets done." This comment was made about the rapid and impressive development of the Tang Dynasty Park in Xi'an mentioned above, but it seems to be in the back of mind for many areas of policy and change. And the government seems to get a great deal of credit for its success over the past thirty years in moving China forward: economic growth, world stature, and a sense of Chinese national pride are all achievements that many citizens accord to the government's decisions and policies. A twenty-something professional said to me: "The government is trying seriously to address China's problems. Our leaders are moving in the right direction. It may take two generations to solve some of our problems (like rural-urban inequality)." I haven't yet been exposed -- in this visit or in prior visits -- to a sense of discontent, whether about the state's control of individual liberties and access to information, or about other aspects of political control. Of course there is discontent in several sectors of China's society -- rural people whose economic progress is slow and whose property is subject to seizure; workers whose wages aren't being paid; urban people whose environments are subject to repeated toxic incidents. But those sources of discontent don't seem to have percolated into a more widespread sense of dissatisfaction in the broader urban public.

Signing off from the home of the Tang Dynasty – I have a temple to visit!

Four years of UnderstandingSociety

Thursday, November 03, 2011

Today marks the fourth anniversary of UnderstandingSociety. This is the 613th posting since I began in November 2007 and the 135th in the past year. I continue to find this medium a good way of pushing forward my own learning and thinking about a swirl of topics around the central thrust, making sense of the social realm in which we live. I've been drawn into lines of thought in the past year that I wouldn't have encountered without the intellectual effort involved in writing the blog. And, of course, it is a good way of meeting a reading public all around the world.

Several topics came in for special focus in the past year. First, there is a fair amount of new material on the philosophy of history. Since finishing *New Contributions to the Philosophy of History* last fall (2010) I've continued to think about history and historiography, and I've found some new issues that I need to think about more fully. There is more to come on this.

Second, I've been thinking about John Rawls's work more in the past year. I first read Rawls as an undergraduate in the late sixties. Then I read *A Theory of Justice* when it appeared in 1971 as I was beginning to take courses from Rawls as a graduate student. Truthfully, I like the work better today than I did then, 40 years ago. And I'm finding that it provides support for a much deeper critique of our society than I thought then. One part of this rethinking is contained in a piece on "Property-owning democracy". Another is a reflection on Rawls's later thoughts about the deficiencies of an excessively consumerist culture in his correspondence with Philippe van Parijs.

Third, I've written quite a bit in the past twelve months that is directed at issues in analytical sociology. The key premises of the AS approach are very consistent with my own understanding of the social world (microfoundations, methodological localism, causal mechanisms). But the new rash of books and conferences on the issues AS raises have been very stimulating to me, and I'm finding that there are good reasons to support the idea of meso-level social causation. (See the "analytical sociology" thread for these postings.) I expect to do more on this topic in the coming year, including perhaps some more thinking about the issues raised by agent-based modeling.

And finally, there are more posts than in previous years on the issues of inequality and power that are creating more and more difficulty in our country. I think that is a reflection of real changes our society is experiencing: more inequality, more divisive rhetoric, and more racism. The number 1 post (in terms of direct visits) reflected this theme, "Inequalities and the ascendant right." (Interestingly, the number 1 post for subscribers this year was "Rawls on the EU," which represents the more philosophical side of these current issues.)

A fairly general but perhaps unexpected observation is that I've found myself looking back to classics in the social sciences over the past fifty years, and have found new things in these works that didn't catch my attention the first time I read them. This is true, actually, of the rereading I've done of Rawls. But posts on Chalmers Johnson, Herbert Simon, Steven Lukes, and Fritz Stern led me to think more fully about their ideas, and to see new insights that were probably there all along but not for me.

Readers come to the blog through two channels. Slightly more than half the visits to the blog are in the form of direct visits to the Blogger site itself, through searches, referrals, and direct links. And the remainder take the form of readers who use a blog reader or RSS feed to follow or subscribe to the blog. These views don't show up in the first measure. The first "channel" represents a broad population of occasional readers interested in a particular topic. The second represents a group of readers who have deliberately chosen to follow the blog.

The readership of UnderstandingSociety has continued to rise. There were 220,474 visits recorded directly to the site, and another 193,971 views through the RSS feed. About 50% of visits are from the United States, and the other half come from 194 countries and territories. There are about 2,000 readers who follow the blog automatically through an RSS feed, and there are over 1,600 people who follow on Facebook or Twitter. Thanks everyone!

The top ten posts written during this past year were:

Direct visits to the blog:

1 Inequalities and the ascendant right (2,501)
2 The math of social networks (2,451)
3 A jobless future? (2,051)
4 Diagrams and economic thought (1,992)
5 The history of economic thought and the present (1,850)
6 Rawls on political liberalism (1,788)
7 Quiet politics (1,747)
8 Violent rhetoric and violent behavior (1,734)

9 Income inequalities and social ills (1,417)
10 Bourdieu's field (1,414)

Views and clicks through the RSS feed (subscribers):

1 Rawls on the EU (2,313)
2 The math of social networks (2,170)
3 Democracy and contentious politics (2,152)
4 Hume as historian (2,150)
5 Quiet politics (2,076)
6 Herbert Simon's satisficing life (2,075)
7 Possessive individualism (2,074)
8 Education a leveler? (2,057)
9 Income inequalities and social ills (2,050)
10 Hate as a social demographic (2,041)

Interestingly, there are only three overlaps on the two lists – "The math of social networks," "Quiet politics," and "Income inequalities and social ills".

To the right is a link to a bookmarked PDF of the blog through July 2011. There will be an update after the beginning of January. I've spent some time on this part of the project because it gives expression to the "virtual book" part of my goal in the blog. By using the bookmarks organized into threads it is possible for the reader to look at all the postings on a certain general topic at once.

Thanks for reading, following, and sometimes commenting!

Beijing Forum 2011

Saturday, November 05, 2011

I'm attending the Beijing Forum 2011 this week, and it's a superb international conference. Much of the conference took place at Peking University. Over three hundred international scholars were invited to participate, and there are dozens of interesting conversations going on at any one time. The goal is to stimulate productive dialog among scholars from many nations about the issues of modernity and tradition we currently face, and the setting works. I've had very interesting discussions with scholars from Thailand, China, Angola, Laos, and Mexico, and it is very interesting to get the different perspectives that we all bring.

The focus is on academic perspectives and dialogues around the overarching theme of "The Harmony of Civilizations and Prosperity for All." This year's organizing theme is "Tradition and Modernity, Transition and Transformation." There are seven themes for the Forum's discussions this year:

- Change and Constancy: Historical Perspectives on the Way to Social Transformation
- Economic Growth in the Context of Globalization: Opportunities, Challenges and Perspectives
- Inheritance and Innovation in Education
- Transformation and Stability: Achievements and Challenges in Developing Countries
- Artistic Heritage and Cultural Innovation
- Urban Transformation and the Future of Mankind
- Deliberative Democracy and Social Harmony

Each group contains a distinguished selection of academics from around the world, heavily focused on European, American, and Asian scholars. (There were only six scholars from sub-Saharan Africa, and only two participants from Latin America.)

My paper, "Justice Matters in Global Economic Development," was included in the Economic Growth theme. I argued five basic points: We generally agree about the basics of a just society. The current state of the world badly contradicts those values (poverty, inequality, abuse and coercion). Amartya Sen's writings provide a powerful basis for those commonsense ideas about justice. The greatest impediment to improving justice is the untrammeled power private and state interests have vis-a-vis the poor. And injustice matters because it causes serious social problems. So states need to strive to reduce injustice.

I didn't really have a good sense of how the argument was received by the participants, but there was a fairly clear split between "laissez-faire" growth advocates and economists who took inequalities of income and health very seriously. I assume the latter group was more receptive than the former.

The academic question I received during the formal discussion period came from an American economist. He pointed out that China's 10% annual growth since the 1990s has greatly improved the standard of living for a hundred million people in coastal China, and created job opportunities for tens of millions of migrant workers. He wanted to know if I was seriously advocating a slower rate of growth as the price of greater justice. The question reflects the assumptions of many of the economists in the session: state policies aimed at enhancing equality are highly destructive to economic growth. So, by inference, preferring economic justice is harmful for a society.

My response, in a nutshell, was "yes". Economic development involves choices. And it is possible that a strategy with a lower growth rate would do a better job of bringing all of China up together, rather than creating a broadening gap between rural poor and affluent urban people. I am indeed arguing that it would be best to choose the second strategy. (This might take the form of investing a larger percentage of China's formidable savings and reserves in substantially enhanced public goods for the rural poor -- education, healthcare, and retirement.)

What is equally important, is that the power differential between poor people and propertied interests in China today almost guarantees that the poor will lose out. Property confiscations by businesses and municipal development authorities are a good example. (Coincidentally, the Thai urban planning expert I talked with said this is precisely the case in and around Bangkok, and the Angola urban planner made similar comments about Angolan farmers and the residual white settlers.) So injustice is as much about power as it is about exploitation. And this means that legal and institutional reforms are needed if China's inequalities are to be reduced.

It was striking to me that the thrust of my talk seemed to be most resonant with the Peking University students in the room. A cluster of them came over to talk about the implications of these ideas for China during the break. These young people seemed genuinely concerned about how China might address some of the large issues of social inequality that have arisen since the economic reforms began in the 1980s. (In fact, even some officials I've talked with here in China believe that more serious attention to justice issues is needed in China's future -- for example, with regard to China's rural poor and to migrant workers and their families.)

(The talk is included as a page on the list at right. I plan to post the bilingual PP as well.)

China's role in world history?

Wednesday, November 09, 2011

People sometimes want to make large statements about China's future in the coming fifty years. These range from a Sinocentric paen -- "The twenty-first century will be marked by a hegemonic China on the world stage", to the dubious -- "China's polity will ultimately shatter under the pressures of regional inequalities and competing political interests among elites." Generally speaking all these large claims seem a bit Hegelian to me; I don't think we can make large predictions about the course of world history. So I don't think that China's role is pre-ordained.

That said, a few things seem fairly clear in China's present, and these features have some implications for the future as well.

One is that China has embarked an a remarkable expansion of its university system in the past twenty years, and these efforts have turned the corner when it comes to the production of talented young people and significant, original innovations in science and technology. There are now something like 15 million university students in China, including a significant percentage in the elite national universities. This is something like a 15-fold increase in the past 30 years. China's research centers in many areas of technology and engineering are world-class today, and they are getting better every year. This means that China will have the talent needed to confront almost any large technological problem. Think of the Great Wall, planned and implemented by a million talented new engineering graduates. For example, the concentration on optoelectronics in Wuhan in universities, research centers, and private companies seems to make it highly likely that China will be a leader in this field in the future. So the idea that many in the West have that the universities in Europe, Australia, or North America are of higher quality, or that the research that takes place in the West is more innovative, seem to be based on wishful thinking rather than sober factual analysis. If the West has an edge in any of these areas today, it is one that is likely enough to disappear in the medium-term future.

It is also worth noting that there is a very high degree of exchange of talent between China and the West. Many of the scientists and leaders one meets in universities and research institutes have done some or all of their advanced training in the United States or the UK or have spent time there as post-doctoral students. I'm sure there are "styles" of Chinese research organization that are distinct from Western models. But there seems to be no reason at all to expect that the rate of new discovery in the future will be substantially different in the West and in China. And given that China is establishing a larger base of research resources, this seems to imply that the production of innovation will shift to China.

Second, and related to this first idea, China's leaders and guiding ministries are very deliberately seeking to steer China's economic activities up the value chain. Much of China's growth in the past thirty years was based on low-wage manufacturing. But China's leaders inside and outside of government are very explicit in their goals of shifting to higher-level goods and services -- exactly the areas where European and American leaders hope to dominate. Moreover, China seems to be much more deliberate than

Western governments about the need to invest in the infrastructure that will provide the basis of this transformation. China has invested massively in transportation, research centers, and universities throughout the country. These investments are synergistic: they make the next steps of high-end development multiplicative rather than additive. The coordination and cooperation that are facilitated by high-speed rail and air connections amplify the ability of researchers, planners, and entrepreneurs to bring their projects to completion. And the investment funds made available by further economic growth success in turn amplify the state's ability, and the growing private sector's ability, to make expanded investment in the following periods.

These factors would point us in the direction of expecting China to move to a position of global economic preeminence in a fairly short period of time. However, contemporary China has obstacles to further progress that are fairly large as well.

One of these handicaps is the governing party's fundamental view of the appropriate flow of information within society. The government seems to take the position that it needs to carefully manage the access to information that the public is able to gain. Its willingness to censor the Internet for its citizens is a symptom of this view. Chinese society would be stronger if there were a fundamental rethinking of openness about information. And eventually China's leaders will need to recognize that Chinese society is stronger, not weaker, when citizens can freely express their views and interests.

Second is the fact of persistent inequalities in Chinese society, by sector (rural-urban), by status (resident and well educated / migrant and poorly educated), and by region (coastal-western regions). These inequalities will eventually hold China back -- they reduce the talent pool and they stimulate resentment and disassociation among the disadvantaged groups.

Third, government non-accountability and its cousin, corruption, create serious obstacles to effective forward progress. The apparent problems of accountability and perhaps corruption that came to light in the railroad ministry a few months ago cast a shadow about the integrity of the rapid expansion of high speed rail -- from safety procedures to construction standards to administrative effectiveness. So more accountability and transparency will be needed in the future, or else China's major aspirations will be frustrated by ineffective implementation.

These are fairly systemic factors that seem likely to impede China's progress in the future. Here is a fact that will seem trivial by comparison, but I think it is not. It is the factor of traffic and pedestrian safety. Each city I've visited has a traffic environment that can only be described as barely constrained anarchy. Drivers cross four lanes of traffic to make an abrupt right turn; motor bikes roar up the inner lane in the wrong direction; traffic snarls to a stop when a bus gets sideways at an intersection; pedestrians try to make their way across eight lanes of non-stop vehicles; drivers hurtle towards pedestrians and bicyclists until they scatter. This sounds trivial (until you're caught in the middle of those eight lanes of traffic), but it seems to reflect a more basic and important fact. Doesn't sound urban planning involve careful design of a traffic system that keeps vehicles moving in the same direction; where pedestrians are largely separated from vehicles; and where signals and road design permit safe pedestrian crossing? And yet those rational plans seem not to have been developed in China's cities. One possible reason is that China's planners have simply not given sufficient priority to creating rules and structures that protect the public's interests -- whether in traffic control or in food safety. Build the buildings, stimulate the economic growth, and don't worry too much about the

consequences. If this is correct, it too indicates a feature that will interfere with China's future development.

In brief, contemporary China seems to display dynamic properties that point in contradictory directions. On the one hand, any visitor can see the dynamic, fast-moving creativity and intelligence that are transforming China and its universities and businesses. On the other hand, there are barriers to "business as usual" development that perhaps set limits to how much further China can go without some important reforms. And it's possible that the governing party may find those reforms to be unacceptable for one reason or another.

So the Owl of Minerva still has its wings quietly folded when it comes to China's role in future world history. It remains for China's people and its governing institutions to write the story.

Health disparities in the US and China

Sunday, November 13, 2011

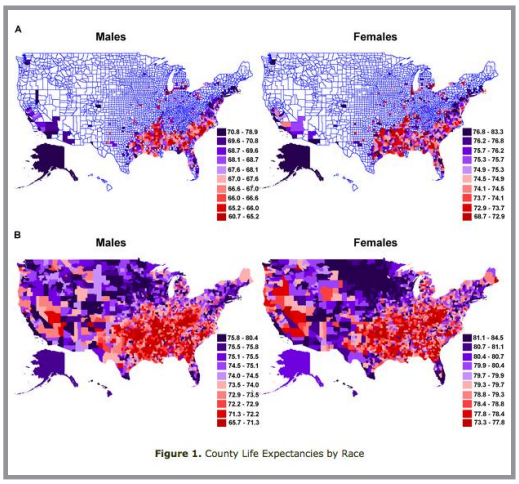


Figure 1. County Life Expectancies by Race

Health disparities across a population are among the most profound indicators of social inequalities that we can find. And the fact of significant disparities across groups is a devastating statement about the circumstances of justice under which a society functions. These disparities translate into shorter lives and lower quality of life for whole groups of people, relative to other groups.

Both the United States and China appear to display significant health disparities across their populations. Here are a couple of studies that draw attention to these facts.

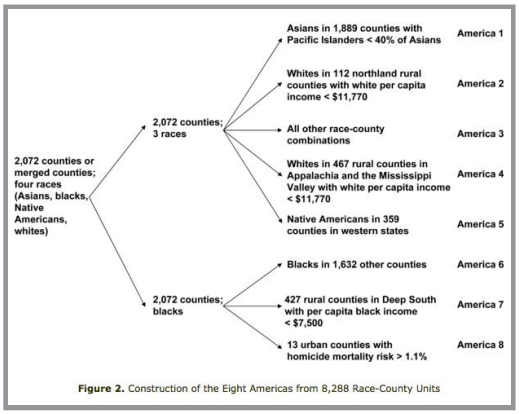

Figure 2. Construction of the Eight Americas from 8,288 Race-County Units

United States

Here is an important new study on the question of health disparities in the United States by public health researchers at Harvard and UCSF. The study is "Eight Americas: Investigating Mortality Disparities across Races, Counties, and Race-Counties in the United States". And the answer the researchers provide to the question above is that the US possesses very significant health disparities across segments of its population. The study is worth reading in detail.

The authors analyze mortality statistics by county, and they break the data down by incorporating racial and demographic characteristics. The data groups fairly well around the eight Americas mentioned in the title:

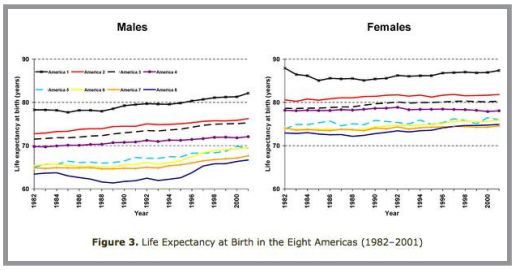

Figure 3. Life Expectancy at Birth in the Eight Americas (1982–2001)

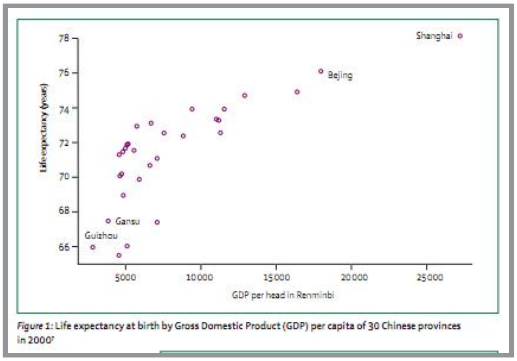

Figure 1: Life expectancy at birth by Gross Domestic Product (GDP) per capita of 30 Chinese provinces in 2000[7]

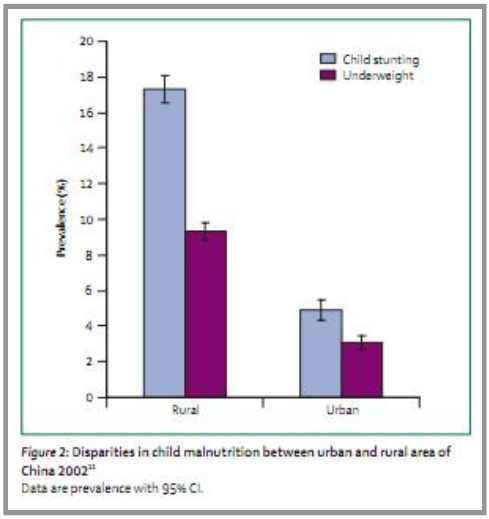

Figure 2: Disparities in child malnutrition between urban and rural area of China 2002[23]
Data are prevalence with 95% CI.

Here is how they describe their findings:

The gap between the highest and lowest life expectancies for race-county combinations in the United States is over 35 y. We divided the race-county combinations of the US population into eight distinct groups, referred to as the "eight Americas," to explore the causes of the disparities that can inform specific public health intervention policies and programs.

And here is their conclusion:

Disparities in mortality across the eight Americas, each consisting of millions or tens of millions of Americans, are enormous by all international standards. The observed disparities in life expectancy cannot be explained by race, income, or basic health-care access and utilization alone. Because policies aimed at reducing fundamental socioeconomic inequalities are currently practically absent in the US, health disparities will have to be at least partly addressed through public health strategies that reduce risk factors for chronic diseases and injuries.

For example, their data show that "the life expectancy gap between the 3.4 million high-risk urban black males and the 5.6 million Asian females was 20.7 y in 2001." This is an enormous difference in longevity for the two groups; and it is a difference that tags fundamental social structures that influence health and risk across these two populations.

Here is a time-series graph of the behavior of longevity for the eight Americas:

So what are the factors that appear to create these extreme differences in mortality across socioeconomic and racial groups in America? They consider health care access and utilization; homicide; accidents; and HIV as primary potential causes of variations in mortality for a group. Most important of all of these factors for the large populations appear to be the health disparities that derive from access and utilization. And here they offer an important set of recommendations:

Opportunities and interventions to reduce health inequalities include (1) reducing socioeconomic inequalities, which are the distal causes of health inequalities, (2) increasing financial access to health care by decreasing the number of Americans without health plan coverage, (3) removing physical, behavioral, and cultural barriers to health care, (4) reducing disparities in the quality of care, (5) designing public health strategies and interventions to reduce health risks at the level of communities (e.g.,

changes in urban/neighborhood design to facilitate physical activity and reduce obesity), and (6) designing public health strategies to reduce health risks that target individuals or population subgroups that are not necessarily in the same community (e.g., tobacco taxation or pharmacological interventions for blood pressure and cholesterol).
These findings are squarely relevant to assessing the justice of our society. The country needs to recognize the severity of the "health/mortality equity" issue, and we need to make appropriate policy reforms so that these disparities begin to lessen.

China

Several research papers address these issues for the case of China. One is a World Bank working paper by David Dollar called "Poverty, Inequality, and Social Disparities During China's Economic Reform" (link). Dollar notes that China has dramatically reduced its poverty rate over the past 25 years, whereas its income inequality measures have increased sharply during the same period. (Albert Park and Sangui Wang review the poverty statistics for this period in China Economic Review; link.) They conclude that these inequalities between rural and urban populations, and between well educated urban professionals and the urban working class, have also resulted in significant inequalities in health status and outcomes for the various sub-populations.

Shenglan Tank, Qingyue Meng, Lincoln Chen, Henk Bekedam, Tim Evans, and Margaret Whitehead review the current evidence available on health equity in China in "Tackling the challenges to health equity in China" (link). "Although health gains have continued, concern for the equitable distribution of social benefits of economic progress has grown" (25). Further:

Disparities in income and wealth between the urban and rural areas, between the eastern and western regions, and between households have widened substantially. In 1990, the richest province had a GDP per person more than seven times larger than the poorest province, but by 2002, the same ratio had grown to 13 times greater.41The Gini coefficient, a measure of income inequality,42increased for China as a whole from 0·31 in 1978–79 to 0·45 in 2004. The level of income inequality in China is now similar to that in the USA, roughly comparable to that in the most inequitable Asian countries—Philippines and Thailand—and approaching the notoriously inequitable levels in Brazil and Mexico. (29-30)
The authors quote Amartya Sen on health equity (Amartya Sen, Why health equity"; link):

Health equity cannot be concerned only with health in isolation. Rather it must come to grips with the larger issue of fairness and justice in social arrangements, including economic allocations, paying attention to the role of health in human life and freedom. Health equity is most certainly not just about the distribution of health, not to mention the even narrower focus on the distribution of health care. Indeed, health equity has an enormously wide reach and relevance.
And inequalities in personal income in different provinces lead to highly different levels of ability to fund public amenities in these provinces, with large effects on public health in poor provinces:

Living conditions differ greatly between areas of different affluence. Safe drinking water is available to 96% of the population of large cities but to less than 30% in poor rural areas. Differences in access to effective sanitation are even larger, 90% of residents in large cities have adequate sanitation, compared with less than 10% in poor rural areas (figure 6).

Two graphs capture the big picture:

In figure 1 the data demonstrate a strong correlation between life expectancy and average income for China's provinces and municipalities, from just about 65 years for the poorest regions to 78 years in Shanghai region. Figure 2 demonstrates major inequalities in child health between rural and urban locations. The authors further report that infant mortality also varies dramatically across regions: "Rural infant mortality rates are nearly five times higher in the poorest rural counties than in the wealthiest countries -- 123 versus 26 per 1000 live births, respectively" (26). One important source of data on these issues that these researchers use is the Chinese National Health Service survey of 1998; link.

The most detailed analysis of health disparities in China I've been able to find is a paper published in 2010 by Feinian Chen, Yang Yang, and Guangya Liu, "Social Change and Socioeconomic Disparities in Health over the Life Course in China: A Cohort Analysis" (link). They make use of the China Health and Nutrition Survey to allow for a longitudinal study of health in several segments of China's population. (Here is a description of the CHNS.) Their conclusion:

Using data from the China Health and Nutrition Survey, we find significant socioeconomic status (SES) differences in the mean level of health and that these SES differentials generally diverge over the life course. We also find strong cohort variations in SES disparities in the mean levels of health and health trajectories. (126)
It would appear that studies of health status in China disaggregated by population segments are not yet as fully developed as one would wish. The CHNS appears to have limited data coverage (much more limited than the national census, for example), and none of the studies mentioned in these articles appear to disaggregate down to levels lower than the province. But the summary findings of all three of these articles point in the same direction: it is probable that there are significant inter-regional and inter-sectoral inequalities in health outcomes for the sub-populations corresponding to these segments.

Neil Gross on mechanisms

Thursday, November 17, 2011

Neil Gross offers a friendly amendment to the growing literature on social mechanisms within sociology in "A Pragmatist Theory of Social Mechanisms" (link). He offers general support for the framework, but criticizes the main efforts at specifying what a social mechanism is. (James Mahoney makes a major effort to capture the main formulations in "Beyond Correlational Analysis"; link. Mahoney identifies 24 statements, all somewhat different.) Gross argues that the existing formulations are too tightly wedded to the metaphor of a physical mechanism -- for example, the cogs, gears, and springs of a clock. And the existing frameworks are too dependent on the assumption of rational actors, rather than a more fluid and relational understanding of social action. In some respects his arguments converge with those of Andrew Abbott considered in an earlier post.

The account of social mechanisms that Gross puts forward is a "pragmatist" theory. Here is how he puts the point in the paper's abstract.

Building on the insight increasingly common among sociological theorists -- that action should be conceptualized in terms of social practices -- I mobilize ideas from the tradition of classical American pragmatism to develop a more adequate theory of mechanisms. (358)

Gross praises the mechanisms approach for its ability to go beyond positivism in the philosophy of social science -- the general idea that social explanations depend on discovering strong social laws. But he finds the literature to be amorphous when it comes to definitions. He identifies five main themes:

1. Mechanisms as not necessarily observable structures or processes
2. Mechanisms as observable processes that do not require the positing of motives
3. Mechanisms as lower-order social processes
4. Mechanisms as triggerable causal powers
5. Mechanisms as transforming events (359-361)

Out of these themes Gross extracts a degree of consensus:

1. Social mechanisms are causal in that they mediate between cause and effect.
2. Social mechanisms unfold in time.
3. Social mechanisms are general, although in varying degrees.
4. Because a social mechanism is an intermediary process, it is necessarily composed of elements analyzed at a lower order of complexity or aggregation than the phenomenon it helps explain. (361-363)

He believes these four points capture the "theoretical consensus" that exists among the main expositions of the idea of a social mechanism. He then identifies several points of difference among these accounts:

1. Methodological individualism versus social ontologism.
2. Formal versus substantive mechanisms.
3. Analytical versus realist models. (363-364)

Now, finally, his own specific definition:

A social mechanism is a more or less general sequence or set of social events or processes analyzed at a lower order of complexity or aggregation by which -- in certain circumstances -- some cause X tends to bring about some effect Y in the realm of human social relations. This sequence or set may or may not be analytically reducible to the actions of individuals who enact it, may underwrite formal or substantive causal processes, and may be observed, unobserved, or in principle unobservable. (364)

A key part of Gross's critique of existing expositions of the social mechanisms approach, largely within the framework of analytical sociology, is the reliance these researchers make on the framework of rational choice theory. Gross believes this is too narrow an understanding of human action, and therefore serves poorly as a foundation for our thinking about real social mechanisms. Gross prefers a "pragmatist" understanding of action and actors, one that is closer to the field of symbolic interactionism than to economics. This approach links action to "practices" and habits more fundamentally than to means-end rationality and goal-seeking behavior. "Pragmatists maintain that instrumental rationality itself, when it does appear, is a kind of habit, a way that some humans can learn to respond to certain situations, and that we should be as interested in the historical processes by which the habit of rationality -- in its various forms -- develops and is situationally deployed as we should be in its effects" (367).

Gross brings these ideas about action and practice into the mechanisms framework with this basic idea.

Pragmatists would view social mechanisms as composed of chains or aggregations of factors confronting problem situations and mobilizing more or less habitual responses. (368)

This approach understands action as more fluid and interactive than deliberative and pre-planned. And it emphasizes the contingency of interactions with other actors that influence the development and unfolding of the swirl of activity and the constitution of the actor him/herself.

Fundamentally Gross's critique comes down to a plea for a better understanding of social action itself, and of the actor, than the mechanisms approach is inclined to offer. And the framework within which to conceptualize action that he prefers is one that derives from inter-action, spontaneity, and adjustment as much as (more than?) the deliberative and calculating processes postulated by rational-actor models.

I think that Gross's approach is fairly consonant with that taken by Chuck Tilly and Doug McAdam in various places. McAdam, Tarrow and Tilly emphasize the "relational" nature of social action in Dynamics of Contention. And here is a nice statement of McAdam's summary view of social action in Political Process and the Development of Black Insurgency, 1930-1970.

One of the virtues of the perspective sketched here is that it is as amenable to the analysis of routine as to that of contentious politics. Too often analysts have reified the distinction between routine politics and social movements, revolutions and the like, and have wound up proposing separate theories to account for the two phenomena. Since I see the latter as almost always growing out of and often transforming the former, I am motivated to propose a framework that is equally adept at explaining both. (xvii)

The account of contentious politics that McAdam favors considers four ideas:

1. Exogenous change processes.
2. Interpretive processes and the collective attribution of opportunity/threat.
3. Appropriation of existing organizational space and routine collective identities.
4. Innovative collective action and the onset of contention. (xvii-xxviii)

This account emphasizes much of Gross's agenda as well: adaptiveness, contingency, a fluid definition of action through inter-action with other actors, and the significance of culture and identity in action.

SSHA 2011

Saturday, November 19, 2011

As always, the Social Science History Association meeting in Boston is brimming with great sessions across a wide range of topic areas. There is evidence of lots of new thinking about the intersections of the social science disciplines and various fields of historical research. Here is the SSHA's description of its mission:

The Social Science History Association is an interdisciplinary group of scholars that shares interests in social life and theory; historiography, and historical and social-scientific methodologies. SSHA might be best seen as a coalition of distinctive scholarly communities. Our substantive intellectual work ranges from everyday life in the medieval world – and sometimes earlier -- to contemporary global politics, but we are united in our historicized approach to understanding human events, explaining social processes, and developing innovative theory.

The term “social science history” has meant different things to different academic

generations. In the 1970s, when the SSHA's first meetings were held, the founding generation of scholars took it to reflect their concern to address pressing questions by combining social-science method and new forms of historical evidence. Quantitative approaches were especially favored by the association's historical demographers, as well as some of the economic, social and women's historians of the time. By the 1980s and 1990s, other waves of scholars – including culturally-oriented historians and anthropologists, geographers, political theorists, and comparative-historical social scientists -- had joined the conversation.

New intellectual directions continue to emerge at the outset of the 21st century. Today's SSHA incorporates a diversity of scholarly styles, with lots of crosstalk among them.

One of the special values of SSHA is the emphasis given to interdisciplinarity. It is a principle of the organization that panels should contain papers by scholars from different disciplines (and different institutions). Why is this valuable? For several reasons. First, every discipline develops a degree of myopia when it comes to the definition of problems and methods. And yet the big questions we would like to address historically do not divide neatly along the domains of the disciplines. Politics, family, culture, environment, markets, warfare -- these all correspond to different disciplines. And yet real historical Burma or France unavoidably involves all of them. So bringing the perspectives of specialists in economics, cultural studies, and population history into productive interaction in connection with a question like "Why and how did France become "France?"" is profoundly creative. It leads us to a significantly broader view of the problem, the processes, and the methods that might illuminate.

The other distinctive feature of SSHA, going back to its establishment in the 1970s, is the conviction that the social sciences are deeply relevant to historical understanding. Sometimes this conviction has led to a cliometric impulse -- an emphasis on quantitative social history. But it has also been very receptive to qualitative and comparative approaches to historical research as well.

Andrew Abbott describes some of the intellectual and institutional currents that led to this emphasis within and around the history profession and historical sociology in *Chaos of Disciplines*.

Another great benefit that derives from participating in SSHA is the renewing exposure it permits to brilliant, innovative young scholars in a variety of fields of theory and research. It is so encouraging to see many young scholars whose work goes significantly beyond existing standard approaches. Sometimes PhD students seem excessively beholden to the ideas of their teachers. In the past several years I've been very pleased to see confident innovation and creative thinking by the coming generation of scholars in many of the fields of social and historical research. A good example is a couple of papers on the subject of processes and temporality by Tulia Falleti ("Decentralization in Time: A Process-Tracing Approach to Federal Dynamics of Change") and Matthew Norton ("Processual and Situational Temporalities in Sociological Explanations"). Isaac Reed is another good example of an innovative young scholar who is offering fresh ideas into debates about theory and social science. His recent *Interpretation and Social Knowledge*, on display at the book exhibit, is a rigorous, fresh approach to post positivist philosophy of social science.

SSHA has been a leader in bringing Geographical Information Systems (GIS) into concrete applications in historical research, and there were a number of panels using this technology with great effectiveness. The Interdisciplinary Consortium for Social and Political Research (ICPSR) is a longstanding partner with SSHA, and there were a

number of sessions that illustrated the value of the large databases and advanced historical methods that ICPSR has championed for years. The current president of SSHA, George Alter, is a distinguished historical demographer and also serves as director of ICPSR at the University of Michigan. I'm looking forward to his address later today, "Life Course, Family, and Community." Historical demography is a longstanding area of focus for scholars within the SSHA orbit.

Some new concepts and methods that are visible in this year's program include application of social network analytical tools to historical topics; new thinking about temporality and events; steady progress on large studies of population history; new thinking about colonialism and post-colonialism; and new ideas about comparative economic history across Eurasia. The language of causal mechanisms is showing up much more frequently across panels than I've noticed in previous years.

The Association's journal, Social Science History, reflects many of the strengths of the organization.

Beyond divergence

Sunday, November 20, 2011

As I've noted in previous posts, there has been a major debate in economic history in the past 20 years about what to make of the contrasts between economic development trajectories in Western Europe and East Asia since 1600. There had been a received view, tracing to Adam Smith and Thomas Malthus, that European "breakthrough" was the norm and Asian "stagnation" or "involution" were the dysfunctional cases. E. L. Jones represents this view among recent comparative economic historians (The European Miracle: Environments, Economies and Geopolitics in the History of Europe and Asia).

Then Kenneth Pomeranz and Bin Wong challenged this received view in a couple of important books. Pomeranz argued in The Great Divergence: China, Europe, and the Making of the Modern World Economy. that the premises were wrong. He argued that Chinese productivity and standard of living were roughly comparable to those of England up to roughly 1800, so China's economy was not backward. And he argued against the received view's main theories of Europe's breakthrough -- the idea that European economic institutions and property rights were superior, or the idea that Europe had a normative or ideological advantage over China. Instead, he argued that Europe -- Britain, to be precise -- had contingent and situational advantages over Asia that permitted rapid growth and industrialization around the end of the eighteenth century. These advantages included large and accessible coal deposits -- crucial for modern steam technology -- and access to low cost labor in the Americas (hidden acreage). Bin Wong made complementary arguments in China Transformed: Historical Change and the Limits of European Experience, where he addressed the parallel processes of development of political and economic institutions in the two sets of polities. Wong's most fundamental insight was that both processes were complex, and that balanced comparison between them is valuable.

Now the debate has taken a new turn with the publication of R. Bin Wong and Jean-Laurent Rosenthal's Before and Beyond Divergence: The Politics of Economic Change in China and Europe. Rosenthal is an accomplished historian of European economic development, and Wong is an expert on Chinese economic, social, and political history. So their collaboration permits this book to bring together into one argument the full

expertise available on both ends of Eurasia.

The book aims to unsettle the debate in fundamental ways. Wong and Rosenthal take issue with a point that is methodologically central to Pomeranz, concerning the units of comparison. Pomerantz wants to compare England with the lower Yangzi region in China, and he gives what are to me convincing arguments for why this makes sense. W&R want to compare Europe with China, making England a special case. And they too have good reasons for their choice.

Second, they disagree with the temporal framing that has generally been accepted within this debate, where economic historians have generally focused their research on the early modern period 1600-1900). Against this, they argue that the causes of divergence between Europe and China must be much earlier. They set their clock to the year 1000, and they examine the large features of political and economic development that started around that time.

Finally, they offer crippling objections to a number of standard hypotheses about Imperial China as a place to do business. They show that there were alternative credit institutions available in Ming and Qing China. They show that the Chinese state was sensitive to levels of taxation, and kept taxes low (generally comparable to European levels). And they show that Imperial social spending (the granary system, for example) was generally effective and well managed, contributing to economic prosperity. So the traditional explanations for Chinese "stagnation" don't work as causal explanations.

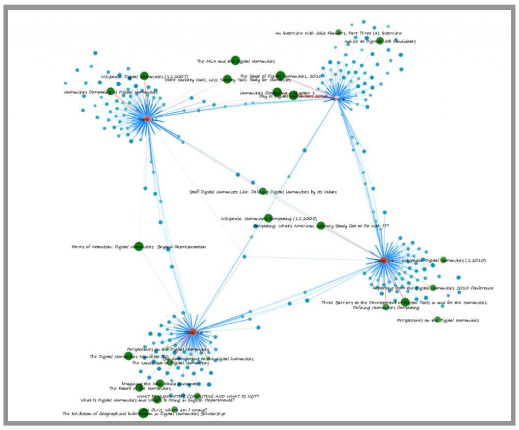
They find one major difference between Europe and Asia during the first part of the second millennium that seems to matter. That is the multiplicity of competing states in Europe and a largely hegemonic Imperial state in China and the scale of the relevant zones of political and economic activity. Chapter 4, "Warfare, Location of Manufacturing, and Economic Growth in China and Europe," lays out this argument. Here are the key points.

We believe that the most persuasive explanation for Europe's late eighteenth- and early nineteenth-century transformations is best provided by comparing the politics of economic change within China and Europe in the centuries that preceded their visible economic divergence. (6)

To explain these differences in factor prices, we will stress conditions that are the outcomes, we will argue, of more basic differences in the spatial scale of polities in China and Eu rope. In this analysis we parallel Robert Allen's recent work on the progress of industrialization in England (2009a). Indeed, Allen puts special emphasis on relatively high wages and low fuel costs in explaining why the technologies we as-sociate with industrialization were developed and deployed in England. (7)

From the perspective of what individuals choose, we think that some of the most important factors influencing different likelihoods of economic change in the early modern era were unintended consequences of actions taken for reasons largely unrelated to improving the economy. (8)

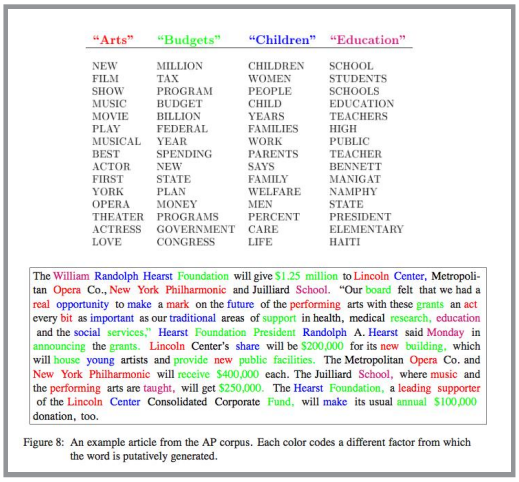
Instead, we take the contrasting spatial scales of Chinese and Europe an polities as key factors that both let and led rulers in these regions to develop different political priorities and policies. (14)
The competing states of Europe were frequently drawn into conflict; and conflict often



resulted in warfare. R&W argue that this fact of competition had a fateful unintended consequence. It made fortified cities much safer places than open countryside. And this in turn changed the calculation about where "manufacture" could occur at lowest cost. Labor costs were higher in cities, so absent warfare, producers were well advised to pursue a putting-out system involving peasant workers (proto-industrialization; link). But with the threat of marauding armies, European producers were pushed into urban locations. And this in turn gave them incentives to develop labor-saving, capital-intensive techniques. Putting the point bluntly: China didn't have an industrial revolution because it was too safe an environment for labor-intensive production.

Another important feature of *Before and Beyond Divergence* is its use of simple economy models to explore the incentive characteristics of various historical circumstances. For example, they provide a simple representation of the costs of contracting in China (76-77), the costs of warfare on manufacturing (108-109), and a mathematical analysis of credit and interest in China (135). Their perspective is one that essentially presupposes the idea of decision-making based on prudence, or a rough-and-ready rational choice framework. They believe that various historical circumstances change the price and opportunity environment for producers and consumers. So once we can estimate the magnitude of these changes, we can also gauge the approximate magnitude of the change in behavior that results. Or in other words, their approach is one of ***economic*** historians, not simply historians of economic institutions and behaviors. They are reluctant to consider cultural or normative sources of behavior.

Certainly this book too will generate a lot of critical response. It is an important contribution.



New tools for digital humanities

Tuesday, November 22, 2011

One of the innovative papers I heard at the SSHA last week was a presentation by Harvard graduate student Ian Miller, with a paper called "Reading 500 Years of Chinese History at Once". (In the end Ian apologized for only getting to the last 188 years of the Qing Dynasty.) I won't mention the details, since Ian hasn't yet published any of this work. But it was a genuinely fascinating exploration of emerging tools in the "digital humanities," to apply topic analysis to a 188-year series of Imperial memoranda. Ian's goal was to identify spikes of interest in topics such as rebels and bandits, and the work was really fascinating to hear about. (Here are a couple of interesting pages on digital humanities; link, link.)

The basic insight that is leading to new research in digital humanities is the fact that vast quantities of texts are now available for quantitative analysis. Humanists typically work with texts, and up till now their approaches have largely taken the form of close readings and semantic interpretations. Now that much of the published corpus of humanity is available in digital form thanks to the Google Books project, and now that many archives

The William Randolph Hearst Foundation will give $1.25 million to Lincoln Center, Metropolitan Opera Co., New York Philharmonic and Juilliard School. "Our board felt that we had a real opportunity to make a mark on the future of the performing arts with these grants an act every bit as important as our traditional areas of support in health, medical research, education and the social services," Hearst Foundation President Randolph A. Hearst said Monday in announcing the grants. Lincoln Center's share will be $200,000 for its new building, which will house young artists and provide new public facilities. The Metropolitan Opera Co. and New York Philharmonic will receive $400,000 each. The Juilliard School, where music and the performing arts are taught, will get $250,000. The Hearst Foundation, a leading supporter of the Lincoln Center Consolidated Corporate Fund, will make its usual annual $100,000 donation, too.

are steadily moving their ephemera to digital versions as well, it is possible for humanities researchers to broaden their toolkit and look for patterns among these published and unpublished texts. Google's NGrams tool allows all of us to do some of this kind of work (link, link), but more specialized tools for statistical analysis and presentation are needed if we are to go beyond compiling of changing frequencies of specific terms.

Statistical techniques for discovering "topics" in documents represent a crucial step forward in this endeavor. As Nelson Goodman noted in a pre-digital time, knowing what a text is "about" requires more than simply knowing what words are included in the document in what frequencies (Problems and Projects). We might have said at that point in the 1960s, that what we need beyond the syntax and the list of terms, is "understanding", an irreplaceably human capability. But a central task for web-based search arises from exactly this issue, and a great deal of research has been done to attempt to do a better job of discovering the "topics" that are central in a given document without invoking a human reader. And surprisingly enough, real progress has been made. This progress is at the heart of the digital humanities. The fundamental problem is this: are there statistical methods that can be used to analyze the frequency of the words included in a given document to provide a compressed analysis of the "topics" included in the document? We might then say that this compressed representation is a good approximation to what the document is "about".

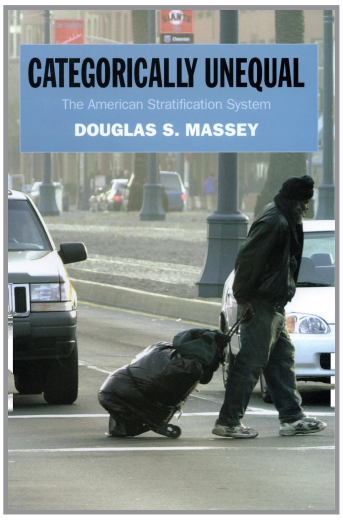
A theoretical advancement, and corresponding set of tools, that is frequently invoked in research projects in this field is a "latent Direchet allocation" (LDA), a statistical technique for using word frequencies in a document to sort out a smaller set of topics. David Blei, Andrew Ng, and Michael Jordan introduced the idea in 2003 (link). (There is a detailed and technical description of the model in Wikipedia; link.) They indicate that this method is similar to algorithms based on "latent semantic indexing". Here is how Blei, Ng, and Jordan describe the approach in the abstract to this paper:

We describe latent Dirichlet allocation (LDA), a generative probabilistic model for collections of discrete data such as text corpora. LDA is a three-level hierarchical Bayesian model, in which each item of a collection is modeled as a finite mixture over an underlying set of topics. Each topic is, in turn, modeled as an infinite mixture over an underlying set of topic probabilities. In the context of text modeling, the topic probabilities provide an explicit representation of a document. We present efficient approximate inference techniques based on variational methods and an EM algorithm for empirical Bayes parameter estimation. We report results in document modeling, text classification, and collaborative filtering, comparing to a mixture of unigrams model and the probabilistic LSI model.

And here is their statement of the goal of LDA analysis:

The goal is to find short descriptions of the members of a collection that enable efficient processing of large collections while preserving the essential statistical relationships that are useful for basic tasks such as classification, novelty detection, summarization, and similarity and relevance judgments. (993)

And here is a summary assessment of the effectiveness of the LDA representation of a set of documents relative to a less compressive representation:



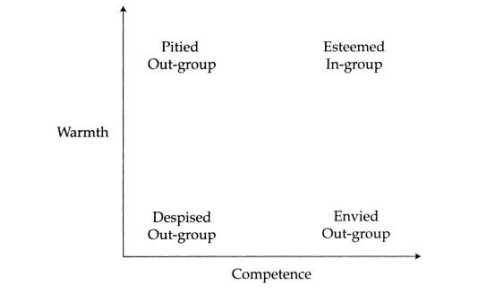
We see that there is little reduction in classification performance in using the LDA-based features; indeed, in almost all cases the performance is improved with the LDA features. Although these results need further substantiation, they suggest that the topic-based representation provided by LDA may be useful as a fast filtering algorithm for feature selection in text classification. (1013)
Here is a table they provide illustrating the kind of topic analysis that this statistical methodology creates:

In some ways the type of application that Ian Miller is making of these tools seems ideal. This kind of statistical methodology can be applied to very large databases of historical texts in order to discover patterns that the authors of those texts would have been entirely unaware of. So methods like LPA seem well designed to uncover historically shifting patterns of topic emphasis by observers and policy makers over time and space.

This is just a first cut for me on the kind of reasoning and statistical analysis that information theorists are employing to do semantic analysis of documents, and I certainly don't have a good understanding of how this works in detail. The power of these frameworks seems very great, though, and well worth studying in greater detail by historians and humanists.

Race and American inequalities

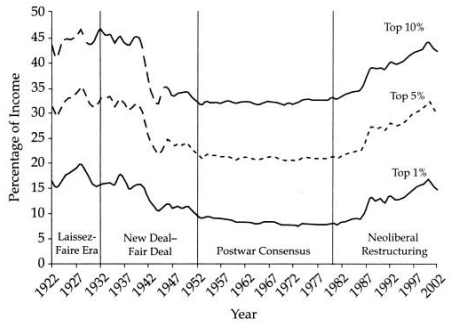
Friday, November 25, 2011



Douglas Massey is a leading US social scientist who has worked on issues of inequality in America throughout his career. His 2008 book (Categorically Unequal: The American Stratification System) is a huge contribution to our understanding of the mechanisms producing inequalities in American society, and it amounts to a stunning indictment of racism and anti-poor public policies over a seventy-five year period. And, unlike other interpretations that attribute current racial inequalities to ***past*** patterns of overt discrimination, Massey argues that these inequalities can be traced to current discrimination by individuals and institutions alike. (An earlier book, American Apartheid, co-authored with Nancy Denton, is also very important.)

Massey is interested in a specific kind of inequality -- what he refers to as "categorical" inequality. "All human societies have a social structure that divides people into categories based on a combination of achieved and ascribed traits" (1). The kinds of categories he cites include gender, race, age, and membership in exclusive social organizations. Categorical inequality, then, is defined as inequalities of income, wealth, or influence that vary systematically with membership in social categories.

How does categorical inequality work? Massey has a simple answer to this question:



Given socially defined categories and people being distributed among them, inequality is

Figure 1.1 The Stereotype Content Model

generated and perpetuated by two basic mechanisms: exploitation and opportunity hoarding (Tilly 1998). *Exploitation* occus when people in one social group expropriate a resource produced by members of another social group and prefent them from realizing the full value of their effort in producing it. *Opportunity hoarding* occurs when one social group restricts access to a scarce resource, either through outright denial or by exercising monopoly control that requires out-group members to pay rent in return for access. Either way, opportunity hoarding in enabled through a *socially defined process of exclusion*. (6)

Massey leads off his analysis with a theory of the social psychology of racism and discrimination against poor people. He argues that the stereotyping that is inevitably associated with social cognition leads to a pattern of discrimination against African-Americans, immigrants, women, and poor people that deepens and entrenches their unequal shares in American society. The twin mechanisms of discrimination and opportunity-hoarding both flow on the basis of the categories of discrimination created by these mental constructs – hence "categorical inequality". (Visit a recent posting for a related argument about the social psychology of prejudice.)

In a very real way, stratification begins psychologically with the creation of cognitive boundaries that allocate people to social categories. Before categorical inequality can be implemented socially, categories must be created cognitively to classify people conceptually based on some set of achieved and ascribed characteristics. The roots of social stratification thus lie ultimately in the cognitive construction of boundaries to make social distinctions, a task that comes naturally to human beings, who are mentally hardwired to engage in categorical thought (Fiske 2004). (8)

People use schemas to evaluate themselves and the social roles, social groups, social events, and individuals they encounter, a process known as social cognition (Fiske 2004). The categories into which they divide up the world may change over time and evolve with experience, but among mature human beings they always exist and people always fall back on them when they interpret objects, events, people, and situations (Fiske 2004). (9)

Massey hypothesizes two dimensions of mental categorization, leading to four gross

categories of people in one's social category scheme: warm-cold (appealing-unappealing) and competent-incompetent. People who are like us are considered "warm" and "competent". The other three quadrants are categorized as "other": warm but incompetent (pitied), competent but cold (envied), and incompetent and cold (despised). And he asserts that American racism places African-Americans in the final category. This in turn is used to explain the harshly negative tilt that US legislation has shown across lines of race and poverty.

Massey argues that these cognitive mechanisms work at a pre-conscious level, and are operative even in the behavior and choices of people who consciously experience their values as democratic and egalitarian. These patterns of ongoing discrimination reinforce and reproduce social institutions that assign very different outcomes to African-Americans, poor people, and other dis-valued people. This works itself out in employment, advancement in a career, access to healthcare, and public policy and legislation.

A particularly valuable part of the book is the mass of elegant graphs that Massey has assembled. These represent an eye-opening narrative of discriminatory public policy over almost a century of legislation. Here is a series of graphs of income inequality over parts of the twentieth century:

The crux of Massey's analysis here is that inequalities of wealth and income are generated by several mechanisms; but that key among these are the forms of discrimination that find their roots in social psychology and become operative through policy and law. The gap between white and black median household income documented in figure 2.2 begins in the 1970s at about $20,000 and remains roughly that magnitude through 2002. And these household income inequalities are created, he argues, through a complex of institutions (economic and political) that serve to compound discrimination and the disadvantages experienced by "out" groups. Moreover, these institutions work to the benefit of the privileged as strongly as they work to the harm of the disadvantaged; so the institutions are unlikely to change. "In other words, whether whites care to admit it or not, they have a selfish interest in maintaining the categorical mechanisms that perpetuate racial stratification. As a result, when pushed by the federal government to end overt discriminatory practices, they are likely to innovate new and more subtle ways to maintain their privileged position in society (Massey 2005c)" (54). This is a gloomy conclusion, and one that argues strongly for a passionate and sustained commitment to remedying the stark racial inequalities that exist in our society.

(Massey refers frequently to Susan Fiske's 2004 book, Social Beings: Core Motives in Social Psychology. Here is a short article by Mary Wheeler and Susan Fiske that lays out some of their research on racial prejudice.)

David Graeber's reflections on money, debt, and violence

Wednesday, November 30, 2011

David Graeber's Debt: The First 5,000 Years has hit a chord with a lot of people who are concerned about rising inequalities in the United States and elsewhere. Graeber is an economic anthropologist, a discipline that pays close attention to the ways that material arrangements worked in detail in pre-state societies. One of the great works in this field is Marshall Sahlins' book, Stone Age Economics, which paid very close ethnographic attention to how the social arrangements worked in hunter-gatherer societies when it came to gathering and consuming food and other necessities of life. (My main recollection is that Sahlins found that hunter-gatherers worked much shorter days than their successors, the farmers, and had much more time to enjoy the finer things of life, including stories and jokes.) Graeber is also described as one of the intellectual sources of the Occupy Wall Street movement, and anti-globalization activism has been an important part of his life for a long time. (Here is a story in Bloomberg that gives a lot of interesting background.)

The book is difficult to characterize. It's about debt and money through history, but it's really not a work in economic history. It offers a lot of ethnographic detail about borrowing, lending, gifting, and reciprocating, but it's not really a work of anthropology. And it offers morally valenced language to describe debt and credit, but it's not really a polemical critique of the present financial system. It is certainly an engaging, interesting, and thought-provoking book, and Graeber appears to know a great deal about the social and institutional histories of the main civilizations of Eurasia.

One line of thought is perfectly clear in the book: Graeber wants to demolish the myth of the truck-and-barter origins of money. This is the standard story within classical and neoclassical economics. But Graeber thinks it is a complete fiction. He regards this as a just-so story that doesn't make any sense ethnographically, and has never been observed in real pre-state societies.

The story, then, is everywhere. It is the founding myth of our system of economic relations. It is so deeply established in common sense, even in places like Madagascar, that most people on earth couldn't imagine any other way that money could possibly have come about.

The problem is there's no evidence that it ever happened, and an enormous amount of evidence suggesting that it did not. (28)
Graeber's case for this position seems to be a sound one. But why exactly does it matter? It seems to be a bit analogous to literal-minded social contract arguments: that the state is legitimate because it descends from a primordial agreement among all citizens to create its authority. But discrediting the origins story doesn't really tell us anything about the functioning system. We have an economic system today that coordinates activity through money and credit, and it doesn't really matter very much if we

know exactly how it came about. I think that Graeber is focused on the issue because he thinks the myth helps to convey the view that the contemporary economist's view of human activity -- self-serving actions designed to maximize one's own utility -- is in fact an historical universal, applying to pre-modern and non-western social settings as well as to the New Orleans cotton exchange.

It's money that had made it possible for us to imagine ourselves in the way economists encourage us to do: as a collection of individuals and nations whose main business is swapping things. (44)
Graeber's view, by contrast, is that most human activity doesn't conform to this model; that the gift relation and the practice of open-ended reciprocity are much more characteristic of the human condition.

There are many startling facts and descriptions that Graeber produces as he tells his story of the development of the ideologies of money, credit, and debt. One of the most interesting to me has to do with *The Wonderful Wizard of Oz*.

L. Frank Baum's book *The Wonderful Wizard of Oz*, which appeared in 1900, is widely recognized to be a parable for the Populist campaign of William Jennings Bryan, who twice ran for president on the Free Silver platform -- vowing to replace the gold standard with a bimetallic system that would allow the free creation of silver money alongside gold. ... According to the Populist reading, the Wicked Witches of the East and West represent the East and West Coast bankers (promoters of and benefactors from the tight money supply), the Scarecrow represented the farmers (who didn't have the brains to avoid the debt trap), the Tin Woodsman was the industrial proletariat (who didn't have the heart to act in solidarity with the farmers), the Cowardly Lion represented the political class (who didn't have the courage to intervene). ... "Oz" is of course the standard abbreviation for "ounce." (52)
(This is roughly as startling to me as an interpretation of Star Wars as an extended allegory on Reaganism (intervention in Nicaragua, scary military officers in the background, etc.). This doesn't quite work, though, since Star Wars appeared in 1977, three years before Reagan's first election as president.)

One of Graeber's recurring themes is that money and debt are reciprocals of each other. He tells many stories about IOU's being passed around within a community: John promises to give X to Alice; Alice passes on the IOU to Robbie in exchange for a beer; Robbie takes the IOU to the nail shop and exchanges it for a pound of nails from Bert; and Bert eventually comes back to John to redeem the IOU. In this circuit, the statement of debt serves as a basis for folk currency within a local society. But Graeber argues that the establishment of Bank of England resulted in bank notes that were no more or less than IOU's from the state (49).

Another theme that comes into the book is the close connection that Graeber draws between money and currency, and violence and war. He argues that trust and extended credit arrangements work very well during periods of peace; whereas a period of extended warfare puts a premium on the portability and anonymity of precious metals. So warfare pushes societies (and monarchs) towards the use of currency made out of precious metals. He goes further: monarchs needed to pay their armies, in Europe, central Asia, and East Asia; and precious metals (coins) work best for the heavily armed and footloose soldiers who made up those armies.

As a result, while credit systems tend to dominate in periods of relative social peace, or

across networks of trust (whether created by states or, in most periods, transnational institutions like merchant guilds or communities of faith), in periods characterized by widespread war and plunder, they tend to be replaced by precious metal. (213)
And:

The Atlantic Slave Trade as a whole was a gigantic network of credit arrangements. Ship-owners based in Liverpool or Bristol would acquire goods on easy credit terms from local wholesalers, expecting to make good by selling slaves (also on credit) to planters int he Antilles and America, with commission agents in the city of London ultimately financing the affair through the profits of the sugar and tobacco trade. (149)
Graeber has a preferred alternative to a society based on barter, market exchange, debt, warfare, slavery, and peonage. It is what he calls a "human economy":

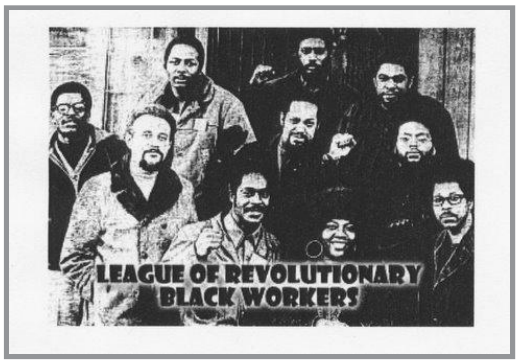
This is why I developed the concept of human economies: ones in which what is considered really important about human beings is the fact that they are each a unique nexus of relations with others -- therefore, that no one could ever be considered exactly equivalent to anything or anyone else. In a human economy, money is not a way of buying or trading human beings, but a way of expressing just how much one cannot do so. (207)
An intriguing, and somewhat perplexing, part of Graeber's analysis is his effort to link the value systems of Eurasia's great civilizations to the social creation of money, credit, and debt. A central thrust here is his analysis of the "Axial Age" -- the period from 800 bc to 600 ad when there was great creativity in the emergence of new spiritual leaders and movements. There was, simultaneously, extensive warfare; and there was the simultaneous invention of currency in several widely separated places. He illustrates this nexus with the case of China:

The golden age of Chinese philosophy was the period of chaos that preceded unification [during the Warring States period], and this followed the typical Axial Age pattern: the same fractured political landscape, the same rise of trained, professional armies and the creation of coined money largely in order to pay them. We also see the same government policies designed to encourage the development of markets, chattel slavery on a scale not seen before or since in Chinese history, the appearance of itinerant philosophers and religious visionaries, battling intellectual schools, and eventually, attempts by political leaders to transform the new philosophies into religions of state. (235)
So what is the connection he wants to draw between value systems, social violence, and money? It is unclear to me; somehow Graeber weaves together a fascinating narrative involving each of these. He does think there is a connection, but it's difficult to see what is thought to be causal in the story.

In fact, some of the historical connections are so uncannily close that they are very hard to explain any other way. Let me give an example. After the first coins were minted around 600 bc in the kingdom of Lydia, the practice quickly spread to Ionia, the Greek cities of the adjacent coast. The greatest of these was the great walled metropolis of Miletus, which also appears to have been the first Greek city to strike its own coins. It was Ionia, too, that provided the bulk of the Greek mercenaries active in the Mediterranean at the time, with Miletus their effective headquarters. Miletus was also the commercial center of the region, and perhaps, the first city in the world where everyday market transactions came to be carried out primarily in coins instead of credit. Greek philosophy, in turn, begins with three men: Thales, of Miletus (c. 624 bc- c546 bc), "Anaximander, of Miletus (c. 610 bc- c546 bc), and Anaximenes, of Miletus (c. 585 bc- c525 bc) -- in other words, men who were living in that city at exactly the time that coinage was first

introduced. (244)
He pulls out "materialism" as a thread in the philosophical systems that emerged in the Axial Age -- China as well as Greece -- and suggests an analogy between the idea of an abstract fundamental physical substance that is the substrate of everything physical, and the idea of an abstract unit of measure of all commodities, money (245); but it's hard to see a consistent and compelling idea here about the intertwining development of philosophy and economics. Here is the closest he comes to a statement of the nature of the connection he finds:

What we see then is a strange kind of back-and-forth, attack and riposte, whereby the market, the state, war, and religion all continually separate and merge with one another. (248)
Where does it all lead? After a walk through the Middle Ages (major improvement in quality of life over the Axial Age, according to Graeber), we get to capitalism:



Starting from our baseline date of 1700, then, what we see at the dawn of modern capitalism is a gigantic financial apparatus of credit and debt that operates -- in practical effect -- to pump more and more labor out of just about everyone with whom it comes into contact, and as a result produces an endlessly expanding volume of material goods. (346)
Does he bring this parable to a practical piece of advice? He does, actually:

In this book I have largely avoided making concrete proposals, but let me end with one. It seems to me that we are long overdue for some kind of Biblical-style Jubilee: one that would affect both international debt and consumer debt. It would be salutary not just because it would relieve so much genuine human suffering, but also because it would be our way of reminding ourselves that money is not ineffable, that paying one's debts is not the essence of morality, that all these things are human arrangements and that if democracy is to mean anything, it is the ability to all agree to arrange things in a different way. (390)
As I mentioned at the start, Graeber is also an activist who has been strongly involved in anti-globalization protests in the past fifteen years. His Direct Action: An Ethnography is an interesting cross-over book bringing together his anthropologist's training and his activist experience; it is an ethnography of the anarchist activism movement as he has experienced it. I'll discuss this work in a future post.

Here are two interviews with Graeber that give a pretty good idea of his style and critical views about the present (link, link). Both are very interesting to listen to.

Transnational labor activism

Friday, December 02, 2011

One of the characteristics that observers notice when they consider the anti-globalization protests of the past decade or so is the extent of transnational relationships that exist among activists and activist organizations. Sidney Tarrow provides a scholarly examination of these kinds of movements in The New Transnational Activism, where he tries to understand the organizational and situational circumstances that either facilitate or impede calls to popular action concerning large issues that affect many countries. (Here is a post on transnational activism and an earlier post on anti-NATO protests in Strasbourg a couple of years ago.) This is important work, and transnational activism is certainly an important feature of the world scene today. Our attention, though, is often restricted to the recent past when we think about transnational activism. So it is useful to consider earlier periods in the twentieth century in which movements succeeded at some level at bringing together multi-national coalitions in support of an important social or political cause.

One important instance is the international alliances that emerged in the radical end of the non-Communist labor movement in the 1950s. Nicola Pizzolato's recent "Transnational Radicals: Labour Dissent and Political Activism in Detroit and Turin (1950-1970)" in a recent issue of international review of social history (link) is a great case study in this light. Pizzolata provides a very useful and detailed account of the political and theoretical developments that transpired in Detroit and Turin among activist workers and thinkers during this period. It is well worth reading for that reason alone. But it also provides a concrete instance of a situation in which workers and activists, located within the industrial system in different parts of the world, were able to form their own understandings and strategies concerning those industrial realities, and the degree to which there was meaningful interaction among these groups.

The piece is particularly interesting to me for the light it sheds on the development of an important strand of radical African-American thought during the 1950s and 1960s. (Also because I had the remarkable pleasure of meeting one of the principal players in the story a few years ago, Grace Lee Boggs.) African-American militancy took a different shape within the industrial labor force than it did in much of the rest of America, and it is a story worth understanding. Dan Georgakas and Marvin Surkin's Detroit: I Do Mind Dying: A Study in Urban Revolution is a valuable monograph on the League of Revolutionary Black Workers. Manning Marable provides a thoughtful foreword. Marable provides a quick sketch of the development of the movement:

By 1968, more than 2.5 million African Americans belonged to the AFL-CIO. Yet the vast majority of black workers were marginalized and alienated from labor's predominantly white conservative leadership. In 1967, black militant workers at Ford Motor Company's automobile plant in Mahwah, New Jersey, initiated the United Black Brothers. In 1968,

African-American steelworkers in Maryland established the Shipyard Workers for Job Equality to oppose the discriminatory policies and practices of both their union and management. Similar black workers' groups, both inside and outside trade unions, began to develop throughout the country. The more moderate liberal to progressive tendency of this upsurgence of black workers was expressed organizationally in 1972 with the establishment of the Coalition of Black Trade Unions.

A much more radical current of black working-class activism developed in Detroit. Only weeks following King's assassination, black workers a tthe Detroit Dodge Main plant of Chrysler Corporation staged a wildcat strike, protesting oppressive working conditions.... The most militant workers established DRUM, the Dodge Revolutionary Union Movement. DRUM soon inspired the initiation of other independent black workers' groups in metro Detroit, such as FRUM, at Ford's massive River Rouge plant, and ELRUM, at Chrysler's Eldon Avenue Gear and Axle plant. (ix-x)

Here is how Pizzolato describes the situation:

In Detroit and Turin, these radicals saw the car factories as the key loci for change -- laboratories for a possible "autonomist" working-class activity that could take over industrial production and overhaul the societal system -- and urged workers to develop their own forms of collective organization, beyond existing labour organization. (5)

The "Correspondence" was a post-Trotskyist version of anti-capitalist theory and activism, rooted in the Detroit auto industry and involving names that are still familiar in Detroit: James Boggs and Grace Lee Boggs, General Baker, Martin Glaberman, Charles Denby, William Gorman and George Rawick (6). (Parenthetically, Wayne State University enters the story at several junctures as a locus for theory and debate.) This segment of politically engaged workers was as critical of organized labor as they were of the companies. A key part of the political activism of the Correspondence consisted in its willingness to confront the racial divisions that existed in society and within the factory. "[Charles Denby's *Indignant Heart: A Black Worker's Journal*] took a particularly strong stand in support of both the possibility of interracial co-operation among workers and the necessity of an autonomous black struggle" (10).

The spontaneous discontent breeding in the factories and in the working-class neighbourhoods of Detroit and Turin in the late 1960s was captured by some radical groups that had incorporated into their programmes many of the insights gleaned in the previous fifteen years by the Johnson-Forest Tendency, Correspondence, Quaderni Rossi, and Classe Operaia -- groups that could engage in a dialogue because, notwithstanding local differences, they located themselves in a similar position within a global opposition to capitalism. (21)

Essentially the developments that Pizzolato describes in Detroit and Turin represent a sustained, theoretically powerful attempt by radical thinkers and activists to rethink the role of working people within a progressive vision. There were a number of strands, but core was the "Johnson-Forest Tendency", deriving from C. L. R. James and Raya Dunayevskaya. The perspective is "autonomist" -- it rejects the idea that Communist parties, workers' states, or bureaucratic union organizations do a good job of furthering workers' interests. Rather, workers need to self-organize, both in terms of production and in terms of strategies and actions. Pizzolato makes the point that it is anti-Fordist, anti-Soviet, and anti-bureaucratic union. And, like the Occupy Wall Street movement today, its theorists attempted to go beyond existing radical dogma for a new radical diagnosis.

The narrative of theory, publication, and activism that Pizzolato offers for both Detroit and Turin is fascinating in its own terms. But equally interesting, and crucial to his argument, is his documentation of the transnational connections that existed within this period of radical
thinking and action. C. L. R. James was an internationally recognized voice. But the influence of the Detroit radical groups on European and Italian working class activism required more direct linkages. What were they? Here are a few of the specific linkages that Pizzolato cites.

For six months in 1948 Grace Lee Boggs resided in Paris and established a "daily collaboration" with the members of the group[Socialism ou Barbarie]. (12)

In his native Cremona, Montaldi founded in 1957 a group called Unita Proletaria, that distanced itself from the Communist Party and established direct contact with Socialisme ou Barbarie, Correspondence, News and Letters, And European groups that espoused the same line: the British Solidarity for Workers' Power, the Belgian Pouvoir Ouvrier, the Dutch Spartakus and others. (13)
In addition to theoretical debates and developments that extended across these specific transnational networks, the examples of large labor actions in 1967 and 1968 -- Renault in France, FIAT in Turin, and the Big Three in Detroit -- served to communicate strategies, tactics, and a spirit of boldness from one group to another.

It was in this context that the intellectual and personal contacts between Detroit and Turin radicals dating back to the 1950s were rekindled by the almost simultaneous workers' struggles in the car factories. (24)

The Italians were also keen to know about Detroit, as very little leaked out in the Italian press about labour unrest in the American cities. "Everyone is asking [for] information about the auto strikes in [the] States," wrote Gambino to Glaberman in 1970. (26)
African-American activist John Watson soon traveled to several cities in Italy in 1970 (his second trip), to share the news about the League of Revolutionary Black Workers.

What is fascinating about this whole story is the light it sheds on the formation of efforts at understanding and challenging a complex social order. There is an emphasis throughout much of this movement on taking workers' experiences within the factory as the starting point. This implicitly challenges the preoccupation of the Old Left on the canonical ideas of Marxism and Leninism -- the structure of capitalism, the vanguard party. But parallel to this independence of thinking is an independence in acting. The activists within this loose transnational community put the emphasis on workers' actions, not the actions of bureaucratized organizations (parties, unions, states). And both aspects of this seem to have some resonance with the anti-globalization movement of the past 20 years.

David Graeber on the anarchist movement

Sunday, December 04, 2011

Progressives seem to be confronted with some real conundrums (or is it conundra?), here in the early part of the 21st century. We want to see a world that is genuinely committed to some basic principles of social justice, equality, and personal freedom. And we generally acknowledge the point that the modern world can only function on the basis of social, political, and economic structures that have a degree of authority over individual

conduct. These two framing ideas are in tension, once we recognize the permanent likelihood of "institutional capture" of social structures by privileged individuals and groups. Capture may result from the access a privileged party has to the sources of wealth and power (the CCP in China) or the astronomically disproportional influence that corporations and private interests have in the legislative and regulatory process (lobbyists in France, the UK, and the US). So is it possible to create a society in which organizing structures exist, but that are genuinely governed by the constraints of justice,equality, and democracy? Can democratic institutions be established and defended that genuinely embody the interests and dignity of poor and working people? In a word, is social democracy actually a feasible outcome in the conditions of the 21st century?

There is a strand of radical thought that answers these questions in the negative. The "autonomist" theories and practices within the labor movement of the 1950s that were described in an earlier post represent one thread in this world. Another is the body of thinking, rhetoric, and action that is involved in the anarchist organizations associated with current anti-globalization activism. David Graeber has done an important service to the rest of us by offering an extended ethnography of this loosely connected movement in Direct Action. The book is the first I've seen to offer a nuanced description of the thinking, practices, and networks that have emerged within this movement over the past fifteen years or so. Unlike much of the journalism that this movement has produced, it resists both caricature and polemic. Graeber is a participant within the movement as well as an observer, and his voice helps to make sense of the thinking and actions that have surfaced in Seattle, Washington, Quebec, Madrid, and London in the past 15 years. And it certainly helps to put voices and faces into the OWS movement. Graeber is, by the way, an unusually appealing writer, so the book is a very engaging read. (It is also very long -- 538 pages of text.)

The first half of the book provides a detailed chronological ethnography of the preparations that several Direct Action groups made to engage in demonstration and resistance at the Summit of the Americas in Quebec in April, 2001. Graeber gives a textured understanding of the personalities and debates that unfolded. (Here is an activist-produced video of the protests; link.) As his description makes clear, this was a transnational network from the start, with alliances and affinities extending from Chiapas to Italy to Spain to Switzerland to the Mohawk Nation spanning the US and Canada border.

The second part of the book is a more analytical exposition of direct action and anarchism. He offers a clear description of what these activists mean by "direct action" (chapter 5), and attempts to capture something of the culture of anarchist activism (chapter 6). Here is an interesting observation about the social composition of anarchist networks in the US, which may also shed some light on OWS:

Speaking broadly, it seems to me activist milieu can best be seen as a juncture, a kind of meeting place, between downwardly mobile elements of the professional classes and upwardly mobile children of the working class. (252)
The groups that Graeber describes include various Direct Action Networks (DAN),

including the one based in New York in which he was involved, NYC DAN. Another is Ya Basta!, also anarchist but with a decided taste for performance. These groups conduct their discussions, planning, and decision-making according to egalitarian, consensual practices: no leaders, no executive committees, no authority. These practices are described in the principles endorsed by one of the oldest Direct Action groups, the Peoples' Global Action (PGA) (link). Here is how Graeber describes the principles of consensus:

DAN employed a formal consensus process with rotating facilitators, an elaborate system of “stacking” designed to ensure no small group of voices dominated the conversation. Smokey and Flamma hated DAN. Like a number of other anarchists in New York—I’ll call them the “hardcores,” for lack of a better name, the sort that were likely to have more experience in Black Blocs, tree sits, or the squatter scene, or anyway used to working in small, intimate collectives—they saw DAN’s formal structure as itself stifling and oppressive. (20)

But the ideal of consensus doesn't imply inability to act as a group. In fact, Graeber describes an extended process of brainstorming, planning, and decision-making leading up to coordination with the Mohawk Warrior Society, Ya Basta!, the International Socialist Organisation (ISO), and other sympathetic groups, and execution of complex actions in Quebec. (Graeber and other DAN participants seem to find the socialist ISO activists particularly annoying because of their apparent opportunism and vanguardism; and yet their egalitarian principles make it impossible for them to exclude them.)

The detailed notes about the tactics and actions in Quebec once the demonstrations began read like an urban combat novel: anarchist groups approaching the fence surrounding the core Summit area, police firing tear gas and water cannons, many injuries and arrests, molotov cocktails from a variety of Blocs against water cannon. Graeber's narrative gives a vivid depiction of what must have been similar actions and tactics in Strasbourg, London, and Seattle, with activists learning new tactics (and equipment) from one siege to another. (The horrendous video and photos from UC-Davis of police methodically pepper-spraying seated demonstrators give another current exposure to the potential for police violence in circumstances of protest and resistance.)

I find some interesting affinities between the movements and ideas that Graeber describes and the views of economic development advocated by Arturo Escobar in Encountering Development: The Making and Unmaking of the Third World. Escobar articulates much of the radical critique of globalization and its effects on poor people that lies at the core of the worldview expressed by the anarchist movement Graeber describes. Escobar's position is strongly anti-neoliberal, taking issue with foundational development ideas about growth and the general beneficence of markets. He too favors a view of the future in which people exercise continuing control over the processes that affect them. And he too likes a future built around fairly autonomous communities, cooperatives, and non-market institutions.

Also resonant are new ideas about deliberative and participatory democracy being developed by Archon Fung and Erik Olin Wright under the rubric of "empowered deliberative democracy"-- for example, in Deepening Democracy. Here is a representative statement of their view of the challenge facing existing democracies:

As the tasks of the state have become more complex and the size of polities larger and more heterogeneous, the institutional forms of liberal democracy developed in the nineteenth century—representative democracy plus techno-bureaucratic

administration—seem increasingly ill suited to the novel problems we face in the twenty-first century. “Democracy” as a way of organizing the state has come to be narrowly identified with territorially based competitive elections of political leadership for legislative and executive offices. Yet, increasingly, this mechanism of political representation seems ineffective in accomplishing the central ideals of democratic politics: facilitating active political involvement of the citizenry, forging political consensus through dialogue, devising and impleenting public policies that ground a productive economy and healthy society, and, in more radical egalitarian versions of the democratic ideal, ensuring that all citizens benefit from the nation's wealth. (3)

There are quite a few political values and perceptions embodied in the Direct Action movement that many progressive people can relate to. It isn't surprising that OWS has caught the attention of many young people. But are the mini-movements of activists that Graeber describes really a potential solution to the conundrum mentioned above? Can we get to a more just world through this kind of activism? Seattle and Quebec can claim some successes in achieving negative goals -- discrediting the IMF, challenging the World Bank, exposing a latent violence in democratic societies through excessive police force and brutality. And perhaps OWS will be successful in pushing back against over-greedy financial institutions. This kind of effect can plausibly come about through spontaneous popular protest. And as Graeber makes clear, these large anarchist actions are organized and planned, even if they are collective and mass-based.

But this just delays the problem, because it doesn't give a basis for creating institutions and structures that really work from the point of view of social justice and participatory democracy. The kinds of activism Graeber describes might be compared to an "immune system" for the periodic disorders of imperfect democracy: activists and their organizations (lymphocytes) swarm around important causes of distress (infections, inflammation), provoking repair responses within the society. But the movement doesn't contribute to the basic metabolism of society and politics. "Direct Action" isn't really a prescription for organizing society in its routine work; the approval of food and drug safety, the plans that states make for energy production, the creation and maintenance of social safety nets. The voice of the people can demand these protections. But then we need institutions that actually do the work. And the funny suits of Ya Basta! and spokescouncils don't fill the bill for this task. In the end, I am more attracted to the kind of work begun by Fung and Wright, which is aimed at creating sustainable institutions of participatory democracy.

Neil Gross's pragmatist sociology

Wednesday, December 07, 2011

	Origins of beliefs about environment of action	Methods for determining which action to perform	View of the actor
Deliberative	Beliefs based on scientific procedures and inference	Calculation of expected utilities of various interventions	Actor as solitary deliberator
Pragmatic	Beliefs based on socially specific cognitive frameworks	Application of socially specific rules of thumb/habits/repertoires	Actor as member of a social group, shaping actions according to social cues

An earlier post discussed Neil Gross's attempt to understand social mechanisms from the point of view of a pragmatist sociology. Gross's attempt to flesh out a pragmatist theory of action is intriguing and worthy of further exploration. So here I'll look at a subsequent article, "Charles Tilly and American Pragmatism" (2010), in which Gross extends this analysis to an interpretation of Charles Tilly. He makes an interesting case that Tilly's theories share a great deal in common with pragmatist theory. I'm not going to evaluate that claim here, though he makes a strong case, but instead want to pull out the essentials of what Gross seems to believe to be the fundamental assumptions of a pragmatist theory of acdtion.

So what are some of the insights from pragmatism that Gross thinks can help us to formulate a more adequate framework of sociological thinking? Here is a suggestive statement:

I aimed for a way of proceeding that would also accord with the turn toward “practice” in contemporary theory—that is, toward the reconceptualization of action as “forms of doing or ways of acting and interacting that appear within particular communities or groups; depend on shared presuppositions or assumptions...; and unfold in individuals’ lives as a result of active, creative, and less than conscious puttings into play of those presuppositions and assumptions in the context of various and intersecting sociobiographical experiences and exigencies.” (342)

This part of the story falls clearly in the zone of attempting to improve upon the theory of action that much social theory has presupposed for more than a century -- the idea of the rational, purposive agent considering options and choosing outcomes (link). Against that hyper-deliberative conception, Gross (and pragmatism) advocates for a more fluid, interactional, and only partially conscious flow of actions. There is a suggestion here of stylized modes of behavior (scripts) within which persons locate their actions, and a suggestion of the importance of specific cognitive fields embodied in social groups that contextualize and rationalize the person's activities (assumptions, for example, of how a doctor should treat a patient in a hospital).

Another important part of Gross's conception of pragmatist action theory is the way we conceive of the individual. According to the pragmatist theory, the individual needs to be considered within the context of a social group, influenced by norms, emotions, and actions of the others in the group. So action should not be "atomized" into a group of individual actors choosing independently. Gross puts this part of the theory in the form of a comment about Tilly:

The motivating claim of *Durable Inequality* is that analysts should dispense with “individualistic” models that seek to explain differences in the life chances of members of social groups in terms of their experiences, properties, and characteristics, whether these are assumed to be a product of genetic endowments, as in Herrnstein and Murray’s (1994) controversial “bell curve” thesis, or social circumstance, as in some versions of human capital theory. (349)

The point emerges in Tilly through his insistence on "relationality" -- his deep objection to attempting to understand actions by individuals without regard to the networks of other individuals whose behavior and thoughts set the context to the actions.

Third, there is the question of how the agent decides what to do in a particular circumstance. The pragmatist view that Gross describes holds that the actor chooses in line with habit and script. Essentially, this is the insight that there are fairly well defined rules of thumb or scripts for how to respond to certain kinds of problems. And the theory holds that the actor generally acts accordingly. When an experienced politician is confronted by a heckler, the play book pretty well specifies how he/she should respond. This contrasts sharply from the deliberativist view of action.

What makes this set of assumptions a "pragmatist" approach? Fundamentally, because it understands the actor as situated within a field of assumptions, modes of behavior, ways of perceiving; and as being stimulated to action by "problem situations". So action is understood as the actor's creative use of scripts, habits, and cognitive frameworks to solve particular problems. (Gross refers to this as an *A-P-H-R* chain: actor, problem

situation, habit, and response; 343.)

How does this compare to the foil of pure deliberative rationality? According to rational choice theory an actor makes a choice in a problem situation by (i) arranging a preference ordering of possible outcomes, including utilities for each outcome; (ii) consulting rational procedures to gain beliefs about the probabilities of various strategies leading to various outcomes; and (iii) choosing that strategy that results in the greatest expected utility (*utility* x *probability*). This account makes choice rational in both aspects: rational acquisition of beliefs about interventions and outcomes, and rational comparison of the relative goodness/badness of the outcomes associated with possible interventions. There is no place in this story for culturally variable cognitive frameworks for perceiving the situation, or for group-specific rules of thumb governing the choice of interventions.

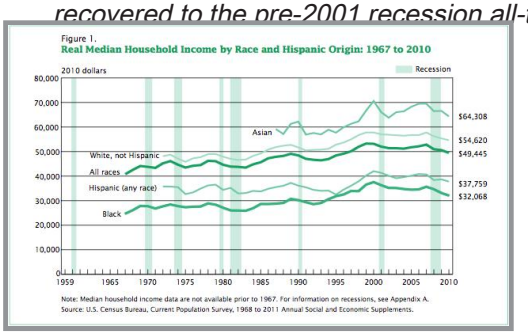
This formulation of the two theories permits fairly direct comparison between them. Consider this table comparing the two theories of action:

So how would we pursue a concrete sociological question differently if we chose one or the other of these theories of action? Let's consider rebellion -- the coordinated activities of resistance of a large population against a powerful ruler. What would a deliberative rationality sociology of rebellion look like? And what would a pragmatist theory look like?

Oddly enough, it seems to me that we have clear illustrations of both approaches in the existing literature on peasant rebellion. In fact, the moral economy debate of the 1970s illustrates both approaches. The protagonists here are Samuel Popkin's The Rational Peasant: The Political Economy of Rural Society in Vietnam and James Scott's The Moral Economy of the Peasant: Rebellion and Subsistence in Southeast Asia. Popkin's analysis of rebellion and revolution in Vietnam is thoroughly grounded in the assumptions of rational choice theory. Popkin tries to understand the actions of each of the players according to their rational behavior in the face of risk and uncertainty and the strategic behavior of others. Peasants rebel when the likelihood of success is great enough to make the discounted rewards of rebellion greater than the discounted costs of failure.

Scott understands rebellion in Southeast Asia in very different terms. He finds that the "moral economy of the peasant" is a powerful source of behavior for villagers as they consider the options of resistance and subordination. He is sympathetic to the idea that peasant perceptions of society, of the power structure, and of the future are powerfully shaped by shared social assumptions and frameworks, here and in other works like Weapons of the Weak: Everyday Forms of Peasant Resistance and Domination and the Arts of Resistance: Hidden Transcripts. So Popkin's assumptions are an almost pure example of rational-choice social research; whereas Scott's assumptions have a very close match with the premises of pragmatist theory of action, as I've reconstructed it here.

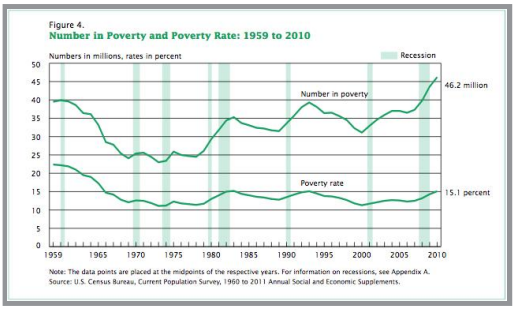
So perhaps James Scott too -- like Tilly, in Gross's interpretation -- has a deeply pragmatist side lurking within his sociological imagination.



Structural adjustment for the middle class?

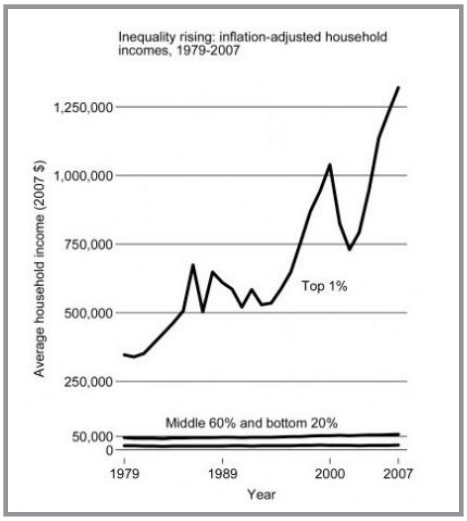
Saturday, December 10, 2011

Working people in the US have suffered big economic losses in the past four years. Losses of jobs in the economy have pushed many working people from high-wage to low-wage jobs, and as we all know, many people have been pushed out of jobs altogether. The national unemployment rate was 8.6% in November, and very much higher in urban areas and African-American and Latino communities. Michigan's rate was 10.6% in October 2011 (link). White non-Hispanic households fell from $55,360 in 2009 to $54,620 (-1.3%), while black households fell from $33,122 to $32,068 (-3.2%) (Table 1). These differences in household income across race are stunning: black households started out at only 63% the level of white households in 2009, and they fell by more than double the percentage rate of loss from 2009 to 2010.



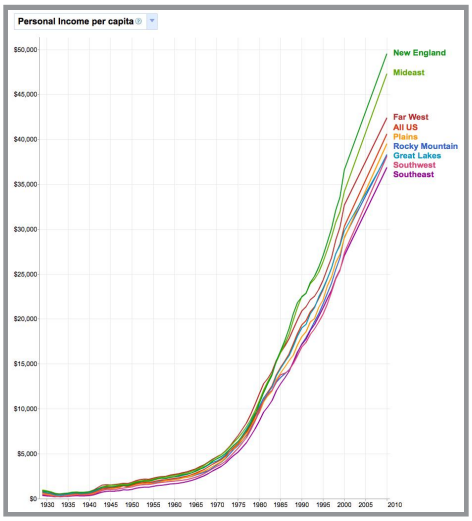
Here is a report from the US Census Bureau, *Income, Poverty, and Health Insurance Coverage in the United States: 2010,* that sheds some light on the changes of the past several years. Here are a few important summary findings:

- *Real median household income was $49,445 in 2010, a 2.3 percent decline from 2009 (Figure 1 and Table 1).*
- *Since 2007, the year before the most recent recession, real median household income has declined 6.4 percent and is 7.1 percent below the median household income peak that occurred in 1999 (Figure 1 and Tables A-1 and A-2).3*
- *Both family and nonfamily households had declines in real median income between 2009 and 2010. The income of family households declined by 1.2 percent to $61,544; the income of nonfamily households declined by 3.9 percent to $29,730 (Table 1).*
- *Real median income declined for White and Black households between 2009 and 2010, while the changes for Asian and Hispanic-origin households were not statistically significant (Table 1).*
- *Real median household income for each race and Hispanic-origin group has not yet recovered to the pre-2001 recession all-time highs (Table A-1).* (5)



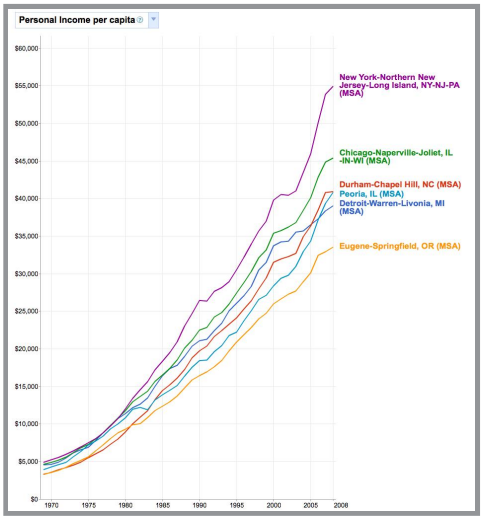
Here is what real median income looks like, broken down by racial group, since 1967.

Now consider the poverty statistics the report contains. Here is a summary graph:



The national poverty rate reached a forty-year low in 2000, at about 12%. Through the decade, however, the national rate has grown to 15.1% in 2010, representing 46.2 million people. Here again there is a stunningly wide gap between white and black populations. The poverty rate in 2010 for white non-Hispanic households is 9.9%, while the rate for black households in 2010 is 27.4% (Table 4).

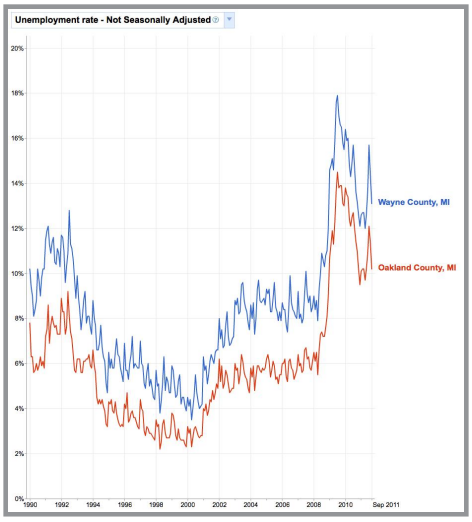
We've tended to think of this period as a difficult economic time that will eventually come to an end. But perhaps that's too optimistic. Perhaps what we are witnessing is a structural adjustment of the US labor



market, with a permanent downward shift in income for middle and low income people. And perhaps these shifts will be most extreme for African-American households. (The past decade seems to bear this out. From 2000 to 2010 white non-Hispanic households had declined 5.5%, while black households declined 14.6% during that same period (8).)

Here the concern is that maybe Bruce Springsteen was right -- "these jobs are going, boys, and they ain't coming back to your hometown." Jobs with decent wages -- manufacturing jobs, union jobs, professional service jobs -- have declined precipitously in the past twenty years (not just since the recession). And that means that the opportunities for many workers to have "middle-class" incomes have become much more restricted. Here is a sober report from Chemical and Engineering News --

The severe national recession of the past several years is having a negative impact on the employment and the starting salaries of chemists and chemical engineers. The latest data from the American Chemical Society on graduates from 2009 found that median starting salaries fell about 5% for those receiving bachelor's and doctoral degrees compared with the previous year. New graduates with master's degrees appeared to have gotten a jump in pay.



Even the banking and financial sector has contracted (link):

The financial services industry, hammered by job cuts and record losses, is in for an even bigger contraction as the global recession deepens, said Marc Faber, publisher of the Gloom, Boom & Doom Report.

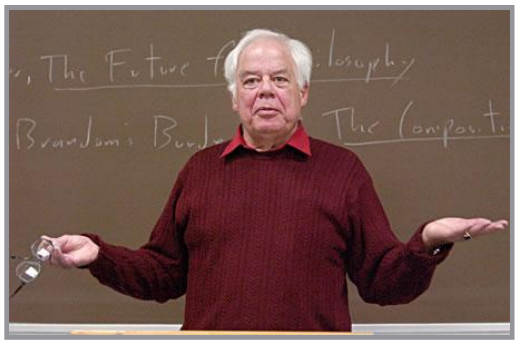
"The financial sector will contract and it will contract much more than we've seen so far," said Faber, who was in Tokyo to speak at an event hosted by CLSA Ltd. Financial professionals have "been in paradise for the past 25 years."

More than 275,000 jobs in the financial industry have been lost in the last two years, according to Bloomberg data, while losses and writedowns at global companies exceeded $1 trillion in the past year. Faber said the contraction could rival declines seen in the 1970s following the collapse of Bernard Cornfeld's Investors Overseas Services

that shook confidence in the industry for a decade.

So the financial industry isn't providing ready opportunities for young MBAs; many of them too will need to find other, less well-paying jobs.

Does this mean that everyone in the US economy is facing downward pressure on wages and salary? Not exactly. There is a segment of the American economy that is doing very well indeed. Here is a graph provided by Lane Kenworthy demonstrating the growth in income of the top 1% (link). (Kenworthy's discussion is very good.) The top line is the median household income of the top 1%. The lower lines, showing virtually no growth, represent the median of the middle three quintiles and the median of the bottom quintile of households.



source: Consider the Evidence (Lane Kenworthy)

So here are two important questions. Is the US economy on a path towards a shift to lower-paid jobs for a large segment of its working population? And are there policies that could be chosen that would result in an outcome that looks more fair than this graph of the recent past, with reasonable growth of income for all American workers and less extreme growth at the very top?

(Here is an interesting Google resource, the Public Data Explorer, that provides visualization tools for basic US economic and demographic data. This particular screen shows the growth of personal income per capita since about 1930, across the regions of the United States. (This is money income, not adjusted for inflation.) The second graph shows personal income per capita for selected metropolitan areas. The third graph shows the unemployment rates for Wayne County and Oakland County in Michigan.)

Sociology of ideas: Richard Rorty

Monday, December 12, 2011

Where do new ideas and directions of thought come from? Is it possible to set a context for important changes in intellectual culture, in the sciences or the humanities? Can we give any explanation for the development of individual thinkers' thought?

These are the key questions that Neil Gross raises in his sociological biography of Richard Rorty in Richard Rorty: The Making of an American Philosopher (2009). The book is excellent in every respect. Gross has gone into thorough detail in discovering and incorporating correspondence with family and friends that allow him to reconstruct the micro setting within which the young Rorty took shape. His exposition of the complex philosophical debates that set the stage for academic philosophy in the United States

from the 1950s to the 1980s is effortless and accurate. And he offers a very coherent interpretation of many of Rorty's most important ideas. Any one of these achievements is noteworthy; together they are exceptional.

Gross is not interested in writing a traditional intellectual biography. Rather, he wants to advance the emerging field of "new sociology of ideas" through an extended case study of the development of a particularly important philosopher. The purpose of the book is to provide a careful and sociologically rich account of the ways in which a humanities discipline (philosophy) developed, through a crucial period (the 1940s through the 1980s).

My goal is to develop, on the basis of immersion in an empirical case, a new theory about the social influences on intellectual choice, particularly for humanists—that is, a theory about the social factors that lead them to fasten onto one idea, or set of ideas, rather than another, during turning points in their intellectual careers. (kindle location 95)

The argument I now want to make is that the developments considered in chapters 1–8 reflect not Rorty’s idiosyncratic and entirely contingent biographical experiences but the operation of more general social mechanisms and processes that shaped and structured his intellectual life and career. (kl 5904)
Here is how he describes the sociology of ideas:

Sociologists of ideas seek to uncover the relatively autonomous social logics and dynamics, the underlying mechanisms and processes, that shape and structure life in the various social settings intellectuals inhabit: academic departments, laboratories, disciplinary fields, scholarly networks, and so on. It is these mechanisms and processes, they claim, that—in interaction with the facts that form the material for reflection—do the most to explain the assumptions, theories, methodologies, interpretations of ambiguous data, and specific ideas to which thinkers come to cleave. (kl 499)
The goal is to provide a sociological interpretation of the development of thinkers and disciplines within the humanities (in deliberate analogy to current studies in the sociology of science). Gross acknowledges but rejects earlier efforts at sociology of knowledge (Marx, Mannheim), as being reductionist to the thinker's location within a set of social structures. Gross is more sympathetic to more recent contributions, including especially the theories of Bourdieu (field) (Homo Academicus) and Randall Collins (interaction ritual chains) (The Sociology of Philosophies: A Global Theory of Intellectual Change). These theories emphasize the incentives and advantages that lead strategically minded professionals in one direction or another within a discipline or field. But Gross argues that these theories too are insufficiently granular and don't provide a basis for accounting for the choices made by particular intellectuals.

One does not have to be a methodological individualist to recognize that meso- and macrolevel social phenomena are constituted out of the actions and interactions of individual persons and that understanding individual-level action—its nature and phenomenology and the conditions and constraints under which it unfolds—is helpful for constructing theories of higher order phenomena, even though the latter have emergent properties and cannot be completely reduced to the former. (kl 158)
To fill this gap he wants to offer a sociology of ideas that brings agency back in. He introduces the idea of the role of the individual's "self-concept", which turns out to be a basis for the choices the young intellectual makes within the context of the strategy-setting realities of the field. A self-concept is a set of values, purposes, and conceptions that the individual has acquired through a variety of social structures, and that continues

to evolve through life. Gross emphasizes the narrative character of a self-conception: it is expressed and embodied through the stories the individual tells him/herself and others about the development of his/her life.

The theory of intellectual self-concept can thus be restated as follows: Thinkers tell stories to themselves and others about who they are as intellectuals. They are then strongly motivated to do intellectual work that will, inter alia, help to express and bring together the disparate elements of these stories. Everything else being equal, they will gravitate toward ideas that make this kind of synthesis possible. (kl 6650)
...
There is good reason to believe that such stories or self-narratives are not epiphenomenal aspects of experience but influences on social action in their own right. Indeed, few notions have been as important in social psychology as those of self and self-concept. (551)

Simply stated, the theory of intellectual self-concept holds that intellectuals tell themselves and others stories about who they are *qua* intellectuals: about their distinctive interests, dispositions, values, capacities, and tastes. (kl 6487)
And Gross thinks that these stories are deeply influential, in terms of the choices that a developing intellectual makes at each stage of life. In particular, he thinks that the academic's choices are often inflected by his/her self-conception to an extent that may override the strategic and prudential considerations that are highlighted by Bourdieu and Collins. Bourdieu and Collins offer "no attempt to think through how the quest for status and upward mobility in an intellectual field may intersect and sometimes compete with thinkers' cognitive and affective interests in remaining true to narratives of intellectual selfhood that have become more or less stable features of their existence" (562). In his view, identity trumps interest--at least sometimes.

Here is how he applies this analysis to Rorty:

My central empirical thesis is that the shift in Rorty's thought from technically oriented philosopher to free-ranging pragmatist reflected a shift from a career stage in which status considerations were central to one in which self-concept considerations became central. (576)
Or in other words, Rorty's early career is well explained by the Bourdieu-Collins theory, whereas his later shift towards pragmatism and more heterodox, pluralistic philosophy is explained by his self-concept.

In Gross's telling of the story, much of Richard Rorty's self-concept was set by the influences of his remarkable parents in childhood and adolescence, James Rorty and Winifred Raushenbush. The parents were politically engaged literary and political intellectuals, and they created an environment of social and intellectual engagement that set aspects of Richard's self-concept that influenced several key choices in his life. Gross's depiction of the social and intellectual commitments of James and Winifred, and the elite milieu in which they circulated, is detailed and striking. This "social capital" served Richard well in his course from the University of Chicago to Yale into his academic career.

Gross believes that the key turns in Rorty's development were these: first, the decision to do a masters thesis on Whitehead at Chicago; then his choice of Yale as a doctoral institution, with a Ph.D. dissertation on "The Concept of Potentiality" (a metaphysical subject); his shift towards analytic philosophy during his first several years of teaching at

Wellesley; his deepening engagement with analytic philosophy in the early years at Princeton; his eventual critique of analytic philosophy in Philosophy and the Mirror of Nature; and his further alienation from analytic philosophy in the years that followed towards a contemporary pragmatism and a more pluralistic view of the domain of philosophical methods. In other words, he began in an environment where pragmatism and substantive metaphysics were valued; he shifted to the more highly valued field of analytic philosophy during the years in which he was building his career and approaching tenure; and he returned to a more pluralistic view of philosophy in the years when his career was well established.

Rorty's turn to analytic philosophy makes sense in a Bourdieuian way. Gross describes his Wellesley-era and early Princeton philosophical writings in these terms:

They represent Rorty's attempt to make contributions to analytic thought of a piece with those that other bright, young analytic philosophers of his generation were making. They were, in other words, part of Rorty's efforts to position himself even more squarely within the mainstream philosophical establishment. (kl 4642)

Those observing Rorty's career from afar might have interpreted this spate of analytic publications, coming on the heels of *The Linguistic Turn*, as evidence that Rorty had joined the ranks of the analytic community and saw his work as of a piece with that being done by other analysts. (kl 4853)

But eventually Rorty shifts his philosophical stance, towards a pluralistic and pragmatist set of ideas about philosophical method and subject matter. Here is how Gross summarizes Rorty's turn to pragmatism:

On this understanding, a pragmatist is someone who holds three beliefs: first, that "there is no wholesale, epistemological way to direct, or criticize, or underwrite, the course of inquiry"; second, that "there is no . . . metaphysical difference between facts and values, nor any methodological difference between morality and science"; and third, that "there are no constraints on inquiry save conversational ones." (kl 719)

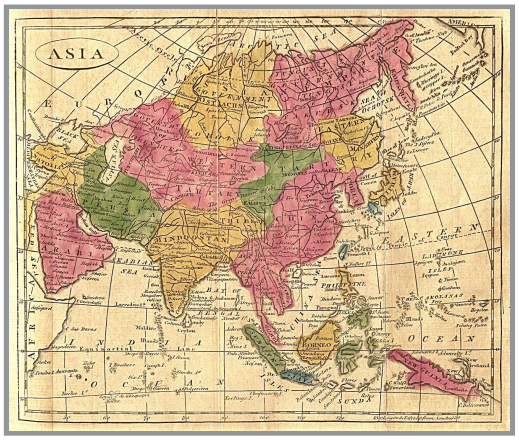
As Rorty went about developing a historicist, therapeutic alternative to the analytic philosophy he saw being practiced by his Princeton colleagues and others, no one's work was more important to him than that of Thomas Kuhn. (kl 5054)

And Gross dates Rorty's impulses towards pragmatism to a much earlier phase of his intellectual development than is usually done:

Far from it being the case, as some Rorty interpreters have claimed, that Rorty's interest in pragmatism arose only after he made a break with analytic philosophy, his earliest work is characterized by a desire to harness pragmatist insights in the service of a revised conception of the analytic project. (kl 4037)

Rorty rode both of these intellectual waves, becoming caught up in the rigorism of the analytic paradigm in the 1960s and then emerging as a leading figure in the antirigorist movement of the 1970s and 1980s. (kl 7058)

The book repays a close reading, in that it sheds a lot of light on a key period in the development of American philosophy and it provides a cogent sociological theory of the factors that influenced this development. It is really a remarkable book. It would be fascinating to see similar accounts of innovative thinkers such as Nelson Goodman, John Rawls, or (from literary studies) Stephen Greenblatt. That's not likely to happen, however, so this book will probably remain a singular illustration of a powerful theory of the sociology of ideas.



Global history?

Wednesday, December 14, 2011

A question that arises in historiography and the philosophy of history is that of the status of the notion of "global history." I've addressed the topic several times here in a limited way -- often by making the case for Eurasian history rather than French history or Japanese history (post). There the view is that expanding the scope of vision from the separate nation states of Europe or Asia to the broader panoply of multiple peoples, cultures, and structures is helpful when it comes to understanding the past four hundred years. But what are some of the more general concerns that make thinking about global history an interesting or important topic?

One important reason for thinking globally as an historian is the fact that the history discipline -- since the Greeks! -- has tended to be eurocentric in its choice of topics, framing assumptions, and methods. Economic and political history, for example, often privileges the industrial revolution in England and the creation of the modern bureaucratic state in France, Britain, and Germany, as being exemplars of "modern" development in economics and politics. This has led to a tendency to look at other countries' development as non-standard or stunted. So global history is, in part, a framework within which the historian **avoids privileging one regional center** as primary and others as secondary or peripheral. Bin Wong makes this point very strongly in China Transformed.

Second is the apparent fact that when Western historical thinkers -- for example, Hegel, Malthus, Montesquieu -- have turned their attention to Asia, they have often engaged in **a high degree of stereotyping** without much factual historical knowledge. The ideas of Oriental despotism, Asian overpopulation, and Chinese stagnation have encouraged a cartoonish replacement of the intricate and diverse processes of development of different parts of Asia by a single-dimensional and reductive set of simplifying frameworks of thought. This is one of the points of Edward Said's critique of orientalism (Orientalism). So doing "global" history means paying rigorous attention to the specificities of social, political, and cultural arrangements in other parts of the world besides Europe.

So a global history can be expected to be more agnostic about patterns of development, and more open to **discovery of surprising patterns, twists, and variations** in the experiences of India (and its many regional differences), China, Indochina, the Arab world, the Ottoman Empire, and Sub-saharan Africa. Variation and complexity are what we should expect, not stereotyped simplicity. (Geertz's historical reconstruction of the "theatre state" of Bali is a case in point -- he uncovers a complex system of governance, symbol, value, and hierarchy that represents a substantially different structure of politics than the models derived from the emergence of bureaucratic states in early modern Europe; Negara: The Theatre State in 19th Century Bali.) A global history needs to free itself from eurocentrism.

This step away from eurocentrism in outlook should also be accompanied by a **broadening of the geographical range** of what is historically interesting. So a global history ought to be global and trans-national in its selection of topics -- even while recognizing the fact that all historical research is selective. A globally oriented historian will recognize that the political systems of classical India are as interesting and complex as the organization of the Roman Republic.

Another aspect of global history falls more on the side of how some historians have thought about historical structures and causes since the 1960s. History itself is a "global" process, in which **events and systems occur that involve activities in many parts of the world simultaneously**. Immanuel Wallerstein is first among these, with his framework of "world systems" (The Modern World-System I: Capitalist Agriculture and the Origins of the European World-Economy in the Sixteenth Century, With a New Prologue). But the basic idea is a compelling one. An effort to explain the English industrial revolution by only referring to factors, influences, and experiences that occur within England or on its edges (western Europe) is inadequate on its face. International trade, the flow of technologies from Asia to Europe, and the flows of ideas and peoples from Asia, Africa, and the Americas have plain consequences for the domestic economy of England in 1800 and the development of machine and power technologies. And a "globally minded" historian will pay close attention to these trans-national influences and interdependencies. This aspect of the interest of global history falls within the area of thinking about the scope of the causal factors that influence more local developments.

An important current underlying much work in global history is the **reality of colonialism** through the nineteenth and twentieth centuries, and the equally important **reality of anti-colonial struggles and nation building** in the 1960s and 1970s. "The world" was important in the capitals of Great Britain, France, Germany, and Belgium because those nations exerted colonial rule in various parts of Africa, Asia, and South America. So there was a specific interest in gaining certain kinds of knowledge about those societies -- in order to better govern them and exploit them. And post-colonial states had a symmetrical interest in supporting global historiography in their own universities and knowledge systems, in order to better understand and better critique the forming relations of the past.

Then there is the issue of climate and climate change. The "little ice age" had major consequences for population, nutrition, trade, and economic activity in western Europe;

but the same climate processes also affected life in other quarters of the globe. So to have a good understanding of the timing and pace of historical change, we often need to know some fairly detailed facts about the global environment.

A final way in which history needs to become "global" is to incorporate the **perspectives and historical traditions of historians in non-western countries** into the mainstream of discussion of major world developments. Indian and Chinese historians have their own intellectual traditions in conducting historical research and explanation; a global history is one that pays attention to the insights and arguments of these traditions.

So global history has to do with --

- a broadened definition of the arena of historical change to include Europe, Asia, Africa, the Middle East, and the Americas
- a recognition of the complexity and sophistication of institutions and systems in many parts of the world
- a recognition of the trans-national interrelatedness that has existed among continents for at least four centuries
- a recognition of the complexity and distinctiveness of different national traditions of historiography

Dominic Sachsenmaier provides a significant recent discussion of some of these issues in Global Perspectives on Global History: Theories and Approaches in a Connected World. Sachsenmaier devotes much of his attention to the last point mentioned here, the "multiple global perspectives" point. He wants to take this idea seriously and try to discover some of the implications of different national traditions of academic historiography. More than half his book is devoted to case studies of global historical research traditions and foci in three distinct national contexts -- Germany, the United States, and China. How do historians trained and en-disciplined in these three traditions think about the core problems of transnational, global history? Sachsenmaier believes that these differences are real, and that they can be productive of future historical insights through more sustained dialogue. But he also believes there are conceptual and methodological barriers to these dialogues, somewhat akin the the "paradigm incommensurability" ideas that Thomas Kuhn advanced for the physical sciences.

The idea that in the future, global history may experience more sustained dialogues between scholars from different world regions leads to deeper theoretical challenges than may be apparent at first sight. Most importantly, there is the question of how to conceptualize "local" viewpoints in today's complex intellectual and academic landscapes. (11)

And he does a good job of articulating what some of these conceptual barriers involve:

In almost all world regions university-based historiography is at least partly an outcome of epistemological discontinuities, outside influences, and shared transformations.... These also had an impact on the conceptions of space underlying world historical scholarship in the widest sense. Prior to spread of history as a modern academic field, forms of border-crossing histories were typically written from a clear perspective of cultural, religious, or even ethical centricity, which means that they tended to be tied to distinct value claims. This situation changed decisively during the nineteenth and twentieth centuries, when either colonial rule or nation-building efforts had a profound impact on what elements were selected into the canon of academic historiography and many earlier forms of knowledge were rendered subaltern. (13)

Certain hierarchies of knowledge became deeply engrained in the conceptual worlds of

modern historiography. Approaching the realities and further possibilities of alternative approaches to global history thus requires us to critically examine changing dynamics and lasting hierarchies which typify historiography as a global professional environment. (17)

It will become quite clear that in European societies the question of historiographical traditions tended to be answered in ways that were profoundly different from most academic communities in other parts of the world. (17)
So Sachsenmaier's attention is directed largely to the conceptual issues and disciplinary frameworks that are pertinent when we consider how different national traditions have done history. What he has to say here is very useful and original. But he also makes several of the points mentioned above as well -- the need to select different definitions of geography in doing history, the need to put aside the stereotypes of eurocentrism, and the value in understanding in depth the alternative traditions of historical understanding that exist in the world.

Protest in Wukan

Sunday, December 18, 2011

A period of demonstration and protest in the Chinese village of Wukan has caught the attention of world media in the past several weeks (link, link). The village is in Guangdong, the dynamic coastal province. The demonstrations began in September against major land seizures by local government in alignment with developers, and became more intense in the past week when leader Xue Jinbo died in police custody. (Here is a good Wikipedia article on the village.) Land seizures seem to be the most volatile issue in China today, producing a large proportion of the roughly 90,000 civil disturbances the country currently faces a year.

Feature	17th century	Mid 18th century	Late 18th century	Early 19th century		Wukan?
State capacity	Low	High	Low	Low		High
Commercial prosperity	Low	High	High	Low		High
Imperial center's moral legitimacy	Low	High	Low	High		Medium
Protest claim	Reactive	Proactive	Reactive	Reactive		Proactive
Protest action	Violent	Less violent	Violent	Violent		Non-violent
Protesters' identities vis-a-vis local authority	Antagonistic	Filial loyal	Antagonistic	Antagonistic		Antagonistic
Protesters' identities vis-a-vis imperial center	Antagonistic	Filial loyal	Antagonistic	Filial loyal		Filial loyal
Frequency of state-resisting vs state-engaging protest	88%	40%	85%	78%		N/A

Source: Hung, table 6.1, figure 6.1 (final column not from Hung!)

Analysts are interested in probing the causes and dynamics of protest and resistance in contemporary China, including C. K. Lee (Against the Law: Labor Protests in China's Rustbelt and Sunbelt) and Kevin O'Brien (Rightful Resistance in Rural China). Here, though, it may also be interesting to compare the current situation with the occurrence of similar incidents during the Qing Dynasty.

Fortunately, it is possible to do so on the basis of a recent relevant study. Ho-Fung Hung's recent Protest with Chinese Characteristics: Demonstrations, Riots, and Petitions in the Mid-Qing Dynasty addresses exactly this issue in historical context. He looks at the period 1740-1839 and finds that the character of protest and resistance varied throughout the period. This is the early modernization period of Chinese history, and Hung believes

that the subject of popular unrest has been overlooked in this period. The grasp of the central power of the state increased during this period, and it also represented a major advance in commercialization of Chinese society.

The main source of data on protests during this period that Hung analyzes is the Veritable Records of the Qing, a compendium of shortened versions of edicts and memorials from the emperor and other officials. Out of the 2,096 volumes of this archive Hung identifies 514 events of popular protest and 450 events of petitions to higher officials (55). His empirical work involves coding hundreds of contentious events during the period, classifying them, and looking for patterns of change over time. But how to categorize? Here is his overview description of his approach:

I classify the documented protest events into different types according to their claims and repertoires. A protest's claim is a set of articulated demands advanced by the participants. The repertoire of a protest is the set of learned or invented acts that the protesters performed to attract the attention of potential participants and the authorities, as well as to persuade or force the authorities to meet their demands. (58)

One distinction between events that he draws from the existing literature on contention and rebellion is between backward looking and modernizing protests. Essentially the former represent demands to secure existing rights (or re-establish recently extinguished rights). The latter take the form of proactive protests aimed at creating new opportunities and rights within an emerging set of economic or social institutions. Hung rightly rejects the idea that European experience can provide a full theory of contentious politics. So he insists on using the evidence of non-western movements as an alternative basis of analysis and theory. China's experience in the mid-Qing provides an ample basis for arriving at such a scheme.

Hung doubts the utility of the concept of "backward-looking" protest in the mid-Qing period. Instead, he argues that protests throughout the period were proactive and aimed at securing better outcomes in the future for the protesters, in light of changing political and economic conditions. The large distinction that Hung favors as a way of categorizing contention has to do with the purpose and style of the mobilization. "Filial protest", or "state-engaging" protest, involves collective action intended to implore the state to honor its obligations. "State-resisting" protest involves action deliberately designed to challenge the authority and power of the state, often with the threat or reality of violence (58). And Hung believes this scheme is valuable for China, in part, because some surprising patterns emerge through these lenses. In particular, he finds the frequency of state-resisting protest varies significantly along this timeframe, from a high point in 1600-44 of 94% to a low in 1740-59 of 40%, rising again between 1776 and 1839 (figure 6.1).

Hung's account highlights several important things about Chinese protest. First is the point that protests exist within a set of material social arrangements that provide the interests that lead to mobilization. So an important dimension of analysis for uncovering the causes of a wave of protests is to analyze the changing economic and political circumstances that created new pressures and opportunities for ordinary people. Second is the point that culture and repertoires of resistance give form to the protests that emerge. Here he gives causal importance to Confucian ideas about the state, but also to heterodox ideas stemming from non-Confucian traditions (for example, White Lotus Buddhism).

A very old feature of Chinese protest involves the delivery of petitions to the central government (emperor) to protest abuses by local officials, tax farmers, or other scourges

of peasant life.

In Qing times (1644-1911), a common remedy for powerless subjects abused by local officials was to travel all the way to Beijing to appeal to the emperor as their grand patriarch, hoping he would sympathize with their plight and penalize corrupt local officials. (1)
And, as Hung points out, this tradition continued through 1989 and beyond.

So what about Wukan? Does Hung's analysis of mid-Qing protest shed any light on the nature of protest there?

Accounts make several things clear. First, the cause of popular unrest that precipitated the first round of protest in Wukan had to do with an important material issue (land seizures) and the actions of potentially corrupt local officials in collusion with powerful developers. Second, the protest intensified dramatically in the past 10 days after security officials took violent action against elected leaders of the protesters, leading to the seizure of Xue Jinbo and his death in police custody. Third, it appears through news reports that protests took the form of non-violent appeals for relief against corrupt officials -- similar to the tradition of filial protest. The tradition of taking the protest to higher officials is also illustrated here, with the stated intention of marching to Lufeng, the local administrative center. Here is an indicative passage from the *New York Times*:

Almost to a person, the villagers are holding out hope that leaders in Beijing will intervene to settle the dispute and to investigate what they contend is widespread corruption in local affairs, including land sales. Saturday's rally, laced with chants like "We love the Communist Party," stressed the villagers' loyalty to the central government. One prominent banner begged the central government to come to their aid. (link)
But the same article raises the possibility that this protest may move from state-engaging to state-resisting as villagers come to believe that they have no recourse from the central government:

"Our original intent was just to get our land back," a 29-year-old homemaker who identified herself only as Mrs. Zhu said as she stood under a Chinese flag, mounted on a makeshift pole at a protesters' checkpoint on the village outskirts. "We never intended that things would get into such a situation."Asked what could be done, she replied: "We have to fight to the end. That's the only way out. If we retreat now, all the hardships the government imposed on us will come true."
Hung provides an interesting tabulation of several important characteristics of protests in mid-Qing China that I've reproduced below. I've supplemented the table in two ways. First, I've included in this table the data Hung reports on the incidence of state-resisting protests, which vary significantly throughout the period he studies (figure 6.1). Second, I've added an additional column of my own indicating how Wukan seems to measure up on these criteria. The finding that I've come to is that Wukan began as a "filial protest" through which villagers sought to engage the state to obtain relief from local officials. The protest has been pushed into a more "state-resisting" posture, however, as a result of the violence and intransigence of local and county officials, and the fact that Beijing has so far ignored the villagers' demands.

A pragmatist action theory

Friday, December 23, 2011

A theory of action is one component of a meta-framework for sociology. It is an organized set of ideas about what individuals are doing when they engage in interactions in the world, and what we think at the highest level of generality about why they behave as they do. Individuals within social interactions constitute the social world; they do things; and they do things for reasons that we would like to understand. A theory of action ought to give us a basic vocabulary for describing behavior in the social world. And it ought to provide some framing hypotheses about the causes or motivations of behavior.

An important aspect of action theory is the idea of "intensionality" and mental representation. This is the conception of the individual as possessing consciousness, purposes, and a mental orientation to the world. He or she "understands" the events that surround him/her -- that is, the individual forms a mental representation of the swirling set of actions and events that surround him or her. And the individual places him/herself within this representation by conceptualizing wants, aversions, aspirations, and intentions concerning what might be achieved through intentional behavior.

This description may seem obvious. Or it may seem to reflect a set of assumptions about how to parse the social world that are substantive, consequential, and debatable. They are consequential because they push our sociological researches in a particular direction: who are the actors that make up a social ensemble? What are they doing? Why are they doing these things?

They are debatable because -- as we've seen in discussions of Abbott and Gross previously -- they privilege the actor over the action, the individual over the interaction. They push us in the direction of a social ontology that is individualistic and perhaps reductionist. Abbott proposes, in contrast, that we begin with the interaction, the flow of moves and responses. Tilly suggests that we start with the relationships and turn to the individual actors only later in the analysis. And Gross suggests starting with the creativity inherent in any complex flow of human activities and interactions.

Each of these thinkers point in the direction of a pragmatist theory of action. So what might a pragmatist theory involve?

One avenue for getting a handle on this question is to turn to the work of Hans Joas, who has contributed deeply to the question of how pragmatism intersects with sociology. His article with Jens Beckert in Jonathan Turner's Handbook of Sociological Theory is a good place to start, since he is specifically concerned there to give an exposition of a theory of action that acknowledges several important sources for such a theory while specifically developing a pragmatist account. (The article covers a lot of the ground presented in Joas's 1997 book, The Creativity of Action. Also important is his Pragmatism and Social Theory.)

Joas begins his account by framing the standard assumptions of existing action theory in terms of two poles: action as rational choice (e.g. James Coleman) and action as conformance to a set of prescriptions and norms (e.g. Durkheim, Parsons). He argues for a view that is separate from both of these, under the heading of "creative action".

However, the alternative that reaches even further beyond the routinized exchanges

between rationalist and normativist theories of action seems to us an action-theoretic conceptualization that focuses on the notion of the creativity of human action. Such a theory can be based primarily on the tradition of American pragmatism that originated in philosophy and psychology but also has a significant sociological tradition. (270)

Common to both traditional views, Joas argues, is the assumption of purposiveness: that action proceeds to bring about explicit pre-articulated goals subject to antecedently recognized constraints. The pragmatist view of action rejects this separation between goals, action, and outcome, and focuses on the fact that goals and actions themselves are formulated within a dynamic and extended process of thought and movement. (Dewey is the chief source of this view.) Tactics, movements, and responses are creative adaptations to fluidly changing circumstances. The basketball player driving to the basket is looking to score a goal or find an open teammate. But it is the rapid flow of movement, response by other players, and position on the floor that shapes the extended action of "driving for a layup." Likewise, a talented public speaker approaches the podium with a few goals and ideas for the speech. But the actual flow of ideas, words, gestures, and flourishes is the result of the thinking speaker interacting dynamically with the audience. Joas puts his view in these terms:

> At the beginning of an action process goals are frequently unspecific and only vaguely understood. They become clearer once the actor has a better understanding of the possible means to achieve the ends; even new goals will arise on the basis of newly available means. (273)

> For the theory of creativity of action the significance of the situation is far greater: Action is not only contingent on the structure of the situation but the situation is constitutive of action. (274)

So what are the features of the situation that intersect with the thinking actor to create the temporally extended action? Joas refers to corporality and sociality. The body is not simply the instrument of the agent. Rather, the physical features and limitations of the body themselves contribute to the unfolding of the action. (This aspect of the theory has much to do with phenomenology.) And the other persons involved in an action are not simply subjects of manipulation. Their own creativity in movement and action defines the changing parameters of the actor's course of action. (Again, think of the analogy of 10 players in a basketball game.)

Joas thinks that this interpretation of action as extended intelligent adaptation to shifting circumstances helps to account for complex social circumstances that rational-actor and normative-actor theories have difficulty with. He illustrates this claim with the extended examples of reciprocity and innovation.

This is a rich and nuanced theory of action, and one that has the potential for offering a basis of a much richer analysis of concrete social circumstances than we currently have. At the same time it should not be thought to be in contradiction to either rational-deliberation or normative-deliberation theories. These creative actors whom Joas describes are purposive in a more diffuse sense, and they are responsive to norms in action. It seems to me that the chief tension Joas offers is between stylized, mono-stranded models of action, and thick theories that incorporate the plain fact of intelligent adaptation and shaping of behavior that occurs in virtually all human activities.

A peaceful world?

Sunday, December 25, 2011

Many people around the world are celebrating Christmas this morning. A central wish around this holiday is "peace and good will for all." Why is enduring peace so difficult to achieve? What are the prospects for us in the twenty-first century?

Peace and conflict are related, but they aren't precise opposites. Conflict between individuals and groups can take many forms, and it is possible to manage or resolve conflicts without violence or hatred. This village uses its pasture and forest for gathering; that village begins to encroach with its livestock herd. The two villages have a conflict over the pasture. This conflict may eventually escalate into violence between the villages, with armed groups from each waging small-scale war against the others. But it doesn't have to work out this way. Leaders of the two villages may negotiate a set of land use customs that do something to satisfy the needs and interests of both villages, and they may be successful in getting their constituents to honor those agreements. Or there may be a state capable of establishing and enforcing property rights that are binding on both groups, while permitting each group to pursue its most important life activities. Or, perhaps, the two groups may have normative and religious bonds of solidarity that lead each member of the group to possess a reservoir of good will that makes resort to violence impossible to imagine.

So conflict of interests and wants doesn't necessarily lead to a breaking of the peace. But these conflicts have the potential to do so. And political theorists in the social contract tradition since Hobbes have held that this is the key role of the state -- to establish an acceptable set of rules for property and person that determine clear rights and obligations for everyone, and clear procedures for punishment if rights are violated. Only through a system of law can we avoid the state of nature which is a state of war of all against all.

Other theorists, notably Elinor Ostrom, have argued that populations have solved the problems of conflict over resources in non-state ways, through "common property resource regimes" (Governing the Commons: The Evolution of Institutions for Collective Action). The conditions under which a CPRR is stable are more complex than those of a state -- essentially, the CPRR needs to be supported by normative and cultural elements that give all participants a reason to honor the rules -- but Ostrom and fellow researchers have documented many successful instances. And, of course, a common property resource regime needs to have some kind of processes for addressing and resolving conflicts among participants -- fishermen who disagree about the catch, water users who disagree about the management of upstream resources.

So what are some of the large causes of breakdowns of peace in populations of people?

A key source of sustained violent conflict on a large scale is perceived unresolved injustice. One party or nation blocks access to resources or opportunities to which

another party believes it has a moral right; demands are made; the situation persists; and violent acts begin to occur.

Another important source is conflict over access to important natural resources -- water, oil, minerals. Conflicts over resources may occur at the local level, or they may rise to the level of inter-country armed conflict and war.

We can't overlook the religious and ideological origins of much conflict in humanity's history. The prolonged conflict, often violent, between Hindus and Muslims over the Babri Mosque in India is a good example. The site has religious importance for both communities; leaders are able to mobilize their followers in defense of their claims; violence ensues.

So what can humanity do to improve the prospects for peace and good will?

Sustained efforts at conflict resolution are a good place to start. People of good will can often enough find the resources they need to bring down the degree of conflict and hostility between groups, and to find procedures that make resort to violence less likely.

Recognizing and addressing injustices between peoples and nations will help. Justice and peace are intertwined.

Promoting the universality of human needs and the value of inter-group tolerance and respect is a very good step. And spiritual leaders of all faiths are sometimes very committed to this work. (Others are not, of course!)

So, this fine Christmas morning in 2011, let us all work for peace and justice for our grandchildren!

Democracy in the mirror

Tuesday, December 27, 2011

Why is democracy something people should strive for? And how are we doing with ours?

Consider first the fundamentals. Why is there a role for democracy in any circumstances? Fundamentally democracy is a form of group decision-making. Political institutions are needed in circumstances in which decisions must be made that affect all members of a group. Each member of a group has his or her own set of preferences about choices that affect the group; so there needs to be a process for arriving at a set of social preferences -- a social choice function. Democracy requires designing a set of arrangements through which each person's preferences will have equal weight in determining the ultimate decision. Otherwise we would have a system in which one person decides (dictatorship) or a minority decides (oligarchy). So democracy represents a set of decision-making institutions that embody respect for the equal worth of all citizens when it comes to making collective choices.

In addition to the aggregation of individual preferences, democratic values consider as well the circumstances under which the members of a group form their beliefs and preferences. Narrow democratic theory takes individual preferences as exogenous. But broader versions of democratic theory attempt to bring democratic values into the social processes through which beliefs and preferences are formed. The theory of *deliberative*

democracy emphasizes in particular the features of civility, mutual respect, and open-mindedness through which debate and critical examination of issues leads to a fuller understanding of issues and a more reflective set of preferences. This aspect of democracy is valuable because it corresponds to a society in which open and uncensored debate leads to the formation of individual and collective preferences and embodies the ideas of democratic equality among citizens. And less-privileged groups can exercise their voices in these forums to attempt to influence other citizens to support more just policies and choices.

There is another reason for cheering democracy: it is possible that democracy is more likely to protect the rights and needs of the relatively powerless in society; democratic institutions can function as a bulwark against the arbitrary power of elites of all kinds. If the powerless have political voice, they then have an ability to advocate for, and democratically support, the policies that favor their perspectives and interests. The fact that otherwise powerless people can express their preferences through democratic means is a substantial form of potential influence for non-privileged groups. (This political power is offset, of course, by the political power and influence wielded by elite minorities in most societies.)

The most fundamental reasons, then, to value democracy are its correspondence to the value of the moral equality of all persons and the capacity it creates for non-elite groups' struggles for fair treatment. Democratic institutions honor the equality of all persons in the fact that each person has an equal voice in deliberating upon and deciding collective policies. A democracy is morally preferable because it best embodies the more basic moral value of fundamental human equality and dignity and it provides a feasible mechanism for pursuing social justice.

So how does the US democracy measure up on these criteria? Take the last point first: the idea that democracy empowers the powerless. The role of money in politics takes a lot of the force out of this point in the US. Corporations and wealthy individuals are able to influence legislation, regulation, and policy in ways that are vastly disproportionate to their numbers (link). It is **possible** for a numerous group to exert political influence through the electoral process to defend its interests; but it is also possible for the powerful to quietly subvert these outcomes as well.

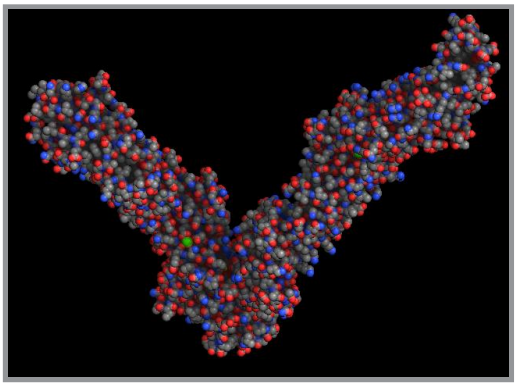
So how about the formative benefits of democracy? Do we find that American citizens are involved in thoughtful debates that bring more facts to the discussion and result in clearer preferences and policies? Here the answer is too often "no" as well. The shouting and vitriol on the media outlets of the right set a tone that discourages or extinguishes respectful debate and clarification. It's hard to see evidence that voters have gotten better at thinking through the issues, the facts, and the underlying values that can subsequently guide their political choices.

And how about the most basic function of democracy, its service as an institution that aggregates individual preferences onto a coherent social preference function? Even here our democracy has challenges. First, we don't seem to be trending towards "coherence" -- instead we have a Congress that mostly serves to block the formation of policy, from legislation to confirmation of appointment out of political opposition to the sitting president. And second, there is only a loose fit between the voting behavior of elected officials and the preferences of their constituents. Constituents have the ability to reject officials of whose voting behavior they strongly disapprove. But election campaigns have more to do with slogans and quick fixes than they do thoughtful efforts to align the

candidate's platform with the diverse preferences of the electorate. Ideology and rhetoric drive electoral strategies, not honest discussion of the issues and the facts that surround them.

Take healthcare reform as an example. The reforms that the Obama administration fought for were plainly advantageous for a very large segment of the American population. Tens of millions of people stood to gain access to health insurance as a consequence of the reforms. And yet the voices of those tens of millions of people played almost no role in the bitter political conflict that ensued. Conservative theories and agendas, widely disseminated falsehoods ("death panels"), and purple rhetoric instead dominated the legislative and electoral process. Eventually a weakened version of healthcare reform became law, of course, but the process did a very poor job of embodying the interests of those most affected by the issue. (Here is a good post by Barbara Ehrenreich that updates her insights in Nickel and Dimed: On (Not) Getting By in America. Ehrenreich makes the importance of healthcare for poor people very clear.)

What American democracy is good at, by and large, is establishing government that is ruled by law. Legal and constitutional protections for citizens are a substantial bulwark against the arbitrary exercise of power by political or social elites. It doesn't need saying that these protections are incomplete, and that various groups in the US have suffered from illegal or unconstitutional treatment. (Consider, for example, the determined efforts being made by some state legislatures to deny partner health benefits to one specific group of citizens.) But by and large, US citizens have justified confidence that their rights will be respected and enforced. They have relatively extensive rights of speech and association, and it is difficult for government to curtail those rights for short term political or individual advantage. Citizens also know that they have the periodic ability to reject the men and women who rule them, which puts some constraints on the behavior of the elected officials.



It is possible that this is the most we can hope for from any government in a modern mass society. But it is also possible that a PhD student in comparative politics from Mars might classify our polity as "constitutionally regulated oligarchy with periodic elections of government officials and extensive infrastructures for managing elections to lead to outcomes that satisfy the elites" -- in other words, something rather different from idealized theories of "democracy" and political institutions well designed for establishing the common good.

(See Jack Knight and Jim Johnson, The Priority of Democracy: Political Consequences of Pragmatism, Ian Shapiro, The State of Democratic Theory, Amy Gutmann and Dennis Thompson, Why Deliberative Democracy?, and Adam Przeworski, Democracy and the Market: Political and Economic Reforms in Eastern Europe and Latin America for different aspects of this issue.)

Supervenience and social entities

Friday, December 30, 2011

What is the ontological status of social entities -- kinship systems, police departments, religious movements? And what is the status of causal powers of social entities? Do we need to "reduce" social entities to the compounds of individuals who make them up? And do we need to derive the causal properties of social entities from the characteristics and interactions of the individuals who make them up? In short, do we need to be reductionist

about the social world?

This is a question that arises in many of the "special" sciences, including in particular psychology and neuroscience. A basic premise of contemporary philosophy is that all phenomena are composed of **physical** entities, processes, and systems. The mind-body problem is the most immediate place where physicalism does some important work. Mind-body dualists held that mental states were independent from physical states, whereas physicalists insist that mental states are embodied in physical processes and systems.

It is plain enough that we make use of a vocabulary that doesn't appear to invoke physical states when we talk about people's actions and states of mind. When I **decide** to have tofu for dinner, or when I **experience** the taste of hot sesame oil, I am engaging in a **mental act** or **qualitative state**. "Deciding", "experiencing", and "having qualitative states" all appear to be terms that refer to private mental states. The physicalist takes it as a piece of ontological certainty, however, that these "mental" states are fully and entirely constituted by the physical substrates of the brain and nervous system.

So what do physicalists have in mind when they say that the phenomena to which these terms refer are really physical states? There are several possibilities:

- eliminative materialism: mental states do not exist, and we need to give definitions of mental terms that allow us to eliminate them in favor of physical terms [reductionism]
- non-eliminative materialism: mental states exist, but they are wholly and exhaustively caused by physical states
- epiphenomenalism: mental states are by-products of physical states without causal powers to influence subsequent physical states
- supervenience: mental states depend upon physical states and nothing else, but it is difficult and unnecessary to reduce facts about mental states to facts about physical states

Is there an analogous situation in the social sciences? Is individualism for the social sciences strongly analogous to physicalism for the natural sciences? Is there something ontologically dubious about referring to social entities and causes?

There is nothing peculiar about the idea that some entities are complex assemblages of other, simpler entities. Virtually every entity that we have an interest in is a compound of simpler entities -- genes, enzymes, or the insulin molecule depicted above. A table has characteristics that depend on the physical features and arrangement of the materials that make it up, but those "table" characteristics are very different from the features of the composing elements -- hardness, stability, load-bearing capacity, etc. And there is no reason whatsoever to insist that "tables do not exist -- only bits of wood exist." Tables are identifiable composite objects, and they have causal properties that we can invoke in explanations. So the fact that there are characteristics of the composite that are dissimilar from the characteristics of the elements is not peculiar. And this is entirely true of social entities as well. The efficiency or corruptibility of a tax-collecting bureau is not a characteristic of the individuals who compose it; it is rather a system-level characteristic that derives from the incentives, oversight mechanisms, and physical infrastructure of the

organization.

So composite entities are not suspect in general. However, there are a couple of challenging questions that we need to confront about composite entities. First, can we explain the properties of the composite by knowing everything about the properties of the elements and the nature of their arrangement and interactions? Can we **derive** the properties of the whole from the properties of the components? Take metallurgy: can we derive the properties of the alloy from the physical characteristics of the tin and copper which make it up? Or are there "emergent" properties that somehow do not depend solely on the properties of the components?

Second, can we attribute causal powers to composite entities directly, or do we need to disaggregate causal claims about the aggregate onto some set of claims about the causal powers of the elements? Do we need to disaggregate the load-bearing capacity of the table onto a set of facts about the properties of the elements (legs, table top) and their configuration? It is certainly true that we can derive the load-bearing capacity of the table from this set of facts; this is what civil engineers do in modeling bridges, for example. The philosophical question is whether we ought to regard this causal property as simply a way of summarizing the underlying physics of the table, or as a stable causal property in its own right.

One appealing answer that has been offered to the question of the relationship between levels of entities is the theory of supervenience. This theory is largely the work of philosopher Jaegwon Kim over the past thirty years. Here is a recent synthesis of his views (Physicalism, or Something Near Enough). He summarizes the basic idea in these terms:

It will suffice to understand [supervenience] as the claim that what happens in our mental life is wholly dependent on, and determined by, what happens with our bodily processes. (14)

And here is how Julie Zahle puts the point in her contribution to Turner and Risjord's Philosophy of Anthropology and Sociology:

Social entities, their properties, actions, etc. may be said to supervene upon individuals, their actions, and so on, insofar as: (1) there can be no difference at the level of social wholes, their properties, actions, etc., unless there is also a difference at the level of individuals, their properties, actions, and so on; (2) individuals, their actions, etc. fix or determine what kinds of social wholes, properties, etc. are instantiated. (327)

Does the idea of supervenience help answer the question of the ontological status of social entities? Is it helpful to judge that social entities supervene upon facts about individuals and nothing else? And does this leave room for the idea of social causation and relative explanatory autonomy? Are we able to acknowledge the dependence of the social world on facts about individuals without abandoning the idea that there is social causation and social science?

Perhaps surprisingly, Kim thinks that the theory will *not* assist us in the last two ways, at least when it comes to psychology:

This view [supervenience] provides the burgeoning science of psychology and cognition with a philosophical rationale as an autonomous science in its own right: it investigates these irreducible psychological properties, functions, and capacities, discovering laws and regularities governing them and generating law-based explanations and predictions.

It is a science with its own proper domain untouched by other sciences, especially those at the lower levels, like biology, chemistry, and physics.

This seductive picture, however, turns out to be a piece of wishful thinking, when we consider the problem of mental causation--how it is possible, on such a picture, for mentality to have causal powers, powers to influence the course of natural events. (15) So I am in a quandary at the moment: I favor the idea of "relatively autonomous social explanations" (link), I like the idea of regarding social entities as legitimate compound entities that don't require elimination, and I think of the theory of supervenience as providing some authority for these views. And yet Kim himself seems to reject this line of thought when it comes to the special sciences of psychology and cognitive science. Kim seems to want to argue that higher level sciences cannot claim relative autonomy; in this respect his own view seems to be reductionist.

What seems clear to me can be summarized in just a few points:

- Social entities and facts are determined and constituted by facts about individuals, their beliefs, their relations, and their actions. So social entities and facts do in fact supervene upon facts about individuals.
- Social entities do have causal properties that can be discovered without needing to eliminate them in terms of properties of individuals.
- The requirement of microfoundations is crucial because it establishes the intellectual discipline required by the first point: we must be able to validate that the claims we make about social properties and causal powers can be provided microfoundations at the level of socially situated individuals.
- There is a legitimate and defensible level of explanation at which social scientists can hypothesize social properties and causal capacities; so there is a place for a "relatively autonomous" social science. We are not forced to be reductionist.
- The "social" is not inherently puzzling in the way that the "mental" is. Social entities are more analogous to chairs and proteins than they are to thoughts and qualia: they are complex entities whose system-level characteristics are the ultimate effects of the interactions and properties of the individual elements that constitute them. We often cannot trace out exactly how the properties of the whole derive from the properties of the components; but we don't need to do so except in unusual circumstances.
