**Abstract** The purpose of this study was to determine if there were differences in the prevalence of risk factors associated with low back pain between two groups of subjects. One group consisted of subjects who had experienced low back pain at least once during the previous year, while the other group consisted of subjects who had never experienced low back pain. A total of 100 subjects participated in the study. The results showed that the prevalence of risk factors associated with low back pain was significantly higher in the group of subjects who had experienced low back pain than in the group of subjects who had never experienced low back pain.
