Urethral stricture คือ pdf

The urinary tract drainage mark for urinary tract drainage for urinary tract drainage is 1. 2. Put to insert chemicals to help diagnose or treat bladder lesions (diagnosis or injection of therapeutic agents), the most common cause of inserting a urinary catheter is acute obstruction or discharge of urine from the nervous bladder. The size of the pee catheter is French (Fr), where 1 Fr is 0.33 mm. The size of the urine catheter is not the size of the outer diameter, the size of the lumen. If the urine is clear, if the urine is opaque or the urine is bloody, choose a 12-16 Fr pee catheter. Choose 20-24 Fr pee catheter in pediatric patients. Here's how to choose a pee catheter: Children under 5-8, children 5-10 years of age, 8-10 Fr, 10-14 years old, 10-14 years old, children over 14 years, 10-14 Fr urine catheters are used. Rubber or latex catheters are used for short-term urination, and silicone catheters are used in the case of allergies. Latex or rubber catheter selves are used in patients who want to use it for a long period of time, the reason that silicon can be used as a long-term catheter is because the silicon is a relatively inert material, the tissue response may be less. E water should not be filled with air or water parts containing electrolytes and glucose as a component, because it can cause obstruction of tubes and valves, if the balloon cannot be contracted, the main reason for not shrinking the balloon is usually caused by the valve of the expansion, if the port port cannot remove the uterus. Problems are likely to be caused by the body of lumens or balloons, which can cause pain in the patient and cause bladder damage, or because it can be residual debris in the bladder, it is recommended to over-expand. Other chemicals that cause balloon rupture are recommended because it can cause chemical cystitis, the introduced procedure is to insert a guild wire to break the valve, so if you do not succeed, an ultrasonic guide needle puncture may be required, it can be made of supra-luvis, vagina or tan. Lumen, bi-directional catheter and three-way catheter, shown in Figure 7, single lumens are used to perform orthodontic drainage or bladder injection bi-directional catheters, are used to require a catheter catheter, are used to monitor urine or discharge urine or blood, and are used to drain and drain the catheter in three ways from the bladder, and is used to drain and irrigate the patient. The most important thing to note when choosing a urinary catheter is that there are more internal lumens, such as a 3-tail 24 Fr urine catheter. Internally, it has less diameter than two tail24 urine catheters. Urethra stenosis, meat stenosis and urethra perforation often show the causes of urinary catheterization, which is caused by enlarged prostate, urethra (strengthening urethra), bladder neck contraction or intrauterine pertinology. Sexually transmitted infections (STD), urethra trauma, urethra surgery, the cause of urinary catheter insertion, often patients over the age of 50 who do not have a history of difficulty. Using a dozen Fr lines, patient care guidelines for the difficulty of inserting a urinary catheter are shown in Table 1, Table 1 indicates the sequence of therapy for patients with urinary catheter insertion. Suprapubic catheterization (SPC) is a urethra stenosis, bladder neck contraction, urethra trauma, such as urethra inaccessible, for example, patients in chronic residential catheter patients can feel more comfortable using a urinary catheter. As for the infection, it was found to reduce the risk factors of bacteriotosis, which only slightly symptoms compared to urinary catheterization. The technique of creating suprapubic catheterizing, patients performing transdermal chorapubic catheterization should detoxify the bladder and explore the edges of the bladder. The wound will be located above 3-4cm of pubic planting. After injecting these areas from the skin layer and applying an 18-gauge syringe, avoiding the syringe 1 to slit the medium line cm.in, the syringe is injected with a syringe, fixed by an aspiration continuous syringe. Use a sharp style to embroider using a set of anti-resection until the bladder urinates. When the catheter cable enters, insert the catheter cord into the style, retract the style, and sew the catheter cord to attach it to the skin.
